The first paper by Schau, Thompson, and Muniz focuses on the creators of CGAs, and examines the collaborative and prolonged process through which the Twilight brand community members collectively create, disseminate, and distill content. Research by Brunel, Lawrence and Fournier shifts the focus towards consumers' reactions to CGA. Based on a lab experiment and a phenomenological inquiry, the authors discuss the potential of CGAs in facilitating consumer engagement and provide insights into the key facets of engagement, the underlying processes, and the conditions under which different patterns of engagement may emerge. In the third paper, Ertimur and Gilly augment our understanding of consumers' reactions to CGA by scrutinizing the communication value of CGAs as evidenced in consumers' evaluations of credibility. Using netnographic and interview data, the authors assess the appeal of CGAs vis-à-vis traditional advertising and highlight the impact of consumers' evaluations on brand associations. Following the presentations, our discussant, Robert Kozinets, offers his insights and comments on the three studies and closes the session with suggestions for future research directions. We hope that these three presentations along with our discussant's integrative comments provide the grounds for building theory regarding this new phenomenon and offer novel insights for consumer researchers interested in advertising theory and practice.

“Fanning the Flames of Consumer Engagement: Inspiring and Nurturing Communally-embedded Consumer Generated Content”

Hope Jensen Schau, University of Arizona, USA
Kate Thompson, University of Arizona, USA
Albert Muniz, De Paul University, USA

Many studies have demonstrated that members of brand communities are capable of extensive creation of brand content (Brown, Kozinets and Sherry 2003; Muniz and Schau 2007; Schau and Muniz 2006; Schau, Muniz and Arnould 2009). Indeed, the

ascendancy of communally-embedded, empowered consumers is now a marketplace reality (Flight 2005; Ives 2004; Morrissey 2005). Such customer evangelism goes by many names, including “homebrew ads” (Kahney 2004), “folk ads” (O'Guinn 2003), “open source” branding (Garfield 2005) and “vigilante marketing” (Ives 2004; Muniz and Schau 2007). While several marketers have begun to actively solicit Consumer Generated Content (CGC) for occasional, ad hoc use in advertising campaigns (e.g. Doritos Super Bowl 2009), little if any research has addressed collaborative CGC, nor the role of the firm in encouraging prolonged CGC endeavors that require relinquishing considerable control of the brand meaning and messages. Moreover, the research on CGC thus far has focused primarily on male consumers with advanced technical skills who work independently or with a discrete set of known partners on a single CGC project for which they most often get explicit credit and even monetary rewards. Currently missing are studies that examine prolonged collaborative CGC among relatively unknown partners where the creative impetus lies in complex and nuanced narrative and character analysis, rather than technological mastery.

Stephenie Meyer, author of the Twilight saga, inspires passion and devotion in individual readers, but importantly she also incites and nurtures widespread collective engagement with the brand in the form of a brand community demonstrating the markers identified in Muñoz and O'Guinn (2001): consciousness of kind, rites and rituals, and moral responsibility. Twilight fans read the books and discuss them in online and offline book clubs and events. Often these fans are brought together by their mutual interest in, and admiration for, the brand and little else (scant contact beyond brand-based experiences). Yet, Twilight fans collectively create CGC and influence brand production.

Our data consist of: the Twilight saga (including an unauthorized draft novel), a feature film, literary and film criticism of the Twilight media products, naturalistic and participant observation in three online fan forums and two offline events, collectively created CGC (videos, images and texts), as well as, email and face-to-face interviews with brand fans inside and outside the brand community and CGC creators. Our data were iteratively collected and thematically coded and recoded following the hermeneutic tradition.

Like American Girl (Diamond, Sherry, Muniz, McGrath, Kozinets and Borghini, 2009), we find the Twilight brand community members are primarily female (currently underrepresented in brand community research), and generally range from 12-65. The older women in the brand community are often the mothers of daughters who were first Twilight fans and “turned them on” to the books. We find that the community contains factions based on age, life stage, character affiliation, plot interpretations, and broad ideological identification.

Through the Twilight brand community we demonstrate the strategic use of open text branding to invite collective action, the deliberate encouragement of vigilante marketing to promote the brand, and the interplay of contrived heterogeneity within the brand community as an impetus for prolonged brand community engagement and collaborative CGC. We find at the center of the phenomenon is the perpetual melodrama emanating from an inability to achieve closure and a desire to close narrative loops. These vampires are immortal, but suspended in adolescence, perpetually coming of age; this means their conflicts cannot be entirely re-

solved. Fans universally find the vampires and werewolves sympathetic and their efforts to exist without harming humans to be noble. The vampire quest for legitimacy and acceptance and the werewolf desire to peacefully co-exist within human society is intriguing and fan discourse compares these to race, ethnicity and class struggles in contemporary society. Collaboratively created CGC employs direct references to larger macro-social plights such as the Civil Rights Movement in the US and abroad, US and global feminist issues and peace activists in their CGC. These macro issues play out against the backdrop of a popular melodramatic media brand with full-approval of the producer. Twilight is a platform for fans to engage in these larger social issues; for many Twilight is the first impetus to consider these topics and the first time that these people have engaged in collective debate of the issues.

Our data demonstrate effective CGC that is collectively created, disseminated and distilled within a strong consumer controlled and producer nurtured brand community. The Twilight collectively created CGC is predominately antithetical to previous studies where CGC is assumed to be inspired by personal brand attachment and/or the desire to see discrete-authored CGC disseminated, or even motivated by monetary reward. Authorship of collaboratively produced CGC is virtually untraceable, unknown and monetarily uncompensated (much like Wikipedia). The true reward is the process and the outcome is not reliant on technical prowess but rather semiotic manipulation, narrative manipulation and complex character development. Like previous studies (Muniz and Schau 2007), we find consumers quite adept at appropriating and mimicking the styles, tropes, logic and grammar of advertising and film trailers. More significantly, Twilight consumers demonstrate mastery of intertextuality (O'Donohoe 1997) by utilizing the permeable boundaries between marketing communications and other socio-cultural texts via appropriation. They demonstrate mastery of polysemy (Kates and Goh 2003; Ritson and Elliott 1999), creating artifacts with different meanings for different groups.

“Towards A Contingency Theory of Consumers’ Engagement with CGAs”

Frédéric Brunel, Boston University, USA
Benjamin Lawrence, Boston University, USA
Susan Fournier, Boston University, USA

With the proliferation of personal digital media technology, today’s consumers have the toolbox to cheaply and quickly produce, distribute and engage in sophisticated marketing content (Muñiz and Schau 2007). Though past studies have looked at the effects of interactive versus traditional advertising (Bezjian-Avery, Calder, and Iacobucci 1998), there has been limited research (Berthon, Pitt, and Campbell 2008; Muñiz and Schau 2007) on CGAs. CGA needs to be better understood with respect to its effectiveness relative to traditional advertising and to the processes that consumers use to interpret and react to these new ads.

Many companies such as Jones Soda have embraced consumer co-creation and CGA as part of their core marketing strategies while others have confined it to specific promotions or competitions (e.g., Frito-Lay, Unilever, Chevrolet, and Heinz). Yet, one thing appears common to all who include CGA in their communication strategies: a belief that CGA engages consumers more deeply with the brand.

Consumer engagement is a central preoccupation in the advertising community, with industry groups such as the Advertising Research Council, the Association of National Advertisers, and the American Association of Advertising Agencies creating specific Engagement Councils “to provide an industry-leading peer discus-

sion forum, for the continuous refinement and application of the Engagement construct” (thearf.org). One ultimate question remains: does CGA actually facilitate consumer engagement? More specifically, do CGAs engage consumers in the same way as traditional company-generated ads? If not, how are they different? What are the key drivers of CGA effectiveness?

We designed a multi-method program of study to answer these questions. First, in a lab experiment, we compared advertising responses when the same advertisements were either identified as having been created by consumers or no source information was provided. This study explored whether CGAs present communication advantages and investigates processing factors that drive CGA responses. We chose Toyota Yaris as the focal brand for this study for two reasons: 1) it is targeted to a young driver audience similar to our pool of student respondents, and 2) consumers have created ads for this brand. Four judges selected four (out of thirty) 30-second Yaris CGAs with varying levels along two dimensions known to affect advertising response: execution quality and product information content (Mitchell 1986). Based on a random assignment, 196 student respondents were assigned to view one of the ads, and were instructed either that the ad had been created by a consumer or were not told anything about the creator.

Confirming our hypothesis there was a significant main effect of ad creator source on various ad response measures. Respondents who were told the ad was a CGA reported higher attitudes toward the ad ($p < .05$) and higher evaluations of the executional quality ($p < .05$). They also reported that the ad was more engaging ($p < .05$) and they were more likely to seek information about the Yaris brand and consider the Yaris as a potential future car (also $p < .05$). Further, additional path analyses suggested the advertising response pattern in the CGA condition was akin to a high involvement/central processing response pattern, whereas the response pattern in the no-source condition was consistent with low involvement processing. These results confirm that consumers appear to react more favorably to CGAs and CGAs can increase engagement.

Our second study was a phenomenological inquiry of responses to CGA in a natural viewing environment that provides a holistic understanding of consumers’ engagement with different types of CGAs. We content analyzed responses (i.e., verbatim transcripts of 671 YouTube posts) to eight CGAs: six contest-driven CGAs (Dove, Doritos, and Chevy HRR) and two organically-created CGAs (Firefox, and Wii). Focal ads spanned multiple product categories, brands, and advertising strategies (i.e., product information, humor, consumer values).

Our findings provide both support for—and challenge of—the contention that CGAs present systematic advantages in terms of consumer engagement. All Dove CGA ads, as well as the Wii and Firefox CGA ads, exhibited high levels of consumer engagement, as defined in terms of personal involvement, cognitive elaboration, and ad elaboration. However, two additional and dominant facets of engagement were uncovered. For the Dove ads, engagement centered on community- and relationship-building dialogues. In particular, the comments evidenced protracted viewer-viewer and viewer-creator conversations involving the ads and the brand, and professed support for and interdependency between viewers. On the other hand, engagement for the Firefox and Wii ads involved brand evangelism, brand advocacy, and the characteristic in-group/out-group brand debates defining community brands. Postings originated from focal brand supporters and also from opposing brand loyalists, spurring heated emotional debate and confrontations. Inducting from our findings, one key difference driving these engagement patterns is the participation and involvement (or absence) of the oppositional community group (i.e., Microsoft Xbox

and Sony PS2 against Wii, and Internet Explorer versus Firefox): a key tenet defining community status for a brand (per Muniz and O'Guinn 2001).

Interestingly, two of the CGAs under study—Chevy HHR and Doritos—did not evidence any of the engagement facets uncovered above. Responses for these ads concerned entertainment value and not much more. In this sense, the humor advertising strategies used in these ads swamped any potential deeper engagement. Based on our findings it seems that depending on the ad strategy, CGA ads may in fact provide no observable engagement benefit.

In summary, across the two studies we found evidence that CGA can influence viewer's engagement and ad response, yet there does not appear to be a "wholesale" CGA effect. CGA effects are complex and must be viewed in the context of the brand type and the ad strategy in which they are embedded. In our lab study, limited to one brand and one product category, we were able to show that CGA can improve consumer reactions and engagement with the ad and brand. However, in a natural environment, different patterns of consumer engagement with CGAs emerged and were manifest only under specific conditions. Together our findings provide the foundation for a contingency-based understanding of the effects of CGA, though a complete contingency theory is yet to be defined.

"The Impact of Consumer-Generated Advertising on Brand Associations"

Burçak Ertimur, Fairleigh Dickinson University, USA
Mary C. Gilly, University of California, Irvine, USA

A common way for organizations to evoke favorable associations is through advertising (Dowling 2001). Yet the effectiveness of such efforts is often questionable because consumers tend to be skeptical about advertising messages and distrust the media as well as corporate advertising (Elliott, Eccles, and Hodgson 1993; Mohr, Webb, and Harris 2001). With the emergence of consumer-generated advertising (CGA), however, advertising is no longer a company-controlled form of communication. CGA also provides a direct avenue for consumers to participate in creating brand images. An emerging stream of research examines what drives consumers to generate ads and whether they are successful in their advertising creation endeavors (e.g., Muniz and Schau 2007). CGAs also reach other current and potential customers of the companies featured in CGA (McConnell and Huba 2007). Little is known, however, about such consumers' perceptions and reactions towards CGA.

In this study, we examine consumers' reactions towards two types of CGAs. The first type is solicited CGA, initiated by companies designing contests and inviting consumers to create ads for their products (e.g., Doritos). The second type is unsolicited CGA, meaning that consumers create an ad on their own without any support from the company (e.g., George Masters' ad for Apple iPod). To assess how different types of CGAs contribute to brand associations, we study consumers' responses to and interpretations of CGAs vis-à-vis traditional ads. We also seek to understand communication value of CGAs, and specifically, how consumers evaluate them in terms of credibility. On the one hand, both types of CGAs may be seen as similar to conventional ads in that they are intended to be persuasive and they look as well as feel like ads. On the other hand, CGAs may be viewed as word-of-mouth (WOM) communications given that they are created by consumers, not marketers, and are not commercially motivated. Subsequently, CGAs may provide benefits such as increased credibility in comparison to traditional ads as is the case in WOM communications.

To address these issues, we investigate and compare consumer responses to both types of CGAs as well as a company ad in contexts where the ad source is known versus unknown. We gathered three different types of ads that feature an instant stain remover produced

by Procter and Gamble (P&G) called Tide-to-Go. P&G ran a Tide-to-Go ad during the Super Bowl in 2008 and followed it up with a CGA contest that asked consumers to create their own version of this ad. In addition to the solicited CGAs and the company ad, there were already CGA for Tide-to-Go that were uploaded on YouTube prior to P&G's announcement of their contest. We use a combination of in-depth interviews (McCracken 1988) and netnography (Kozinets 2002) to collect data from consumers and consumer sites online. We conducted fourteen interviews with target consumers of Tide-to-Go to understand how consumers make sense of the different types of Tide-To-Go ads. The netnographic data consist of consumer comments generated in response to the three types as they appeared on YouTube and the company website as well as company and brand mentions online. While consumers in the face-to-face interviews did not know the source of the ads, the online commentators in the netnographic study knew them. The netnographic data on the company and brand mentions create the background against which consumers' responses to the ads are analyzed. Data collection and analysis followed an iterative process (Spiggle 1994) and the analytic techniques offered by Strauss and Corbin (1998) were used to arrive at themes.

The analysis of online comments shows that consumers recognize CGAs as ads and they understand the underlying effort to sell. However, in contrast to previous work on consumer skepticism toward advertising (e.g., Scott 1994), consumers do not resist being influenced by these ads. Rather they adopt a marketer's frame and critique these ads' effectiveness. They do so by relying on their persuasion knowledge (Friestad and Wright 1994) at the expense of their brand knowledge. This is evident in their evaluations that draw largely on their beliefs about the role played by psychological events evoked by the ad and ad creators' persuasion goals as well as their ideas about the effectiveness and appropriateness of marketers' tactics in general. These responses lack thoughts and beliefs about the brand, accounts of prior experiences with the brand, and the brand message conveyed by the ad. Our face-to-face interviews also substantiate the idea that CGAs are perceived as persuasion attempts and reveal that consumers are capable of differentiating amongst the different types. Consumers recognize the dual source of CGAs, and interactions between the perceptions of these sources determine these ads' credibility. In particular, they perceive the creator component of CGAs' source as unfamiliar, which in turn, makes CGAs' credibility doubtful. Consumers believe that anyone could have created these ads regardless of belonging to the target market or having any experience with the brand. They appreciate other consumers' perspectives on Tide-to-Go conveyed through CGAs; nevertheless they question these creators' expertise and authority. The findings further suggest that this detraction from the credibility of CGAs due to the unfamiliarity with the creator component of the source may somewhat be compensated through knowledge about the sponsor and/or the brand.

In conclusion, we find that consumers evaluate CGAs in their own right, independent of the product they feature, by drawing on their persuasion knowledge as a resource. Although the development of persuasion knowledge is historically contingent (Friestad and Wright 1994), consumers use their existing persuasion knowledge about company ads to make sense of these new forms of ads (i.e., solicited and unsolicited CGAs). Our study also demonstrates that CGAs cannot be merely viewed as word of mouth communications and stresses the complexity of consumers' perceptions of CGA. This new hybrid persuasion device, CGA, is viewed as neither company propaganda nor simple consumer recommendations. Our findings contribute to building theory regarding source credibility in this new medium.

SPECIAL SESSION SUMMARY
Emotional and Motivational Drivers of Our “Want” and “Should” Desires
Cynthia Cryder, Carnegie Mellon University, USA

EXTENDED ABSTRACTS

“Wanting Versus Choosing: A Disconnect between What Moves Us and What We Prefer”

Cynthia E. Cryder, Washington University in St. Louis, USA
Elizabeth, E. Mullen, Carnegie Mellon University, USA
George Loewenstein, Carnegie Mellon University, USA

A growing body of research finds that decisions that we make when considering multiple options yield different preferences than those that we make when considering options one at a time (e.g., Hsee et al. 1999). For example, when considering options one at a time, people prefer options with high relative payoffs to themselves versus an opponent, but when considering multiple options at once, people prefer options with high absolute payoffs to themselves, and relative payoffs become less important (Bazerman et al. 1992).

This preference reversal between separate versus joint evaluation (considering one option at a time versus considering multiple options at a time) prompts a question about how decisions made about motivation, which are typically made in separate evaluation (Will I do a task for Incentive X?), and decisions made about preference, which are typically made in joint evaluation (Do I prefer Incentive X or Incentive Y?), may differ. The current paper seeks to investigate the motivational consequences of joint versus separate preference patterns, and in the process, contribute insights that inform the design of effective incentive and promotion schemes.

Drawing on prior research by Bazerman and colleagues (e.g., Bazerman et al. 1998; 1999), we predicted a discrepancy between rewards that people choose and rewards that most strongly motivate people to act. Across three experiments, when incentives were offered individually, hedonically appealing want incentives like lotteries and chocolate were equally or more motivating than practical should incentives like sure cash payments. In choices between incentives, however, should options were more popular.

In Experiments 1 and 2, in exchange for completing a survey, participants were offered an emotionally evocative want incentive (Experiment 1: a Toblerone candy bar, Experiment 2: a Lottery), a practical should incentive (both experiments: a sure \$3 payment), or a choice between the two incentives. When incentives were offered individually in Experiment 1, participants were equally motivated by want and should incentives; however, when participants decided directly between the two options, they chose the should incentive (\$3) significantly more often. Experiment 2 produced a full preference reversal in which participants were more motivated by the want incentive (a lottery) when the incentives were offered individually, but chose the should incentive (a sure \$3) more often when asked to choose between the two options.

Experiment 3 tested whether an opportunity for comparison was sufficient to make decisions made in separate evaluation to resemble those made using joint evaluation. In a new condition, participants were offered only one incentive in exchange for effort (the Toblerone bar or the sure \$3), but they were informed that the other incentive existed. Consistent with the idea that comparison of multiple options triggers a preference for more practical alternatives, participants in the new condition who had an opportunity to compare were more motivated by the should incentive (the sure \$3) than by the want incentive (the Toblerone bar). These results suggest that, the pattern of preference for should incentives in

matters of choice and want incentives in matters of motivation is primarily due to the structure of the decision task (in joint versus separate evaluation) instead of due to a fundamental difference in the types of incentives that are preferred in motivation versus choice contexts. When participants could compare options as in joint evaluation, preferences in separate evaluation (motivation) contexts resembled those in the joint evaluation (choice) contexts. In fact, simply mentioning the existence of a should incentive was sufficient to change decisions about motivation (made in separate evaluation) to emulate decisions made in joint evaluation.

The findings question a common belief among both behavioral researchers and practicing marketers that individuals' choices among options signal what motivates them or makes them happy. The common practice of asking focus group members to pick between promotional items may not reveal which incentive will be successful in motivating people. Although people may strongly prefer one item over another when both items are presented side-by-side, the favored item may flop as a motivational tool. In sum, this work adds new information about a discrepancy between choice and motivation to a host of research on preference reversals (Grether and Plott 1979; Lichtenstein and Slovic 1973; Slovic and Lichtenstein 1968), all of which underscores the necessity to carefully match the mode of an inquiry to the context in which the results will be applied.

“Reinforcing ‘Shoulds’: The Effect of Mindsets on Sequential Choices”

Kelly Goldsmith, Northwestern University, USA

Uzma Khan, Stanford University, USA

Ravi Dhar, Yale University, USA

Imagine a consumer who is going through his day making a series of choices. Earlier in the day he decides to go to the gym and exercise. Later, as he is walking out of the gym, he is approached by a representative from a local charity with a request for donation. Would choosing to exercise make him more or less likely to donate? Recent research has observed two distinct patterns in sequential choices: reinforcement and balancing (Dhar et al. 2007; Dhar and Simonson 1999; Huber et al. 2007; Khan and Dhar 2006). Reinforcement occurs when an initial choice strengthens commitment to the related goal, leading to a similar subsequent choice. Conversely, balancing occurs when an initial choice satisfies and hence inhibits the related goal, allowing for the pursuit of an alternate goal on a subsequent choice. The present research proposes that reinforcement or balancing in sequential decisions can depend on how the choices are interpreted. Specifically, we posit that an initial choice will lead to reinforcement when the choices are interpreted at a higher level of abstraction. On the other hand, when choices are interpreted more concretely, an initial choice leads to balancing in subsequent decisions. We build on the notion that seemingly different choices (e.g., exercising and charitable giving) may be viewed as more related when interpreted at a higher level, as both indicate relative virtues (or shoulds as opposed to wants, Bazerman et al. 1998). Since choices interpreted at a higher level are also more likely to be seen in terms of their relationship to higher order goals that define one’s self-concept (Trope and Liberman 2003), inconsistent choices would have the negative effect of highlighting a conflicting self image; thus we expect higher level processing to facilitate reinforcement across choices. By the same token, as lower level processing allows the choices to be viewed as unrelated, we predict lower level processing will facilitate balancing across decisions even when the choices are seen as relevant for self-image.

To test our propositions, we turn to abstract vs. concrete consumer mindsets, which have been shown to affect cognitive processes and systematically influence consumers’ interpretation of their choices. For example, prior research on sub-goals has demonstrated that in an abstract mindset actions are seen as indicating goal commitment whereas in concrete mindset actions are seen as indicating goal progress (Fishbach et al. 2006). Specific to the current research, an abstract mindset focuses attention on central, holistic features and higher-order goals whereas a concrete mindset facilitates lower-level representations and goals enriched with details (Trope and Liberman 2003). Building on this, we predict that an initial should choice will beget subsequent unrelated should choices when a consumer is in an abstract mindset. Conversely, an initial should choice will facilitate subsequently unrelated want choices when a consumer is in a concrete mindset. We explore this effect and its underlying mechanism in four experiments. For example, in Experiment 1 participants completed a mindset manipulation and subsequently we manipulated if an initial should choice was made (e.g., a choice between cardiovascular activity vs. weight training at the gym) or not. Finally, all participants were given a choice between working on an assignment (a should) or watching a favorite television show (a want). In line with our predictions, we find that initially choosing a should option in an abstract mindset increases the likelihood of subsequently choosing a should option (i.e., working on an assignment); whereas the opposite pattern holds in a concrete mindset. That is, participants in a concrete mindset were more likely to choose a want option (i.e., watching a favorite television show) after an initial should choice.

We replicate this pattern of results across different sets of initial should choices and should vs. want dependent measures, and the results consistently support the predicted interaction between mindsets and an initial want choice. Further, in support of our predicted process, we demonstrate that participants in an abstract mindset rated seemingly unrelated choices as more related compared to those in a concrete mindset. Lastly, we show that relating the initial choice to the self-concept is a key driver of reinforcement in the abstract mindset.

We believe this research has important implications for accomplishing long term, self-improvement goals. Our work goes beyond research on sub-goals (e.g., Fishbach et al. 2006) as we focus on choices that are not directly related and hence provide insight into goals that require persistence on several dimensions that may not be seen in conflict when viewed at a lower level (e.g., maintaining good health and success in exams).

“Guilt as Motivation: Strategic Self-Management of Motivation in Consumer Self-Control”

Xianchi Dai, INSEAD, France

Klaus Wertenbroch, INSEAD, France

Miguel Brendl, INSEAD, France

We propose a novel consumer self-control strategy, the self-imposition of moral liability. Consumers purposely engage in tempting hedonic activities to increase their motivation to perform subsequent tasks that require self-control. For example, students might prefer to attend a party the night before starting to study for an important exam. Or, consider people’s indulgences during Carnival, which immediately precedes Lent. Building on a mental accounting framework, we show that consumers choose the hedonic behavior to self-impose a moral liability that can be canceled by persisting in the self-control task. For example, farsighted (sophisticated) consumers strategically self-impose guilt when facing self-control problems. Guilt is a self-conscious emotion that induces a desire to repair or undo what we have done to ourselves or to others (Elster 1999; Tangney and Fischer 1995), which yields extra motivation to complete subsequent self-control tasks.

Five studies provide support for our propositions and rule out alternative explanations based on theories of licensing (e.g., Khan and Dhar 2006), balancing (e.g., Dhar and Simonson 1999), self-handicapping (e.g., Berglas and Jones 1978), and ego depletion (e.g., Muraven et al. 1998). Experiment 1 examined consumers’

intuitions about the motivating effects of self-imposed moral liability. Participants predicted the motivational intensity they would experience after resting at home or after going to a party before studying for an exam. For an unimportant task (studying for unimportant exam), resting led to greater predicted motivation and effort, whereas for an important task (studying for an important exam), attending the party led to greater predicted motivation and effort input. These effects on predicted motivation levels were mediated by experienced guilt.

Studies 2 and 3 showed that self-imposed moral liability affects consumer preferences and choices. In study 2, participants who faced a subsequent self-control task, in which they freely chose their effort level (from 1-3 days of volunteer work), were more likely than participants who faced a task with fixed effort levels (3 days of volunteer work) to attend a party in order to motivate themselves to work longer. Individual-level analyses provided further support for our proposition: when the future task effort was fixed, preferences did not differ, whereas when the future task effort was variable (and thus required greater self-control), those low in (self-rated) self-control were more likely to party than stay at home. In study 3, consumers with a variable-effort future self-control task (hiking to 1, 2, or 3 sites) were more likely to buy more luxurious hiking boots than those facing a fixed task (hiking to 3 sites).

Study 4 showed that those who were less confident in their ability to finish an important future task that were more likely to reward themselves before the task (rather than after the task) than those who were more confident. In contrast, when the future self-control task was not important, there was no such difference between those who were more and less confident, again consistent with our proposition that consumers self-impose moral liability to build up their motivation for a future task.

Finally, we examined the dynamics of motivation before and after a decision. We hypothesized that high planners (those who chronically think from a long term perspective) are more likely to self-impose moral liability as a self-control strategy than low planners. Results confirmed our proposition: high planners were more likely to indulge when facing a challenging future task. More importantly, for high planners, those who indulged predicted higher self-efficacy for their future task completion than a control group (high planners who didn't make a choice at all) and those who chose not to indulge. In contrast, low planners showed no difference among these three conditions, suggesting that the low planners' choice of indulgence was not driven by the strategic self-imposition of moral liability.

These results provide converging evidence for our hypothesis of self-imposing moral liability as a self-control strategy. They contribute to the growing literature on consumer self-control by demonstrating a new type of self-control strategy, in addition to the well-known strategies of exercising willpower (e.g., Hoch and Loewenstein 1991; Baumeister 2002) and precommitment (e.g., Ariely and Wertenbroch 2002; Wertenbroch 1998). They also add to the extant literature on emotions, which suggests that people avoid negative emotions. In contrast, our results suggest that consumers strategically self-impose moral liability, a specific type of aversive negative emotion.

“Wanting What I Shouldn’t Have and Finding a Way to Get It: When Guilt Increases Hedonic Consumption”

Yael Zemack-Rugar, Virginia Tech, USA

Lisa A. Cavanaugh, University of Southern California, USA

Gavan J. Fitzsimons, Duke University, USA

Consumer researchers have been interested in guilt because it affects hedonic consumption. Specifically, guilty individuals tend to self-deprive and self-punish (Bybee 1998). As a result, guilt has been shown to be incompatible with hedonic want consumption. This is particularly true for consumers high in an individual measure called guilt-proneness (GP henceforth; Tangney et al. 1992). These guilty, high GP consumers have been shown to consistently reduce consumption of hedonic products (Zemack-Rugar 2009, Zemack-Rugar et al. 2007).

In the present research, we reverse these findings. We provide evidence that guilty participants high in GP sometimes indulge more than both neutral and other guilty (low GP) participants. We examine a situation in which the hedonic product is attached to a charitable cause. We demonstrate several unique effects. We show that attaching a social cause to a hedonic product (1) leads to a larger increase in consumption for guilty, high GP, than for neutral (or guilty, low GP) participants, (2) leads to an increase in consumption even when the charity is disliked or distrusted, and (3) leads to an increase in consumption even when a non-hedonic option associated with charity is available.

In five studies we demonstrate these effects and argue for an underlying process of emotion-regulation. Specifically, we argue that since hedonic consumption is pleasant, it offers the opportunity to feel better. Guilty participants want this opportunity. However, selecting this want product can feel like a should not for guilty, high GP participants who find self-reward inappropriate. Attaching a helping opportunity (e.g., charity) to the product turns the should not into a should allowing guilty, high GP consumers to enjoy what they truly want!

In studies 1a and 1b, we demonstrate our basic effects. We place participants in a neutral/guilty emotion and offer a choice between a utilitarian product and a hedonic want product with/without charity. We also measure GP. We find a three-way interac-

tion of emotion by charity presence by guilt proneness. Participants who are guilty and high in GP indulge more than guilty, low GP and neutral participants. Thus we show that attaching a charity does not simply “rebound” guilty, high GP participants to the level of hedonic consumption typical of their neutral (and low GP) counterparts, but rather catapults them to a hedonic consumption level higher than both.

To further examine this theory, we create a situation in which the charity attached to the hedonic product is disliked. According to existing theories, liking of the charity is critically important (Bhattacharya and Sen 1993). However, we argue that for guilty, high GP individuals, it is not critical. Specifically, if helping is what it takes to allow a guilty, high GP consumer to enjoy the emotional benefits of what they want, then the guilty, high GP consumer will be motivated to interpret any helping as sufficient justification for hedonic consumption.

In study 2 we provided neutral/guilty participants with a hedonic product associated with either a liked/disliked charity and measured GP. We predicted that guilty participants high in GP would be most likely to increase consumption of the “wanted” hedonic product even when the charity was disliked. This was confirmed.

In study 3 we examine this tendency of guilty, high GP consumers to turn want into should through meager excuses, by associating the hedonic product with either a trustworthy/non trustworthy charity. As in study 2, we find that guilty, high GP participants increased consumption of the hedonic product associated with the non-trusted charity compared to both neutral and guilt, low GP participants and compared to when the charity was trusted.

A study in progress examines whether these effects occur simply because guilty, high GP individuals are most likely to help or because they seek an excuse to consume the want item. We provided guilty participants with a pleasant (chocolate for charity) and an unpleasant (cold water dunk for charity) helping option. If guilty, high GP participants just want to help, they should choose the unpleasant charity. However, if they want the dual benefits of helping and indulging, they should choose the pleasant charity. Initial (directional) data shows that guilty, high GP participants chose the pleasant charity more often than the unpleasant one.

These findings together suggest that due to the need to feel better, guilty consumers want to indulge in pleasant and fun hedonic products, but feel they should not. Attaching any charity cause to these products, no matter how meager, gives these consumers a way to do so!

Antecedents and Consequences of Consumer Confusion: Analysis of the Financial Services Industry

Paurav Shukla, University of Brighton, UK
Madhumita Banerjee, The University of Warwick, UK
Phani Tej Adidam, University of Nebraska at Omaha, USA

ABSTRACT

Our study is an empirical test of the antecedents and consequences of consumer confusion in the context of the financial services industry. Using quantitative analysis the findings reveal that expectations, attribute and information confusion significantly affect overall confusion. Moreover, expectations and attribute confusion do not affect satisfaction while information confusion has a significant impact on information satisfaction. Furthermore, we find significant impact of overall confusion, attribute satisfaction and information satisfaction on purchase decision. In comparison with earlier studies the findings also suggest that confusion is an industry specific construct and highlights the need for further research in this area.

INTRODUCTION

In the latter part of the 20th century financial services institutions (FSI) changed their role from consumer banking to multiple financial services providers (Harrison 1994; Brooks 1997). This has altered the structure and function of FSIs and has led to the proliferation of choice in the market for consumers (Henson and Wilson 2002). Consequently, consumers are now subjected to a combination of plentiful and conflicting information, an excessive number of brands, and product replications. For example, most banks today provide multiple types of current accounts, savings accounts, insurance, loans, mortgages, credit cards, capital and bond market investment services and so on. While this one-stop service philosophy brought about ease in transactions, it also created false confidence within the consumers regarding their financial judgment leading to the present day credit crisis (Greenyer 2008). For example, the latest figures reveal that the total outstanding consumer debt has increased by 7.3 per cent to in the UK (Butterworth 2008). Similarly, in the US the Federal Reserve in 2008 announced the total US consumer debt for credit cards alone had reached USD 2.55 trillion at the end of 2007.

Researchers in the field of consumer research have hypothesized that product variety can have a positive effect on consumer decision making (Kahn and Sarin 1998). However, results from empirical studies found that over-choice and overload of information deters customers from engaging with a service provider due to confusion over a product's value (Dhar & Simonson 2003; Herbig & Kramer 1994). The present era of over-choice and information overload, especially in financial services (Turnbull et al. 2000), creates increasing amounts of consumer confusion. While the role of consumer confusion has been recognised within the service industry, earlier studies have focused mostly on products such as telecommunications products (Turnbull et al. 2000), personal computers (Leek and Kun 2006), mobile phones (Leek and Chansawatkit 2006), watches (Mitchell and Papavassiliou 1997), fashion (Cheary 1997), and own-label brands (Balabanis and Craven 1997; Murphy 1997). Despite its importance, no consistent approach has been taken to defining and measuring antecedents and consequences of consumer confusion (Walsh, Hennig -Thurau and Mitchell 2007).

Furthermore, it has been proposed by researchers (Shukla et al. 2008) that confusion has a direct impact on satisfaction and final purchase decision; however limited attention has been paid to the same phenomenon in prior research (Cohen 1999). While conse-

quences of confusion have been mentioned to be elevated amounts of dissatisfaction (Foxman et al. 1990) and decreased tendency to purchase (Mitchell and Papavassiliou 1999), empirical testing of such constructs demands further attention (Walsh et al. 2007). It is also believed that the concept of consumer confusion is highly relevant for managers because confused consumers are less likely to make rational buying decisions and consequently may not choose the optimal offer or best value for money (Huffman and Kahn 1998; Mitchell and Papavassiliou 1999) which may create dissatisfaction later on.

This study builds on previous work in the area of consumer confusion (Cohen 1999; Mitchell & Papavassiliou 1999) and satisfaction (Spreng et al. 1996; Oliver 1997). Furthermore, we extend the model into the area of purchase decision by looking at the impact of satisfaction on purchase decision with regard to consumer confusion. In our paper, we address two specific research questions namely: (1) *what are the causes of consumer confusion?* and (2) *what is the impact of confusion on behavioural constructs such as satisfaction and purchase decision?* We propose and empirically test a model which focuses on the antecedents and consequences of consumer confusion within the FSI sector. Our paper is structured as follows. The next section provides a brief literature review leading to hypotheses development and a model followed by the methodology and results. The final section discusses the research findings and then draws conclusions based on the findings.

LITERATURE REVIEW

Consumer confusion is a mental state characterised by a lack of clear and orderly thought and behaviour (Leek & Kun 2006). Confused consumers find it difficult to select, interpret and evaluate stimuli (Mitchell et al. 2005). With the greater volume of information, excessive amounts of brands and product replications it is easy for a consumer to become confused with FSI services. Prior studies reveal that overall confusion is caused by information overload (Huffman & Kahn, 1998); over choice (Mitchell & Papavassiliou 1999; Drummond 2004); ambiguous and misleading information (Keiser and Krum 1976; Golodner 1993); similarity of characteristics (Loken et al. 1986; Mitchell et al. 2005); and expectations fuelled by various communication avenues (Leek & Kun 2006). The review of previous studies assisted in conceptualizing antecedents of consumer confusion. Our view is that confusion is fuelled by consumers' general expectations, attribute similarity between products or services (i.e. attribute confusion), and overload, conflict or ambiguity of information (i.e. information confusion). This, we believe affects consumers' information processing and decision-making abilities and therefore has a direct effect on satisfaction and purchase decision. With a plethora of me-too products and communication messages (Devlin & Gerrard 2004), FSIs provide an engaging environment to study the above stated phenomenon.

Antecedents of consumer confusion

Expectations have been viewed as the standard against which consequent performance is judged (Westbrook 1987). Most researchers share a similar opinion that consumer expectations, prior to a service encounter, impact on customers' evaluation of service performance (Cronin et al. 2000; Parasuraman *et al.* 1985). In the

service literature the expectations construct has been divided into two parts namely, predictive expectations (Tam, 2007) and evaluative expectations (Spreng et al., 1996). The predictive expectations construct is associated with the level of performance and evaluative expectations construct is associated with an estimation of performance. For example, a consumer holding all his financial transactions including banking, mortgage, credit cards, and personal loans among others with a single FSI (approximately 40.5% of all FSI customers in the UK belong to this category) as suggested by Gower (2008) calls the customer services department for an emergency situation such as stolen cards or identity fraud. At this juncture, the consumer expects the call to be answered in reasonable time (predictive expectations) and also expects that whoever answers the call is in the right frame of mind and possesses knowledge related to the problem (evaluative expectations). In most of the FSIs, all the service departments operate separately and therefore the consumers will be asked to call each of them separately leaving the consumer angry, anxious and confused (Patricio et al. 2008) as to is he dealing with a single FSI or multiple FSIs? Therefore, we believe that expectations have a direct relation with overall consumer confusion. In line with the above discussion, we hypothesise that:

H1: *Expectations have a significant impact on overall consumer confusion.*

Several researchers suggest that tangible attributes of products or services such as the similarity of the offer, lead to consumer confusion (Turnbull et al. 2000; Leek and Chansawakit 2006). Furthermore, Wakefield and Blodgett (1999) argue that intangible features also have a major role in consumer evaluations. For example brand image influences the manner in which consumers perceive a product (Mitchell et al. 2005). Similarity in available tangible and intangible features of products, services and brands in the FSI sector creates the likelihood of consumer confusion (Loken et al. 1986; Mitchell & Papavassiliou 1999). Thus we hypothesise that:

H2: *Attribute confusion (tangible and intangible attributes) has a significant impact on overall consumer confusion.*

Information relating to a product or service aims not only at informing but also persuading consumers to make a specific choice (Cohen 1999). Consumers have limitations in their capacity to assimilate and process large amounts of information (Dhar & Simonson 2003), which leads to information confusion, described as 'Uncertainty Confusion' by Mitchell et al. (2005). Keller and Staelin (1987) suggest that information confusion influences the effectiveness of consumer decision making. This impact can be attributed to two phenomena namely; (a) consumers' inability to locate the relevant information due to the sheer volume of information (overload); (b) oversight in identifying critical insights out of the information presented (ambiguity) and (c) variety of information provided through various information sources (conflict). Therefore, we propose the following hypothesis:

H3: *Information confusion (information overload, ambiguous information and conflicting information) has a significant impact on overall consumer confusion.*

2.2 Consequences of consumer confusion

In recent decades, customer satisfaction has been seen as a pivotal factor through which managers and firms have tried to maintain a positive relationship between their products and con-

sumers (Chitturi, Raghunathan and Mahajan 2008). According to Oliver (1997), the issue of satisfaction is present in any transaction undertaken by consumers. Almost every model of satisfaction formation posits that feelings of satisfaction occur when consumers compare their perceptions with expectations. Many researchers view expectations as primarily perceptions of the likelihood of some event (Westbrook 1987; Westbrook and Reilly 1983). While others argue that expectations consist of an estimate of the likelihood of an event plus an evaluation of the goodness of the event (Churchill and Surprenant 1982; Oliver 1980). Satisfaction literature has focused on expectation disconfirmation as one of the key determinant of satisfaction (Oliver 1997). Spreng et al. (1996) described overall satisfaction as a function of attribute satisfaction and information satisfaction. Attribute satisfaction relates to the satisfaction with product performance when compared to consumers' initial expectations (Spreng et al. 1996). Information satisfaction relates to the evaluation of information about particular products and services, defined as a subjective satisfaction judgment of the information used in the decision making process (Westbrook 1987). With the increasing similarities of the features and brands in the FSI sector as well as the abundance of information available, we believe that expectations, attribute confusion and information confusion will have a significant impact on product satisfaction and information satisfaction respectively.

Repeat purchase is an essential ingredient for a successful long-term relationship which in turn provides a strong measure of loyalty. It depicts the tendency of a customer to choose one business or product over another for a particular need (Oliver 1997). Loyalty has been defined by Dick and Basu (1994) as repeat purchase behaviour led by favourable attitudes or as a consistent purchase behaviour resulting from the psychological decision-making and evaluative process. Previous research depicts a positive effect of cumulative satisfaction on repeat purchase and this is strongly supported across industries (Fornell et al. 1996). Furthermore, researchers suggest that when the decision situation offers many equally acceptable alternatives and none can be easily verified as best, it may create feelings of confusion which leads to a reluctance to commit an action (Dhar 1997). This non-commitment will have a direct effect on consumer purchase decision. However, prior studies have not examined the impact of attribute and information confusion as well as attribute and information satisfaction on purchase decision separately. Therefore, we hypothesise:

H4: *Expectations have a significant impact on (a) attribute satisfaction and (b) information satisfaction.*

H5: *Attribute confusion has a significant impact on (a) attribute satisfaction and (b) information satisfaction.*

H6: *Information confusion has a significant impact on (a) attribute satisfaction and (b) information satisfaction.*

H7: *Overall consumer confusion has a significant impact on purchase decision.*

H8: *Attribute satisfaction has a significant impact on purchase decision.*

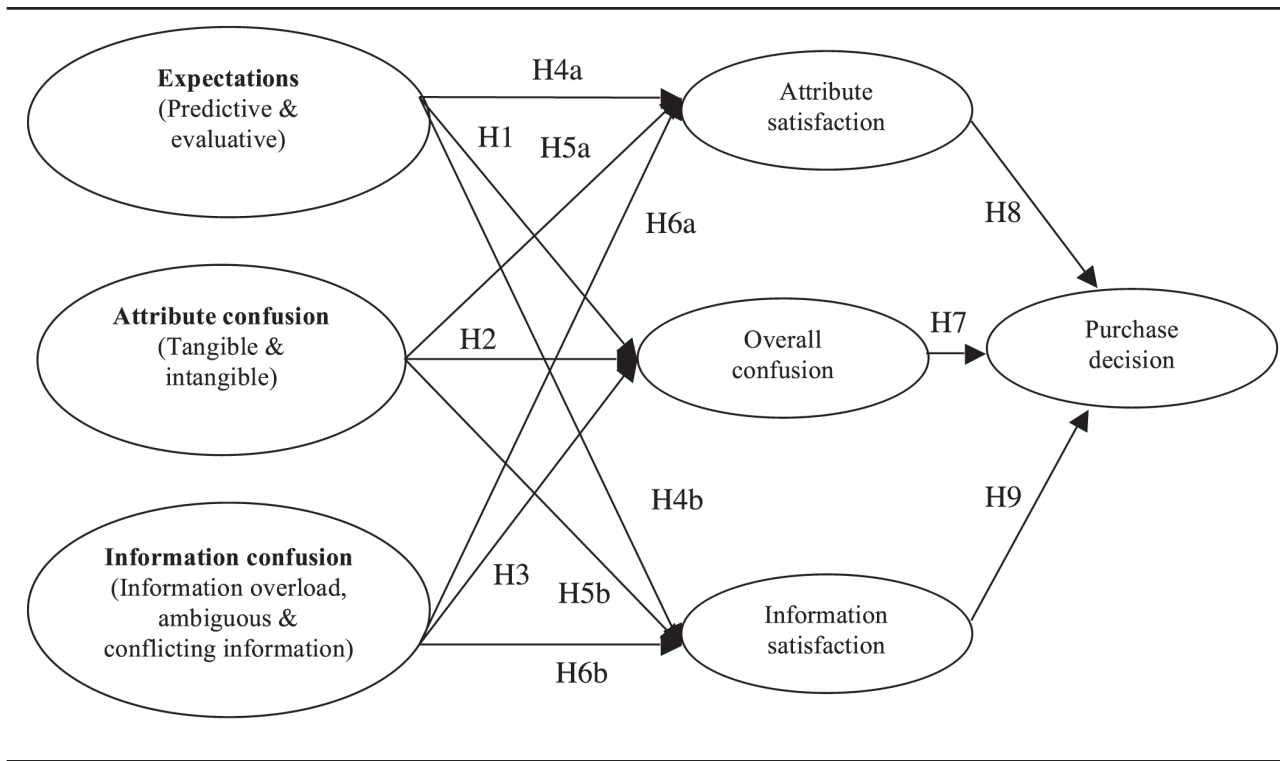

H9: *Information satisfaction has a significant impact on purchase decision.*

The model depicted in Figure 1 represents the hypothesized relationships.

RESEARCH METHODOLOGY

Guided by our aim to measure and validate the antecedents and consequences of consumer confusion, we adopted a quantitative methodology employing a structured questionnaire. The questionnaire was developed modifying various existing scales. Predictive

FIGURE 1
Model overview

and evaluative expectations were measured using the 13 item scale developed by Burgers et al. (2000). The attribute and information confusion scales involved 6 and 4 items respectively which were developed using the study of Leek and Kun (2006), Leek and Chansawatkit (2006) and Turnbull et al. (2000). Overall confusion was measured using 3 items. The attribute and information satisfaction scales included 19 and 7 items respectively and were developed from studies by Spreng et al. (1996) and Hallowell (1996). The purchase decision construct was adopted from McMullan (2005) consisting of 11 items.

The questionnaire was tested for content validity as suggested by Zaichkowsky (1985). The resulting questionnaire was then pretested in a small survey of respondents ($n=12$) adding to the content validity. The questionnaire consisted of three sections. The first section included the classification information focusing on demographics and engagement with FSIs. The second section included the antecedent's related scales and the third section included the consequences scale items.

The questionnaire was administered to more than 900 randomly selected consumers on the high streets of two cities in the UK, of which 460 participated in the study. After coding and editing, 325 (response rate 36.11%) usable questionnaires formed the final sample. All variables in the second and third sections were measured with multiple-item scales. All the items were closed-ended along with a five-point bipolar scale with "strongly agree" to "strongly disagree" as anchors.

RESULTS

Our model was analysed through the maximum likelihood estimator of LISREL8.70 by using the covariance matrix of the measured variables as an input. A two stage approach (Anderson

and Gerbing 1988) was adopted—firstly, estimating the measurement model and obtaining the standardised regression coefficients, and secondly, estimating the structural model. Confirmatory factor analysis (CFA) was used for establishing the validity of the constructs. Unidimensionality is a necessary condition for reliability and construct validation (Mak & Sockel 2001). The unidimensionality of the constructs was analysed by specifying a measurement model for each construct. According to Joreskog (1993), a goodness of fit index (GFI) of 0.90 or above suggests that each of the constructs is unidimensional. The GFI value of all constructs is above the recommended level. Convergent validity was examined using the Normed fit index (NFI) (Bentler and Bonett 1980). All of the constructs have NFI values above the recommended level of 0.90. Therefore, convergent validity was achieved for all the constructs in the study. For reliability, the items were subjected to reliability analysis via Cronbach's alpha. The reliability values of all the factors ranged from 0.71–0.92, satisfying the threshold of 0.70 recommended by Nunnally (1978). The average variance extracted for the measures was found to be 0.50 and above for all constructs, which is greater than the recommended level by Dillon and Goldstein (1984). Discriminant validity was assessed using the test suggested by Fornell and Larcker (1981). This test suggests that a scale possesses discriminant validity if the average variance extracted by the underlying latent variable is greater than the shared variance (i.e. the squared correlation) of a latent variable with other latent variable.

As shown in table 1, this criterion was met by all of the variables in the study as no correlation exceeds the square root of the average variance extracted. Furthermore, the composite reliability was found to be above 0.7 across the constructs, exceeding the recommended threshold value, which also provides strong evi-

dence of discriminant validity. Table 2 presents the summary of results and reports goodness of fit indices, standardised parameter estimates and their t-values for the structural model.

The results clearly show that the model fits the data well on all fit measures, except the chi-square statistics. Fornell and Larcker (1981) expressed doubts over using the chi-square statistics in isolation, as it is considered to be an excessively stringent test of model fit. Its use is generally recommended only in comparative model testing (Joerskog 1993). Overall, the model identification was achieved, and the global fit indices suggested that the model adequately represented the input data, with GFI being 0.94, RMSEA

being 0.06, NFI being 0.94 and CFI being 0.96. From table 2, it can be observed that hypotheses H1, H2, H3, H7 and H8 are accepted while H4, H5 and H6 are partially accepted. The impact of expectations on overall confusion was found to be significant supporting H1 (p<0.01). Furthermore, attribute confusion (H2) and information confusion (H3) significantly impacted overall confusion (p<0.01). Contrary to prior research (Spreng et al. 1996), expectations did not significantly affect attribute (H4a) or information satisfaction (H4b). However, in the case of attribute confusion significant impact on attribute (H5a) and information satisfaction (H5b) was observed (p<0.001). Information confusion was found

to be having significant impact on information satisfaction (H6b) while was not associated with attribute satisfaction (H6a). Overall confusion (H7) had a significant impact on purchase decision ($p < 0.01$). Attribute satisfaction (H8) and information satisfaction (H9) had by far the strongest influence on purchase decision among all parts in the model ($p < 0.01$).

CONCLUSIONS AND IMPLICATIONS

Our study focuses on conceptualizing and empirically testing antecedents and consequences of consumer confusion in the FSI sector. Using quantitative methodology and established scales in the fields of psychology and consumer behaviour, we empirically tested the antecedents and consequences of consumer confusion. The findings suggest that expectations, attribute confusion and information confusion significantly affect overall confusion. Furthermore, we also found that attribute confusion significantly affects attribute and information satisfaction however expectations do not. Furthermore, it was observed that information confusion significantly affected information satisfaction but did not affect attribute satisfaction. We also found the significant impact of overall confusion; attribute satisfaction and information satisfaction on purchase decision. Our results concur with the conceptualization by Mitchell et al. (2005) that consumer confusion is a multi-dimensional phenomenon with significant impact on behavioural intentions. There are several theoretical and managerial implications from the above findings.

Increasing understanding of consumers and decreasing confusion is one of the major aims of any organization. Moreover, in markets like financial services, where many similarities of expectations, attributes and information exist within consumer minds (Patricio et al. 2008), reduction in consumer confusion can become a source of competitive advantage (Walsh et al. 2007). The framework for this study provides managers with a first hand idea of where and how consumer confusion is caused. This will assist managers in optimizing their organizational resources to manage the multi-faceted phenomenon of consumer confusion. Managers treating consumer confusion as a single tier construct may receive undesirable results. For example, just improving the product or service feature may reduce attribute confusion. However, poor communication and highly raised expectations may still elevate the overall confusion. Similarly, a good communication campaign with a less differentiated product or service may also elevate confusion in consumers' minds. Further, the findings indicate that information confusion has an impact on information satisfaction and which in turn, has a strong influence on purchase decision. In the context of financial services industry, this issue merits consideration particularly where consumers are faced with wide ranging technical and complex information on the financial products which can create implications for purchase decision.

Managers can also use the study instrument in developing competitive intelligence by comparing the confusion caused by theirs as well as competitors' products or services. This, we believe will yield rich managerial insights for firms and develop a better and unique campaign in comparison to competitors. The findings highlight the importance of prior expectations in causing confusion. This means that if the company communicates itself via advertisements and other means as a single entity and does not act like one in real-life, there are increased chances that it will make the consumers feel confused. The companies will have to simplify their offer to attract consumers. This is also reflected in the phenomena of attribute and information confusion. To avoid attribute and information confusion, managers will have to differentiate their product and simplify their communication to the consumers. While

this might not be easy especially because of the legal requirements associated with FSI products, it is highly desirable.

The impact of confusion on satisfaction and purchase decision also needs further attention. It was observed that expectations did not affect the attribute or information satisfaction. This suggests that consumers do not see their expectations to be affecting their satisfaction, which is contradictory to earlier research in the area (for further information see, Spreng et al. 1996). Furthermore, the significant impact of attribute confusion on attribute and information satisfaction indicates that the tangible and intangible aspects associated with the service have significant impact on consumer engagement with the service. This requires much close scrutiny by managers there is little differentiation observed in FSIs with regard to attribute differentiation. If in further studies, this is found to be the case, then managers need serious reconsideration with regards to their branding, positioning and differentiation efforts. The significant impact of attribute confusion on attribute and information satisfaction concurs with earlier studies which focused on technology products (Leek & Kun 2006; Leek & Chansawatkit 2006). This suggests that the impact of confusion on satisfaction is not just industry specific. Therefore, managers could use our study dimensions to check the impact of confusion within other industries.

The findings also reveal the significant impact of information confusion on information satisfaction. However the impact is non-significant in the case of attribute satisfaction. Therefore, we suggest the use of attribute and information satisfaction as separate constructs in future studies rather than using overall satisfaction as a single construct. Furthermore, the study findings also highlight the complexity of relationship between the constructs. Managers should ensure that they treat these constructs as stand-alone rather than assuming a causal relationship.

LIMITATIONS AND FUTURE DIRECTIONS

Several limitations associated with this study provide opportunity for future research. First of all, consumer confusion as a construct needs much further consumer research as most prior studies have focused on either trademark infringement issues (Miaoulis and D'Amato 1978) or brand confusion issues (Balabanis and Craven 1997; Foxman, Muehling, and Berger 1990). Our study focused on three confusion constructs and we did not focus on the impact of socio-demographics on consumer confusion. Future research can take into account the impact of socio-demographic matters as well as study the impact of contextual factors on consumer confusion. An investigation of these issues is likely to enrich the construct further. In addition, the level of product and related information complexity and its impact on consumer confusion can be investigated. For example, products such as mortgages, insurance and credit card interest rates are more complex compared to current and savings accounts. Our research has also revealed attribute confusion having a significant impact on attribute satisfaction in the context of financial services. Future research can investigate the same issue in the context of other industries such as retail and airlines for example to test the results presented in this study and uncover other facets. Furthermore, we found the sector specificity of consumer confusion construct and therefore would also suggest looking into cross-national and cross-cultural impact of this construct.

The Influence of Attachment Anxiety on Attitudes for Ads Related to Interpersonal Goals

Hyewook Genevieve Jeong, UCLA, USA

Aimee Drolet, UCLA, USA

ABSTRACT

Researchers have theorized that people with different attachment styles think, feel, and behave differently in a variety of domains. The present research investigated how attachment anxiety influences how consumers process different types of ads, in particular ads that focus on interpersonal versus self goals. Results from a study showed that consumers with higher chronic attachment anxiety had more favorable attitudes towards couple-focused versus self-focused ads. This research provides initial empirical evidence as to the effects of attachment style on persuasion outcomes.

Throughout their lives, people desire to grow closer to and gain approval from their relationship partners, including friends, family members, and romantic partners. Indeed, relationship partners can be strong elicitors of influential motivations that shape our perceptions, attitudes, and behaviors (Fitzsimons and Bargh 2003; Gillath et al. 2006). Recent studies have shown that just thinking about one's significant others can automatically and unconsciously activate goals associated with significant others. For example, when college students are asked to think about their mother, they show higher achievement motivation and better performance on an achievement test (e.g., Shah 2003). Individuals who are motivated in certain respects (e.g., due to high self-monitoring or a need to belong) try to achieve goals that their significant others set for them, even if these goals do not match their own self goals (Morrison, Wheeler, and Smeesters 2007).

Given the importance of relationship partners in daily life, it is not surprising that advertising messages often emphasize how the use of certain products can advance consumers' interpersonal goals. Thus, it is important for researchers to understand how different groups of consumers are influenced by ads that highlight interpersonal goals to different degrees. So far, little research has examined how consumers process and in turn are influenced by persuasive appeals that highlight interpersonal goals versus other goals, in particular self goals.

The present research examined how attachment style influences consumers' responses to ads related to the advancement of interpersonal goals versus personal goals. Past studies have not attempted to link attachment style to persuasion. Our study provides initial empirical evidence as to the effects of attachment style on ad attitudes.

ATTACHMENT THEORY AND RESEARCH

During the first few years of life, infants become emotionally attached to their primary caregiver, the caregiver with whom they interact with the most often. Originally, attachment theory was developed to explain the nature of the infant-caregiver relationship. Later, attachment researchers, notably Bowlby (e.g., 1980, 1982), argued that the core function of the attachment system continues through life. This is the basic assumption of the "internal working model" (Bowlby 1969). Internal working models of attachment are thought to be cognitive-affective motivational schemas. Whereas traditional approaches to schemas have tended to focus on semantic knowledge, internal working models of attachment emphasize the representation of motivational elements, such as needs or goals (Shaver, Collins, and Clark 1996).

Internal working models play an important role in shaping how individuals interpret their interpersonal relationships and the

social world in which they reside. Main, Kaplan, and Cassidy (1985) proposed that an internal working model during childhood is composed of specific experiences of one's self and others. Over time, these specific experiences become more generalized beliefs and expectations about the warmth and responsiveness of others, worthiness of the self, and the level of security in the world. Thus, internal working models are expected to become solidified through repeated experience and increasingly generalized. Although the presentation of self and others changes and evolves over people's lifetimes as they form new relationships with others, research suggests that internal working models remain strongly influential (Collins and Read 1994). Once developed, people's histories of interpersonal experiences and their unique sets of memories, beliefs, and expectations shape how they think and feel about relationships with others and how they behave in relationships. Moreover, these internal working models of attachment function are largely automatic (Bowlby 1979; Collins and Allard 2001). Below, we review research on adult attachment style, which is believed to be rooted in chronic differences in internal working models of the self and others developed in infancy. We then review how these systematic differences would be expected to influence how certain types of ads, those that emphasize interpersonal goals versus self goals, are processed.

Attachment Style and Pursuit of Interpersonal goals

Attachment style refers to an individual's habitual pattern of relational perceptions, emotions, and behaviors in interpersonal relationships (Collins and Read 1990). Researchers have theorized that there are three prototypical attachment styles that develop based on infants' reactions to separation and reunion with a primary caregiver: 1) secure; 2) anxious; and 3) avoidant (Ainsworth, Salter, Blehar, and Wall 1978). Here, we focus on relationships between attachment style and interpersonal goals. People with different attachment styles differ in the extent to which they are motivated to seek closeness, avoid rejection, and maintain autonomy.

Adults with a secure attachment style tend to be more comfortable with closeness, intimacy, and interdependence in their interpersonal relationships. They are generally willing to rely on others when necessary and are confident that they are worthy of the love of others. They tend to have a favorable self view, and this makes securely-attached adults less dependent on receiving other people's validation or support (Collins and Read 1994). Securely-attached people have a more balanced preference for between autonomy versus closeness. Getting close to others does not threaten securely-attached people's sense of autonomy. And, maintaining autonomy does not provoke worries about being abandoned or rejected by others.

On the contrary, insecurely-attached people (both avoidantly-attached and anxiously-attached) are less able to balance closeness and autonomy desires. Because individuals with an avoidant attachment style have a largely negative view of human nature, they tend to distrust other people, maintain emotional distance from them, and show less interest in forming close relationships (Bowlby 1982; Shaver and Hazan 1988). Although individuals with an avoidant attachment style have negative views about others, they generally have a favorable self view. Avoidant people tend to believe that independence and self-reliance are more important than the support or positive views of other people. They desire distance from others and self-control.

Whereas avoidantly-attached people prefer not to depend on others, anxiously-attached people are highly dependent on others' reactions and behaviors. Anxiously-attached people are relatively insecure about their partner's feelings and doubt their partner's love (Hazan and Shaver 1987). They habitually worry about being rejected or abandoned. This anxiety produces a strong desire for closeness, proximity seeking, and dependence on others. Anxiously-attached people tend to pursue interpersonal goals accorded with their strong needs for closeness which causes them to behave in a dependent manner. They tend to think that they are unlovable unless they are able to meet others' expectations (Collins and Read 1990; Mikulincer 1998). Anxiously-attached people are motivated to meet certain standards of worth in order to get approval from others and satisfy others. Indeed, their level of personal happiness and well-being is directly related to the amount of approval they receive from others and to the amount of satisfaction they produce in others (Bartholomew 1990). For example, Collins and colleagues (2004) found that, compared with securely-attached people, the anxiously-attached tend to overemphasize the importance of their partner's love and support. Accordingly, anxiously-attached people are likely to focus their attention on others.

This is in contrast to the tendencies of securely-attached people, who feel confident about the love and availability of their attachment figures, or to tendencies of avoidantly-attached people, who are relatively indifferent to what others think of them (Bartholomew and Horowitz 1991; Davis, Shaver, and Vernon 2004). For these two groups, attentional focus is not on others. For example, because the motivation of the avoidantly-attached is to minimize attachment concerns, they tend to direct attention away from information that makes others' needs salient (Fraleay, Davis, and Shaver 1998).

There has not been much empirical work that has directly assessed the information processing goals of individuals with different attachment styles. However, a few studies provide some evidence. Mikulincer (1997) provided indirect evidence that attachment-related goals influence information processing. In his study, participants were asked to evaluate a product and select how much information they wanted to hear about the product. In addition, they were told that the time spent listening to the information would affect how much time they had left for a second task. Half of the participants were told that the second task was related to a social interaction. The rest of participants were told that it was not related to a social interaction. The study showed that participants with an anxious attachment style chose to spend less time during the first task when the second task was social versus nonsocial. In contrast, participants with an avoidant attachment style preferred to spend more time during the first section when the second task was social versus nonsocial. Participants with a secure attachment style did not show any difference in terms of the amount of time selected during the first section, regardless of whether the second task was social or nonsocial. These results indicate that participants allocated their attention in ways that served their chronically-active goals due to attachment style.

Attachment Style and Persuasion

As discussed above, past research has demonstrated ways in which attachment style affects how people think, feel, and behave in situations such as romantic relationships (Hazan and Shaver 1994) and friendships (Trinke and Bartholomew 1997). Some research has attempted to incorporate attachment theory into the consumer domain. A recent study showed that consumers with different attachment styles are respond differently to types of brand personalities. Specifically, whereas consumers who are both anx-

iously- and avoidantly-attached prefer exciting brands, consumers who are anxiously-attached but not avoidantly-attached prefer sincere brands (Swaminathan, Stilley, and Ahluwalia 2009). Thomson and Johnson (2001) showed that knowledge of different attachment styles can be used to predict satisfaction in consumer-brand relationships. They found that consumers with either higher or lower scores on *both* avoidance and anxiety measures reported greater satisfaction in consumer-brand relationships. Consumers who were higher on one dimension but not the other were likely to report lower satisfaction in consumer-brand relationships. According to Nguyen and Munch (2006), consumers with different attachment styles exhibit different gift-giving behaviors. Anxiously-attached consumers view giving a gift to their romantic partners as an obligation. After giving gifts to their romantic partners, they expect to receive appreciation in return. Alternatively, consumers with high avoidance attachment who give gifts to their romantic partners do not expect gratitude. Another study demonstrated that avoidantly-attached consumers are generally less attached to possessions after a loss than are securely-attached consumers (Ferraro, Escalas, and Bettman 2006).

Overview

As of yet, there have been no studies directly examining the association between attachment style and persuasion. The premise of the present research is that understanding structures and functions of internal working models can provide insight into this issue. In our study, we investigated whether different types of ad appeals, those that focus on the fulfillment of interpersonal goals versus self goals, produce different persuasion effects among anxiously-attached consumers. In the present research, we view an interpersonal ad as an ad that emphasizes how a product can increase social interaction with and the satisfaction of a romantic partner through the use of the advertised product. We view a self ad as an ad that emphasizes the satisfaction the individual consumer can gain through use of the advertised product outside of any interpersonal context. In view of the above, we predicted that consumers with high (vs. low) attachment anxiety would have relatively more favorable attitudes towards an ad highlighting the emotional value a romantic couple (vs. an individual) would receive from buying and using the advertised product.

STUDY

Pretest

In order to create ads that emphasized the fulfillment of interpersonal goals versus personal goals, we conducted a pretest ($n=102$; 56 % female; $M_{age}=21$). Participants viewed an ad that depicted either a single individual (self-focused ad condition) or a couple (couple-focused ad condition) enjoying and benefiting emotionally from a product. The product we selected was a digital camera because consumers can enjoy taking pictures for their own pleasure and/or for the pleasure of others. We used a fictitious brand name for the digital camera so participants could not rely on potentially preexisting brand attitudes. Each of the two ads we created had 11-12 lines of ad copy. The ads differed in that the couple-focused ad showed a romantic couple benefiting from the use of the product whereas the self-focused ad showed an individual benefiting from the use of the product. Each ad included 3-4 clip-art pictures that showed either a happy couple or a happy individual.

All participants read:

"Picture your life with a Pentex digital camera. Pentex digital cameras offer superb image quality with vibrant colors, detail

and performance. Equipped with the latest technology, Pentax digital cameras have all the features you want, and their intuitive design makes using these features easy.”

Participants in the self-focused ad condition then read the following ad copy:

“Taking a photograph is more than just documenting your experience. It’s a way to capture and hold onto the feelings you felt during those singular moments in your life. These photos will reflect those moments that make up the store of your life. Pentax Digital Cameras will make you happy.”

The copy for the couple-focused ad stated:

“Taking a photograph is more than just documenting your experience. It’s a way to capture and hold onto the feelings you shared during those special moments spent with your special someone. These photos will reflect the joy and love that make up the story of your life. Pentax Digital Cameras will make your special someone happy.”

After reading the ad, all participants reported the degree to which the ad made them focus on people with whom they have an interpersonal relationship (1=Not much at all, 7=Very much). As expected, we found that participants in couple-focused ad condition focused more their interpersonal relationships compared to participants in self-focused ad condition ($M_{couple}=4.42$ vs. $M_{self}=3.20$; $t(101)=3.22$, $p<.01$).

Method

The study was a 2 (ad type: self-focused vs. couple-focused) X 3 (attachment style: secure vs. anxious vs. avoidant). These factors were not fully crossed as was possible that participants could score high or low along more than one attachment style (see below). Three hundred and two college-age students (58% female; $M_{age}=21$) at a West Coast University were paid \$5 to participate in an advertising study. Participants were randomly assigned to one of one of the ad conditions. After reading the ad, they rated their attitude toward it (Aad). Participants then completed demographic questions. After several filler items (from unrelated studies), participants completed the Collins and Read (1990)’s adult attachment scale measure. This 18-item scale includes three subscales based on Hazan and Shaver’s (1987) three category measure of adult attachment scale: (a) comfort with closeness (attachment security), (b) comfort depending on others (attachment avoidance), and (c) anxiety in relationships (attachment anxiety). Example items include: “I find it difficult to allow myself to depend on others” (attachment avoidance); “I often worry my partner will not want to stay with me” (attachment anxiety); and “I find it relatively easy to get close to others” (attachment security). Each item was rated on a seven-point Likert scale, from “not at all like me” (1) to “very much like me” (7).

Past studies have used either a categorical measure of the three types of adult attachment style or a two-dimension continuous measure of attachment avoidance and attachment anxiety. Neither of these measures fully captures adult attachment. That is, individuals cannot be cleanly divided into one category of attachment style. Individuals can score high or low on more than one attachment style measure. The two dimensional measure focuses only on attachment avoidance and anxiety ignores attachment security; low attachment avoidance and anxiety are presumed to be high in attachment security. However, some individuals score highly on both attachment anxiety and attachment security, thereby qualifying for both

attachment dimensions. In our research, we used three different continuous attachment measures (secure, anxious, and avoidance) and analyzed each separately. Thus, we do examine potential interactions among different attachment styles, although one might find them. As we discuss below, this may be viewed as a limitation of the present research.

Results

We tested our predictions using three separate ANOVAs. The three attachment styles were analyzed separately. The continuous measure for each attachment style was used in all analyses.

Participants completed 3 items that measured their ad attitudes (bad-good, dislike-like, and unfavorable-favorable, 1-7 scale). We averaged these items ($\alpha=.92$). ANOVA revealed a significant interaction between the anxious attachment measure and ad condition ($F(1, 298)=6.95$, $p<.01$). Follow-up analysis showed that there was no effect of anxious attachment style in the self-focused ad condition ($F(1, 147)=1.86$, $p=.17$) whereas there was a significant positive effect of anxious attachment style in the couple-focused ad condition ($F(1, 151)=5.62$, $p<.02$). A median split (Med.=3.44) illustrates that anxiously-attached participants had more favorable ad attitudes in the couple-focused ad condition compared to participants not anxiously attached ($M_{High}=4.97$ vs. $M_{Low}=4.40$). There were no significant interaction effects on ad attitudes among securely-attached participants ($F(1, 298)=.10$, $p=.75$) or avoidantly-attached ($F(1, 298)=.30$, $p=.58$).

Discussion

These results show that consumers with different attachment styles respond differently to the two ad types. As predicted, anxiously-attached participants had more favorable attitudes toward the couple-focused ad. These results are consistent with the view that anxiously-attached people are more dependent on others and that the couple-focused ad is preferred because it shows how product purchase can fulfill their (chronic) goal of positive interpersonal interaction.

GENERAL DISCUSSION

Summary

Consumer researchers have not paid much attention to the role of attachment style in persuasion. This research investigated the influence of consumers’ attachment styles on ad attitudes. Our study sheds light on the link between attachment style and persuasion outcome. Due to positive and warm interactions with their primary caregivers, people with a secure attachment style seek to balance autonomy and interdependence goals. Due to inconsistent care-giving from their primary caregivers, people with an anxious attachment style doubt their own lovability and depend on others for approval (Mikulincer 1998). Results from our study showed that anxiously-attached versus securely-attached consumers had more favorable attitudes towards a couple-focused ad versus a self-focused ad.

Taken together, this research provides the first empirical evidence that attachment styles are related to responses to ads having to do with interpersonal goals. However, this research should be viewed only as an initial step in the exploration of the complex association between consumers’ attachment style and persuasion process.

Limitations and Follow-up Study

There are several limitations to this research that need to be examined in future research. One limitation of the study was that it used fictional ads and did not have a no-people control condition

(i.e., an ad that shows a picture of an individual or a couple with the product). While this enabled us to control for potential pre-existing brand attitudes, our results might not generalize. We ran a follow-up study ($n=100$; 64% female; $M_{age}=20$) which used real ads and had a no-people control ad condition. The study was a 3 (appeal type: self-focused vs. couple-focused vs. control) X 3 (attachment style: secure vs. anxious vs. avoidant) within subject design. Participants read three ads (randomly ordered). They then completed the attachment measures.

Participants in the self-focused ad condition read:

“Some of the greatest fights don’t involve an opponent. Everlast. Greatness is within.” The ad shows a single person punching a sandbag. In the couple-focused ad condition, participants read:

“Reveal your natural tone and reveal the real you. New NIVEA natural tone moisturizer with even tone complex helps fight the discoloration caused by aging, dryness and too much sun. So you have beautifully even-toned skin in all over. And the confidence to get as close as you want. NIVEA. Touch and be touched.”

The ad shows a couple (two individuals looking at each other. In the control condition, participants read:

“Do you really have to spend “60,000 to get a \$60,000 car? Building an exceptional \$60,000 luxury sedan is an amazing accomplishment. Designing it to cost less than \$40,000, however, is nothing short of a miracle. Which brings us to the remarkable new 2009 Genesis. With rear-wheel drive and a 4.6 L, 375-horsepower V8, it’s more powerful than the far pricier BMW 550i, yet as spacious as a 760Li or Mercedes-Benz S-Class.”

The ad shows only the product (a car) without a person or couple. A manipulation check confirmed that participants viewed the couple-focused ad as more couple-focused compared to the self-focused ad ($M_{couple}=3.79$ vs. $M_{self}=2.26$; $t(182)=5.60$, $p<.001$). ANOVA found a significant interaction effect on ad attitudes between ad condition and attachment anxiety ($F(2, 276)=3.33$, $p<.04$). There was no significant effect of attachment anxiety in the self-focused ad and control ad conditions but there was a significant effect in the couple-focused ad condition ($F(1, 80)=13.90$, $p<.001$). A median split along the attachment anxiety measure (Med.=3.63) showed that anxiously-attached participants (vs. not) had more favorable attitudes towards the couple-focused ad ($M_{High}=4.82$ vs. $M_{Low}=3.92$). As in the main study, there was no significant effect of ad type on the ad attitudes of avoidantly-attached or securely-attached participants. Thus, the results of the follow-up study are consistent with the results of the main study. They confirm that attachment anxiety influences responses to ads related to interpersonal versus self goals. Attachment anxiety did not influence attitudes towards the self-focused or control ads. These results notwithstanding, a clear limitation of the follow-up study is that it does not control for product type across ad conditions.

Another limitation of the main study is that it did not examine interactions among different attachment styles. The three attachment styles were studied separately. Yet, there may be interactions among attachment styles. A further limitation of the present research is that it relies on chronic attachment style to effect variation in attachment style strength. Research has demonstrated that attachment (in)security can be induced by priming techniques (e.g., Swaminathan et al. 2009). Given that, in many cases, marketers

may not know their customers’ attachment styles, it would be extremely useful to confirm our results in a future study that primes attachment style.

Conclusion

Attachment researchers have long theorized that people with different attachment styles think, feel, and behave differently in a variety of domains. Despite the potential importance of attachment style to consumer behavior, attachment style has not been extensively studied by consumer researchers. This research provides initial evidence that consumers with different attachment styles respond differently to ads related to self versus interpersonal goals. Indeed, we believe that attachment theory provides a useful framework for understanding a wide variety of persuasion issues. Our results have implications for marketers who may find it very useful and productive to target different kinds of ads to segments of consumers with different attachment styles.

Consumer Response to Service Failures: The Role of Emotional Intelligence and Coping

Yuliya Strizhakova, Rutgers University, USA
Yelena Tsarenko, Monash University, Australia

ABSTRACT

The goal of the study was to understand how consumers use their intrinsic resources in situations of service failures. Specifically, we examined how consumers applied their Emotional Intelligence (EI) to deal with negative emotions when facing service failures with varying degrees of recovery, to implement their copying strategies and to engage in negative word-of-mouth. We also assessed idiosyncratic effects of the four EI dimensions. Overall, consumer EI played a critical role in managing negative emotions and activating relevant coping strategies but EI dimensions exhibited some antagonistic effects. Recovery efforts by a service provider moderated some EI effects.

INTRODUCTION

Research has established importance of emotions in marketing and consumer decision making (Luce 1998, Nyer 1997, Pham 1998, Ruth 2001); however, the question of how consumers manage and use their emotional capabilities in their everyday consumption remains unanswered. The notion that customers are able to harness and draw on emotions as a resource is based on the assumption that emotions can be understood and managed. Emotions are merely one element of an individual's psychological resources that are instrumentally applied in a range of circumstances (Averill et al. 1994). Mayer and Salovey (1997) refer to this ability as emotional intelligence (EI), i.e., one's ability to skillfully use emotional information to solve problems and reach desired outcomes.

What makes EI of a particular importance to consumer behavior is that it corresponds to a mental process involved in the recognition, use, understanding and management of one's emotional states to solve problems and regulate behaviors (Mayer and Salovey 1997). Understanding consumer employment of emotional resources can assist marketers in better serving customers and in predicting their consumption choices and behaviors. Even though this construct has been widely applied in interpersonal conflict situations (e.g. work productivity, intimate relationships, education and health), only a few studies of buyer-seller interactions that focus solely on customer-oriented selling (Manna and Smith 2004, Rozell et al. 2004) and service provider competency (Bardzil and Slaski 2003, Kernbach and Schutte 2005) have examined it; however, none of these takes the perspective of customers. A recent study by Kidwell, Hardesty and Childers (2008) applies the construct of EI to consumer decision making and calls for more extensive research on EI across multiple consumption contexts, including coping with negative emotions.

The goal of the present study is to examine the role of consumer EI in situations of service failures where negative emotions are inevitably evoked and consumers are forced to cope with them. Several factors make service failures an attractive context for the study. First, service failure is an unavoidable occurrence in service encounters. Second, in an attempt to gain a deeper understanding of the service failure process the emphasis of research has been recently directed toward examining the role of customers in unfavorable service incidents. The way customers manage and express their emotions, cope with stress and evaluate recovery outcomes requires researchers to develop a richer, more fine-grained understanding of the role of consumer personality in the service encounter. Third, understanding the role of consumer EI in

service failures can help providers mitigate negative consequences of such failures and potentially re-establish positive relationships with customers.

Our second goal is to understand consumer processes of coping with event-induced stress, a realm that has largely been neglected in consumer research. Recent research in this area has focused on development of coping scales (Duhachek 2005) and conceptual framework (Moschis 2007); however little research has empirically tested antecedents or outcomes of the coping process. In this paper, we investigate effects of consumer EI on coping and negative word-of-mouth. Our third goal is to explore individual effects of EI dimensions in service failures. Although these dimensions typically form a composite EI construct, their individual effects on consumer behavior in certain contexts may diverge and therefore it is crucial to understand how they impact the overall consumption process (Kidwell, Hardesty and Childers, 2008). We address a gap in consumer research by devising and empirically testing a framework that captures consumers' emotional states under stressful conditions of various degrees.

THEORETICAL PERSPECTIVES

Emotional Intelligence and Negative Emotions

Emotional intelligence has evoked a great deal of interest with its further theoretical and empirical developments in psychology, education, clinical settings (Petrides et al. 2007), and management (Jordan et al. 2002). Although the concept is not new, it has gained popular interest with the release of Goleman's bestseller (1996) in which he argues that emotions and intelligence do not belong to separate domains and that any fundamental distinction between the two is arbitrary. The intersection of emotional and cognitive processes implies that people possess "the ability to perceive accurately, appraise and express emotion; the ability to access and/or generate feelings when they facilitate thought; the ability to understand emotion and emotional knowledge; and the ability to regulate emotions to promote emotional and intellectual growth" (Mayer and Salovey 1997, 35). This mental ability is captured by the EI concept, which differentiates it from other so-called mixed models of EI (e.g., Bar-On 1997, Cooper and Sawaf 1997, Goleman 1996) that combine mental abilities with a variety of characteristics, such as motivation, states of consciousness and social activity (Mayer et al. 2000).

Ability models of EI claim that four distinct processes define the construct: perceiving, facilitating, understanding and managing emotions (Salovey et al. 1999). The first three processes are quite abstract (Kidwell et al. 2008). Perceiving refers to consumer emotional appraisal and expression; facilitating refers to consumer ability to access, generate and use emotions to facilitate problem solving and thinking; and understanding involves consumer ability to analyze and comprehend emotions. Managing is the least abstract dimension that refers to consumer emotional regulation to achieve desired outcomes. Because of varying degrees of abstractness, these individual dimensions are likely to exhibit differentiating effects on consumption and its outcomes across specific contexts.

Even though service recovery efforts have been shown to impact customer behavioral responses to a service failure (Wirtz and Mattila 2004), the role of EI in managing service failures

remains unexplored. In circumstances of a service failure, the disparity between customer expectations and perceived delivery of service inevitably creates negative emotions (Kelley and Davis 1994, Smith and Bolton 2002). Consumers EI is likely to minimize this negativity. Salovey et al. (1999) suggest that EI is used to rebound from negative feelings and to repair damage created by negative moods. Those with high levels of EI are not only attentive to their emotions but have the ability to gain emotional clarity; hence, demonstrate better coping with negative events and are less likely to engage in a prolonged ruminative process. When service providers minimize emotional damage of a service failure by engaging in recovery efforts with a maximum of excellence, effects of EI are likely to be stronger. We predict:

H1a: Consumer EI decreases negative emotions elicited by a service failure.

H1b: Effects of consumer EI on negative emotions are moderated by service recovery efforts: negative effects of EI are stronger when excellent recovery efforts are made.

Because of limited research on individual EI dimensions, we ask:

RQ1: Which EI dimensions decrease negative emotions elicited by a service failure?

Emotional Intelligence and Coping

Coping in the psychological literature is defined as an individual response mechanism that involves “the constant changing of cognitive and behavioral efforts to manage specific external and/or internal demands that are appraised as taxing or exceeding the resources of the person” (Lazarus and Folkman 1984, 141). This suggests that, when faced with negative consumption-related tensions, customers respond by engaging in coping strategies to regulate their emotions and adjust their cognitive and behavioral dispositions in order to better cope with the stressful environment (Nyer 1997, Luce 1998, Yi and Baumgartner 2004).

Coping encompasses a myriad of thoughts, emotions and behaviors that present a challenge to capture and classify in a meaningful typology (Folkman and Moskowitz 2004). The manner of coping is situation-specific and multidimensional. One of the main approaches to coping stems from earlier work by Folkman and Lazarus (1980), which distinguishes problem-focused (managing the problem) and emotion-focused (managing elicited emotions) coping. In the consumption context, Yi and Baumgartner (2004) developed a typology of eight coping strategies and mapped them against these two strategies. Although the two coping strategies are commonly conceptualized at opposite ends of a spectrum, researchers have argued that they should be treated as complementary rather than contrasting (Lazarus 1996).

In contrast, Duhachek (2005) proposed a more universal scale of coping, which can be used in a range of stressful consumption episodes. This scale consists of three dimensions: active coping, expressive coping and avoidance/denial that, in turn, capture eight constructs of coping. The “active” dimension resembles the problem-focused coping and captures the idea of consumer employment of resources to deal with the problem at hand. The “expressive” dimension resembles the emotion-focused coping but captures the idea of consumers’ support seeking behaviors to deal with negative emotions and stress. The “avoidance/denial” dimension reflects an alternative way of coping that is more related to problem dismissal rather than problem solving.

Research that examines the impact of EI on coping is not particularly advanced (Zeidner et al. 2006). Rozell et al. (2004) highlight the fact that emotionally intelligent individuals are more

aware of their own feelings as well as the feelings of others, better able to identify emotions and communicate emotions when appropriate. Salovey and Mayer (1990) also suggest that through EI customers can regulate their own emotions by maintaining positive moods and relieving negative affective states. As Zeidner and Roberts (2002) note, an emotionally intelligent person is not just successfully adapted but adaptable, in the sense of being competent to deal with new challenges (p. 26). Given this adaptability, we expect consumer EI to increase consumer engagement in more approach-oriented coping styles (active and expressive coping) but do not relate to more passive avoidance/denial coping. We hypothesize and posit:

H2: Consumer EI has a positive effect on consumer engagement in “active” and “expressive” coping but is not associated with “avoidance/denial” coping.

RQ2: Which EI dimensions impact a) “active”, b) “expressive” and c) “avoidance/denial” coping?

Emotional Intelligence and Word-of-Mouth

Word-of-mouth is a complex outcome of a service encounter. On the one hand, a positive word-of-mouth is a desired outcome for any service provider as it ameliorates efforts of an organization in promoting its service or products. On the other hand, word-of-mouth is to some degree an extension of the coping process, particularly in negative incidents. Engaging in repeated conversations about one’s own experience with a service provider helps consumers organize and better understand their own thoughts and emotions. By using language to disclose their inner psychological state, customers who experience a service failure are likely to see a negative experience in a more coherent way, i.e., to position it more meaningfully in their world (Salovey et al. 1999). Furthermore, the theory of stress and coping states that successful coping assumes that individuals are open to their emotional experiences and EI plays a central role in how these emotional experiences are framed. Specifically, individuals who use “balance in emotion words (moderate amount of negative words accompanied by a greater amount of positive emotion words)” (Salovey et al. 1999, 155) when disclosing their negative incidents exhibit less distress and cope more effectively overall.

Past consumer research found consumption emotions to be significant predictors of complaining and both positive and negative word-of-mouth (Nyer 1997, Westbrook 1987). Although it can be speculated that the majority of consumers recognize that service failures are inevitable, we expect that customers with higher EI are more likely to arrive at this reasoning due to higher emotional control and more successful coping; thus, they are less likely to engage in negative word-of-mouth as compared to those with lower EI. Given that consumer EI is a personality variable that impacts both emotional reactions to a service failure and coping strategies, its effects on the service outcome (word-of-mouth) are likely to be mediated by the salience of emotional reactions and customer engagement in coping. We predict and posit:

H3a: Consumer EI decreases negative word-of-mouth in circumstances of service failure.

H3b: Effects of EI on negative word-of-mouth are mediated by negative emotions elicited by a service failure and consumer active and expressive coping.

RQ3: Which EI dimensions impact consumer negative word-of-mouth?

TABLE 1
Means and ANOVA F-test by Recovery Conditions

	Poor Recovery	Weak Recovery	Excellent Recovery	F-test
Negative Emotions	4.78	3.85	3.03	89.69***

METHOD

Design

To ensure variability of negative emotional reactions to a service failure, we manipulated recovery efforts expressed by service providers to a service failure in our scenario-based design. The use of scenarios avoids the expense and ethical consideration associated with observing or enacting an actual service failure while avoiding the response bias due to memory lapses and rationalization likely to be present in recall-based surveys (McCullough et al. 2000) and is frequently employed in service failure studies (Bitner 1990). The service failure context was a hotel reservation for a summer vacation trip to a foreign country. In all scenarios, participants experienced a double booking on their reservation. Next, participants either did not receive any room from the hotel staff (poor recovery), received the only vacant room available of smaller size and lower price (weak recovery) or got an upgrade to a suite at the initial price (excellent recovery). After reading the scenario, participants reported their levels of emotional responses to the service failure. Next, they completed questions regarding their coping styles and word-of-mouth. Participants were also asked basic demographic and EI questions.

Sample

Our sample was recruited by a marketing research firm from their existing customer database. Within a week, we collected 655 responses (poor recovery: $n=251$; weak recovery: $n=251$; excellent recovery $n=153$). The sample of respondents was composed of 327 (50%) men and 328 (50%) women, ranging in age from 18 to 79 ($M=48.77$, $SD=14.46$). In terms of education, 50.8% of respondents had a college degree or higher, while 49.2% had a high school diploma or less. ANOVA tests did not indicate any significant differences among participants in relation to their gender ($F(2;653)=1.52$, $p > .05$), age ($F(2;653)=1.48$, $p > .05$), and education ($F(2;653)=1.94$, $p > .05$) composition across the three conditions.

Measures

All measures employed seven-point scales. Based on past research (Jordan et al. 2002, Mayer et al. 2003, Kidwell et al. 2008, Schutte et al. 1998), we adapted 16 items of CEIS to the context of service failures that tapped into four distinct dimensions of EI: perceiving (3 items, $\alpha=.76$, $M=5.26$, $SD=.84$), facilitating (5 items,

$\alpha=.81$, $M=5.04$, $SD=.84$), understanding (3 items, $\alpha=.80$, $M=4.40$, $SD=1.08$) and managing (5 items, $\alpha=.82$, $M=2.78$, $SD=.69$). Pearson correlation coefficients between dimensions were in the .29-.51 range. We also averaged all items to derive a composite measure of EI ($\alpha=.88$, $M=4.37$, $SD=.64$). To measure consumer coping, we adapted Duhachek's (2005) three-dimensional eight-factor coping style scale comprised of 32 items. The three coping styles in our study were "active" coping (16 items, $\alpha=.93$, $M=5.20$, $SD=.87$), "expressive" coping (13 items, $\alpha=.88$, $M=4.44$, $SD=.94$) and "denial" (3 items, $\alpha=.86$, $M=2.46$, $SD=1.21$). To measure consumer negative emotional reactions to a service failure, we asked participants how strongly they felt six emotions: anger, frustration, anxiety, threat, fear and worry after their exposure to a given scenario. EFA resulted in a uni-dimensional resolution explaining 69% of variance ($\alpha=.91$, $M=4.01$, $SD=1.47$). We asked two questions (reverse-coded from Maxham and Netemeyer 2002) to measure negative word-of-mouth ($\alpha=.96$, $M=2.83$, $SD=1.84$). We coded manipulation of recovery efforts as 1=poor, 2=weak and 3=excellent.

RESULTS

Manipulation Check

To assess effectiveness of our manipulation of recovery efforts, we used ANOVA to compare participants' means across recovery conditions. Consistent with our manipulation, participants experienced the weakest negative emotional response when facing excellent recovery efforts and the highest negative emotional response when facing poor recovery efforts. Participants also expressed highest levels of all types of coping (active, expressive and denial) and lowest negative WOM when facing excellent recovery efforts. ANOVA did not reveal any significant differences among participants on their composite EI or any of its dimensions across the three conditions (see Table 1 for means and F-tests).

Analyses

To test our hypotheses and answer research questions, we used simultaneous and hierarchical multiple regression analyses. Our first set of hypotheses and a research question related to effects of EI on the negative emotional response elicited by a service failure (see Tables 2 and 3). As predicted in H1a, consumer EI decreased consumer negative emotional response ($\beta = -.12$). As predicted in

TABLE 2
Regression Analysis on Negative Emotional Response with Composite EI

H1b, the interaction term of EI with recovery efforts was also significant ($\beta = -.32$). Specifically, EI had a strong negative effect on consumer emotional reaction when recovery efforts were excellent ($\beta = -.21, p < .01$); but this effect was only marginally significant in the weak and poor recovery conditions ($\beta = -.08$ and $\beta = -.10, p < .10$). In response to our RQ1, regression analysis indicated that only the managing dimension of EI had a significant negative effect on consumer emotional response ($\beta = -.18$). Similarly, the interaction between recovery efforts and the managing dimension was significant ($\beta = -.28$). The managing dimension of EI had the strongest negative effect when excellent recovery efforts were made ($\beta = -.30, p < .001$), followed by weak ($\beta = -.20, p < .001$), and poor ($\beta = -.12, p < .10$) recovery.

Our H2 and RQ2 discussed effects of EI on consumer coping. We used hierarchical regression analysis where consumer emotional response and recovery efforts were entered at step 1 as controls and consumer EI (model 2a) or its dimensions (model 2b) were entered at step 2. As predicted, consumer EI significantly increased “active” coping ($\beta = .43$) and “expressive” coping ($\beta = .19$) but had no significant effect on “denial” ($\beta = -.02$). Interestingly, consumer negative emotional response had a significant negative effect ($\beta = -.18$) on “active” coping but a positive effect ($\beta = .49$) on “expressive” coping. Excellence in recovery efforts had a significant positive effect on “denial” ($\beta = .11$). Effects of all interactions were not significant ($p > .10$) and were consequently omitted (see Table 4, model 2a). Next, we examined effects of the four EI dimensions on consumer coping. Three EI dimensions had signifi-

cant positive effects on “active” coping: facilitating ($\beta = .30$), perceiving ($\beta = .21$), and managing ($\beta = .10$). Two dimensions had significant positive effects on “expressive” coping: facilitating ($\beta = .14$) and understanding ($\beta = .10$). In relation to “denial” coping, we found antagonistic effects of the two EI dimensions. On the one hand, perceiving emotions had a significant negative effect on “denial” ($\beta = -.24$). On the other hand, managing emotions had a significant positive effect on “denial” ($\beta = .12$). Understanding emotions also increased denial coping ($\beta = .09$). All interaction effects were not significant ($p > .05$) (see Table 4, model 2b).

Finally, we examined effects of EI on consumer negative word-of-mouth. Consistent with H3a, the effect of EI was negative and significant in a bivariate regression ($F(1;654) = 10.56, p < .01, \beta = -.13$). However, this effect became non-significant when consumer coping, emotional response and recovery efforts were entered into the hierarchical regression model. Both “active” coping ($\beta = -.12$) and “denial” ($\beta = -.20$) decreased negative WOM, whereas “expressive” coping increased it ($\beta = .08$). Excellence in recovery efforts had a negative effect ($\beta = -.46$) and negative emotional response had a positive effect ($\beta = .18$) on the word-of-mouth (see Table 5, model 2a). Interaction effects were non-significant ($p > .05$). Consistent with Baron and Kenny’s (1986) mediation steps, 1) EI had significant effects on the negative emotional response, active and expressive coping 2) consumer emotional response, active and expressive coping had significant effects on the word-of-mouth, and 3) the effect of EI on the word-of-mouth became non-significant with the three mediators in the regression. Thus, effects of EI on consumer

negative word-of-mouth were fully mediated by consumer “active” and “expressive” coping and their negative emotional responses to a service failure. Hypothesis 3b was supported. A similar pattern of results was observed for the two EI dimensions: managing and understanding emotions. Although initially they had significant negative effects on the word-of-mouth ($\beta = -.10$ and $\beta = -.12$ correspondingly, $p < .05$), these effects became fully-mediated in a hierarchical model (see Table 5, model 2b). Interaction effects were non-significant ($p > .05$).

DISCUSSION

Research in services marketing has traditionally conceptualized behavioral and emotional responses of the service provider as the main drivers of the service encounter. The customer’s role in service encounters has often been simplified to be that of a passive appraiser that matches pre-established expectations and perceived delivery of the service to evaluate the encounter. This research not only answers the call for a greater understanding of the role of emotions in service encounters and consumption experiences (Bardzil and Slaski 2003, Kernbach and Schutte 2005) but most importantly accounts for the consumer as a co-producer of the unfolding consumption experience. Specifically, we investigate the role of emotional intelligence as an antecedent to customer negative emotional responses, coping, and subsequent word-of-mouth in situations of service failure. Although EI has been extensively applied in psychological and managerial studies (e.g., Jordan et al. 2002, Mayer et al. 2003), examination of consumer EI is a relatively novel topic. A recent study by Kidwell et al. (2008) developed and applied a measure of consumer EI and its individual dimensions to consumer decision making. Our work extends their research on EI to the context of negative service encounters. Additionally, we evaluated effects of individual EI dimensions that in some contexts differed from those of a composite EI measure (consistent with Kidwell et al. 2008). Understanding effects of these dimensions is

crucial to better serving customers and their needs. Finally, we gained a deeper understanding of consumer coping with the event-induced stress and the role of EI in consumer coping.

The first finding of our study confirms that consumer EI plays a significant role in consumption contexts that elicit strong negative emotions. Consumers with high EI are able to control and minimize negative emotions across various levels of service recovery. However, when service providers undertake a maximum of efforts to fix a failure, consumer EI has the strongest effect on the negative emotional response. Thus, appropriate service provider measures at the point of failure corroborated by consumer EI can ultimately minimize induced stress and restore broken customer relationships. Next, we found that EI showed strong positive effects on active and expressive coping. Thus, in stressful consumption contexts, EI helps consumers actively seek issue-resolution and alleviate emotional stress by engaging in expressive behaviors. As a composite trait, EI did not yield any significant effects on denial coping. A stronger negative emotional response to a service incident decreased consumer ability to seek problem resolution but increased expressive coping. In addition, appropriate recovery efforts increase likelihood of consumers denying the failure in the first place. The latter finding is consistent with earlier work on adaptive coping that suggests denial may be an opted choice for consumers who are offered an appropriate and satisfying solution to a stressful event by service providers (Pavia and Mason 2004). Effects of EI on consumer word-of-mouth were fully mediated by emotional response, active and expressive coping. Overall, then, when providers ensure a maximum of recovery efforts, consumers with high EI are able to experience lower levels of induced stress and actively seek resolutions to a failure, which, in its turn, is more likely to result in a positive outcome for the provider.

In addition to analyzing effects of the composite EI measure, we evaluated potential contextual differences across its individual dimensions. In general, consumers were likely to express higher

levels of perceiving emotions and facilitating thinking to resolve the problem rather than managing their emotions. Consistent with Kidwell et al.'s (2008) proposition, perceiving, facilitating and understanding are much more abstract in their nature than the managing dimension. Our results showed that different dimensions were responsible for different effects in situations of service failure. Specifically, managing emotions had a vital role in lowering negative emotions and for consumer active coping and denial. Possibly, then, those who are capable of managing emotions are more likely to either actively solve the issue at hand or deny it depending on its complexity, relevance or importance. In contrast, the most abstract dimension of perceiving decreased consumer denial but increased active coping. Neither the most abstract dimension-perceiving-nor the least abstract dimension-managing-had any effects on expressive coping. Thus, we confirm that different EI dimensions have unique and even antagonistic effects on consumption outcomes and should probably be examined along the composite EI trait.

Our findings suggest that consumer EI should receive attention across multiple aspects of the service process and delivery and not be limited to a service failure alone. More significantly, integration of EI into a service setting reveals that consumer EI influences both a coping response as well as evaluation of the service experience. Future consumer research is warranted that would assess effects of EI on other stressful consumption experiences, purchasing choices and decisions, product failures, and dyadic and group conflicts in consumption situations. Examination of both the composite measure of EI and its individual dimensions can provide valuable insights for both consumer researchers and marketers.

This study is an early step toward integrating the theory of EI in consumption experience, thus several caveats need to be raised. First, the measurement of EI is based on a self-administered questionnaire (for discussion see Dulewicz and Higgs 2000, Davies et al. 1998). It would be of interest to conduct complementary studies that assess customers' level of EI by means of more objective measures (Davies et al. 1998). Second, we relied on a scenario-based methodology that minimizes biases due to memory and recall limitations present in survey research (McCullough et al. 2000). Future observational and experimental studies that observe or manipulate the experience of a service failure are warranted to increase external validity of current findings. We examined only one failure outcome-negative word-of-mouth. Future work should examine additional measures, such as consumer complaining behaviors, re-purchasing behaviors, or actual customer patronage. Finally, the scope of the study does not include illegitimate complaint behavior and dysfunctional customer behavior described by Harris and Ogbonna (2002). But it is acknowledged that the execution of a coping response can be based on deviant intentions facilitated by customers' level of EI.

Lighting and Perceived Temperature: Energy-Saving Levers to Improve Store Evaluations?

Gwenaëlle Briand, University of Paris Dauphine, France

Bernard Pras, University of Paris Dauphine and ESSEC Business School, France¹

ABSTRACT

Light intensity and thermal conditions have energy savings implications. Based on environmental psychology, ergonomics and in-store environment research, this study analyzes the direct and interaction effects of lighting and perceived temperature on store evaluations. Three evaluative dimensions emerged from the factor analysis: stimulation, upmarket positioning and relaxation. A 2 x 2 x 3 experiment (lighting x perceived temperature x retail outlet) shows that lighting and its interaction with perceived temperature influence stimulation and upmarket positioning. Perceived temperature has a direct impact on stimulation. The type of retail outlet (jeans, books, and furniture) affects stimulation, upmarket positioning and relaxation.

Most marketing research studying store environment has focused on variables, such as music, color or scent (e.g., Crowley 1993; Spangenberg, Crowley, and Henderson 1996; Yalch and Spangenberg 2000). Lighting and temperature are said to have a major impact on energy savings and are important variables in this respect.² They also affect the individual's emotions and behaviors (Anderson 1989; Lam 1998; Rosenthal 2005) and are considered essential by retailers and experts in sensometry (Petit, Siekierski, and Lageat 2003; Rouillet 2006). Yet they are understudied aspects of store environment. The influence of in-store lighting has never been studied in a controlled environment. A few researchers have studied the effect of display lighting (Areni and Kim 1994; Summers and Hebert 2001) and of additional lighting in a specific shelf (Bakini Driss, Ben Lalloune Hafsia, and Zghal 2008) on shopping behavior and the effect of pleasant or unpleasant lighting on shoppers' affective reactions (Lemoine 2002). However, a systematic and controlled analysis of the effect of in-store lighting on consumers' evaluation has not yet been done. Furthermore, no marketing research specialized in atmospheric factors has ever been conducted on either actual or perceived temperature.

Assessing the impact of lighting and temperature stimuli on consumers' store evaluations therefore sounds extremely useful. Stramler, Kleiss and Howell (1983) have shown a significant effect of purported temperature increase on perceived comfort, even when the actual temperature is not changed. This means that non-physical factors can play a role in the perception of thermal comfort. Implications for energy savings and in-store atmosphere perception are real. Perceived temperature may affect consumer's sensation of comfort while shopping as well as the actual temperature. Accord-

ing to specialists, an actual 1.8°F decrease, from 68°F (20°C) to 66.2°F (19°C) results in energy savings of 7%. Experts³ in lighting and temperature also suggest that lighting can enhance a store image while temperature can affect consumer's sensation of comfort while shopping. The aim of our research is to highlight the direct and interaction effects of perceived temperature and lighting on consumers' store evaluations. It focuses on the following questions: To what extent do lighting and perceived temperature affect individuals' evaluations and behavior, considering prior ergonomic or psychological results? To what extent can these results be extended to consumers' perception of store environment and store positioning? Consequently, we introduce some propositions and study the influence of two lighting and two perceived temperature levels in three types of retail outlets (clothing, books, furniture) on the individual's evaluations of store environment and store positioning.

CONCEPTUAL FRAMEWORK

First of all, this research is based on environmental psychology applied to a retail store context (Donovan and Rossiter 1982; Spangenberg et al. 1996). Stimuli (S) influence the internal evaluations of the environment (O) which in turn influence the consumer in-store behavior. The internal evaluations of the environment can have affective or stimulating dimensions as well as a positioning dimension (for example perceived quality of the goods, upmarket store). The consumer behavioral responses (R) can be approach or avoidance responses. Many articles in marketing have focused on the behavioral responses (R) consecutive to various stimuli such as color or music (S) (Bitner 1992; Yalch and Spangenberg 1990). We study here less or never studied relevant stimuli, that are lighting and temperature such as suggested by Bitner (1992), and their potential influence on store evaluation (affective, stimulative or positioning perceptions). The positioning relates to perceptions, and the beliefs one has of a product or a store environment, and of a categorization of the store mentally (Bitner 1992). It should also be mentioned that Spangenberg et al. (1996) or Bitner (1992) propositions are an adaptation of Mehrabian and Russell's model (1974) to the store atmosphere context. Among PAD (Pleasure, Arousal and Dominance) dimensions of Mehrabian and Russell's model, Bitner (1992) as well as Spangenberg et al. (1996) do not retain the dominance dimension⁴ in a store context. This is consistent with Donovan and Rossiter (1982) research findings and Russell and Pratt (1980) recommendations.

Second of all, this research is also grounded in the lighting and temperature literature in environmental and applied psychology, and ergonomics. This leads to some propositions in a store evaluation context, further analyzed through an experiment.

¹The authors thank Priya Raghubir for her helpful comments and suggestions.

²Retail buildings account for the largest energy costs (over \$20 billion each year-Source, EIA, CBECS 2003) of commercial buildings in the US, and management's desire to save energy and reduce energy expenses is more and more frequent. Energy efficiency measures are adopted with the help of the Environmental Protection Agency. Moreover, the Energy Independence and Security Act of 2007 focused on energy savings implications of compact fluorescent lights and, actually, will ban the sales of most current incandescent light bulbs by 2014. Assessing the impact of lighting and temperature on store perceptions is of paramount importance.

³Working group: "Lighting and energy saving", Popai France, Paris, October 2008 and Conference: "Light and health", EDF (Electricité de France) and AFE (Lighting French Association), Paris, January 2009.

⁴Dominance "is based on the extent to which he (an individual) feels unrestricted or free to act in a variety of ways" (Russell and Mehrabian, 1974: 19).

Lighting⁵

Research in different scientific fields has revealed the various effects of light on individuals. Psychiatric and medical research have demonstrated that light illuminance modulates circadian rhythm (and specifically hormonal cycles) leading to a succession of stimulating (arousal and activation) and relaxing (detente and sleepy) periods (Lam 1998; Rosenthal 2005). Clinical psychology has suggested an increasing cardiovascular activity and a stimulation of physiological arousal (Kumari and Venkatramaiah 1974). Research in marketing has also demonstrated an effect of light on in-store behavior. Supplemental lighting or bright light influences the number of items examined and handled and the time spent in stores or display (Areni and Kim 1994; Summers and Hebert 2001). Therefore, bright light can be expected to positively affect the stimulative dimension⁶ of store perception.

P. 1: Within normal levels, increasing the lighting's brightness has a positive influence on the stimulative perception of a store environment.

Biological effects of lighting on humans (Lam 1998; Rosenthal 2005) induce psychological responses (cognitive, aesthetic and emotional). According to ergonomic studies, a bright light and a cool light color temperature are more associated with comfort and spaciousness (Manav 2007). In addition, order perception is also achieved with bright light in conditions of wall washing (Durak et al. 2007), the wall washing being a diffuse lighting on the wall. Comfort, spaciousness, and order perceptions will be called here upmarket store perceptions.

P. 2: Within normal levels, increasing the lighting's brightness has a positive influence on upmarket store perception.

However, brightness by itself does not seem to have an influence on relaxation. Subjects have reported more positive affect (Baron 1990), feelings of relaxation and intimacy (Carr and Dabbs 1974; Durak et al. 2007) in conditions of low lighting. Manav (2007) has pointed out that a warm light (2700 K) leads to the impression of a relaxing atmosphere. But a feeling of relaxation can also be reported in conditions of wall-washing (Manav and Yener 1999), uplighting (Manav and Yener 1999: 43–47) and cove lighting (Durak et al. 2007), under different lightings' brightness conditions.

P. 3: Within normal levels, decreasing the lighting's brightness has a positive influence on intimacy, but not necessarily on relaxation.

Finally, the preferred lighting level has been associated with the social situation and the type of activities (Biner et al. 1989). Moreover, Summers and Hebert (2001) have demonstrated an interaction effect between lighting and display. According to the retail merchandising perspective, it seems to be necessary to match the lighting to the retail objectives and characteristics.

⁵Low level of lighting is associated to soft lighting and high level of lighting to bright light. For color temperature, a warm light is associated to red light and cool light is associated to white or blue light.

⁶The stimulative dimension corresponds to "excitement" such as defined by Russell and Pratt's (1980), as meaning the combination of arousing and pleasant.

P. 4: There is an interaction effect of lighting conditions x types of retail outlets upon the evaluations of the stores.

Temperature

A social psychology research has reported an affective impact of temperature on individuals. Aggressive behavior and riots, negative affects and antisocial behavior in a crowded situation (Anderson 1989; Griffitt and Veitch 1971) increase as the temperature increases. The negative affect also grows as temperature dips (< 62°F: Bell and Baron 1977). This suggests that a "range of comfort" exists and that a negative affective state could be attributed to hot or cold temperatures (Baker and Cameron 1996). "Range of comfort" can be assimilated to "thermal comfort" that is the "condition of mind which expresses satisfaction with the thermal environment and is assessed by subjective evaluation" (Rohles 2007, 14). It seems to be impossible to define an optimal temperature level for all individuals, but Fanger (1970) has developed the Predicted Mean Vote (PMV) model with the Predicted Percentage Dissatisfied, used to predict the thermal sensations of a large group of people. The thermal comfort and PMV depend on the activity level and clothing worn by individuals, along with thermal conditions. Indoor thermal comfort perception ranges from 68°F to 74°F, extended to 66°F with warm clothing and 78°F with light clothing, for a low activity level. Stramler et al. (1983) have shown that individuals responded comparably, in terms of perceived comfort shifts, to actual and purported rises of temperature. This is consistent with Rohles and Kerulis' technical report⁷ in which subjects had similar distributions of comfort and thermal sensation votes when they were shown a specific temperature reading (74°F), whether the actual temperature was actually 74°F or in a "68°F-72°F" range. The perceived temperature can therefore be manipulated.

A research in the United Kingdom (Humphreys and Hancock 2007) has used ASHRAE Scale, based on Fanger research (1970). It has demonstrated that most individuals (for a low activity) preferred to experience a "slightly warm" or "warm" rather than "neutral" or "cool" sensation, whatever the seasonal period.⁸ This suggests that for a low level of shopping activity in a store environment, and within the "comfort range", the store evaluation is positively correlated to a moderately high perceived level of temperature rather than to a moderately low perceived level of temperature.

P. 5: Within the comfort range, a high perceived temperature is preferred by consumers and associated to better store evaluations than a relatively low perceived temperature.

Finally, Rohles' ergonomic research (1980) has suggested that temperature is perceived as warmer in decorated and very furnished room than in an empty space, while both spaces are at the same temperature level.

P. 6: The perceived temperature will be lower in a relatively empty space than in a more furnished space.

⁷Technical report, reported by Stramler, Kleiss and Howell (1983:187).

⁸ASHRAE Scale measures the subjective thermal sensation, that is to say the subjective point of view about the personal thermal sensation instead of the temperature of the atmosphere.

- P. 7: There is an interaction effect of perceived temperature x type of retail outlet (more or less furnished) upon store evaluations.

Main effects of lighting versus temperature and interaction effects

Baker and Cameron's (1996) conceptual framework suggests the possibility to study a wide range of environmental factors (such as temperature and lighting) and their influence on affect and the perception of waiting time. Analyzing main and interaction effects of temperature and lighting does seem necessary to explore and understand a "polysensory person".

Indeed, perception will give priority to the "best" sensory modality for the task at hand (Guttman 2005, 228). Perception gives precedence to vision for spatial judgments (Welch 1999). In case of divided attention with various sensory modalities, Schifferstein and Desmet (2007) suggest that, under conditions of normal vision, the information provided by vision attracts the majority of attention, which is in line with claims from previous research. It can be inferred from these findings that, within normal conditions, lighting will take precedence over temperature in store evaluation.

- P. 8: The positioning evaluation of a store will be more influenced by lighting than by perceived temperature.
 P. 9: There is an interaction effect of "lighting x perceived temperature" upon store evaluations.

METHOD

We used a 2 (lighting) X 2 (perceived temperature) X 3 (types of retail outlets) factorial design experiment, based on digitally manipulated pictures in order to create the desired lighting and perceived temperature conditions. The lighting conditions (bright vs. soft), the perceived temperature (low vs. high within the comfort range) and the types of retail outlets (jeans, books and furniture) are presented below as well as the experiment.

Lighting Conditions

Actually, in physics, light is a form of energy known as electromagnetic radiation that may be perceived by the normal unaided human eyes. Light illuminance level (brightness vs. softness) can be associated to a CCT (Correlated Color Temperature that is a cool or a warm color temperature).⁹ CCT describes the ambiance that a lamp provides, i.e. how "warm" or "cool" the light makes a room be perceived.¹⁰ According to experts and following the famous Kruithof (1941) curve,¹¹ the preferred combination of illuminance level (Bright vs. soft) and correlated color temperature (CCT: Cool vs. warm) are "bright and cool lighting" on the one hand and the "soft and warm lighting" on the other hand. On the contrary, two combinations are considered to be unpleasant: "Bright and warm lighting" has been claimed to create a colorful and artificial environment, while "Soft and cool lighting" has been considered to create a drab and cold environment. Therefore, from a managerial point of view, this research focuses on pleasing perceptions of lighting that could entail a positive evaluation of an environment

and in turn entail an approach behavior: "bright and cool lighting" for bright light and "soft and warm lighting" for soft light.¹²

Perceived Temperature and Types of Retail Outlets

As underlined above, we focus on the range of comfort for light and perceived temperature. The critical point is to present visual clues corresponding to different perceived temperature levels. As already indicated, previous research has shown that actual temperature changes within the range of comfort had an impact upon thermal sensations similar to that of identical purported temperature changes (Stramler et al. 1983). Temperature changes of 4-5°F (2.3°C-3.3°C) represent a substantial change in the comfort-response distribution according to well-established norms.

As the comfort level depends on the activity level and the clothing, we used pictures representing a female teenager standing in front of the display, therefore with a low activity. On these pictures, we implemented two temperature levels by changing teenager's clothes: light clothing for warm conditions and a coat for cool conditions. A manipulation check over 180 individuals reveals significant differences in perceived temperature changes, going from 4°F (2.3°C) for furniture store to 6°F (3.3°C) for jeans and bookstore. The average perceived temperatures range from 66°F in the cool conditions to 72.5°F in the warm conditions.¹³

The shopping behavior was perfectly similar in the two lighting conditions ("bright and cool light" and "soft and warm" light) and the three different stores. Pictures got retouched by a professional photographer using Photoshop to create the two lighting conditions. In each store represented on pictures, no brand or no corporate name appeared. Three types of retail outlet were selected according to literature and experts' advice. Besides, each type of retail outlet is expected to allow a homogeneous store environment from one display to another inside the specific store, as compared to supermarkets which are composed of heterogeneous store environments.

Experiment Implementation, Subjects and Questionnaire

Experiment and Subjects. The sample consisted of 115 French "MS in Management" students in Paris, France. A within-subjects experiment was conducted in June and resulted in 12 combinations of temperature, lighting and store. The same room, with the same temperature level and the same light illuminance level, was used during the whole experiment, and the weather remained constant. We constructed four sets of three combinations with three retail outlets¹⁴ that we replicated in order to have eight sets (twice the same four sets x three combinations). The experiment was administered by the same researcher to groups of eight subjects at a time. In each group, subjects were randomly assigned to one of the eight sets. Each respondent had to figure himself in the shopping situa-

¹²Ambient fluorescent tubes lighting in retail stores is commonly Bright cool lighting. The Energy Bill (2007) bans the incandescent light bulbs by 2014, which are to be replaced by energy savings bulbs. These bulbs can be used for accent light in retail stores, and can possibly be bright or soft, and warm or cool.

¹³A manipulation check was necessary since we used pictures (visual stimuli) to simulate temperature levels.

¹⁴Mixing the modalities and the order (with Jeans (S1), Books (S2), Furniture (S3), Bright light (L1), Soft light (L2), Cool temperature (T1), Warm temperature (T2)), the 4 basic sets were: Set 1 (S1L1T1/S2L1T2/S3L2T2); Set 2 (S2L2T2/S3L1T1/S1L2T1); Set 3 (S3L2T1/S1L1T2/S2L1T1); Set 4 (S2L2T1/S1L2T2/S3L1T2).

⁹Light illuminance is expressed in lux and color temperature is measured in Kelvin.

Cronbach's alpha (factor)	$\alpha_1=.886$	$\alpha_2=.747$	$\alpha_3=.659$	
Cronbach's alpha (scale)	$\alpha=.880$			

*We have decided to keep: colorful, well ordered and intimate (communality>.45) according to their conceptual interest (Rossiter 2002) in reference with previous research (Spangenberg et al. 1996; Carr and Dabbs 1974; Durak et al. 2007).

tion. For each photograph, that is each retail outlet with a light/temperature combination, we submitted a questionnaire about the store environment evaluation, the store positioning and the product quality perceptions. The final sample was composed of 110 subjects: 63 females and 47 males. 330 questionnaires were validated, which made 27 or 28 subjects for each combination.

Questionnaire Construction. The questionnaire construction was based on Fisher's scale (1974) and Spangenberg et al. (1996) research. The first list was supplemented with items suggested by 12 individuals from the same population as the respondents. They were asked to write a list of items describing a store environment to guarantee the semantic saturation. Then, one expert in lighting, one expert in thermal comfort and one expert in marketing were also asked to complete and to validate this list and avoid redundant items. The final list was composed of 21 non-redundant items. Evaluation of store environment was measured using the seven-point "Judgments of Environmental Quality Scale" (Stimulating-boring; motivating-unmotivating; comfortable-uncomfortable; cheerful-depressing; positive-negative; attractive-unattractive; lively-unlively; good-bad; bright-dull; pleasant-unpleasant; relaxed-tense; colorful-drab) (Fisher 1974). Four seven-point items have completed the Fisher's (1974) scale according to their relevance to our stimuli (cold welcome-warm welcome; friendly-unfriendly; unstressful-stressful, intimate-impersonal), following interviews with experts. Evaluation of store positioning was measured using four seven-point scales (Spacious-cramped (Durak et al. 2007; Manav 2007); well ordered-unordered (Expert); upmarket-downmarket (Expert); outdated-modern (Bellizzi, Crowley and Hasty 1983). Product evaluation was assessed using a seven-point scale (Low/High Quality) (Spangenberg et al. 1996).

DATA ANALYSIS AND RESULTS

Store Evaluations

To examine the existence of distinct components within the subject's responses to the stimuli, a principal component analysis using Varimax rotation was conducted (table 1).

Three main factors of store evaluation emerged from the analysis: an "activation or stimulative" dimension, in the sense of a lively environment (Russell and Pratt 1980), which combines arousal (stimulating, motivating, lively and colorful) and pleasure (attractive, positive and cheerful) evaluations; an "upmarket positioning" dimension and a "relaxation" dimension (Russell and Pratt 1980) of store evaluation which is composed of relaxed, unstressful and intimate items. The three factors explain 61.5% of the total variance in 14 variables. The eliminated variables loaded poorly on the retained factors, and no additional factor emerged by including these variables.

Effects of Light Illuminance, Perceived Temperature and Type of retail outlet

The effects of light, perceived temperature and type of retail outlet on "stimulation", "upmarket positioning" and "relaxation" are tested (table 2), using MANOVA; the Levene's test for equality of variances is not significant ($p>.05$ for each factor).

A "bright and cool" light influences the "stimulative" evaluation ($F=48.50$; $p<.001$) of a store environment. This result strongly supports Proposition 1 and confirms the stimulation dimension of a store environment in conditions of bright light, consistent with Areni and Kim (1994), Kumari and Venkatramaiah (1974), Mehrabian (1976), and Summers and Hebert (2001) suggestions,

TABLE 2
EFFECTS OF LIGHT AND TEMPERATURE ON STORE EVALUATIONS: STIMULATIVE, UPMARKET POSITIONING AND RELAXATION DIMENSIONS

Stimuli	Factors	<i>F</i>	<i>p</i>
Light	Stimulation	48.50	.000
	Upmarket positioning	5.31	.002
	Relaxation	0.78	.379
Temperature	Stimulation	8.06	.005
	Upmarket positioning	0.20	.658
	Relaxation	0.97	.326
Type of retail outlet	Stimulation	20.87	.000
	Upmarket positioning	88.80	.000
	Relaxation	13.55	.000
Temperature * Light	Stimulation	4.86	.028
	Upmarket positioning	7.77	.006
	Relaxation	0.56	.453
Temperature * Type of retail outlet	Stimulation	0.75	.474
	Upmarket positioning	3.75	.025
	Relaxation	2.08	.127
Light * Type of retail outlet	Stimulation	18.23	.000
	Upmarket positioning	2.05	.130
	Relaxation	0.11	.897
Temperature * Light * Type of retail outlet	Stimulation	0.48	.619
	Upmarket positioning	0.459	.632
	Relaxation	0.547	.579

and with the founding research on internal responses (Mehrabian and Russell 1974). A “soft and warm” light has a significant effect on the “upmarket positioning” dimension ($F=5.31$; $p<.05$) and seems inconsistent with Proposition 2. Actually, a “soft and warm” light has a significant positive impact on the upmarket item but no effect on the modern, spacious and well-ordered items. Further research is needed about these sub-dimensions. As expected, there is no significant effect of the light level upon the “relaxation” dimension perceived by subjects and a “soft and warm” light is positively related to the intimacy item. This indicates that Proposition 3 makes sense. There is a significant interaction effect of “lighting x type of retail outlet” on evaluation of the “stimulative” dimension of store environment such as suggested in Proposition 4 (figure 1). A “bright and cool” light in stores with no product physical involvement such as furniture and bookstores enhances a stimulative evaluation of store environment ($F=18.23$; $p<.001$). Our research has focused on the range of thermal comfort, such as determined by previous research. A perceived warm temperature within this range has a positive effect on the “stimulation” factor ($F=8.06$; $p<.05$), which supports Proposition 5.¹⁵ It has no influence on the “relaxation” dimension but on the intimate item. There is a type of retail outlet effect. The furniture store, which is the most spacious, is perceived as less warm than the others, according to the manipulation check. This result supports Proposition 6. The interaction effect (temperature x type of retail outlet) has a significant impact on the upmarket factor ($F=3.75$; $p<.05$), consistently with Proposition 7 (figure 1). We can also point out that lighting has a

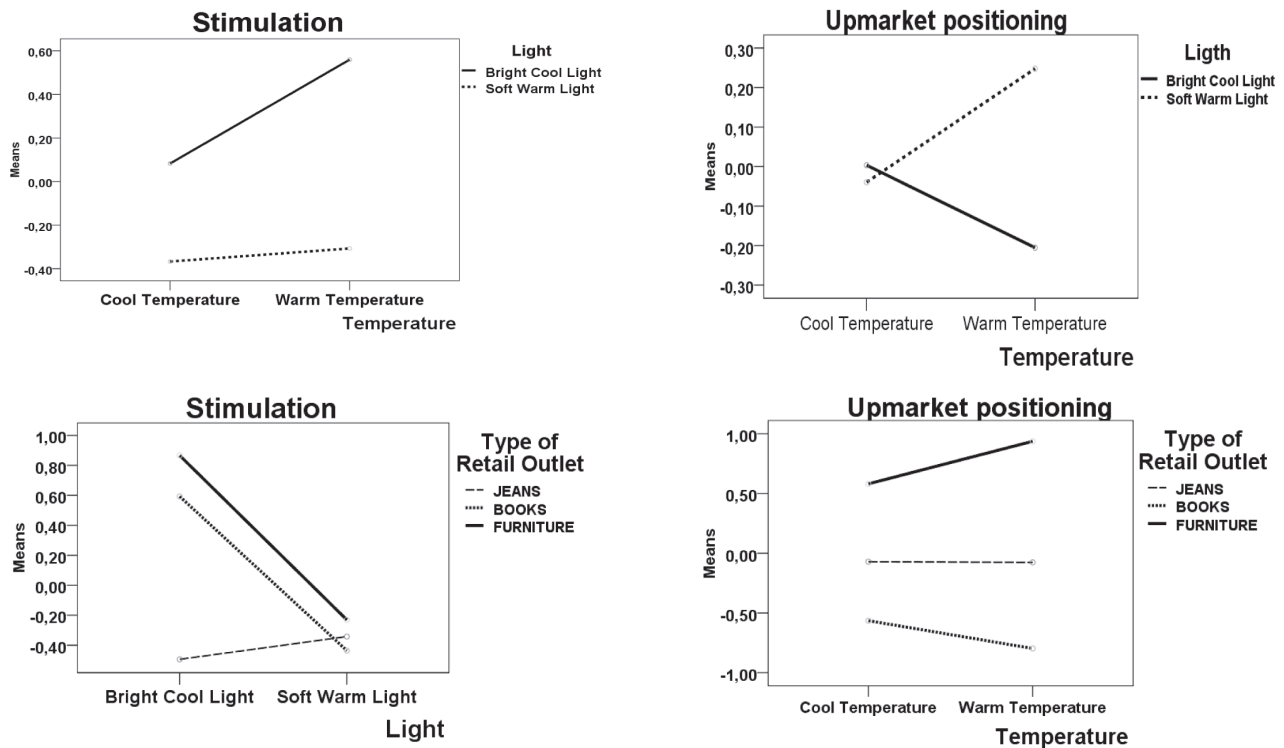

significant effect on “upmarket positioning” while temperature has not, consistently with Proposition 8 which suggested that cognitive evaluation of a store would be more influenced by lighting than by temperature. And the “temperature x light” interaction has a significant effect on the evaluation of the “stimulative” factor ($F=4.86$; $p<.05$) and the upmarket positioning ($F=7.77$; $p<.05$) (figure 1). This interaction effect provides evidence supporting Proposition 9. Finally, the type of retail outlet influences the three dimensions ($p<.001$) emerged from the factor analysis. Consumers perceive the store atmosphere as more relaxing and more stimulating in furniture and bookstores (vs clothing). This could be explained by the “low physical involvement” of furniture and books. Moreover, subjects have considered furniture and clothing stores more upmarket positioned than the bookstore, probably because furniture and clothes are more expensive and show more space than does the bookstore.

DISCUSSION AND CONCLUDING REMARKS

The systematic impact of light intensity, perceived temperature level, type of retail outlet, and lighting x temperature upon the store evaluation on the “stimulative” factor is one of the main

¹⁵Univariate analysis of variance also shows that “warm temperature” has a nearly significant positive impact ($p=0.058$) on perception of a good environment. No other significant result appears with other eliminated items.

FIGURE 1
 INTERACTION EFFECTS OF LIGHT, TEMPERATURE AND TYPE OF RETAIL OUTLET ON STIMULATIVE AND UPMARKET POSITIONING DIMENSIONS

results of this exploratory study. In addition, almost all propositions based on ergonomics and environmental psychology prove well-founded in a store evaluation context. Interestingly enough, even if the upmarket positioning results did not match the propositions exactly, it clearly appears that upmarket positioning is influenced by light intensity, type of retail outlet and temperature x light and temperature x type of retail outlet interactions. As for relaxation, light intensity has an impact upon intimacy perception but not on relaxation. Experiments with wall washing effects would seem useful, following Manav suggestions in ergonomics (2007).

An important element in this exploratory research is the relevance of experiments with simulated temperature levels via pictures, with controlled indicators: winter or summer clothes at a given activity level like recommended by Fanger (1970). Perceived temperature becomes a controllable variable, which has been shown to influence store perceptions. A perceived temperature higher than an actual temperature has high energy savings implications. Another contribution of this research is the range of modalities studied. Even though previous marketing research has focused on illumination or supplemental lighting, practitioners have pointed out the role of Correlated Color Temperature of lighting on the individual's perception. We therefore focused on pleasing modalities of illuminance level, which had not been done before. We also concentrated on the range of comfort. A warmer perceived temperature within comfort range is preferred by respondents. This is consistent with prior studies. Perceived warmth influences the stimulation dimension and the intimacy item of the relaxation factor.

This is the first research on lighting and perceived temperature effects on evaluations of store environment and positioning con-

ducted under controlled conditions. It provides strong enough evidence supporting ergonomic and environmental psychology research to pursue further research in real and controlled settings. This should be done with actual and purported (or perceived) temperature levels.

A limit of this research, as is true of most of the environmental psychology studies, is that we test for effects under a limited set of conditions. Changing the level of any one of the factors (lighting or temperature) is likely to alter the effects of the others. Replicating this research with other levels, and in particular in unpleasant conditions, would be useful in terms of external validity and theory development. Extending the work to look at avoidance behavior rather than simply pleasing perceptions would also respond to managers' concerns when they do not want consumers to linger in some environments.

Tobacco Consumption in the Home: Impact on Social Relationships and Marking Territory

Kathy Hamilton, University of Strathclyde, UK

Louise Hassan, University of St Andrews, UK

ABSTRACT

In this paper we move beyond viewing the home as a mere context for consumer decision-making to explore consumption practices and socio-spatial relationships within the home in relation to tobacco consumption. Based on focus groups conducted across ten European countries, our findings suggest that smokers view the home as a safe haven where they are sheltered from the outside regulatory environment. However, tension between smokers and nonsmokers demonstrates that consumption practices within the home may become a process of negotiation, resulting in smokers marking territory in efforts to avoid conflict.

INTRODUCTION

The home represents the single most expensive purchase that a person is likely to make and as a research setting offers rich possibilities for exploring cultural symbolism and personal meaning (Claiborne and Ozanne 1990). The meaning of home has been a prominent theme within the disciplines of sociology, human geography, architecture, psychology, philosophy and anthropology. However, consumer research on the home is limited and has been studied mainly as a context for consumer decision-making (Bardhi 2006), neglecting the consumption practices that take place within and transform a dwelling unit into a home (Despres 1991). Rose (1999, 248) suggests that physical space needs to be seen as “practised, a matrix of play, dynamic and iterative, its forms and shapes produced through the citational performance of self-other relations”. Thus, in order to gain a deeper understanding of the home, research must focus on the consumption practices and interpersonal relationships that are played out within the home. In this paper, we explore these issues in the context of tobacco consumption.

Nearly one fifth of all deaths in the United States each year are attributed to tobacco, representing almost 440,000 US citizens with 4.8 million smoking related deaths annually worldwide (Centers for Disease Control and Prevention (CDC) 2002). It is therefore unsurprising to find that a significant portion (6-8%) of annual personal health expenditure in the US is directly related to treating tobacco related diseases, namely, lung cancer, heart disease and chronic obstructive pulmonary disease (Warner 2000). Beyond the personal harm caused by tobacco, the Surgeon General’s report on secondhand smoke in 2006 states that “there is no risk-free level of exposure to secondhand smoke” (CDC 2006). To address the dangers of secondhand tobacco smoke many states and countries have enacted comprehensive smoke-free laws in public places. Evaluations have shown support for such legislation and high levels of compliance (Fong et al. 2006, Biener et al. 2007). Recent efforts in tobacco control have moved to restricting smoking in the home within multi-unit dwellings. California is the first state to implement such smoking bans in two cities (Semrad 2007). With continued pressures to legislate in this area it is important to understand the meaning and importance of the home in relation to tobacco consumption. As previous research has predominantly considered smoking in public places and evaluations of smoke-free laws (Fong et al. 2006, Biener et al. 2007), research exploring tobacco consumption in the home is limited. We therefore address this significant and important research gap. In particular, we examine the following research questions: (1) When and where is tobacco consumed in the home? (2) How does tobacco consumption in the

home impact on social relations? (3) In what ways do smokers and non-smokers negotiate consumption of tobacco in the home? Answers to these three research questions will allow us to gain a better understanding of how power is regained by the smoker when the home is free from external legislative constraints, yet within the home such power is subject to negotiations and conferment with inevitable compromises in the attempt at harmony with significant others. Our contribution is twofold; first we offer theoretical contributions in relation to negotiated consumption and assigned consumption space in the home. Second, in light of the increasing acknowledgement of the dangers of secondhand smoke we offer public policy makers insight on issues pertaining to the home.

THE HOME

Meaning of the Home

The home has an increasingly central role in everyday life, with many layers of meaning and a rich social, cultural and historical significance (Moore 2000). Place attachment is a central theme in relation to the home, used to explain the “positively experienced bonds, sometimes occurring without awareness, that are developed over time from the behavioural, affective, and cognitive ties between individuals and/or groups and their socio-physical environment” (Brown and Perkins 1992, 284). Such interactional processes between people and places contribute to identity definition (Kleine and Baker 2004) and in this way, home becomes an important extension of the self (Belk 1988). As Czikszentmihalyi and Rochberg-Halton (1981, 123) suggest “a home is much more than a shelter; it is a world in which a person can create a material environment that embodies what he or she considers significant. In this sense the home becomes the most powerful sign of the self of the inhabitant who dwells within”. The home as self-definition may involve territorial behavior in terms of the personalization of and communication that a place is “owned” by a person or group (Altman 1975). This may include the way in which consumers incorporate aesthetics into their everyday consumption experiences in the home (Venkatesh and Meamber 2008), emphasizing the link between place and possession attachment (Kleine and Baker 2004).

The significance and centrality of the home as having symbolic meaning has been highlighted by consumer researchers considering the loss of the home (Gross 2007, Hill 1991, Sayre 1994). For example, one of Gross’ (2007) informants at the beginning of the foreclosure process lamented “It’s like if you lost a child or something” while one of Sayre’s (1994) informants who lost her home as the result of fire suggested, “What’s missing is my territory, my space. I am still me, but many of the things that identify my purpose and creativity are not there. My territory had my markings, my routines, my responsibilities, my purpose clearly defined.” This issue of territory is further discussed in the following section.

Personal Space and Dominion within the Home

Claiborne and Ozanne (1990) found that consumers often have a need for personal space within the home, a special space which is their own over which they have dominion and control. Place attachment to the home is stronger when a person is able to regulate his or her privacy which in turn provides a basis for a sense

of autonomy, self worth and self identity (Harris, Brown and Werner 1996). While the home is a confined space, the outside is perceived as imposing and demanding different rules of engagement with people, places and things (Mallet 2004). As such, home as privacy represents a freedom from surveillance; a back region where the need to maintain role performance is relaxed and where one can be oneself (Goffman 1971, Saunders and Williams 1988).

This also corresponds to the notion of the home as “safe haven,” a sacred space that has the potential to offer self-transcendence (Belk, Wallendorf and Sherry 1989). As McCracken (2005, 32) suggests, the homey space can be “embracing” in terms of a “descending pattern of enclosure” where the occupant is “protected from the outside world by an intricate series of baffles and mediants”. In this way, McCracken (2005) argues that the homey space has the same symbolic and psychological value as a parental embrace, offering protection from both real and imagined dangers. However, some critics argue that this perspective of the home as safe haven is an idealized notion that neglects to recognize the tensions surrounding the use of domestic space that are characteristic of the lived experience of home. Indeed, the home can be seen as a “major political battleground; feminists see it in terms of gender domination and liberals in terms of personal autonomy and a challenge to state power” (Saunders and Williams 1988, 91).

Socio-spatial relations are central to the construction of home. Drawing on Giddens’ (1984) concept of the locale, Saunders and Williams (1988) suggest that the home is a crucial locale where forms of social relations and social institutions are composed, accomplished and contextualized. Similarly, Valentine (1999, 57) argues that the negotiation of space requires that we position ourselves “physically, socially, morally, politically and metaphorically in relation to others”. Familial relations are particularly central with McCracken (2005, 38) suggesting that homeyness for many people becomes an “adhesive” that attaches them to family.

The concept of the home is important in the context of tobacco consumption for several reasons; firstly, with few exceptions, the home is an unregulated space and governments and the media have raised concerns about how smoke-free legislation in public places may increase consumption of tobacco in the home through displacement, which might be detrimental for other residents, particularly children. However such harmful displacement has yet to be evidenced (Biener et al. 2007). Secondly, anti-smoking adverts such as the European Union “HELP—for a life without tobacco” campaign have used the potential dangers of smoking in the home as a key campaign message. Further insight into this consumption space may benefit the development of future anti-smoking campaigns in the home context. Finally, given that smoking is an emotive issue generating strong opinions, potential for conflict amongst family or household members may be increased.

METHODOLOGY

Findings are based on thirty focus groups conducted across ten European Union member states (three focus groups in each country, see Table 1 for focus group composition). The ten countries were chosen on the basis of geographic spread across Europe, the amount of tobacco control legislation in each country as well as cultural variables and scores. In line with the need for compatible participants in focus groups (Morgan 1998), participants in each country were allocated to focus groups based on their age (15-17, 18-25 and 26-35), smoking status (heavy smoker, light smoker and non-smoker), and social class (working class, middle class). Focus groups were mixed in terms of gender. The research is part of the ‘HELP—for a life without tobacco’ European Union anti-smoking campaign and as a result, the age range of participants was guided by the target age group of the campaign.

A leading market research agency (IPSOS) was employed to recruit respondents, co-ordinate data collection and ensure consistency in practices. The agency employs recruiters who live in each of the countries, resulting in access to information-rich respondents. Additionally, working with a professional recruitment firm lowered the no-show rate (Morgan 1998). Each focus group consisted of between 6 and 8 participants and lasted between 2 and 2 1/2 hours. National representatives from the European Network for Smoking Prevention were also invited to attend the focus groups as observers to increase the likelihood of practical benefits arising from the research and advance the transformative consumer research agenda.

A topic guide was developed to ensure key research areas were covered whilst also encouraging free discussion and the expression of respondents’ ideas in their own terms. The topic guide centered on three areas; general smoking awareness, attitudes and behavior; anti-smoking campaigns and the HELP campaign generally; and pre-testing of specific anti-smoking advertisements. In this paper we draw predominantly on discussions from the first topic area.

With respondent’s consent, all focus groups were recorded and transcribed from the native language into English. Transcripts formed the basis of data analysis, which was carried out using the techniques proposed by Spiggle (1994). This involves categorizing data, completed in an inductive manner as categories emerged from the data rather than identified a priori to the research. Abstraction then grouped categories into more general conceptual classes and comparison allowed the exploration of differences and similarities across incidents within the data and the identification of any patterns. We present our findings in relation to places of tobacco consumption and issues of (dis)empowerment, marking territory in the home and social relations in the home.

ANALYSIS AND DISCUSSION

Places of Tobacco Consumption and Issues of (Dis)empowerment

Many smokers in the study admitted that they feel uncomfortable and experience embarrassment when smoking in public places.¹ This is partly attributable to their belief that others make negative judgments of their decision to smoke, echoing Goffman’s (1963, 18) suggestion that shame can be a central possibility arising from the individual’s perception of falling short of “what he really ought to be.” For example:

“If you are on the street and you are walking along the street there are just people who just grimace at you because they don’t like you smoking.” (Italy, 26-35, Heavy Smokers)

“if I sit with somebody who doesn’t smoke then I feel strange.” (Czech Republic, 18-25, Light Smokers)

For some respondents the negative connotations stem from feelings of exclusion created by regulations that prevent smoking in public places.

“I feel it’s a bit shameful, I have to go outside the restaurant and smoke, banned from coming in, that’s where you can stand and stink up.” (Sweden, 18-25, Light Smokers)

¹It must be noted that this is not generalizable to all smokers; indeed findings suggest that some consumers engage in cigarette consumption primarily to gain social acceptance amongst peer groups and as a route to inclusion in certain social situations.

TABLE 1
Focus Group Composition

Region	Country	Tobacco Policy	Age (Years)	Smoking Status	Social Class
West	UK	High	15-17	Non	Working
West	UK	High	18-25	Heavy	Middle
West	UK	High	26-35	Non	Working
West	Sweden	High	15-17	Non	Middle
West	Sweden	High	18-25	Light	Working
West	Sweden	High	26-35	Non	Middle
South	Italy	High	15-17	Light	Working
South	Italy	High	18-25	Non	Middle
South	Italy	High	26-35	Heavy	Working
West	France	Medium	15-17	Non	Working
West	France	Medium	18-25	Non	Middle
West	France	Medium	26-35	Heavy	Working
East	Czech Republic	Medium	15-17	Heavy	Middle
East	Czech Republic	Medium	18-25	Light	Working
East	Czech Republic	Medium	26-35	Non	Middle
East	Hungary	Medium	15-17	Non	Working
East	Hungary	Medium	18-25	Non	Middle
East	Hungary	Medium	26-35	Heavy	Working
West	Germany	Low	15-17	Non	Working
West	Germany	Low	18-25	Heavy	Middle
West	Germany	Low	26-35	Light	Working
North	Netherlands	Low	15-17	Heavy	Middle
North	Netherlands	Low	18-25	Light	Working
North	Netherlands	Low	26-35	Non	Middle
South	Portugal	Low	15-17	Non	Working
South	Portugal	Low	18-25	Heavy	Middle
South	Portugal	Low	26-35	Light	Working
East	Slovenia	Low	15-17	Light	Middle
East	Slovenia	Low	18-25	Heavy	Working
East	Slovenia	Low	26-35	Light	Middle

NOTE.— The classification of the countries as low, medium and high was based on the WHO country profiles; social class was derived from the occupation of the head of the household, local definitions were used to categorise respondents into working and middle class categories.

“I feel excluded. More and more, and angrier because over some years they’ve created a national level policy that the people that smoke are stupid and disturb everyone because they smoke.” (Portugal, 18-25, Heavy Smokers)

Due to an ever-tightening policy environment, smokers experience physical separation from others in certain public settings. As a result, findings indicate that, even those living in countries with low levels of tobacco restrictions experience a sense of exclusion. Such exclusion goes hand in hand with disempowerment as smokers are restricted and at times prevented from engaging in a consumption practice that they feel is important.

In comparison, the home is seen as personal space and thus an escape where smokers can enjoy smoking outside the gaze of a perceived “disapproving” general public. For some the home has always been a place where smoking has been present:

“If I hadn’t seen it from my very young age at home I would not smoke, but I do because I have seen it since I remember” (Czech Republic, 15-17, Heavy Smokers).

“In the presence of other people sometimes I can be tolerant and other times I can be very intolerant... if I am at my home and somebody comes to see me then I wouldn’t be considerate either because it is my home but when I am somewhere else I have to follow rules and it is alright and then I tolerate it” (Germany, 26-35, Light Smokers).

“I also smoke in my room, my own room so that is my private sphere” (Germany, 26-35, Light Smokers).

The home thus becomes a “back region” (Goffman 1971), a place where smokers do not feel vulnerable to undesirable stereotypes. In this way, the home is established as a safe haven where individuals live by their own rules and are free to regulate their activities and practices, in turn creating empowerment and self worth.

“I think when I smoke it just enables me to be by myself, it’s my cigarette and I. I mean it enabled me to just go away and isolate myself, just by myself, you know... It’s not to share, it’s

just to be by myself, to isolate myself. Cut myself off from the others" (France, 26-35, Heavy Smokers)

The home is then placed in opposition to the world outside (Mallet 2004). In contrast to the regulated outside environment that imposes constraints on smoking behavior, consumers are afforded more freedom in terms of their behavior "behind closed doors" (Miller 2001). As Miller (2001, 1) suggests, "it is the material culture within our home that appears as both our appropriation of the larger world and often as the representation of the world within our private domain". Indeed, cigarette consumption becomes a central ingredient to other activities that occur within the privacy of the home. Respondents smoke "after dinner," "in front of the TV," "in bed," "first thing in the morning" and when drinking coffee—"the two go together virtually all the time." Indeed, some respondents freely admitted that smoking is a "ritual," "a force of habit" and even an "addiction" that leaves them "hooked" and "dependent." Given the centrality of cigarette consumption to smokers' daily lives, it is perhaps unsurprising that for many respondents smoking forms part of a normal ritual in the home where they regain their displaced power. We now move on to consider how this could change when smokers and non-smokers live together.

Social Relations in the Home

Findings suggest that a divergence of attitudes towards smoking can provoke a degree of conflict between smokers and non-smokers as each party competes to have their preferences met, creating a "tricky" and "difficult" relationship. Both smokers and non-smokers discussed the tension that this could create:

"My mate's girlfriend smokes and while we were still in the flat together he initially let her smoke in the flat. I came back in and I smelled it and I said get her out. That started tension between us because of the smoking" (UK, 26-35, Non-smokers).

"I don't live with my parents but they still don't tolerate my smoking. I took up smoking in high school because everybody was smoking but my parents never accepted it and there was constant quarrelling and fighting and when I lived at home I got used to having to go outside to smoke" (Hungary, 26-35, Heavy Smokers).

"I go home and my partner doesn't smoke and she is annoyed by the smoke and sometimes after work I go to the pub with my mates and have a few beers and of course we smoke and then it is the line 'Oh you have been to the pub again'" (Germany, 18-25, Heavy Smokers).

Within the household, conflict has been an elusive concept, particularly within the family context (Commuri and Gentry 2000). However intra-familial and intra-household decisions are more complex than a simple aggregation of individual behaviors (Hall et al. 1995). Rather, within the household, there can be contradictory consumption practices and values that are difficult to reconcile. Such a combination of individual preferences may make conflict probable (Lee and Collins 2000). Within our context, potential for conflict is enhanced because what is essentially a private consumption practice has an impact on other members of the home due to the effects of secondhand tobacco smoke. As such, "where the desire for a purified environment is not shared by all members of a household, the house becomes a place of conflict" (Sibley 1995, 91).

The presence of children within the home adds another dimension to the issue of social relations. Many smokers prefer to avoid smoking in front of young people with one Czech smoker suggesting, "*When young people can see me I feel like I'm spoiling them.*" Many smokers in the study demonstrated awareness that the family context of interpersonal communication has the greatest influence on consumer socialization (Ward 1974) and consequently made efforts to avoid "setting a bad example".

"I've got a baby cousin and I go outside if she's in my house and so does my mum, we don't smoke. Before I even touch her I wash my hands" (UK, 18-25, Heavy Smokers).

"It's also a pretty bad role model for kids to smoking in the future... I do, yes I think about that a lot... I don't smoke in front of my boyfriend's younger sister who is 10/12 or something because she knows I smoke but I won't smoke in front of her because she gets that image" (Sweden, 18-25, Light Smokers)

This reinforces the indirect and emotional power of children to shape consumption practices in the home and encourages smokers to regulate their smoking behavior if young people are present. However, for some smokers, the grip of their addiction is too strong to resist. As one of our Portuguese informants commented, "*I know that I am prejudicing my son. I shouldn't smoke at home, but I can't stop.*" Again, this highlights the additive nature of tobacco that leads some smokers to possess a negative self-view and reduce self esteem. Therefore although smoking in the home can afford an escape from the regulated 'outside' thus releasing feelings of empowerment, the presence of significant others can result in a loss of power in the home and feelings of discomfort. We now move on to consider how this tension is negotiated.

Marking Territory in the Home

In some of the focus groups with non-smokers the issue of smoking in the home provoked strong emotional responses. In the Netherlands focus group of 26-35 year old non-smokers, several respondents agreed that "*in my house there's absolutely no smoking. If someone comes, then they go out, but not in my house.*" Two main reasons emerged for this reaction to smoking. First, in relation to decor, respondents wanted to avoid "*nicotine yellow on the walls*" and second, those who had children didn't want any cigarette smoke in the environment where children are present. Other non-smoking focus groups shared these strong opinions:

"My dad, he smokes but he is only allowed to smoke in the basement and also outside but not in the house" (Germany, 15-17, Non-smokers).

"In my family, my mum used to be a strong smoker. We literally chase her out of the house, even if it's minus 20 degrees, she has to be outside. My father said that he won't tolerate smoking inside the house" (Hungary, 18-25, Non-smokers).

In response to this tension, the issue of marking territory comes to the forefront when smokers and non-smokers share the same living space. The result is the division of space within the home with certain spaces deemed more acceptable for tobacco consumption than others:

"I lived with a non smoker for a while and we marked our territory. I was allowed to smoke in the kitchen, at the window.

Never in the bedroom, not in the dining room or on the balcony" (France, 26-35, Heavy Smokers).

Within the home the negotiation of "acceptable" behavior then becomes central as consumers need to be aware of not only their own but also other people's norms and values. Findings suggest that this is also true for other shared spaces such as cars

"I smoke in the car, it is my car and I can do it but when somebody is with me who doesn't smoke then I open a window" (Germany, 26-35, Light Smokers).

Marking territory can be viewed as a way of "regulating" social interactions for as Altman (1975, 140) suggests, "With everyone having "places," there is no need to continually negotiate who belongs where or who has rights to what, so that day-to-day life smoothes out by virtue of territorial assignments or ownership". In many cases, this "smoothing out" is aided by smokers adopting territories where the smell of tobacco smoke can be easily dispersed or masked, such as "near the chimney" or "at the window." Or as another smoker suggested:

"I light up a candle so I can put out the candle and there's no smell. And I sit on the floor and throw the cigarette to the fire. My husband doesn't smoke so he keeps pestering me. So I don't feel okay sitting on our sofa and smoking" (Portugal, 26-35, Light Smokers).

Some smokers adhered to the viewpoint that smoking could damage the ambience, recognizing that "*in the house it's much better to feel the smell of cleanness than to get into a house that smells like a cigarette*". Here we witness a contradiction in the relationship between smokers and their homes. Despite the desire to smoke, smokers can be aware that cigarette odors can damage the atmosphere in their homes. The challenge then becomes for smokers to create their own private space where they can smoke without disturbing the wider ambience of the home and without complaints from others. Territories are marked for such consumption in areas where the effects of tobacco smoke are minimal thus restoring a safe haven for their "sacred" ritual. So although the home may be free from formal regulations preventing smoking, it can be subject to more informal yet strict regulations that are initiated and negotiated among household members.

CONCLUSIONS

Research interest on spatiality of consumption tends to relate to visible and spectacular sites of consumption such as flagship stores (Peñaloza 1998) and festival shopping malls (Maclaran and Brown 2005), neglecting more private and mundane consumption spaces. In the paper we raise the profile of the home as an important consumption site. We advance current theory that tends to examine the home as a context for consumer decision-making by exploring consumption practices and consumer interpersonal relationships in the home. We suggest first, the home offers an empowering space for consumption practices, second, consumers strive to maintain the home as a sacred space and third, contradictory consumption values incite the negotiation of space and consumer relations within the home.

Our analysis reveals that the home offers a space where consumers have power and dominion, a space where they are separated and sheltered from the outside world and a space where they have greater agency in their consumption practices. The home becomes an escape, a refuge where consumers are freed from the

anxieties and intrusions associated with public scrutiny. It becomes a place for the expression of self-identity and a site of stability in comparison to the ever-changing and restrictive regulation in the external environment. It is a site of emotional attachment, providing "a sense of daily and ongoing security and stimulation, with places and objects offering predictable facilities, opportunities to relax from formal roles, the chance to be creative and control aspects of one's life" (Low and Altman 1992, 10).

In this sense, the home is "a church in that it is the place where ultimate goals can be cultivated" (Csikszentmihalyi and Rochberg-Halton 1981, 123). This religious metaphor parallels research on sacred consumption (Belk, Wallendorf and Sherry 1989) as the home demands reverence and respect and consumers strive to avoid or limit any practices which may taint or contaminate the environment. In this regard, we start to glimpse something of a paradox. On the one hand, the home is a space where consumers have free reign over their consumption activities and on the other hand, the desire to maintain a purified environment may constrain certain consumption activities that threaten such an environment. In this way, cigarette consumption and other consumption practices which may potentially damage the sacred quality of the home demand careful management and negotiation. Given the significance of smoking for some respondents, the fact that consumers are willing to sacrifice and reduce their cigarette consumption provides further evidence of the sacredness of the home.

Our analysis also clearly establishes the link between space and social relations in that consumption practices within the home may become a process of negotiation, reaffirming the home as a site of both individual and collective consumption. As Csikszentmihalyi and Rochberg-Halton (1981) suggest, different people in the home can be seen as inhabiting different symbolic environments even though they are in the same household. Given that prior research has found minimal evidence of conflict in the home (Commuri and Gentry 2000), we argue that tension and conflict is most likely to emerge in relation to risky and emotive consumption practices such as tobacco consumption.

The public policy issues raised by this research are complex. On the one hand, the impact of passive smoking is the home is serious, particularly for children, and policy makers have a responsibility to protect people from these dangers. On the other hand, despite the clear and demonstrable harm caused by tobacco, it is still a legitimate choice for consumers to smoke and smokers' needs must also be considered. Given strong tobacco control policies regarding public space, smokers need private space to exercise dominion to realize the 'benefits' of their consumption. Thus legislators implementing smoke-free laws, and particularly restrictions in personal spaces like the home, need to fully assess the impact of such legislation on not only physical health but also on psychological health and well-being.

The research also questions the effectiveness of anti-smoking adverts concerning smoking in the home as findings indicate that smokers can be resistant to attempts to control their behavior. Although some authors (van den Putte et al. 2005) argue that smokers and non-smokers need to start a dialogue about smoking, this may result in negative consequences if arguments and tensions arise. This power struggle between members of the household will only be a valid target and effective campaign advertising message if cessation is shown and believed to be an effective strategy to reduce this tension. However, if this message is not effectively conveyed, using the home as a campaign setting might evoke negative reactions and resentment if smokers are coerced into facing the home as a battle ground.

Early Adopters in the Diffusion of an HIV/AIDS Public Health Innovation in a Developing Country

Marylouise Caldwell, Norwegian School of Economics and Business Administration, Norway
Ingeborg Astrid Kleppe, Norwegian School of Economics and Business Administration, Norway

ABSTRACT

Public demonstration by early adopters of innovation benefits tends to reduce consumer resistance to HIV/AIDS public health innovations. However, elevated stigmatization, bifurcated culture, gender power relations and poverty make such public displays hard to enact in developing countries. To learn more about this difficult context for diffusion of a public health innovation, we investigate early adopters who act as public spokes-models of HIV/AIDS Positive Living in Botswana. With limited institutional support these consumers create and enact multiple roles, such as buddy, lay educator, support group member/leader and social entrepreneur. Analysis of these highly committed courageous individuals expands our understanding of the requisite personal qualities, capacities and roles of early adopters of HIV/AIDS public health innovations in developing countries.

INTRODUCTION

Early adoption is central to diffusion of innovations theory. Yet the consumer literature is remarkably silent regarding early adoption of HIV/AIDS public health innovations (PHIs) (for an exception see Rothschild 1999). We address this theoretical lacuna by investigating early adopters of HIV/AIDS Positive Living, a public health innovation in Botswana. HIV/AIDS Positive Living comprises a set of interrelated behaviours such as knowing and accepting one's HIV status, disease management including adherence to medication regimes, caring for people living with HIV/AIDS (PLWHAs), supporting the PLWHA community and engaging in social and political outreach. Our research draws upon an ethnographic study of The 2005 Miss HIV/AIDS Stigma Free beauty pageant, The 2006 Mister HIV/AIDS Positive Living contest in Botswana and follow-up interviews in the period 2006-2009. Competitors are some of the very few people living with HIV/AIDS (PLWHAs) in Botswana to go public with their HIV+ status and to advocate positive living. We observe that these consumers attempts to influence potential adopters are severely impacted by: (1) the stigma associated with a potentially deadly sexually transmitted disease, (2) resistance to an obviously Western styled bio-medical model that fails to address negative attitudes to external intervention in post colonial countries (Swidler 2006); and (3) denial of the disease's existence stemming from cultural beliefs about the origins illness, gender relations, fertility and sexual practices (Liddell, Barrett, and Bydewell 2004).

This paper comprises a short literature review of the diffusion of PHIs and early adopter roles in diffusion of HIV/AIDS PHIs. Findings are presented in two sections as follows: (1) the different pathways to the adoption of HIV testing, (2) the adoption of Greater Participation of PLWHAs Principles (GIPA). The discussion highlights implications for HIV/AIDS PHIs. We conclude with contributions and future directions for research.

EARLY ADOPTION OF HIV/AIDS PUBLIC HEALTH INNOVATIONS

Rothschild (1999) explains that consumers typically resist public health innovations (PHIs) for distinctive reasons. When confronted by PHIs, consumers tend to act in a self-centred manner adopting a short term perspective. They refuse to acknowledge that their individual failure to adopt could result in negative conse-

quences for themselves and broader society. The benefits of non adoption are often immediate; while the benefits of innovation adoption are delayed and appear vague. Goldberg (1995) points out that upstream factors, such as economic, political, cultural, technological, and public sector infrastructure factors, can increase consumer resistance to PHIs (Goldberg 1995). For example, PLWHAs who are poor and have poor food security can stop taking their anti-retrovirals (ARVs) because the medication increases their appetite and prevents them from experiencing a restful night's sleep.

Who are the most effective endorsers of HIV/AIDS innovations? An extensive review of spokespersons in HIV/AIDS PHIs finds that experts, rather than HIV+ educators are most influential when they demographically and behaviourally match their target audience (Durantini, Albarracín, Mitchell, Earl, and Gillette 2006). Elaborating upon this idea, Watts and Dodds' (2007) propose that a critical mass of "moderately influential" early adopters (the common man) are the ones who propagate widespread diffusion of innovations generally. Rossiter and Bellman (2005) suggest that the common man is well suited to public health announcements as targets typically seek to identify with the spokespersons in such messages. These ideas suggest that one way to optimize the advantage of expert credibility and consumer matching is to sufficiently increase common-man consumer expertise.

Consumers are likely to face numerous barriers when considering testing to know one's HIV status, the essential first step in Positive Living. The primary barrier to HIV testing is the fear of learning one's status (Valdiserri et al. 1999). High risk persons may be more worried about the result and tend to postpone HIV testing. Most HIV-infected persons remain undiagnosed until the onset of AIDS (Valdiserri et al. 1999). For consumers in developing nations such as Botswana, social stigma, lack of perceived HIV risk, and fear of having to change sexual practices also hinder testing (Weiser et al. 2006b). In developing countries with limited social security and employee rights protection, a sero-positive HIV- test tends to change a person's one's life radically. PLWHAs often lose most sources of emotional and economic support, namely their jobs, partners and friends.

Informed by this short review, this paper focuses on two broad research questions: (1) what propels consumers in developing nations to adopt bio-medical HIV-testing and how do they adapt to their sero-positive status?; and (2) what roles do early adopters who go public with their positive status take in the early diffusion of knowledge about living positively with HIV/AIDS? In Botswana, as in many other countries, very few PLWHAs talk about their status. Hence the testimonies of PLWHA informants who want to play a public role in diffusion of HIV/AIDS PHIs are very unique.

RESEARCH CONTEXT AND METHOD

Botswana, an economic and socially stable postcolonial African democracy, has one of the highest HIV/AIDS prevalence rates in the world (NACA 2009). Despite substantial government health campaigns since 1989 (Avert 2009), by the end of 2004, only 11.4% of Botswana's population of 1.7 million had ever tested to know their HIV status (NACA 2009). Estimates around this time placed Botswana's infection rate as 24% of adults (Stover et al., 2008). In 2002, Botswana was the first African country to provide free antiretroviral treatment countrywide. In 2004 Botswana introduced

routine testing public health facilities (NACA 2009) to reduce the stigma linked to seeking testing at designated HIV/AIDS testing centres.

Data sources: Data comprises multiple types and sources. Field notes and conducted interviews were conducted at the Global Health Conference and Gender Office in November 2005 in Gaborone, Botswana. This data collection was followed by extensive video-taping of interviews in March-April 2006 in Botswana of two participants from The 2005 Miss HIV Stigma Free Beauty Contest, six participants in 2006 Mr Positive Living Contests, five HIV/AIDS experts working in the public health sector, a national leader of a PLWHA support group, a Pentecostal pastor and a volunteer youth leader. Thereafter follow-up interviews via email, phone and face were conducted in the period 2006-2009. See Appendix 1 for Informant Details.

We shot video-tape of The Mr Positive Living Contest, related workshops and events. Subsequently we regularly collected data via email, telephone conversations and follow-up interviews over a period of three years. We collected over fifty related press articles. We transcribed videos produced by the BBC, Botswana TV and home videos made by informant's families. All interviews and footage were transcribed and described in full. Materials in Setswana¹ were translated into English by a native Setswana speaker. The two authors individually and together watched all the video footage and read the transcripts. Throughout this interactive process we structured and coded the data/quotes guided by theory. A research assistant from Botswana with over eight years experience in medicine, public health and HIV/AIDS in Botswana reviewed our findings for factual reliability and face validity.

FINDINGS

Informants' reports indicate that early adoption of HIV/AIDS Positive Living involves two adoption processes: 1) initial HIV/AIDS testing, and 2) adoption of The Greater Participation of People Living with HIV (GIPA) Principles. HIV/AIDS testing involves two sub-pathways: The normative and delayed testing pathways. Figure 2 presents these early adoption pathways as flow charts. We discuss these pathways below.

1. HIV/AIDS Testing Adoption Pathways

1.1 The Normative Testing Pathway (NTP): The normative testing pathway is the mode of early adoption to HIV testing typically underlying PHI design. This pathway assumes a proactive consumer who is educated about the disease and on his/her own accord seeks testing. Three of our informants fit the definition of NTP as they clearly recall exposure to the HIV/AIDS PHI messages in the media and/or at public health facilities, which makes them aware of their high risk lifestyles. Subsequently they attend health facilities and request testing. "I just took the initiative to do such, urged by what I regularly heard on the radio, TV... So considering my life style... recollecting all that I had done... is what made me plunge the courage to go testing. I wasn't exactly an innocent and careful boy, you know" (Otsile-smiles). Amogelang, also admitting to multiple sex partners, initially tests because she wants a baby. After testing negative, she has unprotected sex with males who reassure her of their negative status. Retesting reveals she has subsequently become infected with the virus. To outsiders, her behaviour might seem reckless, yet it is more understandable when one appreciates that in Botswana infertile individuals are socially invisible (Upton 2001). Joseph and Bontle do not openly admit to a sense of risk but test anyway: "We heard on the radio... When we went for testing, we did not suspect we were HIV+. We just went to know our status" (Bontle). Perhaps Joseph's period in the army, in which he spent many months away from his wife, and his

discharge from the army for drunkenness, is an unspoken reason for testing between husband and wife.

1.2 The Delayed Testing Pathway (DTP): This pathway suggests that consumers are in heavy denial of their HIV/AIDS risk and hence resist testing, despite suffering chronic illnesses. They provide not any, or only vague reports of exposure to HIV/AIDS PHI messages. Arguably high risk consumers attend poorly to such messages because they do not regard themselves as part of high risk groups (Raghubir and Menon 1998; Valdiserri et al. 1999). Precious, a technical college educated ex-legal secretary, with a school teacher mother, admits her to promiscuous ways. She believed that she was immune from the disease; perceiving she was not from the social-class linked to the disease, that is, poor, rural, and uneducated. She elaborates that the family of her HIV+ boyfriend's upper middle-class family does not openly acknowledge his HIV+ status, despite the death of his previous girlfriend and their baby (a grandchild) from HIV/AIDS. After testing positive, Precious becomes very suspicious that not one of the upper level Batswana² officials that test publicly, tests positive. These accounts add weight to the idea that Batswana, like many people worldwide, regard HIV/AIDS as the disease of a heavily stigmatised other.

DTP informants acknowledge the contribution of excess alcohol to unsafe sex. Joseph, an ex-soldier, explains that drunken men don't take no for an answer. "When he is drunk, there is no control. If a girl says: "No, no I don't like it."... He will force the lady to make love, or to have sex with him. "After learning of their HIV+ status, some DTP informants experience prolonged self-stigma, anger, denial, and desire to escape, including contemplating or attempting suicide. Precious explains: "Then they told me 'Woman, you're HIV positive.' Then I just took off ... I had anger, denial, blame to an extent that I even started saying I had been bewitched by my family... I thought I was a black sheep in the family (Precious)." Precious suffers many serious illnesses before a doctor persuades her to test in 2000. Critical to her test decision, is the influence of an international PLWHA celebrity role model, and the knowledge that treatment is available. "Then they showed me these tablets-'Combivir' and said 'these days it's unlike before, when you are positive-you can be given antiretroviral medication to help you. So if they detect the virus in you, then you can take these tablets and you'll be just like Magic Johnson.' Because I used to be a sports lady playing table tennis ... because I had heard about Magic Johnson, I wanted to be just like Magic Johnson! Then I said 'Okay. Well let me go have the test.' (Precious)." In 2000 only .02% of Batswana had ever tested (NACA 2009) and Precious's bravery cannot be overstated.

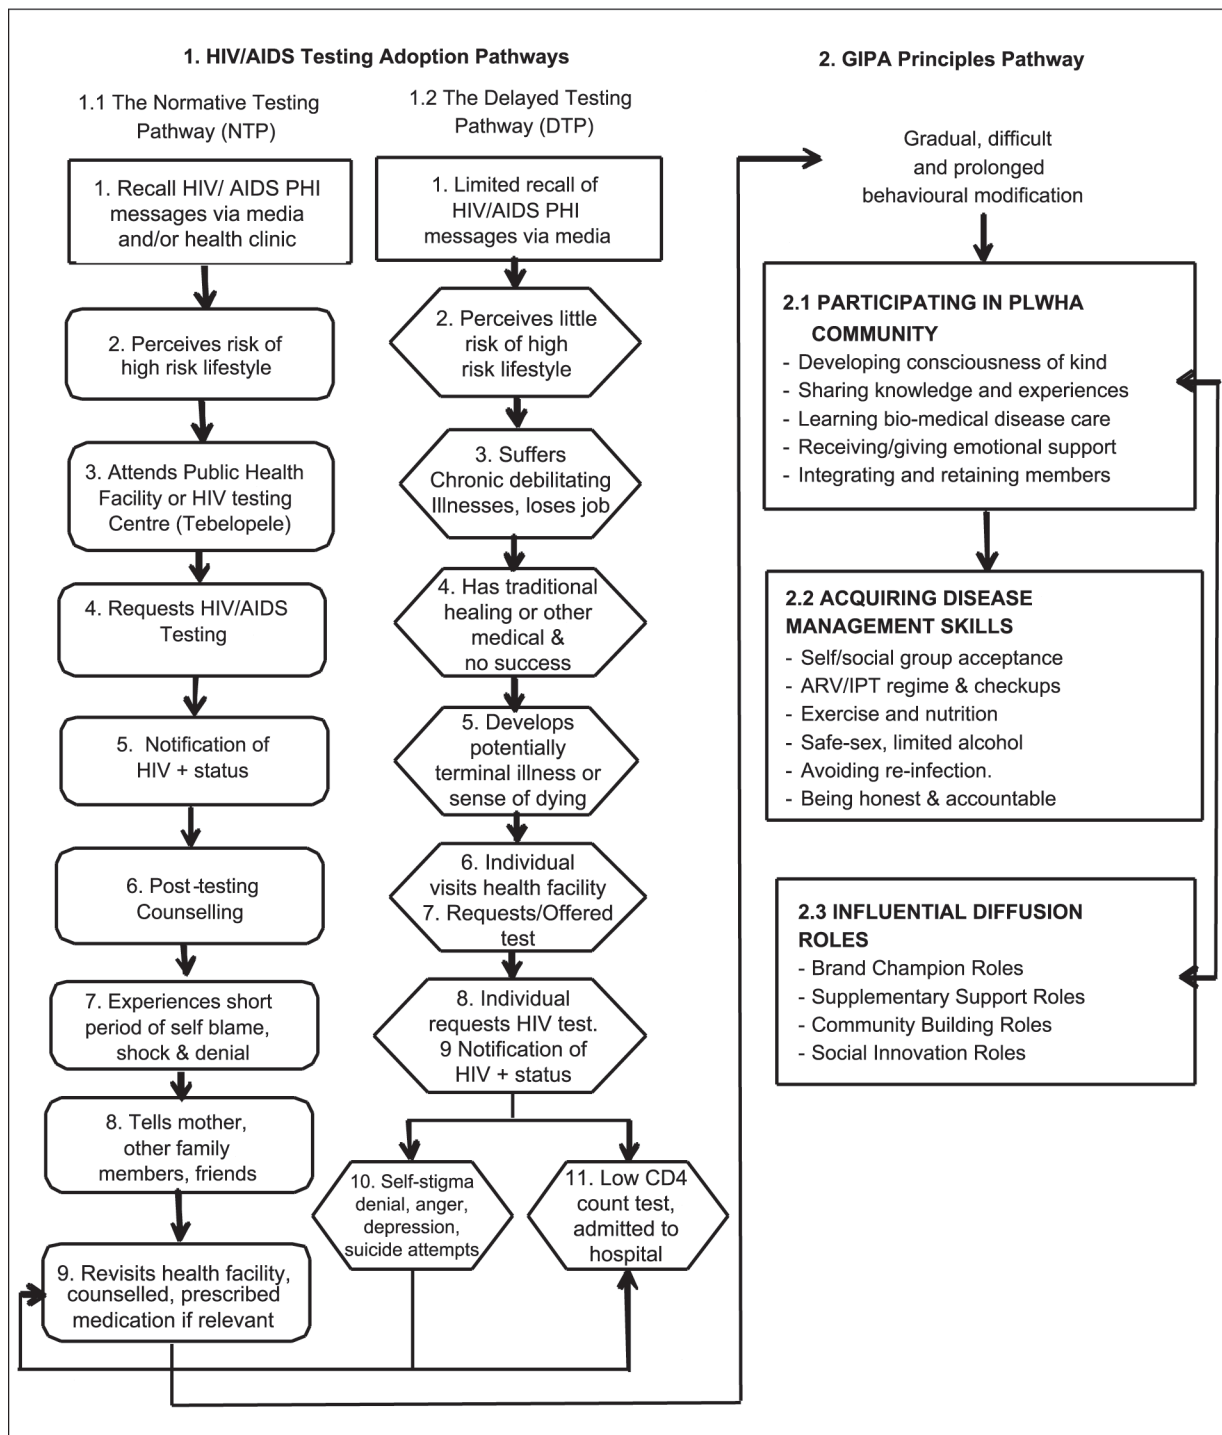

A comparison of the normative and delayed testing pathways points to aspects of theory. Testing by our informants suggests that they have a greater preparedness to take risks compared to the rest of the population. As stated earlier only 11.4% of Batswana had ever tested by December 2004 (NACA 2009), a time point at which all informants had tested. This finding validates the diffusion of innovation literature, which suggests that early adopters (typically first 16% of the population to adopt) are more risk-prone (Watts and Dodds 2007). However deviating from the diffusion of innovation literature, most of our informants do not have higher incomes, formal education or greater social participation compared to others. Rather they tend to come from poor backgrounds, have little formal education and confine themselves to village life.

Informants' behaviour suggests that the degree to which a person experiences feelings of self efficacy after learning of a HIV+

¹ Setswana is the national and majority language of Botswana.

² Batswana are members of a Bantu people living chiefly in Botswana and western South Africa.

FIGURE 2
EARLY ADOPTION PATHWAYS FOR POSITIVE LIVING

result influences their ability to manage the disease. Schwarzer and Renner (2000) find that a person with high self efficacy is likely to take positive steps to address HIV+ status, whereas a person with low self efficacy is likely to experience feelings of hopelessness. Contrasting Paul and Precious’s cases illustrates this point. Paul refuses to stigmatize himself and takes a matter of fact attitude towards his medication. “I sat down, and re-evaluated myself. And then came up with a thought of say ‘What is this?’ ‘This is just a condition I acquired’. And I couldn’t do anything because I never

made an application to it...I have to accept. Because I don’t want to die—I don’t want to kill myself... So I must accept...I’m taking the ARVs, it’s more like food...you are eating food in order to live...it doesn’t bother me (Paul).”

At the other extreme are Precious’s mixed reactions. After testing positive, Precious falls into despair, despite strong family support. She does not take her ARVs regularly and becomes resistant to the drugs. She attempts suicide. Upon recovering, she resolves no longer to play the AIDS victim. She strictly adheres to

a drug of last resort. She becomes an active member of the PLWHA community and goes on to become a celebrity spokes model for positive living. Despite her efforts, Precious develops a severe form of uterine cancer and receives radiation therapy to eliminate the tumour. So weakened is her health by the radiation, that she develops a deadly strain tuberculosis during a trip to a HIV/AIDS conference in Canada. After six months hospitalisation, she is flown home. Tragically Precious dies a few days later, six years after testing positive. Precious's plight underscores the importance of testing to know one's status. Drug therapies don't work so well for those who have been infected for a long time (Brashers, Neidig, Cardillo, Dobbs, Russell and Hass 1999).

Implicit to the normative and delayed testing pathways are very different assumptions about the tactics that induce early adoption of HIV testing. The normative testing pathway assumes that few factors impede the motivation, opportunity and ability to test (Rothschild 1999). Consumers are motivated to test by self interest, because free life-saving ARVs are available (NACA 2009). Consumers have the opportunity to test because testing sites are conveniently located in Botswana (Steen et al. 2007). Finally, partners or family do not reduce consumer's ability to test through social disapproval. The delayed testing pathway wrongly assumes that education is enough to motivate testing and hence fails. Unless consumers truly believe that effective and manageable treatment is available and that they are at risk, the extreme stigma associated with a deadly contagious sexually transmitted disease such as HIV/AIDS will largely prevent testing.

2. Adopting Greater Participation of PLWHAs' (GIPA) Pathway

Informants report that adopting GIPA principles is a gradual, difficult and prolonged process. "It is not an overnight thing you can achieve" (Paul). Essential to this adoption process is participation in the PLWHA community, by initially becoming a member of a local support group.

2.1 Participating in PLWHA Community. All informants report substantial benefits from attending local support groups. First and foremost, meeting regularly with other PLWHAs and sharing stories, makes them feel less isolated, less ashamed and better able to manage their disease. "After meeting with the leader of the support group, she... told me that she herself is HIV positive, that she has been living positively with HIV for many years. That she is public and open about her positive living with HIV... Therefore, that encouraged me to be open and tell my friends about my HIV positive status (Otsile)." These sentiments contrast markedly with Otsile's previous stigmatisation of PLWHAs. "Before I knew my status, I didn't want anything to do with an individual living with HIV...I hated them (Otsile)." For Precious, meeting with other PLWHAs changes her life. "That was a turning point...I saw an advert written 'Coping Centre for People Living with HIV and AIDS-COCEPWA', saying they were looking for a secretary-someone living with the virus...but I thought 'let me just go to COCEPWA and hear-maybe I will have more information about HIV/AIDS'." At COCEPWA Precious learns about the HIV virus and AIDS and trains in counselling and public speaking. She goes public about living with HIV. Her opening line in public settings becomes "My name is Precious and I am a lady living with HIV/AIDS." Such a bold statement is very unique for a PLWHA anywhere, and should be considered a peak moment for expressed consumer voice in a developing nation.

Informants realise that going public about their sero-positive status contributes to building a consciousness of kind amongst PLWHAs in Botswana. "If I become Mr Positive Living, HIV Positive Living...I want to see the people taking action identifying

themselves with me-to create or establish a common front or the onslaught of this virus (Paul)." They also realise that PLWHA community building is a means of gaining empowerment and achieving better treatment from civil society and the government. "The leaders think that as PLWHAs... we are powerless and worthless. So there is no one advocating for us, (so we do) (Precious)."

2.2 Acquiring Disease Management Skills. Being accepted by others as well as self is important for PLWHAs. Public disclosure reduces the high stress of living secretly with the disease that can erode the immune system (Holt, Court, Verdharma, Nott, Homes and Snow 1998). Some asymptomatic informants report that achieving social acceptance within their immediate social groups is difficult. People don't believe they are infected. "After I went public about my status, some people accused me of lying... I mean even when I show them my hospital records; some of them disregard them and insist on wanting to have unprotected sex" (Amogelang). PLWHAs need to have safe sex if they wish to reduce HIV infection rates. They also need to publicly show that they are being socially responsible otherwise they will be further stigmatised. Precious states: "It's my virus. I do not share it with no one." PLWHAs should also seek to avoid re-infection; unprotected sex can result in cumulative re-infection as well as infection by new strains of HIV/AIDS. PLWHA couples can find conversion to safe sex difficult. "It was hard for us to change our behaviour. Especially using condoms...In the beginning I was worried she is falling in love with someone but in the end I heard what the counsellors said (Joseph)." In strongly patriarchal societies, such as Botswana, condom adherence may be especially difficult. A widespread saying in Botswana, derides use of male condoms: "A sweet is never eaten with the wrapper-you have to uncover the sweet and then it becomes-sweet" (Helle-Valle 1999). Informants often emphasised the importance of eating nutritious meals to stave off disease progression. However observation suggests that on a daily basis PLWHA informants often had little idea of where their next meal would be coming from.

2.3 Influential Diffusion Roles. An emic account of the data suggests that early adopters who are public spokes models can adopt at least twelve roles that potentially influence adoption of Positive Living. The capacity of informants to enact such roles is a function of i) individual commitment and goals and ii) role related competencies. The latter are in part developed through participation in support group workshops in which PLWHAs are trained in lay counselling, public speaking, speaking to journalists and advocating change to politicians. We present details of these roles, in the context of four broad categories likely to associate with the diffusion of GIPA: 1) Brand Champion Roles, 2) Supplementary Service Roles, 3) Community Building Roles and 4) Social Innovation Roles.

1. Brand Champion Roles: These roles associate with being the first people to promote positive living and provide "social proof" that the disease exists through public disclosure.

(i) *Pioneers:* are amongst the very first people to test and to publicly admit nationally their HIV+ status. Pioneers need to be courageous, determined and visionary. As Donald explains: "Discrimination and isolation was very rife at the time... [A study in Kasane, Botswana] revealed that the majority of people said all people living with HIV/AIDS should be castrated, ostracised and quarantined. It became even more scary. The AIDS/STD Unit of Ministry of Health and Red Cross continued to give me all the necessary support and counselling...24th of November, 1993 I declared my status in public through the radio and television" (Donald).

(ii) *Local Initiators:* are the first to admit within a social group

to having tested HIV+. Local initiators need to be open, autonomous and qualified risk-takers. Despite the fear of stigma, they share their experiences with family and friends, admitting that the burden of their sero-positive status is too hard to bear alone. They are often very aware that the news of their positive status will spread to other locals. "I knew that telling one individual will automatically lead to a chain reaction because they would not be able to keep it between us (Otsile)."

(iii) Public Spokes Models: act as role models and public speakers about effectively living with HIV/AIDS for PLWHAS nationally. Public spokes-models need to be accountable, high self-monitors, articulate and be well versed in effective disease management. "My transformation...I used to change partners...I drank every day and big time. So by the time I went public with my status I was like I have to practice what I preach... I can't just go to a bar and sit down with people drinking... because maybe I will get tempted and start drinking again. And what will people start thinking of me (Precious)." Public spokes-models are typically competitors from The Miss HIV Stigma Free or Mr Positive Living contests.

2. *Supplementary Service Roles*: These roles complement the inadequate government services needed to maintain widespread PLWHA adherence to Positive Living. Failure to achieve this goal is loaded with huge social and political significance. "The need for treatment outstrips our ability to deliver it. There is a lot of pressure on us, because if we fail people will say: 'Botswana had everything going for it and it failed, so why should we help anyone in Africa?' (Dr Moffat, superintendent Princess Marina clinic)" (Avert 2009).

(iv) Lay Counsellors: regularly encourage others within their social networks to test and give homespun advice about disease and lifestyle management. Lay counsellors need to be friendly, patient, giving and available to others. "You can't go to the men and say he must goand check their status. No. First of all you must be friendly to a person. Start to be friendly to a person be patient. Come to a person. Visit a person. If he needs your help, then help him. Until you see that your friendship gets close. That's the time you can start to [talk to him] (Joseph)."

(v) Volunteer Carers: look after PLWHAS who are suffering from the chronic illnesses that typify HIV, often because they cannot be cared for by the public health system. Volunteer carers need to be in good health, compassionate and realise that their behaviour likely fortify norms of reciprocity amongst PLWHAS. "I go there—changing their nappies, feeding them. Because I know how it is living with HIV and AIDS. I have experience of it. Maybe one day it will be me. And somebody else will come and help me. So that's what I am doing at the moment" (Precious).

(vi) Buddies: are experienced with ARVs and acts as guides to PLWHAS beginning the drug regime. Buddies need to be experienced and reliable. "Ah, a buddy operation is whereby you give the sick I would say...love, care, and support...to get for the medication or the doctor...medical services, health services...because when you get onto the services you get confused a bit then. Which are the better ones [What are the challenges to working on the buddy program?]. First of all you give yourself time to remind, to always frequent, visit the client. To check how on well he or she is keeping up...any side effects, and nutrition" (Paul).

3. *Community Building Roles*: These roles reflect the need to access the financial, personnel, and socio-political resources needed to consolidate and grow the PLWHA community nationally/internationally.

(vii) Support Group Members: As earlier discussed, support group members are essential to sharing information about disease management, providing emotional support and completing projects intended to enhance government PHIs. Support group members need to sharing, co-operative and committed to support group goals.

(viii) PLWHA Support Group Leaders: ensure that local support group members are motivated to complete group projects. Support group leaders need to be consumer oriented, accountable, resourceful, respected and have organisational ability. "It's good to prioritise, even if you are busy at home with your own projects...be involved and available, for patients and people in your support group. As a chairperson, you need to lead by example, be disciplined with whatever financial support of funding you get not to abuse it. Serve the purpose of... the agreed agenda or people will lose hope, alienate and abandon the project (Joseph)."

(ix) National PLWHA Community Leaders: inspire broader society to acceptance PLWHAS by acting as a community spokesperson and advocate. They forge useful connections between PLWHAS and non-PWHAS leaders. They need to be articulate, confident, open to change and aware of the general populations attitudes to PLWHAS. Kagiso warns: "They know to be careful not to bite the hand that feeds them!"

4. *Social Innovation Roles*: These roles underpin the modification or creation of HIV/AIDS PHIs by PLWHAS and hence tend to reflect an improved and much needed consumer orientation.

(x) Social Entrepreneurs: initiate support groups or other community organisations likely to enhance PLWHAS physical, emotional and material wellbeing. Social entrepreneurs need to be innovative, highly passionate, determined and connected. Donald, as indicated is a pioneer. He now heads up a major national PLWHA support group founded by him. He is also a frequent critic of the Botswana governments' inadequate support of PLWHAS. Another example is Precious's care and counselling centre for HIV affected youth in her home village, set up posthumously by her family according to her wishes.

(xi) Advocates: fight for better treatment of infected and affected individuals of HIV/AIDS who are neglected by the government or NGOS. Advocates need to be exceedingly resourceful, independent, passionate and long term oriented. "These kids really need help...I'm advocating for them because there's no one to advocate for them. I'm a person living with HIV and AIDS, I'm not working but I'm able. How 'bout these kids? They don't have anything... It's only from my heart...It's a long process...The government I can say...are not giving us support" (Precious).

(xii) The Politician: wants the power to create change. Not one informant was a politician but at least two of them aspired to the position: "You see I'm more politically inclined really. My challenge is to see visible changes in our country, changes for the better....I want everyone employed (Amogelang)."

Summary: An overview of the twelve roles suggests two underlying dimensions: 1) The Capacity for Positive Deviance and 2) The Capacity for Social Outreach. The former dimension asso-

ciates with the capacity of everyday people to create beneficial solutions for themselves to social, economic and/or health problems that differ from the mainstream (Sternin et al; 1998). The latter dimension includes social domains ranging from self/family/social group, to local and national PLWHA community to broader society, nationally and internationally

DISCUSSION AND CONCLUSIONS

This study is an early attempt to unpack the different early adopter roles to which consumers adapt in the extremely challenging context of HIV/AIDS in a developing nation. More research on this topic is needed to further theorize the roles PLWHAs can play in HIV/AIDS PHIs and their effectiveness. However our informants are living proof that PLWHAs can have strong motivation and resources to play public roles in disseminating HIV/AIDS message, educating other PLWHAs, and in modifying and expanding existing HIV/AIDS PHIs. They have negotiated and made their own way from private despair to a position where they can help others. They are the “moderately influential” early adopters who can propagate the diffusion process because they give the disease a face with which other PLWHAs easily can identify (Watts and Dodds 2007). However, PLWHAs are heavily stigmatized and are hence a deviant minority. They lack power, status, and often competence to instigate validation processes and to exert influence. They badly need more public support, especially from powerful politicians who support the views and activities of PLWHA spokespersons.

Informant Details (all names are pseudonyms)

Informant Demographic Details	Year of diagnosis	Disease orientation
PLWHAS		
Amogelang • 29 years old, female, single • Unemployed • Runner-up Miss HIV Stigma Free Beauty Pageant • Aspiring politician	• 2003 • Early presenter as no illness apparent	• Currently on ARVs • Tested negative 1996, then tried to become pregnant through unprotected sex with males who stated they were HIV negative. • 2005-one of less than 20 people to go public with HIV+ status
Andrew • In 30' s, male, defacto relationship with 3 children • Unemployed (former building contractor)	• 2004 • Late presenter (very sick at diagnosis)	• Currently on ARVs • Sexually active, uses condoms • 2006-went public nationally.
Bontle • 30 years old, female, Wife of Joseph, 2 children, younger child HIV+ • Housewife	• 2004 • Early presenter as no illness apparent	• Currently on ARVs • Sexually active, uses condoms • 2006-went public in local community
Donald • 56 years old, male, married at least twice, three children and two grandchildren • Founder/Director National PLWHA Support Group – membership of 4000 (former truck driver and farmer)	• 1993 • Late presenter (very sick at diagnosis)	• Currently on ARVs • Sexually active, uses condoms • First person in Botswana to go public with HIV+ status.
Joseph 37 years old, male, Married with 2 children, younger child HIV+ Commercial Artist (former soldier)	• 2004 • Early presenter as no illness apparent	• Currently on ARVs • Sexually active, uses condoms 2006-went public nationally
Otsile 27 years old, male, single, lives with parents, at least one child Un-employed, recreational football player in HIV+ team and bodybuilder.	• 2004 • Early presenter as no illness apparent	Not on ARVs but on IPT (TB prevention medication) Not sexually active 2006 went public nationally
Paul 40 years old, male, single, 6 children Volunteer (Local home-based-care society) and Buddy	• 2004 Late presenter, very sick at diagnosis	Currently on ARVs Not sexually active 2006 went public nationally
Precious • 37 years old, female, single, • Part-time receptionist, volunteer advocate, spokesperson, public role model (former legal secretary) • Winner Miss HIV Stigma Free Beauty Pageant	• 2000 • Late presenter, very sick at diagnosis	• Currently on last ARV combination possible. • Not sexually active • 2005-one of less than 20 people to go public with HIV+ status.
Robert • 37 years old, male, has a girlfriend. • Volunteer carer, former insurance consultant/ driving school instructor, HIV/AIDS Volunteer • Runner Up Mr Positive Living	• 2002 • Late presenter (very sick at diagnosis)	• Currently on ARVs • Sexually active • 2006 went public nationally
Non PLWHA Consumers		
Ruth	• Volunteer community organiser, local rural youth community organisation

Itumeleng	• Consultant to Ministry of Health, Botswana	
Kefilwe	• Officer, Gender Affairs, Botswana	

Does a Marketer's Responsibility for a Surcharge Moderate Price Partitioning Effects?

Silke Bambauer-Sachse, University of Fribourg, Switzerland

Sabrina Mangold, University of Fribourg, Switzerland

ABSTRACT

In this paper we build on an established model that contains basic effects of price partitioning and introduce a new variable which has not been considered in previous studies yet. Based on the so-developed theoretical framework, we conduct a new empirical study. The results of our empirical study show that the marketer's responsibility for a surcharge on the base price plays an important role in the context of effects of partitioned versus total prices.

INTRODUCTION

Some products and services are divided into several (often two) components which are charged single prices but can only be bought in combination (Bertini and Wathieu 2005; Lee and Han 2002). An examples is a fitness club membership and the joining fee. Morwitz, Greenleaf, and Johnson (1998) call this strategy partitioned pricing and refer to the larger price component as the base price and to the smaller component as the surcharge. Surcharges are most often monetary surcharges, but in some cases the surcharge is a percentage of the base price.

Although some authors dealt with basic effects of price partitioning and found either positive (Chakravarti et al. 2002; Morwitz et al. 1998; Xia and Monroe 2004) or negative effects (Bambauer-Sachse and Gierl 2008; Gierl and Bambauer-Sachse 2007; Lee and Han 2002), the body of research on conditions under which price partitioning is rather advantageous or disadvantageous is limited. Therefore, we build on an established model that contains basic effects of price partitioning and introduce and examine a new variable that might be relevant in the context of price partitioning effects but that has not been considered in previous studies. The variable we look at in this paper is the marketer's responsibility for the surcharge. Examples from marketing practice show that in some cases in which partitioned prices are used, the marketer is responsible for a surcharge on a base price. For example, charging a fee for the parking lot in addition to the price for a hotel room is at the marketer's own discretion. However, there are other cases in which the marketer is not responsible for the surcharge. For example, an airline has to charge an airport tax in addition to the price of the airline ticket itself or hotel managers have to charge a visitor tax in addition to the room price.

As attribution theory suggests that people think about the reasons other people have for a certain behavior (Kelley and Michela 1980), we think that it could be interesting to examine whether this reasoning also applies to the context of price partitioning effects and whether effects of partitioned versus total prices differ depending on the marketer's responsibility for a surcharge on a base price.

By deriving possible effects of a new moderator variable from existing theory and testing the assumed effects in an empirical study, which means looking in detail at conditions under which price partitioning effects might differ, our paper extends the existing body of research. Therefore, the approach presented here offers new insights in the mechanisms that underlie the effects of partitioned versus total prices.

In addition to addressing researchers, our paper addresses marketers who need to know under which conditions it might be beneficial to use partitioned prices instead of total prices. By explaining under which conditions price partitioning is rather advantageous or rather disadvantageous, our research enables mar-

eters to plan their pricing strategies more carefully when deciding whether to indicate total or partitioned prices.

THEORETICAL AND EMPIRICAL BACKGROUND

Previous Research on Effects of Price Partitioning

In a first step, we shortly summarize major findings of previous studies on price partitioning effects. Morwitz et al. (1998) found that price partitioning increases consumer demand compared to all-inclusive prices. Lee and Han (2002) report from their findings that using partitioned prices can cause negative consumer reactions, which leads to a negative change of brand attitude. Chakravarti et al. (2002) found that a product with a partitioned price for its components was evaluated more favorably and chosen more frequently than the same product with a total price. Xia and Monroe (2004) report that price partitioning has positive effects on consumers' price satisfaction and their purchase intentions. Burman and Biswas (2007) found support for their assumption that price presentation (partitioned price vs. total price) only has effects on consumers with a high need for cognition. Their findings show that these consumers interpret partitioned prices as comparatively fair prices. Sheng, Bao, and Pan (2007) derive from their results that price partitioning (using total prices) is more advantageous with regard to purchase intention if the surcharge is only a small (a comparatively large) fraction of the base price. Moreover, they found that in the case of an unfair (fair) surcharge, consumers have lower (higher) purchase intentions when exposed to partitioned prices than when exposed to total prices. A study conducted by Carlson and Weathers (2008) shows that partitioning prices into a large number of price components negatively affects perceived fairness and purchase intentions when the total price is not presented. Clark and Ward (2008) found in their study on price partitioning effects in online auctions where bidders had to pay their bid plus shipping costs that many bidders appear to be subject to an anchoring and adjustment bias or even to ignore the shipping costs completely. Thus, their findings suggest a positive effect of price partitioning. In a recent study, Hamilton and Srivastava (2008) focused on effects of different partitions of the same total price. The results of their four studies show that consumers prefer partitions in which they pay a lower amount for the low-perceived benefit component and a higher amount for the high-perceived benefit component. Bertini and Wathieu (2008) conducted four studies to examine attention arousal through price partitioning and found that total prices distract consumers from a thorough evaluation of the offer while partitioned prices draw consumers' attention to secondary product attributes.

Two studies that are most appropriate to build the basis of our new empirical study are the studies conducted by Bambauer-Sachse and Gierl (2008) and Gierl and Bambauer-Sachse (2007). In one of their papers, they developed and tested a basic model that is able to reflect both positive and negative effects of price partitioning (vs. using total prices) on product evaluation. In a consecutive study, they extended this model by including the cognitive effort spent on processing price information as a moderator variable. The major finding of this study was that using partitioned prices can only be recommended if consumers spend little cognitive effort in the situation of processing price information and if low surcharges

are used. We will integrate the moderator variable we are interested in here in the basic model presented in the two studies of Bambauer-Sachse and Gierl (2008) and Gierl and Bambauer-Sachse (2007) because this model is the only model that can be found in the existing literature that explicitly captures both positive and negative effects of price partitioning.

In the next section we will shortly summarize the theoretical background that led to the model that we will use as a theoretical basis of our new study.

Theoretical Background of Basic Price Partitioning Effects

In the context of explaining price partitioning effects, three variables proved to be relevant mediators in the relation between price presentation (partitioned prices vs. total price) and product evaluation (Bambauer-Sachse and Gierl 2008; Gierl and Bambauer-Sachse 2007). These variables are perceived price attractiveness, clarity versus complexity of the price structure (Xia and Monroe 2004) and consumers' feeling of being manipulated by the marketer.

Price Attractiveness. The concept of price attractiveness has often been analyzed in studies on pricing effects (Danziger and Segev 2006; Janiszewski and Lichtenstein 1999) and refers to the idea that consumers have beliefs about normal prices for certain product categories and that they judge prices on this basis. Xia and Monroe (2004) referred to a similar concept as "satisfaction with the price". Lichtenstein, Bloch, and Black (1988) used the term "price acceptance" for a similar phenomenon. Some theoretical approaches that are appropriate to explain the effect of price partitioning on perceived price attractiveness let assume a positive effect whereas others suggest a negative effect. As previous studies found this effect to be predominantly positive (Bambauer-Sachse and Gierl 2008; Gierl and Bambauer-Sachse 2007), we only summarize theoretical approaches that provide arguments for a positive effect.

When being faced with partitioned prices consumers can either ignore the surcharge which is the smaller price component (Morwitz et al. 1998) or try to calculate the total price. In the first case, perceived price attractiveness is believed to be comparatively high because one price component is not at all processed. In the second case, most of the consumers are believed to apply simplifying heuristics (Tversky and Kahneman 1974) to estimate the total price because they might find it too difficult to exactly calculate the total price (Biswas and Burton 1993). One such heuristic that lets assume positive effects on perceived price attractiveness is the so-called anchoring and adjustment heuristic (Block and Harper 1991; Carlson and Weathers 2008; Chapman and Johnson 1994; Davis, Hoch, and Ragsdale 1986; Jacobowitz and Kahneman 1995; Northcraft and Neale 1987). Applying the anchoring and adjustment argument to the processing of partitioned prices leads to the assumption that consumers anchor on the base price, the larger price component. Estimating the total price by starting from this anchor is likely to lead to an estimate that is biased toward the base price (Morwitz et al. 1998). Consequently, price attractiveness is believed to be comparatively high.

Consumers' Feeling of Being Manipulated by the Marketer. The fact that consumers might feel manipulated by the marketer can be based on the following arguments. Research on consumer persuasion knowledge provides the notion that consumers develop beliefs about the objectives marketers pursue with certain persuasion strategies (Friestad and Wright 1994; Hardesty, Bearden, and Carlson 2007). Research on pricing strategies has shown that consumers sometimes speculate on the marketer's motives for applying certain strategies (Hamilton and Koukova 2008; Homburg, Hoyer, and Koschate 2005). This phenomenon occurs when

prices are unusual, for example, in the case of an unexpected price increase (Campbell 1995; Maxwell 1995). As price partitioning might come across unexpectedly and surprisingly in some situations, consumers might speculate on the marketer's motives for using this pricing technique. Thus, a plausible explanation from the consumer point of view might be that the marketer tries to mask a possibly excessive total price and to mislead the consumer by indicating a partitioned price, which serves to increase his profit. When being faced with partitioned prices consumers are believed to ascribe a higher manipulative intent to the marketer than when being faced with total prices because they might assume that the marketer tries to mislead them by using several price components. This assumption is likely to lead to a comparatively unfavorable product evaluation.

Perceived Complexity of the Price Structure. The concept of perceived complexity of the price structure mirrors the fact that consumers have more or less difficulties in determining the correct total price when being faced with a partitioned price. As consumers expect marketers to use transparent prices, they might be dissatisfied when the price structure is more complex (less transparent) than they have expected (Lee and Han 2002). Presumably the price structure of a partitioned price is more complex than the one of a total price because in the first case there are at least two components which have to be processed. The dissatisfaction resulting from the unexpectedly high complexity is believed to be transferred to the product and thus to lead to a negative attitude toward the product.

In the next section we present theoretical arguments that can be applied to explain effects of the marketer's responsibility for the surcharge.

Theoretical Background of Effects of the Marketer's Responsibility

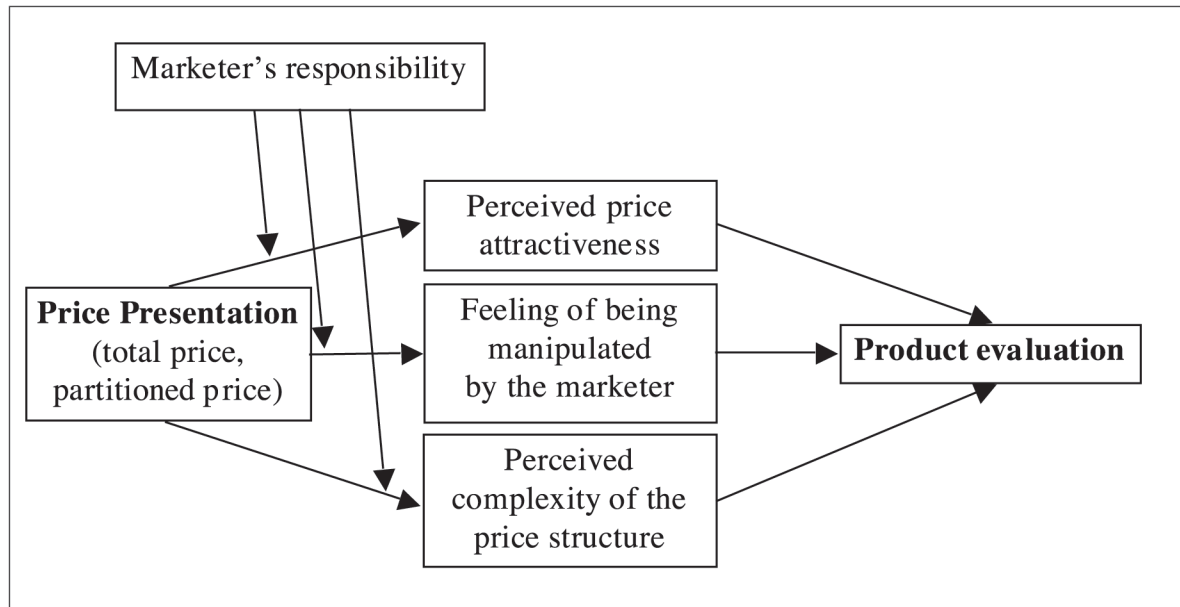

In this section, we argue that the marketer's responsibility for a surcharge has a moderating effect on the three basic effects of price partitioning versus using total prices discussed above.

Before presenting a theoretical background of effects of the marketer's responsibility, we have to differentiate the concept of responsibility considered here from another concept which might appear as a similar concept but which is different in fact. Sheng et al. (2007) examined effects of perceived fairness in the context of consumers' processing of partitioned prices. This latter concept is broader than the marketer's responsibility because the surcharge can be perceived as being unfair for other reasons than for the reason that the marketer is responsible for this surcharge.

In order to explain the role of the marketer's responsibility for the surcharge in the context of price partitioning effects, we draw on attribution theory which has already been applied to other contexts where people try to explain the behavior of other people they are in any relationship with. Such contexts were for example employees who tried to understand the rationale behind certain management practices of their employer (Nishii, Lepak, and Schneider 2008), consumers' coping strategies with regard to disasters related to companies they were customers of (Jorgensen 1994), customers' reactions to negative publicity for a company (Dean 2004; Griffin, Babin, and Attaway 1991), consumers' responses to negative word of mouth communication (Laczniak, DeCarlo, and Ramaswami 2001), and consumers' reactions to product failure (Folkes 1984).

Attribution theory in general deals with causal principles that people use to explain other people's behavior. According to this theoretical approach, people have a basic need to predict and control the environment. Understanding the causes of behaviors or events enables them to do so (Heider 1958). Moreover, people's interpretations of causes of behavior have effects on their attitudes and their own behavior (Kelley and Michela 1980). Furthermore,

FIGURE 1
RESEARCH MODEL

when people try to find reasons for a certain behavior of other people, they think about whether the locus of causality is internal (dispositional) or external (environmental) to the person of interest (Kelley and Michela 1980). Internal attributions are more strongly related with cognitions, feelings, and behavior (Weiner et al. 1972) than external attributions which reveal less about the underlying motivation of the behavior of the person of interest (Jones, Davis, and Gergen 1961; Jones and McGillis 1976; Kelley and Michela 1980). Following these arguments, we assume that consumers try to elaborate whether the marketer is responsible for charging a surcharge on a base price. Moreover, attribution research provides the notion that the more a person judges another person to be responsible for his or her behavior, the stronger is the effect of this behavior from the first person's point of view (Weiner 1979). Thus, transferred to the case considered here, we argue that if consumers have the impression that the marketer is responsible for charging the surcharge, the effect of charging the surcharge is comparatively strong. Combining this assumption with the notion that price partitioning (vs. using total prices) has positive effects on price attractiveness leads to our first hypothesis:

- H1: If the marketer is responsible (not responsible) for the surcharge, price attractiveness is higher in the total price (partitioned price) condition.

Furthermore, attribution literature provides the argument that frustrating actions that are internally attributed have even more intensive and more negative effects (Kelley and Michela 1980) than externally attributed actions. Transferred to the case considered here, we argue that the fact of being confronted with such a negative add-on as a surcharge on a base price is somehow frustrating to consumers. Consequently, we argue that consumers' belief that a marketer is responsible for the surcharge has comparatively negative effects and thus worsens negative effects of using partitioned prices. Based on these arguments, we assume with respect to the two mediator variables that mirror negative effects of price partitioning:

- H2a: The feeling of being manipulated by the marketer is stronger in the case of partitioned than in the case of total prices.
 H2b: In the partitioned price condition, the feeling of being manipulated is even stronger if the marketer is responsible for the surcharge.
 H3a: Perceived complexity of the price structure is stronger in the case of partitioned than in the case of total prices.
 H3b: In the partitioned price condition, perceived complexity of the price structure is even higher if the marketer is responsible for the surcharge.

The theoretical considerations presented above lead to the research model shown in Figure 1.

Research Model

In order to analyze moderator effects of the marketer's responsibility for the surcharge in the context of price partitioning effects, we integrate the new variable into the basic model of price partitioning effects described by Bambauer-Sachse and Gierl (2008). The resulting model is shown in Figure 1.

EMPIRICAL STUDY

Experimental Design

In our empirical study we used partitioned prices that consisted of two components and total prices. We chose test stimuli that were familiar to the respondents. Furthermore, the examples were chosen in compliance with the condition that both total and partitioned prices were realistic for these products. We only used a low monetary surcharge because high and percentage surcharges have been shown to have negative effects in previous studies (Bambauer-Sachse and Gierl 2008; Gierl and Bambauer-Sachse 2007; Sheng et al. 2007). The selected surcharge amount was 3.5 percent of the base price. With regard to many real surcharges in marketing practice, this amount is a realistic value. In addition, this amount falls into the range of low surcharges proposed by Sheng et al.

TABLE 1
Experimental Design

Product example (base price)	Total price condition	Partitioned price condition
City hotel (room price per night)	€ 60	€ 58 + € 2
Airline ticket (flight price)	€ 90	€ 87 + € 3

TABLE 2
Manipulation Check

Manipulated responsibility	Respondents' perception of marketer's responsibility*					
	Pooled data (<i>n</i> =320)		Hotel data (<i>n</i> =160)		Airline data (<i>n</i> =160)	
Marketer is not responsible	2.49	<i>t</i> =29.83	2.53	<i>t</i> =21.49	2.45	<i>t</i> =20.70
Marketer is responsible	5.69	(<i>p</i> <.001)	5.80	(<i>p</i> <.001)	5.59	(<i>p</i> <.001)

* measured on a 7-point rating scale ranging from 1=rather not responsible to 7=rather responsible

(2007). We chose two examples for each experimental condition (city hotel, airline ticket). Table 1 gives an overview of the chosen product examples and their prices. The total product prices are equal across conditions.

Responsibility was manipulated by selecting different types of surcharges a marketer typically is responsible (is not responsible) for. In the "marketer is responsible" condition, we used parking and fuel fees as surcharges. In the "marketer is not responsible" condition, we used a visitor and an airport tax as surcharges. Regarding the responsibility manipulation we did a manipulation check with two objectives. First, we intended to prove that the responsibility manipulation has been generally successful. Second, we wanted to show that the manipulations are comparably successful for the two different products. The results (mean values, t-test statistics) of the manipulation check are summarized in Table 2.

The findings in Table 1 show that the responsibility manipulation has been successful and that the manipulations are comparable across product examples. However, one might criticize that the responsibility for the surcharge is confounded with product attributes because different product attributes were chosen to represent the responsibility conditions (e.g., surcharge for parking vs. surcharge for visitor tax). However, we think that choosing two different product attributes that realistically represent responsibility is more credible than using only one attribute for the surcharge and manipulating responsibility by indicating in one condition that the marketer is responsible for the surcharge and indicating in the other condition that the marketer is not responsible for the same surcharge.

Scenarios and Measures

We created short scenarios containing product and price information to put the respondents in purchase situations which were as realistic as possible. The basic scenarios for both product examples were as follows: "Please imagine you are planning a weekend in Paris, you are planning to get there by car, and you are looking for a nice hotel!" (city hotel) and "Please imagine you are planning to visit a good friend in Berlin over the weekend and you decide to go there by plane because doing so saves lots of time"

(airline ticket). The varying scenario descriptions that followed these basic scenarios are shown in Table 3.

The model variables were measured by using several items. Price attractiveness was measured by using three items such as "well-priced" (Alpha=.91). The feeling of being manipulated and perceived complexity of the price structure were operationalized through two items each. The items used to measure the feeling of being manipulated were "supplier demands an unfair price" and "my friends would judge this price as being unfair" (correlation: .53). Perceived complexity of the price structure was measured by using the items "price presentation is unclear" and "cannot notice this price at a glance" (correlation: .62). Product evaluation was operationalized through four items such as "this offer is convincing" (Alpha=.93). We used seven-point scales to measure the model constructs. High/low scale values represent a positive/negative product evaluation, high/low price attractiveness, high/low perceived complexity of the price structure, and a strong/weak feeling of being manipulated by the marketer. The sufficiently high Alpha values and correlations allow for calculating the overall construct means as arithmetical means of the single indicators for each construct. These arithmetical means are used in the analyses presented subsequently.

The constructs perceived complexity of the price structure and feeling of being manipulated might be considered as being related. However, the correlation between both variables is comparatively low (.204). Consequently, both constructs can be clearly separated from each other.

Procedure

160 respondents (75 men, 85 women) participated in our study in 2008 in Germany (80 participants per experimental group). Each respondent evaluated the two product examples shown in Table 2 in the same experimental condition. Having each participant evaluating two examples served as a sample multiplier. The respondents read the first scenario, evaluated the first product, and indicated their perception of price attractiveness, of complexity of the price structure and their feeling of being manipulated by the marketer (statements on 7-point scales). They then read the second scenario

TABLE 3
Scenarios

Product example (base price)	Marketer <i>is</i> responsible		Marketer <i>is not</i> responsible	
	Total price condition	Partitioned price condition	Total price condition	Partitioned price condition
City hotel (room price per night)	The hotel that meets your expectations best, offers you a room at □ 60 per night including parking lot.	The hotel that meets your expectations best, offers you a room at □ 58 per night plus □ 2 for the parking lot.	The hotel that meets your expectations best, offers you a room at □ 60 per night including visitor tax.	The hotel that meets your expectations best, offers you a room at □ 58 per night plus a □ 2 visitor tax.
Airline ticket (flight price)	The flight that fits best into your schedule is offered at □ 90 including fuel charges.	The flight that fits best into your schedule is offered at □ 87 plus □ 3 fuel charge.	The flight that fits best into your schedule is offered at □ 90 including airport tax.	The flight that fits best into your schedule is offered at □ 87 plus □ 3 airport tax.

TABLE 4
Effects on the Mediator Variables

Mediator variable	Interaction effect of price presentation and marketer's responsibility				<i>F</i> _{price presentation x responsibility} (<i>p</i> value)
	Marketer <i>is not</i> responsible for the surcharge		Marketer <i>is</i> responsible for the surcharge		
	Total price	Partitioned price	Total price	Partitioned price	
Perceived price attractiveness ¹	4.49	4.90	4.89	4.87	<i>F</i> =2.17 (<i>p</i> >.10)
Feeling of being manipulated ³	2.86	4.70	4.80	5.11	<i>F</i> =19.07 (<i>p</i> <.001)
Perceived complexity of the price structure ²	2.58	3.04	3.18	4.94	<i>F</i> =12.51 (<i>p</i> <.001)
<i>N</i>	80	80	80	80	

1: 1=very low price attractiveness, ..., 7=very high price attractiveness

2: 1=low complexity, ..., 7=high complexity

3: 1=weak feeling of being manipulated, ..., 7=strong feeling of being manipulated by the marketer

and completed the corresponding scales. The order of the scenarios varied from person to person to counterbalance order effects. Finally, the respondents provided demographic information. Both groups are structurally equal with regard to age ($t=1.04, p>.10$) and gender ($X^2=1.26, p>.20$).

Data Analysis and Results

The paths of the basic model have already been tested in previous studies (e.g., Bambauer-Sachse and Gierl 2008; Gierl and Bambauer-Sachse 2007), but for reasons of completeness, we show that the data collected for this study are able to reproduce the assumed effects. In a first step we prove the existence of the right part of our research model (effects of the mediator variables on product evaluation). The results of a regression analysis ($R^2=.71$)

show that perceived price attractiveness ($\beta=.65, t=15.10, p<.001$) has a significantly positive effect on product evaluation, whereas perceived complexity of the price structure ($\beta=-.10, t=-3.48, p<.01$) and the feeling of being manipulated ($\beta=-.23, t=-4.71, p<.001$) have significantly negative effects on product evaluation.

In the second step, we focus on the left part of the research model that consists of the effects of price partitioning versus using total prices on the mediator variables as well as of the moderator effect of the marketer's responsibility. The effects assumed with regard to this part of the model are examined by using an ANOVA with interaction effects. The results are summarized in Table 4.

With regard to the effect of price presentation on perceived price attractiveness, the results show that if the marketer is not responsible for the surcharge, perceived price attractiveness is

higher in the partitioned price condition than in the total price condition ($M=4.90$ vs. 4.49 , $t=1.68$, $p<.05$). However, contrarily to the initial assumption we found that if the marketer is responsible for the surcharge, perceived price attractiveness is not significantly higher in the total price condition than in the partitioned price condition ($M=4.89$ vs. 4.87 , $t=0.09$, $p>.10$). Thus, the data indicate that the positive sign of the effect of price partitioning on perceived price attractiveness does not turn negative if the marketer is responsible for the surcharge. However, the positive effect is neutralized if the marketer is responsible for the surcharge. Consequently, hypothesis 1 is only partly supported.

With regard to the effect of price presentation on consumers' feeling of being manipulated, the results show that the feeling of being manipulated is significantly higher in the partitioned price condition than in the total price condition (marketer is not responsible: $M=4.70$ vs. 2.86 , $t=7.49$, $p<.001$; marketer is responsible: $M=5.11$ vs. 4.80 , $t=1.39$, $p<.10$). Moreover, in the partitioned price condition, consumers' feeling of being manipulated is even stronger if the marketer is responsible for the surcharge ($M=5.11$ vs. 4.70 , $t=2.04$, $p<.05$). Thus, hypotheses 2a and 2b are supported.

The findings for the effect of price presentation on perceived complexity of the price structure show that price structure is perceived as being more complex in the partitioned price condition than in the total price condition (marketer is not responsible: $M=3.04$ vs. 2.58 , $t=1.79$, $p<.05$; marketer is responsible: $M=4.94$ vs. 3.18 , $t=2.52$, $p<.01$). In addition, the results indicate that in the partitioned price condition, perceived complexity is significantly higher if the marketer is responsible for the surcharge ($M=4.94$ vs. 3.04 , $t=7.71$, $p<.001$). Thus, hypotheses 3a and 3b are supported.

CONCLUSION

The goal of the present paper was to draw on previous research on price partitioning effects and to extend the existing body of research by examining moderator effects of a new variable that might play a role in the context of price partitioning effects.

First of all, our data confirmed the paths assumed in the basic models by Bambauer-Sachse and Gierl (2008) and Gierl and Bambauer-Sachse (2007). Moreover, the results of our study show that the marketer's responsibility indeed plays an important role in the context of effects of partitioned versus total prices. In more detail, we found that, when processing partitioned prices, consumers consider whether the marketer is responsible for the surcharge on the base price or not. Based on our finding that negative effects of price partitioning are less strong if the marketer does not account for the surcharge, we recommend using partitioned prices only under this condition. In cases where the marketer is responsible for the surcharge, the negative effects of using partitioned instead of total prices are even stronger.

A first starting point for further studies might be to analyze circumstances that drive consumers to ascribe responsibility for a surcharge to a marketer. In addition, we suggest analyzing price partitioning effects in field experiments in retail stores because up to now, such effects have only been analyzed in simulated experiments. Moreover, it might be interesting to examine price partitioning effects for very low or very high priced products because the products considered in the study here are medium-priced. Finally, consumers' knowledge about the marketer's objectives that are pursued with a specific pricing strategy might also play a role in the context of effects of partitioned prices and thus might be an interesting variable to be examined in further studies.

Word-of-Mouth: Are We Hearing What the Consumer is Saying?

Martin A. Pyle, Queen's University, Canada

On a given night, if you look at the moon through a telescope you will see peaks and valleys, craters and crevices. From this perspective, you can make numerous assumptions and study individual elements which combine to make the whole. However, what you see is only half of a sphere; the other half is shrouded in darkness. This is akin to taking a singular perspective for examining word-of-mouth (WOM), which raises the question: what are we missing? The motivation behind WOM research over the past fifty years has been primarily managerial, seeking to understand and harness word-of-mouth's persuasive power. Generally approaching the phenomenon of WOM from a positivist perspective, marketing researchers have sought an understanding of the causal link between company actions and consumer WOM responses. Two underlying assumptions guide most of the work in this area: (1) consumers are information-seeking cognitive processors seeking to maximize their utility and (2) the sole purpose of word-of-mouth is to spread an evaluation of the product or service between fellow consumers. These assumptions are deeply rooted in the origins of WOM research and manifest themselves in how researchers commonly define WOM: an informal communication of information about, and evaluations of, a company or brand between two individuals (Brown, Barry, Dacin and Gunst 2005; Chung and Darke 2006; Dichter 1966). However, by relaxing the assumption that consumers are only spreading information about products or services to make rational decisions, and examining word-of-mouth through a lens of consumer culture theory (which adopts different philosophical assumptions), we can explore WOM from a new perspective and reveal what is hidden about WOM.

Extant research examining word-of-mouth (WOM) can be broadly subdivided into three streams of research. In the mid 1960s WOM researchers began examining the network aspect of WOM in an attempt to understand how the information moved from consumer to consumer (e.g., Arndt 1967, Sheth 1971) and the role of individuals as marketplace influencers (e.g., opinion leaders) and information seekers (e.g., Reynolds and Darden 1971; Stafford 1966). In the 1980s two other WOM streams emerged: an examination of negative WOM (e.g., Richins 1983) and individual constructs which influence the persuasiveness of WOM (e.g., Bearden and Etzen 1982). When combined, all three streams of research have produced a large, rich body of literature expanding our understanding of WOM. However, the underlying assumptions and motivations have left certain unexplained gaps and have not captured important factors required for a better understanding of WOM phenomena. Adopting a different perspective would allow us to apply different assumptions and address the unexplored aspects of the WOM phenomenon.

This conceptual paper begins with the dominant perspective of the consumer in the existing WOM research and subsequently demonstrates how early development in the area has led to the three major streams of WOM research. Next, I highlight the limitations of the extant WOM research and suggest that the consumer culture theory (CCT) literature offers a unique perspective that can complement and extend our understanding of the phenomenon. I conclude the paper by proposing three new WOM research domains derived from integrating the CCT identity literature with the extant WOM research.

WOM: PERCEPTIONS OF THE CONSUMER

The roots of the marketing discipline itself have influenced the direction taken by many WOM researchers. Marketing research flowed out of economics, resulting in many early marketing researchers also adopting the *economic man* view of the consumer. The *economic man* framework depicts the consumer as someone who is motivated by the desire to maximize the economic utility of his decisions. To accomplish this goal, the individual seeks as much information as possible about the available alternatives in his consideration set, and with this information, the person is able to make the most rational and value-maximizing decision (e.g., Whyte 1954). While this perspective has been overtly dropped from the literature, many of the assumptions from this view continue to permeate WOM research.

THE DIFFUSION LITERATURE

Social Networks

Although researchers and practitioners have long been aware of the existence of WOM as a persuasive influence, very little was known about WOM's underlying mechanisms early on. As Arndt (1967) described, "[w]ord-of-mouth advertising [had] been thought to be an almost mysterious force, with its effects taken for granted" (Arndt 1967, 291). This gap in understanding led to the emergence of the WOM diffusion literature, which focused on social networks and the role of marketplace influencers.

Whyte (1954) provided one of the first examinations of the makeup of a social network. During a walk through Philadelphia, Whyte (1954) observed a striking phenomenon. By marking homes that displayed air conditioners in the window on a diagram of the neighborhood, it was possible to discern a pattern of ownership. He followed up these findings by conducting interviews with family members from a portion of these households and found that many of the decisions to buy the air conditioners could be linked to the influence of neighbors. The diffusion research continued through the 1980s, examining the relationships within the social networks and seeking to understand their inner workings (e.g., Reingen, Brown, Foster and Seidman 1984; Reingen and Kernan 1986). In general, this stream of research suggested that strong social ties were not required for passing along opinions. Weak ties could provide the bridge from one social group to the next, allowing word-of-mouth to spread a great distance (Brown and Reingen, 1987).

More recently, the diffusion literature has examined social networks in the context of the Internet. As consumers began to embrace online word-of-mouth, it became apparent that this technology provided an unprecedented increase in the size of social networks (Dellarocas 2003) and the amount of information available to consumers (Chatterjee 2001) far exceeded traditional word-of-mouth. However, increasing the scope and scale of word-of-mouth has not generated many unique or significant insights about how information travels within and between social networks. In short, as a body of research, the diffusion literature has contributed to our understanding of how information travels through social networks, however this research stream would benefit from an infusion of new perspectives that can generate new research questions, rather than applying existing knowledge to new contexts.

Marketplace Influencers

During this same period of network examination, another group of researchers was concurrently seeking to identify and understand the originators of the networks. Marketing literature has defined three distinct categories of marketplace influencers: opinion leaders, innovators and 'market mavens'. Opinion leaders tend to have influence within a specific domain or product category (Reynolds and Darden 1971; Stafford 1966;). Innovators are early product adopters who spread the word to others about the benefits (or faults) of the product or service (Clark and Goldsmith 2005; Leonard-Barton 1985). Marketing mavens tend to be the most sought-after supporters by retailers as they influence the decisions of other consumers in multiple product domains (Feick and Price 1987).

Marketing researchers have extensively sought an understanding of the marketplace influencers' motivation for disseminating product information. Swan and Combs (1976) believed a logical motivating factor for spreading WOM was product satisfaction. An early definition of satisfaction reflects the perception of the consumer as a logical, information seeker: consumers gathered information about products, made predictions about performance of a product leading to expectations, consumed the product, and then compared the actual and predicted performance on relevant attributes (Swan and Combs 1976). In this bi-modal view, if the comparison was favorable, the consumer was satisfied; otherwise he was dissatisfied. Tying together satisfaction with identification, some research has shown that one's level of commitment has a moderating influence on the link between satisfaction and positive word-of-mouth (Brown, Barry, Dacin and Gunst 2005). However, the extant literature is somewhat equivocal in linking positive WOM to satisfaction with a product or service. While Brown et al. (2005) were able to demonstrate this link, other researchers have offered evidence that satisfaction cannot be related to WOM dissemination (e.g., Arnett, German and Hunt 2003; Bettencourt 1997).

THE RELEVANCE OF VALENCE

Emerging out of the satisfaction and opinion leader literature, the second stream of WOM research examines the effects of valence on the persuasiveness of WOM. In particular, marketing researchers examining negative WOM have focused on the cognitive reasons why negative information is more persuasive than positive WOM and the underlying motivations behind disseminating negative feedback. Arndt's (1967) study indicated that while favorable product experiences were more numerous, unfavorable word-of-mouth was far more effective at deterring new product adoption. Examining this differential influence, Mizerski (1982) suggested an attribution-based explanation for why negative information appeared to be more persuasive (i.e., the negativity effect). Specifically, while the motivation behind positive WOM could be attributed to a variety of reasons (e.g., social norms, message source), negative WOM tended to be attributed solely to the product itself (Mizerski 1982). Just as the extant WOM diffusion literature assumes that satisfaction stemming from direct contact with the product or service drives positive WOM, much of the negative WOM literature is based on the assumption that disseminators of negative WOM have experienced dissatisfaction with the product or service (e.g., Richins 1983).

The product-centric assumptions from the initial research examining WOM are also prevalent in the WOM valence literature. This literature suggests that the consumer spreading negative information to his fellow information seekers does so based on a poor experience with a product and is seeking justice for this wrongdoing (e.g., Blodgett, Granbois and Walters 1993). Furthermore,

the valence literature tends to focus on the dissuasion of consumers by this negative information. These assumptions bias the research questions being examined, and yield gaps that remain unexplained. For example, Liu (2006) examined the relationship between WOM and movie success using a data set from a popular online message board. In summary, Liu found that the volume of WOM (*regardless of valence*) acted as a good predictor for box-office revenue, suggesting that negative feedback did not have the predicted effect of dissuading others from purchasing the product. The proscribed relationship between product experience, dissatisfaction and negative WOM also does not explain anecdotal evidence whereby consumers spread negative WOM based on a company's policies, without having direct experience with that company (e.g., negative WOM regarding Wal-Mart's anti-union position). Researchers have also spent considerable time examining which factors, beyond valence, impact the persuasiveness of WOM communications.

CHARACTERISTICS AFFECTING PERSUASIVENESS

The third stream of WOM research adopts a reductionist perspective on the topic, identifying specific characteristics which impact the persuasiveness of WOM and testing them in an experiment. For example, researchers have demonstrated an effect on the persuasiveness of interpersonal influence by source credibility (Dichter 1966), the type of product (i.e., luxury or necessity), private versus public consumption (Bearden and Etzel 1982), as well as the similarity of the referent and his/her perceived expertise (Price, Feick and Higie 1989). Bone (1995) examined the effects of WOM on short- and long-term judgments and found effects for both, particularly when the information was contrary to previous experience. Another factor found to be influential in the level of persuasion was vividness of the positive word-of-mouth description (Herr, Kardes and Kim 1991). The authors found that participants retrieved vividly presented information more easily from memory, and this information had a positive influence on subsequent judgments.

Although researchers have examined the effect of many characteristics on WOM, the researchers have tended towards a positivist approach using experimental methodologies. This methodological approach removes the contextual impact from WOM, attempts to determine causal relationships and thus, may miss certain relevant factors. For example, information received from an acquaintance at a party may be interpreted differently than when that same person provides information in a workplace.

LIMITATIONS IN CURRENT WOM RESEARCH

An analysis of the extant WOM research highlights the dominance of the positivist approach to examining the WOM phenomenon. This, in turn, has resulted in a singular method of examination (primarily experimental) as well as certain deep-seated assumptions. Cumulatively, this approach has impacted the nature of the questions researchers in the area have sought to answer. The majority of WOM research has typically adopted a view of the consumer as an information-seeking and information-processing individual. This perspective of the consumer has tended to result in a product-centric approach to WOM content, whereby the focus of the communication is strictly on the brand. This focus on the consumer as a product-information-seeker led to the assumption of a sole motivation for generating WOM: a reaction to a direct experience with a product or service.

I suggest that WOM research would benefit from an integration of the philosophical perspectives and research stemming from the CCT paradigm, and the methodological approaches typically adopted within this research stream. This perspective brings with it

a different set of assumptions (e.g., different views of the consumer and the impact of context) and thus seeks to address different research questions. Positivism and interpretivism differ at an epistemological level, and though it can be (and has been) argued that the two are therefore incommensurable, I propose that the research deriving from these philosophical positions is complementary and serves to enhance our understanding of various phenomena. In the context of WOM, the existing and future positivist research exposes one view of WOM, while an interpretivist approach to future research in the area, drawing on a different body of literature and methodologies, would serve to illuminate additional elements of WOM which currently remain unexplored (Figure 1).

CONSUMER CULTURE THEORY: AN OVERVIEW

Consumer culture theory is not one specific theory, but rather a theoretical perspective that views consumer actions, the market and cultural meanings as interconnected (Arnould and Thompson 2005). At a broad level, CCT research focuses on "...how consumers actively rework and transform symbolic meanings encoded in advertisements, brands, retail settings, or material goods to manifest their particular personal and social circumstances and further their identity and lifestyle goals" (Arnould and Thompson 2005, 871). Work in the identity subsection of CCT research conceives of the consumer as an identity seeker and maker. CCT researchers seek to investigate the consumption experience within the sociocultural context because "...an understanding of consumer symbolism and lifestyle orientations is essential to successful marketing strategies" (Arnould and Thompson 2005, 871).

WOM AND CCT: SHARED VIEWS

Integrating the CCT identity stream of literature into WOM research is not an unreasonable task. The two bodies of research share several similar conceptual frameworks based on networks, particularly in the WOM diffusion area of research. Arnould and Thompson (2005) describe consumer culture itself as "...a densely woven network of global connections and extensions through which local cultures are increasingly interpenetrated by the forces of transnational capital and the global mediascape" (Arnould and Thompson 2005, 869), a description similar to how researchers envision WOM networks.

The WOM research on marketplace influencers also provides a good example how WOM and the CCT identity literature relate at the construct level. Taking a reductionist approach, some WOM researchers have examined opinion leaders and marketing mavens to determine if they share particular traits or motivations for engaging in WOM communication (e.g., Feick and Price 1987). The extant research in the area suggests that a common motivation is the desire to be perceived as an 'expert' by others (Walsh, Gwinner and Swanson 2004). The CCT identity literature expands on this social motivation by suggesting that consumers classify themselves through specific action-related consumptive experiences such as rituals or traditions (Holt 1995). For example, Holt (1995) refers to "mentoring" as being an action which contributes to an individual's authority and legitimacy, strengthening the individual's socially visible bond to the brand. As Holt (1995) describes it, mentoring is akin to a demonstration of one's expertise on a particular topic.

CCT: PERCEPTIONS OF THE CONSUMER AND CONSUMPTION

Arnould and Thompson (2005) suggest that the consumer is a social being and part of a community. This cultural view conceptualizes the consumer as someone who engages in an ongoing

personal narrative and creates personal meaning through consumption experiences (Thompson and Troester 2002). Whereas the traditional marketing view suggests that brand meanings emanate from the company, the CCT perspective tends to conceptualize meaning as being co-created with the consumer drawing together various cultural meanings in a form of bricolage to create a personally relevant meaning. Furthermore, these symbolic meanings are not static, but instead "[i]n narrative, people continually make sense of their world 'on the fly' ... the flow of events is given an articulate form, made into a kind of model" (Shore 1996, as cited in Thompson and Troester 2002, p. 553). Thus, these consumer narratives are fluid and contextually dependent, drawing on salient elements from the given situation (Thompson 1997).

Holt and Thompson (2004) explore the idea of internal conflict resolution as it applies to this notion of a personal narrative. The authors suggest that consumers often address internal tension caused by perceptions of conflicting social norms by drawing on cultural artifacts and meanings in a playful manner to create a personal space where there is no conflict. The concept of play is related to how we draw from the varying cultural artifacts and put them together in new and varied combinations. At times these combinations can serve a social purpose, as with the consumer-created Doppelgänger brands attacking Starbucks (Thompson, Rindfleisch and Arsel 2006), while in other contexts this playfulness is related to consumer fantasy (e.g., Kozinets et al. 2004).

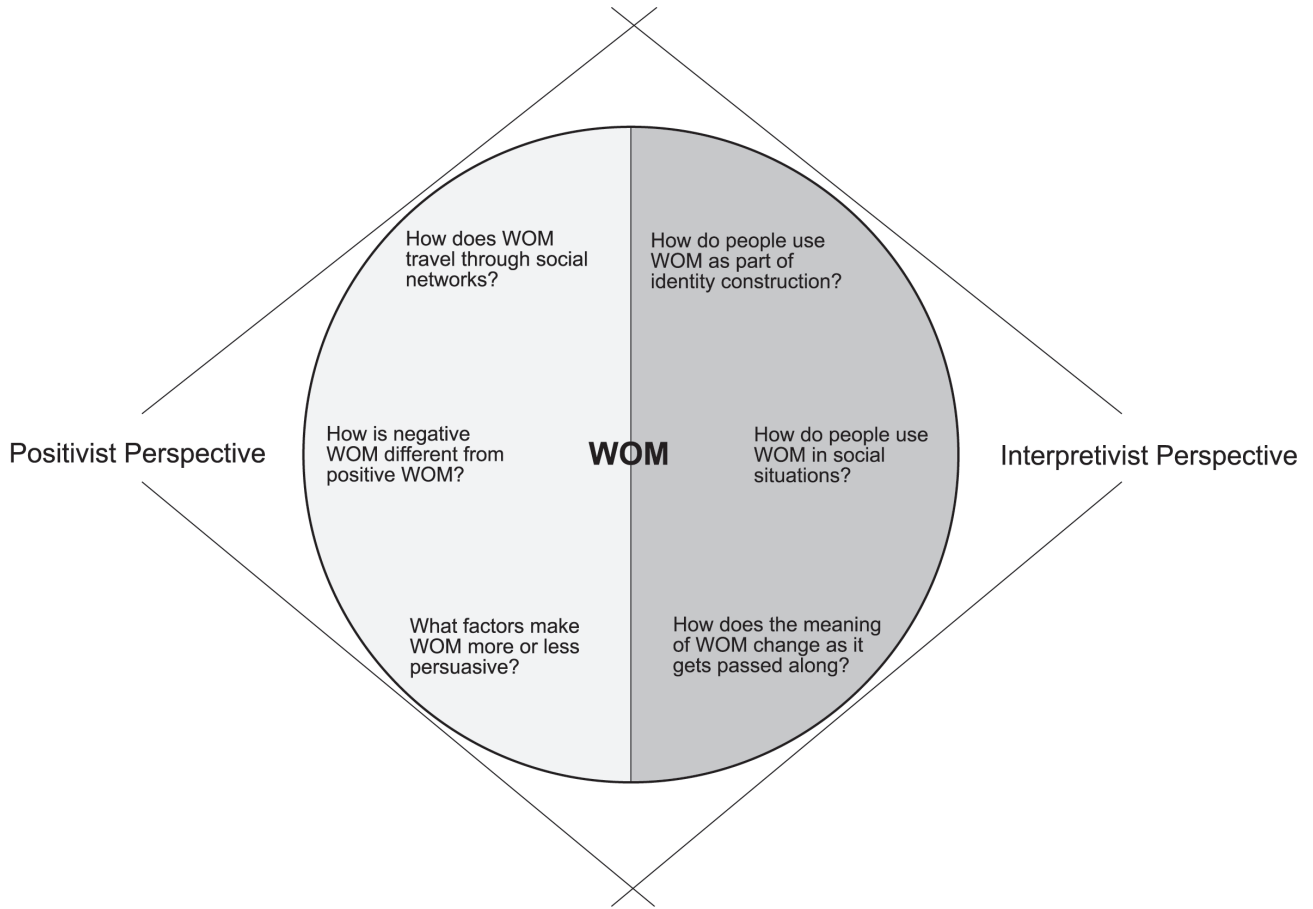

From this perspective, we can suggest that WOM is part of the ongoing consumer narrative, but it is a distinguishable subsection in that while the storytelling aspect described by CCT authors refers to all consumption experiences, WOM in particular assumes an evaluative position for or against a brand. The concept of play suggests that consumers can create these ongoing narratives by drawing from a variety of cultural and personal meanings and combining them in ways that suit the context. Using this alternative view of consumers, we can shift from viewing WOM as product-centric and instead consider a consumer-centric perspective where WOM becomes a particular form of narrative for other uses.

IMPLICATIONS: IDENTITY CONSTRUCTION

The CCT identity literature can contribute to WOM research by supporting the notion that WOM provides consumers with a means for constructing their identities. Holt (1995) argues that consumers sometimes use consumption as a means of classifying themselves for others, that "[c]onsuming not only involves directly engaging consumption objects but also includes using consumption objects as resources to interact with fellow consumers" (Holt 1995, 9). In a social situation, discussing a common brand association can serve "... to construct and sustain meaningful ties between otherwise heterogeneous consumers" (Holt 1995, 10). In this sense, adopting an evaluative position about a brand can act as a heuristic or short-hand for signaling to others a particular aspect of one's identity. The specific meanings associated with this position are derived both through the cultural meanings available at the time, and the personal meanings created by the individual.

Using an experimental approach, Chung and Darke (2006) demonstrate that people are more likely to engage in WOM with others when the product is personally relevant as compared to products which they perceive as utilitarian. In their theoretical development, Chung and Darke (2006) suggest that people may use WOM as a means of self-presentation, and that impression management goals may, in fact, cause consumers to adjust the views which they choose to reveal. In short, the authors demonstrate a link between WOM volume and the self-relevance of the brand in question, but they do not examine how the participants integrate

FIGURE 1

aspects of self-presentation into their comments. The experimental nature of this research demonstrates that identity construction can be a motivation but does not capture *how* we discuss and use brands to create these identities. To gather this richness of understanding we turn to the interpretivist methodologies and theories.

Drawing on self-presentation theory, but from an interpretivist perspective, Schau and Gilly (2003) suggest that consumers use a personal Web space as a means of broadcasting constructed identities to the masses, demonstrating that it "...is a consumer narrative where multiple selves are made comprehensible" (Schau and Gilly 2003, 400). The authors found evidence that their participants were reflective about the content and construction of these Web sites, planning and integrating aspects of their identities through discourse and brand images, extending the physical self into the digital context. Some participants maintained multiple Web sites with different themes representing differing aspects of their lives (e.g., a site for promoting professional qualifications and a second fan site for music tastes).

While maintaining a personal Web space is similar to engaging in interpersonal WOM in many ways, it also differs in meaningful aspects. Incorporating brand logos and discussing favored or disliked brands on a Web space is akin to making recommendations during a social interaction. However, whereas a broad audience may read the recommendations on a Web space, when engaging in interpersonal WOM we may customize what we say based on our specific audience and the responses we may have gotten from previous discussions. Schau and Gilly (2003) found that their participants spent time consciously deciding how to construct their

digital identity, and while the authors found that the digital self was not vastly different from the real-life self, the specific fragments of participants' identities were purposefully chosen and comparatively static. Because many consumer narratives, interpersonal WOM in particular, occur in 'real-time', such conversations are much more fluid and dynamic, resulting in both conscious and unconscious influences which affect both the content and the framing of the message. In describing the personal Web space, Schau and Gilly (2003) treat it as a digitally created identity, something linked to the creator's identity but also separate from the person in that it exists without the creator's presence. Interpersonal WOM, on the other hand, is far more ephemeral, integrated with the speaker as part of a conversation, and ceases to exist in any tangible way once spoken. Considering WOM in this way, one can see how consumers might use their evaluations to construct and communicate a particular identity to another person. This also leads one to consider other ways in which consumers integrate WOM into their narratives during social interactions.

IMPLICATIONS: SOCIAL INTERACTION

Much of the existing WOM research assumes that a person who disseminates information is doing so from a direct relationship with the product or service. Thompson, Rindfleisch and Arsel, however, demonstrate the power and influence of social perceptions with respect to WOM. As the authors suggest, "...brand image is much more a matter of perceived meaning and cultural mythology ... than an aggregation of verified evidence" (Thompson, Rindfleisch and Arsel 2006, 55). In social situations, consumers may

alter their personal narrative as a means of fitting-in with others, adopting a particular position on a brand to solidify in-group membership without necessarily having had that direct experience. In other words, at a social gathering a person may define himself as anti-Starbucks without ever having been into one of the coffee shops, simply because the cultural meaning of such a position can be used to enhance and clarify his identity.

Adopting this CCT perspective about consumers and WOM allows for the pursuit of another interesting stream of research: examining how consumers adjust identity-relevant WOM based on the social context. Because such a stream of research would focus on subtle changes to content and 'real-world' social contexts, a phenomenological or ethnographical method would be well suited to gaining this understanding. This approach would provide insights into how consumers play with the fusion of social context, larger cultural meanings and microcultural specific meanings to adapt and adopt specific positions about brands. This adjustment of WOM meaning could also lead to questions regarding how meaning changes as people pass along WOM.

IMPLICATIONS: MEANING TRANSFORMATION

Children will sometimes engage in a form of play called "The Telephone Game". The children sit in a circle and one child will whisper a phrase into his neighbor's ear. The children pass along the phrase until it returns back to the original speaker, at which point the message typically has been garbled significantly, resulting in laughter by all involved. Adopting the views of personal narratives and play, researchers can examine how WOM moves between speakers and how the meaning of the message changes as it moves through a social network. Assuming that consumers integrate elements of their own identities when sharing information, and that they playfully draw from multiple cultural resources when engaging in narratives, much like the Telephone Game, the nature and meaning of the information being passed along will quickly cease to resemble the original message. Consumers will likely not simply pass along the message verbatim as they hear it, but rather integrate related meanings into their narrative.

Such a research stream might have larger implications for understanding the formation of cultural myths and misconceptions. Often times, these myths can transform into perceived fact by consumers, as more and more 'credible' sources provide the same or supporting evidence. For example, despite being influential in the significant rise in the overall number of coffee shops, a common consumer perception is that Starbucks is responsible for crushing the local entrepreneur (Thompson, Rindfleisch and Arsel 2006). While a positivist approach could provide insight into how information travels through social networks and perhaps make predictions as to which factors might increase the likelihood of passing along WOM, the standard tools and methodologies used are ill-equipped to examine the subtle transformations of meaning during this journey. Conversely, interpretivist approaches, drawing on methodologies such as netnographies and hermeneutics are particularly adept for capturing and interpreting the necessary data, drawing theoretical support from the CCT body of literature. Together, these approaches could provide researchers in both domains with a more thorough understanding of the phenomenon.

SUMMARY

The goal of this paper has been to examine the development of WOM literature in order to appreciate the current state of thought and research in the area. As part of this analysis, I have identified limitations and assumptions which result in gaps in our understanding of WOM. By relaxing these assumptions and infusing this research with insights from the CCT perspective, this paper demon-

strates how these limitations may be addressed and our knowledge of WOM broadened.

By integrating the work from the CCT literature, I am able to suggest how a consumer's identity narrative may impact WOM and how engaging in WOM can be perceived as a form of identity construction. The CCT perspective also offers a means for examining the simultaneous shaping which occurs in social situations involving WOM, how we might adopt positions based on the social context in which we find ourselves. Working from the assumption that identity and social factors impact the content of WOM, a further research stream can be developed to examine WOM communications as a means of understanding consumer-created myths. A deeper understanding of WOM communications can also contribute back to the CCT literature by yielding additional insight into how consumers playfully combine and integrate cultural meanings into their larger consumption narrative. For over 50 years, researchers and practitioners have been listening to consumers talk amongst themselves, but until we expand our views of WOM, we will miss out on a lot of the conversation.

Threshold Lives: Exploring the Liminal Consumption of Tweens

Kevina Cody, Dublin Institute of Technology, Ireland, UK

Katrina Lawlor, Dublin Institute of Technology, Ireland, UK

Pauline Maclaran, Royal Holloway, University of London, UK

"It is in this gap between ordered worlds that almost anything can happen" (Turner, 1974: 13)

INTRODUCTION

The intervening spaces of socio-cultural organisation have proved sources of fascination and powerful theory development in the fields of sociology, psychology and anthropology (e.g. Douglas, 1966; Van Gennep, 1961; Freud, 1950, Foucault, 1977). Consumer culture research has hitherto acknowledged the potency of studying transitional phenomena, spaces and places and the interactions of varied ontologies with the consumption experiences of the individuals or group in flux and evolution (e.g. Davies and Fitchett, 2004; Maldonado and Tansuhaj, 1999; Gentry, 1997; Schouten, 1991). But what of those whose reality is the threshold between two ordered and defined worlds, the centre of nowhere?

This research focuses on the premise that for those whose sense of self is vague or blurred by the experience of existing midway between two distinct social spheres, belonging to neither, but embedded in both, consumption practices take on a divergent focus. Centring specifically on the pre-adolescent or tween, who has come to embody conceptualisations of a categorical anomaly (James, Jenks and Prout, 1998; Cook, 2004), a socio-cultural miasma (Jenks, 2005), the lived experience of a tween is explored using personal diaries, in-depth interviews and accompanied shopping trips. Thus we set out to explore the dynamics of consumer culture most recently articulated as 'a social arrangement in which the relations between lived culture and social resources, and between meaningful ways of life and the symbolic and material resources on which they depend, are mediated through markets' (Arnould & Thompson, 2005: 869), specifically amongst those who exist on the threshold of sociocultural organisation. This paper presents one of the theoretical conclusions of this longitudinal research project—the theory of metaconsumption—which explores consumption within their liminal shadow of activity and regeneration readying these social neophytes for the biggest performance of their lives.

EVERYTHING AND NOTHING—THE THEORETICAL FRAMEWORK OF LIMINALITY

Defined by Turner & Turner (1978: p.249) as 'the state and process of mid-transition in a rite of passage', a 'moment in and out of time' (Turner, 1969: p.96), the liminal phase of a transition, represents an instance of incompleteness, when the liminars (the ritual subjects in this phase) 'elude or slip through the network of classifications that normally locate states and positions in cultural space' (Turner, 1969: p.95). Understanding the attributes of liminal entities also serves to illustrate the core ideologies of the theory. One such attribute is structural and social invisibility, seclusion from the spheres of everyday life (Turner, 1967). In addition, ideologies of liminal theory espouse characteristics such as *tabula rasa*, symbolisation of concurrent degeneration and gestation or parturition (Turner, 1967), heteronomy, silence, equality and obscurity.

Turner's (1967, 110) 'invitation to investigators of culture to focus their attention on the phenomena and processes of mid-transition' has resulted in contrasting disciplines welcoming liminality and its constituent dimensions into their midst to enrich

an understanding and analysis of many phases of cultural change. Several bodies of literature forming a hybridism of theoretical perspectives with liminality unite around a core trope of illness and loss (e.g. Little et al, 1998; Gough, 2005, Jones et al, 2007). Anderson (2003), Campbell et al (2005), Landzelius (2001) and Waskul (2005) have engaged with contextual specificities such as implantable cardioverter defibrillators (ICDs), advertising, incubated pre-term babies and internet personas respectively in their integration of this anthropological theory of structural anomalies.

Contexts as disparate as place and space (Pritchard & Morgan, 2006; Matthews et al, 2000), performance (Dunne, 2002; Rill, 2006; Brown, 2007; Hooker, 2007), and Postmodernity (Bhabha, 2004; Zukin, 1991; Bettis, 1996) highlight the infusion and contribution of many areas of socio-cultural research with ideologies of the liminal, adding vividness and analytical depth to contemporary lived experiences of socio-cultural evolution and disruption.

LIMINAL CONSUMPTION

But what of liminal consumption? Have the ideologies of interim states been used as a lens of analysis for consumption practices and behaviours? Schouten (1991) represents the inaugural integration of this anthropological perspective on mid-transition with individual consumption practices. Despite introducing a link between liminality and consumption, the overall emphasis of Schouten's (1991) research is divided between self-concept theories, role transitions, rites of passage and liminal ideologies. This multi-theoretical focus implies that less in-depth insights of specifically liminal consumption behaviours are garnished. Schouten (1991, 422) himself concludes that 'little is yet known about the consumption behaviours of liminal people'.

Despite focusing on a proposed relationship between liminal transitions, symbolic consumption and the extended self, the work of Noble & Walker (1997) gravitates around the notion of transitions as opposed to the state of liminality itself and additionally utilises a positivist framework and quantitative methodology to align with its dissemination in predominantly psychologically oriented fields of inquiry.

Several other studies have approached the phenomenon of consumption in a liminal state (Hogg et al, 2004; Landzelius, 2001; Pavia & Mason, 2004). Although generating fascinating insights in their own right, these studies commonly relegate the liminal to a constituent dimension of a wider terrain of focus. It appeared that Schouten's (1991) cry to rally the troops towards explorations of this potential reservoir of symbolic meaning and consumer experiences had been relegated to the margins of interpretivist consumer research. Thus this research aimed to explore the interweaving of consumption and identity amongst those whose sense of self is as much about past as future; selves that are embedded in what was but gravitating towards what is to come.

METHODS

In order to explore the interaction of liminal lived experiences and tween consumption practices, there were several methodological considerations and implications. Firstly, cognisant of the inherent ideologies of liminality, an instance of time deemed fundamentally disruptive or ambiguous in the life of a pre-adolescent was selected so as to capture lived experience of 'betwixt and between'

at its most lucid. Therefore, a longitudinal study of a year was undertaken spanning the participants' final months of primary school and early months of secondary education.¹ Three main sites of access were utilised; drama schools, personal contacts and primary schools.

Second, in line with Richardson's (1994) conceptualisation of multiple methods within the interpretivist domain as 'crystallisation', this year-long exploratory research project was interjected at various points by a constellation of data collection techniques. A focal point of Richardson's (1994) theorisation is the premise that 'what we see depends on the angle of our repose' (p.523). Five data collection methods were employed; namely in-depth interviews (which were conducted at two separate intervals), personal diaries, accompanied shopping trips, e-collages and researcher diaries. Each method was chosen so as to reflect a divergent angle of repose on the lived experience and consumption practices of a liminal. However, due to space constraints, only interview data will be integrated into this paper.

Analysis of such a myriad set of data collection techniques required a specific combination of rigour and creativity. In line with the work of Strauss and Corbin (1998), a grounded theory process of analysis was used which proved 'mechanistic and indeterminate in roughly equal portions' (McCracken, 1988: p.41). Following this process of analysis which inherently involves stages of memo writing, axial coding and selective coding, core categories were developed around which the other categories and constructs revolved and offered explanatory power (Spiggle, 1994). This process of data analysis culminated in a stage of data interpretation in the manner of 'a hermeneutic circle' (Arnold and Fischer, 1994: p.63).

RESEARCH FINDINGS AND INTERPRETATION

The following section details one of the central findings of the first phase of data collection—during the last months of primary school—the theory of metaconsumption. Although the main focus of this paper is the metaconsumption theorised as reflective of the consumption practices engaged with by the liminal tweens, it is necessary to briefly ground this theory in the context in which it emerged. This contextual grounding lays the foundation for the emergence of the metaconsumption theory.

The Liminal Tween

As discussed throughout the literature review, the theoretical framework of liminality (Turner, 1967; 1969; 1974) was utilised as a prism for interpreting the cultural and social categorisation of these ambiguously located beings. Due to space constraints there will be a brief delineation of one of the component concepts of the notion of the liminal tween. This and many other instances of liminality that emerged throughout the data add empirical credence to the social invisibility experienced by these 'betwixt and between' girls. This sense of being socially imperceptible would emerge as a focal point for the metaconsumption strategies engaged with by these interstitial consumers.

Legal Vs Social Age

One of the most overtly liminal components of the tween identity was the tension experienced between their legal and social age. Testament to the conceptualisation that these girls are no longer; but not yet, their social and legal categorisations were often at odds with one another, resulting in an acute sense of social invisibility for the girls. Elaine informs me that although she is

given the responsibility of caring for her own brother and sister, many people outside of her family would consider her 12 years of age, too young to be held responsible for young children. However she is keen to point out that she does not hold the same view:

- E: *'but I am far more mature than a lot of 13 year olds I know. I think it is more to do with the fact that people hear 12 years old and they think oh that's too young to babysit children..'*
- K: *'and when do you think they would be okay with it...other people?'*
- E: *'I think at about 14 or 15 it is more acceptable, by other people, to be babysitting for children'.*

Here Elaine finds herself grappling with her own sense of social development and the views of those who ascribe to the legal indications of age-aligned development. She exists uncomfortably at the threshold of what is deemed acceptable legally and how she considers herself socially. This incongruence between legal and social age is manifest also in the social invisibility that seems to pervade their existence. Angela points out that their ambiguous social categorisation, their alignment with the interstices of culture means that an outlet for them in the community is often lacking or intangible.

- K: *'what is it like being 12...?'*
- A: *'I don't know...it's not deadly anyway...coz you can't do much'*
- K: *'what do you mean...what can't you do?'*
- A: *'there's nothing to do in Kilkenny and there's nothing to do around here really'*
- K: *'and what kind of stuff do you want to do that maybe you can't'*
- A: *'well you can't really go to the cinema much at my age coz you're always too young to see them....like something could look really good but it's probably like 15s or something'.*

The Egocentric Tween

The incorporation of a theoretical perspective from the field of psychology was an emergent development following initial data analysis. Elkind's (1967) notion of egocentrism is considered by those specialising in the field of adolescent psychology, to be an under-researched idea, with constructive potential for anyone attempting to theorise on the lived experiences of young adolescents (Elliot & Feldman, 1990). In essence, Elkind's theory centres on the advanced cognitive capabilities of those approaching adolescence status in particular their increased ability to incorporate the perspectives of others into their own way of thinking and understanding themselves and the world around them. What differentiates adolescents however, and perhaps most pertinent to this research, is the tendency of this group to overgeneralise and believe themselves to be the focus of most other people's attention all of the time akin to an 'imaginary audience' (Elkind, 1967).

Amanda's interview illustrates vividly her tendency to incorporate an imagined audience into her developing self-system. She explains that the impending move to secondary school has meant divesting herself of any stationary that would be considered young or child like, in the hope of avoiding what she imagines would be certain disdain and ridicule from her new class mates.

- K: *'what else did you have to buy for secondary school?'*
- A: *'yea like I used to have all these little parers and little fancy girly parers but then I was like I'd probably get into*

¹These stages of education correspond to junior and senior high school in the United States

trouble...people would be like 'why do you have that'...so I went for a plain pencil parer'...

K: *'what would people think if you have a plain pencil parer?'*

A: *'if you had a big girl sittin up on the table they might be like hmmmm...baby....'*

Here Amanda is using the imagined reactions of her peers to alter her consumption repertoire and future buying habits. It is almost like how she envisages her class-mates reacting to her display of consumption objects, is harnessed and utilised as a gauge for what will be suitable to bring along to secondary school. At this point in time, Amanda has not yet experienced the social environs of secondary school at first hand. However her advancing cognitive abilities have allowed her to consider the perspective of those girls she has yet to meet, albeit to an exaggerated degree. Even something as seemingly unrelated to social judgements and ridicule as the theft of her MP3 player is reflective of the egocentric nature of Amanda's developing self.

A: *'I nearly made myself sick thinking about it...i dunno why I got so upset about it...'*

K: *'was it to do with losing your zen...or that it was robbed by someone...'*

A: *'I dunno...I guess it was a bit of both...i just dunno...i just cracked...i imagined everyone will think I can't look after stuff...'*

In this example it appears that what had unsettled Amanda so much following the theft of her MP3 player was less to do with the physical void of the item but more with what she imagined the incident conveyed to others about her ability to be responsible for her possessions. Egocentrically, she believes this mishap to be the sole focus of others' attentions.

Metaconsumption

As outlined above, the liminars' lived experiences are characterised by social ambiguity, categorical invisibility and an overt preoccupation with how they appear in the eyes of those around them. It emerged throughout the data analysis that despite their conveyed annoyance at their status as social non-descriptors, their shadowed realities were a vital resource.

As evidenced in the data, various consumption strategies were being utilised by the tweens in order to paradoxically evade definite categorisation via consumption owing to their egocentric tendencies and fear of social reprisal, prior to a more assured and competent entry into teenager-hood. But concurrently these strategies enable the tweens to tentatively participate in the consumer culture towards which they know their imperatives must be oriented if they are to be accepted by friends and envisaged onlookers.

A relatively recent consideration within the domain of cognitive analysis is that of second order thinking; or 'thinking about thinking' (Keating, 1990). Metacognition is frequently studied within the realm of psychology as 'the ability to monitor one's own cognitive abilities and activity for consistency, for gaps in information that need to be filled' (Keating, 1990: p75). This theory appeared to have potential for application within the domain of this instance of consumer research. When re-appropriated to analyse the emergent consumption practices of these liminal tweens, the theory of metaconsumption emerged as a viable theoretical process.

Fundamentally metaconsumption was envisaged as involving consumption about consumption. During this liminal existence, metaconsumption strategies served to realise the main preoccupation of a tween; remaining covertly active. It appears to be one of the primary preoccupations of the liminal experience, the main product

of this ambiguous, obscure interval. Eluding definite categorisation as either child or teen, the tweens channel this cultural anonymity into preparing for one of the most socially pertinent roles of their lives thus far; becoming a teenager. These metaconsumption strategies, as will be delineated, allow the girls to paradoxically both evade definite categorisation via consumption prior to a more assured and competent entry into teenager-hood but also enables them to tentatively participate in the consumer culture towards which their imperatives must be oriented.

Brand Apathy

The nexus of the metaconsumption strategy is thus the maintenance of an unobtrusive, yet concurrently burgeoning site of consumption, which the liminal period appears to represent for these girls. Several strategies had at their core the notion that any activity, which wrenched the girls from the comfort of their categorical ambiguity and assign them to either a child or teen status before they feel prepared, is detrimental. One concept reflective of the tweens' striving towards consumption practices that facilitate preservation of their social anonymity, for fear of premature emergence before their imagined audience, is brand apathy. Pervasive throughout the first interview data is a definite reluctance by the girls to express an alignment with or affinity to branded products for fear of making an error conducive to social exclusion and ridicule. Contrary to the abundant secondary research in this area (e.g. Siegal et al, 2004; Lindstrom, 2003b; McNeal, 1992), the girls displayed a noticeable reticence when a discussion of brands and their importance to them arose.

In this example Nicola dismisses the notion that brands are important to her, but acknowledges that 'some people' like to revolve their consumption patterns around them.

K: *'so do you think brands matter to people your age?'*

N: *'well some people do...like they have to get all the brand...it doesn't matter to me'*

K: *'does it not...so what's important to you'*

N: *'just kind of if I like the top or not.'*

At this stage, she is still a novice when it comes to buying her way into the teen/consumption dialectic. By refusing to commit to an engagement with brand labels, she is not expected to know anything about them and thus cannot err in her discourse around brands and consumption. Her social status cannot be allocated and she can remain in the interstices of categorisation until such a time when she is equipped with enough social-kudos oriented information to emerge.

Another metaconsumption strategy seemingly utilized in order to convey a purposeful apathy about branded items is price preoccupation. There are numerous examples throughout the first interview data, which suggest that reverting to the reliable utilitarian justification of 'because non-branded things are cheaper', allays the possibility that their incompetence with consumer culture will be brought to notice.

Two excerpts from Rachel's interview add credence to the notion that apathy or resistance toward acknowledging the centrality of brands to their lived experiences is a strategic defence mechanism often couched in a fixation on value for money, designed to protect the shadow side of their being, their liminal regeneration.

K: *'and do you think brands matter to people in your class...well not just your class...but your friends...do ye talk about brands at all?'*

R: *'amm...not really...the main place that we go is penneys²...coz its so cheap and it actually does have some*

nice clothes and stuff...and they just have everything at a really cheap price... and say if you went into somewhere else...like where would you go...am...really expensive like Pauls or somewhere...and you'd see the same string top or the same jumper for like fifty euro and like the one you could get in penneys would be like fifteen or twenty...'

In this first passage, Rachel's attitude is analogous to the other tweens, in that she justifies her supposed detachment from branded goods by referral to the value for money at non-branded stores. However just minutes later, Rachel recalls the experience of buying a new outfit for her confirmation a couple of months previously.

K: *'and what other shops would you go to....say if you went in with your mum?'*

R: *'well radical³ I bought my confirmation outfit in.*

K: *'what kind of outfit did you get?'*

R: *'well I got these grey bench combats....they're really nice and I got this tee-shirt and I love it I wear it all the time...and I got a bench hoody....and am its really cool you can put on the sleeve you can put your thumb through a little hole in it...its really cool...and I got my runners⁴ there aswell....they're van.'*

It is clear therefore that Rachel's earlier expressed indifference to brands is not consistent with her behaviour. In this instance, when her mother's financial agency enters the equation, and Rachel has had a tangible experience with a brand, Rachel's priorities change and the non-branded shop doesn't get a mention. Rather she manages to list two big brands in her purchases. Surely if the non-branded store is such good value, her mother's financial resources would have gone a long way further? Clearly Rachel's interview, visible in part through this inconsistency, suggests that indifference is a defence mechanism. Expressing a detachment from the world of labels, logos and symbolism is less important a goal when resources not available to the neophyte materialise.

Parody

Cognisant of the fact that the core of the metaconsumption strategy is its focus on existing without exhibiting, I was made aware of yet another component of this strategy during the accompanied shopping trips. This strategy centred on the agentic dimension of this liminal shadow in which the tweens exist; consumption strategies that evinced monitoring and acquiring of information and competencies needed when the time came to lead their liminal cocoon and embrace young teen identity.

During these shopping trips, the ambiguity and ensuing tension that the girls experienced in many of the shops seemed to stem from their recurring mislocation as a group or social category. At times the shops we visited were so beyond the realm of possibility for these girls on every level, while concurrently other stores evinced notions of a former childhood self that they were eager to forsake. In other words, it was palpable throughout these trips, that expressing interest in particular items was a risky, value-laden endeavour. Signalling interest in an item deemed 'inappropriate' in any dimension appeared to represent social suicide. I soon realised that these weren't just shopping trips, but opportunities to manage, protect and accumulate the knowledge that was expected of them as young, female consumers.

The concept of parody emerged as a means through which the girls could openly experiment with possible signifiers and configurations of consumption, but maintain a distance from any personal reflections ensuing because of these experiments at the same time. It allowed them to exist without exhibiting. During the shopping trip with three tweens for example, I witnessed first hand the use of this strategy. On entering one particular store, the girls picked up random tops and skirts claiming 'this is so you' or 'this is my dream outfit'. I only realised after chatting to the girls later on, that this was a statement of sarcasm meant to denote that something was not to their taste and they weren't at all genuine in their sentiments. However although it was not genuine admiration they espoused, expressing opinions or preferences couched in parody or mockery, protects the girls' vulnerability at a time when their level of consumer experience is limited.

The Fake Facilitators

This concept refers to the conclusion that many of the girls chose to forsake a preoccupation with having the genuine brand and instead focused on manipulating and utilising the sign value even associated with counterfeit versions to assert a provisional foot into the world of teen consumption. Therefore although many of the 'brands' they possess are in fact fakes, these products nonetheless facilitate a participation in a version of consumer culture, however diluted. This strategy allows for an engagement with the imperatives that dominate teen consumption but concurrently does not demand the resources only attributed to those of a more defined societal categorisation such as finances, life experience or definite market place allocation. In this example, Katie is taking me through some of the possession in her room, including a fake Von-Dutch cap. Interestingly she herself points out that it is a fake.

K: *'What other brands do you use?'*

KL: *'von dutch...I got those in Majorca...they have lasted me two years now'*

K: *'wow...and do you have any other von dutch stuff....do you know much about the brand?'*

Katie roots underneath her bed

K: *'ooh a cap...do you wear that much'*

KL: *'yeah...its fake von dutch...but it's still von dutch'*

What Katie seems to mean here is that to others, it still appears to be Von Dutch, or at the very least she is appearing to others to be engaging with the brands that form the appropriate staple diet of any normative teen. The important thing for Katie then is appearances rather than authenticity. Appearances maintain the shadow side of their being so that they can incur as little anticipated social ridicule as possible while they experiment with the intricacies of the teen persona/consumption dialectic.

Rachel also displayed an affinity for the non-authentic version of some well-known brands.

K: *(reading diary)...Louis Vitton is one of my favourite designers. I love his bags....so which one is yours?'*

R: *'well I got the both of them off my next door neighbour (laughs), she got them...'*

K: *'what do you like about those bags?'*

R: *'I think they look really cool...and I don't mind of they're fake...because no-one really knows'*

Rachel here articulates the key element of the fake facilitator concept, as a metaconsumption strategy. Counterfeit products allow the liminal tweens, despite their lack of agency as a socially ambiguous category, to engage with a desirable facet of consumer

²Penney's is a discount clothing and accessories store in Ireland

³Radical is a store in Ireland which stocks branded clothing and footwear

⁴Runners is Irish slang for trainers/sneakers

culture; the repository of symbolic meaning and social implications behind the Louis Vuitton logo. Although the use of fake brands is not a consumption practice limited to this age group, the role that these brands play in the lived experience of a liminal tween is significant towards understanding how consumption is enacted during a time of social invisibility.

DISCUSSION

This paper has described some of the constituent parts of metaconsumption; the theorisation of the liminars' consumption practices. Being neither a child consumer nor a teen purchaser implies that there exists a gap between the self they were and the self they long to be and the liminal status that ensues. In addition, advancing cognitive capacities instil the tweens with a flagrant sense of trepidation regarding their neophyte-like social standing and potential public transgressions. Consequently they long to reside in the shadowed side of being, attempting to learn, monitor and accumulate socially oriented consumer knowledge, but all the while protect and maintain the anonymity that shields them from social scrutiny and insinuations. This intense period of 'consumption focused on consumption' aligning oneself with the nuances and mores of the social sphere which will help sculpt their entry into teenager-hood, provides examples of a myriad consumption strategies and practices which further a theorisation of liminal beings and their consumption practices.

Thus this desire to exist without exhibiting is the core characteristic of the liminal existence and subsequently the theory of metaconsumption has an integral role in its manifestation. For example, the visible propensity of the tweens to convey decided apathy and even resistance towards branded consumption with the variant but related strategy of price preoccupation, was reflective of an effort to preserve the unspecific nature of their social categorisation. Not committing to a brand meant not committing to an (unfinished) teen identity. This theoretical conclusion stands in stark contrast to the prevalent literature on branded consumption, whether conceptually, theoretically or managerially oriented (Lindstrom, 2003; McDougall & Chantrey, 2004; Elliot & Leonard, 2004) that convey brand-oriented consumption as a transparently positive and desired facet of tween consumer culture.

However it is equally as intrinsic to the liminal existence that this period of time is not entirely static. As theorised by Douglas (1966, p.137) in relation to interstitial existences 'there is energy in the margins and unstructured areas'. A degree of agency must become part of the metaconsumptive practices of the tween if they are to progress towards the essence of their teen identity (Jenks, 2003). Thus the concepts of the fake facilitators and parody encapsulate the covert but fervent accumulation of consumer-oriented knowledge and experience that concurrently embodies the liminar's 'betwixt and between' existence. For example, parody, akin to the foundational premise of the other metaconsumption strategies is both an enabling and a protective mechanism in that it facilitates the tweens' engagement with the appearance of teen consumerism but yet safeguards the anonymity necessary to prevent premature alignment with a teen identity that are ill prepared for.

Cognisant of the tweens' concurrent engagement with and detachment from consumption practices, the liminal period is proposed to represent a fruitful darkness (Turner, 1967, p110). Akin to understudies waiting in the wings anxiously ingesting as much information as possible in order to better prepare themselves for the biggest performative role of their lives to date—which as of yet is just out of sight—the fructile chaos of the fruitful darkness facilitates a private rehearsal for what will eventually be a very public performance. The metaphor of the fruitful darkness embod-

ies the concurrent darkness and energy, the restorative obscurity that epitomises the liminars' experiences with consumer culture within the interstices of socio-cultural categorisation. Although at times the tweens appear passive or nonchalant about many of the signifiers of teen culture, this passivity appears to belie a fervent task. Turner (1967, p.102) similarly theorised when he claimed that during the liminal period 'his apparent passivity is revealed as an absorption of powers which will become active after his social status has been redefined...'

CONCLUSION

Fundamentally the theory of metaconsumption engages with the work of those who revel in exploring the myriad ways in which socio-cultural contexts and identity interact with and are mediated by market forces. This theory reflecting on the tendency of those who exist in an ambiguously defined social category to engage with 'consumption about consumption' also resonates with the 'consumer as identity seeker' conceptualisation pursued by those within the field of interpretive research. As argued by Arnould & Thompson (2005), what is most integral to the strength of consumer culture theory is its ability to transcend context and generate theoretical insight. In the case of this research, although the tween is an integral component of this work, the theory of metaconsumption has the potential to surpass its genesis within the micro-level of the lived experience of young adolescents and become an effective theoretical lens at a meso-level for exploring consumption practices throughout many other liminal experiences.

Causes Customers Ascribe to Low Prices in Discount Stores

Stephan Zielke, University of Göttingen, Germany

ABSTRACT

This paper identifies and analyzes the causes customers ascribe to low prices in discount stores. Such causes are inferior product quality, unfair relations to employees and suppliers, fair relations to customers (profit waive), an efficient business model, and psychological tricks in price communication. The paper demonstrates how these attributions impact perceptions, emotions and behavioral intentions to buy in discount stores. The results underline that each attribution type has specific effects on certain dependent variables. The study has important implications, as it shows that companies can influence customer perceptions, emotions and shopping intentions by changing specific attributions to low prices.

INTRODUCTION

Grocery discounters have experienced rising market shares in many European countries (Colla 2003; Delleersnyder et al. 2007), and they are also successful in the US (Brown and Bury 2008; Springer 2008). Discounters offer continuously low prices and many products are cheaper than in stores from other formats (Rondán Cataluña et al. 2005; Wood and Pearson 2006).

Although discounters have this price advantage, they attract certain customers while others avoid these stores. Attribution theory (Heider 1958; Kelley 1973; Kelley and Michela 1980) offers an explanation for this observation, as customers can ascribe different causes to low prices in discount stores. Customers might, for example, believe that discount stores offer lower prices than supermarkets because they compromise product quality. Other causes might be unfair relations to employees and suppliers, fair relations to customers (profit waive), an efficient business model, and psychological tricks in price communication.

Even though attribution theory is used in many different marketing contexts (Folkes 1988; Mizerski et al. 1979), attributions to low prices are not analyzed systematically. This paper closes this gap by analyzing attributions to low prices in grocery retailing. It identifies the positive and negative causes customers ascribe to low prices in discount stores and demonstrates how the diverse attributions impact perceptions, emotions and behavioral intentions to buy in discount stores. The results underline that each attribution type has *specific* effects on certain dependent variables. The study has important implications, as it shows that companies can influence customer perceptions, emotions and shopping intentions by changing specific attributions to low prices.

THEORETICAL FRAMEWORK AND LITERATURE ANALYSIS

Attribution theory constitutes the theoretical framework of this study (Heider 1958; Kelley 1973; Kelley and Michela 1980). This theory concerns the way in which individuals assign causes to observed actions or events. According to Folkes (1988), "attribution is concerned with all aspects of inference: how people arrive at causal inferences, what sort of inferences they make, and what the consequences of these inferences are". In marketing and consumer behavior literature, many applications of this theory exist (Folkes 1988; Mizerski et al. 1979).

However, the literature does not provide many applications of attribution theory in price-related contexts. One research stream investigates attributions regarding price promotions with discount claims. Lichtenstein et al. (1989) found that attributions concerning the advertiser's motives for a price discount offer have a significant effect on the consumers' evaluations of the offer. Burton et al.

(1994) observed that the extent of retailer and product attributions regarding a discount claim depends on the price positioning of the retailer. They also demonstrated that attributions to the retailer have a positive effect on different psychological and behavioral variables (perceived value, attitude toward the ad, shopping intentions) while product attributions have a negative effect. Other researchers investigated internal (customer) or external attributions with regard to price deals and satisfaction with rebate shopping experiences (Hunt et al. 1995; Schindler 1989, 1998).

A second research stream analyzes attributions to price increases. Several researchers argue that the inferred motives for a price increase have an impact on the perceived price fairness (Campbell 1999; Kahneman et al. 1986). Vaidyanathan and Aggarwal (2003) apply attribution theory to investigate the conditions under which even cost-justified price increases are perceived as unfair. They demonstrate that a cost-justified price increase is perceived as less fair when the locus of causality is internal to the seller and/or when the price increase is within the volitional control of the respective company.

The literature analysis illustrates that most applications of attribution theory are related to person (retailer) vs. stimulus (product) and circumstance (situational) or internal (customer) vs. external (other causes) attributions. In contrast to these studies, the present research analyzes attributions on a less abstract level. The aim of this study is to identify concrete causes to which customers attribute low prices in discount stores, and to analyze their impact on store perceptions, emotions and shopping intentions. It is noteworthy that the present paper also differs from previous studies in that it focuses on attributions regarding the price level of a store instead of a single product, promotion or price increase.

ATTRIBUTIONS TO LOW PRICES IN DISCOUNT STORES

Before developing hypotheses about the impact of attributions to low prices in discount stores, the nature of such attributions should be discussed.

Product-related attributions exist if customers attribute a discount store's low prices to the *inferior quality* of the assortment. These attributions might be the consequence of price-quality inferences, where customers associate higher prices with better quality. Many empirical studies have identified such inferences (Völckner and Hofmann 2007). The inferior quality attribution is not necessarily limited to search and experience qualities, such as color or taste. Especially concerns about credence qualities might prove relevant in price-quality inferences for food products. Credence qualities include food safety, origin of products, environmental compatibility and animal welfare (Becker 2000; Brunsø et al. 2002; Grunert 2005; Northen 2000). To sum up, the inferior quality attribution is a product-related attribution with a negative character.

In contrast, retailer-related attributions for low prices are often described as positive attributions. Burton et al. (1994) give examples of such positive attributions, e. g. "meeting competitors' prices" or "passing on savings from bulk purchases from manufacturers". Generally, discount retailers can meet their competitors' prices by smaller margins or lower costs. Smaller margins can be interpreted as *fair relations to customers*, as managers or owners waive a part of their profit. A *more efficient business model* is a positive cause for lower cost. It costs far less to operate a discount store than a mainstream supermarket (Kaas 1994). Furthermore, discount retailers buy large quantities of exclusive private label

products, resulting in lower purchase costs and a more efficient supply chain management (Colla 2003). Customers might believe that discount stores are low-priced because they pass on these savings.

However, negative retailer attributions also exist. Customers might infer that discount stores have lower prices than other stores because they *behave unethically towards different stakeholders*, for example employees and suppliers. These attributions are supported by press reports on aggressive purchasing policies (e. g. McGreevy 2008) and the exploitation of employees (e. g. Boyes 2008). Even if some discount retailers actually pay higher wages than some of their supermarket competitors (Springer 2008), their customers might believe the contrary.

Finally, customers can ascribe the competitive price image of discount stores to *psychological tricks in price communication*. Customers might be aware of pricing tactics retailers use to improve their price perception (Hardesty et al. 2007) and they might be skeptical towards price claims in advertisements (Obermiller and Spangenberg 2000).

To recapitulate, customers can ascribe five types of causes to low prices in discount stores. These are inferior quality, unfair relations to suppliers and employees, fair relations to customers (profit waive), the efficiency of the business model and psychological tricks in price communication.

HYPOTHESES

The following section derives hypotheses about the impact of the five types of attributions on different dependent variables, such as perceptions, emotions and shopping intentions.

Perceptions

Firstly, it is assumed that customer attributions have an impact on several perceptions, such as price level perception, quality perception, perceived value for money, price fairness and ease of price evaluation. With the exception of product quality, these constructs are all dimensions of a retailer's price image (Zielke 2006, 2009a).

Price level perception refers to the amount of money customers have to pay for a selected basket of goods without taking quality differences compared to other stores into account. The efficiency and the tricks attribution should especially have an impact on price level perception. If customers believe that discount stores operate more efficiently than other stores, they should perceive discount store prices as more competitive. However, if they suppose that the discount stores' price image results from psychological tricks, they will rate the prices as more expensive.

H1: The stronger (a) the efficiency and the weaker (b) the tricks attribution, the better (lower) the perceived price level.

The inferior quality attribution should especially determine the quality perception of the store. This results from the nature of both constructs.

H2: The weaker (a) the inferior quality attribution, the better the perceived quality.

Value for money is defined as the result of matching price and performance evaluations (Dodds and Monroe 1985; Zeithaml 1988). Hence, the attributions influencing price level and quality perception should also influence perceived value.

H3: The weaker (a) the inferior quality and (b) the tricks attribution, and the stronger (c) the efficiency attribution, the better the perceived value for money.

Price fairness is defined as a judgment if prices are reasonable, acceptable or just (Xia et al. 2004). Some studies in the literature explain the perceived fairness of a price increase based on customer attributions related to the cause of the increase (Campbell 1999; Kahnemann et al. 1986; Vaidyanathan and Aggarwal 2003). Furthermore, previous research found strong relations between value and fairness and some authors even operationalize price fairness very similarly to value for money (Bei and Chiao 2001). Hence, the attributions influencing value perception should also influence price fairness. In addition, the fair relations to customers and the unfair relations to stakeholders attributions should influence this construct.

H4: The weaker (a) the inferior quality, (b) the unfairness and (c) the tricks attribution, and the stronger (d) the fairness and (e) the efficiency attribution, the better the perceived price fairness.

Ease of price evaluation is related to price uncertainty (Mazumdar and Jun 1992) and describes how easily customers perceive the evaluation of a store's prices (Zielke 2006, 2009a). The psychological tricks attribution should especially influence this price image dimension, as the prices might seem to be more competitive than they really are.

H5: The weaker the (a) psychological tricks attribution, the better the ease of price evaluation.

Emotions

Secondly, attributions to low prices should influence several emotions which are related to price and quality perception. The role of attributions as antecedents of emotions is extensively discussed in the literature, such as in Weiner's attributional theory of emotions (Weiner 1985, 1986). The emotional consequences of attributions to low prices may be manifold; however, the present study concentrates on the negative emotions of shame and guilt, which might be especially relevant and interesting in discount shopping contexts.

Shame and guilt are both self-related emotions. Guilt results when customers believe that their actions violate societal or internal standards (Dahl et al. 2003), while shame or embarrassment result when actions violating moral or societal standards are observable for others (Izard 1977). Customers might believe that buying low quality food for the sake of saving money violates standards of good nutrition. Similarly, buying in a store that exploits farmers and employees to offer low prices might be perceived as a violation of standards regarding fairness in business relationships. Hence, the inferior quality and the unfair relations to stakeholders attribution should increase shame and guilt.

H6: The stronger (a) the inferior quality attribution and (b) the unfairness attribution, the greater the shame.

H7: The stronger (a) the inferior quality attribution and (b) the unfairness attribution, the greater the guilt.

Shopping intentions

Finally, it is assumed that all attributions influence intentions to buy in discount stores. This hypothesis is supported by previous

studies, where price-related attributions influenced shopping intentions and behavior (e. g. Burton et al. 1994; Schindler 1998).

H8: The weaker (a) the inferior quality, (b) the unfairness and (c) the tricks attribution, and the stronger (d) the fairness and (e) the efficiency attribution, the stronger the intentions to buy in discount stores.

RESEARCH DESIGN AND SAMPLE

A paper-and-pencil questionnaire was designed to test the hypotheses. The item-scale for the attributions was developed based on a discussion with students from a Master's course in retail pricing at a large European University. The question "why are prices in discount stores so low?" was discussed with the students, their arguments were collected and then translated into an item-scale. A pre-test proved that the wording of the items was clear and understandable. The twenty items cover aspects of product quality, fair relations to customers, the efficiency of the business model, relations to employees and suppliers, and psychological tricks in price communication. A large scale pilot study with 597 respondents confirmed the hypothesized factor structure of the attributions (Zielke 2007). However, as the factor loadings and alpha values were not completely satisfactory, the item-scale was refined to a shorter and more manageable scale of 13 items. In this scale, each attribution is measured by not more than three items. Perceptions, emotions and behavioral intentions were measured with three to five items each. Scales for all these dependent variables are based on prior research (Zielke 2009a, 2009b) and presented in the appendix. All items were measured on 7-point scales ranging from 1 (strongly disagree) to 7 (strongly agree).

The respondents were asked to evaluate one particular discount store. Similar to Zielke (2009a, 2009b), they selected the store from a list of different grocery discounters. This was necessary to guarantee that the respondents have at least a rudimental impression of the store they evaluate. The questionnaires were distributed to people of different levels of age, gender, household size and income buying groceries at least once a week. The respondents usually completed the questionnaires at home and then returned them to the research team personally or by post. This procedure resulted in 402 usable questionnaires. The mean age of the respondents was 35 years, 57.8 percent of the respondents were female and the median net income ranged between 1,501 and 2,000 euros per month.

ANALYSIS AND RESULTS

The first part of the results section analyzes the factor structure of the attributions to low prices in discount stores. The second part investigates the hypothesized effects of these attributions on perceptions, emotions and shopping intentions.

The factor structure of attributions

Firstly, the factor structure of the attribution scale was analyzed with exploratory and confirmatory factor analyses. The exploratory analysis was conducted to replicate the results from the pilot study. The principal component analysis of the 13 attribution items yielded five factors with eigenvalues greater than one, explaining 74.1 percent of the item variance (table 1). The factors are identical to those found in the pilot study and clearly interpretable as inferior quality (F1), unfair relations to stakeholders (F2), profit waive or fair relations to customers (F3), the efficiency of the business model (F4) and psychological tricks in price communication (F5). Alpha values indicate an acceptable amount of convergent validity. Only the alpha value for fairness to customers is slightly below the level of .70.

In addition to the principal component analysis, a confirmatory factor analysis tested the convergent and discriminant validity. Table 2 presents the results from a confirmatory analysis conducted in Mplus using the MLR estimator (Muthén and Muthén 2007). The fit indexes are acceptable (CFI: .955, RMSEA: .048, SRMR: .055, χ^2/df : 122/55). For each attribution type, the variance explained is larger than any squared correlation with another attribution. Hence, the discriminant validity is given according to Fornell and Larcker's criterion. Furthermore, the average variance explained for each attribution is close to or above 50 percent.

The impact of attributions on perceptions, emotions and shopping intentions

Before testing the hypotheses, alpha values for the dependent variables were calculated. Only the coefficient for ease of price evaluation was below .70, but still acceptable (.61). Furthermore, discriminant validity between attributions and all dependent variables was sufficient according to Fornell and Larcker's criterion. The only exception was the inferior quality attribution, which correlates strongly with quality perception. After testing convergent and discriminant validity, a separate structural equation model was calculated for each dependent variable. Again, all fit-indexes are acceptable, CFI is between .940 and .964 and SRMR is between .044 and .050 (table 3).

H1 assumed that the stronger the efficiency and weaker the tricks attribution, the better the perceived price level. The results support this hypothesis with a positive coefficient for efficiency (.50) and a negative coefficient for the tricks attribution (-.26). Furthermore, H2 is supported by a negative impact of the inferior quality attribution on quality perception (-.82). In addition, there are small effects from the fairness (.16) and efficiency attribution (.14), which were not hypothesized. Supporting H3, the inferior quality (-.30), the efficiency (.37) and the tricks (-.23) attribution influence value in the hypothesized direction. H4 is only partly supported. The inferior quality (-.32), the unfairness (-.23) and the psychological tricks attribution (-.22) have a negative impact on price fairness. The coefficient for efficiency (.12) is only significant for a ten percent level of significance. Surprisingly, the fairness to customers attribution has no impact on price fairness. Supporting H5, psychological tricks have a negative effect on the ease of price evaluation (-.27). In addition, the efficiency attribution has a positive effect on the ease of price evaluation, which was not hypothesized (.24).

H6 is supported by the positive impact of the inferior quality attribution on shame (.32). Interestingly, the effect of the unfairness attribution on shame is small and not significant. H7, in contrast, is completely supported. The inferior quality (.34) and the unfairness attribution (.31) both have a significant impact on guilt.

According to H8, the inferior quality, the unfairness to stakeholders and the psychological tricks attribution should have a negative impact on shopping intentions, while the fairness to customers and the efficient business model attribution should have a positive impact. However, the results only support H8 for the inferior quality (-.36), the unfairness to stakeholders (-.20) and the efficiency of the business model attributions (.23).

GENERAL DISCUSSION

The results support most of the hypothesized effects. Beyond the (intuitive) finding that positive attributions have positive effects while negative attributions have a negative impact, the results illustrate that specific attributions influence different dependent variables and that some attributions have stronger effects than others. The inferior quality attribution is the strongest predictor of perceived quality, price fairness, shame, guilt and shopping inten-

TABLE 1
Factor structure of attributions

Prices in discount stores are so low ...	Factor 1	Factor 2	Factor 3	Factor 4	Factor 5
because they do not attach great importance to quality management	.81				
because they compromise product quality	.84				
because their products contain more artificial ingredients	.74				
because discount stores exploit their employees		.82			
because discount stores exploit their suppliers		.84			
because discount stores behave unethically towards suppliers and farmers		.84			
because management salaries are smaller than in other companies			.85		
because owners and managers are more modest than in other companies			.86		
because these companies buy larger quantities				.81	
because the business model is more efficient				.77	
because they purchase products at lower prices				.79	
however, prices in these stores are not as low as many people believe					.87
however, these stores are only perceived as low-priced because they use psychological tricks					.86
Cronbach's alpha	.77	.84	.65	.72	.82
Factor loadings smaller than .40 are suppressed

Fair relations	FAIR	.01	.00	.56		
Efficient business model	EFF	.06	.01	.03	.46	
Psychological tricks	TRICK	.22	.18	.02	.14	.70

CFI: .955; RMSEA: .048; SRMR: .055; χ^2/df : 122/55

tions. The efficiency attribution influences price level perception and value for money most strongly. The psychological tricks attribution is the strongest predictor of the ease of price evaluation. Unfairness to stakeholders is also an important attribution, which influences price fairness, guilt and shopping intentions. Fairness to customers (profit waive) seems the least important as this attribution only has a small impact on the quality perception.

The study has several theoretical implications. It extends the previous research by providing a typology of attributions to low

prices. In addition, the empirical results underline that these attributions explain differences in customers' perceptions of discount stores, emotions related to these stores and their shopping intentions. Therefore, the results contribute to the understanding of discount buying.

Some effects are especially interesting from a theoretical perspective. The results contribute to price fairness research as they show that unfairness to employees and suppliers has a strong impact on general price fairness. Therefore, unfair relations to stakeholders

TABLE 3
Results of hypotheses tests

Dependent Variable	QUAL Beta (sig.)	UNF Beta (sig.)	FAIR Beta (sig.)	EFF Beta (sig.)	TRICK Beta (sig.)	Latent Var. R-Square	CFI SRMR

should be integrated in price fairness research. Also, the effects on shame and guilt are remarkable. While guilt has different attributional antecedents (inferior quality and unfair relations), only the inferior quality attribution influences shame. Customers do not feel ashamed when they attribute low prices to the exploitation of employees and suppliers. Hence, although shame and guilt are similar constructs, they depend on different antecedents. The findings for the tricks attribution are also remarkable. This attribution has a negative impact on a number of perceptions, while the effects on emotions and shopping intentions are not significant. Hence, customers are aware of such tricks, but they do not change their behavior. This explains why some stores which are known for using such tricks are still very successful.

The results also have important managerial implications. They show that retailers can influence store perceptions, emotions and shopping intentions by influencing customers' attributions to low prices. If discount retailers want to improve shopping intentions, they should especially communicate the existence of quality management systems and results from independent product tests to their customers, but also the efficiency of their business model. While communicating results from product tests is a matter of course, communicating the business model's efficiency is not common practice. This is problematic as the results show that the efficiency attribution significantly influences price and quality perceptions.

Moreover, discount retailers should attach greater importance to establishing and communicating fair relations to their employees and suppliers. Reducing the unfairness to stakeholders attribution is important as this attribution has a negative impact on perceived price fairness and increases guilt. In practice, some discount retailers pay their cashiers higher wages than their supermarket competitors, although this is often unknown to the public (Springer 2008).

If discounters want to improve price and quality perception, they should also try to reduce the psychological tricks attribution by conducting and communicating objective price comparisons with their competitors. However, whether this also increases customer shopping intentions is questionable.

Finally, some limitations and implications for future research should be discussed. Firstly, this study analyzed the impact of attributions on a number of different dependent variables with separate structural equation models. This allowed a clean analysis of the hypothesized effects. However, as there might be relationships between emotions, perceptions and shopping intentions, attributions can influence shopping intentions via a number of indirect effects. Hence, future research should develop an integrated model of attributions, emotions and perceptions to explain discount buying more holistically. Another limitation refers to individual differences in the strength and impact of attributions. Future research should investigate whether customer segments with different attributions to low prices exist. Furthermore, customers selected the evaluated store from a list of different grocery discounters. This procedure guaranteed that the respondents have at least a rudimentary impression of the store, but store selection can also bias the results. Finally, the fair relations to customers scale seems somewhat problematic as the items are only indirectly related to concerns about customer welfare. This might explain why this factor had so little impact on the dependent variables.

APPENDIX
Item-scale

Price level perception	The prices are more competitive than in other stores. The prices are generally very low here. You can buy cheap groceries here.
<hr/>	
Quality Perception	You can buy good quality products in this store. In this store, the product quality is only moderate.* The product quality is perfectly alright. The product quality is considerably better compared to other stores. The product quality is here worse than in other stores.*
<hr/>	
Value for money	The prices here are appropriate in relation to what I get for my money. The prices here are excessive in relation to what I get for my money.* I get good value for money here. Compared to other stores, the price-performance ratio is very good here. The ratio between price and performance is considerably worse here than in other stores.*
<hr/>	
Price fairness	This store sometimes behaves unfairly regarding the prices.* This store sometimes behaves dubiously regarding the prices.* This store always behaves very correctly regarding prices.
<hr/>	
Ease of price evaluation	I can assess this store very well regarding the prices. I cannot assess this store at all regarding the prices.* I find it difficult to assess the prices in this shopping establishment.*
<hr/>	
Shame	I feel embarrassed buying food in this shop. I feel a bit embarrassed when I have to shop here. I feel awkward offering guests food from this shop.
<hr/>	
Guilt	I have a bad conscience when I buy groceries here. It is not correct to buy food from this shop. I feel irresponsible when I buy groceries here.
<hr/>	
Shopping intentions	I should shop at this store as often as possible. I should shop at this store as seldom as possible.* I should consider this store for my shopping. I should disregard this store for my shopping.*

INTRODUCTION

“Consumers don’t eat as healthily as they should”. This is a claim that a vast amount of people all over the world now accepts as a truth. Due to the individual and socio-economic costs of the current obesity-epidemic, there is great public concern about healthy living. This is underlined by various reports from transnational health agencies as well as national agencies in America and Europe but increasingly also the Asian region and was mentioned as one of the most important issues to be dealt with by transformative consumer research in the introduction to a recent special issue of the *Journal of Consumer Research* (Mick 2008).

The traditional way of dealing with public health promotion has been through promotional campaigns that provide consumers with information on healthy eating: education on healthy diet, nutrition labels on food products, campaigns trying to promote healthy product categories like fruits and vegetables, etc. This reflects a nutrition policy that typically focuses on individual food choices and how they can be best informed (Holm 2003: 534). However, nutritional information and education is not sufficient to change consumer behavior. One major review of 58 European studies and reports concluded that there is a widespread interest in nutritional information on labels, that there is a positive attitude towards simplified information on the front of the packaging, but also that there is little knowledge about how nutritional information and labeling is used in real-life shopping situations (Grunert & Wills 2007).

The work of Wansink and Chandon (2007, 2006) has tried to sophisticate the “nutritional labeling approach” and thereby overcoming some of its limitations by addressing the lure of “health halos”—health claims from suppliers that are thought to provide relatively healthy food—which make consumers underestimate the caloric content of the food consumed. Furthermore, Wansink and van Ittersum (2007) and Wansink, Painter and North (2005) investigated the effects of visual cues such as the impact of portion sizes on quantities consumed. Considering the widespread affirmative signs that we are in the middle of an obesity-epidemic, it is not surprising that 6 out of 13 contributions to the abovementioned recent special issue of *Journal of Consumer Research* dealt with health, and four of those more specifically with eating patterns and obesity issues. Three of these contributions are more or less direct extensions and qualifications of Wansink’s research on visual cues, this time focusing on packaging size and investigate for example avoidance of extreme package size (leading to industry motivations to “upsized” standards) (Sharpe, Staelin & Huber 2008), and perverse effects of package size leading consumers to consume more when packages are smaller, contrary to what was found by Wansink in his studies (Coelho do Vale, Pieters and Zeelenberg 2008). Finally, in the third of the three articles, similar results were reported by Scott, Nowlis, Mandel and Morales (2008) with the significant addition that the “perverse effect” (consuming more when packages are smaller) was found to be dependent on whether

the consumer could be classified as so-called “restrained eater” or not. These studies highlight the relationship between package size and inclination to consume as well as the importance of distinguishing between different types of consumers and their personal life worlds when it comes to health-related eating behavior. Most notably, the study of Scott et al. (2008) points towards the relevance of such issues.

Consumer researchers may look towards CCT related research (Arnould & Thompson 2005) in order to better grasp the social context of eating and health-oriented behaviour. It is therefore interesting to note that health-oriented behavior is relatively absent from the tradition of CCT. Closest to establishing such a tradition is the work of Craig Thompson with its focus in the socialized body (Thompson & Hirschman 1995), the consumption of natural health and the mythologies attached to it (Thompson and Troester 2002; Thompson 2004), and the risk perception linked to “natural birth practices” (Thompson 2005). Beyond this stream of research, there is relatively little coverage of health-oriented consumption in the CCT literature. Within the consumer research tradition pertaining to the general issues of relations between eating behavior and health policies there exist only a few studies (Holm 2008, Järvelä et al. 2006)

Mick (2008) calls for a more contextually embedded insight into consumer behaviour in the daily shopping and cooking practices, and how the contemporary discourses about health influence (or fail to influence) this behavior. He notes that “the problems and challenges related to consumer behaviours today include, but are not restricted to, unhealthy eating... (p. 377)”. Such a broadening of the scope on consumer behaviour related to health and eating reflects the call for new approaches in relation to improve strategies for health promotion (World Health Organization 2003; 2007) following the prevalence of changing life styles and dietary related diseases. The Danish government and its agencies for public health and nutritional information have decades of experience concerning informational campaigns about relations between food consumption and health. However, these campaigns have almost exclusively been based on providing information to consumers, thus tacitly adopting the picture of the consumer as an information-processing agent, who will change evaluation of food alternatives based on information about their potential impact on personal health. .

As a consequence of this search, and in order to test new strategies for changing consumers’ eating behaviours, The Danish Strategic Research Council has sponsored a large, cross-disciplinary research project in order to investigate the usefulness of branding techniques as a supplement to or a replacement for the traditional information based approach. The study, which is cross-disciplinary in character, includes an ethnographic study of consumer discourses relevant in the social construction of health, a major study evaluating various ways in which branding techniques can be applied for the promotion of healthier eating behaviour and a philosophical study of the ethical issues permeating publicly sponsored health branding efforts.

THE STUDY

In this paper, we present initial results from the part of the general health branding project that investigates the social con-

¹Acknowledgements: This study presents results from the project “Health Branding” funded by the Danish Strategic Research Council.

struction of “health” in consumers’ everyday lives and their construction of consumption practices based on contemporary ideas about health as well as inherited and/or adopted food cultural patterns. This project, then, aims at obtaining a deeper understanding of symbols and meanings that consumers relate to in response to health. An interdisciplinary group of researchers, including an anthropologist, two consumer researchers, and a philosopher specializing in ethics, conducted the study. The primary data consists of in depth interviews with 34 consumers (25 women and 9 men) between 20 and 60 years of age. In some cases also family members were included in the data collection. The study includes in depth interviews about food culture and eating behaviour, observational studies in shopping and cooking contexts and a follow-up interview on health and brand symbolism. Within the limits of the study, we have tried to get a rich picture of the consumers’ life styles. The focus of the analysis has been on moral values and perceptions of healthy food/unhealthy food (Warde 1997), brands & health claims (e.g., Evans 2008), dietary recommendations, notions of performance and body image (Thompson & Hirschman 1995; Turner 1997).

Approximately half of the interviews were conducted in the capital city of Denmark, and half were conducted in a major provincial city. Due to space limits, we will not go any further into demographic and geographical differences here. A preliminary coding and analysis of the interviews demonstrated that the post-structuralist life style dimensions (Holt 1997) used as a frame of analysis of American and Danish women’s relation to the use of cooking fat and their culinary life styles (Askegaard, Jensen & Holt 1999) were prevalent also in the current material. Thus, these dimensions have been applied in order to analyze similarities and differences among our informants and the discourses concerning health and eating. Furthermore, the application of this framework of analysis has permitted the updating and qualification of a two-by-two matrix reflecting fundamental variations in social meanings concerning health and eating behaviour. As a consequence, it can be used to distinguish different kinds of discourses in relation to health and eating.

THE PUBLIC HEALTH DISCOURSE IN A DANISH CONTEXT

Contemporary commercial marketers and public health campaigns in Northern European countries perceive health as a notion associated with personal responsibility, informed choice and the availability of healthy food products (Vallgård 2001, 2007a, 2007b; Yoder 2002). Thus, both public health promotion and commercial health branding² is based on the notion, that citizens and consumers make voluntary, responsible and healthy choices, if proper information and healthy food products are available. Another underlying link and a powerful incitement for improving the health condition of the citizens is the association between health and economy. As stated in a recent article “If consumers are unable to process and comprehend the needed information, they will be unable to make the healthiest and most financially prudent decision. The result is increased cost to society” (Levy & Royne 2009: 368). The moral and social implications of this viewpoint have been pointed out by several scholars, among these Scott Yoder, who argues that a discourse based on personal responsibility and autonomy often leads to a victim-blaming “We are told how to improve our health or reduce our risk of illness by eating properly, exercising regularly, or taking a aspirin daily. While this information empowers us, it also burdens us. If we can control our health, we can be blamed for being ill” (Yoder 2002: 23).

Turning to the Danish context similar ideas emerge. According to the historian Signild Vallgård Denmark, Norway and

Sweden share the same major health problems, that is, cancer, heart disease, diabetes, musculoskeletal diseases, and mental illness (Vallgård 2007: 205). The political strategy to deal with health problems, however, varies to a high degree. By comparing public health white papers from Denmark, Norway and Sweden, Vallgård argues that the Danish programme differs from its Norwegian and Swedish counterparts with regard to explanations and suggested solutions to the problems. Whereas the Danish programme stresses the importance of individual behaviour, personal responsibility and autonomy, the Norwegian and Swedish counterparts stress social relations, living conditions as well as political responsibility. Furthermore, the Danish programme focuses almost exclusively on lifestyles and risk factors associated with certain forms of behaviour (Vallgård 2007: 208). In Denmark all age groups are hit by the obesity-epidemic. From 1985-1994 massive national public campaigns were conducted to reduce the fat intake in the Danish population (Astrup 1998: 573).

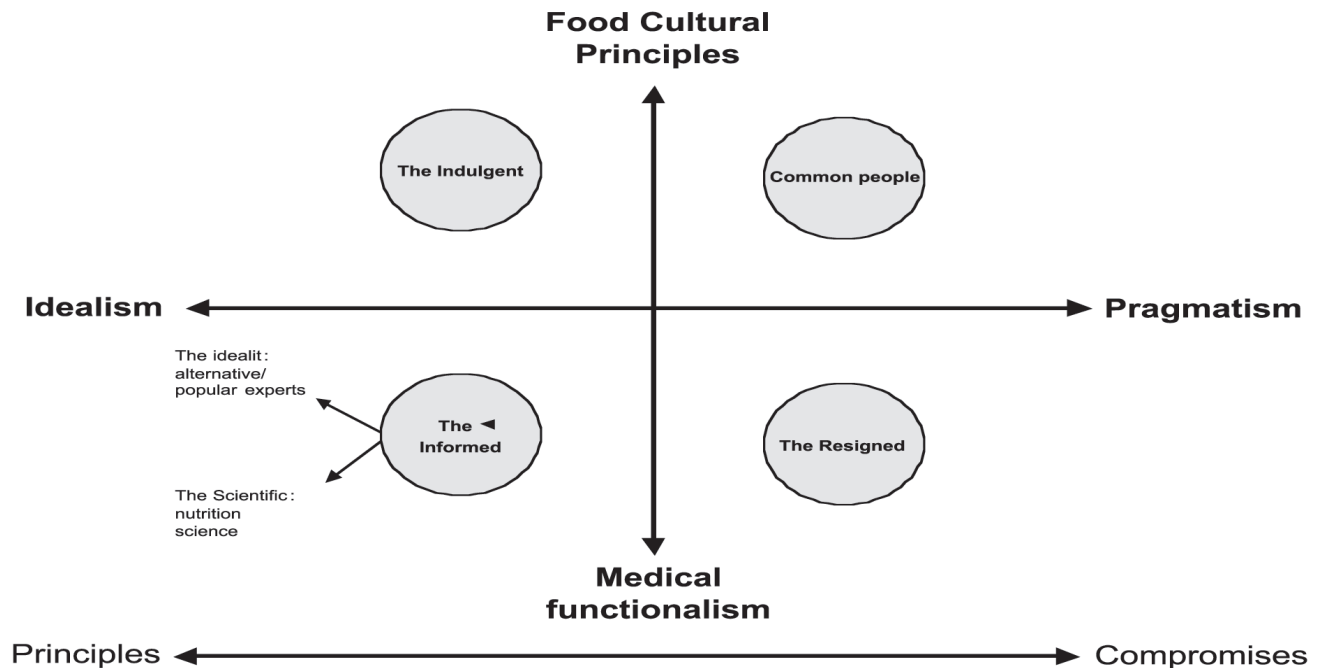

Key areas in current health promotion include; tobacco, alcohol, diet and exercise. The public authorities have the obligation to inform the population about risky and unhealthy behaviours as well as to deliver messages and provide solutions (Vallgård 2001: 390). Thus, in the public health discourse in Denmark unhealthy behaviour is primarily regarded as the major cause of disease and behaviour that is dependent on the individuals’ free choice. Therefore, the individual is assumed to be responsible for his/her health condition (Ibid). In the Danish white paper it is phrased in the following way: “Individuals are responsible for their own lives. Everyone has the right to live their lives as they wish: to make their own choices”. “Respecting individual autonomy is decisive. The public sector should not control our lives” (cited in Vallgård 2007a: 208). The health improvement strategy is to help citizens make their own informed choices. As a consequence poor health is overall depicted as the result of individuals inappropriate behaviour (Vallgård 2007b: 45). However, and very importantly, the role of the state is much more active with regard to “vulnerable” and “disadvantaged”³ adults, who should be introduced to health programmes in order to change their behaviour. This intervention normally takes place through public health professionals. Respecting the autonomy of these groups seem to be less of an issue (Vallgård 2007a: 209)

The Danish public discourse on health leads us to hypothesize that, in the consumers’ life worlds, the notions of the individual responsibility and autonomy is strongly present. In fact, it was crucial for the people in this study to show that they were capable of controlling their food consumption acting as responsible and morally respectable citizens. However, this focus on individual control, discipline and principles, also creates various moral dilemmas, especially in the relation to the notion of health risk and the consumers’ capabilities to respond to this. Further the public discourse of health apparently produces different health discourses

²Commercial marketers use branding to build strong relationships (positive associations, identification, and loyalty) between consumer and healthy products/ brands (Evans 2008), and thereby encourage the individual consumer to make ‘the right’ choices.

³The disadvantaged groups were by the social democratic minister of health Birte Weiss in 1998 described as “people who belong to a high-risk social group and who also suffer from bad health and may therefore require help from social agencies as well as health services, are often found among long-term recipients of disability benefits and dole money, as well as among people with frequent contacts with social services department, doctors and hospitals” (Weiss 1998, cited in Vallgård 2007b: 50)

FIGURE 1
A typology* of four different approaches to food and health

*We are currently validating the consumer discourses through a quantitative survey of 400 Danish respondents, thereby also turning the mapping of discourses into a potential tool for distinguishing between different consumer “health segments”. However, as of this writing, the survey is still in the data collection phase, and we are not able to discuss the more specific character of each of the potential segments, nor are we able to generate reliable estimates of the relative size of different segments. Due to the recurring structure distinguishing principle versus pragmatic orientations and gastronomical versus medical-functional orientations as found also by Askegaard et al. (1999), we are confident, however, that the structuring principles will not be or only be slightly modified by the survey results, since a pilot study has already been carried out in order to eliminate the variables of insufficient reliability with satisfying results.

and classifications of people in the consumers’ life-world. By presenting social meanings and moralisms, which Danish consumers attach to health and eating, we would like to question to the idea of the consumer as an independent and rational agent who makes rational choices if properly informed. It is important to show that consumers’ health behaviour is emotional and embedded in a social context rather than rational, because the notion of the consumer as a rational decision maker is still a prevalent assumption in public health promotion in Scandinavia. The findings are supported by Bourdieu (1992), Lindbladh & Lyttkens (1992), Thomson & Hirschman (1995), and Rose (1998), who all underline that a strictly individualistic and rational-agent approach is insufficient to account for health-related behaviour. This is because such an approach it fails to consider the social order and political agenda and its emergent discourses and its impact on consumers’ discourses.

TOWARDS A SOCIAL UNIVERSE OF HEALTH DISCOURSES

Our findings show that the informants respond very differently to the notions of health, risk and morality. On this backdrop, we suggest a typology of four different types of consumer discourses; “common people’s discourse”, “informed discourse”, “resigned discourse” and “the indulgent discourse”. Figure 1 illustrates the relationship between these four discourses. One of the oppositions, on which this approach is based, relates to a medical and functionalistic approach to food based on a perception of health risk (medical functionalism axis) as opposed to an approach of gastronomical and a notion of “the good life” (food cultural prin-

ciples). The main principle behind medical functionalism is that consumers are more interested in the functional content of food and health risk thus sacrificing taste or quality (i.e. a “gastronomically” good life). This means that this type of consumers are willing to compromise on taste or quality (i.e. a “gastronomically” good life) to reduce risk and/or optimise nutritional content. On the other opposition, food cultural principles are associated with culinary pleasure; as a consequence these consumers are willing to sacrifice healthy eating for the sake of a culinary pleasure. The other opposition is between an idealistic approach to the structuration of eating behaviour (idealism axis) and a pragmatic approach (pragmatism axis). In terms of healthy eating, the idealistic approach is related to firm principles towards a healthy diet as a response to health risk. On the other hand, the pragmatic approach is regarded as an aversion towards firm principles in relation to healthy diet and a movement towards compromises.

The discourse of what we dub common people is the most dominant one. Its main characteristic is a balanced and relaxed attitude towards health claims and health in general. These consumers are concerned with food cultural principles, living a good life and not being too extreme towards healthy eating. In contrast, indulgent consumers are closely aligned to a discourse that put strong emphasis on food cultural principles and the “good life” and who are not much concerned about health risk. To them taste and quality are the most important product characteristics. Informed consumers—as opposed “common people” – stress strict discipline and firm principles and are very conscious of health risks and healthy eating. To some extent resigned consumers resemble “com-

mon people” due to their pragmatic attitude towards healthy eating. However, resigned consumers have to a certain degree adopted the discourse of the informed with its emphasis on health risk, but apparently lack the balance between indulgence and discipline. The resigned tend to think that an unbalanced lifestyle is partly produced by external conditions and constraints, and partly caused by a morally weak character. In the next section we will exemplify the theoretical model through a presentation and discussion of major findings from our qualitative study.

COMMON PEOPLE: THE SIGNS OF AN UNHEALTHY BODY

“Cola makes you fat and unhealthy. You do not see fat people on the street without a cola in their hand. They always come strolling down the streets with this 1/2 litre bottle of cola in their hand...people seem addicted to that stuff...and again, those fat people, I cannot stand the thought of it...drinking cola is one of the great sins for the real overweight people...it makes me...uhh...cola is being gulped down in huge amounts. Maybe we should ration the purchase of cola. Then each family could buy no more than one litre of cola a week...that would be a great idea...of course it is up to people themselves if they want to be fat...but some just need help...when I look at all the teenagers and grown ups who are getting fat I feel really sorry for them. No one feels good about looking fat...I feel so sorry for them”

The quote is from Rikke, a middle-aged woman living in a major Danish city, who in recent years has gained an increased interest in healthy living due to her daughter’s diagnosis of rheumatism. Rikke leads a healthy life style as this is crucial to both her own and her family’s well being. She is very concerned about family-life and traditions, loves cooking and thinks she has always been aware of eating quite healthy in the sense that vegetables have always been a part of her daily food intake. She is trying to reduce high fat and sometimes buy organic vegetables, and does not consider highly processed food as healthy.

Even though Rikke has become increasingly health conscious during the last year, she can still be characterized as belonging to the discourse of the common people, because she is primarily concerned with living a good life and does not adhere to strict discipline and principles towards healthy eating. She aims at what she considers a sound balance between indulgence and principles towards healthy eating. There should be a space for sinning and for both healthy and unhealthy eating, but in a regulated and controlled way. Rikke herself has a love for cakes, and feels a bit guilty, but also manages to control her desire. Though in no way fanatic, many people as Rikke associate fat intake with morality. If you eat too much fat food or consume too much coca cola, you feel “guilty”, while exercise and eating vegetables makes you feel good “in the soul”. As indicated in the quote from Rikke common people seem very judgemental towards people who do not control their intake of unhealthy food. And the bodyweight seems to be the indicator for whether you lead a problematic life in the sense of being socially incapable of controlling your own life.

In other words common people are not too concerned about health on a daily basis, but do connect health risk with lack of control of food consumption. In the quote from Rikke cola stands as the direct cause of obesity and an unhealthy body condition, and the consumption of cola is considered a sign of an unhealthy body. Moreover the quote illustrates the perception among common people that health is first and foremost an individual responsibility; the consequence is that obesity is perceived as a consequence of

lack of discipline and therefore connected to moral meanings and judgements. Those who fail to make healthy choices, are the ones to pity as well as the ones who are exposed to a moral judgement that questions their capacity to live a good life and to make healthy choices. In the quote it is suggested that the state should interfere. Here we clearly see the parallel to the public discourse on health, which exactly considers that the state should take a more active intervening role in connection with “vulnerable” groups. To Rikke such a group is represented as “fat people with uncontrolled consumption of cola”. Rikke as many other consumers attributes positive characteristics as the ability to self-manage and control impulses to people who have the right body size. Furthermore many associate healthiness with a hard-working character. Hardly surprising many of the common consumers describe unhealthy people as “people without character” as “lazy” and “people who do not work”. A 42-year-old woman described this the following way: “To me an unhealthy person is one who is overweight and who neglects himself, and might also be unemployed”. The physical appearance is here taken as the major sign of a person’s moral character.

Gudrun is 59-year-old woman, who is very concerned with good quality in food. This contributes to an increased life quality in her family life. She is a mother of two, and together with her husband she used to run a clothes shop. However due to her husband’s health problem (heart condition) they have both retired. Now they are very occupied with enjoying the last part of their life. Gudrun likes food and cooking and always goes for the best quality, which to her is associated with good vegetables, fruit, and low fat meat. She prefers well-known and Danish brands and likes to shop in local shops, for instance the local butcher. The bread is always homemade. She avoids fat and sugar, and exercises regularly to keep fit and slim. To her health is very much about the display of personal responsibility of being healthy, which she associates with discipline and good manners. Gudrun associates discipline, health, moral character and physical appearance in this way:

“A healthy person is someone who takes responsibility for his own life. *You yourself have to do something, this also concerns health.* I know that there are people who become sick, who cannot do much about it, you can still become sick even though you live healthy. But if you smoke 40 cigarettes a day then you have NOT taken the responsibility of being healthy.

I: How would you describe a healthy person to me?

B: A healthy person is one who is not too blurred. I am here referring to physical appearance, but also to good behaviour. It makes me totally insane when you go to Copenhagen and you see people in a café with their legs on the chairs. I simply cannot tolerate that. Then you don’t respect people around you”.

As in the quote from Rikke, we see how health is closely intertwined with a notion of self-control and to the idea that the state of one’s body is a material sign of a moral character (Thompson & Hirschman 1995). To many consumers who can be said to represent the discourse of common people, health is connected to moral discourse that echoes Christian notions of morality, where unhealthy eating and drinking (mostly of fat food and alcohol) is considered “a sin” that makes you feel guilty, while healthy living makes you feel “good in the soul”. Gudrun seems to be rather influenced by recent health campaigns; she mentions a campaign of eating fish twice a week that set a standard for consumption of fish. She has consumed lots of fruits for many years, but after the launch of campaign “6 a day” (which aimed at increasing the average intake of fruit and vegetables to six a day), she reports her intake of fruits

and vegetables to have increased. Each morning she eats what she estimates as “400 gram of fruits”. That means that she is close to the target of eating 600 grams or 6 a day already from the beginning of the day. But eating healthily is not considered the main factor in securing a good quality in life.

“What is healthiness? It is not just a matter of what you eat, but it also has to do with your life quality. I consider it of vital importance that you are happy and satisfied with your life, that you are not stressed that you are content with husband and kid. Frankly speaking that is more important than what you eat”.

However, Gudrun feels there is too much focus on health today, and that there are too many conflicting messages “one day they tell you that red wine is healthy, and the next day they forbid it”. There also has to be room for the “sinning”, which in Gudrun’s case means having a glass of good quality beer or wine and some sweets or good chips. As she says: “When I sin I do it properly”. She opposes herself strongly to people, who adapt to strict rules and regimes in eating and to all fanaticism.

“If young ladies think it is necessary to get up early and make fibre rolls in order for you kids to survive, then things have gone completely wrong. It must be difficult to be young today and live with all those rules. When I was young and had small kids, we used to slaughter pigs, and of course we ate all of it. Of course we also ate all the bacon. And my kids became competitive swimmer and they are both healthy and big. They did not suffer any injuries. In that sense I believe it is all very exaggerated”.

In this way the discourse of the common people both put moral judgements on those failing to control and discipline their food consumption, as those too concerned about health risk with very strict principles in regard to eating.

THE INDULGENT: LIVING THE GOOD LIFE

The discourse of the indulgent evolves around the desire of living a “good life”. For the consumers aligned with the indulgent discourse taste and quality are more important product characteristics than healthiness. Hence they are willing to spend more money to get the best quality. The discourse represented by the indulgent is autonomy in the sense that most recommendations from neither the food industry nor the public health authorities taken into account. This does not mean that the indulgent is leading an unhealthy lifestyle, but he feels comfortable judging for himself what is “good or bad”.

Per represents a typical consumer living through the discourse of the indulgent. Per seems very relaxed concerning all aspects in life, and to him living the good and pleasant life is highly prevalent. He is of course concerned about societal affairs such as for example animal welfare and environmental aspects, but nothing seems to bother him to such an extent that it would interfere with his food preferences. To him the good life is pretty much about one of the big qualities in life is being able to enjoying the best of food. Eating tasty and good food is important not only as an individual pleasure, but also as a social act. Per is quite suspicious and sceptical towards commercials and advertisements promoting healthy food, and when choosing food he feels better off judging from own experience and common sense. The indulgent is convinced that the producers do only have a commercial interest in selling their products and are not very concerned with moral aspects towards the consumers as such. When it comes to food the general perception

is that when you buy food of good quality it is also healthy—or at least not that unhealthy. Consequently the principles of eating for this kind of consumer is associated with high quality food which equals good taste. Fast food is only an option in very few occasions if you are really busy. That is enjoying life and life quality plays a dominant role, while healthiness plays a minor role in their everyday life and food choices.

THE INFORMED; KNOWLEDGE, DISCIPLINE AND THE SEARCH FOR THE UNSPOILED

Another consumer discourse is represented by the informed, who is characterized by having firm principles and a strict discipline with respect to healthy eating. Consumers aligned with this discourse are very concerned about both healthy eating and nutritional knowledge, and are constantly seeking information on how to find healthy food. Generally food they refer to health food as “natural” and “pure”. The informed does not seem to trust experts, authorities and food claims from the food industry. He is skeptical and therefore filters and evaluates any type of information he receives. The informed considers health as a more important characteristic of his diet than quality and taste and any advice to healthy eating should resonate with either scientific proof or/and his inner feelings.

Lars is a medical doctor of 38, married with three children, and lives in major city in Denmark; he describes himself as very health-conscious. As a consumer he is of course also confused by divergent health messages, but never gives up trying to navigate through the health jungle, and his medical training here provides him with certain skills. He is aware of the premises or conditions for scientific knowledge, and the fact that it is sometimes difficult to live in accordance with this knowledge, as it changes and brings up divergent messages. But he will, unlike the more pragmatic types, never give up trying to evaluate what is healthy or unhealthy. He is kind of calculating with a certain margin for being mistaken once in a while.

“Even though it is annoying never really feeling secure that you do the right thing, I never give up. I remember when my girl was a baby; I loved her so much and only wanted to do the best for her. So I bought this cold-pressed organic thistle oil for her, and later on it was taken off the market because it turned out to be bad to your health.”

So the informed are characterized by being very resolute in the search for the right things to do, as the alternative to sometimes being mistaken, is to give up and become resigned. As he says: “what is the alternative, should I just accept to eat something bad and mass produced food...oh I can’t even think of it, so I just have to accept the conditions...”

Lars is a consumer, who is often referring to scientific statements, numbers and specific claims, and is typically reflecting upon the messages trying to evaluate possible risks and benefits of food. The primary motivation for eating healthy is as Lars claims: “if you eat unhealthy, there will be a bill to pay later on”. In this way Lars is quite judgemental against people—as the common people—who fail to reflect on health risk and to adopt a strict dietary regime based on nutritional knowledge. Here most informed perceive natural and organic as nutritional, while anything artificial and ready-made food is considered as unhealthy and potentially risky to eat, therefore one should keep one’s intake of additional and e.g. artificial sugar at a minimum. And of course this kind of consumer knows the scientific words for different ingredients. The informative label is of interest to this consumer, and different labelling systems are

referred to and are well known. Lars is almost reflecting, counting and evaluating everything his children eat, and he is very worried if they will not eat the amount of fruit and vegetables he has planned for them to eat. Then he starts compensating. And he is quite upset because most of what they want to eat is from the bottom of the food pyramid. He then starts to calculate what they actually eat during the day, and feels a little relieved when he concludes that maybe they do not get that many vegetables but on the other hand they eat a lot of fruit. He spends quite some time considering how he makes them eat “the right things”.

Other informed are less concerned with scientific proof and calculation and prefer to depend on what they coin “their own inner feelings”. Their notion of health is based on holism that is a equilibrium between body, mind, and spirit. An example is the 41-year-old Birgit, who considers healthy eating as absolutely crucial for feeling good about one-self. She is characterized by a profound scepticism against authorities and marketers, whom she accuses for not being “truly” concerned about the health of the people. Hardly surprising she is often criticising information from the health authorities for being too simple and sometimes even misleading, even though she is sympathetic to some campaigns, for instance the advice of eating “6 a day”⁴ and a campaign for eating fish twice a week. But she feels that she lacks clear guidance of how actually to eat healthy. She has also a pronounced scepticism towards the food industry, which she blames for not being responsible towards people’s health but only interested in financial profit. This is shown in the way they add unhealthy ingredients to many food products.

Birgit: *“I really find it grotesque that it is so difficult to find a pure product. Apparently they put all sorts of things into it such as colouring, food additives, and apparently also sugar. And I ask myself, why has it developed in this way, why hasn’t the industry been more concerned about healthy food, I find it really strange, is it because it is much cheaper adding all these things than doing it in a healthy way?”*

Hardly surprising, the scepticism towards commercials is also very profound. Christine a 28-year old tension educator says:

Christine: *“There is so much seduction in commercials. They just want to tempt you to buy something that will not make you any happier. Ideally people should not need commercials to find out what they need to put in their shopping basket. The horse knows by itself that grass is what it needs. We should feel inside ourselves, what we really need”*.

She believes that common peoples’ belief that fat is the main risk for a good health, is far too simplified and even misleading and they accuse them of ignorance and lack of principles in health matters. To her health is strongly associated with clear principles and ethics, and she finds really no excuse for not eating healthy, if you want to feel good about yourself. By putting emphasis on priorities and principles, the informed somehow escapes the oscillation between healthy/unhealthy eating, and its associated characteristics of sin/guilt. The informed in a way admits to feel superior to people who fail to prioritize and find no valid excuses. As Christine says:

⁴ is to be understood as recommendations to eat 600 grams of fruit/vegetables a day

“It is really a question of priorities. I buy a lot of fruit and vegetables that are sometimes a bit costly, but then I would never consider buying a Coca Cola or a pizza. I don’t have a television, I don’t smoke, I never go out to have an expensive drink (laughs) when I am in town. It is really a question of priorities”.

Healthy eating is a top priority, and for this reason Christine uses quite a lot of energy in seeking information about healthy food products through social circles, books, public debate, and the Internet. She also prefers shops with clear ethical, humanitarian and environmental principles, and doesn’t mind to pay extra for a product. In sum the informed are characterized by a strong awareness of health risk; this creates various moral dilemmas, firstly their own quest for finding “really” healthy and “pure” products that fulfil their criteria, secondly their demand for full control of both their body and the marketplace is very ambitious. Here knowledge—based on science or their own inner feelings—is the most important tool. However this very occupation with knowledge and principles often make them appear too fanatic and hysterical in the eyes of other segments, as the example with Gudrun shows. Furthermore it may go to such an extreme that the informed become obsessed with healthy food, the so-called *ortorexia nerviosa*, a term proposed by the American doctor Steven Bratman. Most informed, hardly surprising, however, are quite upset about this term, and do find their own interest in health as sound and necessary.

THE RESIGNED: THE BURDEN OF THOSE FAILING TO LIVE HEALTHILY

The last type of discourse that we will present in this paper is presented by consumers being judged as “unhealthy” by others. In this context we prefer to use the denominator the resigned. To a certain degree these consumers have adopted the discourse of the common people with their pragmatic alternation between principles/ discipline on the one hand and indulgence on the other, however with one crucial difference. That is they themselves have not managed to balance indulgence and discipline, which they themselves explain as a result of a lack of time due to long working hours (working for a “living”) or more often through the lack of personal discipline and moral character (“the guilty ones”). The resigned do have knowledge about health risk, which they mostly associate with uncontrolled intake of fat, sugar and additives. To some extent they have adopted the ideology of self-control and discipline as the way to a healthy and morally correct life. In this way their self-perception is informed by the discourses that surround them, of which health risk plays a crucial part.

Mogens is a 41-year-old factory worker, who has moved from a smaller city to the capital Copenhagen. He is single and hard-working man, and finds it difficult to find time and resources to live and eat healthy: “A lot of us eat the wrong things. I eat too much of that (points to a cake) and many are eating at McDonalds far too often ... I have considered going on a diet. But I need to be stronger first”. Mogens is quite health conscious, but lacks clear principles and the discipline to follow them, as he often feels overruled by his desire for the “forbidden”. Mogens has given up on actively searching for health information but remains a passive receiver of any health information that may come up. In this case, however, this leads to a moral judgement—both by consumers aligned with the other discourses—and by himself. He claims that he fails to live up to a healthy live style as he gives into temptation far too often.

Sara is a 20-year-old girl in high school. She is the daughter of Yugoslavian immigrants, but is born and raised in Denmark. As most high school girls she seems very occupied with her look: She

is smartly dressed wearing a lot of jewellery along with a perfect make-up and seems very well-articulated. Apparently she is also very concerned about eating the “right and healthy food” and gave us a long lecture on tasty and healthy eating at the first interview in the supermarket. Getting a closer glance of her world, one realizes that she lives in a world full of rules that she can not herself live up to, as well as a constant anxiety caused by her failure to keep a strict diet. She really likes vegetables and fruits and does normally go for low fat and light products in order to keep fit and healthy. However, she complains about her failures in keeping slim. She has tried what she refers to as a “tons of diets”, and does regularly have periods where she exercises very intensively. However, she lacks perseverance, and also suffers from “attacks, where she indulges in sweets and cakes. She regards her overweight as the main indicator of her “failure” to keep a strict discipline, a fact that she constantly returns to in conversation. Another theme both she and her mother—a cleaning assistant – bring up, is the social isolation and lack of resources they felt as belonging to people with another ethnic background. However, as in the discourse of common people, Sara is sure that obesity is a clear sign of the unhealthy body, and that the main sinners here are fat and sugar. Nevertheless even though she considers fat as unhealthy, she herself believe she has a weak character, in this way she also connects obesity with morality, but claims to have given up. Even though she in no way considers herself as “healthy” she is actually quite occupied with health risk, at the point of having monthly tests taken at the medical doctor.

Sara: *“It is not like that I eat a kilo of bread and potatoes. I don’t-I also do eat healthy food, but sometimes I just have days, where I just need to have something sweet.”*

Interviewer: *“Is it some special days?”*

Sara: *It happens mostly during weekends. Then we relax and eat sweets. But when I have a bad day, then I have to find something sweet in the house, and if I don’t find any then everything just goes wrong. I get tired, but I still try to fight, because I have health problems. I go to see a medical doctor each month, to have my blood tested and everything, and luckily everything is fine. That is I don’t have problems with increased blood pressure. But I do have a little overweight, but I have heard that it is not that unhealthy.*

As this last quote illustrates, the eating habits of Sara—a resigned—may resemble the eating habits of the common people. What marks the difference, however, is the picture of herself as belonging to the category of the “uncontrolled” and therefore “morally weak”. Even though she apparently does not lack nutritional information and to some degree is concerned about health risk and susceptible to health messages and health claims, healthiness is a topic that brings up emotions and frustrations. In the following quote from Sara it is illustrated that the focus on control and individual responsibility for making the “right” food choices, apparently increases a sense of anxiety.

Sara: *I just think, there are these days where there is so much focus on what is healthy and what is unhealthy, who is fat and who is slim. In a way I don’t care, I don’t care because I know how I want to live, I just don’t think the society should decide how we should live. If they were really concerned about our health they would raise the*

prices of the unhealthy and reduce the prices of the healthy.

Interviewer: *Are you saying that in a way society does not help people to become healthy and at the same time they point fingers at you?*

Sara: *Yes, then they complain that overweight cost billions and billions each year. There is just too much focus on that part. I know it by own experience, I have tried a ton of diets, I have tried everything, pills, powder, and with what gain? I am still the way I am. I am overweight, but I am not going to feel ashamed about my body. If people cannot accept the way I look I don’t really care.*

Interviewer: *And have you experienced that some people could not accept the way you look?*

Sara: *Yes, bloody hell. One day a guy said that fat people would be prohibited to go to McDonalds. I felt like hitting him. Why on earth should he decide whether I could go to McDonalds?*

We here see a link between the public health discourse in Denmark and Sara’s self-perception. As a person who consumes “unhealthy” food products (cake, sweets, coca-cola) and who is also overweight, she is not adhering to the picture of the responsible and autonomous consumer who takes informed and healthy choices. In the consumers’ discourses this is expressed as an association between physical appearance, principles and morality. The fat person is a person who lacks discipline and principles and consumes the “wrong” food in an uncontrolled way; this is taken as a threat to public morality. To avoid this threat that the fat body presents, it is proposed that society regulates the food consumption of these morally weak persons. As the suggestion of prohibition of going to McDonalds, and as Rikke suggests; if people are not capable of being responsible in their own lives, society should take over the regulation. Hence we have a public discourse that regards health as first and foremost an individual responsibility and ascribes autonomy and personal responsibility to the capable citizens, furthermore it proposes intervention in the case of the more “vulnerable” group. It is interesting seeing how this discourse is echoed in the consumers’ discourses, but in a somehow distorted version. In Sara’s case, being fat is not explained with reference to any genetic disposition, nor is it seen in the light of her social and economic background. Rather the overweight is the display of a public failure to take control of ones life: to this reason she is considered an “economic burden”. No wonder Sara responds to the “pointed fingers” in a quite aggressive way. Furthermore, hardly surprisingly, she is also overtly self-defensive and argues in the following way “I actually think it is possible to have 40 kilos overweight and still be a good person”.

CONCLUSION

In this paper we have presented preliminary data from a qualitative study of consumers’ perception of healthy food. Food represents part of our identity construction, and as Fischler (1988) puts it: “Food makes the eater”. Hence food defines and communicates who you are, and within this construction a dilemma arises: the balance between desire and control. A negotiation between health risk, the good life and control (personal restraints that comes from body images, public health claims etc); this is mirrored in life style and identity (who am I, what do I want to signalize to myself and the surroundings). Since nobody (or very few) seem to escape the oscillation between the pleasures of eating and the potential health consequences that are often associated with eating and food

choice, we concur with Wilk (2001) that the sin/guilt cycle provides a basic rhythm of consumer culture. The food market definitely constitutes a domain of “moral conflicts over consumption”, as Wilk calls it. Additionally, the current discourse of obesity epidemics allegedly drabbing many parts of the world adds new, ironic and for some tragic meaning to the moral discourse of (and against) overconsumption.

We have described the public health discourse in Denmark and its focus on individual responsibility and autonomy. We have presented how this discourse has penetrated consumers’ notion of health as closely connected to notions of personal responsibility, discipline and control, as well as moral meanings and judgements. We have proposed that the public discourse has produced four main discourses among consumers that both serves to classify people and as displaying a guiding principle in eating behaviour. In the paper we have described four types of consumer discourses, which we have labelled discourses of the common people, the informed, the indulgent and the resigned. Lastly we have suggested that by individualizing health factors and by failing to take into consideration genetic, structural and social determinants of health, the dominant discourse of health among Danish consumer poses a risk of stigmatizing people suffering from especially life style diseases (Ogden 2003). Furthermore by attributing responsibility to individuals for their own health you risk blaming people for being ill and for taking “unhealthy” choices, as in the case of Sara. The consequence is that overweight and obese persons come to present a failure to respond to health risk though discipline and control, despite the fact that the correlation between what is taken as “signs of an unhealthy body” and actual medical risk is, however, far from straightforward (Gard & Wright 2005). We thus conclude, that under the pretext of promoting health the dominant public discourse contributes to creation of new moralities in consumers’ discourses that implicates a construction of social stigma and lower life quality in certain parts of the population.

The Impact of Un/ethical Corporate Conduct on Consumers' Ethical Perceptions-A Multidimensional Framework

Katja H. Brunk, Université Libre de Bruxelles, Belgium
Christian Bluemelhuber, Université Libre de Bruxelles, Belgium

INTRODUCTION

In the context of globalization, large-scale industrial changes have taken place, which have been brought about through mergers, takeovers, or bankruptcies of many businesses in the marketplace. This consolidation has led to the creation of large multi-national corporations and conglomerates that have altered the social, political, cultural, and physical environment in which they operate. Gradually, the influence of corporations reached far beyond the normal business context and into politics and policymaking and, in line with their size, grew their overall societal impact. Numerous well-known, high-profile scandals (i.e., Nike, GAP, Shell, Nestlé) illustrate how corporations abused their increasingly powerful positions. The subsequent public outrage and gradual loss of trust in the business community resulted in the emergence of discourses centering on the power and legitimization of the corporation, the morality of corporate behavior and the overall societal impact of business. Anti-globalization and anti-corporate movements fuelled the debate, focusing on the notion of corporate greed and encouraging consumer boycotts that not only caused a decrease in sales revenues but also sustainably damaged brand image and the reputation of the affected corporations.

Grounded in the socio-historical debate on globalization, issues of business ethics and Corporate Social Responsibility (CSR) have increasingly taken centre stage in public discourse leaving companies concerned about their ethical image. Today, most corporations designate resources (i.e., CSR managers—a job profile largely unknown 10 years ago) at the highest seniority level to audit internal and external activities of the company, negotiate among constituents and, most importantly, portray the company and its brands as ethical players. Altruistic behaviors, such as cultural sponsoring, community involvement or charitable giving are among the types of activities companies openly engage in in order to showcase their commitment to being a good citizen—to be perceived as ethical.

In spite of ample evidence confirming the impact of unethical perceptions on consumer attitudes and purchasing behavior, to this day, little is known about how an un/ethical image of a company emerges in the consumer's mind. This article conceptualizes the way in which business practices may influence consumer perceived ethicality (CPE), understood as the consumer's aggregate perception of a subject's (i.e., a company, brand, product or service) ethicality. An improved understanding of CPE formation will facilitate a deeper insight into ethical consumerism and provide an essential extension to existing work.

BACKGROUND

A plethora of diverse issues relating to the broad subject of ethical consumerism have recently been investigated. The book *The Ethical Consumer* (Harrison, Newholm, and Shaw 2005) and the October 2007 special edition of the "Journal of Consumer Behaviour" which studied ethical consumption (Newholm and Shaw 2007) reflect expanding interest in this important area of research. Acknowledging that the subject is barely in its adolescence and that many questions remain open, various scholars emphasize the need for further in-depth exploration of the consumer (versus corporate) perspective of business ethics and CSR

(Mohr, Webb, and Harris 2001; Newholm and Shaw 2007; Sen and Bhattacharya 2001).

Recent research establishes a link between a company's CSR or business ethics and consumer responses (Berens, Van Riel, and Van Bruggen 2005; Biehal and Sheinin 2007; Creyer and Ross 1996 1997; De Pelsmacker, Driesen, and Rayp 2005; Folkes and Kamins 1999; Gürhan-Canli and Batra 2004; Lichtenstein, Drumwright, and Braig 2004; Luo and Bhattacharya 2006; Madrigal and Boush 2008; Sen and Bhattacharya 2001). Favorable or unfavorable perceptions about a company's ethics impact consumer evaluation of that business, their attitude towards and relationship with its brands, and may consequently steer purchase behavior. Yet, the question of how such a positive or negative ethical image of a brand or company evolves in consumers' minds has not been investigated.

The majority of existing studies focusing on consumer reactions to corporate ethics and CSR consists of experiments that induce CPE with the help of various hypothetical examples of un/ethical company behavior. Commonly the choice of manipulation scenario relates to prototypical ethical issues such as employment practices like sweatshop conditions, child labor and suppressed wages (Sen and Bhattacharya 2001; Carrigan and Attala 2001; Folkes and Kamins 1999; Lichtenstein et al. 2004); deceiving the consumer about product benefits (Creyer and Ross 1996); environmental records; and philanthropy such as charitable giving (Berens et al. 2005; Brown and Dacin 1997; Creyer and Ross 1996; Lichtenstein et al. 2004; Madrigal and Boush 2008; Mohr and Webb 2005). In most cases, the selection of the type of corporate behavior intended to manipulate CPE appears arbitrary and authors refrain from reasoning about their choice of scenario. In other studies, consumers are subjected to a company characterized as unethical, without reference to the origin of this negative connotation (Creyer and Ross 1997).

While the creation of scenarios referring to child labor and environmental pollution will almost guarantee negative perceptions, it may not be the case that all un/ethical behaviors have the same impact on CPE, a conjecture nourished by findings from an experiment conducted by Mohr and Webb (2005). The authors induce levels of CSR with the help of environment- and philanthropy-related scenarios and observe that "CSR had a stronger effect on evaluation of the company when it was in the environmental than in the philanthropic domain" (141-2). Bearing in mind both this finding and the multiplicity of activities capable of evoking ethical connotations (Brunk forthcoming), attention must be directed towards the intriguing question of how ethical perceptions are shaped by various kinds of corporate behavior. Conceptualizing these dynamics will facilitate an improved understanding of CPE formation and fill a research gap in the existing corporate ethics and ethical consumerism literature. Results should not only prove valuable for future explorations but may have implications for interpreting existing research findings.

METHOD

The lack of earlier research in the area called for an explorative approach aimed at seeking a grounded understanding of consumers' ethical perception formation process. The objective of exploration (versus quantification) naturally pointed towards qualitative

research. As part of a larger study face-to-face consumer interviews were conducted and serve as the main source of data collection.

Sample

Typically, qualitative research focuses on an in-depth exploration of a small and diverse sample. McCracken (1988, 17) considers eight respondents sufficient for most research purposes. For this research, 20 long interviews (*ibid.*) were conducted with general consumers. Creating contrast in respondent selection is of utmost importance in order to “manufacture distance” (*ibid.*, 37) and to enable as broad a review as possible (Stake 1995; Strauss and Corbin 1990)—a prerequisite for capturing the variety of prevailing attitudes, evaluations and perceptions. To achieve such a diverse respondent pool, a theoretical sampling procedure was followed, guided by its characteristic ongoing comparison process (*ibid.*). Contrary to existing, US-dominated research on CSR and business ethics, the focus is on European consumers, with Germany and the UK as the countries of research. Interviewees were recruited via convenience and multiplicity (snowball) sampling. The resulting pool of participants offers diversity in terms of age (17–83 years old), gender, marital status, education, and employment status to include students, retirees, self-employed, unemployed, as well as employees at various seniority levels (management versus non-management). A full list of all interviewees’ demographic profiles is available upon request.

Data Collection

Taking into account that consumers’ evaluation of ethics or morality is an inherently personal, subjective and sensitive topic and therefore, as previous research points out, prone to social desirability effects (Mohr et al. 2001; Vantomme et al. 2006; Vermeir and Verbeke 2006; Worcester and Dawkins 2005), face-to-face interviews were considered the most appropriate method of data collection and preferred over focus groups in order to minimize self-presentational concerns (Wooten and Reed 2000) and circumvent the danger of participants complying with the opinion of dominant members (Bristol and Fern 2003).

Interviews were conducted at the respondents’ home. A semi-structured interview format provided a focused, yet open form of dialog and encouraged discussion. The more informal interview style combined with the familiar and comfortable surroundings of their home created a relaxed atmosphere and consequently participants were very willing to engage and answer openly. This was crucial given the sensitivity of the subject and the objective of minimizing social desirability bias.

The interview guide was developed following four expert interviews and a review of analytical and cultural categories to facilitate a process of familiarization and defamiliarization (McCracken 1988). Subject to minor refinements after pilot testing, the guide continually evolved in line with emerging concepts and patterns (Strauss and Corbin 1990). The question format was open and all respondents covered the same topics, starting with more general grand-tour questions referring to responsibilities of businesses today, and then becoming increasingly specific, concluding with examples of various types of perceived un/ethical behavior and a discussion of company/brand-specific cases. The data-collection phase concluded after 20 interviews, when the last three interviews failed to reveal any new concepts and dynamics, suggesting theoretical saturation. Depending on the level of active participation and interaction, interviews lasted between 45 and 120 minutes.

Data Analysis

With the permission of participants, all but one interview—with an 83-year-old female feeling intimidated by the presence of the tape recorder—were recorded and transcribed at full length, yielding a total of 308 pages of verbatim transcripts and 47 pages of field notes for analysis.

Data analysis was on-going and gradually evolved throughout the data-collection process (Strauss and Corbin 1990). The constant comparison and subsequent refinement allowed both processes to intermingle, a strategy particularly useful for exploratory research purposes (McCracken 1988).

To extract meaning, transcripts were re-read repeatedly and analyzed in search of recurring patterns, themes and relationships between them. In line with Spiggle (1994), analysis proceeded by employing the recommended procedures of categorization (coding deductively and inductively), abstraction, comparison, dimensionalization, integration, iteration, and refutation. Following these analytical operations and the subsequent integration of the data, a dialog and review process was initiated in order to strengthen the validity of the findings (Kvale 1996). This confirmation phase included sharing results with six of the interviewees and two experts. Reviewers were requested to provide feedback on the interpretations and to debate any issues in question.

No significant differences between emerging categories were detected when the data from the UK and Germany was compared. As the types of corporate actions that participants perceive as ethical/unethical are close to identical in both countries, the findings presented hereafter reflect the views of the combined sample from the UK and Germany.

FINDINGS

Identifying CPE Impact Dimensions

The analysis of the consumer data results in the finding that the impact of un/ethical business transactions on consumers’ ethical perception is asymmetric. Consumer narratives suggest varying degrees of impact on CPE, meaning that not all types of business conduct commonly regarded as ethical or unethical resonate with the same intensity. The notion is in line with findings from the previously mentioned experiment by Mohr and Webb (2005). Three categories of corporate behavior that differ in direction and magnitude of impact on consumers ethical perceptions emerge from the data as follows:

- 1) Positive/Negative: Activities that can have either a positive or negative effect and proportionally in/decrease CPE depending on the company’s commitment.
- 2) Negative: Corporate behavior that has a detrimental effect when consumer expectations are not met but does not generate a positive impact when exceeded.
- 3) Positive: Transactions that have the ability to positively enhance CPE, yet their omission does not cause unethical connotations.

The dynamics, nature and dimensionality of the identified categories bear resemblance with existing quality or satisfaction models (Cadotte and Turgeon 1988; Herzberg, Mausner, and Snyderman 1959; Kano 1984; Oliver 1995, 1997; Swan and Combs 1976), which broadly summarize antecedents into: satisfiers, dissatisfiers, criticals and neutrals, based on their influence on (product-, customer-, and employee-) satisfaction (Vargo et al. 2007). These satisfaction models’ main contribution lies in the discovery of the

FIGURES 1A)–C)
The Three Dimensions of CPE Impact

existence of varying impact dimensions. The identification of features that may be attributed to each dimension is highly case-specific, hence in order to understand which feature acts as a dis/satisfier individual, product-specific tests are required. Reflecting the close resemblance between the identified CPE and satisfaction model impact dimensions, the above CPE impact dimensions were named bivalent ethical dis/satisfiers, monovalent ethical dissatisfiers, and monovalent ethical satisfiers respectively.

Linking Types of Un/Ethical Corporate Behavior with CPE Impact Dimensions

While existing dis/satisfaction models are unable to reach beyond the broader categorization into satisfier, dissatisfier, critical, and neutral dimensions, the data generated throughout this research not only reveals the existence of various impact dimensions but furthermore allows for a conceptualization of the types of behavior comprising each dimension. Therefore, the resulting CPE impact taxonomy presented here extends beyond a general classification by linking types of business behavior with each impact dimension and by distinguishing the nature of corporate activities that can act as either monovalent or bivalent ethical dis/satisfiers.

Figures 1a-1c depict the emerging conceptualization after communalities and differences across categories with varying dynamics had been identified. The framework presents each CPE impact dimension by relating the nature of business activities to one of the following principles:

- Norms (Monovalent ethical dissatisfier),
- Balancing needs (Bivalent ethical dis/satisfier) or
- Altruism (Monovalent ethical satisfier).

Furthermore a zone of tolerance depicts an area within which corporate efforts are likely to remain without consequences on consumers' ethical perceptions.

Norms (Monovalent ethical dissatisfier). Monovalent ethical dissatisfiers are transactions that relate to the principle of fulfilling norms. The most basic and fundamental of the three CPE impact dimensions comprises the kind of behavior consumers take for granted and resembles the must-be dimension of the Kano model (Kano 1984; Walden 1993). In line with Joyner and Payne (2002) who state that insufficient compliance with legal regulation may be deadly, participants expect companies to fully comply with legal standards and act in accordance with basic moral norms. Failing to

adhere to laws and norms violates these “minimum requirements”, leading to a detrimental effect on CPE, as highlighted by Maria, one of the participants, who refers to the moral principle of honesty: “The thing that happened with the meat. When they repacked it and resold it despite the sell-by date was expired. Being so dishonest is the worst for me, without a doubt. That’s not just unethical, it’s close to criminal even.”

Compliance on the other hand simply meets these basic consumer expectations and consequently causes a neutral—but not a positive—reaction, as James underlines: “They (companies) have to abide by the laws, the financial laws of the state or the country, on top of that, environmental, they need to adhere to the environmental rules and laws of the country, and last, the labor laws of the country. It doesn’t mean I’d consider them particularly ethical because that’s like the absolute minimum I would expect, just fulfilling their obligation.”

Balancing Needs (Bivalent ethical dis/satisfier). This impact dimension refers to activities that can have both a favorable and unfavorable effect on CPE. The core evaluation principle is to strike the optimal balance between harm and welfare for all affected by the business activity or transaction in question. Balancing needs calls for corporate decision making processes that involve careful weighing of positive or negative consequences on any of the company’s stakeholders. Fiona stresses the importance of this principle by describing her perceptions of a company that disregards potential harm to the environment: “Knowingly damaging the environment if [emphasized] you can do something about it is very unethical... I think if you are doing everything you can to reduce it, then it’s not unethical but if people just don’t worry about it at all then it’s highly unethical.” Or take Peter, whose narrative connects to the ongoing socio-cultural discourses on the morality of outsourcing production abroad and increasing unemployment in the home country. His quote highlights that the (perceived) motivation of the company’s action is a key component of his judgment: “If suddenly they close a factory in Wales that’s got no chance of other employment, then I guess it becomes really unethical! If they are just doing it to make more profit and more, you know, damage the community and damage a lot of people. But if it’s just a natural sort of process that it slowly moves into, then it’s ok, it really depends how it’s done.”

The expected impact is commensurate with a company’s efforts. Therefore, the more a company appears to act righteously and balances its business needs versus the interests of others, the

more favorable the effect on CPE. Referring to the car manufacturer Volkswagen, Sandra offers one such positive example: "For me that's ethical: For instance, when firstly you communicate you have such and such problem, so everyone can comprehend the situation. OK. The normal consequence would be that we would have to let a certain number of employees go. But then, it is about looking for solutions in collaboration with the employees, for instance to say: OK, you won't get a 13th month salary and won't get a raise for a while and maybe some of you have to work part-time, but in return, we will guarantee your job until 2010, despite our financial challenges. That for me, this is really ethical... But to just throw people out on the street without actively looking for a suitable solution for everyone, that is just unacceptable!"

Conversely, the same participant goes on to demonstrate how acting purely out of self-interest and therefore harming others will generate a detrimental impact, citing a case of self-righteous management behavior: "I have to spontaneously think about Deutsche Telekom because I found this truly absurd. They laid-off so many people, at the same time the compensation of the Board of Directors was considerably increased. And now, here it comes, they can still afford to have Robbie Williams sing at their Christmas party. Something like that, it really makes me sick... If they hadn't got Robbie Williams, maybe they could have kept some of their people employed."

It has to be acknowledged that, due to the subjective nature of perceptions, a company's well-intended efforts and motivations to balance the interests of all stakeholders may not be recognized as such by the public. For instance, a decision to outsource production to a low-wage country may genuinely be the optimal solution for all constituents involved (i.e., as a measure of securing the company's survival), yet consumers could simply fail to perceive the decision as balanced. Shaped by the prevailing public discourse on corporate greed, the act of outsourcing could instead be interpreted as self-righteously motivated to increase profits while creating unemployment at home, in which case the impact on CPE would be a negative one. The subjectivity of perceptions highlights the fact that effective communication is critical and that—particularly with highly debated, contentious matters central to public discourse, such as outsourcing—well-intended efforts must be clearly conveyed and openly publicized in order to avert misperceptions and counteract prevailing truths, such as 'all corporations are greedy'.

Altruism (Monovalent ethical satisfier). Monovalent ethical satisfiers are corporate transactions of altruistic character, such as philanthropy, or activities going well above and beyond the company's core business responsibilities. In fact, many of these acts are not directly linked to its day-to-day business. By nature the altruism dimension mirrors the delighter category in the Kano (1984) taxonomy, characterized as nice-to-see but not expected. Hence, in comparison with the other two dimensions, these activities do not share the same level of importance with consumers. Frank supports this notion with his remark about firms that actively engage in social activities and charitable giving: "In principle I think it's really good that it exists and that many companies do these kind of things, and I think it's a pity that some don't engage in these kind of things... But, it's not criteria number one for me, very clearly. But in principle I think it's good and important." Others, like John, expect altruistic actions only from companies that make sufficient profit: "...a company can give money to charity as well as a good cause. What's the word—philanthropy—for the companies with a lot of spare money around."

Not only philanthropic engagement, such as charitable giving, but also other altruistically motivated acts pertain to this dimension, such as employee benefits extending far beyond the normal scope

of duty as suggested by Emily: "You know the other thing that would be nice to see, if they (companies) could make sure their employees have adequate homes, or adequate facilities to get a mortgage."

While engaging in altruistic behavior may enhance CPE, its omission will not cause a detrimental effect. Hence, refraining from engaging in philanthropy or other pro-social corporate activities remains without consequences. Yet a company's association with altruistic behavior can delight consumers and result in positive ethical connotations.

In reality however, such noticeable positive impact on CPE rarely occurs. Very few interviewees were able to cite a company or brand they perceived as ethical, an observation Worchester and Dawkins (2005) and Folkes and Kamins (1999) share. According to the data, altruistic efforts can only enhance ethical perceptions under the condition that consumer expectations on the other two dimensions are met. This suggests that a vital prerequisite for a positive ethical loading to occur is to refrain from vice, as Frank illustrates: "... behind our backs they lead their waste into the river but then they say, yes, but here we made a big donation, making a big fuss and that way just diverting attention away from the things where they do not behave correctly... and when I read things like that, I really don't want anything to do with them (company) anymore." Frank's quote furthermore underlines the non-compensatory nature of the altruism dimension, meaning that the display of virtuous qualities, such as philanthropy, cannot offset other transgressions. Skowronski and Carlston (1987) provide a possible explanation with their cue diagnosticity framework of impression formation by suggesting a negativity bias with morality based judgments. It builds on the assumption that bad people do not consistently display negative behavior but sometimes act in a virtuous way, while good people almost exclusively act in a positive way. For a company to be considered ethical, behavior must be consistently virtuous, whereas a single transgression is sufficient to establish a negative perception. Therefore, it is crucial a company avoids and refrains from activities known to generate unethical perceptions.

The lesser likelihood of positive ethical association is also connected to the type of information on which consumers base their judgment. In line with Berry and McEachern (2005) and Mohr and Webb (2005), participants inherently mistrust corporate communication that openly demonstrates virtuous behavior. Thus they prefer to rely on independent media as their primary source of information. However, media reporting skews towards highlighting misconduct and prevailing sensationalism fosters predominantly negative reporting.

Discussions with consumers convey the impression that graphically the slope of the altruism dimension runs less steeply when compared to the norms dimension, implying that marginal impacts differ across dimensions. Given a similar variation in absolute company performance, the magnitude of negative impact on CPE, when violating norms, is larger than the positive impact of altruistic behavior. The finding is in accordance with prospect theory (Kahneman and Tversky 1979; Tversky and Kahneman 1992) which posits that people are risk-averse. They care more about negative than positive outcomes, hence perceived losses have a bigger impact than gains. However, providing empirical evidence in support of this hypothesis is beyond the scope of this exploration.

Zone of Tolerance. Consumer narratives point to the existence of a zone of tolerance. Corporate activities within this zone are unlikely to generate any effect on ethical perceptions, hence a zone of tolerance exhibits consumers' threshold of acceptability before negative or positive loading occurs. Talking about his negative

ethical perceptions of the company Müller, Frank implies the presence of an impact threshold: "Well with Müller, it really made an impression on me, with other companies I might not be aware of it, but when something becomes so severe then I really pay attention... almost like when a certain acceptance limit has been reached."

The present study only detects such a threshold in conjunction with negative examples (i.e., in the context of unethical behavior) which is not surprising given that the majority of consumer comments are negative. However, despite the lack of grounded evidence substantiating the presence of a positively valenced zone of tolerance, its existence is probable, and also likely to be somewhat larger than its negative counterpart, due to differences in the dimensions' slopes.

CONCLUSIONS AND IMPLICATIONS

This research contributes to the existing literature on ethical consumerism by investigating the impact strength and dimensionality of un/ethical business practices on consumers' ethical perceptions. Grounded in data, the study reveals the novel finding that the effect of im/moral corporate behavior is multi-dimensional. The resulting taxonomy not only establishes the existence of three distinctive CPE impact dimensions, but additionally identifies the nature of business practices pertaining to each dimension: (1) Monovalent ethical dissatisfiers are corporate acts that can have a negative impact on CPE and refer to adhering to norms; (2) Bivalent ethical dis/satisfiers are business activities that relate to the principle of balancing the needs of the company versus others and, commensurate with a company's efforts, can positively or negatively influence global CPE; and (3) Monovalent ethical satisfiers may have a positive impact on CPE and include all company transactions relating to altruism, such as philanthropy or other activities going well beyond the scope of standard business responsibilities. A crucial prerequisite for the ethical satisfiers' ability to favorably influence ethical perceptions is that consumers' expectations on the norms and balancing needs dimension are met.

The presented findings have important implications for the academic community investigating ethical consumption and the business community, specifically CSR and general management as well as marketing professionals. The fact that altruistic engagement may only enhance ethical perceptions when all other basic moral expectations are met, presents an essential lesson for managers. A company's first priority should therefore be to get their house in order (so to speak) and prevent any type of behavior known to negatively affect CPE, such as disrespecting laws and moral norms as well as insufficiently balanced decision making. For some companies this may call for strategic re-prioritization of CSR activities, particularly in the common case where a companies' CSR focus is predominantly on philanthropy. Such altruistic efforts must be backed-up by a scrutinizing audit of operational procedures, processes and standards of business conduct encompassing all business units and suppliers for any potential sources of perceived misconduct, which need to be addressed in turn.

In terms of academic implications, the results of this study provide a useful perspective for interpreting previously cited experimental research that focuses on consumer reactions to un/ethical corporate behavior or CSR initiatives. The fact that not all business transactions have the same degree of impact on CPE requires consideration when interpreting and generalizing findings. Furthermore, considering the prerequisites for a positive ethical loading to occur, employing philanthropy-related stimuli (as in many of the above studies) may lead to an overestimation of CPE enhancement.

Consumer Cognitive Perspectives of Web Ads: Country Comparisons, Analysis, and Implications

Chin-Feng Lin, National Pingtung Institute of Commerce, Taiwan

ABSTRACT

This study based the means-end chain methodology aims to understand consumer cognition of mutual fund advertisements on the Internet. Through constructing the hierarchical value maps, this study focuses mainly on elucidating consumer cognition of mutual funds, revealing cross-country website cognitive structures of mutual funds, comparing the differences in cognitive structures between consumers and cross-country websites and, finally, understanding important mutual fund attributes for both consumers and website designs in terms of values. The analytical results can not only provide marketers with valuable information for designing web ad content, but also be used to develop effective marketing strategies on the Internet.

INTRODUCTION

The commercial opportunities associated with the accelerated growth the Internet have brought business into the battle for Internet advertising. According to a NetValue survey (<http://tw.netvalue.com>), approximately one-fifth of Taiwanese Internet users habitually browse financial or securities websites and complete financial transactions on the Internet. Hence, financial institutions and companies have responded to new Internet business opportunities by exploring the feasibility of web applications for further development of their businesses.

Since 1991, the National Science Foundation in the United States has encouraged the opening of the Internet for commercial use. The trade patterns of e-commerce have gradually replaced traditional one-way marketing with interactive web marketing. Internet advertising campaigns are now an inevitable trend. Thus, some business strategies have been forced to change in order to meet new web applications and developments. Through advanced Internet technologies, businesses can not only introduce or promote their products by placing text, graphics, images, animation and sound on the web, but can also process customer orders and requests immediately.

Given increasingly shorter product life cycles, business product design has focused on product development and miscellaneous product mixes, explaining the increasing diversity of investment products. Hence, satisfying target customer demands and developing effective interactive marketing strategies are the keys to business survival in this environment. In the marketing field, means-end chain (MEC) methodology proposed by Gutman (1982) is the predominant approach for analyzing the relationship between consumer product preference and value satisfaction. Such a relation enables marketers to design their products to comply with consumer preferences.

The research objects in this study are mutual fund websites. Analyzing product characteristics of mutual fund websites by applying the MEC methodology reveals consumer cognitive structures associated with these websites. Such cognitive structures demonstrate the product attributes preferred by consumers, the perceived benefits or consequences upon product consumption and how consumer value demands can be achieved in terms of attribute-consequence-value (A-C-V) chains. Understanding consumer A-C-V chains enables marketers to design effective advertisements on their mutual fund web pages. This study analyzes the survey results

to understand consumer preferences for various mutual fund attributes; the web ad contents of different sales agencies (investment trust, investment adviser, securities dealers, and banks) were compared regions, i.e. China, Hong Kong, Taiwan and the United States, to reveal differences in Internet marketing. This study focuses mainly on elucidating consumer cognition of mutual funds, revealing cross-country website cognitive structures of mutual funds, comparing the differences in cognitive structures between consumers and cross-country websites and, finally, understanding important mutual fund attributes for both consumers and mutual fund website designs in terms of values.

LITERATURE REVIEW

Origin and Development of Mutual Funds

Mutual fund investing originated in Europe, and the first pooled fund in the United States was formed for the staff and faculty of Harvard University in 1893. In 1924, the first publicly listed mutual fund was created: the Massachusetts Investors Trust. The individual retirement account introduced in 1981 contributed to the rapid development of the mutual fund since it created a new mutual fund type for employers and employees. Owing to its liquidity and easy-to-operate characters, such mutual funds are still very popular today.

According to investorwords.com (2008), a mutual fund is “an open-ended fund operated by an investment company which raises money from shareholders and invests in a group of assets, in accordance with a stated set of objectives. Mutual funds raise money by selling shares of the fund to the public and then take the money they receive from the sale of their shares to purchase various investment vehicles, such as equity, bonds and money market instruments.” Mutual funds based on specific investment vehicles include money market funds, bond/income funds, balanced funds, equity funds, global/international funds, specialty funds and index funds (Levinthal & Myatt, 1994; Chordia, 1996).

Means-End Chains (MECs)

Means-end chain (MEC) methodology is a laddering approach for linking product attribute (A), consequence (C) and value (V) in a hierarchical cognition structure for consumers (Gutman, 1982). Peter and Olson (1993) indicated that product attributes are conferred by the benefit or value cognitions of consumers upon product consumption. Restated, such attributes are means of achieving consumer desires in terms of product benefits or values.

The knowledge structure of means-end chain broadly includes personal cognitions of a particular product or brand. Different consumers may have different perspectives, prefer different product attributes, perceive different consequences or perceive different benefits upon product consumption, and all of which may result in different value satisfaction (Lin, 2003; Reynolds and Olson, 2001). Reynolds and Gutman (1988) proposed the MEC methodology for constructing consumer attribute-consequence-value (A-C-V) hierarchies. In consumer self-construction, product attribute preferences, consequence upon product consumption and value satisfaction do not link to each other; restated, there is no concrete A-C-V existing in the consumer minds. Consequently, how to elicit ab-

TABLE 1
Product attribute and attribute level

Item	Attribute (A)	Attribute level (A _i)
1	Fund numbers	Fund count
2	Fund type	<ul style="list-style-type: none"> ● Investment targets: Equity fund, Bond fund, Balanced fund, and Currency fund. ● Investment regions: Global fund, Regional fund, and a Single National fund
3	Fund manager	Gender, Years of service, Qualification, Experience, and Investment ideas
4	Time of return	One month, Three months, Six months, One year, Three years, Five years and Ten years.
5	Related fees	Processing fee, Management fee, and the Percentage of Custodial fee
6	Minimum purchase amount	Single and periodic investment amount
7	Fund size	Currency base: NT\$ 10 million
8	Currency	NT\$, US\$, HK\$, RMB\$, British Pound, and the Euro

10	Sales agency	Investment trust, Investment adviser, Securities dealers, Banks, Fund management company, Asset management company and etc.
11	Custody bank	Public sector bank, Private bank and Foreign bank

stract thoughts of consumers through in-depth interviews and transform them into concrete means-end hierarchies has become important for understanding the psychological cognitions of consumers.

Classifications of Value

The customer orientation advocates that establishing the constructs of consumer consumption processes and experiences provides information regarding consumer cognitions of product position, which can be used by marketers to formulate effective product strategies (Day *et al.*, 1979; Gutman, 1981). Practically, the cognitive structures of consumers are related to their value systems (Rokeach, 1968; Vinson *et al.*, 1977). Several researchers (Reynolds & Gutman, 1988; Gutman, 1982) have emphasized that consumer value systems can be evaluated by micro or macro perspectives. Micro perspectives focus on the connections between product attributes and consequences whereas macro perspectives focus on classifications using consumer value systems such as VALS2 (value and lifestyles 2) of SRI company (Kotler, 1997), LOV (List of Values) (Kahle & Kennedy, 1989) and RVS (Rokeach Value Survey) (Rokeach, 1968).

METHODOLOGY

Variables

Kotler (1994) asserted that a product attribute is composed of several attribute levels. Thus, this study adopted attribute level (A_L), attribute (A), benefit (B) and value (V) as the research variables to construct consumer cognitive structures.

1). Attribute level (A_L) and attribute (A): Based on investment manuals (*e.g.*, enterprise brochure, mutual fund DM, *etc.*) of mutual fund companies, this study summarized eleven characteristics (attributes). Table 1 describes the elements (attribute level) of each characteristic.

2). Consequence (benefit): According to the web ads of mutual fund sales agencies, this study summarized fourteen benefits perceived by consumers: “profession”, “tax saver”, “low investment cost”, “good performance”, “portfolio variety”, “spreading risk”, “transnational investment”, “investment as-

sistance”, “liquidity”, “well known”, “good reputation”, “large scale”, “convenience” and “safe”.

3). Value: This study directly adopted the LOV inventory developed by Kahle and Kennedy (1989) which includes the following measures: “sense of belonging”, “excitement”, “warm relationships with others”, “self-fulfillment”, “being well respected”, “fun and enjoyment of life”, “security”, “self-respect” and “sense of accomplishment”.

Questionnaire and Data Collection

Separate questionnaires were developed for individual investors and the companies with mutual fund web ads; each included three categories: A-C-V linkages of mutual funds; mutual fund attribute levels; personal or company information.

Based on the information provided by the official finance websites of China, Hong Kong, Taiwan and the United States, this study gathered data from the websites of mutual fund sales agencies and from interviews with mutual fund investors. Table 2 lists the official finance websites of the four countries.

To understand the cognitive structures of individual investors or customers, this study interviewed mutual fund investors in banks, investment trusts, securities dealers and others. Two hundred thirteen valid samples were gathered. For analysis of web ads of mutual funds, this study examined whether the sales agency has a web address, whether it sells mutual funds and whether its website provides mutual fund information to gather data from its web ads. The 145 analyzed companies or institutions included ninety companies in Taiwan, eleven in China, thirty-four in Hong Kong and ten in the United States. Each company or institution selected ten mutual funds. If the company offered more than ten mutual funds, then ten funds were randomly selected for analysis; otherwise, all company funds were analyzed. Thus, 1242 mutual funds were selected for analysis.

Analytical Method

Means-end methodology was applied by surveying consumer perspectives of a given mutual fund by in-depth interviews. Through a laddering technique, all interview data were tabulated and transformed to construct a hierarchical value map. Content analysis of the web ads was performed to reveal mutual fund attribute levels,

attributes, and the contents of benefits and values for attracting investors.

1). Category and analytical unit: In this study, the first questionnaire category was related to the A-C-V linkages of mutual funds; the benefits upon mutual fund investment were classified by fourteen items, and the nine values were directly adopted from LOV (Kahle & Kennedy, 1989).

2). Coding and reliability: Based on the 1242 web pages (web ads) for 145 sales agencies in four different regions, this study analyzed the contents of web ads by the word stems in the text of the web ads. Through content analysis, four coders exam-

ined the web ad content and classified the word stems. The mean intercoder agreement benefit and value variables were 0.868 and 0.804, respectively. The reliabilities were 0.96 and 0.94 for benefits and values, respectively, which meet the acceptable criteria proposed by Kassirjian (1977).

DISCUSSION

Data Description

Table 3 lists consumer demographics. Risk tolerance represents the acceptable net volatility of \$10 investment and the minimum annual return acceptable to an investor. Table 4 summa-

rizes the attribute levels preferred by investors. Such attribute levels can help mutual fund managers design their portfolios.

Table 5 lists the analytical results for the mutual fund institution web pages. Table 6 lists the attribute levels of individual mutual funds available on web sites and the preference percentages of investors.

Mutual Fund Cognitive Structure of Consumers and Web Pages

Based on the interview data and web ad messages, all data were entered into the summary implication matrix to construct mutual fund cognitive ladders (Attribute-Benefit-Value; A-B-V). Using the 93rd percentile as a cutoff point, the valid A-B-V linkages were used to construct a hierarchical value map (HVM) for mutual fund investors. In the HVM, the deciles 3 of these valid A-B-V linkages defined as strong, medium and weak linkages are illustrated by thick, middle and thin lines.

According to Figure 1, investors indicated that “fund type”, “fund manager”, “custody bank” and “related fee” attributes (strong linkages) were quite important investing considerations. These salient attributes may yield different perceived benefits to investors and further satisfy different value demands. For example, a given “fund type” attribute (A) can provide investors with “good performance” benefits (B) and yield “security” (V) value satisfaction. Further, a “fund manager” (A) is also important to investors for his “professionalism” (B), which increases investor “security” (V) value.

This study also examined the A-B-V linkages of mutual fund web ads across four regions (China, Hong Kong, Taiwan and the United States). The 93rd percentile was used as a cutoff point. The three deciles of these valid A-B-V linkages were also defined as strong, medium and weak linkages. In Taiwan, the web ads emphasized the importance of “fund type” and “time of return” due to considerations of “portfolio variety” and “investment assistance” benefits yielding “self-fulfillment” and “security” values (Figure 2).

Figures 3, 4 and 5 illustrate the web ads HVM for Hong Kong, Mainland China and USA, respectively. Different regions may have different emphases in their mutual fund web ads due to different investor desires of value satisfactions.

Comparisons of Investor Cognitions and Web Ads Offering

In Taiwan, both investors and mutual fund web pages emphasized the importance of “security” and “sense of belonging” value achievement (Table 7). For investors, “fund type”, “fund number”, “fund scale”, “time of return”, “fund manager” and “custody bank” attributes may yield “portfolio variety”, “spreading risk”, “profession”, “good performance”, “well known”, “good reputation”, and “large scale” benefits satisfying their “security” value demand. However, for the web ads to achieve investor “security” value satisfaction, “fund type”, “time of return”, “currency”, “fund manager”, and “sales agency” are more important attributes to help investors obtain “portfolio variety”, “spreading risk”, “transnational investment”, and “investment assistance” benefits were considered

most important. Further, to achieve “sense of belonging” value, investors who perceived the “related fee” attribute as offering a “low investment cost” benefit. Web ads, conversely, expected that “fund manager” attributes provide a “professional” image for investors. Additionally, from the investor perspective, “fund type”, “time of return” and “fund manager” are means of achieving their “sense of accomplishment” value desire whereas web ads are expected to provide investors with “excitement” and “fun and enjoyment of life” value satisfaction.

Comparing the web ads of China, Hong Kong, Taiwan and the United States revealed that “sense of accomplishment”, “fun and enjoyment of life” and “security” messages were the ultimate values that businesses try to deliver to their investors (see Table 8). In the “sense of accomplishment” message delivery, web ads use “fund manager”, “sales agency”, “time of return”, “related fee” and “fund type” attributes offer “convenience” and “investment assistance” benefits to attract investors. Moreover, web ads in four regions emphasize the importance of “sales agency” to obtain the “convenience” benefit, which yields “fun and enjoyment of life” value. Notably, the U.S. web ads were the only ads that attempted to deliver “being well respected” value to the public investors.

Based on the previous analytical results, this study further used the fund attributes investors and web ads preferred the most to construct an extended HVM. The extended HVM can not only demonstrate the most important A-B-V linkages but also shows more detailed attribute characteristics referred to here as “attribute levels.”

Figure 7 illustrates that “fund type”, “fund manager” and “custody bank” were the most important fund attributes for both investors and web ads designs. To examine further, the author found that “equity funds (A_L)” and “global funds (A_L)” were the two “fund types (A)” most preferred by investors because of their “good performance (B)” leading to investors’ “sense of accomplishment (V)” value satisfaction. Investors also care about the “investment idea (A_L)” and “qualification (A_L)” of “fund manager (A)”, be-

cause these two attribute levels can show the “profession” of fund managers and then attain “sense of belonging” and “security” values of investors. Moreover, investors believed that the “public sector bank (A_L)” is more trustworthy than “custody bank (A)” for investment. It provides “safety (B)” and “security (V)” to investors. Thus, the extended HVM provides marketers with more precise data regarding the product characteristics preferred by investors than the original HVM does.

For the mutual fund web pages across the four regions in Figure 8, “equity funds (A_L)” and “a single national fund (A_L)” are the emphasis of “fund type (A)”, because of the “investment assistance (B)” benefit and “security (V)” value achievement. On the web pages, the “time of return (A)” includes “one month (A_L)”, “three months (A_L)”, “six months (A_L)”, “one year (A_L)” and “three years (A_L)”. These fund-attribute levels yield “portfolio variety (B)” benefit and lead to “security (V)” and “sense of accomplishment (V)” value satisfaction.

CONCLUSION, LIMITATION, AND FUTURE RESEARCH

The Internet pervades daily life. On-line transactions are now common for purchasing products and services. On-line transactions involve no real shops-entities. Hence, web ads are important for attracting customers or investors. Whether the ads can communicate with target investors and whether such ads can effectively adhere to investor needs is now an important issue in web page design. Based on the analytical results, the suggestions for web designers of mutual fund are shown as followings:

- 1). Investors: Most fund attributes, benefits and values preferred by investors are exactly as shown on fund web pages. However, the interviews revealed that many investors were disappointed by the low rates of return on their fund investments. Consequently, they felt that their fund investments had accomplished little. Thus, mutual fund managers may con-

FIGURE 7
The extended HVM of investors

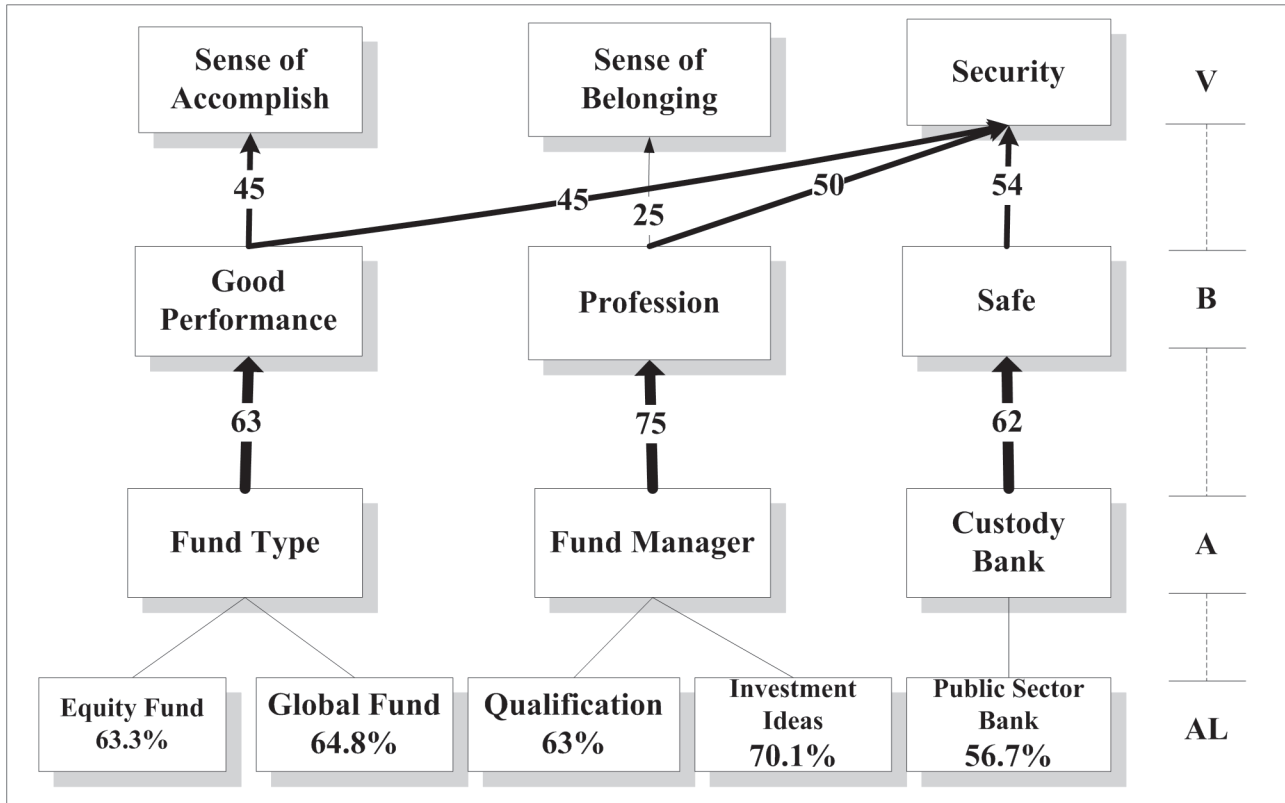

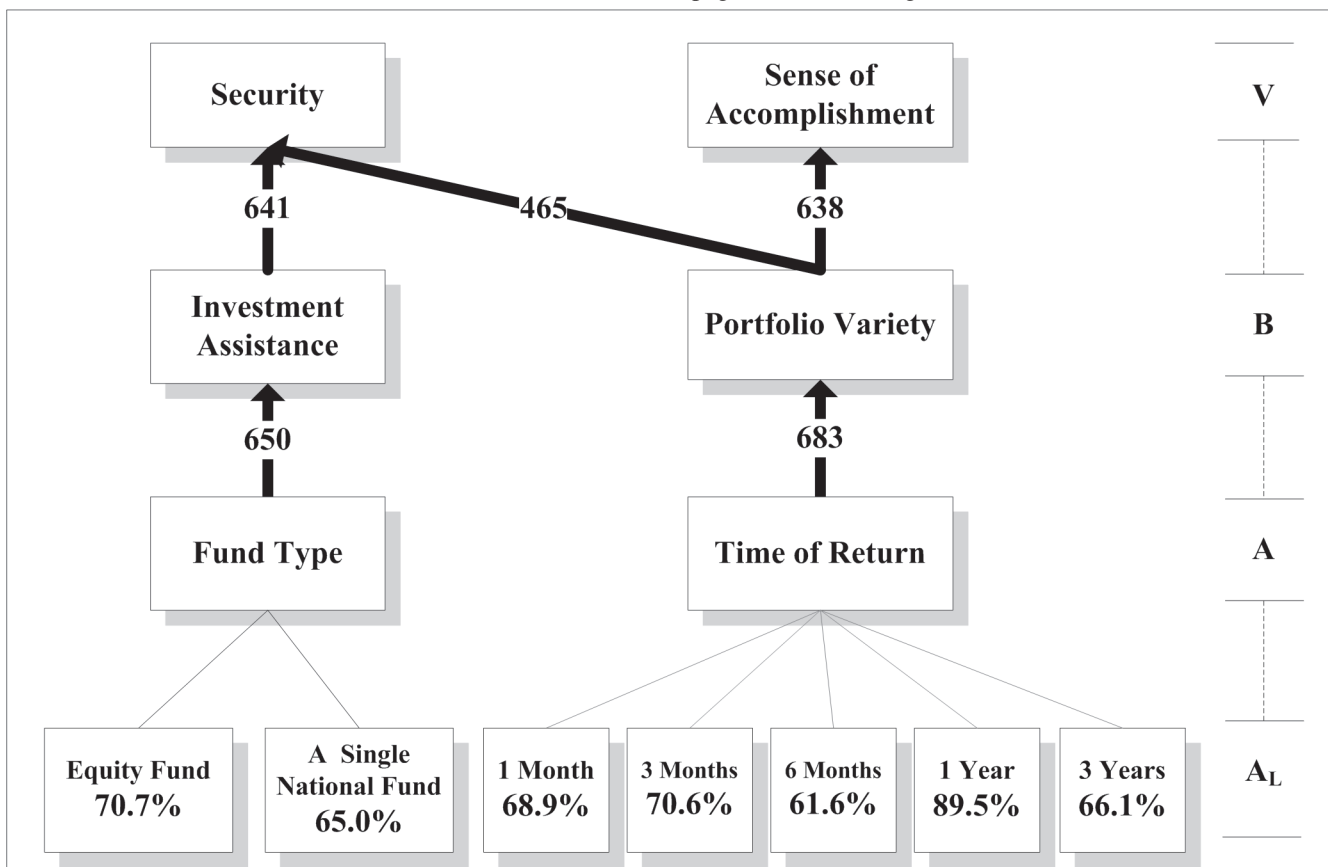

FIGURE 8
The extended HVM of fund web pages across four regions

sider providing investors with more positive and persuasive news to encourage them in the dynamic environment.

2). China: Chinese websites lacked key information. The web designers may consider adding more fund-attribute information such as "currency" and "minimum purchase amount" and content which provides investors with value satisfaction such as "excitement" and "sense of belonging".

3). Hong Kong: In this study, Hong Kong was the only region that provided complete fund attributes on the web pages. The web designers may need to enhance their web pages by delivering "sense of accomplishment" and "being well respected" messages to their target investors.

4). Taiwan: Web designers can refer to USA web ads for adding the element of "being well respected" to investors. Also, designers may consider including messages regarding "minimum purchase amount" and "good performance" in their web ad designs.

5). United States: The USA web pages provided investors with the most information in achieving investors' value satisfaction. The web page designs may require more information about the benefits of investing in funds such as "spreading risk" and "good performance" of certain funds.

This study compared the web ads of only four regions. Therefore, the analytical results cannot be generalized to global web ad design. Future researchers may consider increasing the number of research objects in various countries or adopting an individual country as a research object to make a cross-national comparison. Furthermore, investment products are significantly influenced by dynamic economy. Hence, comparing the contents of cross-nation HVM toward a give investment instrument in different stage of economic dynamics can help business understand the timing for developing effective promotion or advertising strategies. Additionally, fund investments are only one investment instrument. Other financial products require further comparisons in order to provide investors with valuable information for investment.

Status within a Consumption-Oriented Counterculture: An Ethnographic Investigation of the Australian Hip Hop Culture

Damien Arthur, University of Adelaide, Australia

Claire Sherman, University of Adelaide, Australia

ABSTRACT

This study identifies the determinants of status within a consumption-oriented counterculture. The results of an ethnographic study of the Australian Hip Hop culture suggest that embodied subcultural capital and subculture-specific social capital confer status on countercultural members. In contrast to previous findings, these two forms of capital were found to more consistently confer status than a member's commitment to the culture's consumption values or their commitment of time and resources. This distinction is most prevalent amongst hard-core members who vary in both levels of commitment and their objectification of subcultural capital. Theoretical and managerial implications are discussed.

The purpose of this study is to explore the nature of status within a consumption-oriented counterculture. The paper begins with a review of the literature, specifically that which deals with the nature and structure of consumption-oriented countercultures and their relationship with subcultural capital. An overview of the methodology, a four-year ethnographic study of the Australian Hip Hop culture, is then provided. An analysis of the findings which identify the determinants of status within a consumption-oriented counterculture follows, and a discussion of the theoretical and managerial implications concludes the paper.

LITERATURE REVIEW

Consumption-Oriented Countercultures

Consumption-oriented countercultures are entities that provide space for members to develop and express their self-concepts alongside other members with similar interests, while at the same time allowing them to position their unique values, attitudes and opinions against the dominant and mass culture. Consumption-oriented countercultural theory emerged in the 1970's, largely from researchers at the Birmingham Centre for Contemporary Cultural Studies who investigated the punk (Hebdige 1979), mod (Hebdige 1975), motorbike boy (Willis 1978), ted (Jefferson 1975), skinhead (Clarke 1975a), and hippy (Willis 1975, 1978) cultures.

These studies found that members of countercultures consumed distinctive, yet uniform styles opposing the dominant and mass cultures which they found to be politically manipulated and undifferentiated (e.g. Clarke 1975a; Hebdige 1979; Willis 1978). In doing so, counterculture members consumed in a manner which strictly adhered to their counterculture's rules and expressed their allegiance to the counterculture's values and attitudes (Clarke 1975b). The expression of a culture's values through the consumption of a style that closely parallels the culture's ideology has been termed 'homology' and was the focus of many of the early counterculture studies (Willis 1978). For example, Willis (1978) found that 'the motor-bike boys' did not dress with the functional requirements of riding a motor cycle in mind, instead their dress was found to be a formidable expression of identity which was powerfully developed around many of the culture's central values. Similarly, homologous relationships were also found between the values of the hippy, ted, punk, skinhead and mod cultures and their members' consumption habits (Clarke 1975a; Hebdige 1975, 1979; Jefferson 1975; Willis 1978).

While more recent studies of consumption-oriented countercultures have not focused specifically on their homologous nature, their results tend to support the earlier findings and describe a homologous relationship between the consumption of the subculture's members and the values of the group (Arthur 2006a; Kozinets 2001; Schouten and McAlexander 1995). For example, Schouten and McAlexander's (1995) ethnography of the new bikers found that the core values of the counterculture were based around personal freedom, patriotism and machismo, and were visually expressed through the consumption of long hair, bushy beards, loud powerful bikes, the American flag, the bald eagle, tattoos and black leather. One exception, a study by Kates (2002), found that no single homologous style existed in the gay community. Instead, Kates found consumption to be characterized by a multitude of shifting, malleable meanings open to multiple interpretations and considerable debate. Hence, unlike the consumers presented in previously mentioned studies, these subcultural members did not sacrifice creative self-expression in order to communicate their belonging to a group, they accomplished both simultaneously.

The Structure of a Consumption-Oriented Counterculture

Consumption-oriented countercultures have been found to be comprised of individuals who vary in their level of identification and commitment, with some members being very closely tied to the group and others being only peripherally related (Fox 1987; Hebdige 1979; Kates 2002; Schouten and McAlexander 1995). Fox (1987) first described the structure as a series of three concentric circles based on one's level of commitment to the subcultures ideology. Those participants most heavily committed to the counterculture were located within the most inner-concentric circle and hence became known as the hard-core members.

Hard-core members devotion and commitment to their counterculture's values has been found to be a full time and enduring process, and can represent a major dimension in their lives and conceptualization of self (Fox 1987; Hebdige 1979; Schouten and McAlexander 1995). As such, previous studies suggest that hard-core members must be relatively uncommitted to other cultural groups, and have the freedom and spare time to devote themselves wholly to the counterculture's cause (Irwin 1973). In contrast, the next concentric circle consists of 'soft-core' members whose commitment to the subculture is less complete and whose roles are subordinate to, and dictated by, the hard-core members. While these individuals are less dedicated to the subculture, their degree of involvement with the subculture is still high, though not necessarily enduring. As such, while they outnumber the hard-core members, they are less respected and do not occupy the same social status or demand the same level of influence (Fox 1987). Furthermore, soft-core members tend to be more interested in the symbolic qualities of the products, brands and activities consumed than their functional attributes, as they rely on such consumption to communicate their self and group identity to others.

In her study of the punk counterculture, Fox (1987) described the outer circle of peripheral members as 'preppie punks'. While these individuals frequent the countercultural site and consume in a homologous fashion, the hard and soft-core members do not necessarily see them as part of the subculture as they lack the

ideological commitment. These individuals are often only interested in the counterculture for the novelty it provides and because, at a particular point in time, it is deemed fashionable. As such, for many it is seen as a passing fad, or a bit of light relief from the monotonous but none the less paramount realities of school, home and work (Hebdige 1979). Hence, these members treat such subcultural experiences as identity play and are able to quickly abandon their associations in situations that would sanction them negatively.

Whilst the framework for viewing the structure of a consumption-oriented counterculture as three distinct categories has received much academic support (e.g. Fox 1987; Schouten and McAlexander 1995), Kates (2002) suggests that such a categorisation imposes a fixed, rigid structure that does not resemble the reality of the neo-tribal consumer (Maffesoli 1996). In contrast, Kates found an individual's position in the gay community to be based on a fluid, contested and negotiated assessment of the individual's accumulated subcultural capital.

Subcultural Capital

In her study of club cultures, Thornton (1995) coined the term subcultural capital to describe the knowledge, experience and skills that bestow status within a subculture. Her work is guided by that of Pierre Bourdieu, and specifically his book 'Distinction' (1984), in which he used the term 'cultural capital' to describe the knowledge that is acquired through our upbringing and education and which confers status and enhances one's standing within society. Bourdieu conceptualized the structure of society as being dictated by the consumption of markers of distinction which affirm one's taste. While Thornton has been credited for taking the concept out of the realm of 'high class' consumption via her definition (Bennett 1999; Kates 2002), a closer reading of Bourdieu (1984) reveals that he did not mean for the term to be so confined. In fact, throughout his work he argues that in all fields, including subcultures, a system of differences exists where expressive consumption and social differences are made explicit.

Expanding on the concept in a later article, Bourdieu (1986) argues that capital can present itself in three fundamental forms: as cultural capital, economic capital and social capital. Cultural capital, being the knowledge one has acquired that is expressed through one's taste, can be found in three states: embodied, objectified, and institutionalized. Embodied cultural capital is the knowledge, skills and expertise that exist within an individual that is acquired through the process of education, both formal and informal. This may be expressed through an understanding of a culture's values, rituals and traditions. For example, within high class culture good manners and an appreciation and understanding of fine art and wine are examples of embodied cultural capital (Bourdieu 1984). In contrast, amongst Thornton's (1995) ravers, subcultural capital was embodied in the form of being 'in the know,' understanding and using current slang and performing the latest dance styles. The accumulation of such embodied cultural capital presupposes a personal cost of time and other sacrifices and cannot be transmitted easily or instantaneously (Bourdieu 1986). It can however be acquired over time, and the accumulation can be hastened if one has freedom from other commitments.

Once one has acquired embodied cultural capital, it may be objectified through the consumption of symbolic goods that infer such knowledge. For example, in the high class culture the display of books and paintings in the family home constitute objectified cultural capital. Alternately, in Thornton's (1995) rave culture, subcultural capital was objectified in the form of fashionable haircuts and carefully assembled record collections. Hence, knowledge of the symbolic properties of goods and consumption styles is an example of embodied cultural capital, whereas the consumption

of these symbolic goods is an example of objectified cultural capital. Economic capital will facilitate this process, however, knowing what products to consume and the manner in which to consume them to enhance one's standing in society requires the accumulation of embodied cultural capital (Bourdieu 1986). Lastly, institutionalized cultural capital is expressed in the form of qualifications which are presumed to guarantee cultural capital, such as formally recognized education (Bourdieu 1986).

In addition to cultural capital, Bourdieu (1986) describes social capital as the value that is created through the use and influence of social networks. The value created is dependent on how much cultural and economic capital is created upon mobilizing one's social network. Hence, those with many and/or powerful connections have an abundance of social capital and an elevated status within society.

As explained, each of these forms of capital may be used to enhance status; yet, the majority of research investigating the structure of consumption-oriented countercultures has overlooked this finding and assumes commitment to be the primary determinant of one's position in the status hierarchy. The findings presented in this study address this gap. The Australian Hip Hop culture was selected as it is a counterculture firmly rooted in the consumer based objects of music, clothes and symbols. Furthermore, previous research has shown it to be excellent site for gaining insights into the symbolic consumption practices of countercultural members (Arthur 2006a, b; Chalmers and Arthur 2008; Maxwell 2003).

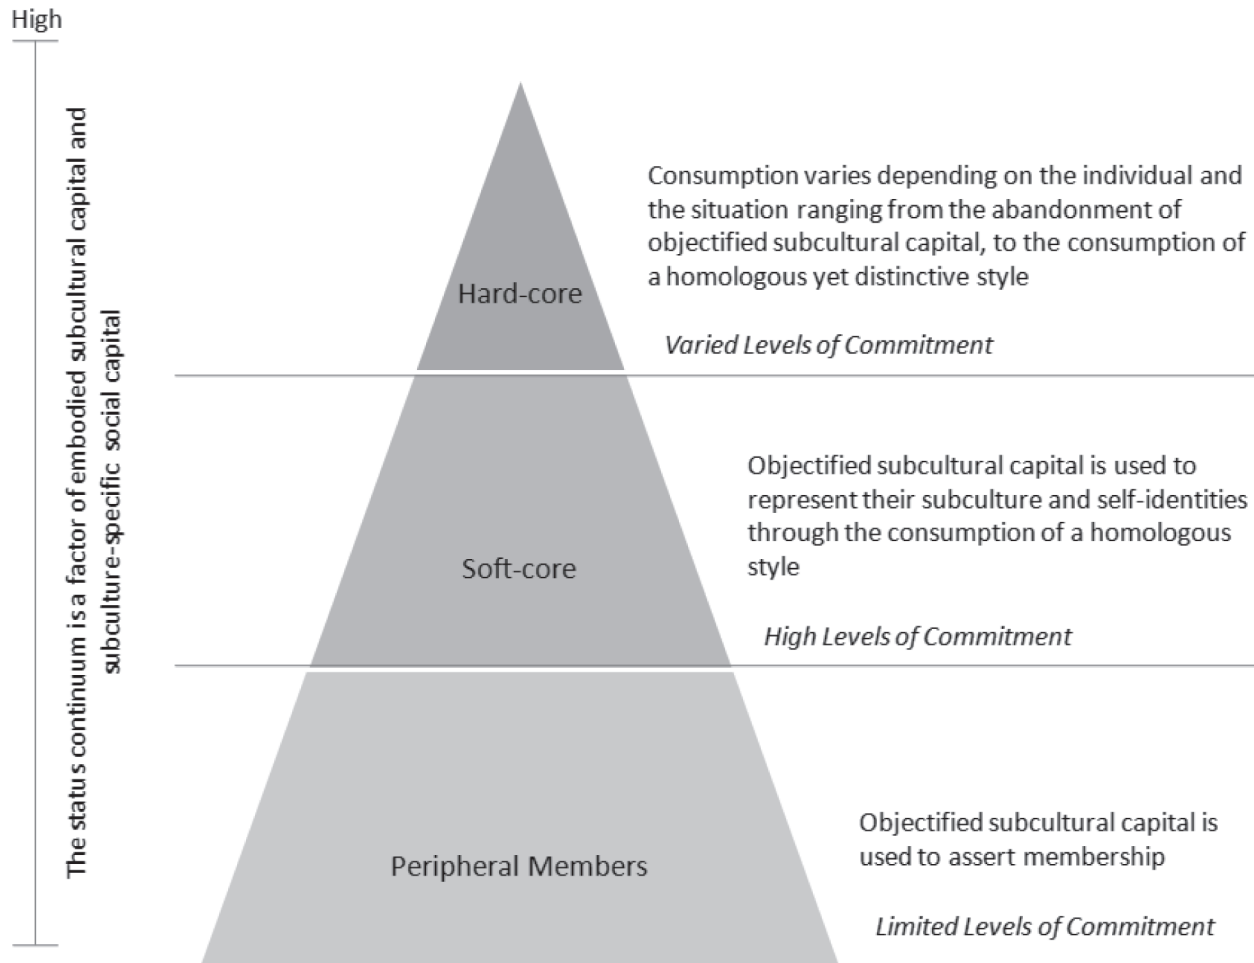

METHODOLOGY

Status within the Australian Hip Hop culture was investigated using five methods of ethnographic research: prolonged participant observation, researcher introspection, semi-structured in-depth interviews, non-participant netnography, and an ongoing review of the literature. Ethnography was chosen as this approach has been found to be particularly effective when little is known about a targeted group (Mariampolski 2006). A grounded approach to theory generation was utilised as it is the standard approach adopted by ethnographers and has been acknowledged to have considerable potential within the field of consumer behaviour (Goulding 1998).

The first author undertook the ethnographic research between June 2002 and June 2006. Extended presence and participation in the field allowed the researcher to 'learn the language' of those under investigation, and to experience life as one of the subjects (Elliott and Jankel-Elliott 2003). The Hip Hop culture revolves around four key activities: rapping, graffiti art, breakdancing and DJing. An Adelaide Hip Hop DJ who was an acquaintance of the researcher facilitated initial entry into the Hip Hop culture in Australia and the researcher accompanied the gatekeeper and a number of his friends to around 150 Hip Hop nights held across Adelaide, and around Australia. In addition, the researcher accompanied the gatekeeper through a wide variety of contexts that Agar (1996) would describe as 'hanging out' such as playing records, playing basketball, watching television, shopping, socialising, drinking and partying.

Becoming a member of a counterculture meant entering as an aspiring member and undergoing a process of socialisation whereby status was obtained. Hence, the nature of the ethnographic process was evolving, which allowed the researcher to interact with different elements of the counterculture and to experience the signifying practices of Hip Hop consumption as an insider. During this period, the researcher kept field notes of his observations and informal conversations, which were then written up as soon as possible after the event. Furthermore, the researcher kept a personal diary of the process, which was a useful record of his cognitive and emotional

FIGURE 1
Status Within A Consumption-Oriented Counterculture

experience, and allowed him to conduct personal introspection (Elliott and Jankel-Elliott 2003; Shankar 2000).

During the course of the study, 30 semi-structured in-depth interviews with peripheral, soft-core and hard-core members of the Australian Hip Hop culture were undertaken. The researcher utilised guided introspection to obtain the necessary data: as he had obtained membership status himself, a good rapport with the interviewees was established, and hence the information was of quality (Elliott and Jankel-Elliott 2003; Shankar 2000). This technique was chosen as it has been found to be particularly useful when cultural categories are under investigation (McCracken 1988; Wells 1993). Furthermore, netnographic research of a web forum regularly visited by members of the Australian Hip Hop culture www.ozhiphop.com was conducted using the methods prescribed by Kozinets (2002b).

The researcher's field notes, personal diary, interview transcripts and netnographic threads were imported into QSR N6 for coding. Selective coding was used to synthesise and relate data to conceptual topics of interest, such as subcultural commitment and symbolic consumption. This process ensured that the resulting interpretation reflected persistent themes, and enhanced the researcher's familiarity with the data, thus facilitating the derivation of meaning (Pettigrew 2002). Finally, every effort has been made to conduct the ethnographic investigation into the Australian Hip

Hop culture in an ethical manner and as such the names of all the participants have been changed.

FINDINGS

The subculture investigated was inherently countercultural in nature. It provided members with the opportunity to develop and express their unique and local identities alongside likeminded individuals and to position their values, attitudes and opinions against the dominant and mass culture. In addition, the Australian Hip Hop culture was found to be a gender salient, neo-tribal, male enclave where the rebel model of masculinity was enacted (Arthur 2006c; Holt and Thompson 2004). Furthermore, it should be noted that the predominantly white members of the Australian Hip Hop culture overcome their race and claimed Hip Hop authenticity via proficient knowledge of and respect toward the culture, and truthful representation of their identity (Arthur 2006a).

The overall findings of the ethnographic research have been summarised and presented in Figure 1. The analysis revealed that one's position within the counterculture's status hierarchy was a factor of one's embodied subcultural capital and subculture-specific social capital. Hence, over time, as individuals advanced their Hip Hop skills and acquired further Hip Hop and specifically Australian Hip Hop knowledge, their status within the Australian Hip Hop community was enhanced. This discovery supports previ-

ous findings which suggest that subcultural capital confers within-group status amongst countercultural participants (Kates 2002; Thornton 1995b). However, the results of this study further our understanding of the nature of status within consumption-oriented countercultures through the inclusion of subculture-specific social capital as a determinant of status. That is, the findings revealed that the standing of an individual's social connections and the individual's ability to influence them also had an impact on their position in the status hierarchy. For example, personally knowing a well-respected DJ enhanced one's standing in the status hierarchy, and securing his services for a party advanced one's standing further.

In addition, the results of this study further our understanding of the phenomenon by revealing that the objectification of subcultural capital through consumption was not necessarily more common as one's status advanced. That is, while Thornton's findings were mirrored in that both embodied and objectified subcultural capital conferred status, only embodied subcultural capital was found to be consistently associated with one's position within the status hierarchy. In contrast, the use of objectified subcultural capital as a marker of distinction varied as individuals evolved through the status hierarchy. Peripheral members used objectified subcultural capital to assert their membership, whereas soft-core members were found to use objectified subcultural capital to represent their culture through homology. In contrast, the consumption of objectified subcultural capital for hard-core members was found to vary depending on the individual, as illustrated in the following quote by hard-core member Kab:

Kab: People who get involved in something, anything they feel passionate about, once they get to a point of being sort of accepted, say socially in those kind of groups, and they're doing something of a quality level, there's no need for any kind of identity clothes-wise... Some of the best dudes that do graffiti, you could not pick them out in the crowd man. They just wear nothing that's related to Hip Hop. Usually the better ones go into other areas as well because they don't feel confined by subculture. That's basically what happens, as people get older and better they tend to sort of move into other areas as well. And then there's guys who are into Hip Hop one hundred per cent, four element theory, all that stuff, dress that way and they're wild writers as well.

It should be noted that whilst Figure 1 presents the findings as if an individual progresses through a structured transformation commencing as a non-member and culminating with hard-core membership, the researcher rarely found himself or others being placed in such distinct, fixed and rigid categories by the countercultural participants. Rather, as individuals furthered their Hip Hop skills and knowledge, and advanced social relationships with Hip Hop members, their status within the Australian Hip Hop culture was enhanced. Henceforth, status within the Australian Hip Hop culture was viewed as a continuum ranging from those individuals with no embodied subcultural capital or subculture-specific social capital to those with an abundance of it. Furthermore, an individual's position in the status hierarchy was found to be fluid, contested, frequently negotiated and dependent on the individual making the evaluation. That is, gauging one's status was in effect an approximation of one's accumulated skills and knowledge and the value of one's social network. These approximations were often revised as new information came to hand that provided a more accurate indication. In addition, evaluations of both subcultural capital and subculture-specific social capital varied considerably depending on the subcultural capital of the individual making the

assessment. Hence, while an individual's subcultural capital and the extent and influence of their social network may have remained constant, perceptions of their position in the status hierarchy differed depending on the Hip Hop knowledge of the individual making the evaluation. As such, an individual's position within the status hierarchy frequently moves up and down as different members make and revise assessments of their capital, however, over time, as they expand their network, advance their relationships, and further their Hip Hop knowledge and skills, they generally advance up the hierarchy. While the structure encountered was more fluid and negotiated than the three distinct groups reported by Fox (1987) and Schouten and McAlexander (1995), these broad categories did exist, and as such, as displayed in Figure 1, have been transposed upon the status continuum to enhance the analysis of consumption as an individual evolves through the status hierarchy, and to enable the comparison of findings with previous studies.

The results presented in this study, specifically that one's position within a consumption-oriented counterculture was dependent on one's embodied subcultural capital and subculture-specific social capital, is in contrast to previous research findings by Fox (1987) and Schouten and McAlexander (1995). As previously discussed, their findings suggest that one's position in the status hierarchy is dependent on one's commitment to the ideology and consumption values of the counterculture. As such, these studies found that for hard-core punks and bikers, participation was a full-time commitment that was displayed conspicuously in a homologous style, such as through the consumption of amphetamines and mohawks, or a Harley Davidson and associated garb. While these studies should be commended for drawing our attention to the evolution of a subcultural self, their theory could not be applied to the current case for two reasons. First, within the neo-tribal Australian Hip Hop culture a full-time commitment was not a necessary requirement of hard-core membership. Whereas the hard-core punks and bikers were found to have looked down upon those with a less than full-time commitment (Fox 1987, Schouten and McAlexander 1995), part-time participation was accepted within the Australian Hip Hop culture, as it was for Goulding, Shankar and Elliot's (2002) ravers. While the results show that a full-time commitment to the culture's ideology was the norm for soft-core members, and this commitment increased steadily as they had progressed through the status hierarchy, hard-core members were found to be more likely and capable of compartmentalising their work, family and leisure. As a number of the hard-core members had aged beyond their teens and early twenties, the responsibilities of work and family had, for many, encroached on their countercultural lifestyles. Furthermore, the leisure pursuits of hard-core members had often broadened beyond Hip Hop. These hard-core members were still admired and respected for their embodied subcultural capital and subculture-specific social capital, despite their current lack of full-time commitment. Hence, the results suggest that a near full-time commitment was necessary for members as they climbed the countercultural hierarchy as much time and effort was required to enhance their subcultural skills and knowledge, and to develop and nurture social relationships with other Hip Hop members. In contrast, hard-core members had already obtained much embodied subcultural capital and the amount of time required to keep these skills and knowledge up-to-date was less substantial. Similarly, their social networks were well established and their maintenance required a less significant time contribution by comparison. Hence, hard-core members' abundance of embodied subcultural capital and subculture specific-social capital exonerated them from the full-time subcultural commitment required for gaining Hip Hop knowledge and skills, and developing social relationships.

In addition, the results of this study show that in the case of the Australian Hip Hop culture one's commitment to the subculture's consumption values did not necessarily increase as one advanced up the status hierarchy. Once again, this contradicts the previous findings by Fox (1987), and Schouten and McAlexander (1995), where hard-core members were found to display their extreme commitment to the subculture's values through the consumption of a homologous style. In the current study, commitment to the subculture's consumption values heightened as members advanced through the peripheral and soft-core membership stages, but varied considerably once an individual had achieved hard-core membership. As indicated in Figure 1, due to their abundance of embodied subcultural capital and subculture-specific social capital, it was not necessary for hard-core members to display extreme levels of commitment to the subculture's consumption values. Rather, commitment to the subculture's consumption values was found to vary depending on the individual.

The results of the analysis were consistent with the views of the countercultural participants who flatly rejected the assertion that one's position in the status hierarchy was in part determined by one's commitment to the culture's consumption values. Members perceived Australian Hip Hop to be a masculine and esoteric counterculture and members remarked that status based on one's consumption habits implied shallow, weak, conformist and feminine qualities. In contrast, the assertion that a subcultural hierarchy was based on one's Hip Hop knowledge and skill was met with strong support. In fact, on occasions, members of the Australian Hip Hop culture referred to 'Hip Hop knowledge' as being the fifth element of Hip Hop culture (in addition to DJing, MCing, graffiti, and break-dancing), an interpretation that was promoted by Hip Hop DJ and Pioneer Afrika Bambaataa (2008). As such, obtaining a basic understanding of Hip Hop's history was viewed as an essential criterion for Hip Hop membership and having an advanced knowledge of Hip Hop history enhanced one's position in the hierarchy. Take the following extract from an interview with OB MC for example:

OB MC: It's poisoned man... You've got kids coming out of school that are listening to all that poof, that real faggot shit... It's really destroying our culture, because music like that has got no culture. I want to see 50 Cent here in front of me, I'll give him a spray can and tell him to do me a piece or I'll put him on a deck and say scratch to this beat, he wouldn't know what's going on, and I think that's wrong. To get into Hip Hop, the real Hip Hop, you've got to know the elements, you've got to know who started it, you've got to know who Grandmaster Flash is, who Afrika Bambaataa is. You've got to appreciate the thing you're in not just because it's great to be in, but you've got to pay homage, you've got to pay respect to the people that invented it, you've got your KRS-Ones, you know people like that, there should be temples man where people can go and pray to these fucking people, you know what I mean? I think you're missing the point if you don't know who these people are and who's done this, or who was the first person to scratch, or who was the first person to do a blockbuster piece, you know? Who the first person was to ever do a train, who was the first person was to do a tag in New York, or in the Bronx, the first break dancing crews, you know what I mean?

Throughout the interview OB MC reveals that he treats seminal people, places and events in Hip Hop history with what Belk, Wallendorf, and Sherry (1989) would describe as sacred reverence. Such an admiration was common amongst hard-core Hip Hop

members. Participation in the culture with ignorance of such valued knowledge, or a lack of Hip Hop skill, was perceived as inauthentic and profane as it failed to differentiate the Australian Hip Hop culture from the mass culture (personified by artists such as 50 Cent) which members positioned themselves against. Hence, OB MC perceives individuals who partake in Hip Hop with a lack of Hip Hop skills and understanding of the culture's history and values as non-members who are 'missing the point' and threatening the subculture's legitimacy. As such, esteem was placed upon members based on the assessor's perception of the individuals Hip Hop knowledge and skills. Hence, in the above example embodied subcultural capital explained one's standing within the community rather than one's commitment to culture's ideology and consumption values. While this may not have been the case in previous studies that link one's commitment to the counterculture's consumption values to one's position in the status hierarchy (Fox 1987; Schouten and McAlexander 1995), it is possible that the researchers have misinterpreted their findings and confused simultaneity between the two constructs with causation, particularly as one evolves through peripheral and soft-core membership stages. For example, Schouten and McAlexander's (1995) reading of the seniority, participation, leadership in group activities, and riding experience as commitment, could have just as easily been interpreted as the informal education necessary to have acquired much embodied subcultural capital. Similarly, the visible indicators of commitment described in the study (tattoos, motorcycle customisation, club-specific clothing, and sew-on patches), could easily have been interpreted as the objectification of subcultural capital by soft-core members and a limited number of hard-core members. In fact, Schouten and McAlexander (1995) even provide some indication that a small number of the hard-core bikers had abandoned the use of objectified subcultural capital or were consuming in a homologous yet distinctive style of consumption as they were 'at liberty to deviate from established customery and create individual styles' (p.56).

DISCUSSION

The findings from this study make several important contributions to consumer research. The identification of embodied subcultural capital and subculture-specific social capital as determinants of status enhances our understanding of status conferral within consumption-oriented countercultures. That is, in addition to one's knowledge and skills, the value of one's social network will enhance one's position in the status hierarchy. Hence, a well-connected and influential countercultural member is capable of playing a pertinent role in shaping the consumption values of the counterculture. Also, hard-core members have been found to be opinion leaders (Donnelly 1981), and are often identified and targeted by marketers due to their influence, thus practitioners would also be advised to look for more than the skills, knowledge and expertise that a member possesses and also consider the breadth and power of their connections within a counterculture. Furthermore, researchers should theorize status within consumption-oriented countercultures in light of this new status continuum. In addition, future studies should verify whether a similar status continuum exists in brand-focused and non-brand focused consumption-oriented subcultures that are not countercultural in nature.

The findings outlined here differ from previous studies as they have identified embodied subcultural capital and subculture-specific social capital as the determinants of status within consumption-oriented countercultures rather than a member's commitment of time, effort and resources, or their commitment to the culture's

consumption values. In a practical sense, this theorization is not necessarily problematic as a commitment of time, effort and resources will often facilitate the achievement of the relevant knowledge, skills and expertise. Thus the two processes are often paralleled. However, it should be noted that both the input and outcome are not the same. Much like economic capital, commitment of time and effort may help to achieve embodied subcultural capital, but alone does not necessarily generate the skills, knowledge and expertise that are valued. Thus, a highly committed member does not necessarily have the most embodied subcultural capital and members with an abundance of embodied subcultural capital are not always the most committed. This is an important theoretical distinction and contributes to a more accurate definition of the hard-core member. In addition to time and effort, the findings suggest that a commitment to the consumption values of the culture is not a necessary requirement for hard-core members. This finding has implications for consumer research as it refocuses the importance of consumption values to the earlier stages of subcultural membership.

The results also suggest that a distinction between embodied and objectified subcultural capital is important as both forms have different effects on status as the individual moves along the status continuum. Where embodied subcultural capital maintains a positive relationship with status, the objectification of subcultural capital does so only at the peripheral and soft-core membership stages. Moreover, hard-core members' objectification of subcultural capital varied considerably ranging from an abandonment of symbolic consumption through to the consumption of a homologous yet distinctive style. As hard-core members are most influential in disseminating countercultural styles, marketing practitioners should engage hard-core members who continue to consume the homologous style to endorse their Hip Hop brands. Furthermore, as hard-core members who continued to consume the homologous style did so in a way that differentiates them from the group, new lines of Hip Hop brands will have great appeal to these hard-core members as they provide a means for consumption that is simultaneously expressive of the subculture, yet distinguishes them as unique.

In conclusion, the purpose of this study was to explore the nature of status within a consumption-oriented counterculture. Our ethnographic investigation of the Australian Hip Hop culture identified embodied subcultural capital and subcultural-specific social capital as the determinants. How embodied subcultural capital was attained influenced its ability to act as a differentiating symbol. In addition, this study found that an individual's commitment and use of objectified subcultural capital did not necessarily enhance as one's position in the status hierarchy advanced. Theoretical and practitioner implications were discussed.

“Pixelize Me!”: A Semiotic Approach of Self-digitalization in Fashion Blogs

Gachoucha Kretz, HEC School of Management, France

ABSTRACT

Drawing on Jensen Schau and Gilly’s findings (2003) on self-presentation on personal webspaces, the purpose of this research is to get a better description of how consumers self digitalize on personal webspaces using specific digital stimuli. Using a semiotic approach on fashion blogs, we demonstrate that consumers self-digitalize to generate authenticity, caricature, fiction or artefact. Strategies employed pertain to exemplarity, “mise-en-scène”, “digital likeness” or “brand overwhelming”. Possible impacts on brand relationship management are further developed, for example, brand-consumer association through self-stereotypes.

INTRODUCTION

Consumption markets have become a place where consumers serve identity projects (Belk 1988; Holt 2002; Levy 1981) through the consumption of “mythic and symbolic resources” (Arnould and Thompson 2005). Favourite possessions help consumers self-present. Self-presentation may be defined as the performance of actions that “symbolically communicate information about the self to others” (Schlenker 2003) and therefore, as a meaning making process about the self. Accumulating specific possessions may thus carry symbolic meanings that influence the responses of others to self and help self-presentation goals. Literature building on the relationship between possessions and self-construal has mainly considered material possessions (Belk 1988).

However, Jensen Schau and Gilly (2003) have demonstrated that possessions need not be physically material to digitally present the self. Indeed, whereas possessions need to exist physically in the Real Life, constructing a “telepresence” to readers on personal webspaces only requires digital elements consumers do not necessarily possess in the Real Life. Consequently, carefully selected digital items help consumers present a desired “digital self” (Jensen Schau and Gilly 2003) on personal websites. However, even if the authors mention the digital elements used as usually taking the shape of “digital stimuli”, hyperlinks, products and brands, they do not provide further detail on their nature, form, presentation or combination on personal webspaces, and even more important, on their possible meaning.

Personal web sites appear as a “playground for postmodern personalities” and thus appeal to the consumers whose aim is to “invest time to create and maintain identities” (Marcus, Machilek, and Schutz 2006). And yet, consumer research (as opposed to communication research) has hardly addressed self-presentation on personal websites, nor the digital processes through which desired identities are translated from the real life to the personal webspaces. Jensen Schau and Gilly (2003) have reported that consumers usually enact specific and self-valuable real-life selves with which they choose to communicate with other Web participants. The authors have also shown how consumers select digital stimuli, links, products and brands to present themselves on their personal webspaces. That symbolic use of digital possessions reveals highly semiotic in nature, in that digital objects and possessions used as a means for self-presentation may serve as “digital collages” (Jensen Schau and Gilly 2003), hence as “signifiers” for a deeper and more intangible “signified” identity or self-concept. Consequently, semiotics may prove useful to disentangle such a meaning-making process as digital self-presentation and to point out some possible exemplars of selves thus created in a sample of personal websites. Substantial conceptual issues related to the study of identity and

self-concept may occur, making the “core” or “real” self hardly tangible for researchers. Therefore, limiting investigation to the level of self-presentation, that is, where identity meaning is made thanks to a combination of digital “signifiers”, may alleviate such conceptual issues while making it possible to focus on the meaning-making processes that lead to generate “exemplars” of identities on those websites.

Personal webspaces and more precisely Web logs (or “blogs”) offer consumers an almost unlimited space for self-expression on the Internet (Kozinets 2006). Blogs are personal websites, “usually maintained by an individual with regular entries of commentary, descriptions of events, or other material such as graphics or video, where entries are commonly displayed in reverse-chronological order” (Wikipedia 2009). Some popular bloggers attract a large audience (346 million readers worldwide and 78 million unique visitors in the United States according to Wikipedia) and are considered by brands a new kind of journalists, or at least influencers who may turn into brands’ advocates thanks to VIP treatments.

Popular bloggers thus reveal a relevant sample for the study of digital self-presentation, especially when it comes, first to defining self-digitalization, second to understanding the role of brands in such processes, where “individualized brand meanings and brand practices is accessible” (Kozinets 2006). The present research focused on popular fashion blogs held by so-called “Fashionistas” for several reasons. First, because popular fashion bloggers highly maintain and improve their personal pages, and particularly through the insertion of digital stimuli, links, products and brands; second, because they ensure daily ongoing and rich nurturance of their web space; last, because daily visitors are numerous.

The purpose of this research is to get a better description of how consumers organize and process their digital self-presentation (or “self-digitalization”), using specific digital stimuli, hyperlinks, products and brands and therefore to better understand the consumer-brand association processes and their possible impacts on the consumer-brand relationships (Fournier 1998).

CONCEPTUAL FRAMEWORK

Consumers who hold personal weblogs and particularly “fashionistas” usually make use of the Internet to self-present, particularly through their consumption habits of fashion and luxury brands. Literature on self-presentation therefore proves relevant to analyse the “self-digitalization” process.

Self-Presentation in the “Real Life”

Self-presentation in the Real Life is described as a means for an individual to control impressions of themselves towards an audience (Schlenker 2003). In sociology, self-presentation has been popularized by Ervin Goffman. For Goffman (1959), people behave as actors, creating identities by playing different roles on different stages and to different audiences. People thus modify their behavior to influence the impressions other people form about them, and perform self-presentation by doing so. Self-presentation in the Real Life has been much tackled by different research disciplines. In his review of self-presentation literature in the Real Life, Schlenker (2003) reports the major themes and directions that have generated much of the research. They mainly pertain to authenticity and deceptiveness in self-presentation, the automatic versus controlled processes in self-presentation, configuring of self-presentations and the influence and role of others in self-

presentation. How self-presentations are configured and constructed may reveal of high interest for the present study and will therefore be addressed subsequently.

Self-Presentation in virtual spaces or "self-digitalization"

Self-presentation in virtual spaces (or "self-digitalization"), has mostly been studied by communication research that either focused on the mere description of personal pages thanks to socio-demographical and psychographic elements (Magnuson and Dundes 2008; Marcus et al. 2006; Schutz and Machilek 2003), or more deeply analyzed the self-presentation strategies developed by personal webpages owners (Gibbs, Ellison, and Heino 2006; Taejin, Hyunsook, and McClung 2007). Descriptive studies thus report the websites' content such as pictures, links, textual contents, style, self and personality cues or insights on the gender, age and personality traits of the informants selected (Marcus et al. 2006; Schutz and Machilek 2003), or study gender differences in self-presentation in personal webspaces (Magnuson and Dundes 2008). However, they do not mention self-presentation strategies. Gibbs et al. (2006) have addressed self-presentation in the context of online dating and anticipated future offline relationships but only through a successful expected outcome. Indeed, self-presenters were considered to self-disclose in a way that would lead to self-presentation success defined as "the degree to which users feel they are able to make a good impression on others and achieve favorable self-presentation through online dating". However, self-presenters may also not want to practice such a "selective self-presentation" (Walther and Burgoon 1992) but instead genuinely and authentically self-present, should they make a "not-so-good" impression on others. Taejin et al. (2007) have addressed that issue by making account of the five self-presentation strategies used in the Real Life and developed by Jones (1990), including unfavorable "intimidation" ("I want you to think I am dangerous") and "supplication" ("I want you to think I am weak and powerless") that rely on negative self-disclosure to create potentially negatively perceived self-presentation. The authors finally found that bloggers use self-presentation strategies and are motivated in ways identical to those described by Jones (1990). In consumer research, Jensen Schau and Gilly (2003) have made a great contribution to the theory of self-presentation on virtual spaces, bringing valuable insights on the rationale driving consumers to self-present on personal webspaces and describing their self-presentation strategies. However, the authors conclude that individuals seem to always practice favorable self-presentation through "selective self-presentation", which seems to contradict previous findings. In addition, how the digital self, likeness and associations are constructed thanks to digital stimuli, links, brands and products (or self-presentation configuration), has been partially mentioned. Literature drawing upon configuring self-presentation in the Real Life may serve as a helpful theoretical framework for translating self-presentation configuration in the Real Life to self-presentation configuration in virtual spaces (or "self-digitalization").

Configuring Self-Presentation and Self-Digitalization

"Self-presentations incorporate features of the actor's self-concept, personality style, salient social roles, and beliefs about their audience's preferences" (Schlenker 2003). On personal webspaces self-digitalization may then go through the digital actualization or enactment of those features thanks to the combination of digital stimuli (images, pictures, colours, fonts, page organization ...), links, brands and products, to generate meaning about the self. Jensen Schau and Gilly's findings (2003) about how consumers create a digital self and especially what real features are enacted to become digital ones are consistent with existing research on self-presentation configuration in the real life.

Exemplar-Based Self-Presentation. Consumers may construct a digital self relating to "one or more roles played by an informant" (Jensen Schau and Gilly 2003). Indeed, social psychology reports that individuals have a good knowledge of a vast array of exemplars of identity types ("Clint Eastwood, the tough" for example), social roles (the banker or the hairdresser), or personality traits (introversion versus extraversion). When "self-digitalizing", informants may thus create "self exemplars" designed to produce exemplar-based inferences within the audience. There has been so far no insight on how those self-exemplars have been created. Hypothesis could be made that consumers exaggerate carefully selected salient features and therefore digitally distort self-presentation to some salient features' benefit (as would a favorable caricature do). Drawing on that premise, chances are that consumers use "selective self-presentation" (Walther and Burgoon, 1992) by selecting digital features, links, products and brands that help magnify the selected self-exemplar(s). By carefully selecting self-exemplars to manage self-presentation and impressions on others, the consumers might present a self on a continuum starting from a balance between favorable and less positive exemplars describing the self in the Real Life, to an end where selected exemplars are overwhelmingly favorable. Since the literature provides a strong support for the general principle that people search for beneficial self-presentations (Schlenker 2003), the possibility of an existing wholly negative end to that continuum has been ruled out. The balanced end of the continuum may pertain to some caricatured presentation of the self, whereas the positive end of that continuum may relate to some "self-myth creation", see some self-glorification. In their findings, Jensen Schau and Gilly (2003) do not mention the possibility for a "balanced" self-presentation, where favorable and less favorable salient self-attributes are presented on personal websites.

Presenting a desired self: a transactional view. In the Real Life, research shows that individuals present a desired (and therefore favorable) self according to motivational goals (Baumeister 1982; Schlenker 2003). The strategies developed differ in their goals and audiences. For Schlenker (2003), any self-presentation integrates the audience's beliefs of preferences or feedbacks. According to that transactional view, it is important to understand how individuals create a desirable self in the Real Life and why others find those self-presenters desirable or not, so as to understand how to "digitalize" such desirability. Research on self-presentation strategies (ingratiation and self-construction) and self-presentation criteria for desirability (beneficial and desirable) in the Real Life may prove transferable to online spaces.

"Ingratiation" consists in "pleasing the audience" to gain potential reward (Baumeister 1982) such as self-esteem enhancement (Leary and Baumeister 2000; Schlenker 2003), by presenting oneself "favorably" according to an audience's values and expectations. Alternatively, "self-construction" (Baumeister 1982) or "self-consistency" (Schlenker 2003) consists in both attaining a self fitting one's ideals and values and impressing others, by making one's public image congruent with one's ideal self (Baumeister 1982). Such self-presenters show "good qualities" to others that are equivalent to their own values and ideals.

Two features help define the desirability of self-presentations: is self-presentation beneficial to the individual? Is it believable? Beneficial self-presentations will help the individual reach his or her goals, values and ideals. Literature review on that issue, however, shows that self-presentation need not be favorable or socially desirable. That contradicts Jensen Schau and Gilly's (2003) conclusion that individuals seem to always want to present a favorable and desirable self on digital spaces. Further investigation should therefore analyse whether personal websites may present unfavorable self-features. In addition, people create desirable self-

image directly, by communicating self qualities and accomplishments, and indirectly, by linking with associates or enemies whose qualities and glory may reflect on them (Cialdini, Finch, and De Nicholas 1990): inference of qualities is made between the concepts that have been linked in the minds of the perceivers. By linking themselves to successful and admirable others, individuals look better to others and feel better about themselves. Jensen Schau and Gilly (2003) have shown that consumers use links as a self-presentation device. Therefore, drawing on the literature about indirect desirable self-presentation, investigation on what links are selected, how, by whom and on what association is made by the self-presenter between him- or herself and the objects linked (people, brands or products for example) may generate further knowledge on consumer-brand association and consumer-brand relationships. Believable self-presentations need to be accurate and honest enough to be perceived as credible. Social norms prescribe that people be reliable and trustworthy and produce obligations for individuals who self-present to be what they say they are, with the risk of personal and interpersonal sanctions (Goffman 1959). Further investigation is needed to understand how trustworthiness and credibility are created, probably through “authenticity-generating devices”.

METHODOLOGY

The objective of the present study was to gain specific insight about a bloggers' community of female fashion and luxury brands' addicts (“Fashionistas”). Since understanding “consumers in the online communal and cultural context” (Kozinets 2006) of fashion bloggers was of main interest, Netnography (Kozinets 2002) has been selected as the methodology most capable of building “Grounded Knowledge” (Kozinets 2002) on Fashionistas and particularly on how such consumers self-digitalize in the blogs they maintain. Observational netnography (Brown, Kozinets, and Sherry 2003; Langer and Beckman 2005) was carried out since mere unobtrusive research was intentionally sought for. Because a forthcoming research plans to interview Fashionistas and thus needs “unbiasing” and unobtrusive observation, the selected bloggers did not know they were monitored and no member checks were made. Therefore, only “entrée” and “data collection and analysis” procedures (Kozinets 2002) were followed. Finally, choice was made, for the present study, to focus on visual digital stimuli used for self-presentation. Further analysis focusing on textual elements (usually self narratives) will be presented in a forthcoming research.

Entrée

Why select fashion blogs? Fashion and luxury brands' addicts were hypothesized to put more effort into self-digitalizing on their blogs than any other kind of bloggers, since fashion addicts carefully self-present in the Real Life. In addition, whereas most bloggers usually do not spend much of their expression space to describe particular consumption habits and brands' stories (Kozinets 2006), self-brand stories, fashion and luxury products or brands' consumption habits, brand practices and meanings seem to be more central to Fashionistas in their blogs. A fashion bloggers' community thus revealed highly relevant for the research question aiming at studying self-digitalization, specifically through digital stimuli, links, products and brands.

Constitution of the corpus. A first corpus of blogs was built up by typing in “fashion blogs” into Google.fr. Results lead to a very active fashion bloggers' community at that time (www.hautetfort.com in June 2006). As time has passed by, many influential bloggers of that community migrated to more efficient blogging platforms in terms of storage and maintenance facilities. However, records and archives were also transferred and such a

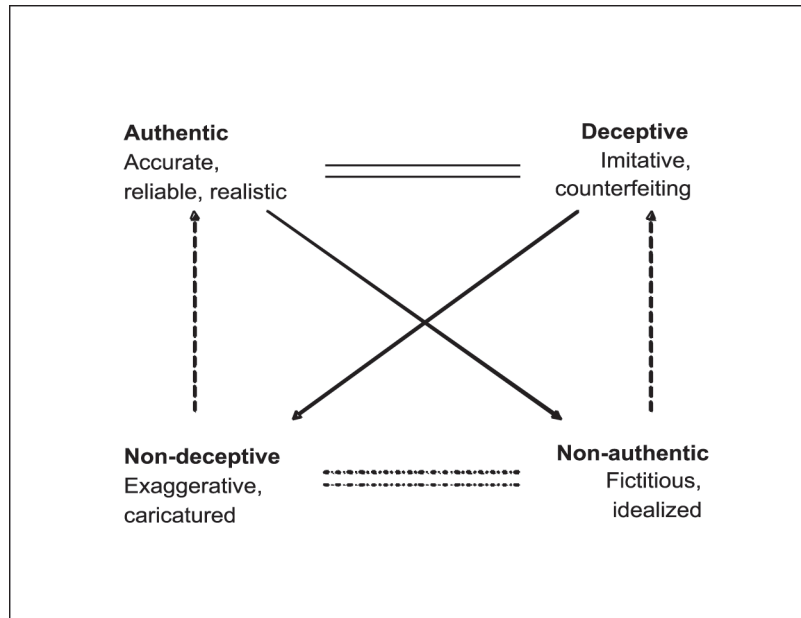

migration had no impact for the present study. Criteria retained to select bloggers among that community followed those prescribed by Kozinets (2006): high traffic, high number of posts, high level of social interactions (comments and links) and rich self-presentation data (particularly visual material such as pictures, logos and drawings) combined with detailed description of self-brand stories and brand practices. The majority of the blogs selected were linked one to another. The sample turned out to consist of too homogeneous and similar blogs, especially because of imitation behaviors occurred among the fashion bloggers. Since the collected data was to be studied through a visual semiotic analysis, the constituted corpus needed to reach saturation to ensure representativeness. Greimas and Courtés (1979) define saturation as “the model, constructed on the basis of a segment chosen intuitively, is later on applied for confirmation, complement, or rejection to other segments until all the data are used”. The next blogs were thus selected either randomly or because they were frequently quoted in fashion magazines. The variety of the corpus dramatically increased and saturation occurred pretty fast. The sample finally consists in 60 fashion blogs held by Fashionistas.

Data collection and analysis

Netnographic data collection. Direct data collected pertains to the blogs' content, that is, very diverse visual and textual elements, such as pictures, drawings, logos, wallpapers, texts, colors, videos ... Observation data relates to the researcher's inscribing of the observations about the fashion bloggers' community. Since self-digitalization through visual digital stimuli was the focus of the study, observation data consists in a synchronic report of how pages are visually configured (combining different visual parts such as banners, wallpapers, pictures, links ...) and what similarities and differences appear throughout blogs. Pointing out differences and similarities is required as a first step for any semiotic analysis and shows that structural invariant visual features stand across blogs: for example, personal banners, introducing the blog on the top of the welcome page, wallpapers, side-column tags, links, archives, categories and miscellaneous. A central text body supports written posts, illustrative drawings, pictures or even videos and varies with each post. Reversely, differences may embody for example in the presence or absence of a self-disclosure page and/or picture, of a contact e-mail address, of advertisements' inserts and commercial links, or of a personal signature (a small sentence describing the content of the blog and sometimes explaining the name of the blog).

Semiotic visual data analysis. Semiotics provides powerful techniques and rich theories to explore consumption behaviors and communication (Mick 1986; Mick and Oswald 2006). “Semiotics analyses the structures of meaning-producing events, both verbal and non-verbal [...] investigate[s] the sign systems or codes [...] with a more intense focus on meaning” (Mick 1986). Semiotics thus proves highly relevant when it comes to studying self-digitalization in fashion blogs thanks to visual codes fostering symbolic meanings and practices. Semiotics has been used for some time in consumer research (Floch 2003; Holbrook and Hirschmann 1993; Mick and Oswald 2006; Zhao and Belk 2008). However, the existing research most of the time addresses textual or verbal elements, exploiting semiotic techniques derived from linguists' work like Saussure (1968) or Barthes, but scarcely studies visual-only elements (Floch 2003). And yet, Courtés (1995), building upon Saussure's paradigmatic and syntagmatic relations between words (Saussure 1968), offers insight on how to analyse visual systems. The first step, or paradigmatic analysis (Courtés 1995; Saussure 1968), consists in drawing out similarities and differences across the corpus to designate invariants and more episodic visual stimuli already mentioned as “blog content”. The second step, or syntagmatic analysis (Courtés

FIGURE 1
Semiotic square of self-digitalization (credibility semantic plane)

1995; Saussure 1968), shows how visual signs combine to provide meanings and values about self-digitalization. Finally, results about visual self-digitalization are presented in a "semiotic square" (Greimas and Rastier 1968), building on the latent values and ideals revealed by the semiotic visual analysis.

FINDINGS

Effects of self-digitalization on audience's perceptions

How the audience perceives of the bloggers will depend on the self-digitalization process and effects, specifically concerning credibility. The semiotic square presented in figure 1 helps structuring the audience's different possible perceptions of self-digitalization processed on fashion blogs.

Literature review on self-presentation has shown that credibility (as opposed to desirability) is always required. Consequently, credibility was selected as a semantic plane for self-digitalization. Since it may be attained by presenting a realistic, sincere and reliable self (Schlenker 2003), thus requiring accuracy, the semantic axis opposed "authenticity" to "deceptiveness", which proved relevant with existing literature on self-digitalization (Walker 2000). "Deceptiveness" describes counterfeiting, imitative and labored self-digitalization processes, or presentations that are not what they seem, introducing the notion of dishonesty. "Non-authenticity" relies on fictitiousness but dishonest intentions are not taken into account. "Non-deceptiveness" is not dishonest and aims at some accuracy but is not necessarily identical to reality, exaggerating salient more or less favorable "Real Life features" translated to the online space.

The semiotic square elaborated on the credibility plane presents how readers may perceive fashion bloggers when self-digitalizing. Self-digitalization may thus be perceived as reliable and realistic, imitative and counterfeiting, fictitious or exaggerative and caricatured by the audience.

How do consumers self-digitalize?

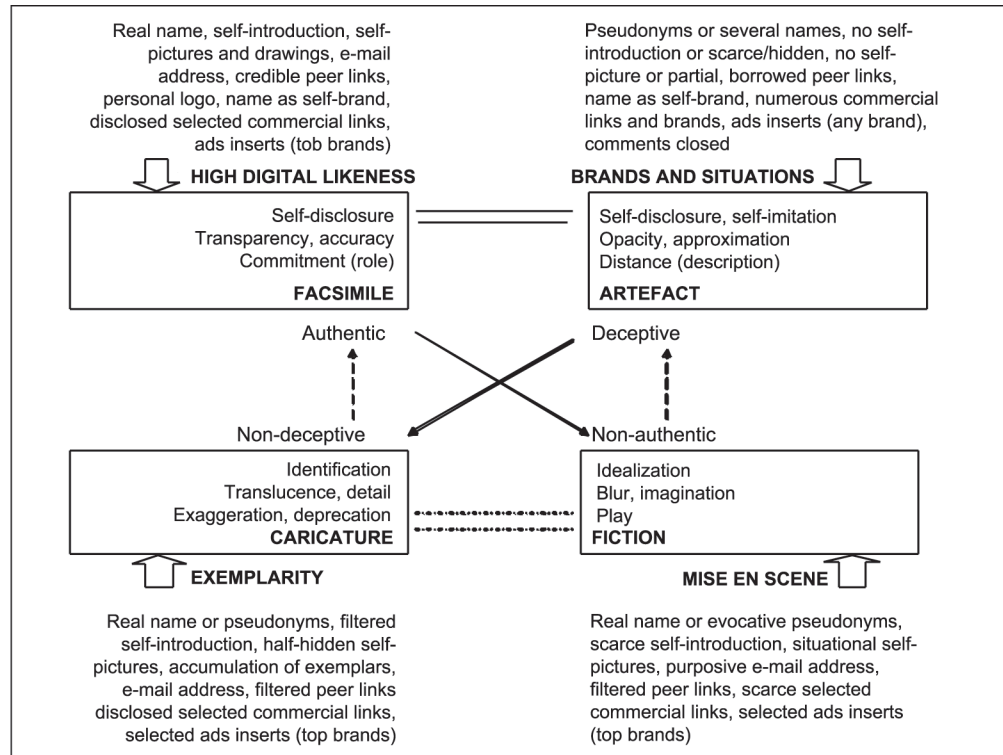

Figure 2 details how fashion bloggers self-digitalize. Drawing upon the credibility semantic plane and semiotic square, digital

stimuli combinations were studied, in order to describe self-digitalization methods used by fashion bloggers. Bloggers aiming at authenticity use high digital likeness (Jensen Schau and Gilly 2003), that is translate as many Real Life stimuli as possible to the digital world. Self-disclosure, accuracy and transparency are the blogs' guidelines. Bloggers are really committed into their blogs and use them almost as a business card. Self-digitalization thus follows the rules of a facsimile. Bloggers who target idealized and fictitious presentation use a *mise-en-scène* of the self. They try to create evocative settings, personal self-fantasies, private universes. Their blog is a place where they can play with themselves and others, and use their imagination. Self-digitalization here follows the rules of a fiction. Bloggers who are searching for non-deceptiveness and exaggeration carefully select all the Real Life stimuli they chose to translate to their virtual spaces. By being that selective, bloggers self-stereotype through a systematic search for exemplarity. Stress is put on specificities, details and identification to reach typicality and exemplarity of the Fashion addict. Careful selection of brands and links is thus here crucial. Self-digitalization, in that case, follows the rules of caricature. Finally, some bloggers hold personal pages mainly for commercial or business purposes. Of course, they do not so to say pursue deceptiveness but readers do perceive their blogs as such and "flame" those bloggers in the spaces left for comments (when comments are not closed). Those blogs borrow all the codes and stimuli used by the other bloggers. However, cues such as a felt distance, too many commercial links, an overwhelming mentioning of brands and/or events, no clear self-disclosure, mentions that the author is not paid for advertising or comments closed are quite accurate warnings for a deceptive fashion personal blog. Here, self-digitalization follows the rules of artefacts.

DISCUSSION

Authentic blogs in the corpus are mainly composed of fashion experts' and professionals. "CaféMode" started her blog when she attended Paris fashion school "Institut Français de la Mode" four years ago. She has progressively made herself known as a fashion specialist: she now uses her blog as a window-dressing for her

FIGURE 2
Self-digitalization options

consulting and journalist’s activities, and thus for self-consistency. Fictitious blogs comprise blogs where individuals present an idealized self, which makes up for the majority of the fashion blogs we monitored. They set up a *mise-en-scène* of themselves as would do a fashion magazine with models or celebrities. Those bloggers really love fashion, work in the industry or usually occupy jobs close to arts, marketing or communication. For example, “Pandora” studies the Fine Arts in Paris but want to present as a sharp fashion expert with her own universe and fashion fantasies. Usually, bloggers who managed to present a successful “fictitious” blog quickly gain rewards such as integrating brands’ databases as “influencers” and trendsetters which gives access to prestigious parties, complimentary luxury week-ends, high value gifts or are proposed thrilling positions in the fashion industry. Fictitious blogs therefore seem first, to digitalize self-presenters who pursue ingratiation in order to gain rewards, confirming that ingratiation may be translated to personal webspaces, second, to be the step preceding a “professionalization” of the blog and blogger. They gain credibility because their self-digitalization usually “fits” fashion brands or fashion magazines. Deceptive or counterfeiting blogs are fashion blogs that look like personal ones, but serve the blogger’s or one or several brands’ commercial purposes. For example, “Be fashion” presents and praises pretended loved new products or brands. However, she is also brand strategy consultant and works for many of the praised brands and thus might be prone to interest conflicts. Such blogs are scarce because their strategies backfire on themselves: readers usually violently criticize such hidden commercial purposes and launch “flaming” campaigns in the comments to destroy the blog’s reputation on the Web. Audience reaction to deceptive blogs is consistent with Schlenker’s claim that self-presentation must be credible and trustworthy and confirms that self-digitalization needs credibility and particularly honesty. Caricatured blogs present fashion bloggers both in favorable and less favorable situations. Self-presenters exaggerate their existing “Real Life” features, whether positive or not, to generate either humorous or caricatured self-presentation. For example, “Galliane” presents herself in funny and often ridiculous situations or outfits. This finding somewhat contradicts Jensen Schau and Gilly (2003) in that self-digitalization is not always aiming at favorable self-presentation, at least, at first intent. However, caricatured blogs may use self-deprecation or exaggerated honesty either to attract the readers’ sympathy through humour or to enhance credibility, that explanation being consistent with communication research’s findings on source credibility. Those bloggers are often fashion-addicts who also end up in the fashion industry or in close job positions. They made end up as professionals because they set up credibility on honesty or self-deprecation.

captured blogs present fashion bloggers both in favorable and less favorable situations. Self-presenters exaggerate their existing “Real Life” features, whether positive or not, to generate either humorous or caricatured self-presentation. For example, “Galliane” presents herself in funny and often ridiculous situations or outfits. This finding somewhat contradicts Jensen Schau and Gilly (2003) in that self-digitalization is not always aiming at favorable self-presentation, at least, at first intent. However, caricatured blogs may use self-deprecation or exaggerated honesty either to attract the readers’ sympathy through humour or to enhance credibility, that explanation being consistent with communication research’s findings on source credibility. Those bloggers are often fashion-addicts who also end up in the fashion industry or in close job positions. They made end up as professionals because they set up credibility on honesty or self-deprecation.

CONCLUSION

The present research builds on Jensen Schau and Gilly’s (2003) previous research. Consistent with their findings, we concluded that “digital likeness” does occur. However, further investigation on that self-digitalization strategy shows that, consumers use full “digital likeness” only when they want or need to stress a specific role or expertise, particularly because they “professionalized” thanks to their blogs. Thus, “digital likeness” may turn to “exemplarity” when bloggers want to self-digitalize as stereotypes such as “fashion-addicts”, or to “*mise-en-scène*” when they want to self-digitalize as an ideal character they would like to embody on their virtual space. As for personal fashion blogs that end up showing commercial intentions, overwhelming brands, products, situations, and commercial links appear. Such blogs are usually deceptive. In addition, full detail of the digital stimuli combined to self-digitalize depending on the self-digitalization

option has been presented. Important conclusions concerning brand-consumers relationship on the Net appear. Indeed, expert bloggers are more likely not to accept sponsors, or very few, for the sake of credibility and honesty. Caricatured bloggers may accept sponsors who perfectly fit with their self-stereotypes, and not only fashion or luxury brands since incongruity may be a source for self-deprecation or humour. Idealized bloggers may accept only fashion and luxury brands fully congruent with their imagined universe and digital self. Finally, since deceptive sites are subject to flaming and brand cluttering, brands should avoid them systematically.

The "Real Life" self-presentational goals (self-consistency and ingratiation) seem to translate perfectly to virtual webspaces. Particularly, self-consistency may be pursued in authentic, professional and expert blogs, whereas ingratiation may be looked for by bloggers who want to create some idealized character. Results also show that bloggers not always target desirable self presentation on blogs, which contradicts Jensen Schau and Gilly (2003). This might be explained by the fact that individuals may use honesty see self-deprecation to appear more credible. Credibility is indeed a crucial criterion in self-digitalization and relies either on the fit between the self-digitalized and the fashion brands and magazines praised, either on honesty or humorous self-deprecation.

Finally, consumers seem to first self-digitalize either as fictitious fashion characters or as fashion caricatures before entering the small world of experts and professionals if their blogs encounter large audience and success. Self-digitalization may thus imply evolution throughout time needing further investigation.

LIMITATIONS

How readers may perceive of the different self-digitalization options need cross validation through interviews with the readers. In addition, further investigation should be carried out to better understand the brand-consumer association depending on the self-digitalization option. Finally, conclusions show that further longitudinal analysis of self-digitalization is needed.

Context as a Source of Clarity: The Effects of Ad Context and Gender on Consumers' Processing of Product Incongruity

Theodore J. Noseworthy, University of Western Ontario, Canada
Seung Hwan (Mark) Lee, University of Western Ontario, Canada
June Cotte, University of Western Ontario, Canada

ABSTRACT

In two studies, the authors provide evidence that ad context can be used to alter the elaboration threshold for both males and females. The findings suggest that in a competing ad context (a series of ads for similar goods), females were better able to resolve an extremely incongruent product (an extremely odd-looking camera), and males, counter to their natural predisposition for item-specific elaboration, processed information in a relational manner. In both instances, their extremity of evaluation was enhanced. However, in the unrelated ad context (a series of ads for disparate goods), all gender differences in elaboration were extinguished.

Marketers of an extremely novel product face a challenge when deciding how best to promote their new offering. One key question is whether they want consumers to compare the new product to others of its ilk (that camera is different!), or to allow the new product to stand on its own (is that a camera?). We argue that a competing ad context (several ads for similar goods) will cue relational elaboration and facilitate the processing of an extremely incongruent product. Conversely, an unrelated ad context (several ads for disparate goods) will cue item-specific elaboration, making it difficult to process extreme incongruity. Furthermore, we believe these effects will vary by gender. As researchers have argued that females are more amenable to relational elaboration, we predict that they will have little difficulty resolving extreme incongruity in a competing ad context. Males, on the other hand, due to a natural predisposition for item-specific elaboration, should find the task decidedly more difficult.

CONCEPTUAL BACKGROUND

Consistent with previous research, we define product incongruity as the degree of fit (or lack thereof) between a product and its respective product category (Campbell and Goodstein 2001; Meyers-Levy and Tybout 1989; Peracchio and Tybout 1996). An example might be a circular (rather than square) laptop computer. Research has shown that the act of resolving product incongruity can enhance consumers' extremity of evaluation (Aggarwal and McGill 2007; Campbell and Goodstein 2001; Meyers-Levy and Tybout 1989; Peracchio and Tybout 1995; Stayman, Alden, and Smith 1992). This phenomenon has been coined the schema congruity effect (Meyers-Levy and Tybout 1989).

Mandler (1982) cautioned that enhanced evaluations only occur when consumers can successfully discern the incongruent object and fit it into an existing schema. When incongruity levels rise past a certain threshold, the ability to elaborate diminishes exponentially (Meyers-Levy and Tybout 1989). The task is then often too taxing, resulting in negative evaluation ("I can't understand it, so I don't like it"). This nonmonotonic effect has proven to be very robust (Campbell and Goodstein 2001; Mandler 1982; Meyers-Levy and Tybout 1989; Peracchio and Tybout 1996; Stayman et al. 1992).

While the schema congruity effect has been extended to predict consumers' processing of anthropomorphized products (Aggarwal and McGill 2007), brand extensions (Meyers-Levy, Louie, and Curren 1994), taste (Stayman et al. 1992), and new

product attributes (Meyers-Levy and Tybout 1989), research has yet to explore whether the advertisement context itself can affect the robust nature of the phenomenon. Moreover, literature has yet to examine how incongruity is actually processed when accommodation occurs. Thus, we turn to Einstein and Hunt's work (1980) for some insights into the cognitive underpinnings of the different types of processing.

Research on elaboration suggests that there are at least two types of cognitive processing: item-specific and relational (Einstein and Hunt 1980; Hunt and Einstein 1981; Klein, Loftus, and Shell, 1994; Malaviya, Meyers-Levy, and Sternthal 1999). (Please note that the prior work has used elaboration and processing as synonyms. Perhaps the term should be elaborative processing, but for simplicity, we follow the prior linguistic convention.) Item-specific processing emphasizes attribute information that is distinct to a particular claim (Meyers-Levy 1991). This involves the generation of precise associations to a particular product, in isolation of other products (Malaviya, Kisielius, and Sternthal 1996; Malaviya et al. 1999). In contrast, relational processing emphasizes shared themes among disparate goods (Meyers-Levy 1991) and focuses the consumer on the category in which the target product holds membership (Malaviya et al. 1999; Malaviya et al. 1996).

Although the literature has yet to explore the two types of elaboration in terms of the schema congruity effect, there is research that suggests that product evaluations can be enhanced when the ad context evokes both item-specific and relational processing, as opposed to when one of these is dominant (Malaviya et al. 1996; Malaviya 2007). Because item-specific processing enables consumers to focus on the particular features and attributes of the product, and relational processing enables consumers to access the product category, together they increase the persuasive impact of the ad. Malaviya (2007) coined this phenomenon the dual elaboration hypothesis. It seems plausible that the dual elaboration hypothesis could help explain the processing of incongruent product information.

If we are to test our idea that consumers' processing influences the resolution of extreme incongruity, we must also explore whether specific circumstances encourage one type of processing over another. We will further explore one of the more obvious and well-defined dichotomies that has been shown to be associated with different modes of processing: gender (Meyers-Levy and Maheswaran 1991; Meyers-Levy and Sternthal 1991).

Researchers have demonstrated that men and women process information differently (Kempf, Laczniak, and Smith 2006; Meyers-Levy and Maheswaran 1991; Meyers-Levy and Sternthal 1991). McGuinness and Pribram (1979) found, for example, that males processed objects in terms of physical attributes, whereas females processed objects in terms of interpretive concepts. This distinction became the catalyst for the selectivity hypothesis (Meyers-Levy 1989; Meyers-Levy and Maheswaran 1991; Meyers-Levy and Sternthal 1991), which proposed that women engage in more elaborative processing, unless extrinsic motivational factors prompt men to do so as well. Putrevu (2001) also argued that men are more likely to perform item-specific processing, focusing on attributes, and refraining from drawing relationships among message cues. In

contrast, women are more likely to relationally process, actively exploring interrelationships among message cues (Kempf et al. 2006; Putrevu 2001).

Meyers-Levy and Sternthal (1991) found that when cued to elaborate on an incongruent event, women were more deliberate and attentive in their processing than men. They concluded that women tend to elaborate on incongruity, and thus facilitate similarity judgments, whereas men were less responsive to such subtle cues. Similarly, Meyers-Levy and Maheswaran (1991) found that females were indeed more likely to elaborate than males, however, when the task became taxing these differences were eliminated. These studies did not examine the schema congruity effect, nor was that their intent. Moreover, neither study explored the ability of advertising context to enhance a gender-related predisposition in elaboration. This is the goal of our research.

As discussed, a key tenet of the dual elaboration hypothesis is that when both forms of elaboration cue simultaneously, the process should enhance consumers' extremity of evaluation (Malaviya 2007; Malaviya et al. 1996). Accordingly, if males are naturally predisposed to item-specific elaboration, and an ad context is introduced that facilitates relational elaboration, males will engage in both types of processing; this will increase evaluation extremity. We predict, however, that this phenomenon will only manifest for males. If females have a natural predisposition for relational elaboration, an ad context featuring competing products would only serve to augment their dominant processing style (relational).

H1: Males will view a competing ad context more favorably than an unrelated ad context. Females will not differ in evaluations, regardless of ad context.

Item-specific elaboration is more likely to happen when a target ad is presented with ads that belong to unrelated categories, whereas relational elaboration is more likely to happen when a target ad is presented alongside competing ads that make the product category more salient (Malaviya 2007). In part, we propose to replicate Malaviya's findings. However, we posit an underlying gender difference he did not examine. Specifically, we predict that males will engage in more item-specific elaboration when the target ad is positioned with unrelated goods, but not when the ad is positioned with competing goods. Conversely, because females are already oriented towards relational elaboration, we predict this will hold across both conditions.

H2: Males will demonstrate a greater propensity for item-specific elaboration when the ad is viewed within an unrelated context than a competing context. Female will use relational elaboration, regardless of ad context.

STUDY 1: GENDER DIFFERENCES IN CONTEXTUALLY DERIVED PROCESSING

Method

Design. A total of 125 university students (51% females) were recruited to participate in the study for course credit. Participants were assigned to one of four experimental conditions in a 2 (advertising context: unrelated vs. competing) x 2 (gender) between-subject factorial design.

Stimuli. The manipulation of advertising context followed prior procedures (Malaviya 2007). In the unrelated condition, the target advertisement (Minox camera) was placed with three unrelated ads from disparate product categories (Hawth Beer, Nexus Bags, and ProPal Calculators). In the competing condition, the

target advertisement was placed with three competing ads from the same product category (Nexus, ProPal, and Hawth cameras). Both ad context manipulations had identical copy and consistent visuals in terms of size, spacing and positioning within the ads. The ad placements were counterbalanced to control for order effects, and the color schema and fonts were counterbalanced to control for preference. A pre-test ($n=43$) confirmed that there were no discrepancies in comprehensiveness, informativeness, and familiarity among the ads ($F_s < 1$). Moreover, post-test analyses verified the absence of order effects ($F < 1$).

Procedure. Participants were provided with a booklet that consisted of a series of the four fictitious ads and a questionnaire. After examining the ads, participants evaluated the target camera (Minox) on five seven-point evaluation items (bad/good, likeable/unlikeable, few/many unique features, low/high performance product, lacks/offers important benefits).

Next, in accordance with the procedures outlined by Malaviya et al. (1996), participants were asked to list as many thoughts as they could about the target ad. A two-minute time limit was imposed during the thought-listing task to increase the likelihood of capturing only the most accessible thoughts (Cacioppo and Petty 1981). The thoughts were coded by two unaffiliated judges, both of whom were unaware of the research hypotheses. The judges were instructed to rate any thought that relates to the target ad as item specific (e.g., "I like the flash on the Minox"), and any thought that relates to the product category (e.g., "digital cameras are more stylish than other cameras") or usage (e.g., "it's good to take on vacation") as relational. The two coders' results were consistent ($r=.87$). All outstanding disagreements were resolved through discussion.

Participants also responded to demographic questions, including measures of their knowledge and expertise with cameras, as well as their familiarity with the (fictitious) brands. Post-test analyses confirmed that these variables had no influence ($F_s < 1$).

Results

ANOVAs were conducted on a 2 (context) x 2 (gender) between-subject factorial design. Table 1 reports all treatment means and standard deviations for experiment 1.

Product Evaluation. A factor analysis confirmed that all evaluation items loaded on one factor. Thus, the items were averaged to form an internally consistent measure ($\alpha=.91$). A two-way ANOVA indicated the presence of a main effect of advertisement context; participants rated the target product more favorably in the competing ad context ($M=4.33$) than in the unrelated ad context ($M=3.63$), ($F(1, 121)=10.41$, $p<.005$, $\omega^2=.07$). As predicted (hypothesis 1), a planned comparison revealed that male participants viewed the target ad in the competing context more favorably ($M=4.21$) than in the unrelated context ($M=3.53$), ($F(1, 121)=8.83$, $p<.005$, $\omega^2=.06$), whereas females did not significantly differ in their evaluations across ad context conditions ($F < 1$).

Elaboration Index. Consistent with prior research, an elaboration index was constructed by taking the difference between the number of item-specific thoughts and the number of relational thoughts, divided by the total number of thoughts (Malaviya 2007; Malaviya et al. 1996). Zero indicates an equal number of item-specific and relational thoughts, a positive number indicates more item-specific thoughts, and a negative number more relational thoughts.

A main effect of ad context was observed; participants scored the unrelated context as more item-specific ($M=.09$) and the competing context as more relational ($M=-.04$), ($F(1, 121)=3.86$, $p=.05$, $\omega^2=.02$). A main effect of gender was also observed; males pro-

cessed more in an item-specific manner ($M=.10$), females in a relational manner ($M=-.06$), ($F(1, 121)=5.75$, $p<.05$, $\omega^2=.04$). As predicted (hypothesis 2), these main effects were qualified by an interaction between gender and context ($F(1, 121)=4.07$, $p<.05$, $\omega^2=.02$). Simple effects tests revealed males processed the unrelated ad context as more item-specific ($M=.23$) and the competing ad context as more relational ($M=-.03$), ($F(1, 121)=7.87$, $p<.01$, $\omega^2=.05$). Females processed both contexts in a relational manner ($M_{Unrelated}=-.06$ vs. $M_{Competing}=-.05$), ($F<1$).

Discussion

In this study, we offer additional support for claims that advertising context can alter consumers' elaboration (Malaviya 2007; Malaviya et al. 1996). An unrelated context can cue more item-specific than relational processing, whereas a competing context can cue more relational than item-specific processing. We also support existing theory on gender differences in processing (Meyers-Levy 1989; Putrevu 2001). Males were more likely to engage in item-specific processing, whereas females were more likely to engage in relational processing. The contribution of this study, however, is in the interaction between the two. Processing predispositions were moderated by advertisement context; males tended to process in an item-specific manner when the ads were presented within an unrelated ad context, but not within a competing ad context. Females tended to process in a relational manner regardless of the context.

On the surface, it may seem that males and females respond differently in a competing ad context. There is, however, an alternate explanation. The competing context might have equally contributed to relational processing for both genders, but because females are oriented that way (Meyers-Levy 1989), the impact of ad context could have been far more obvious for males (sort of like a ceiling effect). This is supported by our finding that males viewed the competing context more favorably than the unrelated context, whereas females did not differ in their evaluations. Consistent with the dual elaboration hypothesis (Malaviya 2007; Malaviya et al. 1996), male evaluations may have increased because of their natural predisposition for item-specific processing in conjunction with a competing ad context that encouraged them to engage in relational processing. This line of reasoning would also explain why evaluations did not change for females (both their predisposition and the ad context reinforced only relational processing). Thus, female evaluations did not benefit from aggregating two styles.

What is perhaps more interesting than individual differences, is the suggestion that ad context may enhance a predisposed processing style. In particular, evidence from study 1 alludes to the possibility that females may be able to extend their elaboration thresholds given the proper contextual stimulus. This brings us back to our initial research question: What happens when the advertising context incorporates inconsistent or incongruent information? Could a context help give an object membership? Researchers have yet to test product incongruity across varying ad contexts. Perhaps individuals use context to enhance their cognitive elaboration when accommodating incongruity. This would suggest that the ad context might raise a consumer's elaboration threshold to accommodate a level of incongruity that might be otherwise too taxing to resolve (extreme incongruity).

It has been argued that extreme incongruity results in negative evaluations due to one's inability to accommodate an object at the superordinate level (Meyers-Levy and Tybout 1989). Given that females have an elaboration threshold that can tease out fine distinctions (Meyers-Levy 1989), they should be better equipped to utilize the ad context to handle extreme product variations. We predict that if assisted through a competing ad context, females will be able to process levels of incongruity that males cannot distinguish.

H3: Females will view an extremely incongruent product more favorably in a competing ad context than in an unrelated ad context. Males will not differ in their evaluations of an extremely incongruent product, regardless of ad context.

If females are better equipped to use a competing ad context, they should demonstrate a greater propensity for relational processing when appraising an extremely incongruent product. In contrast, if male elaboration thresholds are such that they are unable to process extreme incongruity regardless of the context, then males should revert to item-specific processing.

H4: When an extremely incongruent product is positioned within a competing context, females will engage in more relational (vs. item-specific) processing, whereas males will engage in more item-specific (vs. relational) processing. When an extremely incongruent product is positioned within an unrelated context, there will be no difference in processing between males and females.

STUDY 2: THE EFFECTS OF CONTEXT AND GENDER ON THE ACCOMODATION OF INCONGRUENT GOODS

Method

Design. In total, 286 students (49.7% females) participated in the study for course credit. Each participant was randomly assigned to one of 12 experimental conditions, creating a 2 (advertising context: unrelated vs. competing) \times 2 (gender) \times 3 (product congruity: congruent vs. moderately incongruent vs. extremely incongruent) between-subject factorial design.

Stimuli. We used the same ad context manipulation as described in study 1. Given the nature of the manipulation (unrelated vs. competing), two pre-tests were conducted to secure the product congruity manipulation within-subjects ($n=40$; 50% females) as well as between-subjects ($n=130$; 44% females). Using real digital cameras that were newly introduced to the market, a preliminary examination ($n=52$) reduced the initial selection (five cameras) to three by excluding any camera that did not significantly vary in perceived typicality (three 7-point scales anchored by not at all unique/very unique, very unlikely/very likely, and (matches) not at all well/very well). Similar to previous work (Campbell and Goodstein 2001), the pre-test items loaded on one factor and were averaged to form an internally consistent measure ($\alpha=.67$).

The between-subjects pre-test confirmed a main effect of camera type on perceived typicality ($F(2, 124)=37.43, p<.001$). The within-subjects pre-test replicated the effect ($F(1.93, 73.17)=263.46, p<.001$). Planned/repeated comparisons verified that camera #1 (standard) was viewed as more typical ($M_{\text{Between}}=5.30$ and $M_{\text{Within}}=6.15$) than camera #2 (ultra thin) ($M_{\text{Between}}=4.55; F(1, 124)=7.31, p<.01$ and $M_{\text{Within}}=5.85; F(1, 38)=5.22, p<.05$), which in turn was rated far more typical than camera #3 (round) ($M_{\text{Between}}=2.97; F(1, 124)=37.22, p<.001$ and $M_{\text{Within}}=2.63; F(1, 38)=257.22, p<.001$). There was no effect of camera order in the within-subjects pre-test ($F_s<1$). More importantly, there was no effect of gender on measures of evaluation, price perception or perceived typicality in either pre-test ($F_s<1$). Both pre-tests confirmed that the standard camera was seen as congruent, the ultra-thin camera as moderately incongruent, and the round camera as extremely incongruent.

Procedure. Participants were instructed that the purpose of the study is to learn their opinions about different advertisements. Each research participant was asked to review a seven-page booklet (visual and editorial content) at his or her own pace and to complete the accompanying tasks. In line with experiment 1, the booklets consisted of either four camera ads (competing) or four disparate ads (unrelated), with the target camera ad being the incongruity manipulation in both contexts. On average, it took respondents 10-minutes to complete the task.

Participants first evaluated the target camera (Minox) on 10 seven-point items (bad/good, dislike/like, few/many unique features, low/high performance product, poor/good picture quality, lacks/offers important benefits, not useful/useful, not superior/superior, difficult/easy to use, and poor/good lens quality). Embedded with these items were three seven-point typicality items (listed previously). Lastly, participants were asked to complete the same thought task listed in study 1. In addition to the procedures described in the first experiment, the two unaffiliated judges were required to further record whether respondents—if prone to engage in relational processing—were dissimilarity-focused (“this camera looks easier to use than other cameras”) or similarity-focused (“digital cameras are easy to use”; Kim and Meyers-Levy 2008).

The judges’ results were indexed and any outstanding disagreements were resolved through discussion.

Once again, as possible covariates, participants responded to a set of demographic questions, including measures pertaining to expertise with cameras, how attentive they were during the task, as well as their familiarity with the (fictitious) brands used in the study. None of these factors contributed to the treatment effects ($F_s<1$).

Results

ANOVAs were conducted on a 2 (context) \times 2 (gender) \times 3 (product congruity) between-subject factorial design. Table 2 reports all treatment means for experiment 2.

Perceived Typicality. In line with our pre-test results, the three typicality items loaded on one factor and were averaged to form an internally consistent measure ($\alpha=.71$). A planned comparison using a Bonferroni adjusted alpha level of .017 per test (.05/3) indicated that the congruent product was perceived to be far more typical ($M=5.43$) than the moderately incongruent product ($M=3.82$), ($F(1, 274)=123.52, p<.001, \omega^2=.18$), which was in turn seen as far more typical than the extremely incongruent product ($M=2.62$), ($F(1, 274)=68.4, p<.001, \omega^2=.10$). The average typicality of the two incongruity conditions combined ($M=3.21$) was significantly lower than that of the congruent condition ($M=5.43$), ($F(1, 274)=322.01, p<.001, \omega^2=.47$). Thus, the congruity manipulation was perceived as intended.

Product Evaluation. Consistent with prior research (Malaviya 2007), the 10 evaluation items loaded on one factor and thus were averaged ($\alpha=.85$). An ANOVA revealed a three-way interaction of advertising context, product congruity, and gender on product evaluation ($F(2, 274)=3.74, p<.05, \omega^2=.02$). Simple effects tests revealed that product evaluations varied by gender. Specifically, when the target ad was evaluated by male participants, a significant main effect of product congruity emerged ($F(2, 274)=10.88, p<.001, \omega^2=.06$). Consistent with the schema congruity effect (Meyers-Levy and Tybout 1989), planned contrasts revealed that males perceived the moderately incongruent product more favorably ($M=4.51$) than both the congruent product ($M=4.03$), ($F(1, 274)=6.25, p<.05, \omega^2=.02$), and the extremely incongruent product ($M=3.63$), ($F(1, 274)=21.32, p<.001, \omega^2=.07$).

In contrast, when the target ad was evaluated by female participants, a significant interaction between product congruity and ad context emerged ($F(2, 274)=3.25, p<.05, \omega^2=.01$). Simple effects revealed that the nature of the interaction was such that the schema congruity effect manifested for females only in the unrelated ad context ($F(1, 274)=7.30, p<.005, \omega^2=.04$); females evaluated the moderately incongruent product ($M_{\text{Unrelated}}=4.67$) more favorably than both the congruent product ($M_{\text{Unrelated}}=4.10$), ($F(1, 274)=4.43, p<.05, \omega^2=.01$) and the extremely incongruent product ($M_{\text{Unrelated}}=3.63$), ($F(1, 274)=14.55, p<.001, \omega^2=.04$). There were no differences in female evaluations across the product congruity conditions in the competing ad context ($F_s<1$). As predicted (hypothesis 3), a planned comparison confirmed that females viewed the extremely incongruent product more favorably in the competing ad context ($M=4.23$) than in the unrelated ad context ($M=3.63$), ($F(1, 274)=4.97, p<.05, \omega^2=.01$). Thus, the absence of the schema congruity effect in the competing ad context was due to female participants evaluating the extremely incongruent product on par with the moderately incongruent and congruent products.

Elaboration Index. Following the same procedures outlined in study 1, participants’ thoughts were catalogued by two unaffiliated coders ($r=.91$) and an index was calculated. Consistent with the first experiment, a main effect of advertising context emerged; partici-

Note: Standard deviations are reported in parentheses; Elaboration = elaboration index

participants processed the unrelated context as more item-specific ($M=.02$) and the competing context as more relational ($M=-.05$), ($F(1, 274)=5.10$, $p<.05$, $\omega^2=.01$). Similarly, there was a main effect of gender; males processed more in an item-specific manner ($M=.02$), females in a relational manner ($M=-.05$), ($F(1, 274)=4.58$, $p<.05$, $\omega^2=.01$). The effects were qualified by a three-way interaction of advertising context, product congruity and gender ($F(2, 274)=4.96$, $p<.05$, $\omega^2=.03$). Closer examination revealed that the nature of the interaction varied by the level of product congruity. Specifically when respondents evaluated the congruent target product, a significant interaction between gender and ad context emerged ($F(1, 274)=4.90$, $p<.05$, $\omega^2=.01$). In line with study 1, simple effects tests revealed that males processed the unrelated ad context as more item-specific ($M=.12$) and the competing ad context as more relational ($M=-.09$), ($F(1, 274)=7.06$, $p<.01$, $\omega^2=.02$). In contrast, females processed both the unrelated and competing congruent ad context in a relational manner ($M_{\text{Unrelated}}=-.06$ vs. $M_{\text{Competing}}=-.02$), ($F<1$).

As predicted, the pattern of effects were reversed when participants evaluated the extremely incongruent product; females processed the unrelated ad context as more item-specific ($M=.02$) and the competing ad context as more relational ($M=-.14$), ($F(1, 274)=4.46$, $p<.05$, $\omega^2=.01$). In contrast, males processed both the unrelated and competing extremely incongruent ad contexts in an item-specific manner ($M_{\text{Unrelated}}=.06$ vs. $M_{\text{Competing}}=.06$), ($F<1$). Males and females did not significantly differ in their elaborations between the unrelated or competing moderately incongruent ad contexts ($p>.05$).

Discussion

In this experiment, we not only replicate effects from study 1, but we also offer additional support for the nonmonotonic relationship between product congruity and product evaluation (vis. the schema congruity effect; Meyers-Levy and Tybout 1989). The contribution of this study, however, lies in the interaction between context, gender and incongruity. Consistent with past examinations (viewing a product in isolation from comparable goods), the schema congruity effect was robust in the unrelated ad context. In the competing ad context, however, the phenomenon only manifested for males. The lack of effect for females, coupled with the increase

in relational elaboration as the product increased in perceived typicality, supports our core proposition: using the competing ad context, females were able to extend their processing to accommodate an extremely incongruent product. They properly understood it within its product category and evaluated it more positively.

GENERAL DISCUSSION

The two experiments here provide strong evidence that advertising context can be used to facilitate consumers' ability to accommodate incongruent goods. Malaviya (2007) illustrated the merits of the dual elaboration hypothesis. We were able to replicate and extend his framework to provide evidence that ad context can be used to alter the elaboration threshold of both males (experiment 1) and females (experiment 2), and do so in different ways. Furthermore, the two experiments not only replicated the schema congruity effect (Meyers-Levy and Tybout 1989), but they also lent support to the notion that males and females differ in their elaboration strategies. Our findings suggest that given a context that facilitates a means of comparison, women can resolve what would otherwise be too difficult (an extremely odd-looking camera). Additionally, given that same contextual cue, males will adopt a processing strategy that is antithetical to a natural predisposition (they will begin to relationally process information, instead of processing in an item-specific manner).

In line with the selectivity hypothesis (Meyers-Levy and Maheswaran 1991), when the task alone was too difficult (unrelated), all gender differences in elaboration were extinguished. However, when the task was accompanied by a context that facilitated a means of comparison (competing), the differences re-emerged and were even more dramatic. These findings have important implications for marketing practice. Both males and females seemed to enjoy the product the most when it was at least moderately incongruent, and when the product was in a context of similar goods that helped to classify it. Indeed, such a technique could be used in product placement on retail shelves, end of aisle displays, and special features in magazines and newspapers. What is perhaps more interesting, however, is the idea that a competing context could be used to facilitate the introduction of an extremely incongruent good. In such a scenario, the results of this study would caution that marketers be sensitive to gender variations in elaboration.

tion, which seem to gain in severity as the product becomes increasingly novel. Future research will have to explore limits of this phenomenon.

To Be or not to Be? Virtual Experience and Immersion on a 3D Commercial Web Site

Marion Garnier, SKEMA, LSMRC, Univ. Nord de France, France

Ingrid Poncin, SKEMA, LSMRC, Univ. Nord de France, France

INTRODUCTION

The rapid growth of multimedia technologies and the Internet in its various forms is changing the way of doing e-commerce. The success of virtual universes such as Second Life (SL), or games such as World of Warcraft (WOW) has now opened new opportunities for the development of online shopping experience. Major technological developments in advanced interactive techniques drawn from MMORPG¹ and virtual universes now sustain and allow fully 3D shopping malls, showrooms or shopping websites. In the realm of current technological development, the practice is ahead of theory in some instances, mainly due to the rapid pace of emerging new technologies, thus leaving academic researchers a little behind in their efforts to make sense of their impact. At the same time, as underlined by Venkatesh (1998), the pioneers in the world of practice need guidance from academic researchers to provide conceptual schemes that can sharpen their practices in hypercompetitive environments.

Despite the huge potential, we know little about the way to use adequately these new technologies to improve consumers experience on a commercial website. There is a big gap in management's understanding of what constitutes a shopping experience on 3D commercial website for a consumer. This issue, until recently, was a black box to academic scholars as well. The situation is now changing, since the seminal work of Hoffman and Novak (1996), literature has highlighted flow, immersion and social and spatial presences as important antecedents of Internet behaviour. If some researchers have studied these concepts in virtual reality (Tomasetti, Ruiz and Reynolds, 2009), only few have focused on the context of a 3D commercial website, if we except precursory and visionary reflexion of Burke (1996) on virtual shopping. Hence, most of the academic literature has been devoted to demonstrate that using an interactive animated 'avatar' on computer screens could provide a source of social presence and trust building capabilities (Wood, Solomon and Englis, 2005; Holzwarth, Janiszewski and Neumann, 2006; Keeling and McGoldrick, 2008). But, to our knowledge, if many researches were interested in avatars in universes such as SL, only one published research has dealt with the representation of the consumer by an avatar on a commercial website (Crete, Saint-Onge, Merle, Arsenaault and Nantel, 2008).

Therefore, our research aims at understanding what could be the influence of the 3D technology on the shopping experience on a 3D commercial website. More especially, this research contributes to explain how the consumer-avatar is a key issue in the virtual experience on a 3D merchant website, through its links with embodiment, realism and presence. To begin with, the concept of virtual experience will be briefly introduced. The second part of the paper will present our research methodology and analyses: an interpretative and understanding qualitative research process was adopted, that leads the researcher to a theoretical elaboration building on the collected verbatims. The third part will then deal with results of the research, on the basis of constant comparison with theory. Conclusion will highlight main contributions, limits and research perspectives.

VIRTUAL EXPERIENCE AT THE AGE OF 3D

Improving the virtual experience has become a major issue for e-marketers. As stated by Childers, Carr and Peck (2001) or Mathwick, Malhotra and Rigdon (2001), developing the hedonic value of websites and improving the virtual shopping experience on Internet should lead to a better conversion rate, more satisfaction, stickiness and loyalty. Visiting a website can be considered as a consumption activity through the interaction with the consumption object (Holt, 1995). This activity can also be considered as an experience beyond a potential utilitarian value (acquisition of information or material goods...), and covers symbolic and hedonic dimensions (spending an enjoyable time shopping on an online shop for example). Since Hirschman and Holbrook (1982)'s seminal work on consumption experience, high attention has been paid to the way consumption can lead individuals to satisfy hedonic and experiential needs beyond functional needs (Csikszentmihalyi, 2000). And even if the Internet offers wide utilitarian opportunities, some authors stated that the more immersive, hedonic aspects of Internet could play at least an equal role in predicting online attitudes and behaviours (Childers et al., 2001; Mathwick et al., 2001). In this perspective, 3D websites seem particularly adapted to generate diversified sensorial stimulations, immersion and experience in consequence.

Immersion in computer-mediated environment is defined as "the extent to which the computer displays are capable of delivering an illusion of reality to the senses of the human participant" (Slater and Wilbur, 1997). On a broader scope, immersion appears in any case in which an individual is plunged, involved or absorbed in a totally different world (Fornerino, Helme-Guizon and Gotteland, 2006). This immersion-that can be partial or total, durable or temporary, wanted or undergone-or "feeling of" immersion of an individual in a physical or virtual universe consists in entering the universe and absorb / be absorbed by its atmosphere. In computer-mediated environments, immersion is often considered through the concept of flow (Hoffman and Novak, 1996; Csikszentmihalyi, 1990; Novak, Hoffman and Yung, 2000). Flow is defined as "the state occurring during network navigation which is characterized by a seamless sequence of responses facilitated by machine interactivity, intrinsically enjoyable, accompanied by a loss of self-consciousness and self-reinforcing" (Novak et al. 2000). If immersion and flow share concentration and focus on the consumption object, flow also implies a high control of actions, due to a confrontation between high stakes and high skills (Fornerino et al., 2006) while this is not a basic condition for immersion to develop.

Rich media technologies and web 2.0 concepts have considerably broadened the extent to which websites can be used in an experiential and entertaining way (Helme-Guizon, 2001; Jeandrain and Limbourg, 2002) and possibly generate immersion by going beyond the flat "inhuman" screen and display of traditional websites. Those techniques, such as high quality sound, video/audio streaming or 3D object manipulation can lead to a decrease in the perception of the computer mediation. Jeandrain and Diesbach (2008) noticed that those technologies all follow the same pattern: reach media transparency and generate immersion, or so called feeling of "presence", the perceptual illusion of non-mediation (Lombard and Ditton, 1997). In consequence, our research aims at understanding to what extent and how a commercial 3D website can generate experiential value to its users and contributions will

TABLE 1
Samples descriptions

	Focus Groups	Individual interviews
Number	8	35
Total nb of respondents	58	35
Age of respondents	From 20 to 22 years old	From 22 to 59 years olds:
Men/women repartition	Men: 33% Women: 66%	Men: 45% Women: 55%
Sample characteristics	Exclusively students. Variety in Internet expertise and Internet usage habits.	Variety in professional categories, education levels, Internet expertise and Internet usage habits
Time length	1h per focus group	40 to 90 mns per interview

demonstrate how and why the representation of the consumer as an avatar is a key issue.

METHODOLOGY

3D Website Application Case: Victoria Couture

Access to Victoria Couture 3D website can be found on the brand 2D website. Direct access to the 3D shop is available on <http://www.victoriacouture.com/boutique3d-e-6-g-3d.html>. This is the first integrally 3D e-shop on which it is possible to buy products: if other 3D commercial malls or e-shops exist, they do not allow online purchase—for which consumers are then connected to traditional 2D websites. In Victoria Couture 3D Shop, The user enters a fully 3D shop (environment, structures and shelves, product display) and is represented by an avatar he can personalize and uses it to navigate. He can also visualize (picture or 3D display) products and try them on, chat online with avatars of other consumers, and possibly ends his visit by purchasing.

Sample And Data Collection

Two qualitative data collections were conducted: semi-directive individual interviews and focus groups. Both are relevant qualitative methods for an exploratory study aiming at a deep understanding of consumption situations and new or unknown phenomenons (Morgan, 1998; Malhotra, 1999; Evrard et al., 2003). A description of samples is provided in Table 1.

Each data collection followed the same process: (1) display and effective visit of the website (manipulation of the website, navigation and test of the functionalities—avatar personalization, online chat, 3D product display, trial of the clothes, etc.); and (2) semi-directive discussion during and after the visit. They were conducted on the basis of a guide, as recommended in qualitative research (for a summary: see Jolibert and Jourdan, 2006). The interview guide was only composed of a restricted number of themes: interviewer's function was to deepen each important element in the respondents' speeches and to remain flexible on the progress of the discussion, while encouraging respondent's freedom of expression. As each focus group was supposed to last only one hour, one theme was assigned to and deepened in each session (avatar, virtual experience, shopping in 2D vs 3D, shopping online vs shopping in real shops—2 focus groups per theme were realized), so to complete and saturate data from individual interviews dealing with all issues. Each interview and focus group was fully retranscribed in order to preserve the accurateness of recorded

speeches. The data corpus is finally composed of 510 pages and around 265 000 words (interventions of interviewers included).

Data Analysis

Data analysis was conducted according to an interpretative process and double coding, using the content analysis software Weft QDA: textual data were analyzed by two independent coders, on the basis of the interview guide and same coding units (groups of words). Flexibility was preserved through an open coding process, to identify and integrate new themes that could emerge from data. Codings were then compared and discussed so to reach consensus. Semantical saturation was reached with the 25th individual interview². Focus groups and additional interviews comforted categories stability and reinforced semantical saturation. In the second step of the analysis, theory emerged on the principle of constant comparison that is to say by systematically confronting open coding results to literature.

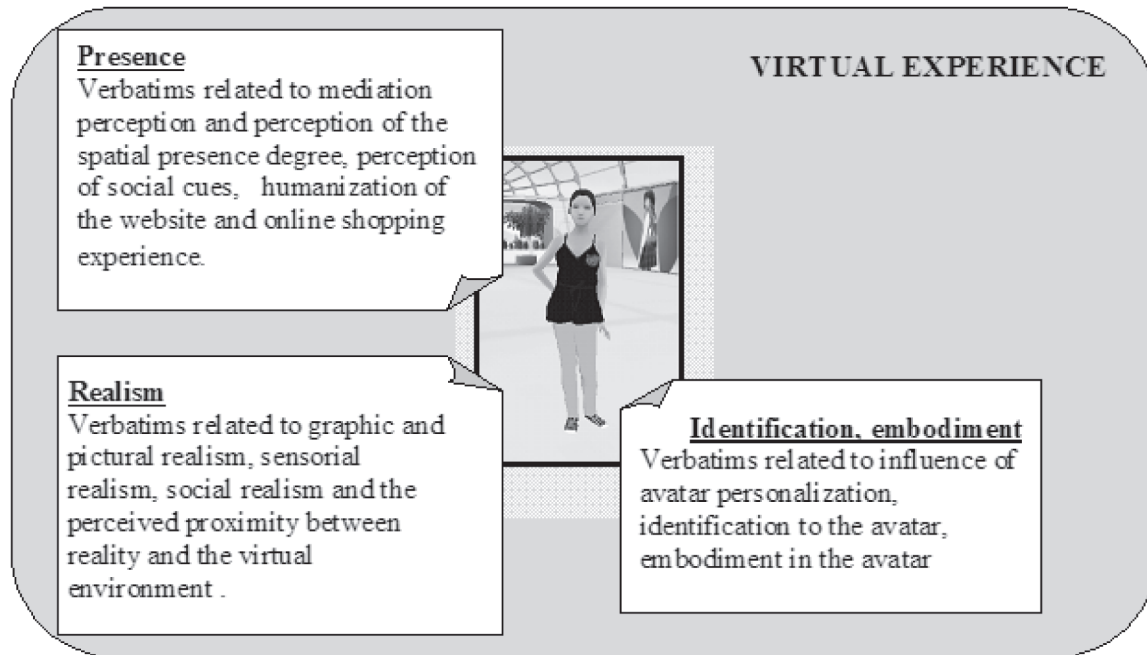

RESULTS AND DISCUSSION

Corpus analysis highlights various aspects of the experience related to immersion and experience in the 3D environment that justify the identified categories (Figure 1). As a matter of fact, the consumer-avatar (an avatar representing the consumer in the virtual shop) emerges as a central issue in the understanding of the virtual experience on the website.

In a computer-mediated environment, an avatar is defined as “a pictorial representation of a human in a chat environment” (Bahorsky, Jeffrey and Mason, 1998), “a representation of the user as an animated character in virtual worlds” (Loos, 2003), or “graphic personifications of computers or processes that run on computers” (Halfhill, 1996). Many researches have dealt with Embodied Virtual Agents (EVA) and their impact on consumer behaviour and consumption experience (Cassell et al. 2000; Holzwarth et al. 2006; Wang et al., 2007; Jeandrain and Diesbach

²Beyond themes and categories that are dealt with in this paper, more larger and/or peripheric themes were evoked and discussed by respondents (perspectives and attitudes towards utilitarian vs hedonic features and use of the website, comparison of 3D shopping with real-life and 2D shopping, virtual experience on a whole, brand-related features, etc.). All those themes help reaching saturation but couldn't be explored in this paper, focused on the key issue of the avatar.

FIGURE 1
Categories

2008) or with avatars in other settings (for example Wood, Solomon and Allan, 2008 in Second Life; Yong, Baker and Song, 2007 in virtual communities). But, to our knowledge, only one research (Crete et al., 2008) deals with the influence of consumer-avatar, that is to say an avatar representing the consumer on a shopping website.

Identification to The Avatar and Embodiment. As a majority, respondents spontaneously attempted to create an avatar that looked like them, so to be represented and embodied on the website: “What I am interested in is to create a character like me. To know how I will be” (Monique, female, 58). Nevertheless, respondents then express a general lack of identification to and embodiment the avatar. A great majority of respondents refer to the avatar using words such as “person”, “model”, “fellow”, “character” controlled through technology. “That sort of statue with that kind of bunches, it is far from being sufficiently human... It is difficult to identify with. (...) Yes, it a model but also someone in reality. It is not sufficiently human.” (Barbara, female, 33). Such metaphors serve as “moving less-than-conscious thought into the realm of consciousness” (Joy and Sherry, 2003): through the language participants used, embodiment, or here lack of embodiment and identification, is expressed.

Indeed, identification to an avatar refers to the imaginary process invoked in response to a character represented in the mediated environment (Peng, 2008): narration is absorbed and the virtual identity can take place of the real-life identity. Thanks to embodiment in the avatar, users can play an active role, providing himself a nearly direct experience (enactive experience), more powerful than mere observation. Though, in our case, the weak identification seems highly related to a strong detachment from the avatar that is no more referred to as an embodied representation of the user, but as an other artificial being. Indeed, the pronoun “I” is not used to refer to avatar’s actions-referred as “he” or “she”-but to individual’s actions in the real world. The avatar is perceived as a puppet controlled through the computer (arrows, mouse): respondents clearly mention they are on a computer, manipulating the avatar and not “shopping for real”: “You go for a walk like you

could go for a walk on Saturday in the malls... You go for a walk but “it is not for real” like we said when we were younger” (Franck, male, 40) “Unfortunately, there is always this space between me and the computer” (Emilie, female, 23). Acting on the 3D shopping website appears as a metaphor of the real, with distinct spaces and bodies (the real-life environment and body vs the online world and character controlled via the real world).

So, while theories on immersion in computer-mediated environments suggest an illusion of non-mediation by the human-machine interface (Lombard and Ditton, 1997), with embodiment in the avatar facilitating this illusion, the perception of this mediation is particularly prominent in speeches, especially through references made by participants to their own avatar. The perceived outstanding mediation implies respondents don’t seem to feel immersed in the virtual environment thanks to the avatar, and despite resemblance between them and their avatar, they don’t feel embodied on the virtual universe: “Honestly, for me, it is a character, it is not me” (Dominique, female, 48). Though, the perception of one’s own physical body related to self-construction and projection in a virtual body has been showed to be an important issue in virtual environments (Ulusoy and Vicdan, 2009) as embodiment plays an essential role in human experience (Joy and Sherry, 2003), even in virtual universes experiences. Three main related explanations can be suggested to understand why participants expressed such as frontier and detachment between them and the avatar.

First, the 3rd-person view seems to decrease the possible embodiment by creating strong detachment and weak appropriation of the space (Carù and Cova, 2003). In online gaming, 3rd-person view is giving the gamer a direct observation angle on his character, usually from behind. This view is usually opposed to the 1st-person or subjective view, in which the gamer is taking the character’s place, seeing the world through its eyes, as he sees the real world through his own eyes (Computer Gaming Lexicon, available at <http://www.jeuxvideopc.com/lexique/>). One specificity of 3D universes is to allow a subjective vision through the eyes of

the avatar, with regard to an external vision of the scene. Tisseron (2008, p.178) presents the specificities and consequences of those different points of view: "In each of his moves, my avatar allows me to see the world with "his eyes"—through subjective view—or to see it detached from myself, as in a dream. Either I live inside of him or outside of him. In the first case, I only see of him what I can see of my own body: my arms, my legs, ... In the second case, I'm free to observe all parts of my anatomy that are usually invisible to me, such as my back or the top of my head. I can even stare at a point where I'm not and see myself in middle of the environment."

Moreover, Tisseron (2008) suggested that manipulating an avatar necessarily implies detachment: the individual need to think about moves to make, and how to make them. Behavior of any organism (human or else) is not a series of discrete actions but a continuous flow of activity: the flow of unconscious low-level or automatic moves (for example, folding knees and pelvis) turns into high-level behaviours (sitting down on a chair) (Whalen, Petriu, Petriu and Cordea, 2003). Technology for controlling the avatar allows executing a restricted set of atomic moves through keyboards and mousing in order to accomplish high-level behaviors. On a shopping website, it more specifically implies to be aware of automatic everyday high-level behavior such walking, turning left or right, taking a cloth on a shelf, so to execute appropriate atomic moves with the help of technology (click in the appropriate way so that the avatar moves his arm and hand toward the shelf). This is at the opposite of fantasy and unusual acting in MMORPG-where high immersion can be found -, in which high-level behaviours, as they are unusual (for example throwing a fireball), have to be consciously learned: in turn, atomic moves more rapidly become automatism, thus reducing detachment with the avatar. So, in some cases, the ability to act does not necessarily require detachment: one can be taken in the process of flow and simply perform what has to be done (Joy and Sherry, 2003): when the body performs an activity unconsciously, individuals tend to experience flow (Csikszentmihalyi and Robinson 1990), the body simply takes over because of competence and experience (Joy and Sherry, 2003). So self-projection and embodiment in the avatar, as in virtual universes (Tisseron, 2008) and its impact on immersion could be questioned and deepened on merchant 3D websites as a key issue of the virtual experience.

Finally, lack of self-projection and embodiment in the virtual universe can be related, as expressed by respondents, to poor realism of the experience.

Realism on 3D The Commercial Website. As stated by Rosenblom (2003), some virtual universes can be very affective at creating the illusion of reality: the more they immerse users in stimuli corresponding to their expectations of the virtual world, the more compelling is their experience. This is especially relevant for a realistic virtual universe such as a 3D merchant website.

Three kinds of realism have been identified in participants' speeches: graphic (or pictural) realism, sensory realism and social realism. Analysis clearly points out the lack of realism of the avatar and the 3D environment on those three facets.

Graphic Realism And Sight Sense Mobilization. Participants explicitly verbalize their difficulties with the visual characteristics and atmosphere of the website: "That is to say that the shop looks like a fake. It really looks like cubes and rods; while clothes should have looked as real as possible. (...) One doesn't know if it's real or not real" (Emilie H., female, 23) "Whatever improvements that could be done, it's not the same sight as with our eyes. (...) It's flat. (...) There is no relief" (Marc, male, 59). This feeling is enhanced by the low perceived realism of the avatar, considered as "cartoon-like" and too much virtual and imprecise to convey visual aspects of a real human body. "It is like Albatos. It is like cartoons. What a

pity!" (Barbara, female, 33) "I have the feeling to be in a game, to be a Sims... in the Sims game" (Damien A., male, 29)

As stated by Tisseron (2008, p.170), "In virtual worlds, there is no way to touch. Everything is deliciously or desperately visual, according to your ability to be satisfied with it."

Sight sense, although it is supposed to be highly stimulated by 3D display, is not enough to mobilize senses in a sufficiently comprehensive and satisfying way to favour experience. As stated by Joy and Sherry (2003), the experience is tightly linked to the ability to sense accurately: "If you use only one of the senses, you acquire only one-fifth of the aesthetic experience. In synesthesia, however, several of the senses are included, and, hence, a more holistic appreciation is possible." This issue is particularly prevalent and relevant in a computer-mediated environment.

Sensory realism. In the unavoidable absence of touch sense on the Internet, a great majority of respondents highlight a further sensory isolation due to the absence of noise or music. "I don't like that too virtual aspect. There is even no music. (She looks for something to turn sound on the computer). (...) I find it so weird there is no music. When you go in a shop, there is music!" (Marion, female, 26). « Well... everything happens with our eyes, you can't touch, you can't... well... You can't hear noise coming from other persons... We are completely cut off the world... This is slightly limiting the shopping feeling we can have, compared to classical shopping" (Emilie H. female, 23)

Ambient music, voice noises (discussions) or step noises play a fundamental role in sales point atmosphere. But this sense is not really mobilized on Internet in general and particularly on the website, though it has been shown for example that subjects can 'lose' themselves when immersed in sound, (Dyson 1996; Schafer 1977 in Joy and Sherry, 2003). Moreover, beyond creating realism compared to a traditional sales point, using music and noise on websites can contribute to improve website visit experience (Galan and Helme-Guizon, 2003). According to Volle (2000), virtual atmosphere distinguishes from real atmosphere through the weak number of stimulated senses, as well as through a supposed higher degree of interactivity, which is inherent to Internet (Ghose et Dhou, 1998). As any website can be highly interactive, virtual atmosphere has a crucial differentiating role to play, by counterbalancing the freedom of quitting and finding another interactive website. A 3D website should benefit from this advantage on more classical configurations, through its capacity to associate product and service to an universe that can be sensory immersive and stimulate mental imagery in a more persuasive way.

Social realism. "You are rarely alone when you go for shopping on a Saturday at 5.00pm in a supermarket. So, I expected to meet other people there. But there, there is no salesman, a person you can click (...) I expected also to be with more clients to see which articles are the most attractive for people... see what they think about these articles there. Try to make a kind of small discussion group (chat) on the site, discuss with the avatar of someone else who is in Paris or Marseille... (...), but there is nobody in there!" as states Damien A (male, 25). Neither consumer-avatar in 3D nor the online chat tool seem to be able to compensate for the lack of humanity and the impersonality people usually blame websites for. But paradoxically, if some respondents blame the website for its social emptiness and seem to be longing for communication with others, many respondents also blame that social aspect of meeting and chatting with other people, because it could turn them away from their purchase goal, as if online shopping was considered as mainly utilitarian: "We turn away from the goal, we forget the purchase and we focus on the avatar. It becomes like a game in which we are walking... one meeting other avatars" (Nacera, female, 22).

Crete et al. (2008), in the only research dealing with consumer-avatar, studied its impact on a merchant website, through the use of a personalized avatar specific tool on a traditional 2D fictitious website, and demonstrated its positive influence on website perceived quality, attitude and stickiness. In that case, the consumer-avatar was mainly utilitarian: it was not used to wander in a fully 3D shop, and, as a consequence, was not considered as a potentially immersive and experiential cue, while in our case, consumer-avatar can be considered as a socializing asset of the website, enhancing perceived humanity as the consumer is represented in the e-shop and can socialize with other clients represented by their own avatars. Indeed, the physical sense of interacting with others should contribute to the experience of embodied perception (Joy and Sherry, 2003). Though, the question can be asked to what extent this is possible in a virtual worlds of avatars, as individuals can be embodied in multiple identities (real-life individual or multiple identities and roles, virtual identity(ies)). The lack of social realism encountered could also be related to the perception of a potentially blurred "social game" due to those identities issues.

With regards to those findings on identification, embodiment, self-projection and sensory realism on one hand and social realism on the other hand related to virtual experience and immersion on the 3D website, the proxy of the concept of presence, usually considered when dealing with immersion in a computer-mediated environment, emerges as the more relevant way to characterize the virtual experience and immersion through the eyes of an avatar.

Avatar and Presence. Presence refers to "a psychological state in which even though part or all of an individual's current experience is generated by/or filtered through human-made technology, part or all of the individual perception fails to accurately acknowledge the role of the technology in the experience" (ISPR, 2003): the individual has the perceptual illusion of non-mediation by technology (Lombard and Ditton, 1997) and feels deeply immersed in the experience. The feeling of presence (or telepresence, Steuer, 1992) is then seen as a basic condition for immersion or flow to develop. As stated by Van Schaik et al. (2004), realism associated with presence leads to immersion. Immersion can then be seen as a direct consequence of being present in the virtual world.

Lombard and Ditton (1997) distinguish two kinds of presence: (1) spatial presence, defined as "the extent to which a person feels his/her existence as rather located in the mediated space than in the real environment": the higher spatial presence is, the more the individual feels transported in the mediated place, the more he/she is attentive to stimuli from the mediated environment and less to those from the real environment (Csikszentmihalyi 1990); and (2) social presence, that refers to the sense of "being together with another", inducing perceptual awareness of other entities, access to their cognitive and affective states and a shared sense of intersubjective interaction (Bickmore and Picard, 2003): social presence can lead to "as if" para-social relationships (Lombard and Ditton, 1997).

On the one hand, with high spatial presence, an individual is supposed to behave as an actor and adopt behaviors as in the real world (Lombard and Ditton, 1997). In our case, as previously stated on embodiment, respondents seem to feel spectators of their avatar, experiencing a lack of coherence between their real actions (click to move) and what happens (hitting a shelf). They clearly don't perceive their existence in the virtual world

and express that their experience is an "as if" experience. "Precisely, the fact that we have an avatar, so as to take a walk in a store, make window-shopping, perhaps behave as a real client in real life" (Ouardia, female, 28). So, as in Jeandrain and Diesbach (2008), respondents reject the idea of full spatial presence.

On the other hand, as all consumers are humanly represented

in the 3D shop, social presence should be enhanced. Indeed, avatars are implemented in order to humanize e-shopping and create a feeling of social interactions. But due to the lack of spatial presence, and despite the presence of a chat module, consumer-avatar doesn't seem to be an outstanding enough social cue, as it has been demonstrated for virtual communities (Yong et al., 2007): "The avatar will never replace someone, the opinion of a person or a friend" (Agathe, female, 22)

Nevertheless, a special interest emerged for EVA: all our respondents mentioned they were expecting or looking for a salesperson as the main social cue of the website. "Can I sit down here and wait for a saleswoman?" (Damien M., male, 29) "There are no saleswomen (...) A presence is missing." (Françoise, female, 54).

Those results are related to findings on the influence of EVA (Cassell et al., 2000; Holzwarth et al., 2006), especially on presence and immersion (Jeandrain et Diesbach, 2008). Though, results are contrasted: Jeandrain and Diesbach (2008) highlighted the negative impact of the EVA on social presence, while Wang et al. (2007) concluded on the positive impact of an EVA as a social cue on a shopping website.

CONCLUSION

Although we live in a three-dimensional world, nowadays most of the commercial websites are primarily in two dimensions. However, improving the virtual experience has become a major issue for e-marketers. As already stated, developing the hedonic value of websites and improving the virtual shopping experience on Internet should lead to a better conversion rate, more satisfaction, stickiness and loyalty (Childers et al., 2001). In this perspective, our findings are quite telling. In line with Malter, Antonio and Garbarino (2008) pointing the importance of the online avatar's realism and authentic representation of the real world, our work highlights the key role of the avatar and the concepts of presence (Steuer, 1992; Lombard and Ditton, 1997) and realism as basic conditions for immersion in the context of a 3D commercial website. Specifically, we bring to the light the importance of the avatar embodiment for consumer in merchant 3D environments and its influence on immersion as well as the importance of social presence. The context of interviews does not favour a natural situation of immersion and might explain why most respondents seem to feel spectators of their avatar and don't express the illusion of non-mediation that should make them actors. However, we observe interestingly that four of our respondents (Jean-Marc (male, 59), Emilie (female, 23), Medhi (male, 23) and Romain (male, 25) experienced a kind of immersion since they have interrupted the interviewer in order to further explore the website.

Perceived value is one of the essential outcomes of the marketing activity (Holbrook 1999). In this perspective, the retail experience, in this case the commercial website visit, must deliver value so to turn a one-time visitor into a repeat customer. Both practitioners and researchers believe that the best way to gain customer loyalty is to ensure that customers have an "emotional" experience with products or service or in the retailing environment (Holbrook, 1999, Filser, 2002). Building on the work of Holt (1995), the 3D commercial website visit might be considered as a consumption activity in the sense of interaction with the consumption's object. Holt (1995, p.2) considers two dimensions of the consumption, structure and purpose: "In terms of structure, consuming consists both of actions in which consumers directly engage: consumption objects (object actions) and interactions with other people, in which consumption objects serve as focal resources (interpersonal actions). In terms of purpose, consumers' actions can be both ends in themselves (autotelic actions) and means to some further ends (instrumental actions)". In this two-by-two matrix, the value of the

3D commercial website might appear more as autotelic, consuming as a play (social presence, hedonic value of the experience) or as experience than instrumental. In this line, Jeandrain and Limbourg (2002) observed that experiential shoppers seem to prefer 3D online environments, whereas the instrumental shopper is less impressed by it. Therefore, the adding value seems to lay more in experiential retailing than in merchandise itself. As consumers are living more and more of their lives online, the possibility to interact with other consumers, to share experience of shopping represent an avenue of possible researches in order to understand how shared experiences on the web contribute to the perceived value of a commercial website as well as to consumer social relationships both online and offline.

Managerial consequences are multiples. The impact of the 3D commercial website has to be considered both directly in terms of direct sales but mainly indirectly in terms of consumers' community, image of the company and potential vector of transchannel behaviour of consumers. In the perspective of virtual malls, these two points appear as particularly prevalent. From a theoretical point of view, this research contributes to a better understanding of the virtual experience in a 3D commercial website context, pointing out the key role of the avatar. While technological development are outpacing consumers' ability to cope with developments, researchers are struggling to develop and apply appropriate models of consumer behaviour that would potentially enrich consumers participation in those new shopping environments. Research and managerial perspectives can be suggested, especially website configuration and display, above all concerning the view, and presence of an EVA and interactions with consumer-avatars.

Some limits can be highlighted. The study was realized mainly on one website, related to a specific product category. Victoria Couture is a high-range brand, with few physical shops, and this could have been a reason why few people were connected on the website, inducing a possible bias on social presence perception. The website is mainly designed for women, and though precautions have been taken with male respondents (they were asked to imagine they were buying something for a female friend/girlfriend/wife), this could have caused a bias in the perception and evaluation of the avatar. Our research qualitative method by interviews is not the most favourable for immersion, as respondents are forced to detachment and "go back to reality" to express their feelings and discuss with the interviewer. Finally, this paper, as stated previously, focuses on key issues around the role of avatar in the embodied experience and immersion. Other themes such as utilitarian vs hedonic aspects of shopping in this settings, identity role-playing in a social presence context, will have to be analyzed.

Research perspectives cover a wide area of confirmatory researches, both qualitative (deeper analyses to highlight specific patterns through speeches, new interviews with actual users, expert or future users such as teenagers who are used to 3D virtual universes and games) and quantitative, through experiments, related to the consumer-avatar and its impact on presence and immersion, the influence of sensory (sight, hearing) display of the 3D environment on virtual experience. Perspectives in line with actual Human-Computer Interfaces research issues can also be considered: aesthetics in designing those 3D shopping interfaces and the link of aesthetics with experience, anthropomorphism (or fantasy) in avatar design, emotions and affect in 3D retailing-as an embodied experience can generate highly intense feelings. In fact, the present investigation has obviously just scratched the surface of an enormous iceberg.

Developing Brand Literacy among Affluent Chinese Consumers A Semiotic Perspective

Laura R. Oswald, University of Illinois, USA

ABSTRACT

In this paper, I focus on a form of consumer acculturation I call “brand literacy,” e.g. the ability of consumers in emerging markets to acquire and manipulate the codes structuring brand meaning as it is communicated in advertising signs and symbols, retail spaces, and packaging. I base this theoretical inquiry on early stage findings from an ethnography of affluent consumers in Shanghai (2007-2008). Findings suggest that Chinese consumers purchase luxury goods such as watches, bags, and cosmetics, without tapping into the deep, emotional, and imaginary worlds that create value for European luxury brands. Respondents in Shanghai tended to collapse brand distinctions into a somewhat generic association of all luxury brands with high price, status, and distinction. They claimed that luxury purchases did not express their own personalities, and that luxury advertising fell short of helping them personalize their brands. I contend that acquiring the rather sophisticated codes necessary to read and integrate brand discourses resembles language learning, because brand literacy, like language acquisition, is structured by cultural codes and follows specific stages of acquisition. I develop a structural semiotics approach to brand “literacy,” and suggest ways that advertising may contribute to this type of acculturation process.

INTRODUCTION

In this paper I develop a theory of brand literacy that accounts for the stages involved in the acquisition of fluency in reading and internalizing brand meanings. This research has particular resonance for consumers in developing markets, such as the People’s Republic of China, who may be the first or second generation of consumers to purchase branded products instead of trading vouchers for commodities. Findings have implications for consumer acculturation theory, advertising research, and brand management.

Drawing upon structural semiotics, I approach brands as discourses that are structured by codes. Since semiotic codes are rooted in cultural conventions similar to language, they offer a window onto the mechanisms involved in meaning exchange across cultural borders. In this paper I examine early stage findings from in-depth consumer research with 16 affluent consumers in Shanghai between 2007 and 2008, on the topic of luxury brand consumption. The study was limited to research on European fashion categories, from leather goods to couture, watches, and cosmetics. Consumers discussed their own experiences of luxury, their understanding of Chinese luxury traditions, their perception of European brands, and their interpretation of brand communication in magazine advertisements for global brands such as Louis Vuitton, Dior, and Patek Philippe.

Early stage findings suggest that Chinese consumers stop short of identifying the emotional associations that distinguish luxury brands from each other and as a result, often lack a visceral, personal connection to the brands they purchase. Since brand value on the marketplace is founded on nothing less than the personal and emotional associations consumers associate with brands, these findings have serious implications for the growth of the European luxury sector and also raise important questions about brands in translation, consumer cultures in contact, and the limits of consumer assimilation to global consumer culture.

Findings Summary

The next generation of the new rich in China expect more of luxury brands than to display their money and success. They expect luxury brands to both express and inform their *savoir faire*, personality, and taste. They also expect advertising to assist them in learning how to “read” and appreciate brand meanings. Respondents moving up the economic ladder with their new MBA’s and rich husbands consistently expressed disappointment with their expensive purchases because they did not identify with the persona of the brand or the emotional dimensions of luxury that were suggested in luxury advertising. They had trouble making qualitative distinctions between luxury brands and failed to connect with brands in a “visceral” way (Wetlaufer 2001). Though they sought brands that would reflect their personalities, the brands they bought did not satisfy this need. Their luxury bags and shoes did not extend their personal identities much beyond the meanings of ‘status’ and *savoir faire*. Several respondents reported losing interest in their LV bags once they got them home, leaving them in the closet with indifference. As the goods piled up in their closets, these same consumers expressed strong interest in finding a “match” with a brand that satisfied their need for self-expression and met their expectations, fueled by advertising, that luxury consumption would enrich their fantasy life.

Consumers struggled to move beyond the somewhat generic interpretation of luxury brands as “expensive” and “high quality.” They also interpreted luxury through the lens of Confucian values, associating luxury consumption with a noble character and, ironically, the simple life.

THE HISTORICAL CONTEXT

Specific historical and ideological conditions in China have interfered with local traditions of luxury, not only since the victory of Communism in 1949, but as one author suggests (Xiou 2008), for the past 150 years, as the result of colonial invasions, wars, and the frugal ideology of Confucianism. Most recently, luxury traditions and values were repressed by Mao Tse Dong, who tortured rich property owners, destroyed or stole their luxury possessions, and banished them to the countryside during the Cultural Revolution.

This may explain why respondents did not draw upon local traditions and values related to luxury as means of interpreting and assessing the meaning and value of European luxury brands. The signs and symbols of luxury represented in European ads were thus meanings that lacked a referent in a deep, context-rich experience of luxury. As a result, consumer responses to European luxury focused on the most general meanings of luxury, such as price. In linguistic terms, their responses betrayed tensions between the meaning and reference of brand symbolism. The CG logo may signify success, because they are so well known, etc. But these brands do not conjure up any emotional experience, fantasy, or image that the consumer can relate to. Consumers struggle to find a brand that links brand symbolism to their personal values, lifestyles, and fantasies.

Barriers to identification

The same respondents seemed to have less difficulty assimilating the meaning of goods in other product categories, such as

household goods. I discuss further on the case of one respondent who had adopted lock, stock, and barrel what I call the “Good Housekeeping” consumer culture of the West, including Kohler kitchens and baths, a child centric household, and a self-effacing yet stylish demeanor. Other researchers also report that in categories such as spirits and tourism, managers have been able to forge transnational brand identities by means of advertising that plays with contrasts and similarities among national identities and values (see Cayla and Eckhardt 2008).

Thus history and ideology have diminished the meaning and value of luxury in the popular consciousness. As a result, consumers grasped the general meanings of luxury, such as “expensive,” “successful,” and “royal” (“like the British royal family”). They also interpreted luxury through the lens of Confucianism, a philosophy that values personal virtues and filial piety over materialism. Several respondents actually stated that people who purchased luxury fashion brands were probably “took care of their parents.” Luxury brands can also make other people happy.

BRAND LITERACY

In semiotic perspective, I claim that the acquisition of brand literacy follows a course similar to the acquisition and of language and is regulated by semiotic codes. I focus in particular on the work of Russian linguist Roman Jakobson. I then extrapolate the theories of language acquisition and cognition to the realm of social semiotics and the acquisition of the cultural codes that enable consumers to understand what each luxury brand “means.” Moreover, rather than simply take the European meaning of luxury at face value, the brand literate consumer would be able to manipulate the luxury codes in ways that would enable them to transform brand meanings from a foreign culture into their own personal brand experiences. The purpose of this investigation is to find out what stands in the way of brand literacy for Chinese affluents in this sector, and to suggest ways that marketers could improve this process through changes in current marketing strategy.

Barriers to Acceptance

To summarize, research findings suggest that several factors inhibit Chinese consumers’ ability to make qualitative distinctions between brands and to use luxury brands to express their personal tastes or “extend” their personas (Belk 1988). They include:

- Misleading assumptions about the meaning and function of luxury for Chinese consumers. Bourke (1996) and Cayla & Eckardt (2008) show that the acculturation of consumers in emerging markets depends upon a two-way understanding and appreciation of the complex cultural systems of the brand culture on the one hand, and the local consumer culture on the other, for successful brand adoption.
- Over-reliance on the single-image luxury magazine ad by marketers. As Bourke (1996) demonstrates in his analysis of consumer acculturation in Zimbabwe, an array of marketing events, including in-home demonstrations and personal selling, contribute to the acculturation process.
- Insufficient contextualization of the brand—not to mention the luxury category in general—in the culture of consumers.
- Lack of an account of cultural differences in the way Asians, as opposed to Westerners, interpret the world of meaning in general.

LITERATURE REVIEW

The current paper fills a gap in the literature on consumer acculturation, brand meaning, and advertising by proposing a

theoretical account of the ways consumers learn how to read brands and acquire “brand literacy” over time. (Otnes and Scott 1996, Hirschman et al 1998, McCracken 1986, Sherry and Camargo 1987; McQuarrie and Mick 1999; Mick 1986, Mick and Buhl 1992; Stern 2007, Fournier 1998, Grayson and Schulman 2000, Cook 2004, Douglas and Isherwood 1996/1976, Belk 1988, Hirschman et al 1989, Sherry and Camargo 1987). The question of brand literacy may seem moot in developed markets such as North America, even though it applies to advanced consumer cultures as well. Brand literacy has obvious consequences in developing economies, where individuals may still be learning to become consumers, relate to advertising, and make brand choices based on the strengths of advertising to communicate the benefits of one brand over another.

Sherry (1987, p.456) first referenced the idea of brand literacy in an essay in *Marketing and Semiotics*, using the term ‘illiterati’ to reference consumers in developing consumer societies targeted by advertising. Sherry emphasizes the role of advertising in the dialectical process of consumer acculturation, as advertising forms a site for communicating messages and also for consumers to project their own meanings into the advertisement. Sherry anticipated the cultural tensions that globalization would foster as consumer culture expanded beyond its western borders, encountering deeply entrenched indigenous cultures in its wake.

The issue of brand literacy might suggest to some that consumers in the developing world should “learn the dominant language,” and assimilate into global consumer culture. To the contrary, I contend that developing markets are more likely to resist cultural hegemony by becoming brand literate, inasmuch as brand literacy does not stop at teaching consumers how to ‘read’ western culture, but enables consumers to manipulate cultural codes along the lines of local values, meanings, and priorities.

The researcher seeking to understand *how* brands mean must consider advertising as a medium for moderating the intersection of cultures in contact and for potentially providing a guidebook for translating brand meanings from one cultural system to another. As findings from the current ethnography suggest, translating brands is a dialectical process moderated by the intersection of the marketing message and the perceptions of consumers. Our research suggests that consumers in developing markets are not likely to be assimilated easily or completely into a monolithic global consumer culture, because they either fail to link the signs in the ads with anything beyond the literal meaning, or filter these messages through the lens of local values and ideology and misconstrue the brand meaning altogether.

Becoming a Consumer in China. The current study stands out from the current literature on consumer acculturation in Asia, by deriving insights from speaking directly with consumers about their brand perceptions. Extant research relies primarily on inferences from advertising analysis (Zhou and Belk 2004). Notable and worthy examples include Zhao and Belk (2008a, 2008b), who analyze communication strategies for resolving tensions between the Communist egalitarian ideology and consumer spending in Chinese advertising; Cayla and Eckhardt (2008), who examine advertising strategies that leverage common goals and cultural distinctions among regional Asian cultures to create a pan-Asian consumer culture; and Tse et al (1989) who infer cultural and ideological differences among consumers in the PRC, Taiwan, and Hong Kong, by means of a content analysis of advertisements in those locations. Such studies are based on the assumption that advertising is a “cultural system” that reflects the needs and wants of consumers in the marketplace (see Sherry 1987). However, such studies do not account for the complexity of the cognitive and cultural processes involved in reading and internalizing brands.

Consumer Acculturation. The current study advances the literature on consumer acculturation in several ways. It extends Cook's (2004) work on the acculturation of children into consumer culture by breaking down the consumer acculturation process into stages of acquisition, internalization, and implementation of brand awareness and identity. By drawing parallels between brand literacy and language acquisition, I show how brand literacy develops in stages and is influenced by social, educational, and marketing variables. I extend Schroeder's work on visual culture by foregrounding the role of cultural codes to structure the way consumers unite in a kind of collective imagination around the brand. I even place in question the tendency of marketers in the West, most notably in the luxury sector, to privilege vision over the other senses, which may form a barrier to acceptance among consumers of other cultures.

Advertising Research. My approach also advances extant research on advertising communication. First, I approach brands as discourses structured, like language, by codes and modeled after structural semiotics. These semiotic codes account for the ability of consumers to share meanings communicated in advertising. Second, I focus on consumers in emerging markets who do not automatically "speak the language" of Western consumer culture. Third, I study the acquisition of brand literacy in diachronic perspective, highlighting the stages consumers must pass through in order to understand the depth and breadth of meanings associated with brands.

1. *Brands as discourses.* The advertising research literature abounds with theories of the ways consumers interpret meanings, from content analysis to reader response theory and semiotics. However, most studies make inferences about the question of advertising as a language based on the effects of advertising on consumers, rather than on analysis of the codes structuring meaning production in the brand discourse (Mick and Buhl 1992; Scott 1994; Hirschman et al 1998; Scott and Vargas 2008). The argument goes something like this: if consumers all agree on the meaning of an ad, or change their behavior because of a marketing campaign, then, by a logic of cause and effect, the advertisement must be structured like a language.

2. *Multi-Cultural Research.* The extant research has been conducted mainly with mainstream American consumers who have high fluency in reading brand discourses because American culture is inseparable from consumer culture. In emerging markets, consumers must translate Western brands into terms that have meaning and relevance for their values, ideology, and history. Research that is limited to consumers in developed markets take for granted that we all speak the same "language" when it comes to understanding the codes shaping symbolic consumption. Symbolic consumption is structured by sophisticated, culture-specific rules that transform commodities into meaning-systems that consumers learn to love. Cross-cultural advertising research sheds light on meaning exchange between cultures in contact and draws attention to semiotic and cognitive processes that transform goods into meanings in any social context.

3. *Brand Literacy in Diachronic Perspective.* Previous approaches to the question of how consumers make meanings of advertising have focused on the synchronic structure of individual ads and consumers' readings of them. Findings from an ethnographic study of affluent consumers in Shanghai suggest that consumers in emerging markets pass through various stages of brand literacy in order to identify and identify with the precise meanings and worlds associated with brands. I therefore approach brand literacy from a diachronic perspective, in order to account for specific stages of literacy acquisition.

Stages of Brand Literacy

During the fieldwork I identified three consumer segments based on their readiness to interpret brand meanings represented in western ads for luxury brands. The stages in this process include: 1. a literal reading of the message, e.g. Louis Vuitton is a famous luxury brand from France, 2. a nuanced reading of connotations associated with the message by reference to a context e.g. wearing Louis Vuitton communicates that I have *savoir faire* and participate in the global luxury culture), and 3. internalization of the brand message and wearing the brand to express or extend one's self-construction and culture. Each stage of this literacy acquisition process involves distinct semiotic operations. They include deciphering the literal meaning of a brand message; reading the nuances and connotations of the message; and relating the message to the context, including the mindsets of consumers.

The Role of Advertising. Degree of brand literacy was associated with several social factors, including 1) travel to advanced consumer societies, including Hong Kong, 2) the kind of work one did (the housewife was more knowledgeable about household brands, 3) a passion for design and luxury, which prompted respondents to find out more about the luxury category and culture. However, I am more interested in the ways western luxury advertising may create barriers to brand literacy by failing to relate brand meanings in a single ad to a cultural context that has relevance for affluent consumers in developing consumer markets. For example, while marketers might use personal selling, shopping mall tutorials, and other non-traditional media to educate consumers about a category or brand, luxury marketers rely to a great extent on the single magazine photograph. Luxury advertising isolates the brand from the lived context and experience of consumers and privileges visual culture over other forms of communication. Both of these factors present barriers to acceptance for Chinese consumers.

A Semiotic Perspective

The very notion of brand literacy is grounded in the assumption that non-linguistic sign systems such as advertising are structured like language, by means of codes or conventions that are embedded in the culture of consumers. Structural semiotics, like linguistics, offers a rigorous, repeatable methodology for analyzing the codes underlying the structure of meaning and reference to the cultural context in discourses such as advertising and consumer behavior. Semiotics has the advantage over content analysis by identifying objective criteria such as codes, rhetorical operations, and other formal dimensions, that transcend the content of the message itself and point to structural systems, patterns, and rules that bring order and meaning to phenomena under the rubric of culture.

Structural semiotics transcends its origins in Russian Formalism (Lemon and Reis 1965) by moving beyond the simple formal analysis of texts and taking account of the implication of form and meaning in a given cultural context, such as the family meal. Though meals have a beginning, middle, and end, the meal preparation, the disposition of the family members around the table, and the foods brought to the table are inseparable from the cultural values, priorities, and traditions of the family.

The notion that discourses are structured both by the internal organization of signs and external references to the context of the communication originates with the linguistic theories of Swiss linguist Ferdinand de Saussure ((1833/1971/1913) in the 19th century. It has been refined and expanded over the years by experts in the areas of semantics and culture theory. They emphasize the importance not only of the structure of discourse but the reference of discourse to the context of the communication.

Brand literacy operates both on the level of the *structural* meaning of signs—their literal, “dictionary meaning,” and the *semantic* meaning of signs formed by the relation of the dictionary meaning to the context of discourse. Writers such as Eco (1979), Greimas (1983/1966), and Benveniste (1971) extend structural semiotics by emphasizing that discourses are not only meaningful because of the codes structuring the coherence of the sign system itself, but the semantic codes that embed discourses in the context of the communication event. Irony is a good example of the importance of context. The utterance, “What a beautiful day!” taken at face value, signifies meanings associated with good weather. When someone utters this same statement in order to remark on yet another cold and rainy day in Detroit, the meaning becomes an ironic comment on the bad weather. In other words, two distinct levels of semiotic organization—the internal structure of signs and the reference to a semantic context, drive meaning production.

The distinction between the meaning and reference of discourse, we shall see, has great importance for understanding the dynamics of brand literacy. Though I will elaborate in more detail on this dynamic further on, suffice it to say that consumers must be able to not only understand the meaning of brand signifiers (e.g. “This is an expensive brand.”)—but relate them to the semantic context of the brand world, the product category, and their own lifestyles (e.g. “This brand expresses my desire to be youthful, reckless, and sexy.”). It is precisely the inability of consumers in this study to relate luxury European brands to their own lifestyles that forms a barrier to differentiating, personalizing, and choosing one brand over another.

Levels of Meaning

Brand literacy affects various levels of brand semiotics, from the logo to the broad system of associations brands communicate over time. These levels include

- Denotation, or the literal association of a signifier with a signified, the way logos stand for the company. The CC logo references the Coco Chanel brand.
- Connotation, the association of a signifier with an esthetic signified, such as the association of the logo with the brand’s quality, positioning, and benefits for consumers. The sign /CC/ stands for exclusivity, high status, and classic beauty;
- Symbolism, the association of brand signifiers, from the logo to celebrity endorsers, with the brand culture and identity. The Chanel woman is classic, intelligent, assertive, and sophisticated.

THE SEMIOTICS OF LUXURY ADVERTISING

In this section I reproduce an exercise I use in the classroom to initiate students into the practice of semiotic analysis. It involves sorting, classifying, and analyzing brand distinctions in a set of advertisements for luxury perfume. The exercise displays the complexity of the semiotic systems at work in advertising that contribute to brand distinctiveness, appeal, and cultural relevance, all of which contribute to the value of brands. It also defines the parameters of the kinds of meanings that consumers, with some prodding, can identify in advertisements. Students in the West are able rather quickly to enter into the analysis of the ads, highlighting a range of semiotic operations and levels of meaning that structure differences and similarities between major brands and contributed to consumer distinctions between brands as personalities. However, most respondents in Shanghai produced a limited repertoire of emotional associations with the advertisements, which led to their

difficulty differentiating one brand from the other on the basis of qualitative values.

Luxury perfume advertisements are distinct from everyday brands inasmuch as they reinforce the fantasy of the woman set apart from the mundane details associated with shopping and saving money. A quick binary sort of the ads produced a binary set of images: one set used only black and white, the other stack only used color photography. The black and white ads employed metonymy to engage the spectator in the narrative depicted in the image—we see a part of a story and must fill in the details; the color ads employed metaphor to make comparisons between the perfume and the feminine icon in the image. Further analysis revealed a paradigmatic set of oppositions beginning with rhetorical style and extending to the kinds of characters, their points of view in the image, the camera angles, and cultural cues. (Figure 1)

Branding Cultural Myths

Like works of art, luxury brands tap into the myths and icons of culture, and promise the consumer access to transcendent experiences such as beauty, limitless wealth, and immortality. Since perfume itself is ephemeral and impermanent, the brand benefits of the luxury perfume category are entirely based on the delivery of intangible esthetic associations of the brands with idealized representations of women at personal, social, and existential levels of discourse. The strategic question, then, was how different luxury brands were positioned with reference to the question, “What is Woman?”

Though a longer account would draw attention to the broad and complex range of meanings communicated in the ads in this exercise, this limited discussion highlights how, with some probing, consumers make sense of advertising, reference advertising to build an image or personality for specific brands, and acquire preferences and emotional attachments to some brands rather than others.

This cursory analysis nonetheless highlights the difficulties consumers in non-Western markets might have to enter into this semiotic game, missing the nuances and emotional meanings that define brand equity and identity. Though even undergraduate students in the United States are able to identify the semiotic dimensions of these ads to some extent, respondents in Shanghai displayed, to varying degrees, limited abilities to elaborate upon the distinctions among brands or the cultures represented by these brands. Such consumer responses to advertising are symptomatic of a deep divide between the culture of the target market and the culture of the brand, and threaten the perceived value of the brand for these consumers.

The Structure of Literacy

Russian linguist and semiotician Roman Jakobson (1956/1990) discovered that language literacy occurred in stages and that not all people followed these stages in the same way. By studying the stages of language loss experienced by aphasics and comparing findings with the stages children pass through to in language acquisition, Jakobson developed a binary schema for mapping the literacy process in terms of a double axis formed by associations by similarity (the paradigm or set of all possible replacements) and associations by contiguity (the syntagm or concatenation of all terms in a given message). These semiotic structures, in Jakobson’s schema, parallel cognitive operations of substitution and alignment in the mind.

Jakobson also identified two distinct types of aphasia, distinguished by the relative emphasis on the ability to create associations by similarity and the ability to create associations by contiguity. He

FIGURE 1
Positioning the Feminine

finds that one set of aphasics gradually loses the ability to combine signs on the basis of their similarity—they can define a word, for instance, but they cannot replace it with something like it, as in the paradigmatic association of a knife with similar tools using a blade. The other set of aphasics gradually loses the ability to combine signs on the basis of their contiguity—their logical or physical association with each other, as in the linear or syntagmatic association of the table knife with all other utensils in a serving set.

In typical Structuralist fashion, Jakobson extrapolates these findings about two types of aphasic disturbances to a general theory of “two aspects of language” that account for non-linguistic forms of literacy associated with cultural systems other than language, such as prose and poetry.

Jakobson’s schema has important implications for consumer acculturation and brand literacy because it enables the researcher to separate the broad associations consumers make between a brand in the paradigmatic set defined by a product category, such as all luxury brands, and the unique associations they make between the brand and other meanings, rituals, and symbols on the syntagmatic axis, associations that distinguish it from other brands in the category. By mapping consumer responses to brands on these two axes, we are able to identify sites of semiotic productivity and resistance in relation to the luxury category.

In the present, Chinese context, we could say that affluent consumers seem better able to associate one brand with others in the paradigmatic set of all luxury brands, but have limited ability to find syntagmatic associations between a single brand and the meanings, rituals, and personal identities that contribute to the brand’s positioning in the marketplace. The inhibition of consumers’ ability to generate rich associations with the brand on the syntagmatic axis is symptomatic of low brand performance in this market, due perhaps to cultural barriers between the way Western luxury is communi-

cated in advertising and the way Chinese consumers experience these messages.

The Limits of Structural Semiotics

Though it is important to know that there are broad mental operations governing the association of semiotic units in discourses, there are limitations to Jakobson’s structural system. Though he defines the structural parameters shaping the acquisition of language (semiotic) literacy, his approach does not account for the role of the cultural context in this process. This criticism forms a dividing line between structuralism and post-structuralism in semiotic theory, because as it stands Jakobson’s approach defines an ideal world of language, rather than language exposed to the instability and play of speakers/consumers as they navigate cross-cultural contexts.

I propose to extend Jakobson’s binary system of discourse by including a third term, the relationship of the isolated meaning of a statement and references to the cultural context of the communication event. For it is at this juncture that advertising in the European luxury sector falls short. It takes for granted the unity of luxury signifier and signified in a single vision of luxury culture, fails to establish the cultural parameters which provide depth and breadth of associations between the brand and the world of luxury, and fails in its larger purpose of negotiating differences between the codes of western luxury and the values, beliefs, ideology and history of luxury consumers in emerging economies.

Implications for Advertising Strategy

The brand literacy of consumers in these growth economies has important economic implications, not only for particular companies but for the global economy, inasmuch as brands grow in value to the extent that consumers understand brand messages

about the perception of quality, develop loyal relationships with brands, and expand the meanings of brands into personal associations (Aaker 1991, Fournier 1996, Yankelovich 1964).

Economic Implications

Luxury manufacturers in the West rely on the double-digit growth in emerging markets such as China. Revenues for LVMH have declined steadily since 2006, reflecting not only the global economic downturn, but declining brand value in this sector. While the first generation new rich in China may have been content to show off famous, expensive brand names even if they did not connect with them on emotional levels, the newer generation of affluent consumers may seek other outlets for their luxury purchases because the current brands do not satisfy their needs for brand relationship and self-expression. Perhaps the models do not communicate the values and distinctions Chinese consumers expect of luxury goods. Advertising plays a role here, since advertising has the ability to link brand identity with the culture of consumers by means of multi-cultural signs and symbols (Sherry 1989; Cayla and Eckhardt 2008). Perhaps luxury advertisers should follow the lead of marketers in other categories, abandoning the assumption that luxury transcends time and culture (Wetlaufer 2001) and finding ways of weaving their brands into the lives of Chinese consumers. Perhaps they should follow the lead of the Louis Vuitton "Journey" campaign and feature notable celebrities in advertising that speak to the moral values and beliefs the Chinese associate with luxury, not just their fashion appeal. (On the role of celebrity endorsers and consumer morality, see Wicks et al. 2007).

Advertisers may err in assuming that Chinese consumers already know the 'rules of the road' relating to luxury goods, rituals, and culture. With the market opening in China in the 1980's, global advertising has the potential to exceed its marketing function and serve as a moderator for consumer acculturation in relation to western representations of luxury. Moderating consumer acculturation means strengthening the relevance and intensity of the emotional and cultural connections Chinese consumers make with Western brands and consumer rituals, thereby growing loyalty and future growth in the European luxury sector.

Galloping through the Global Brandscape: Consumers in a Branded Reality

Kaleel Rahman, American University in Dubai, United Arab Emirates

Helene Cherrier, American University in Dubai, United Arab Emirates

ABSTRACT

The idea that endless numbers of brands shape people's day-to-day life is known as "brandscape" (Biel, 1993; Sherry, 1998; Soloman, 2003). When consumers live in another country for an extended period of time not only it is necessary to engage in various consumer behaviors in order to conduct everyday life but also brandscape becomes part of their life. The aim of this study was to explore consumer acculturation to an unfamiliar brandscape. A grounded theory analysis of case study type interviews resulted in three broader domains with seven themes: "sentiments" with *experiential tension, nostalgia and patriotism*; "brandscape" with *global brands, missing brands, ethno-brands and beloved brands*; and "consumer acculturation". The paper discusses the findings of the study and the implications of the emergent themes.

INTRODUCTION

Jordan, a 34 year old Aussie bloke! Jordan woke up this morning at 6.40, jumped out of his *Ikea* bed, put on his weird *Dunlop* slippers, rushed into the bathroom, brushed his teeth using his *Colgate* toothpaste, had a clean shave with his *Gillette Sensor* razor and *Old Spice* shaving cream, and had a warm shower scented with his *Herbal Essence*. Having had a quick breakfast and a quick spray of *Obsession by Calvin Klein*, he jumped into his *Toyota Camry*, switched on to *2DayFM* radio. On the way, he filled up at the *Mobil* petrol station next to the *Microsoft* head office. Jordan arrived at work, approached his hot desk, said 'good morning' to his colleague who had her aromatic *Starbucks* coffee cup, and he sat on his chair and switched on the *Dell* desktop.

Although I have not described even two hours of Jordan's life, you may have gained a reasonably good picture about what kind of a person he is. Flavoured by his likes and dislikes, the brands I have mentioned define who he is. The idea that endless numbers of brands shape people's day-to-day life is known as "brandscape" (Biel, 1993; Sherry, 1998; Soloman, 2003). As you may notice, Jordan merely know some of these brands, others he uses frequently; He has strong feelings towards some but not towards some others.

Assume that suddenly you go to a new country to spend about three years. Would you take all of "your" brands with you? Would you expect your brands to be available in that country? Would you miss the brands that you leave at home? How would you react to the new brands that you encounter in the new country? What are some of the feelings, emotions and thoughts, both positive and negative, that you would experience with regard to brands when you are in the new country? As a consumer, how would you acculturate to your new brand-related environment? These questions motivate this research.

The study of global brands has become an important area of research in marketing. The special issue devoted to "branding in the global marketplace" in the *Journal of International Marketing* in 2008 with notable contributions from consumer researchers (Cayla and Arnould, 2008) who critique the currently prevalent technique-oriented scholarship in global branding, and practitioner-related books like "The Global Brand: How to Create and Develop Lasting Brand Value in the World Market" (Hollis, 2008), are some examples reflecting this importance. Although there is substantial research relating to consumers' reactions to the globalization of

brands, almost all this research generally focuses on consumers in the home country. For instance, Echhardt and Houston (2002) studied how McDonald's is perceived by people in Shanghai, and Dimofte and his colleagues (2008) recently studied reactions of U.S. consumers to global brands. In a search of the existing literature the author found no research on how consumers react to their familiar and new brands when they are in a foreign land.

Understanding how consumers react to their brands in a foreign country is important for several reasons. When living in another country for an extended period of time it is necessary to engage in various consumer behaviors in order to conduct everyday life. Often, the marketplace brandscape is very different from that which was left behind, both in terms of the brands available and the way of conducting transactions. In addition, when consumers leave their country of birth their meaning of brands and possessions may change because most of their own possessions and brands are left behind (Belk, 1992). From a practical point of view, one aspect of globalization of brands is known as "glocalization" where certain product features, brand elements, and distribution systems of a brand are customized to local consumer tastes (Svensson, 2001). For example, Nestle has a very strong emphasis on meeting local tastes while preserving its global orientation. As consumers move across the nations, encountering their brands being glocalized may evoke certain feelings, and it is important to understand how they react to such glocalization of their brands. Next, there are large numbers of students who move to foreign countries for their higher education. For example, in the US alone there were 454,000 international students enrolled in colleges (Field, 1999), and in the UK overseas students made up 12.7% of the higher education population (*Students in Higher Education Institutions*, 2003), while in Australia 18.8% of all commencing tertiary students in 2000 were international fee-paying students (Michael et al., 2003) and the income from overseas students has become "bigger than wool, nearly as big as wheat" (King, 2002). In addition, developments in information technology and increases in the service-based economy have all resulted in a situation where a large number of short-term immigrants are moving across countries as expatriates (Thompson and Tambyah, 1999). How do these people who move to a new country react to the unfamiliar brandscape in general?

The aim of this study was to explore consumers' reactions to their brandscape in the context of consumer acculturation. To address this question, a phenomenological in-depth interview approach was undertaken. Interviews were analysed using "grounded theory" and "associative group analysis" approaches. The theoretical background of the study is presented here along with the research questions, followed by the findings of the study and a discussion of implications for researchers and practitioners.

CONCEPTUAL BACKGROUND AND RESEARCH QUESTIONS

Since branding has become an effective tool for marketers to package a whole range of meanings (Kapferer, 2008), consumers today are faced with a proliferation of brands in their daily life—a branded reality. The idea of branded reality has been advanced by several authors, with terms including Sherry's "brandscape" (1998), Biel's "brandspace" (1993), and Soloman's "consumerspace" (2003). A brandscape is a "material and symbolic environment that consumers build with marketplace products, images, and messages, that they invest with local meaning, and whose totemic significance

largely shapes the adaptation consumers make to the modern world” (Sherry, 1998, p. 112). As Solomon (2003) suggests, people tend to rely upon brands to define their identities and make sense of the world around themselves. Thus, what a brand means is largely derived from associations emanating from the *contexts* where the brand is consumed (Biel, 1993). As McCracken’s meaning transfer model (1986) posits, meaning moves from aspects of the cultural world such as fashion, class systems and advertising to the brands, and then from these brands to the individual consumer. However, as Penaloza (1989) posits, a consumer enters the new culture with an abundance of consumption knowledge previously acquired in the consumer’s culture of origin. What would happen to the consumer (who has already been defined by his own consumption context) if he or she moves to a different culture where the fashions, social classes and advertising all are different? According to McCracken, the consumers must redefine themselves; as changes happen, they would be constantly constructing and reconstructing themselves by a way of new meaning or new ways of defining themselves as they react to the brands in a new cultural context.

This new way of defining themselves in a new culture may be understood by consumer acculturation (Penaloza, 1994; Askagaard et al., 2005; Ustuner and Holt, 2007) which refers to “the acquisition of skills and knowledge relevant to engaging in consumer behavior in one culture by *members* of another culture” (Penaloza, 1989, p. 110). Acculturation is a term typically used in reference to immigrants planning to stay permanently in their host country (Penaloza, 1994). Yet, it can also apply to other forms of movement (e.g., peasants into cities) even within the same country (Ustuner and Holt, 2007). Since the goal of this paper is to understand how consumers “feel” in response to their brandscape as part of their acculturation, a brief review of feelings warrants attention.

Prior research contends that certain feelings can be “evoked” in response to brands (Keller, 2001). Kahle and his colleagues (1998) point out six types of feelings that may be evoked in response to a brand: warmth, fun, excitement, security, social approval and self-respect. According to the notion of “brand relationships”, consumers not only have feelings toward brands but also consider brands as relationship partners (Fournier, 1998). She posits that consumers have feelings and possible forms of relationships with their brands, akin to arranged marriages, casual friendships, committed partnerships, enmities, and secret affairs. As the former CEO of Saatchi and Saatchi posits, future success of brands largely depends on their ability to evoke emotional responses such as joy, surprise, pride and love (Roberts, 2004).

The present paper, specifically in the context of the consumers being in a new country, examines the emerging concepts relating to the emotions they feel towards the brands they had back home and the brands they encounter in the host country. Keeping the background of brandscape, consumer acculturation, brand feelings and brand relationships in mind, the following research question is put forward: How do consumers coming into a new country acculturate to an unfamiliar brandscape?

METHODOLOGY

In keeping with the exploratory and theory-developing objectives of the study, in-depth interviews were used to reveal consumers’ reaction to a new brandscape, permitting an understanding of the subjective meaning of consumers’ experiences with brands in a new country. This method also provides a deep understanding of a phenomenon from the consumer’s perspective (Hudson and Ozanne, 1988).

Because of the small sample size permitted by the context of the study, purposive sampling was employed. Participants were

selected on the basis of specific criteria so that they shared broad similarities (Lincoln and Guba, 1985). While maintaining these similarities, participants from different parts of the world were recruited. Thus in-depth case study interviews were conducted in Australia with seven selected participants: (1) Zhao, a 24-year-old doctoral student in Finance coming from Vietnam (Ms V); (2) Shelly, a 23-year-old Masters student in Marketing coming from England (Ms E); (3) Gordon, a 26-year-old Masters student in Sociology coming from Canada (Mr C); (4) Heidi, a 25-year-old doctoral student in Sociology coming from France (Ms F); (5) Shaima, a 32-year-old doctoral student in Economics coming from Bangladesh (Ms. B); (6) Rachel, a 24 year old Masters student in Public Health coming from Canada (Ms. C); (7) Ali, 41 year old doctoral student in Organizational Behavior coming from Saudi Arabia (Mr. S).

These participants had been in Australia for an average of six months and each had a student visa. They were recruited through collegial networks and no compensation was provided for their participation. The interviews lasted an average of 65 minutes (range 40–85 minutes). Each interview was conducted on a one-to-one basis, with the participant being assured of anonymity and the freedom to withdraw at any stage. An interview guide which consisted of direct questions in terms of his/her interactions with brands was used. Although an interview guide was used, the questions were adapted in the course of the interview and the flow was largely determined by the informants. In order to maintain a holistic perspective, as employed by Fournier (1998), all interviews and analyses were conducted by the author. The interviews were audio-taped and transcribed verbatim into pages of text. In addition, the interviewer noted comments relating to each participant’s behaviour, verbal expression, and other nonverbal circumstances.

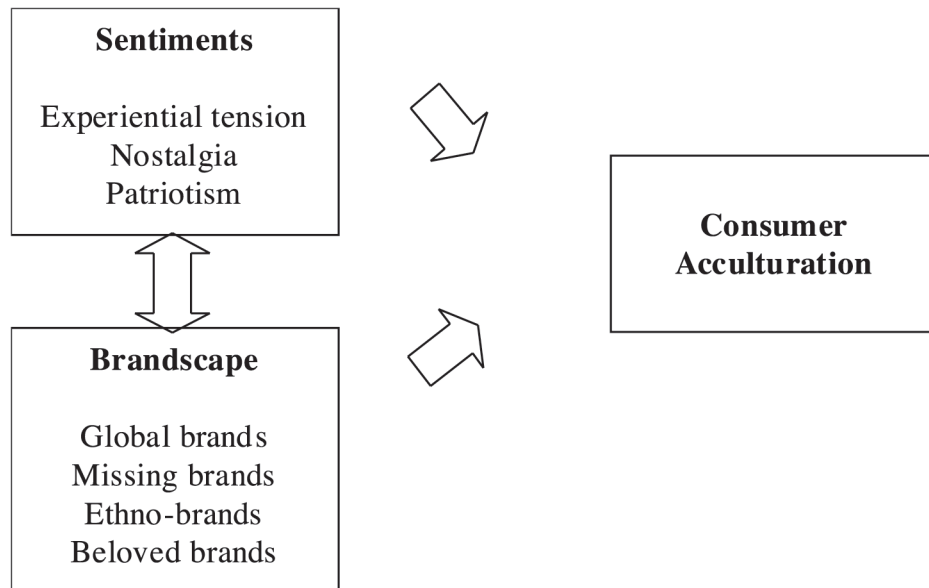

Furthermore, a member check phase (Wallendorf and Belk, 1989) was conducted whereby participants were each given a draft report of their case study and asked to critique it, comment on it, or request amendments. The purpose of this process was to confirm that the report had captured the information as delivered by the participants or, if not, for them to correct, amend or extend it. As a result of this procedure, some minor modifications were made to the transcripts.

The transcripts were coded based on Straus and Corbin’s (1998) grounded theory method, including open, axial and selective coding, and theoretical sampling techniques. Accordingly, the first interview was coded and analysed before conducting the second interview. Based on this approach, an attempt was made to identify emerging themes, and to map relationships between these themes from the interviews. The data collection process was extended until no new themes emerged from the interview data (Lincoln and Guba, 1985; Straus and Corbin, 1998). Grounded theory method was supplemented by associative group analysis (Szalay and Bryson, 1974) in which any particular “domain” consists of several “themes” and a theme consists of several individual concepts. For example, in a study by Szalay and Deese (1978), the *domain* of “education” consisted of the *themes* politeness, school features, knowledge, educated, and educators. The *theme* “politeness” in turn consisted of a range of concepts including polite, decent, respect, manners, social, good, and agreeable. In addition to transcripts, the data examined in the analysis also included details observed (e.g., facial expression) during the interviews.

FINDINGS

In this section, an overview of findings is presented along with an emerging conceptual framework followed by details of emergent themes. The grounded theory analysis of the interviews based

FIGURE I
A Framework of the host country brandscape

on concepts, properties and dimensions (Straus and Corbin, 1998) along with themes and domains of associative group analysis (Szalay and Bryson, 1974) can be postulated in a meaningful framework as presented in Figure I. The framework comprises three broader domains of themes. The “sentiments” domain emerged as participants expressed their emotions in terms of experiential tension of being in a new culture, feelings of patriotism and nostalgic reactions. The “brandscape” domain emerged as they narrated their brand stories referring to global brands, brands with which they had had close relationships, brands available and unavailable in the host country, and brands that they were unable to find in the host country. The “consumer acculturation” domain emerged as they reported the way they adjusted to their new environment, in terms both of their life in general and of brands in particular. Despite the presence of arrows leading to subsequent domains in Figure I, there was no attempt in this study to establish causal relations between these domains, since its purpose was exploratory in nature. In the following section the emergent themes are discussed in detail.

Sentiments domain

Experiential tension. The first theme that emerged was consumer experiential tension. Experiential tension is a milder form of cultural shock, usually resulting from differences in culture, consumption situation and product unavailability. Experiential tension is characterized by feelings of conflict and ambivalence, such as “emotional work involved in establishing new social networks, the stresses of learning how to be a consumer in the new locale, and small pleasures of established routines as well as familiar surrounding and products” (Thompson and Thambyah, 1999 p. 221). All seven participants expressed some form of experiential tension relating to their own experiences. One aspect of this tension is very similar to cultural shock (Winkelman, 1994):

“I think there is too much emphasis here on independence... like people respect privacy too much—it makes you isolated—

when I came here first there was a neighbour next room and that person did not want to know about me! That upset me” (Ms V).

“I lived all my life in Saudi, I was born there, all my friends are there, my social network is there, by coming here I lose all of that, I lose the social network, I come into a place where I know no one, I have no friends, I have no family!” (Mr. S).

Another aspect of experiential tension was directly related to the consumption of goods and services. Some of the concepts emerged where the participants found that the same brands were offered but had a different taste, an identification of some globalization (Svensson, 2001): “cheese is another category I miss, they have the same brands here but taste different” (Mr C); “Cadbury’s dairy milk, but we got them here in Australia but the ones from the UK taste completely different—that’s the ones I am used to. Australian ones are sweeter.” (Ms E).

The participants also complained that package sizes or quantities were also different from their previous experience: “Every product is bigger here... I was really surprised to see when people buy huge popcorn in the cinemas! None will buy that in France!” (Ms F); “Everything you can buy in bulk in Canada. I remember some girls complaining in my class about when they buy razor blades in the US they buy a big bag of razors but here they buy 2 or 3, very expensive” (Mr. C).

Although complaints regarding smaller packaging are related to the cost factor, participants also made direct comments about prices and charges where products and services in Australia were perceived as being relatively more expensive than in their home country: “The (bank) charges are terrible, like the amounts they charge for using an ATM is absolutely terrible. They charge you for everything. Every little thing you can think of they charge you.” (Ms E).

Nostalgia. As one would expect, the next emergent theme was nostalgic in nature. Nostalgia is usually characterized by “things used to be better in the good old days” (Rindfleisch and Sprott,

2000). Research in consumer behaviour suggests that products and brands are likely to evoke memories of past times and to inspire nostalgic reflection (Holbrook, 1993). Nostalgic reflection was strongly evident amongst most of the participants regarding to brands that they used back home:

“Not the shampoo, not the toothpaste, but the bags (Mountain Equipment) yes. Every time I go out I carry the bag, and it reminds me of my old bags” (Mr. C).

“We got Foxtel recently and we got UK TV, that reminds me of back home, all UK programs, you watch it just for nostalgia you watch it and I go you know, oh God, that’s England, that noise, that sound the look of drizzle, rain, and the settings!” (Ms E).

“Recently, a friend of mine took me to Home Bush Bay outlet mall and I found a D&G t-shirt there. You know what? I got the same thing, same color! That day I was thinking about my bedroom, my friends and smoking shisha with them” (Mr. S).

Patriotism. The third theme emerging in the “sentiments” domain was patriotic sentiment in general. Three of the participants specifically commented on various aspects of patriotic sentiment. At times, their body language was also obvious in such reactions. The first aspect of patriotic feeling identified was directly expressed patriotism (Gelb, 2002) towards the home country.

“Out here we are English, that link.. England is doing really well. I really wanted to buy an England t- shirt, I probably wouldn’t have done if I were in England, because I am here I wanted to identify with my country” (Ms E).

However, much of the patriotic feeling was expressed through “ethnocentrism” (Shimp and Sharma, 1987) and “country of origin effect” led by emotions (Maheswaran and Chen, 2006). From an ethnocentric point of view, the respondent from England made reference to Richard Branson as a successful Englishman and took pride in expressing her “Englishness”. This sentiment was also evident in her reference to the Mini Cooper as a “very British” car. On the contrary, from a country-of-origin point of view, the respondent from Vietnam was delighted to see some global brands that were made in Vietnam, as the following quote illustrates:

“When I bought Nescafe I found that was made in Vietnam. You know I use Colgate toothpaste, my favourite one, once I found that was made in Vietnam too. See, I am in Australia and they are selling these products from my country! These brands go with my feelings, but not Visa or Coke since I cannot really relate them to my country” (Ms V).

Similarly, the participants also commented about patriotic activities in Australia. Specifically, all of the participants’ comments indicated that they had noticed the “Buy Australian Made” campaign (Acharya and Elliott, 2003), and surprisingly it annoyed them in some cases. For example, the informant from England sarcastically hinted “obviously the big thing they have over here is Australian Holden!” The informant from Canada was annoyed about the strong emphasis on domestic goods:

“I find that there is more emphasis on domestic goods here. ... even though GM is American, the Aussies think it (Holden) as an Australian icon. Australians are proud of that—Canadians don’t have that. ... Here on TV, they go—here the three reasons to buy this products, reason 1, reason 2, reason 3, buy Australian!” (Mr C).

Brandscape domain

Global brands. In terms of the brandscape domain, one of the most obvious themes was centered around some references and reactions to global brands (Holt, 2002). With their multinational presence, global brands are usually quite familiar to the global audience. Accordingly, the participants were very familiar with the global brands.

One obvious comment about global brands were related to ‘convenience’ which means saving time and effort. Although convenience generally refers to certain convenient product categories such as ‘fast food’ or ‘frozen vegetables’, the importance of convenience as a construct applicable to brands in general has been noted (Berry et. al., 2002). The participant from Bangladesh said encountering Western global brands did not evoke any feelings but they were still “convenient” as she knew these brands would be available in a “Western country”. She further commented “I used Dove soap in Bangladesh and I use it here too, I didn’t have to look for any other brand... no I didn’t bother if it would be available in Australia, it is just a soap you know”. When asked her reaction to specific global brand like Coca Cola, Kodak, and Pantene, the participant from Vietnam said “these brands make my life easier since I already know these brands”.

A somewhat related to convenience was ‘global brands as objects’. That is, encountering objects such as pencil, a toothbrush or shoes should evoke no surprise from anyone from any part of the globe as people generally expect them to be present everywhere. Similarly, as the participants hinted, encountering brands such as Visa, Coca Cola and McDonald’s in a new country should surprise none. The following quotes illustrate this premise:

“These brands you pretty much expect anywhere you go in the world. It’s not something that you are surprised about” (Ms E).

“Because everyone has Coke, it may be a bit insulting to ask this question” (Ms F).

“They are everywhere! I saw Kodak store, ...Coca Cola signs and all that around me in Vancouver in the downtown area— all those signs. So used to having them everywhere” (Mr C).

Although global brands in general do not surprise anyone, it seems to come as a surprise when consumers find such brands positioned differently, again some reference to ‘glocalization’ (Svensson, 2001). To illustrate, the participants from Vietnam and Bangladesh reported that McDonald’s is a prestige and upper class brand in their countries but they find that McDonald’s is the cheapest food in Australia. They also reported that ANZ Bank and Pizza Hut seem to have a similar gap in brand image between the countries. Although one might attribute this phenomenon to the level of development of the countries involved, the brand image disparity was evident in other respondents’ comments as well:

“Esprit, a French one originally, I thought it’s too expensive and upper class, never went even inside in the UK. For some reason it seems to be a lower class here in Australian and I actually go into Esprit here” (Ms E).

“A car like Honda Civic is very common, very average in Saudi, but here in Australia it seems like a cool car” (Mr S).

Missing (absent) brands. The next emergent theme was “missing brands”, which involves (non-global) brands one normally used at home but is unable to find in the host country. Although they do not seem to have strong feelings towards these brands, they still had trusted these brands from their prior experience with them, and in someway expected them to be present in a host country. As is

evident, missing brands often result in some form of experiential tension. For example, one respondent tried to apply for a Visa Debit card:

“In the UK you can use your debit card like a credit card (Barklay Visa debit), like you can buy things online, they don’t do that over here, it’s very annoying when you can’t buy things online even though you got money” (Ms E).

Although consumers may not have strong feelings toward certain brands and may use them only occasionally, the brands may still be important, as the following quote indicates:

“There is this eye-drop I used in Vancouver called Gentel, very common in Canada, my optometrist had recommended that too, and I went into a chemist shop and asked for a Gentel eye drop, and they go “what?” they don’t have that here. Okay, “can I buy something similar to that?” and then, “well, what’s in it?” then I said, “I don’t know what’s in it, I buy it all the time”, now I have to find what I usually use and find what is the ingredient it’s got. But I don’t know what’s in it—how do I find what’s in it? I was really surprised about that” (Mr C).

Beloved brands. Beloved brands refer to brands towards which consumers have developed strong feelings, but which are not usually found in the host country. ‘Beloved brands’ theme is different from ‘missing brands’ theme because beloved brand theme is associated to strong feelings. Since these brands were not accessible to the participants in Australia, the brand stories of the informants generally resulted in nostalgic reactions, as the following quotes illustrate:

“My school bag, the best backpack in Canada is Mountain Equipment Corp. Very well known very high quality back packs. I have three bags and they are Mountain Equipments. The reason that the Mountain Equipment is hanging around with me is because I really like the brand, it’s really good quality, it’s not cheap. The first bag I got was when I was 13, so I still have that bag, but I tried other brands in the meantime, but they are bad” (Mr C).

“I miss Marks and Spencers sooo much and their sandwiches are absolutely amazing, they are the number one sandwich maker, it’s got such good choice, I miss that a lot” (Ms E).

“I miss my Ispahani tea brand a lot, we wanted to bring some when went last time but unfortunately forgot, so we got some from our friend’s” (Ms B).

At times, consumers can develop strong feelings towards certain brands even though they are not the leading brands in a category. Despite its being a low profile brand, the Canadian informant had strong feelings toward Washburn guitars, as the following quote illustrates:

“This means lot to me because that’s the first guitar I ever bought—it is called Washburn, never forgot the name. It’s not available in Australia. ... It was the first thing I bought from my own money. Very memorable ... Over a year of savings, \$60-70 a month work.” (Mr C).

Ethno-brands. Another emergent theme regarding brandscape was “ethno brands”. Ethno brands refer to brands for which consumers have strongly developed feelings from their home country, and the brand is also available in the host country. The participants

expressed their strong feelings towards such brands both verbally and nonverbally while narrating their stories. There were some cases where the participants expressed strong feelings when they found brands which were unique to their home country. For example:

“I also found L’ccitante from my country, it’s like the Body Shop, I was really surprised to see that in Queen Victoria Building, I bought a lot of things there. (Ms F)

“We have a very popular noodle called PhuQuoc and I found that even in Australian supermarkets ...” (Ms V).

“Marmite, yes, I found it in British Lolly Shop, I was happy to see it here. Otherwise I have to get my friends to bring it here” (Ms E).

Participants also reported that they found their favourite brands, not necessarily unique to their home country, in Australia. They become close to these brands from their home country:

“My Fender Strata Castor, the electric one. It’s considered to be the best guitar in the world, it’s available in Australia. I love to play guitar in my room on my own. It’s the same guitar Jimmy Henry used, top guitar in the world. I would have been surprised if I didn’t find that in Australia” (Mr C).

“I actually use the same shampoo Herbal Essence I used back home. Don’t know if it’s made in France, but I love it” (Ms F).

“I use Finesse typically. I tried other ones, I tried Head and Shoulders, and others, say 5 or 6, I didn’t like them, but when I tried this I liked it” (Mr S).

Consumer Acculturation domain

The last theme (and domain) that emerged was consumer acculturation. The present study found evidence of consumer acculturation where participants found ways to adjust their feelings regarding their life in general and brands in particular. While finding alternative brands in place of their regular brands, the participants eventually fell in love with some Australian brands. The participant from Canada, extremely conscious of his spending, reported that he was addicted to a new apple juice called “Australian Fresh” although it was almost double the price of other brands of fresh apple juice. The participants from France and England were delighted to report not only that they regularly bought Australian Tim Tam biscuits but also that they would take a lot of them home. Coming from a very basic consumption culture where most of the grocery purchases are made by counter-feeding, the participant from Bangladesh had to adjust to her new consumption context: She was surprised to see that Nivea moisturizer was available in different flavours and versions while she had known only a single Nivea Moisturiser back home; she found her new Nivea Moisturiser by experimenting a few of them. She had never tasted a pizza but she got almost addicted to Dominos in Sydney. She was surprised to see the number of Kellogg’s cereal options available to her and she noted “sometime I spend even half an hour browsing and choosing the right cereal!” On the other hand, the participant from Saudi Arabia, coming from a very upscale family brought up in an ultra luxury setting changed his style in a dramatic way: he learned to mingle with everyone in the hostel “because I had no choice”, he said, “I ate what they ate, I bought what they bought” and “this was the first time I ever travelled in a Hyundai car, and I liked it”.

The following quote captures this theme succinctly:

“It kind of gets confused because I have now become familiar with Australian brands and I will miss some of these when I go to the UK. Sometimes you actually forget what was available

back home, what wasn't available here, and vice versa, and you go, "you sure we have that in England or Australia?" My boyfriend's the same. You know he says something and goes, "we could get that in England" and I go, "no you couldn't". We sort of forget what was available in the UK and you become familiar with Australian ones. I found that funny when I went to the UK I actually missed some of the things from Australia. Some of the silly things like Twisties, Tim Tams. They have Vegemite there, I don't know why they don't sell Marmite here. Boundaries between countries have become a lot less. Brands should become available in all the different countries" (Ms E).

DISCUSSION AND CONCLUSION

This paper has presented the findings of a study of consumer acculturation to an unfamiliar brandscape. The study illustrates the way consumers feel about their brands when they move to a new country for an extended but limited period of time. While living in the new country for some time they go through a range of sentiments including experiential tension, patriotic reactions and nostalgic excitement. They also manifest none to very close feelings towards their brandscape, some of which relate to brands not available to them in the host country. Their brandscapes were identified as comprising global brands, missing brands, ethno brands and beloved brands. Finally, largely influenced by the presence of alternative and new brands in the host country, their brandscape becomes acculturated to the point where they adjust their life both in terms of their brands and their sentiments.

This study provides strong support for the notion of brandscape (Biel, 1993; Sherry, 1988; Solomon, 2003), where consumers are bombarded with a large number of brands that shape their identity both knowingly and unknowingly. The following quote illustrates this notion: "brands not only furnish the environment in which I live, but they also enrobe me, and by doing so, help define who I am" (Biel, 1993, p. 68). This study showed that consumers continue to engage with their brand environment—they comment on the global brands, the brands unique to their home country, the brands with which they have strong feelings towards, the brands they wanted to use but unable find, the brands they used in the past and left at home. More specifically, the study showed that consumers are well aware of the image differences of brands, which implies that they use them to express their identity. The participants easily recognized some differently positioned brands in different countries. Thus, the present study extends the notion of brandscape to a context in which consumers face a challenging situation where they have, in many cases, no access to the brands they used back home, are presented with alternative brands for their routine consumption, and are faced with new brands they never heard of. Consequently, as McCracken's (1986) meaning transfer model hinted, the participants voluntarily adjusted their brand usage by becoming acculturated to the new environment. For example, Shaima, the participant from Bangladesh was redefined to some extent by her new usage of Domino's Pizza, new Nivea Moisturiser, and the effort spent browsing a large number Kellogg's cereal varieties available to her. The participant from England, by acculturated to her new brandscape, eventually got confused whether some brands belonged to Australia or England.

Several researchers have pointed out the importance of emotions in understanding consumer behaviour (Richins, 1997). This study supports the premise that consumers have emotional relationships with (Fournier, 1998) or feelings towards (Keller, 2001) brands and circumstances involving brands can evoke different types of feelings (Kahle, 1998). According to Roberts (2004), there are two types of emotions: people feel primary emotions such as joy and surprise when they are alone; they feel secondary emotions

such as love and pride when they relate to someone else. This study found that consumers exhibit a range of primary and secondary emotions when they interact with brands when they are in new country. Experiential tension was related to irritation and uneasy feelings, nostalgia was like pleasant excitement, and patriotic sentiments were related to joy, excitement and happy. Missing brands evoked some frustration, beloved brands evoked some sadness, and ethno-brands evoked some excitement. This observation is also consistent with much previous research where brands are anthropomorphized, consumers are reported to accord even sacred status to brands (Belk et al., 1989), and brands are perceived as having personalities (Aaker, 1997).

Several implications can also be drawn from the findings. As a larger number of people than ever before travel to other countries to study and work, it is important to understand how these people feel about their brands in the new country. The findings of this study suggest that, if marketed successfully across countries, brands can offer convenience as a "time and effort-saving heuristic" (Berry et al., 2002 p.9). The findings also suggest that brands can achieve the status of objects where they may become some standard of international comparison. For example, the presence or absence of McDonald's in a country may provide two different images of that country. When asked about Coca Cola, it was warned that it may be a bit insulting to ask if they have Coke in their country since brands like that considered as objects or even symbols. This is in line with the contention that buying global brands make consumers feel like the citizens of the world (Strizkova, Coulter and Price, 2008). The study also suggests that consumers take special pride in identifying with brands specific to their own country or brands made in their country, and brands serve as a form of national pride. The respondent from England was excited to refer to Richard Branson as a successful "Englishman" and Mini Cooper as a "very British" brand. These findings are consistent with brand as "citizen-artists", contributing as a cultural resource (Holt, 2002) and global brands as a cultural form (Cayla and Arnould, 2008) such as folk tales. The study also implies that relationships with and feelings towards brands left at home become even stronger and enduring as consumers recollect such brands with nostalgia.

Another important implication refers to glocalization—adapting features and branding to local tastes. Accordingly, certain brands are forced to be positioned differently in different countries. This difference seemed to cause some surprise to the participants as the brands they had known had changed in some ways. For example, the respondent from England found Espirit to be somewhat lower class leading her to feel more comfortable in shopping at Espirit in Australia. However, because her Dairy Milk chocolates in Australia tasted sweeter, she had to order her originals from England. The Canadian participant was annoyed as he could not buy his shampoo in bigger bottles.

In sum, this paper contributes to the literature concerning brands by (a) showing how consumers feel about "their" brands in a new country; (b) providing a framework of domains of themes incorporating sentiments, brandscape and consumer acculturation in terms of possible antecedents and consequences of brandscape in a host country; and (c) describing and interpreting the specific themes that emerged.

Ultimately, although the study provides grounded empirical evidence of the way some individuals feel about their brands in a foreign country, further research would enrich the findings and would reveal whether the themes uncovered in this study have relevance and potential application. Future research efforts could be directed towards increasing the sample size in order to strengthen the generalizability of findings. Furthermore, quantitative research also needs to be undertaken to test the frameworks that emerged in

this research. Finally, the study should be replicated in different geographical locations employing informants from other parts of the world.

Consumers' Attitude Towards Applying fMRI in Marketing Research

Monika Koller, Vienna University of Economics and Business (WU Wien), Austria

INTRODUCTION

Observational research techniques have had a long history in marketing research in general and consumer behavior research in particular (Lee and Broderick 2007). Regarding contemporary marketing research, sophisticated technological innovations such as internet-based innovations like Web 2.0 but also technologies adopted from other disciplines such as neuroscience allow for new insight into consumer behavior from another angle and on a higher level of precision and accuracy. Whereas Web 2.0 provides new possibilities regarding some parts of the research process, such as, data collection and recruitment of participants (see, e.g., Kozinets 2002), methods from neuroscience revolutionize the whole research process. The predominantly employed research tools can be roughly grouped into two main categories according to the underlying mechanisms measured, electroencephalography (EEG) and magnetoencephalography (MEG) measuring electrical brain activity versus positron-emission-tomography (PET) and functional magnetic resonance imaging (fMRI) measuring metabolic activity (for a more detailed discussion of these methods see, e.g., Cacioppo et al. 2003; Houser and McCabe 2009; Kenning et al. 2007a; Schilke and Reimann 2007; Willingham and Dunn 2003). Among those four techniques, EEG, MEG and fMRI have proven to serve particularly well regarding experimental procedures in marketing research (see, e.g., Ambler et al. 2004; Kenning et al. 2007a; Lee et al. 2007; Schilke and Reimann 2007; Senior et al. 2007). As PET uses radioactive tracers, the application to a wider population in marketing research is limited. Compared to EEG, MEG has a better spatial resolution but incurs relatively high costs of measurement. The complex data analysis further limits its practical applicability (Kenning et al. 2007a). EEG provides a good temporal resolution, implies relatively moderate equipment costs and a straightforward data analysis. Moreover, it has had a long tradition in marketing research and related disciplines such as psychology (Murphy et al. 2008; Rothschild et al. 1988). For instance, well-established latent constructs like cognitive dissonance, in which both psychology and marketing have always been interested, was investigated in an EEG-study (Harmon-Jones et al. 2008). Recently, there have been several methodological publications on the combined application of fMRI and EEG to obtain both spatial and temporal resolution (Herrmann and Debener 2008; Moosmann et al. 2008), but this technique is not well established yet (Willingham and Dunn 2003), especially in marketing research. In a marketing research context, fMRI is currently the most frequently used brain imaging technique, as it has a very good spatial resolution (Kenning et al. 2007a) and therefore serves best for mapping brain activities providing neural correlates of, e.g., decision-making, brand perception and, most important, unconscious emotional processes accompanying and/or influencing conscious decision-processes (Hubert and Kenning 2008). Explaining individual purchase decision-making has always been of high interest in consumer behavior. Over the past 50 years, various models have been established incorporating underlying cognitive and emotional phenomena (for an overview see, e.g., Hansen 1972; Hansen 2005). Since the technological innovation of fMRI in the early 1990s, a new era of explaining human behavior has started (Bandettini 2007; Senior et al. 2007). "Neuromarketing" (see Wilson et al. 2008 for a detailed description on the emergence of this term) is by no means a step towards mind-

reading (Grimes 2006), however, the understanding of brain functions substantially contributes to fundamental knowledge and perfectly complements contemporary consumer behavior research.

As the application of fMRI has been constantly increasing in consumer behavior research, it is essential to have a closer look at the consumers' evaluation of this development. It is the consumer who serves as a test subject in empirical marketing research studies and it is finally also the consumer who is wanted to buy the products or services created and advertised by industry based on the data gained from market research. Apart from the leading work by Albaum, Evangelista and Medina (1998) and Evangelista, Albaum and Poon (1999) on theoretical explanations of survey response behavior (Albaum et al. 1998; Evangelista et al. 1999), to the best of my knowledge, little is known about how people feel about various methods and research techniques applied for marketing research purposes, neither regarding traditional behavioral methods nor alternative neuroscientific ones. This is a major shortcoming, because more detailed knowledge would provide guidance to researchers in terms of enhancing respondent cooperation and therewith accurate and truthful reporting of data. Scholarly publications are dealing with issues such as how to increase response rates and the usage of incentives (Cobanoglu and Cobanoglu 2003; Deutskens et al. 2004) but empirical studies on psychological constructs and personality traits explaining the willingness to participate as test subjects are scarce. This is unfortunate as an over- or underrepresentation of test subjects regarding certain parameter values can lead to problems regarding the generalizability of results. In the present study it is hypothesized that people scoring higher on psychological constructs such as perceived risk or technology anxiety are less willing to take part in an fMRI-experiment and may therefore be underrepresented. While the interest in "neuromarketing" started in marketing research more than a decade ago, the "neuromarketing"-approach has become quite popular nowadays in the industry as well and attracts public interest. Following Wilson, Gaines and Hill (2008), today there are more than 90 consulting agencies who specialized in "neuromarketing" (Wilson et al. 2008). "Googling" the term "neuromarketing" currently yields more than 800 000 hits" (Hubert and Kenning 2008, p. 274) and even newspapers have started to report about this emerging issue. Esch (2008) notes that besides the groundbreaking findings in research there are also various questionable publications and objectives (Esch 2008). Consequently, all the information on "what neuromarketing can or cannot do" can be quite confusing for the consumer. Concerns and ethical reservations about "neuromarketing" as both method of data collection and marketing and communication approach applied by the industry, are more likely to arise compared to traditional questionnaire-based and self-report methods. Based on these issues, the present paper is about consumers' attitude towards the application of fMRI in marketing research. An online-questionnaire with a final sample of n=901 was administered, investigating psychological constructs explaining the acceptance of this alternative approach in consumer behavior. Based on these quantitative findings, a mixed-methods-design was followed by subsequently addressing selected important topical areas such as "ethics in neuromarketing" in a first focus group discussion as basis for further research.

THEORETICAL BACKGROUND

Neuroscientific Methods in Marketing Research—Promises and Limitations

Whereas the main advantages of applying neuroimaging techniques within the field of marketing research are quite evident from a scientific point of view—alternative possibility of investigating unconscious phenomena and emotions, better handling of response bias or measurement effects occurring in traditional self-report-studies—this is not necessarily the case from the perspective of the consumer who in the end is asked to participate as a test subject. Regarding the future application of neuroscientific methods in marketing research, among neuroimaging techniques, EEG and fMRI applied in combination with traditional quantitative and qualitative methods are thought to have the greatest potential (Page 2008). For pragmatic reasons, EEG is likely to see wider use than fMRI, but its application to everyday marketing field research is also limited. Moreover, another possible big winner is eye-tracking (see, e.g., Lorigo et al. 2008), as the technology has advanced to be essentially robust and also cost-efficient (Page 2008). Regarding future fundamental research in consumer behavior, fMRI-studies are the most promising for which the present study exclusively addresses the application of fMRI in marketing research. Neural information complements traditional methods of investigating human behavior and especially human decision-making. This is analogous to what Harmon-Jones and Devine (2003) cite about the application of neuroscientific methods in social psychology: “[...] to understand mechanisms underlying mind and behavior, both biological and social approaches are needed.” (Cacioppo and Berntson 2002, in Harmon-Jones and Devine 2003, p. 590). Neuroimaging techniques can contribute to fundamental research in terms of a better conceptual understanding of latent constructs in consumer behavior. Measuring neural correlates within an fMRI-experiment allows not only for challenging but also adding new facets and providing a better explanation of already well-established models of decision-making, processing of information or the perception of brand and advertisements. For instance, Yoon et al. (2006) added new information regarding the brand personality concept based on fMRI data (Yoon et al. 2006). Regarding the measurement of latent constructs, these techniques explore neural correlates and thereby contribute to content and construct validity of traditional measures. As these concepts have been developed within traditional experimental settings and/or qualitative and quantitative field studies, additional information from neuroscience is appreciated. This knowledge will contribute to overcoming the obstacles traditional quantitative marketing research has always had to deal with and will help to establish sound and valid measures to capture, e.g., cognitions, emotions or attitudes. All in all, the author supports the view that it is the combination of traditional and technology-based new and multidisciplinary methods that will significantly frame the future of consumer behavior research. Besides these advantages of fMRI in marketing research, there are still some major limitations. An fMRI-study is very cost-intensive, regarding both the need for an experienced and skilled multidisciplinary research team and financially (Ambler 2008). Furthermore, there are issues of internal as well as external validity that have to be taken into account. Being in an fMRI-scanner during a laboratory experiment is not really comparable to a real consumption situation. Taking part in an fMRI-experiment can be stressful for the test subjects. The operating expense of the whole experiment is high. Regarding the status quo and the possible future development of fMRI in marketing and consumer behavior research, Ambler (2008) maintains that: “The tools have not advanced to the point where researchers can offer practitioners significant paybacks

with any certainty. No doubt this will happen just as X rays moved from Marie Curie’s laboratory to every dentist’s surgery but that took 70 years.” (Ambler 2008, p. 9).

Consumers’ evaluation of research methods in marketing research

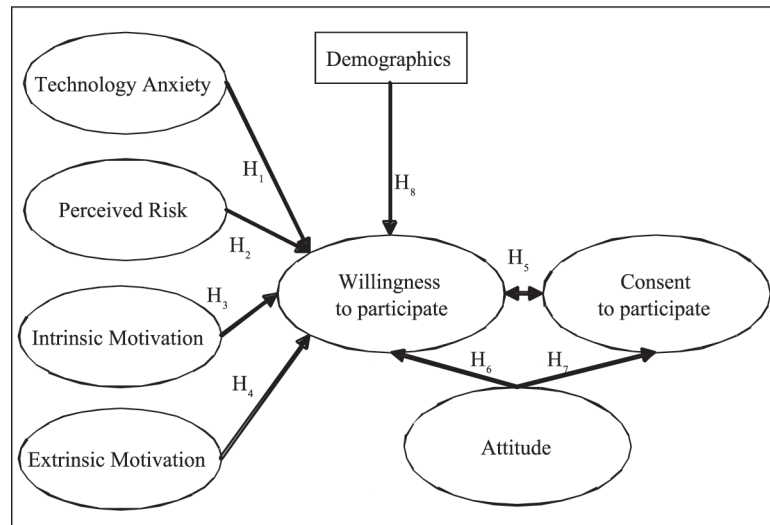

To be able to conduct more neuroimaging studies in the near future, people willing to participate in these studies are needed. The quality of results heavily depends, among other factors, on the participants’ compliance with the tasks they have to perform. There are special requirements regarding the person itself as well as the data collection procedure that have to be granted. For instance, the whole experiment is very time consuming (the average scanning procedure for one participant takes between 60 and 90 minutes (Schilke and Reimann 2007). There is a considerable space restriction within the scanner and there is the necessity of non-metallic clothing and removal of any (body) jewellery because of the strong magnetic field. Respondents’ attitudes towards different research methods can significantly influence the whole data collection process, if, e.g., the test person doesn’t want to properly accomplish the tasks required. Roe et al. (2009) found out that recruits with more conservative general risk attitudes and higher measures of harm avoidance are less likely to agree to participate in biomedical experiments involving a fMRI session or a blood sample obtained via phlebotomy. These results indicate a major threat to the generalizability of economic studies applying biomedical techniques to the general population due to a possible sampling bias. In order to enhance the quality of the results as well as to avoid loss of resources, those possible threats should be taken into account when designing fMRI experiments. Even with traditional marketing research techniques, there is still known little about, e.g., motives or personality traits influencing the willingness to participate. Ognibene’s results suggesting that questionnaire response is affected by leadership traits and ambitious reading habits date back to the 1970s (Ognibene 1970). Regarding the quality of marketing research in terms of representative samples, more in-depth and up-to-date knowledge about these issues is important. As new technologies have found their way into marketing research, a better understanding of peoples’ attitudes towards current methods and techniques is vital. This knowledge can help to establish a meaningful database (e.g., online-panels) for conducting offline- and/or online-surveys. In the case of neuroscientific methods, the issue is even more challenging. The application of neuroimaging methods is often quite new to researchers and even more unfamiliar to test subjects involved in empirical studies. Taking part in an EEG, MEG or fMRI-study is not an everyday experience for the average consumer. Still a small number of publications have dealt with participants’ needs and requirements when taking part in neuroscientific studies. Roe et al. (2009) discussed the issue of a possible selection bias in test subject pools for experiments involving neuroimaging and blood samples (Roe et al. 2009). Cooke et al. (2007) and Senior et al. (2007) addressed the participants’ experiences of taking part in research involving fMRI or MEG procedures by applying a mix of quantitative and qualitative methods. As they interviewed people right after their participation in an fMRI or MEG experiment, the sample size was rather small (n=21 for fMRI and n=23 for MEG) (Cooke et al. 2007; Senior et al. 2007).

EMPIRICAL DEMONSTRATION

Quantitative Study—Conceptual Research Model and Empirical Design

As consumer behavior research is interested in the consumer in order to derive knowledge about real-life purchasing, the author

FIGURE 1
Conceptual Research Model

wanted to gain information on what the average consumer thinks about the usage of fMRI for marketing research purposes, under which conditions people would be willing to participate, whether there is a need for providing (financial) incentives or whether they have any concerns, e.g., health-related or ethical reservations. Getting information on participants' needs and requirements will help designing future projects and evading any interferences due to non-compliance of the participants during data collection. As fMRI-studies are very cost-intensive (Ambler 2008), the researcher is advised to have comprehensive knowledge not only about the whole experimental procedure but also about the participant's needs and requirements in order to be able to prevent any disturbances during the experiment. The present study covers both exploratory questions to gain first descriptive insight into how consumers feel about the topic in general and an effort to reveal (causal) relations between explanatory psychological phenomena and the willingness to participate as a test subject in an fMRI-study. In the questionnaire, after the exploratory questions, there was a detailed description of applying fMRI in marketing research in order to guarantee that all participants in the survey had sufficient knowledge about what they would have to expect as test subjects in an fMRI-experiment. Literature-based information on the application of fMRI in marketing research in general and on the possible experimental setting in particular was given. A picture of a person lying in an fMRI-scanner complemented the explanation. The conceptual research model was based on the key findings of Cooke, Peel, Shaw and Senior (2007) and Senior, Smyth, Cooke, Shaw and Peel (2007) as well as on general literature regarding psychological constructs involved in explaining attitude and behavioral intention. Regarding the latter, literature on (technology) acceptance models applied in a marketing context (James et al. 2006; Kulviwat et al. 2007; Meuter et al. 2005; Meuter et al. 2000; Suh and Han 2002; Yoon and Kim 2007; Yu et al. 2005) caught the author's attention. Some explanatory variables for the willingness (intention) to participate in a highly technology-driven experimental setting lend themselves to being applied. The validated measurement scales for perceived risk, intrinsic and extrinsic motivation, technology anxiety and attitude were adopted to the present research context. The dependent variable, i.e., the expressed willingness to participate, is complemented by another behavioral control variable named "con-

sent to participate". Whereas the "willingness to participate" doesn't involve a concrete action, in answering the variable of "consent to participate" respondents had to act on their intention. This control variable allows for a more accurate estimation of how the respondents really feel. While agreeing to the question whether one would be willing to participate (willingness to participate) expresses some commitment, filling in ones contact details in a binding list of participants (consent to participate, for more details on the operationalization of the main constructs see table 1) represents a particularly high degree of commitment. Figure 1 shows the conceptual research model.

The hypothesized relationships incorporated are as follows:

- H₁₋₄: Perceived risk, technology anxiety, intrinsic and extrinsic motivation are assumed to explain the willingness to participate in a causal way. Following the findings of Evangelista, Albaum and Poon (1999) on the relevance of exchange theory, intrinsic and extrinsic motivation are assumed to explain the willingness to participate as a test subject. As fMRI is a quite unfamiliar new technology for most of the participants, perceived risk and technology anxiety are assumed to be negatively related to the willingness to participate.
- H₅: The articulated willingness to participate and the consent to participate are assumed to have a high positive correlation.
- H₆₋₇: Attitude and both willingness to participate and consent to participate are assumed to be positively correlated.
- H₈: Demographic variables (gender, age, income, blood donation behavior and previous medical MRI-experience) are assumed to explain the willingness to participate. Age is expected to be negatively correlated with the willingness to participate as older people tend to be more averse to accept new technologies.

Demographics and Selected Descriptive Results

The final sample consists of 901 respondents with 38.4% males and 61.6% females. The average age is 25.26 with the youngest participant being male and 15 years of age and the oldest

being 61 and also male. In terms of education, 1.6% have basic education, 1.2% attended high school, 77.8% completed college level, and 19.4% obtained a university degree. The relatively young age and high level of education go along with the job categories mentioned; 74.7% are students, 19.9% employees, 3.1% entrepreneurs, 0.6% unemployed and 1.8% have another sort of occupation. Regarding monthly income, 79.9% earn up to \$2,325, 12.8% between \$2,325 and \$4,651 and 7.4% more than \$4,651. As it is to a large extent a student sample, the comparability with and the evaluation of previous fMRI-studies, which were often based on student samples as well, is granted. Nevertheless, regarding the literature on the problematic issue of using mainly student subjects in marketing research (Burnett and Dunne 1986), this limitation of the present study has to be taken into account when interpreting the findings. Furthermore, information on health-related behavioral tendencies was collected. For instance, the respondents were asked whether they donate blood or plasma on a regular basis. 11.2% do so in case of blood donation but only 1% regularly donate plasma. 93.3% have already heard about magnetic resonance imaging, and 29.1% indicate that they already collected some more information on the technology. 22.9% have already had a medical examination involving magnetic resonance imaging, 25.2% had already undergone a computed tomography (CT). Those people who indicated that they had already a medical MRI-examination were asked additional questions on how they experienced the whole process in the scanner. Items worded like 'How did you experience the noise' were offered with a rating-scale ranging from 1=very pleasant to 5=very unpleasant. The majority of respondents experienced the whole setting rather negatively, especially regarding the disturbing noise ($M=3.43$, 83.9% of the respondents were scoring between 3 and 5, therefore assumed to have had a rather negative experience), the confined space in the scanner ($M=3.07$, 69.1% scoring between 3 and 5), the length of the procedure ($M=2.99$, 68.6% scoring between 3 and 5), the ban on moving ($M=2.97$, 63.4% scoring between 3 and 5) and the examination in general ($M=2.76$, 58.6% scoring between 3 and 5). These findings confirm the results found by Cooke, Peel, Shaw and Senior (2007) where 43% indicated the confined space being "a bit upsetting". On the other hand, regarding the percentages stated above, there were also a number of respondents in the present study who remember the medical MRI-examination as a rather positive experience, respectively. Nevertheless, when being asked in an open-ended question what they remember most, the disturbing noise, the ban on moving and the confined space are mentioned most frequently. Importantly, 46.4% have considerable ethical concerns regarding the application of fMRI for marketing research purposes. This is a very interesting finding that needs to be investigated further. By now, there are still few publications dealing with the ethical issue in neuromarketing (see, e.g., Murphy et al. 2008; Wilson et al. 2008). Therefore, as a second empirical step, a focus group discussion (seven students aged between 22 and 28 years) on "ethics in neuromarketing" was conducted. Preliminary results indicate, that people are ambivalent regarding ethical issues in the "neuromarketing"-context. The focus group participants were very excited about fMRI-studies, very interested in the whole topic and also willing to participate as test subjects in the future. However, the fact that results of fMRI-experiments in marketing research can in the end be the basis for tailored marketing activities by a company raised some discomfort among the participants. More focus groups are already scheduled in order to recheck the initial findings.

Furthermore, the removal of any metallic material is inevitable for a participation due to the strong magnetic field. When participating in an fMRI-study, almost 95% ($n=901$) would be willing to remove all metallic parts of clothing (scoring between 1 and 2 on a

5-point rating scale, end-points verbalized as 1=fully agree, 5=fully disagree), and 94.1% would remove any piercings jewellery or hair styling gel. These results indicate that the rest is unwilling to participate by not fulfilling the requirements properly. Surprisingly, only 88.9% indicate that they would fully comply with the instructions given by the research team. Only 61.7% would fully trust in the expertise of the research team. 92.8% want to get detailed information about the whole experimental procedure before giving their consent to participate. These results indicate that people are slightly skeptical about the whole procedure. For instance, 10.8% even think that MRT-examinations are a health hazard. At least 25.1% think that fMRI should not be applied in marketing research (item: "I am against the application of fMRI in marketing research", scoring 1 and 2 on a 5-point rating scale, end-points verbalized as 1=fully agree, 5=fully disagree).

Constructs and Scale Assessment

Each item measuring the latent independent constructs in the questionnaire was offered with a 5-point rating scale with end points verbalized as 1="fully agree" and 5="fully disagree". Items taken from existing scales were adapted to the present application of attitude towards fMRI in marketing research. Additionally, some new items were generated based on qualitative pre-studies. The present paper can be classified as first empirical large sample sized insight into the topic. Due to this reason, next to the above stated framework of hypothesized causal relationships between attitudinal and behavioral constructs, there was a set of descriptive questions helping to gain first ideas about the overall topic. Therefore, confirmatory factor analysis or structural equation modelling was not applied at this stage of the project. Scale purification was based on exploratory factor analysis and Cronbach's alpha using SPSS 15.0.

Regarding validity of the central constructs, exploratory factor analyses indicated stable unidimensional results. In the case of perceived risk, 2 items had to be eliminated due to low factor loadings. As shown in table 1, alpha coefficients are on a satisfactory level. The dependent variable "willingness to participate" was measured by two items.

FINDINGS

H_{1-4} assume a causal relationship between perceived risk, technology anxiety, intrinsic motivation, and extrinsic motivation as the independent variables and the willingness to participate as the dependent variable. The results of the multiple regression analysis only partly support this assumption. While technology anxiety had no significant impact on the willingness to participate in an fMRI-study ($p=.725$), perceived risk, intrinsic and extrinsic motivation explain almost 73% of the variance of the willingness to participate ($r^2=.725$, $p<.001$, $n=901$). Standardized beta-coefficients indicate intrinsic motivation (.79) to have by far the strongest influence on the willingness to participate, followed by perceived risk (-.13) and extrinsic motivation (.11). The existence of intrinsic motivation is therefore the most important precondition. More than two-thirds of the respondents are motivated by the prospect of watching their brains work ('I love the idea of watching my brain work', scoring 1 or 2). Extrinsic motivators such as monetary incentives or vouchers have a minor impact. People are either willing to participate because they are personally driven or nothing, not even monetary incentives, can persuade them. In case of incentives for participation being offered, 90.1% would prefer to get paid. When being asked in an open-ended question, more than 63% mention amounts between \$7 to \$80 as an appropriate compensation. Extreme responses range from \$0 to \$100,000. Some said 'this amount is not quantifiable', 'inestimable'. Asked about participation for about

TABLE 1
Central Constructs of the Study

Construct	# of items		Reliability	Wording of items
	Initially ^a	After FA ^b	Alpha	(Examples partly abbreviated)
Perceived Risk	11	9 (47.89)	.885	"I think the magnetic field is a health risk" "Thinking about being in the scanner makes me feel uncomfortable"
Technology Anxiety	4	4 (45.59)	.745	"I have avoided technology because it is unfamiliar to me"
Intrinsic Motivation	4	4 (55.16)	.820	"I like the idea of watching my brain work" "I would like to participate for serving science"
Extrinsic Motivation	operationalized by two items, score (mean) for further analysis			"Monetary incentives would motivate me to participate" "I would not participate without being paid"
Attitude	9	9 (43.60)	.848	"I feel positive about fMRI-studies" "fMRI should not be applied in marketing research"
Willingness to Participate	operationalized by two items, score (mean) for further analysis			"I basically feel up to participating in an fMRI-study" "I would love to take part in an fMRI-study"
Consent to Participate	operationalized by the item: "I want to participate in an fMRI-study and will therefore fill in my contact data in ..." - response categories offered: a) "a binding list of participants", b) "a non-binding list of participants", c) "I am not interested at all".			

^a Items administered in the questionnaire; ^b Items in the final scale after scale evaluation applying Exploratory Factor Analysis (total variance explained in % in brackets) and Reliability Analysis

\$45, which reflects the average actual amount paid reported in literature, 59% agreed and 41% disagreed respectively.

H₅ postulates the intention to participate to be positively related to the expressed consent to participate. The non-parametric correlation amounts to Spearman rho = .64 (n=901, p<.001) affirming H₅. The relatively low correlation coefficient again underlines the discrepancy that non-binding expression of intention is not necessarily equivalent to actual behavior.

H₆₋₇ postulate attitude towards fMRI in marketing research to be positively related to the intention to participate. The same relationship should hold for the expressed consent of participation. The correlation amounts to r = .79 (n=901, p<.001) for attitude and intention and to Spearman rho = .54 (n=901, p<.001) for attitude and consent to participate affirming H₆₋₇.

H₈ assumes demographics and health related personal tendencies to explain the variance of the willingness to participate. The ANOVA showed no significant influence of gender, income, blood donation behavior and previous medical MRI experience (p = .283). There was only found a significant but very low correlation between age and the willingness to participate (r = .14, p < .001). Younger people are more willing to serve as test subjects. Regarding this finding, recruiting among students is appropriate. New technological advances such as Web 2.0 offer new possibilities of recruitment. As the younger age group is also more affine to these innovations, recruiting in, e.g., online communities is promising. Surprisingly, except age, all other demographic variables have no influence on the willingness to participate in fMRI-studies. Most astonishing, previous experience gained by medical MRI-examinations has also no influence on the expressed willingness to participate.

Qualitative analysis of additional individual statements indicate, that for respondents who are basically positive about brain research but rather negative about market research, it is not easy to state their attitude and opinion on the application of fMRI in marketing. To test whether the general attitude towards marketing research has an impact on the willingness to participate in fMRI-

studies, 5 items measuring the construct of "attitude towards marketing research" (EFA: 54.25% of variance explained, Cronbach's alpha = .853) were administered. The correlation between this construct and the willingness to participate amounts to r = .33, p < .001 (n = 901). Respondents who are basically positive about marketing research have a higher intention to participate also in neuroscientific marketing studies.

As the variable "consent to participate" reflects actual behavior it is of particular interest. If respondents had chosen the answers a) or b) (see table 1), they were asked to fill in their contact details in a registration form subsequently. 21 out of 22 respondents indicating response a = "binding list of participants" filled in the binding registration form. Only 246 out of 308 respondents indicating b = "non-binding list of participants" effectively stated their contact information. The majority of respondents, 63.4% (n = 571), indicated not being interested in actually participating. These results clearly reflect the discrepancy between indicated intention and actual behavior. This finding has to be considered when interpreting (technology) acceptance studies where intentional behavior is modeled as the dependent variable. Another explanation of the discrepancy could lie in the fact that it was an online questionnaire. A lack of trust in secure data processing via the internet could have kept some people from filling in their contact details.

DISCUSSION AND FURTHER RESEARCH

The number of marketing-related studies applying neuroscientific methods has been constantly increasing over the past decade (Ambler et al. 2004; Chamberlain and Broderick 2007; Kenning et al. 2007b; Lee et al. 2007; Plassmann et al. 2007; Schilke and Reimann 2007; Weber et al. 2007). The results of the present study show, that the application of fMRI in marketing is not universally embraced by the respondents. There are, e.g., some ethical reservations. Overall, the attitude towards the application of fMRI in marketing research is ambivalent, albeit slightly positive (M = 2.88, n = 901). In any case, there is potential for enhancement in

order to boost the willingness to participate as a test subject. Detailed information prior to the experiment is inevitable to enhance trust in the expertise of the research team and the technology. If the actual experience during the experiment does not match prior expectations, proper data collection is at risk for the test subject does not comply with the specific requirements associated with fMRI. Providing more information about the strengths and advantages of the method to a broader population can also enhance trust in and attitude towards its application in marketing research. Intrinsic motivation turned out to have the highest impact on the willingness to participate. This is an interesting finding easing the argumentation in the recruiting process. On the other side, results of fMRI-studies are at risk to be blurred by a sampling bias, if only people scoring high on intrinsic motivation take part in fMRI-experiments as they may also be different from the general population regarding other personality trait variables.

Furthermore, the present study revealed that some negatively toned phenomena are relevant as well. As the whole scanning process can be experienced as rather unsettling, it turned out to be very important to actively enhance the scanning experience. In order to lower any perceived risk involved, detailed information on the whole experimental setting, the scanning procedure, the technology itself, the role of the participant her/himself should be given even prior to the participant's final consent to participate. It is important that the research team is sensitive to any discomfort experienced by the participant during each single experimental run. These observations should be included in the development of future experimental designs being more "participant friendly". The comfort of the participant is certainly a major concern when measuring neural correlates as it can easily bias the affective state. Only satisfied and fully cooperative participants provide high quality data without any disturbances due to moving artefacts. Further research is needed regarding participants' preferences for different marketing research methods in general and regarding different experimental, physiological and neuroscientific procedures in particular. By now, theoretical explanations on why people prefer, e.g., quantitative methods over qualitative ones or vice versa are still scarce. As consumer behavior research has always been interested in the motives and underlying psychological phenomena of why people show a certain behavior, it is necessary to also pay more attention and get more comprehensive knowledge about the empirical methods it is applying.

The Ritualization of Cultural, Social, and Economic Capital in Establishing In-Group Acceptance

Lee McGinnis, Stonehill College, USA
James Gentry, University of Nebraska-Lincoln, USA

ABSTRACT

Using Bourdieu's three forms of capital (economic, social, and cultural), we demonstrate how in a short period of time these forms become part of the ritual of inclusion and exclusion in golf. Because golf on its face is not a highly masculine activity (i.e., lacking physicality, machismo, and endurance), more benign methods are used to include or exclude same gender players. The transformation of power happens quickly through four stages: the greeting, the feeling out, the chest pounding, and acceptance/rejection. It is through these stages that one either becomes part of the capital elite or excluded.

INTRODUCTION

In this study, we formulate an understanding of how three forms of capital (Bourdieu 1986) become ritualized in a round of golf, which is considered a ritual performance in and of itself (McGinnis, Gentry, and Gao 2008). Through observations with male golfers, we show how cultural, social, and economic capital weave their way through golf's ritual stages in establishing either inclusion or exclusion. In-group inclusion is evident in several consumption subcultures. Knowing the group's norms, understanding how to conduct oneself intellectually, and having appropriate economic resources and proper social connections all interact to create a hierarchy of inclusion or exclusion within the in-group.

LITERATURE REVIEW

Bourdieu (1986) provides three types of capital: economic, social and cultural. Economic capital is maintained through domination of cash, assets, property, and other forms of currency that give certain individuals power. Those with high economic capital but not necessarily high cultural capital tend to have consumption patterns that are reflective of middlebrow tastes (Trigg 2001).

Social capital is using the influence of friends and social networks to maintain or establish power and significance. Having such capital is important not only for achieving social status, but can also have an impact on earnings (Kim 2009). Furthermore, Bourdieu (1986) indicates that such capital is linked to the possession of a durable network of institutionalized relationships with mutual acquaintances. In this case then, social capital acts upon those social relationships that are perceived as prestigious and commonly known throughout a given social sphere or community. It can also be imparted through membership in a group, whether it is a common last name, a class, or school. Social capital gains its strength through shared understandings and limits of relationships, which are reproduced through unceasing efforts of sociability (Bourdieu 1986). It follows from this account that those who well known are worthy of being known due to more widespread capital.

Cultural capital presents itself in terms of the skills, knowledge, and attitude that parents or other significant influences pass onto their children or others. Cultural capital in the United States creates a divide in terms of taste, with those having high cultural capital enjoying a privileged life in terms of occupations, the arts, and cosmopolitan consumption, while those with low cultural capital consume objects that have more mass appeal and therefore are considered less cultured (Holt 1998). The power of cultural capital in terms of acquiring such things as extreme success (Gladwell

2008) and scholarly advantage (Sacks 2007) has been well advanced in popular literature.

Bourdieu (1986) speaks of three types or states of cultural capital: embodied, objectified, and institutionalized. The embodied is so called because of its direct link to the body, which often implies a sacrifice of the body itself in terms of physical exertion, mental labor (e.g., an education) time, and money. In the objectified state, capital can be transmitted in terms of ownership, such as when one takes over ownership of artwork or some other cultural artifact. The institutionalized state infers that a standard can be made with capital thus allowing for shared meanings of its value.

Rituals are symbolic behaviors or performances that tend to be repeated over time, which include as well as exclude participants (Rothenbuhler 1998). Rituals provide social order, transformation, and community (Driver 1991), all of which can be advantages or disadvantages to participants and non-participants alike. Rook (1985) suggests that there are four components of ritual: artifacts, a script, performance roles, and an audience, all of which can be present in a round of golf (McGinnis 2002).

The role of rituals and ritual behavior in marketing has been explored in advertising (Otnes and Scott 1996), college-aged drinking (Treise, Wolburg, and Otnes 1999), hair grooming (Rook 1985), baseball viewing (Holt 1992, 1995), Thanksgiving (Wallendorf and Arnould 1991), and sacred consumption (Belk, Wallendorf, and Sherry 1989). Ritual use has also been noted in skydiving (Celsi, Rose, and Leigh 1993) and whitewater rafting (Arnould and Price 1993). Gainer (1995) showed how consumers use rituals in performing arts to construct themselves socially.

In this study we use golf as our context because it has been noted to involve rituals capable of producing *communitas*, to have symbolic behaviors and artifacts, and to have explicit and implicit rules for behavior (McGinnis 2002). Golf, too, has been referred to as an activity that is not necessarily replete with masculine markers (McGinnis, McQuillan, and Chapple 2005). We contend that male golfers must find ways to make their domain more rugged in a world and atmosphere that Holt and Thompson (2004) argue has become emasculated. Confusion as to what it means to be a man in Western society has increased greatly in past decades (Garcia 2008; Lemon 1995; Pleck 1981; Salzman, Mathathia, and O'Reilly 2005; Seidler 2006; Thompson and Fletcher 2006).

METHOD

Observations for this study were conducted over the spring and summer of 2008. We chose golf because of its public accessibility, ritual enactments, and elitist perceptions. The primary author, who himself has 30 years of avid golf experience, observed approximately 25 rounds of golf (either 9 or 18 holes) to determine the ritual activity that might be occurring in exclusive domains, and from there developed preliminary working categories from the elite perspective (see Holt 1995). The primary author played golf primarily with foursomes, where he was often the fourth person added or the "outsider," which provided him with firsthand experience of the different ways in which in-group participation is formed. He also played with some groups and single golfers multiple times in which singles or twosomes were added. In these latter cases, the primary author was able to see in-group movement from the "insider"

TABLE 1
Capital Usages Displayed During Ritual Formalization in Golf

Ritual stage	Capital displays
Stage I: The Greeting	Dominated by cultural capital displays of handshakes, introductions, etiquette, and rules of golf.
Stage II: The Feeling Out	Dominated by social capital displays of social networks, knowing prominent golfers, and banter.
Stage III: The Chest Pounding	Dominated by economic displays of courses played, equipment, and careers.
Stage IV: Acceptance/Rejection	Dominated by social capital exchanges if relationship is accepting and economic and cultural capital displays if relationship is being rejected.

perspective. Management would often place a single or twosome in the group in order to improve time efficiencies and profitability.

We used a grounded theory method (Glaser and Strauss 1967) to establish the major themes involved in the ritualization of in-group formation. Specifically, we started with open coding to gain an idea of how the concepts fit the data (Strauss 1987). For example, examination of our early notes indicated that in the beginning of each round, participants would often demonstrate their intricate knowledge of the game by showing a sound pre-shot routine. Conceptually stepping back from the data, a common practice in open coding when one may know too much experientially about the phenomenon of interest (Strauss 1987), and reading the literature indicated that this might be considered an element of the cultural capital. At this point, we became aware of other forms of capital that might be present and observed them more acutely in our data in the different stages of in-group inclusion. We then used an axial coding process once we discovered that elements of capital were prevalent in establishing in-group acceptance. Axial coding can be used to show the conditions around which a process occurs (Strauss 1987). In doing so, we noticed that exchanges of cultural, social, and economic capital were prevalent in forming relationships, and that the usage of these different forms was considered the major constraints in establishing these barriers.

FINDINGS

Stage I: The Greeting

Our results indicated that cultural capital is used primarily in the beginning stage of the ritual to demonstrate one's knowledge of proper manners and the intricate knowledge and formalities of golf (see table 1). Demonstrations not necessarily unique to golf include the handshake, eye contact, and forms of salutation. This is where the "sizing up" of the fellow golfer or competitor was initialized. A failure in this impression management exercise (Goffman 1967) could negatively set the tone for the rest of the round, where if an unfamiliar player did not extend his hand in the round or failed to introduce himself properly to others he would be treated somewhat coldly. Greetings (i.e., handshakes) are considered serious forms of ritual (Rook 1985).

Context specific forms of the greeting (i.e., those that are unique to golf) included establishing order of play, partners, and in some cases betting games. The cultural capital being displayed here

was that of insider knowledge, which is gained through years of playing golf. As Allen and Anderson (1994) argued and found in our data as well, the cultural capital earned here is achieved through a "comfortable familiarity" with the game and not some special knowledge that is naturally bestowed upon the cultural elite. It takes on the embodied form because the owner through years of time investment earns it. It is used in the same vein one might be weeded out in other consumption groups for being pretenders or wannabes (Fox 1987; Schouten and McAlexander 1995). Establishing order of play among strangers was often done through the tossing of a golf tee, whereupon the sharp end of the tee indicated first to play. It was in this stage, too, that participants commonly gained knowledge of others' capital by throwing out such betting terms as "skins," "presses," and "two-two-two." Failure to understand or use these terms correctly could create barriers to ritual inclusion. Not understanding bets or formats of play could also indicate low cultural capital, such as when one would call a game a "best ball" (when each player plays his own ball and best score net handicap is posted for the pair or group) when it was actually a "scramble" (when all players hit from the spot of the most optimal shot in the group). Insider knowledge of the more obscure games indicated knowledge that Bourdieu might term as ideationally difficult to obtain (Holt 1998) and would therefore signify in this realm high cultural capital. Lack of rules knowledge could doom the new player, especially when violations occurred in league play or times when competition was more serious. Golf rules are quite rigid and are generally followed, though many foursomes will bend them to some extent. Determining the magnitude of that extent can create awkwardness when the members of the foursome do not know each other well.

Although participants in golf used the greeting as a way to determine unknown or relatively unknown participants' worthiness, the next aspect of this stage determined whether one could "walk the walk." The first shot on the tee signified one's savvy in terms of play, where those who demonstrated knowledge of the game had to match their game with a sound pre-shot routine (i.e., perfected practice swing and alignment). Players of all levels when matched with unfamiliar others could be seen as nervous.

Etiquette and rules of the game were vital on the first tee. Taking a prolonged period of time in the pre-shot routine (e.g., excessive practice swings and standing too long over the ball) could set a negative tone, with the other participants giving each other

incredulous looks behind the primary actor's back. Lacking cultural capital in this case meant the existence either of self-awareness of one's wrongdoings or of inconsideration by not helping others establish a rhythm and flow. This would be akin to a person talking excessively about oneself in a social setting or simply being unaware.

The greeting stage, too, was when players would first discover the extent to which they could get away with informal play, such as using "mulligans" (an extra tee shot, usually on the first tee), "winter rules" (i.e., preferred lies), and "gimmes" (putts given within a certain distance). Each of these forms of cultural capital represents violations of the rules of golf, but were often altered when poor conditions warranted such actions, when players had marginal skill, when it took a while to "warm up," or, and perhaps more importantly, when one was trying to gauge latitude. Each form also represented a way to establish rapport, as if the reaction to the violation was a way to test the waters of serious play, and because the one asking usually presented the requests in a half-joking manner, it allowed him to "save face" (Goffman 1967) if the other person were more serious.

Betting seemed to be a harbinger as to what other activities one might expect (e.g., drinking, risqué jokes, derogatory conversation, etc.). If a bet were on, or if play occurred during serious competition, liberal bending of the rules could dampen future relations. Usually, however, newcomers to the group would know from the first tee the expectations of serious play. Liberal gimmes were used during league play, even though play was serious, as the format (i.e., match play) usually permitted such action under the rules. However, length of the gimmes seemed to vary with the seriousness of the competition, with friendlier pairings giving longer putts. Wagering appeared to be hugely symbolic of the relationship. Though many bets were extremely nominal, where the loser might end up paying \$10 at the most, the act itself signified the nature of the competition and relationship. How one responded to such an act was clearly a difference maker in the first step toward invitation to join the in-group.

Stage II: The Feeling Out

Social and economic capital displays were dominant in the feeling out stage. Using social capital as a basis for ritualization, participants in this study used name-dropping, banter, and nostalgic ties as ways to either include or exclude, the tone of which was determined by felt commonality with the new golfer. It was incumbent among groups where members were new to each other to show their cards in terms of common acquaintances. In some cases, the common people were used to further connections within the group with benign intent while other times it was used to demonstrate superiority. The ritual would usually begin with a question of what do you do for a living or where do you normally play golf. Narratives of power connections took place when the participants connected themselves to head golf professionals, tour players, and other superior players. At this stage, participants were feeling the others out in mostly a socially compliant way in order to establish influence parameters, pecking orders, and willingness to reciprocate. The name-dropping displays indicated a sense of network vitality and to determine whether the person with whom the exchange was taking place was worthy of being known (see Bourdieu 1986). Many of the informants demonstrated their knowledge of other golfers both at the club to which they belonged or in the larger golfer community in the city or region. This showed currency in the field, much like an academician citing notable authors and scholars. Social capital was also exchanged when participants would gain knowledge of where one went to college or

high school, or membership in civic organizations or church affiliations.

Banter also provided a means toward acceptance. Usage of profanity was common, as was making light of one's masculinity or lack thereof. Not going for long shots or being too tentative was often an invitation for giving one the "business" for lacking manhood or masculinity. Indicating that one must have suffered a castration or lacking testicles was a common expression. Retorting with customary f-bombs was also common. These forms of banter showed a willingness to participate and thus encouraged further engagement, indicating his belonging to the group (Lennox Terrion and Ashforth 2002).

Social capital would often be displayed in terms of nostalgia as well, especially when the players wanted to demonstrate to the outsider in the group how long they had known one another. Oftentimes, golfers could alienate younger newcomers by discussing items that were unique to their age cohort, thus creating a barrier to entry for the younger golfer by demonstrating "membership" in an age group. If the younger golfer tried to relate, the conversation could end abruptly, could result in the older golfers laughing off the younger golfer's act of entry, or "code switching" (Goffman 1981) could occur where the older golfers altered their language to references hard for the younger golfer to understand. This act of having "been-there" represented a pilgrimage of sorts in which those with common experiences could only relate, such as that found after white water rafting (Arnould and Price 1993) or in skydiving (Celsi et al. 1993).

Stage III: The Chest Pounding Stage

Displays of economic capital usually prevailed after social capital or in conjunction with it in the "chest pounding stage." At this stage, the participants would often brag of equipment, courses played, and sometimes careers and cars. These occurrences seemed to increase when play was more serious or when a player was not performing well. They would also become more prevalent if the relationship had taken a turn for the worse, or if disparities occurred between levels of either cultural or social capital. For example, if one player displayed cultural capital that was superior to his new acquaintance in terms of knowledge, skill level, or etiquette, the deficit holder (in terms of the form of equipment and/or places played) would often seek redemption. In this sense, the deficit holder would often attempt to "buy his game," an expression commonly known in golf for those who are unskilled, lazy, or too time-deprived to develop a game "legitimately." Oftentimes, in order to thwart this perception, golfers with high cultural capital (Holt 1998) carry in their bags old, unique, or special clubs, clubs that had been "around the block" and had unique stories attached to them. Buying a game among lesser players is often seen as uncultured, thereby an expression of low cultural capital (Holt 1998).

Several of the respondents donned hats, clothing, and equipment that provided lead-ins to "been-there" type stories. The stories began with a logo on a hat, a bag badge, or club that had a long history of either great performances or experiences. The golfers would normally wait for some other golfer to respond to the display in a "funny-you-should-ask" humility, which would then lead to a series of questions and answers that allowed the holder of the item to demonstrate his cultural capital.

Stage IV: Acceptance/Rejection

The next stage of the capital establishment is the make it or break it stage of in-group inclusion, or the stage in which exclusionary practices were either heightened and players just tolerated one another or when players welcomed each other and developed closer

ties. If players welcomed the outsider, friendly banter increased and displays of economic capital seemed to lessen. For example, in-group participants would often give the outsider golf tips, make fun of poor shots, make noise during shots, or include him in jokes or some other form of banter to indicate group inclusion. If, however, the relationship worsened, capital displays often increased. If an outsider was obviously left out of the in-group, any misstep with cultural capital could be heightened. Being overly sensitive to etiquette infractions was common, such as being ridiculed for standing in a golfer's line of site during a putt, talking during a pre-shot routine, or casting a shadow in a golfer's peripheral vision.

Inclusion into the in-group would often result in discussion of drinking or getting drinks at the 19th hole (i.e., the clubhouse), from the beverage cart, or at the turn (i.e., between the ninth and tenth holes). Outsiders given the green light would often be included in this ritual by being offered a drink. Though most of the drinking commenced after the round was completed, a few of the participants engaged in moderate to heavy drinking at the midway point or during the round when the beverage service arrived. Drinking was given the same latitude on the course as it is in bars, where excessive consumption was allowed. Some respondents tied golf and the ritual of drinking so closely that disposing of or changing the nature of this ritual artifact (see Rook 1985) would be nearly impossible, similar to the rite of passage of binge drinking among college students when they turn the age of 21 (Treise et al. 1999). Lack of drinking in golf appeared to be more mocked than drinking itself.

DISCUSSION

The findings in this study can be applied to many consumer-to-consumer contexts where initiation into the in-group happens in a short period of time and where different forms of capital are present in making an impression. For example, the same process might be found in hunting trips, girls' nights out, white-water rafting, group aerobic exercises, and even motorcycle clubs. This process may be present anytime entry into a consumption subculture is marked by superior knowledge of the activity's rituals, where above average financial resources is needed, and where peers value such activities. Service providers need to be more sensitive to exclusionary processes involved in customer-to-customer interactions, as their own efforts to attract customers may be undermined by those C2C exchanges.

We find that the Bourdieu forms of capital appear to happen primarily in sequence and are used to establish worthiness of peers in a very systematic way. If one happens before the other (e.g., enactments of economic capital before cultural capital), the actor doing so may either be stigmatized (Goffman 1963) and be forced to redeem himself or save face (Goffman 1959). Early faux pas in the cultural capital stage can render subsequent displays of social and economic capital useless.

Economic capital enactments are often seen as displays of desperation and can be perceived as boorish or uncultured, preserved for those lacking in the other two forms of capital. Future studies may determine that those resorting to economic superiority displays tend to be the least satisfied with their golfing lives (i.e., or general lives, for that matter), and turn to economic displays when dissonance occurs in other capital areas. Burroughs and Rindfleisch (2002) have found similar relationships between materialism and general well being.

We contend that the cultural capital stage is the most important step in this ritual sequence because of first impression management (Goffman 1959) and that it should be the focus among managers seeking to reduce churns or retain customers, thereby helping to establish community and perhaps *communitas*, which may ulti-

mately lead to enduring involvement (McGinnis et al. 2008). Knowledge of game rules, local rules, etiquette, and other subtle nuances establish confidence and open the doors for cultural and social capital to be honed, developed, and demonstrated. Managers should take an active role in creating better customer-to-customer relationships.

An Exploratory Study into the Disposition Behaviour of Poor Bottom-of-the-Pyramid Urban Consumers

Stephen G. Saunders, Monash University, Australia

ABSTRACT

This study explores the critical events, decisions and emotions associated with the disposition of basic household items of poor urban consumers. The method chosen to describe the poor consumers experience in the disposition of possessions was that of existential-phenomenology. Open-ended in-depth interviews were conducted with 10 poor urban consumers. The results showed that the disposition behaviour of these poor consumers, while significantly influenced by their religious beliefs, occupied the same psychological stages of disposition as observed by Roster (1989). However, while the psychological stages of disposition were very similar, the behavioural outcomes were quite different to that experienced in wealthier communities. These differences were presented before discussing the implications of these differences. In particular, the decisive role that religion played in influencing disposal behaviour of these poor consumers was discussed before suggesting areas of further research.

INTRODUCTION

Consumer behaviour is defined by Schiffman, et al. (2005:6) as the behaviour that consumers display in “seeking, purchasing, using, evaluating and disposing of products and services”. While the academic marketing literature publishes any abundance of theories and empirical studies on seeking, purchasing, using and evaluating behaviour, there are very few studies on the disposition of products and services. Some notable exceptions include a taxonomy for describing consumer disposition behaviour (Jacoby, Berning and Dietvorst, 1977; Hanson, 1980), a conceptual model of consumer disposition of possessions (Young and Wallendorf, 1989), two empirical studies into the disposition of special possessions by older consumers and disposition possessions among families of people living with AIDS (Price, Arnould and Curasi, 2000; Kates, 2001), and a theoretical model on the disposition of meaningful possessions to strangers (Lastovicka and Fernandez, 2005).

It is surprising that the disposition facet of consumer behaviour is so under researched given that the study of disposition is highly relevant to a number of contemporary marketing problems. First, disposition behaviour is an integral component of the consumption cycle and potentially an important antecedent of future consumer buying behaviour. As consumption behaviour is cyclical in nature, an understanding of the disposition of “old” goods and services prior to “new” purchases would underscore a diversity of marketing implications (Jacoby et al., 1977). In fact, early pioneers of consumer theory such as Belk (1988) encouraged research into the experiential facets of consumption that included disposition processes; recommending that the disposition phenomena should be analysed from a macro-, meso- and micro-theoretical perspective (Arnould and Thompson, 2005).

Second, there is some evidence that an understanding of consumer disposition could provide a new perspective on consumer attitudes and expectations. For example, the current cultural trends towards anti-consumerism could be aided by an understanding of consumer voluntary disposition (Cherrier and Murray, 2007).

Third, understanding consumer disposition of products especially environmentally unsafe products and services (i.e. medical products, batteries, computers and other potentially harmful products) is a necessary element to an effective environmentalist marketing strategy. Marketers are increasingly interested in the impact that marketing has on the environment and the need to

market products that are easier to recover, reuse and recycle (Hart, 1997).

Last, marketing has begun to acknowledge that poor (the so called “bottom of the pyramid”) consumers are a significant untapped marketing opportunity (Prahalad, 2004). As possessions of the poor consumer are relatively scarce, an understanding of disposition decisions and behaviour is perhaps a logical precondition to understanding the poor consumers’ behaviour. In other words, to gain a comprehensive view of the poor consumer, the analysis of disposition is as important as acquisition and consumption behaviour. Successfully building markets at the “bottom-of-the-pyramid” will require marketers to understand poor consumers seeking, purchasing, using and evaluating behaviour but also understanding poor consumer’s disposition behaviour.

This article explores the preceding events, emotions and decisions associated with the disposition of possessions by poor consumers. The research examines the disposition of basic goods that are seen as indispensable to poor consumers. These potentially include stoves, pots, bed, shoes, clothing, mattresses and basic hygiene items. For poor consumers possessions are scarce (Mehta and Belk, 1991) and disposition of these scarce, often “irreplaceable” or “special” possessions requires the researcher to focus on the preceding events, emotions and decisions associated with disposition, providing valuable insight in the behaviour of poor consumers (Grayson and Shulman, 2000; Price et al., 2000).

The theoretical foundations of consumer disposition are presented, before describing the empirical methods. A thematic description of the consumers lived experience is presented. Finally conclusions and directions for future research are provided.

DISPOSITION

Research into consumer behaviour over the past 20 years has tended to focus on developing and refining theories on consumer acquisition and consumption as these processes were perceived to affect shopping behaviour and that could be induced by the power of marketing (Arnould and Thompson, 2005). Research into disposition behaviour (i.e. the act of getting rid of something), on the other hand, has received comparatively little attention, despite early consumer theorists such as Jacoby et al (1977) and Hanson (1980) insight that disposition behaviour could affect subsequent acquisition and consumption intentions.

Jacoby et al (1977) called attention to disposition decisions by describing the taxonomy of consumer disposition behaviour. The three general choices available to consumer when contemplating disposition of a product and the related consumer decisions are presented in Figure 1.

Jacoby et al (1977) found that the decisions of consumers when contemplating disposition is based on psychological decisions of the consumer (e.g. personality, attitudes, emotions, perceptions, peer pressure, social conscience), factors intrinsic to the product (condition, size, style, value, technological innovation, adaptability, reliability, durability, initial cost, replacement cost), and situational factors extrinsic to the product (e.g. finances, storage space, urgency, fashion changes, circumstances of acquisition, functional use, economics, legal considerations). Hanson (1980) extended the work of Jacoby et al (1977) by offering a framework of consumer product disposition processes. According to Hanson (1980) the disposition process consists of four stages: problem recognition

FIGURE 1
Taxonomy for Describing Consumer Disposition Behaviour

Keep the product	-Continue to use it for its origin purpose -Convert it to serve another purpose -Store it, perhaps for later use
Permanently dispose of the product	-Throw it away or abandon it -Give it away -Sell it -Trade it
Temporarily dispose of the product	-Loan it -Rent it to someone else

Adapted from Jacoby et al (1977:22)

(i.e. a cue that triggers a need to dispose), search and evaluation (i.e. information sources are utilised which have a varying influence on disposition behaviour), disposition decision, and post disposition outcomes (i.e. disposition decisions influence attitudes toward subsequent disposition and acquisition intentions). Continuing the research stream initiated by Jacoby et al (1977) and Hanson (1980), Harrell and McConocha (1992) investigated the rationale consumers' use when choosing disposal options, including redistribution options (such as charities, donations and waste management) which were not previously considered.

Young and Wallendorf (1989: 34) concluded that "disposition is a process rather than a discrete event" where it is "impossible to pinpoint the moment when emotional or physical detachment occurs". Supporting these conclusions, Roster (2001) found that disposition involves a psychological process from initial detachment (distancing behaviour, critical events, and ongoing value and performance assessments) to physical severance, outcome assessment and finally psychological and emotional severance.

The subsequent research into disposition of products dealt largely with the symbolic and emotional meaning of disposition and the significance of disposition on a consumer's self concept (Price, et al., 2000; Kates, 2001; Lastovicka and Fernandez, 2005; Shelton and Okleshen Peters, 2006; Cherrier and Murray, 2007). While this research contributed to a better understanding of the preceding events, emotions and decisions associated with disposition, they tended to focus on exceptional dispositional events rather than dispositional events experienced by a wide range of consumers. For example, Price et al. (2000) and Kates (2001) explore the disposition of special possessions by old consumers and the disposition of possessions among families of people living with AIDS. Similarly, Shelton and Okleshen Peters (2006) investigates the disposition of tattoos (i.e. tattoo removal), Lastovicka and Fernandez (2005) examined garage sales and on-line auctions, while Cherrier and Murray (2007) explores the disposition of possessions of individual who have radically changed their consumption lifestyle by consuming less (i.e. downshifting). This contemporary research into disposition made a meaningful contribution to the disposition literature and the understanding of consumer behaviour; however, the research was focused on exceptional dispositional behaviour that most consumers do not experience in everyday life. Inglis (2005) argues that the great majority of consumer behavioural activities occur-not during exceptional experiences-but during the "banality" (i.e. unexceptional, mundane routine) of everyday life. Rather than focusing on exceptional dispositional events, this research focuses on the disposition of common household possessions by poor consumers as part of everyday life experiences.

METHOD

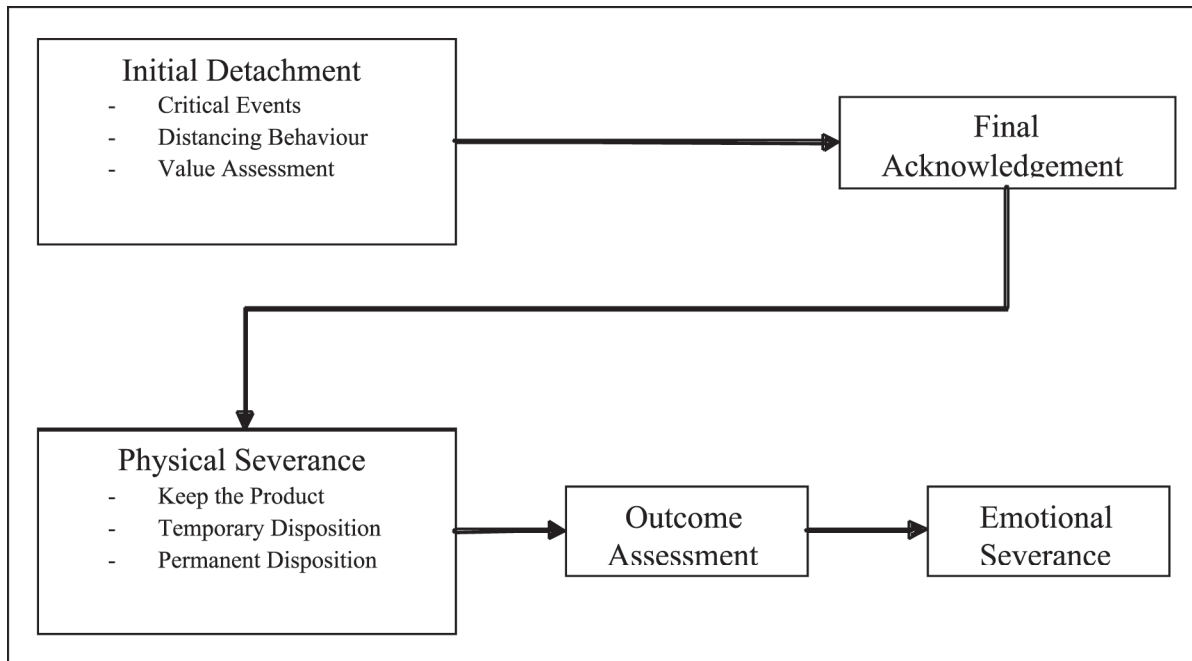

The method chosen to describe the poor consumers experience in the disposition of possessions is that of existential-phenomenology (Thompson, Locander and Pollio, 1989). Existential-phenomenological description provides a basis for exploring consumer experience in non-dualistic terms which allows for a first-person description of lived experiences. While the emphasis is on the experience of the first-person, the first-person is influenced by the social and cultural beliefs of the lived experience. Infusing the consumer experience, with a description of the lived meaning, can significantly benefit the understanding of the behaviour of poor consumers. The research goal is to provide a thematic description of the experience of the disposition of possessions by poor consumers.

The data collection process began by placing an advertisement in the community centre of a very poor informal (shack) settlement north of Johannesburg, South Africa. The advert invited residents to participate in a market research project. A toll-free number was provided to avoid any expense for the potential participants. Each potential participant who contacted the researcher was screened to ensure that they were a resident of the informal settlement. In total 10 participants were chosen to participate.

Given that the goal of the research was to provide a thematic description of the experience of the disposition of possessions by poor consumers, the researchers conducted open-ended in-depth interviews on the disposition experiences relating to common household possessions that were seen as indispensable to poor consumers. The format resembled the methodology of existential-phenomenological interviewing (Thompson, Locander and Pollio, 1989). The interviewer began by asking if the participant owns any of the following possessions: stove, pots, bed, shoes, clothing, mobile phone and a toothbrush. The interviewer then systematically asked if the participant had disposed of any of these possessions or similar possessions in the past. If the participant did dispose of any of these possessions, the participant would be asked for details regarding the preceding events, emotions and decisions associated with the disposition of that possession. The dialogue with the participant was conversational and allowed to emerge on the basis of the participant's story. When conducting the interviews, every effort was made to keep the participants on track by prompting the participant for details regarding the disposition experience (without being directive).

Consistent with existential-phenomenological interpretation (Thompson, Locander and Pollio, 1989), the transcribed interviews were interpreted by means of an iterative back-and-forth process of relating individual parts of the verbatim text to the whole text, so making it possible to form interpretations in the context of the lived

FIGURE 2
The Process of Disposition Model

Adapted from Jacoby et al (1977) and Roster (2001)

meaning. After each interview was interpreted, the researcher widened the interpretive context to identify common patterns across interview transcripts. These common patterns were labelled under various 'themes'. The "themes" were then interpreted in terms of Roster's (2001) psychological process of disposition and Jacoby et al (1977) taxonomy for describing consumer disposition behaviour. The process of disposition model is presented in Figure 2.

RESULTS AND INTERPRETATIONS

All the participants were very poor unemployed urban consumers that could be classified as "bottom-of-the-pyramid" consumers. While the ages of the participants varied from 25-56 years (six females and four males), the experiences and emotions conveyed during the interviews were all very similar, resulting in data saturation after the 10 interviews. In the interviews all the participants expressed the hardships experienced of coming to Johannesburg with absolutely no possessions other than the clothes on their back and the constant daily struggle to feed themselves and their families. The participants also expressed a sense of absolute desperation when first arriving in Johannesburg as there was little hope of employment or any source of income.

The average day, in the informal settlement, was spent fetching water, cooking, praying, sleeping and talking to fellow community members. Sundays morning were spent attending church. From time-to-time the participants did engage in casual employment, (averaging no more than two to three days work per month) which was largely arranged by the local church.

After analysis and interpretation of the text, three broad conceptual categories or themes emerged. These were very similar to Roster's (2001) themes for the psychological process of

disposition. As the themes were very similar, it was decided to use Roster's categories for the analysis of the themes, namely: initial detachment, physical severance, outcome assessment and psychological and emotional severance.

Initial Detachment

When participants were asked if they owned any basic possessions, all of the participants commented that all the possessions that they owned (other than some high value items) were given to them by a nearby Christian church.

"Many things I wear today, it comes from the church; the father gives me blankets, duvets, clothes, shoes" (BF 41).

For all the participants the initial detachment for items was always preceded by some "critical event". The overriding "critical event" mentioned by all the participants was the initial meeting with the Pastor of the nearby Christian church. The participants recounted the "critical event" of meeting the pastor of the nearby Christian church on the first day or two of arriving in Johannesburg. The pastor would offer food to the participants and invite them to the church.

"Now I give you this bread and I think you can go to the church and pray to God, God can give you bread everyday until you die and after that I go with Pastor and see that Pastor give me a big, big, big night for the god. I am with Pastor and I see that I am not suffering because the days before I was suffering but now I am not suffering...I said I got no food, I see that Pastor can come to give me food, if got no clothes, Pastor can give me clothes" (BF 43).

“He is working by the squatter camp and give the people food and tell the people about God and tell the people that food come from God, because me I got food because I know God, and I think if you go to the church you can know of God” (BF 44).

All the participants were invited to join the church and were all (except one person) baptised by the Pastor.

“And then all of the sudden I get Pastor under Father’s [Gods] ministry and I was baptised and then all my life get changed...” (BF 56).

“I am with Pastor and I see that I am suffering because the days before [baptism] I was suffering but now I am not suffering” (BF 43).

After joining the church the participants were not only provided food but clothes, shoes, blankets, and basic toiletries (such as soap, Vaseline and toothbrushes). In fact, the participants provided the church with their clothing and shoe sizes so that the church could source the correct size of clothing or shoes. These items were given to the church by the church members.

At times, when the participants were able to gain casual employment (normally organised by the church), the participants would buy a 10kg bag of maize meal and often more basic toiletries. This food and basic toiletries would be made to last until the participants received another source of income.

Some of the participants owned “high value” possessions such as mattresses, furniture, paraffin stoves, mobile phones and car batteries (to power radios or lights). These possessions (other than the mattresses and furniture) were also acquired after earning some money through casual employment.

“When that people give me money, I put the money away. I put the money away because I get the food from Pastor, and the clothes from Pastor, and when it was enough I buy the phone. I buy Motorola for R279” (BF 44).

The mattresses and furniture were either given to them from a family member, found at the local rubbish dump, or borrowed from a friend.

“I was suffering. I was staying with my cousins. She get married now and now she give me old mattress” (BM 43)

Physical Severance

Using Jacoby’s (1977) taxonomy to group the general choices available to the participants when contemplating physical severance from a product, it was found that all three choices were displayed. Each choice is discussed in turn.

Keep the Product. A number of participants expressed the desire to store items that did not work. For example, a number of participants had found non-working televisions and radios at the local rubbish dump and even though they never anticipated that they would be fixed, they continued to store these items indefinitely. For example, a TV was often displayed in a prominent place in the shack, with the participant proudly remarking that they owned a television, even though they admitted it did not work and probably would never be fixed.

Temporarily dispose of the product. Temporary disposition of items was largely restricted to furniture or mattresses that were lent

to family members or friends. These items were never loaned for monetary gain but temporary lent until they were needed again.

“I am sleeping on the bed, but it is not mine. It’s for another somebody, who is staying here...I don’t know when he will take it [back] but maybe in two months...Before I was using a sponge to sleep on. I give [loan] it to somebody who’s like me, before I was sleeping up there [on the bed]” (BF 25).

The death of a family member who was using the mattress or chair was often cited as a reason for loaning the item. The participants remarked that the item would be recalled if an additional member of their family came to live with them in Johannesburg. There seemed to be a strong sense of sharing “high value” possessions in the community. As Belk (2007) comments sharing is another form of distribution that is distinct from market exchange and gift-giving, that fosters a community spirit, saves resources and creates certain synergies. Belk (2000) established that African cultures have a strong tradition of sharing their wealth with extend family and the community.

Permanently dispose of the product. The permanent disposition of items showed some similarities in disposition patterns as observed by Hibbert, Horne and Tagg (2003). Some of the similar patterns that emerged were the trading-in of old batteries and the selling of stove burners for scrap metal.

“I take it to the Battery Bay, I sell it back again, so when I sell it, they sell a battery for R250 that is new...so when you sell that old battery is not working you have to add R150 on that battery so you must get the other new battery” (BF 41).

“[When the stove burner] is broken we sell it to some other old man who take the stove to scrap yard and there he sells it for scrap” (BF 20).

However for other items a very different pattern of disposition emerged. For items that the participant considered “beyond repair”, “broken” “too old” or “of no use”, the participant would throw the item in a fire so that the item would be destroyed. These items included old clothing, shoes, furniture and mattresses. Two participants reasoned that it was better to burn these items than throw them away so as to “not to destroy the environment” or the physical surroundings. This behaviour is rather surprising as the participants acknowledged that these items, if not burnt, would be found in the streets or municipal rubbish bins and subsequently used by fellow residents.

“When they are torn, eh, I am going to burn them [so] there is no way out...they are still over, they are torn, they are teared all over, there’s no way out” (BM 25).

These participants expressed that it would be undignified for a member of the community to give away clothing or shoes that they have deemed “beyond repair”, “broken” “too old” or “of no use”. It was seen that the appropriate behaviour was to avoid giving other members of the community the choice to decide if the pair of clothing is wearable or an item is usable.

Old toothbrushes and other personal hygiene items were also destroyed. However, this was done for very different reasons to the above. All the participants that have disposed of these items cited hygiene reasons for destroying their toothbrush or other basic hygiene items.

“When [it] is old, not right to use it, I can put, eh, make a fire and put by the fire and light the fire and toothbrush can burn, because I don’t want somebody to use my toothbrush... because I know the toothbrush got a disease, I can’t give somebody toothbrush I am using” (BF 43).

“If don’t want to give the people if I got something... like a nail cutter [clipper] if is broken, I put it by the toilet, because I don’t want somebody to use because of disease (BM 42).

Items that were deemed “useable” by participants were never sold but given away to other members of the community, (even if these items had a relatively high emotional connection or monetary value to the participant).

“I sell nothing because I see that nobody sell something to me, but I get everything from the church and by the church I can’t pay a cent to take the clothes, new shoes, blankets to sleep and now I don’t like to sell something to somebody if I see I got enough I take it and I give to somebody” (BF 25).

What was interesting was that these acts of disposition are all associated with the participant’s religious identity and the Christian practice of giving to the poor as a means of further identifying with the suffering of Jesus Christ (Shelton and Okleshen, 2006). These disposed items are seen as religiously “sacred” (Belk, Wallendorf and Sherry, 1989) and the act of disposition served as a means of expressing the social role of the “Good Christian Samaritan”.

Outcome Assessment and Psychological Severance

According to Roster’s (1998) Psychological Process of Dispossession, participants often reflect on their decisions to dispose of certain items, and the impact this may have on the participant’s relationship with the severed item. For all the participants, the reflection elicited positive emotions, and never feelings of relief that they were free from the obligations of the item (as found by Pavia, 1993). The participants express the joy of being able to demonstrate the same sense of generosity that was previously shown to them. Furthermore, the outcome assessment was largely verbalised through “storytelling” (Roster, 1998). Participants would relay the story of first meeting the Pastor and how their religious conversion ensured a better life.

“I tell how Pastor find the people to go to church to know God, how God helps you... how the church gives us things to wear and to eat” (BF 42).

Unlike Belk’s et al (1989) view that “sacred” items are never sold or disposed, the participants expressed a sense of “community relationships” involving meeting other people’s needs without regard for reciprocity (Clark and Mills, 1979).

“You just give, because even Pastor don’t want money from me, just to give, because he teach us if you give somebody, God can give you” (BF 43).

Similarly, unlike Young and Wallendorf’s (1989) view that disposition is a painful process “in which consumers experience the death of the piece of their lives with each possession lost” (Lastovicka and Fernandez, 2005:814), participants expressed a sense of religious elucidation with the disposition of items.

“If I see the people haven’t got that thing, I give it. I feel much better it I can share because Pastor give me and that one

[person] is not going to church and [they] know nothing about the church. I sit down and tell them that Pastor give me shoes because I am going to the church. Because you know, when we go to church we make prayer, and you can see everything can come to you. Now I give to that lady or child who haven’t got” (BF 37).

This disposition behaviour is very similar to the disposition of special possessions of older consumers. Price et al. (2000) found that older consumers disposing of cherished possessions tried to ensure a good home for the items and/or influence the future lives of the recipients. In fact, the participants through their disposition behaviour seemed to play an important role in poverty relief for other poor consumers. While there is no clear consensus on the role that religion plays in prompting relief for the poor (Regnerus, Smith and Sikkink, 1998), the participant’s disposal of items to other poor consumers had a clear intent of religious conversion. Bem (1967) presents a theory of self perception where disposition provides the consumer with a means to incorporate a new role in society into their existing self-concept. The new role of also giving to the poor provides additional evidence of their existing self-concept of being the “Good Samaritan”.

“If I see I can be nice to somebody, I can give it to somebody... I never sell” (BM 34).

While disposition is typically seen as a means of separating an undesirable feature of a person’s self-concept through the disposal of an item that is no longer compatible with the self (Belk, 1988; Young, 1991) or as a means of emptying the meaning of an item before passing it along (McCracken, 1986), the participants rather saw disposition as a means of passing on religious symbolism which was consistent with the persons religious identity or self-concept. Recently, Lastovicka and Fernandez (2005: 821) demonstrates how a shared self leads a “consumer to believe that the stranger—who may become the new owner of a meaningful possession—would perpetuate the meaningful possession’s legacy”. In the case of the participants, it would be the legacy of the “Good Samaritan”.

According to Roster (2001) critical events (such as changes in employment status, health and size of family) can alter the relationship between owner and item by heightening a sense that the product no longer represents relevant aspects of the self. However, the critical event of religious conversion of the participants created a heightened sense that the product was a more relevant aspect of the self and that emotional and psychological ties associated with the item were strengthened. Severance from the item was not a matter of emptying the meaning and symbolic properties of the item, but rather ensuring, the “safe passage” of the item (Richins, 1994).

CONCLUSIONS AND DIRECTIONS FOR FUTURE RESEARCH

To gain a better understanding of the four billion poor consumers worldwide, it is not only important to understand their consumption behaviour, but also their disposition behaviour. As first it would seem contradictory that poor consumers would want to voluntarily dispose of items that are not only treated as “special” (in the words of Price et al, 2000), but that are so scarce in poor communities. Furthermore, it would also seem contradictory that such poor consumers would voluntarily give away (i.e. “never sell”) these disposed items or to take it upon themselves to decide if an item is useful for other members of the community, (often burning the item rather than letting somebody else decide the usefulness, value or worth of the item).

In this study poor consumer occupied the same psychological stages of disposition as observed by Roster (1989); however the behavioural outcomes were quite different to that experienced in wealthier communities. Firstly the results clearly showed that disposition plays an important role in the consumption cycle but may not necessarily be the antecedent to future purchasing behaviour. In fact, participants often acquired “new” items before making a decision about disposing of any “old” items. This suggests that the consumption cycle does not necessarily progress in a uni-directional fashion but may in fact be multi-directional.

Second poor consumers provided a new perspective on consumer attitudes and expectations. For example, poor consumers seem to want to keep items of high social value (e.g. televisions), even though these items never work and in all probability would never be fixed. In this case the television may reflect a symbolic connection to a better life or as Campbell (1987) argues, the poor emulate the wealthier communities for purposes of identity enhancement.

The temporary disposition behaviour of poor consumers also provided a new perspective on consumer attitudes. Contrary to the notion of Western materialism and possessive individualism (Belk, 2007), these very poor African consumers demonstrated a true sense of sharing with the extended community. It was found that the temporary disposition behaviour extended beyond immediate family and friends (as is typical Western culture) to all members of the community and that it was mainly “high value” possessions that were shared. Loaning items was never done for monetary gain and always fostered a sense of community spirit. This type of consideration for compassion and communality displayed by African cultures through their disposition behaviour is often referred to as the African concept of “ubuntu” or humaneness. According to Mangaliso, (2001) Christianity is becoming more prevalent within the belief system of Ubuntu, as found in this study.

Thirdly, poor consumers made the decision to permanently dispose of certain items that were deemed “beyond repair”, “broken” “too old” or “of no use” even though other poor consumers, in all probability, would value these items. Two explanations emerged from the findings. The first explanation is that consumers expressed that if an item is of no worth to them, it would be demeaning to allow a fellow member of the community the undignified option of using or wearing the item. In Ubuntu, fellow members of the community are always treated as ones own family. If the item is of no use to the family it cannot be of use to others. The second explanation is the misplaced belief that items that deal with personal hygiene cannot be “sterilised” and then used by another person. The simple act of boiling a toothbrush to “sterilise” the item was either not known or considered. This further provides a unique perspective on the disposition of “unsafe” items where the consumer wrongly believes that the item to be “unsafe” so not allowing the item to be recovered, reused or recycled. This then raises the point (that environmentalist marketing strategies need to take into consideration), that consumers may have the wrong beliefs about what can and cannot be recovered, reused and recycled.

Finally, there are a number of limitations that need to be considered when interpreting the findings from this study. First, the collected data was restricted to one small informal (shack) settlement in Johannesburg. While the socio-economic status of this settlement is largely representative of urban informal settlements in Southern Africa, the economic survival of the members of the community were largely dependent on a single Christian organisation in the area. Furthermore, the findings may not elucidate the differences in disposal behaviour in other poor communities where other religious, governmental, non-governmental and charity groups are the major economic contributor to the poor consumer. The study also recounts

the participants reported behaviour rather than actual disposal behaviour. The level of actual disposal of items to other members of the community may be less than reported due to a social desirability of altruistic behaviour (Hibbert et al, 2005).

In order to build on this study, attention needs to be placed on the influence that religion plays in influencing disposal behaviour amongst vulnerable communities (in particular the poor). This study has shown that religion plays a decisive role in influencing the disposal behaviour of poor consumers and needs to be investigated further.

The More the Merrier: Imagined Social Presence and Service Failure

Yi He, California State University, East Bay, USA

Qimei Chen, University of Hawai'i, USA

Dana L. Alden, University of Hawai'i, USA

EXTENDED ABSTRACT

Most customers can recall a service failure, in which he/she experiences problems in a service delivery process (Lewis and Spyropoulos 2001). Usually, during such a service failure, the customer may find him/herself become the focus of other customers' attention as a result of a heated conversation. This phenomenon begs answer to an interesting question: what is the effect of social presence on an individual's reactions to a service failure? Does it exaggerate the negative outcome of a service failure? Or more interestingly, does it alleviate such negative outcome? And how? The answers to all these questions lie in the premise that social presence may dramatically shift a customer's service failure experience.

Despite the topic's clear importance, social presence effects on consumption remain understudied (for a few exceptions, see Dahl, Manchanda and Argo 2001; Argo, Dahl and Manchanda 2005; Zhou and Soman 2003; Mangleburg, Doney and Bristol 2004). In particular, researchers have not integrated this social factor into the service literature. In addition, the underlying mechanism of social presence effects has yet to be uncovered. Seeking to bridge these gaps, we have conducted an experiment to: 1) evaluate the impact of social presence during a service failure, 2) examine the processing mechanism under which social presence impacts service evaluation, and 3) build a nomological net that features social presence and outcome attribution.

Investigations concerning the effects of social presence have thus far based upon two major theories: the Evaluation-Apprehension theory and the Distraction-Conflict theory. The first one is linked to seeking and maintaining positive public image (e.g., Bone 1982; Seta et al. 1989; Baumeister 1982), and the latter is associated with attention conflict and cognitive overload (Baron 1986; Baron, Moor and Sanders 1978). The Evaluation-Apprehension theory (Cottrell 1972; Bond 1982; Berger et al. 1981; Baumeister 1982) suggests that with the presence of a social audience, individuals tends to inspect themselves from an observer's perspective (Duval and Wicklund 1972; Wicklund and Duval 1971). In so doing, the difference between the current self and the ideal self becomes salient and produces an aversive state, which alters emotional response. Following the Evaluation-Apprehension theory, the direct consequence of social presence is altered emotional experience. In other words, the underlying processing mechanism of social presence effects may be affective in nature. For example, the negative emotions (e.g., embarrassment) elicited by a service failure may become more salient due to social presence. The intensified negative emotions may consequently affect evaluation.

A rival theory of social presence, the Distraction-Conflict theory, asserts that social presence creates attention conflict and leads to cognitive overload (Baron 1986; Baron, Moor and Sanders 1978). Following the Distraction-Conflict theory, the social presence effect may be explained based upon a cognitive processing mechanism. For example, it can be argued that as a result of reduced cognitive resources caused by a public audience, customers may have difficulty forming a negative evaluation for a service failure.

The two rival theories propose competing explanations for social presence effects. To date, attempts to pinpoint a superior theory have yet to reach any conclusive results (e.g., Feinberg and

Aiello 2006). Most recently, researchers interested in this line of research have argued for an integrative model, which posits that an individual may have multiple reactions to social presence that are co-occurring (Uziel 2007). This research applies this integrated model and posits that each different reaction to social presence can be made salient at a given moment due to a situational factor, outcome attribution. We argue that the Evaluation-Apprehension theory explains social presence effects when the service failure is externally-attributed, whereas the Distraction-Conflict theory accounts for social presence effects when the service failure is internally-attributed.

The experiment examined the impact of social presence on service evaluation during a service failure and tested the two rival theories that explain social presence effects. A total of 121 college students participated in the experiment. Participants were asked to read a cartoon scenario depicting a disagreement between a customer and a bookstore cashier. Internally- versus externally-attributed service failure were manipulated by scenarios in which either the bookstore employees or the customer was clearly responsible for the problem leading to the disagreement. This treatment was pre-tested to ensure that it induced the intended emotions. The second factor, social presence, was manipulated by depicting other customers (versus no customers) in the vicinity of the checkout counter and cashier. As such, the experiment featured a 2 social presence (no social presence versus social presence) X 2 outcome attribution (external-attribution versus internal-attribution) between-subject factorial design.

The planned contrast results indicated that compared with no social presence condition, social presence was associated with higher service evaluation pertaining to the service failure regardless of outcome attribution [$M's=3.31$ versus 4.25 , $t(106)=3.09$, $p<.01$]. Further mediating analyses, however, uncovered the complexity of the above findings. In particular, the results demonstrated that anger fully mediated the relationship between social presence and service evaluation when a service failure was externally-attributed. When the service failure was internally-attributed, number of negative thoughts fully mediated the relationship between social presence and service evaluation. This indicated that when the service failure was externally-attributed, the affective process proposed by the Distraction-Conflict theory accounted for the social presence effects. When the service failure was internally-attributed, the cognitive process suggested by the Evaluation-Apprehension theory drove the social presence effects.

To conclude, this research holds theoretical significance in that investigating social presence as a moderating factor related to consumer reactions to a service failure helps enrich the traditional service evaluation paradigm. This research also holds managerial significance as understanding the crucial role of social presence in service encounter may help service providers to be more conscientious about the social environment, which consequently leads to improved service evaluation.

Ambivalence in Consumption: The Case of Anticipatory Emotions

Colleen Bee, Oregon State University, USA
Robert Madrigal, University of Oregon, USA

EXTENDED ABSTRACT

Emotion plays an important role in marketing, particularly in understanding consumer behavior. In fact, it may be difficult to identify a purchase situation where multiple emotional elements are not present. This research examines factors that affect emotional ambivalence in the consumption experience. Appraisal theory is used as a theoretical foundation in the current research. Cognitive appraisal theorists believe that emotions are elicited from an appraisal of a situation or event and it is not the specific event that produces the emotion, but the appraisal of the event (Roseman and Smith 2001; Smith and Ellsworth 1985). Key appraisals considered in this research are congruence, which determines valence based on goal desirability, and outcome probability, which identifies the specific emotion within a congruence appraisal. Two categories of emotions studied in this research are anticipatory emotions (optimism and worry) and outcome-based emotions (joy and anger). In the only research that explicitly examines anticipatory emotions, Baumgartner, Pieters, and Bagozzi (2008) differentiated between anticipatory and anticipated emotions and related both to behavioral intentions. However, optimism and worry have not been explicitly examined in marketing and consumer behavior research, yet these emotions seem particularly relevant in purchase and consumption decisions as many consumption situations involve elements of uncertainty and differing levels of desirability.

The purpose of study 1 is to consider information congruency appraisals and examine the relevance of anticipatory emotions in consumption. The first hypothesis proposes that conflicting information (i.e., congruent and incongruent) will lead to higher levels of emotional ambivalence. Second, we propose that the anticipatory emotions of optimism and worry will be experienced more strongly than the outcome-based emotions of joy and anger emotions, as discrete emotions and as emotional ambivalence. Finally, we expect that optimism-worry objective ambivalence will be a better predictor of subjective ambivalence than discrete emotions or joy-anger objective ambivalence.

The results in study 1 indicate that information congruency significantly affects the valence of emotions and that conflicting information significantly increases the experience of emotional ambivalence. Anticipatory emotions were experienced more strongly than outcome-based emotions. Although multiple emotions are experienced, the anticipatory set of mixed emotions was a better predictor of subjective ambivalence.

In study two we consider how congruency appraisals affect ambivalence and confidence at different points in time in the consumption process. Additionally, the mediating role of subjective ambivalence is considered. Although the experience of conflict is similar among dissonance, attitude ambivalence, and emotional ambivalence, a key differentiating factor is that dissonance typically occurs after a commitment has been made, whereas emotional ambivalence can occur prior to making a commitment or decision (van Harreveld et al., 2009). In fact, van Harreveld et al. propose that level of commitment to an available alternative is the primary distinction between ambivalence and dissonance. In this case, feelings of conflict and discomfort related to ambivalence will be most pronounced when a choice needs to be made. When a situation does not involve choice, there is not as much reason for ambivalence and subsequent discomfort. Ambivalence should therefore be enhanced with the prospect of a decision.

The consumption process is dynamic and changing, where consumers receive multiple pieces of information at different stages of the process. As a result, not only is it expected that ambivalence will be affected by the information presented but also by the timing of this information. van Harreveld et al. (2009) suggest that when people are forced to make a discrete choice that they anticipate possible negative and positive outcomes associated with each alternative. This indicates that perhaps a choice situation can lead to modest levels of ambivalence even in the absence of conflicting information. Ambivalence and confidence levels are expected to fluctuate based on the information presented and the timing of this information.

In the second study, information congruency and time of information were found to interact in their influence on ambivalence and confidence. Specifically, prior to a favorable purchase, ambivalence is higher than prior to consumption as consumers anticipate positives and negatives. In contrast, ambivalence is lessened prior to an undesirable purchase when compared to consumption as there are few positives. With conflicting information it is difficult to integrate contradictory evaluations and ambivalence persists throughout a consumption experience. Confidence was found to have an inverse relationship with ambivalence. Finally, the discomfort that consumers feel in the form of subjective ambivalence mediates the effect of optimism-worry emotional ambivalence on confidence.

Optimism and worry are two categories of emotion likely to be elicited during purchase and consumption experiences. However, these two emotions have not been explicitly examined in previous consumer behavior research. In the current research, optimism and worry are future-directed emotions that were found to be important in influencing feelings of ambivalence, discomfort and confidence in decision making. Additionally, extending appraisal theory, consumers presented with conflicting information experienced more emotional ambivalence than those presented with consistent information. Consumption is dynamic and, in addition to information congruency, the stage of the purchase process is important in determining the level of ambivalence experienced. Finally, the experience of emotional ambivalence is associated with feelings of conflict and uncertainty. These feelings of conflict were found to mediate the effect of emotional ambivalence on confidence.

Be Tolerable or Be Angry? A Situation of Relationship Norm Conflict in Failure

Lisa C. Wan, Lingnan University, Hong Kong, China

Michael K. Hui, Chinese University of Hong Kong, Hong Kong, China

EXTENDED ABSTRACT

Prior research has generally agreed that establishing friendships with consumers work well in mitigating consumer dissatisfaction in failures. However, this paper argues that a friendship may not always work and sometimes it may even magnify consumer dissatisfaction in failures. Drawing from the communal-exchange relationship framework (Clark and Mills 1979), this paper proposes two conflicting norms may have been activated simultaneously in communal relationships when a failure happens. The first norm focuses on self-obligation, that is, because s/he is my good friend, I have to tolerate his/her mistakes. The second norm focuses on other-obligation, that is, because s/he is my good friend, s/he has to provide me with good services. The relative salience of these two conflicting norms may influence communal consumers' dissatisfaction level to be different from exchange consumers. Building on the psychological contract theory (Rousseau 1989), it is suggested that promise breach type is a moderator that influences the relative salience of the two norms in governing communal consumer responses. Specifically, communal (vs. exchange) consumers would be less dissatisfied in an implicit promise breach, but the reverse pattern would occur in an explicit promise breach.

In addition, this paper demonstrates that self-construal further moderate the interactive effect of relationship type and promise breach type on consumer dissatisfaction. Note that people reactions to social norms and obligations have been demonstrated to vary significantly according to their independent and interdependent self-construals (Markus and Kitayama 1991; Singelis 1994). Given that relationship norms are the key in driving the different dissatisfaction levels across communal and exchange relationships in failures, it is possible that the interactive relationship between relationship type and promise breach type on consumer dissatisfaction would also differ across independent and interdependent self-construals. Two experiments with different consumption contexts provide convergent evidence of the proposed hypotheses.

Research Hypotheses

- H1: When there is an implicit promise breach in a failure, communal consumers will be less dissatisfied than exchange consumers.
- H2: When there is an explicit promise breach in a failure, communal consumers will be more dissatisfied than exchange consumers.
- H3: When there is an implicit promise breach in a failure: (a) The pattern of communal consumers are less dissatisfied than exchange consumers would be more pronounced for interdependents than for independents, and (b) this pattern is mediated by the tendency of self-obligation thought.
- H4: When there is an explicit promise breach in a failure: (a) The pattern of communal consumers are more dissatisfied than exchange consumers would be more pronounced for interdependents than for independents, and (b) this pattern is mediated by betrayal feeling.

Method and Results

In experiment 1, a 2 (relationship type: communal vs. exchange) x 3 (promise breach: no promise vs. implicit promise vs. explicit promise) between-subjects design was used. Results confirm that the impact of relationship type on consumer dissatisfac-

tion is contingent on promise breach type. Specifically, communal (vs. exchange) consumers are less dissatisfied in an implicit promise breach, but the reverse pattern occurs in an explicit promise breach. In addition, self-obligation thought is the mediator of an implicit promise breach and betrayal feeling is the mediator of an explicit promise breach.

In experiment 2, a 2 (self-construal prime: independent versus interdependent) x 2 (relationship type: communal versus exchange) x 2 (promise breach type: implicit promise breach versus explicit promise breach) between subject design was used. It demonstrates that self-construal moderates the interactive effect of relationship type and promise breach type on consumer dissatisfaction. More specifically, communal participants were less dissatisfied than exchange participants in an implicit promise breach, and this pattern was more pronounced in the interdependent self-construal condition than in the independent self-construal condition. In contrast, communal participants were more dissatisfied than exchange participants in an explicit promise breach, and this pattern, again, was more pronounced for participants who primed with an interdependent (vs. independent) self-construal. In addition, convergent evidences were found for the underlying mechanism between an implicit and an explicit promise breach. In brief, the self-obligation thought (betrayal feeling) tendency mediates the interactive effect of relationship type and promise breach type on consumer dissatisfaction in an implicit (explicit) promise breach.

Consumer Response to Firm Crisis Information: The Moderating Role of Regulatory Focus on Selective Exposure

Sunghun Chung, KAIST Business School, Korea
Yeosun Yoon, KAIST Business School, Korea
Ingoo Han, KAIST Business School, Korea

EXTENDED ABSTRACT

Firms frequently must deal with anomalous events, referred to as firm crisis, that induce high levels of uncertainty and are potential crucial factors to viability (Pearson and Clair 1998). Consumers today have access to a wide variety of firm crisis-relevant information, including traditional media and new media, such as online news forums, webcasts, and personal home pages. Batteries in electronic products spark fires, and negative publicity in case of the Enron incident are recognized as examples of firm crisis. Despite the potential impact of firm crisis in the market, there are few studies dealing with how consumers process such information and how firms can make strategies to overcome its effects. In addition, crisis research that addresses marketing issues is scant, and little is known about the effects of different response strategies resulting from critical motivation variables such as the regulatory focus.

In this research, we lay the foundation for a theoretical framework of firm crisis information processing by focusing on consumers' motivational orientation: self-regulation. The objective of our research is to provide an understanding of how consumers react to firm crisis information, and we argue that motivational orientation factor—namely, regulatory focus—moderate the processing and impact of firm crisis information. Also, we expect that increasing firm crisis-relevant information leads the firm in an opposite attitudinal direction, depending on the regulatory focus of the consumers.

According to regulatory focus theory (Higgins 1997), promotion-focused people emphasize aspirations and achievements and focus on the presence and absence of positive outcomes. However, prevention-focused people are concerned with responsibilities and safety and focus on the presence and absence of negative outcomes (Idson et al. 2000; Shah et al. 1998). In this regard, in the context of firm crisis, promotion-focused consumers display greater eagerness in striving toward a positive-framed outcome (inconsistent with firm crisis facts) than moving away from its absence (consistent with firm crisis facts). In contrast, prevention-focused consumers are concerned about a negative-framed outcome (consistent with firm crisis facts) more intensely than a positive framed outcome. Through experiment, we tested the differential responses to firm crisis by consumers who are either prevention or promotion orientated in self-regulation, and the psychological processes as firm crisis-relevant information increases.

Fischer and his colleagues (2008) make clear psychological processes that underlie the moderating role of information quantity on selective exposure. According to their study, when confronted with 10 pieces of information, consumers systematically preferred information that is consistent with their prior evaluation, whereas when confronted with only 2 pieces of information, they strongly preferred inconsistent information. Building upon Fischer's work (2008), we tested how consumers' regulatory focus moderates the effect of information quantity on selective exposure. We contend that whether firm crisis-relevant information will be discounted in a biased manner or will be weighted heavily depends on the consumer's self-regulation (promotion-focused or prevention-focused), and the quantity of firm crisis-relevant information will moderate these outcomes.

Finally, we confirmed the moderating role of consumers' regulatory focus to the effect of information quantity on selective

exposure in the context of firm crisis. According to mediational analysis, prevention-focused consumers exhibited a lower evaluation in response to increasing the quantity of firm crisis-relevant information because they support-argued it solidly, whereas the promotion-focused consumers resisted information quantity because they effectively counterargued it. Further, the underlying response strategies of both prevention-focused consumers and promotion-focused consumers (support argument vs. counterargument) trigger negatively in the case that they are faced with the restricted quantity of firm crisis-relevant information. Theoretically, we added consumers' regulatory focus as an important moderator to previous crisis literatures dealing with factors such as commitment (Ahluwalia et al. 2000), consumer expectations (Dawar and Pillutla 2000), cognitive style (Monga and John 2008), and even the face of company (Gorn et al. 2008).

From a managerial perspective, in new media such as online news, consumers' opinions dealing with firm crisis facts (online commentaries) can influence others' evaluations on the firm, and be a fitting instrument for the context of selective exposure. The results of the study indicate that a firm has little to lose by taking an affirmative public atmosphere through media. Inconsistent information on firm crisis in market is likely to redress consumers' lowering attitude, but consistent information on firm crisis is likely to cause consumers' disappointment and suspicion. Marketers may have help by considering different filtering responses of firm crisis including consistent or inconsistent with crisis facts depending on consumers' regulatory focus.

Collectively, current findings provide an impetus for further investigations of each of the firm crises characterizing either corporate ability or corporate social responsibility. Further understanding of the psychological processes that underlie consumers' reactions to real companies should help companies to manage their crisis more efficiently and effectively to achieve both goals.

Fantasies Come True, and Soon: Mental Construal as a Function of Regulatory State and Time Horizon

Yael Steinhart, University of Haifa, Israel
David Mazursky, The Hebrew University of Jerusalem, Israel
Michael A. Kamins, Stony Brook University, USA

EXTENDED ABSTRACT

Part of our indulgence in desired experiences to come, may involve thinking in detail about just how our experience may be. We savor with anticipation and cloak ourselves with exciting expectations about those wonderful moments to come. Essentially we borrow the expected feeling from the future and place it in the here and now, so as to brighten up our present. Conversely, if that future event is undesired, we may try to shun it, and avoid thinking about it in detail, giving way to what we current experience, for whatever it is worth.

The current research examines the nature of the mental construal process as a function of the consumer's regulatory focus state and time horizon. It proposes that when individuals are in a promotion state, such as being offered an attractive job when graduating, they savor the experience through anticipation and therefore are expected to consider a more detailed shopping list for the graduation party in the distant as opposed to near future. Alternatively, when individuals are in a prevention state, such as graduating with no job offer, they are expected to shun the experience and avoid thinking about it in details in the distance future more so than in the near future when they ultimately have to "face the music".

Recent research has directly focused on the form of mental construal as a function of the time horizon. In addition, there is ample evidence about the relationship between regulatory focus and the abstractness of mental construal. However, the role of temporal perspective in mediating the relationship between the type of regulatory state and the type of mental construal process has not been examined until now.

The research consists of four studies which demonstrate the "savor or shun" effect and its underlying mechanism in varying consumer contexts. The first study is designed to measure the anticipated breadth of categories formed in a decision task as a function of regulatory state and events that take place either in the near or distant future. It explores the research hypotheses under a realistic scenario of facing either an economic recession or prosperity, today or in the distant future, and asks participants to prepare a shopping list for each of the conditions. Its findings demonstrate that participants generated more categories in the distant future than in the near future when expecting prosperity; whereas the number of categories was higher in the near future than the distant future when expecting an economic recession. The second study extends the first by keeping the event constant (family weekend) and manipulating the regulatory state in an unrelated manner to the event. It further provides the participants with the list of items (rather than coming up with list by themselves) in order to better control the categorization process. Its findings replicate the ones of the first study both in terms of the number of categories and in terms of their content. The third study examines the "savor or shun" effect on actual decision choice, contingent with the item's level of abstractness. Results indicate that when exposed to both abstract and concrete items within a shopping list, individuals under a promotion focus selected relatively more abstract than concrete items in the near future than in the distant future. Alternatively, individuals under a prevention focus selected relatively more abstract over concrete items in the distant future than in the near one.

Finally, the fourth study demonstrates the underlying mechanism of the "savor or shun" effect through mediation by scales relating to shunning and savoring.

From a practical perspective, the "savor or shun" effect has significant managerial implications by highlighting how marketers should frame the product (i.e. elaborate about the process of reaching the decision or about its post-usage benefits) and the amount of details they should provide given the state the consumer is in. In terms of positioning, the current research proposes that under a promotion state, consumers would prefer to get more information about the process of reaching a decision over the consequence of their decision. Therefore, when promoting promotional products, marketers should communicate about the process of attaining the product more than about the benefits of having the product. On the other hand, under a prevention state, consumers would prefer to get more information about the consequences of completing their decision than about the process of reaching it. In terms of how to describe the process or the outcomes; the proposed research implies that the degree of abstractness of the product description, should be as a function of the consumer's level of anticipation toward the product, and/or the time frame of the impending decision, because such factors affect the way information is categorized. Consider consumers anticipating the new model year of their desired car or a couple planning their wedding. In these cases, as the time frame approaches for the launching of the new model or for the wedding, our research suggests that consumers favor a broader description. This is especially true for events that are fixed at a given point in time and hence occur at the same time for everyone (e.g. Valentine's Day).

The Persuasive Power of Regulatory Nonfit

Lora Harding, Northwestern University, USA

Monika Lisjak, Northwestern University, USA

Angela Y. Lee, Northwestern University, USA

EXTENDED ABSTRACT

Past research has shown that persuasive appeals that fit (vs. conflict) with a person's regulatory focus tend to be more persuasive (Lee and Higgins 2009). Because regulatory fit information is consistent with people's current motivational orientation or way of thinking, it is easier to process and understand than information that is inconsistent with their regulatory orientation and thus tends to be processed more deeply (Lee and Aaker 2004). Recent research suggests that fit information is most persuasive when people allocate few cognitive resources to process information. For example, Wang and Lee (2006) reported that participants were more persuaded by information that fit their regulatory focus, but only under low-involvement conditions.

An important question is: What happens when people are motivated to process persuasive appeals? To the extent that elaboration leads to greater persuasion, our view is that people will be more persuaded by information that mismatches their regulatory focus. To fully comprehend regulatory nonfit information, we expect that highly involved people will engage in more extensive processing due to the fact that nonfit information is inconsistent with their current way of thinking. As a result of more elaborative processing of regulatory nonfit information, highly involved people will be more persuaded by regulatory nonfit appeals. In contrast, people who are less motivated to process information will selectively attend to regulatory fit information because it is easier to process, and thus will be more persuaded by regulatory fit appeals.

We tested this hypothesis in experiment 1, manipulating level of involvement (high vs. low), regulatory focus (promotion vs. prevention), and appeal type (promotion vs. prevention) in a between-subjects design, collapsing regulatory focus and appeal type conditions into fit and nonfit cells for analysis. Participants in the promotion-prime condition were asked to list five current hopes or aspirations as well as three attributes they would ideally like to possess, whereas those in the prevention-prime condition were asked to list five current duties and obligations as well as three attributes they ought to possess (Higgins et al. 1994; Higgins, Shah, and Friedman 1997). Next, they were exposed to a high- or low-involvement manipulation (Briley and Aaker 2006). Participants then read one of two advertisements for Welch's grape juice, one emphasizing its promotion benefits and the other emphasizing its prevention benefits (Aaker and Lee 2001). Finally, they evaluated the target product. As expected, a two-way interaction between involvement and regulatory fit emerged, whereby nonfit (fit) appeals were more persuasive under high- (low-) involvement conditions. These results provide the first evidence that regulatory nonfit appeals may indeed be more persuasive than fit appeals, but only when people are motivated and able to process nonfit information.

Experiment 2 was designed to test the robustness of the nonfit effect under high involvement as well as to provide insight into the underlying process. Specifically, we predicted that nonfit appeals would prompt greater processing engagement, resulting in greater persuasion. In order to test this prediction, all participants were first told that the study was very important and instructed to pay close attention. They were then given a promotion or prevention prime (see experiment 1) and asked to read a promotion- or prevention-oriented Welch's appeal. Participants then evaluated the product and reported their processing engagement (i.e., how involved and

interested they were while processing the appeal). The results revealed a main effect of regulatory fit on persuasion, such that nonfit (vs. fit) appeals elicited more favorable brand attitudes under high-involvement conditions. The results also revealed the predicted main effect of regulatory fit on processing engagement, such that participants were more engaged while reviewing the nonfit (vs. fit) appeal. Finally, we found that heightened processing engagement mediated the positive relationship between nonfit appeals and brand attitudes, thus providing support for the processing engagement mechanism.

Experiment 3 was designed to provide further evidence of the mechanism underlying the regulatory nonfit effect. We reasoned that if highly involved people were more engaged while processing nonfit (vs. fit) information, then those exposed to nonfit (vs. fit) appeals should be more sensitive to differences in argument strength. Therefore, in addition to priming regulatory focus (asked to write an essay about their hopes and aspirations or duties and obligations; Higgins et al. 1994) and giving all participants a high-involvement manipulation (told that the advertised sun protection product, SunSkin, was targeted exclusively to college students and would be launched locally in just a few months; Wang and Lee 2006), we also manipulated the strength of the message arguments. Specifically, participants were exposed to one of four appeals—strong promotion, weak promotion, strong prevention, or weak prevention—followed by a request to evaluate the product. Aside from a main effect of argument strength, whereby strong appeals elicited more favorable attitudes, the results also revealed the expected two-way interaction between argument strength and regulatory fit, such that participants exposed to nonfit appeals were more discerning between strong and weak arguments than those exposed to fit appeals. Thus, these results provide further evidence of the process underlying the regulatory nonfit effect on persuasion by conforming to the premise that if people exposed to nonfit (vs. fit) appeals are indeed more engaged, they should be more sensitive to differences in argument strength.

In summary, the results across the three experiments provide convergent evidence for the hypothesized moderating role of involvement in regulatory focus-based persuasion. Whereas fit appeals are more persuasive under low-involvement conditions, nonfit appeals are more persuasive under high-involvement conditions. Furthermore, we find that the nonfit effect on persuasion is the result of heightened processing engagement, whereby people are more discerning of argument strength. These results provide the first evidence that regulatory nonfit appeals may be more persuasive than fit appeals, but only when people are motivated and able to process nonfit information.

The Role of Regulatory Focus in the Endorsement of Material Values

Inge Lens, K.U. Leuven, Belgium

Mario Pandelaere, Ghent University, Belgium

L. J. Shrum, University of Texas at San Antonio, USA

Jaehoon Lee, University of Texas at San Antonio, USA

EXTENDED ABSTRACT

Materialism reflects the belief that wealth is an essential determinant of a successful, happy life (Richins and Dawson 1992). Apart from the influence of materialism, consumers' goal-striving is driven by their regulatory focus (cf. Higgins 1997). A promotion focus directs consumers' attention to their aspirations and hopes (ideals), whereas a prevention focus directs their attention to duties and responsibilities (oughts). Three studies are presented to test the proposition that both promotion and prevention are related to materialism, but through different mechanisms.

Research has shown that prevention is negatively related to self-esteem, whereas promotion is positively related to self-esteem (McGregor et al. 2007; Moss 2009). Because materialism is associated with uncertainty feelings (e.g. Chang and Arkin 2002; Christopher et al. 2006) that may stem from an unfulfilled need for self-esteem (Chaplin and John 2007; Kasser 2002), we propose that promotion and prevention foci may have opposite effects on materialism, given their opposite effects on self-esteem. In addition to differences in self-esteem, differences in extrinsic goal pursuit between prevention- and promotion-focused consumers may also lead to differences in materialism. In many capitalist societies, wealth is considered the key to a successful life (cf. Ger and Belk 1996). Correspondingly, striving for money and status (extrinsic goals; Deci and Ryan 2000; Kasser and Ryan 1993, 1996) is related to materialism (Kasser 2002). Given their concern with success, achievement (Higgins 1997), and realizing their ideal self (Lockwood, Jordan, and Kunda 2002), promotion-focused individuals may be more likely to adopt culturally promoted, extrinsic goals than prevention focused consumers. This is to some extent evidenced in their preference for luxury and hedonic consumption (Higgins 2002; Wang and Lee 2006; Werth and Förster 2007).

In sum, we hypothesize that promotion will be related to materialism through two routes, a positive one (mediated by extrinsic goal pursuit) and a negative one (mediated by self-esteem). In contrast, prevention will be negatively related to self-esteem, which in turn will be negatively related to materialism (net positive relation between prevention and materialism). In addition to the general materialism effects, we expect promotion and prevention focus to relate differentially to specific dimensions of materialism. It would be consistent with striving for achievement and success (cf. Higgins 1997) that promotion-focused consumers in particular believe that wealth communicates success. Thus, promotion may be particularly highly correlated with the success subscale of materialism (Richins and Dawson 1992). If prevention is related to materialism, and if low self-esteem accounts for this relation, it is plausible that prevention-focused consumers think that money would buy them happiness. Thus, prevention focus may be particularly highly correlated with Richins and Dawson's (1992) happiness subscale.

Study 1 used European students to test the hypothesis that regulatory focus is related to materialism. Regulatory focus was assessed with the Regulatory Focus Questionnaire (Lockwood et al. 2002). Materialism was measured with the Material Values Scale (Richins and Dawson 1992). Overall, our hypotheses were supported. Prevention significantly predicts overall materialism, but promotion does not, consistent with our reasoning that promotion

influences materialism both positively and negatively through different mechanisms, thus suppressing the effect. In addition, prevention, not promotion, significantly predicts scores on the happiness dimension of materialism. Promotion positively predicts scores on the success dimension, but prevention does not.

Study 1 confirmed that prevention is positively related to materialism, but this study did not allow testing both predicted paths between promotion and materialism. If our assumptions hold, materialism should decrease in consumers who are in an induced promotion focus who experience a self-esteem boost, compared to promotion focused individuals whose self-esteem is not boosted. In study 2, 38 participants were randomly assigned to either think about achieved goals (past promotion), or about future aspirations (future promotion). Considering achieved and future aspirations induces promotion focus (cf. Lockwood et al. 2002; Pham and Avnet 2004; Zhu and Meyers-Levy 2007), and thinking of past successes was expected to enhance self-esteem (cf. Leonardelli et al. 2007). Next, participants indicated selling prices for five products. Selling price has been shown to be a reliable measure of (temporal) materialism (Lens and Pandelaere 2009). As predicted, participants in the past promotion condition demanded lower prices than participants in the future promotion condition, suggesting that enhanced self-esteem due to promotion success decreases materialistic pursuits.

In study 3, we replicated the findings of studies 1 and 2 in an American, non-student sample. This study extends the previous studies by explicitly measuring self-esteem (Rosenberg 1965) and extrinsic goal pursuit (Aspiration Index; Kasser and Ryan 1993, 1996). Regulatory focus and materialism were measured as in study 1. To assess the predicted relations between overall materialism, prevention, and promotion, we estimated a path model. The model adequately fits the data. In a second model, happiness and success were regressed separately on self-esteem and extrinsic goal pursuit. The model is improved significantly if we allow for a direct relation between prevention and happiness (not mediated by self-esteem). As expected, prevention was positively related to materialism, and this effect was mediated by self-esteem. Promotion was positively related to materialism via the mediating role of extrinsic goal pursuit, but negatively related to materialism through self-esteem. In addition, as hypothesized, the effects for prevention on materialism were driven by the happiness dimension, whereas the effects for promotion were driven by the success factor.

These findings show that consumers may adopt different "types" of materialism, and through different mechanisms, as suggested by the fact that promotion- and prevention-focused consumers tend to value different aspects of materialism congruent with their goal orientation.

Decision Making on the Small Screen: Adaptive Behavior in Constrained Information Environments

Nicholas H. Lurie, Georgia Institute of Technology, USA
Doe-Hyun Song, Digital Solutions Inc., USA
Sridhar Narasimhan, Georgia Institute of Technology, USA¹

EXTENDED ABSTRACT

More and more, consumers are accessing large amounts of information through small screen devices. For consumers in many countries, the mobile phone is the primary portal to the Internet (Wright 2008). High-speed wireless networks and the growing distribution of ever more powerful cell phones and wireless devices mean that even consumers with access to traditional desktop displays are increasingly using mobile devices to gather product information and make purchases (Alam Khan 2008). Despite a dramatic increase in the usage of mobile devices, little is known about how such devices affect consumer behavior.

Examining how decisions are made in environments that substantially constrain the decision maker's visual field raises a number of interesting issues not addressed in prior research. For example, most research on decision processes is conducted in environments in which decision makers can view all available information simultaneously (e.g., Bettman et al. 1993; Payne, Bettman, and Johnson 1988) but users of small screen devices can often only see a small portion of the information that desktop users see (Chae and Kim 2004). Prior research on decision making has also focused almost exclusively on how informational characteristics affect the *cognitive* processes associated with different decision strategies (e.g., Bettman et al. 1993; Jarvenpaa 1989; Lurie 2004; Payne et al. 1988), but small screens also require substantial *physical* effort (e.g., Albers and Kim 2000; Chae and Kim 2004). Finally, previous research has assumed that the way in which information is displayed to the consumer is under the control of the marketer (Diehl 2005; Häubl and Trifts 2000); yet mobile users view and access information on devices that vary in the amount of information displayed and whether more information is displayed on the vertical versus horizontal axis. These device-specific differences in the visual representation of information likely change the way in which information is used to make decisions (Lurie and Mason 2007; Wedel and Pieters 2007).

This article argues that, when using small screen devices to make decisions, consumers will adapt their decision processes in two important ways: 1) Consumers will account for physical as well as cognitive effort in their information acquisition and decision strategies; and (2) They will adapt their information acquisition and decision strategies to reflect the amount of information that can be accessed simultaneously (i.e., that portion of the underlying information that can be seen without scrolling). If consumers are able to employ decision strategies that minimize effort while maintaining fairly high levels of accuracy (Payne et al. 1988), declines in decision quality when using small screens should be small. If the accuracy of decision strategies depends on whether decision makers process by alternative or by attribute (Bettman et al. 1993), decision quality should be influenced by screen orientation as well as size.

These ideas are tested in two process-tracing experiments and a Monte-Carlo simulation. Results from the first experiment support the idea that the increased physical effort of making decision on small screen devices leads to reductions in cognitive effort. In

particular, a reduction in screen size leads consumers to acquire less information, spend less time per acquisition, spend less time on information acquisition, and be more likely to process by attribute than by alternative. This leads to significant declines in decision quality but these declines are not as large as might be expected given large differences in the amount of information displayed. Experiment results also support the proposal that the constraints of the small screen lead consumers to focus on information that is currently shown, reducing the information reacquisition and decreasing selectivity. Importantly, Experiment 1 also shows that what information is shown is as important as how much information is shown. In particular, screens that show more attributes than alternatives lead to by-alternative processing and higher quality decisions. The second experiment shows that the results found in Study 1 hold regardless of whether attributes are displayed in rows or in columns.

To help explain the experimental results, a Monte-Carlo simulation examined how screen characteristics affect the effort and accuracy of five idealized decision strategies (Johnson and Payne 1985; Payne et al. 1988), that account for physical as well as cognitive processes. Results from the simulation show that screen size has a much smaller effect on decision effort for non-compensatory than compensatory decision strategies. Although effort increases substantially when compensatory decision strategies are employed, increases in effort are minimal for non-compensatory strategies. The Monte-Carlo simulation also explicitly shows how screen orientation changes the effort involved with employing by-attribute or by-alternative strategies and helps explain why changing screen orientation leads to shifts in decision strategies that affect decision quality.

Beyond these substantive implications for decision making on mobile devices in particular, this article contributes to decision-making research more generally. First, the perspective taken here integrates the physical costs of searching for information with the cognitive costs of processing it; suggesting that consumers make tradeoffs between physical and cognitive costs when making decisions. In this way, this article bridges research on information search (Moorthy, Ratchford, and Talukdar 1997; Ratchford, Lee, and Talukdar 2003) and research on how characteristics of information affect decision making (Bettman et al. 1993; Lurie 2004). Second, this article suggests that the visual representation of information; more specifically, depth of field (Lurie and Mason 2007), affects decision strategies. Finally, this article builds on prior research on the use of simulations of human decision making (Bettman et al. 1993; Hastie and Stasser 2000; Johnson and Payne 1985; Payne et al. 1988) to show that simulations can be used to explicitly account for environmental as well as cognitive characteristics when modeling decision processes. This approach can be generalized to assess a wide variety of decision environments in which device characteristics are likely to affect the way in which decisions are made.

The Effect of Customization Strategy and Recommendations on Consumer Decision-Making

Brent Coker, University of Melbourne, Australia

Anish Nagpal, University of Melbourne, Australia

Partha Krishnamurthy, University of Houston at Texas, USA

EXTENDED ABSTRACT

As a result of recent advances in production and selling technologies, firms are increasingly offering their customers a degree of customization in their product offerings. Although offering customized products benefits the firm as well as customers (Dellaert and Stremersch 2005; Dewan et al. 2003; Syam and Kumar 2006), the degree of mental effort required to make a purchase is considerably more than when decisions on attribute inclusion or exclusion are not required (Bettman et al. 1990; Dellaert and Stremersch 2005; Payne et al. 1993; Shugan 1980). To ease this effort, firms such as Dell offer a recommendation of which attribute to choose. For example Dell, in addition to offering several sizes of hard drive to the consumer, will also recommend one of the options (say, 240 GB hard drive). Little is known about how recommendations such as these offered during a product customization task influence decision making. In this research, we studied the impact recommendations have on customized choices.

We evaluated the effect of recommendation in two types of customization strategy. In the first type, participants were given a base model notebook computer (default model) and invited to increase attribute level options to their desired configuration (more hard drive space, more memory, faster CPU etc.). In the second customization strategy, participants were given a fully featured notebook computer (default model), and invited to remove attribute option levels they did not need. When no recommendations are offered by the vendor, the default configuration provides a point of reference from which decisions to add or remove options are made. However, when a recommendation is offered, there exists two points of reference, one is the default configuration, and the other is the recommended configuration. Based on prior research, we suggest that consumers will be influenced by one of the reference points more than the other, depending on the relative salience of the reference point (Crum et al. 1981; Kahneman and Tversky 1979; Kristensen and Garling 1997; March and Shapira 1987; March and Shapira 1992; White et al. 1994). The salience of the reference point is a function of feature specification, with higher feature specifications having more salience than lower feature specifications.

We hypothesized that 1) When adding options, the price of the final configured product for those given a recommendation will be significantly higher than those not given a recommendation; 2) When removing options, the price of the final configured product for those given a recommendation will not be significantly different from those not given a recommendation, and; 3) People will have more recommendation-based thoughts when adding options than when removing options.

Our hypotheses were tested in three experiments. Study 1 was a 2 (Customization Strategy: Building-up/Paring-down) x 2 (Recommendation: Yes/No) between-subjects design conducted online. Participants were given the chance to customize a computer online, either by adding or removing attributes, in a similar fashion to the Dell.com website. For those in the paring down condition, the highest level of each attribute was pre-selected (default option). For those in the building up condition, the lowest level of each attribute was pre-selected (default option). Recommendation was also manipulated between subjects, and operationalized as a suggestion to

choose the mid range option level of each attribute. Final configured price was the dependent variable. Hypotheses 1 and 2 were tested and supported.

In study two, the design was the same, but with a bigger range of attribute levels given for each attribute, and two extra conditions of a higher level recommendation (two-thirds of the way up the range of level options), and a lower recommendation (one-third of the way up). Although we again found support for the hypotheses 1 and 2, the results suggested that when the price of the recommended option is too high, people will not respond to the recommendation as they would when the recommendation was at the middle option level.

In study 3, the design was similar to studies 1 and 2, but the recommendation was manipulated within subjects to evaluate the robustness of the effects. Also included in study 3 were open ended and scale questions to compare the number of recommendation-based thoughts in each condition to test hypothesis 3. We found that participants had more number of recommendation-based thoughts when building-up than when paring-down, indicating the greater influence of the recommendation when building-up. Second, consumers using a building-up customization strategy had equal number of feature-based and price-based thoughts, indicative of the recommendation becoming more salient, leading to reference point shifting from the base model to the recommended level. Third, consumers in the paring-down customization strategy had a greater number of feature-based thoughts than price-based thoughts, indicative of the recommendation not becoming salient, leading to the reference point not shifting to the recommended option. Taken together, the open-ended responses provide evidence that the reference-point may shift in the building-up strategy but not in the paring-down strategy.

Overall, our results suggest that recommendations influence decisions adding options, but are ignored when removing options. These findings have implications for marketers offering customized product options, and shed light onto conditions of reference point shift when decision making.

The Influence of Social Norms in Consumer Behavior: A Meta-Analysis

Vladimir Melnyk, Wageningen University, The Netherlands
Erica van Herpen, Wageningen University, The Netherlands
Hans C. M. van Trijp, Wageningen University, The Netherlands

EXTENDED ABSTRACT

Social norms are major drivers of human behavior and crucial in consumer decision making. Consumers often take expectations and behavior of others into consideration when they decide what is appropriate and social norms thus profoundly influence their preferences and behavior (Cialdini, Reno, and Kallgren 1990). How much to drink at a party, whether to subscribe to a fitness club and how much to eat are all decisions that are at least partly guided by social norms. Although social norms can substantially influence consumer decision making, understanding of how the specification of the norm determines its effect is limited. Despite a large body of research on social norms, empirical findings about their effect in consumer decision making are not consistent (Schultz et al. 2007). For example, Sheeran, Abraham, and Orbell (1999), in their meta-analysis of the willingness to use condoms (121 studies out of which 21 include social norms) find that subjective norms are weak predictors of intentions ($r=.26$), whereas Ravis and Sheeran (2003) in their meta-analysis of the theory of planned behavior (21 studies) find a more substantial correlation between norms and intentions ($r=.44$).

This meta-analysis examines the association between social norms on the one hand and consumer's attitudes, behavioral intentions, and behavior on the other hand, while accounting for study characteristics (study domain, gender and age of participants, type of culture) and methodological factors. We expect that several aspects of norm specification will influence the strength of these associations. First, norms can be specified in a descriptive or prescriptive (i.e., injunctive) way, a distinction which has previously been shown to determine their influence on consumer decision making (Cialdini et al. 1990). Injunctive norms focus consumers on what is approved and may activate the typical attitudes associated with the group, whereas descriptive norms specify the behavior of others, and consumers may follow such norms without giving it much thought. Thus we expect descriptive norms have a larger effect on behavior but a smaller effect on attitudes than an injunctive norms. Second, the influence of social norms may depend on the concreteness with which the required behavior, the consequences of following or deviating from the norm, and the target person are specified (Shaffer 1983). Concrete information is generally more engaging and memorable than abstract information, and could therefore be more persuasive. Third, norms may be more relevant, and hence more influential, when these come from persons with whom the consumer can easily identify. Fourth, because public behavior is noticed and corrected by others, norms relating to public behavior should have more influence than norms relating to private behavior.

The sample consisted of 200 studies, producing 659 effect sizes. As a measure for effect sizes, we chose the Pearson correlation coefficient, converted to the normally distributed Fisher's z scores. Because attitudes are both strongly correlated with norms and have a strong influence on intentions (behavior), the total correlation between norms and intentions (behavior) may contain some of the effect of attitudes and thus overestimate the effect of social norms. To account for this, we also examined partial correlations between norms and intentions (behavior), controlling for attitudes.

Results showed that effect sizes obtained from partial correlations were significantly lower than effect sizes obtained from total correlations for both behavioral intentions and behavior. This implies that indeed a substantial part of the effect of social norms on intentions and behavior can be accounted for by the covariation between attitudes and social norms. Descriptive norms were shown to have a larger effect on behavior than injunctive norms, whereas injunctive norms have a larger effect on attitudes than descriptive norms. Hence, for changing attitudes, injunctive norms may be more effective, whereas for changing behavior, descriptive norms are more appropriate. Effects on behavior are also stronger when norms come from close and concrete sources (vs. authority figures or abstract others) and when the behavior is public (vs. private). No effects were found for specifications of the expected behavior, the consequences, or the target person. In addition, we examined interaction effects between independent variables and no significant effects were found.

The study also demonstrated that the effect of social norms differed across domains. Compared with decisions related to healthy lifestyle, social responsibility, or sex, everyday consumption decisions such as choices between food, drinks, and leisure time activities showed a high consistency between social norms and attitudes. Interestingly, social norms had a relatively large effect on social responsible behaviors. These are behaviors where societal benefits are involved, and where social norms should drive human behavior to prevent free-riding problems. Our study showed that social norms indeed are relatively influential for consumer behavior in this domain.

Our study has several implications. The meta-analysis reveals a high association between social norms and attitudes, and one possible extension to theoretical models that include normative components is to examine this relationship. It has recently been posited that social norms influence attitudes (Terry et al. 2000), and our study shows that the strength of this influence depends on the specification of norm aspects.

Additionally, consumers respond differently to injunctive versus descriptive norms, and, more importantly, an injunctive specification of a norm leads to stronger effects on attitudes but weaker effects on behavior than a descriptive formulation. This implies that an investigation of the effect of social norms which examines only attitudes or only behavior does not provide a complete picture of the effect of social norms. To truly understand the effect of social norms, attitudes, behavioral intentions, and behavior need all be examined. In addition, further research could examine other aspects of social norms, such as group size, or uncertainty, which could influence their effectiveness. This meta-analysis is obviously bound to prior research that has been conducted, but more aspects remain to be investigated. We hope that our study presents a stepping stone towards a deeper understanding of when and how social norms drive consumer attitudes, intentions, and behavior.

Feeling, Thinking, and Differential Decision Making Under Risk

Steven J. Andrews, University of Oregon, USA

Joan L. Giese, University of Oregon, USA

David M. Boush, University of Oregon, USA

EXTENDED ABSTRACT

Prospect theory is one of the most influential theories that deal with how people make decisions under risk and uncertainty. A key tenet of prospect theory is that the same person might be more risk averse in some contexts than in others. The original proponents of prospect theory acknowledged that there were still unexplained inconsistencies in their own observations of decision making that need to be addressed. To date, the reasons for nonconformity have never been thoroughly examined. The research question this study explored involves whether individual differences in preferences for using affective or cognitive decision making processes might systematically lead some people to exhibit differential decision making behavior under risk than what would be predicted by prospect theory.

Modern decision theory formally acknowledges the importance and centrality of affect in decision making. There is abundant evidence that affect plays a primary role in decision making because affective information includes information about the subjective value of the environmental cues being responded to in the decision process. More recent theories demonstrate both the centrality of affect in the decision making process and the potential for integration of affective and cognitive information in decision making. The theory of affect-as-information plausibly asserts that emotions are not merely byproducts or after-effects of a decision, but that emotional content deemed relevant to a decision is used in real-time during the decision making process. Furthermore, the risk-as-feelings hypothesis, in conjunction with theories of the affect heuristic in risky decision making, assert that affective and cognitive decision making systems are separate but potentially integrated systems. When the two systems diverge, however, it is actually the affective system that most prominently drives the decision making process.

The degree to which affect is utilized as information translates into meaningful difference in judgment and behavior. Based on the call to study individual difference phenomena in specific domains and in the context of theoretical frameworks, the present research builds on the affect-as-information and the risk-as-feelings frameworks to examine more closely differential decision making behavior under risk that is not accounted for by prospect theory. Specifically, this research categorizes people according to whether their decisions tend to involve a lot of thought (high cognition), a lot of feeling (high affect) or both (high cognition/affect) in the context of decision making under risk. This research sought to establish that such differential decision making tendencies are meaningful and that they influence the underlying mechanisms involved in making risky decisions.

The first study explored the extent to which information processing tendencies might influence differential decision making behavior within the original prospect theory risky decision making contexts. There is evidence that high affect/high cognition people seem to be amenable to making risky choices. Also, people who are high in affect but low in cognition might be most likely to succumb too heavily to highly aversive emotional influences in a risky decision context and would seek the least risky option, regardless of whether the decision is framed as a gain or a loss. Using an individual difference measure derived from the Need for Cognition

scale and an internally developed scale measuring the tendency to use affect as information, participants were categorized into four information processing groups based on median splits in the two scales. Next, participants examined four risky decision scenarios, two framed as a potential loss and two framed as a potential gain, taken from the work of Kahneman and Tversky (1982) and Tversky and Kahneman (1981). Choice probabilities were such that prospect theory predicted the risky choice in all four scenarios. Results showed that high affect/high cognition took significant risk when the decision was framed as a potential loss of \$750, whereas high affect only subjects avoided risk when the decision was framed as a potential \$240 gain. Looking at high affect and low affect participants only, those high in affect were considerably less likely to take a risk even when expected to do so by prospect theory.

The second study explored more directly the extent to which people with different information processing tendencies anticipate negative consequences associated with risk in everyday situations. This study also examined differential anticipation of well-documented psychological factors, specifically regret, inherent in making decisions under risk. Participants were categorized into information processing groups as in study 1. Next, participants identified three common decisions they make every day that contains an element of risk and they identified the risky element. These answers will be used in future studies to create more content-appropriate decision tasks for studying college students. Participants then rated on a scale from 1 to 7 the expected severity of the consequences of the risky outcome if it were to happen. Finally, participants rated from 1 to 7 the extent to which they anticipated feeling regret if the risky outcome were to happen. Results showed that people high in affective processing and low in cognitive processing were much more likely to rate the consequences of the risky outcome as severe, and these same people were much more likely to anticipate feeling regret if the risky outcome were to happen.

In summary, this research showed that differential tendencies in affective and cognitive information processing provided some explanation as to why some people fail to conform to prospect theory under some decision contexts. This research also shed some light on the differential influence that key psychological mechanisms involved in risky decision making have on people who process information in different ways. Regret as a component of decision making under risk was originally established as a justification for prospect theory's predictions that people do not always make the rational choice. Regret is a complex emotion with a cognitive component consisting of counterfactual thinking and a particularly aversive emotional component centered on self-accountability. Future studies should probe more deeply into the differential effects that negative anticipation of the consequences of risk and the anticipation of regret had on decision making in relation to information processing tendencies.

Schadenfreude and the Self: The Effect of Self-Construal on Malicious Delight at Others' Unfortunate Decisions

Thomas Kramer, Baruch College, CUNY, USA
Ozge Yucel Aybat, Baruch College, CUNY, USA

EXTENDED ABSTRACT

"Mr. Borovina is indulging in what seems to be the summer's favorite guilty pleasure—delighting in others' misfortune, or schadenfreude. Between Martha Stewart, Michael Ovitz, L. Dennis Kozlowski, Kenneth Lay and Jeffrey Skilling, and Samuel D. Waksal, there is plenty of misfortune going around, and, as it turns out, plenty of delight."
St. John (2002)

Usually, we feel happy when good things happen to others, and sad when misfortunes befall them. However, at times it is others' bad luck that makes us happy and induces schadenfreude—pleasure in their misfortunes (Heider 1958). Referred to as a socially reprehensible emotion that is elicited through social comparison in response to others' failure (Feather and Sherman 2002; Foster 1972), schadenfreude is certainly not a new phenomenon. Socrates ruminated on a trigger for malicious pleasure over 2,500 years ago: "Did we not say that pleasure in the misfortunes of friends was caused by envy?" (cited by Smith et al. 1996). In another recent instance of malicious joy, or schadenfreude, coffee drinkers rejoiced at Starbucks' financial woes and its subsequent decision to close down 600 stores: "I'm so happy; I'm so not a Starbucks person," says one aficionado of small independent cafes (Wulforst 2008). Finally, persuasive messages often seek to elicit schadenfreude. For example, the recent "more bars in more places" AT&T advertising campaign featured comical situations in which misfortunes (such as a house destroyed by an exploding deep-fried frozen turkey) befall cell phone owners because they had made the wrong choice of cell phone service and could hence not be reached in time to avert the calamity.

Yet, even though schadenfreude is often discussed in the popular press and may indeed arise in many situations, it has received surprisingly little attention in the psychology and marketing literatures. Recent research has started to examine empirically the antecedents of schadenfreude, including envy (Smith et al. 1996), liking (Hareli and Weiner 2002), resentment (Feather and Nairn 2005; Feather and Sherman 2002), and deservingness (Brigham et al. 1997; van Dijk et al. 2005). For example, Smith et al. (1996) found that student subjects felt significantly more schadenfreude when an academically superior versus average student was caught stealing amphetamines, even when controlling for subjects' level of self esteem and liking for the target student.

Furthermore, the degree to which everyday choices can elicit schadenfreude has not been explored. For example, do individuals find delight in others' decisions that turn out badly, such as their choice of a risky over a safe option and losing, and if so, under which conditions? Clearly, others' unfortunate choices will not elicit the same level of schadenfreude in all individuals alike. We propose that self-construal is one important variable likely to impact schadenfreude in decision-making that has not received any attention, even though a great deal of literature suggests that differences in self-construal have robust effects on everyday experiences, including on cognition, affect, and motivation (e.g., Aaker and Williams 1998; Markus and Kitayama 1991; Mesquita and Frijda 1992). Self-construal describes how individuals construe the self, others, and the interdependence between the two (Markus and Kitayama 1991). An independent self-construal is associated with

an emphasis on separateness, individuals' internal attributes, and the importance of uniqueness. Conversely, individuals with an interdependent self tend to be more relationship-driven and stress relationships with others, connectedness, and the social context. We expect that those individuals who are relatively close to others, care for others, or in general feel more interdependent with them, will get less pleasure out of others' unfortunate choices. Although many people may feel happy when a competitor's choices turn out badly, one would hardly expect the same kind of response following the unfortunate choices of close others, like family or friends. Further, individuals with interdependent selves, for whom maintaining connectedness and harmony with others is important, tend to be more sensitive to others. For these individuals, feelings of schadenfreude would be detrimental to their focus on maintaining close social relationships.

The purpose of the current research is therefore to explore the effect of self-construal on schadenfreude in decision-making to start filling this gap in the literature. In particular, we seek to examine if, or more specifically, under which conditions others' choices of options that turn out badly elicit schadenfreude. Study 1 shows that schadenfreude in response to others' unfortunate choices of a granola bar is greater for individuals with a predominant independent (vs. interdependent) self-construal. Next, study 2 replicates this finding for others' unfortunate choices of a bet option and also demonstrates that the differential levels of schadenfreude are driven by differences in competitive tendencies associated with an independent versus interdependent self-construal. Based on our proposition that others' choices that go against the norm may be perceived as more deserving of misfortune, study 3 finds that self-construal has a greater impact on schadenfreude when others' choices of an unconventional (i.e., a hedonic option: a foot massage), as compared to a conventional (i.e., a utilitarian option: school supplies) option turns out badly. Finally, our last study demonstrates the impact of schadenfreude on decision-making of individuals who differ in their self-construal, and differentiates it from that of happiness. In particular, we show that the experience of schadenfreude, as compared to happiness, increased the choice share of a conventional (i.e., compromise) option for individuals with a predominant independent self. Presumably, once schadenfreude is accessible, individuals with an independent self seek to avoid a misfortune similar to the one they feel happy about, and become more risk-averse by choosing a compromise option. In contrast, self-construal has no effect on choice share of the compromise option for those who had been primed with happiness. Overall, these results suggest that schadenfreude as happiness in response to others' misfortunes has a unique impact on choice for individuals differing in their self-construal; an impact distinct from that of happiness in response to others' fortunes.

Effect of Self-Construal on New Product Adoption Decisions: Role of Innovation Newness and Risk Type

Zhenfeng Ma, University of Ontario Institute of Technology, Canada
Zhiyong Yang, University of Texas at Arlington, USA

EXTENDED ABSTRACT

The self-construal theory recognizes two distinct self-views, that is, the independent versus interdependent self-views. The two self-views are associated with different social orientation and regulatory focus. Individuals with predominantly independent self-views (the 'independents') view themselves as different from others and are motivated to seek autonomy, achievements, and success relative to others (Trafimow et al. 1991). People with predominantly interdependent self-views define themselves as part of a group and are motivated to seek social harmony, affiliation with others, and avoidance of risks (Aaker and Lee 2001). Although the existing literature has examined the effect of self-construal on various marketing outcomes such as persuasion, risk-taking, and impulsive consumption, there is little research into the effect of self-construal on new product adoption decisions. We posit that situationally primed self-views have systematic effect on consumers' new product adoption decisions, and that such effects are dependent on both the innovation newness of the products and on the salience of different risks associated with the products (e.g. performance vs. social risks).

Research on innovation distinguishes between incrementally new products (INPs) and really new products (RNPs) (Hoeffler 2003). RNPs offer newer and more unique benefits but also pose higher risks than INPs (Ram and Sheth 1989). Given the independents' and interdependents' different proclivity to risks and benefits, it can be expected that consumers primed with different self-views may react differently to products that vary in innovation newness. Prior research also shows that situational contexts can make certain types of risks salient to consumers. We posit that the independents' and interdependents' purchase intentions towards RNPs and INPs may vary according to whether the risks associated with the products are salient, and if they are salient, the types of risks that are made salient (e.g. social vs. performance risks).

When the risks associated with the products are implicit, the interdependents would give more weight to the unique benefits of RNPs than to the potential risks of such products, given their orientation towards achievements and self-enhancement. On the contrary, the interdependents may attend more to the potential risks of RNPs than their benefits, owing to their general inclination to avoid risks. However, when the product is an INP, the independents may not be more likely to adopt the product than the interdependents, because the limited incremental benefits offered by INPs are not sufficient to satisfy the independents' promotion-oriented goals.

H1: When the product innovation newness is high, consumers primed with independent self-views state higher purchase intention than those primed with interdependent self-views. When the product innovation newness is low, consumers primed with independent versus interdependent self-views do not differ in stated purchase intention.

When social risks about the new products are made salient, the independents may be either more or less willing to adopt the product than the interdependents, depending on the innovation newness of the product. When the product is an RNP, social risks information

may have minimal impact on the independents' adoption intentions, because the unique benefits offered by RNPs in terms of self-expression and self-enhancements are weighed more heavily by the independents than the risks of social disapproval. Thus, when social risks are salient, the independents may still be more willing to adopt RNPs than the interdependents. However, when the product is an INP, the independents are not motivated to adopt the products in the first place, due to limited incremental benefits of such products. Moreover, in the absence of strong motivation to adopt, the salience of social risks may further dampen the independents' adoption intention towards the INP. This is because the independents would expect to gain little from such products in terms of intrinsic benefits or differentiation from others. Thus, the independents may exhibit lower purchase intentions toward the INP than the interdependents when social risks are salient.

H2: When a product's social risks are made salient, consumers primed with independent self-views are more willing to adopt a really new product, but less willing to adopt an incrementally new product than consumers primed with interdependent self-views.

When the performance risks about the products are made explicit, the independents and interdependents may be equally unlikely to adopt the product. Performance risks associated with a product not only have the potential to render the product incapable of delivering the intended benefits, but may also cause safety hazards to the users. When the products' safety or reliability is called into question, the independents will be as unlikely as the interdependents to adopt the products, regardless of their innovation newness.

H3: When performance risks are salient, the independents and interdependents do not differ in their product adoption decisions, regardless of innovation newness of the product.

We tested the research hypotheses using two experimental studies. The purpose of Experiment 1 is to test the effect of self-construal on new product adoption decisions when risks are not salient (H1). Ninety-eight undergraduate students participated in Experiment 1, which featured a 2 (independent vs. interdependent self views) x 2 (INPs vs. RNPs) design. Participants first read a scenario about a tennis match that was pretested to elicit different self-views, and were then prompted to imagine a scenario about a new car, which were pretested to differ in terms of innovation newness. ANOVA of stated purchase intention (PI) showed that, consistent with H1, the independents reported higher PI than the interdependents when the product was an RNP, but their PI did not differ when the products are INPs. Mediation analysis suggests that the effect of self-construal and innovation newness was mediated by perceived product benefits.

The purpose of Experiment 2 is to test the effect of self-construal on new product adoption decisions when different types of risks (social vs. performance risks) are made salient. Two hundred and ninety two undergraduate students participated in this

experiment, which featured a 2 (self construal) x 2 (newness) x 2 (risk types: social vs. performance risks) designs. Both self-construal and innovation newness were manipulated in the same way as in Experiment 1. Social risks about the products were made salient by highlighting the negative feedback from other consumers to the car in a purported news report. Performance risks were made salient by highlighting the fact that the car's safety and reliability has not been fully proven. An ANOVA of stated PI showed a three-way interaction among self-construal, newness and risk types. Separate ANOVA of PI within the social risk context shows that consumers primed with independent self-views are more willing to adopt a really new product, but less willing to adopt an incrementally new product than consumers primed with interdependent self-views. Thus, H2 was supported. Moreover, mediation analysis shows that observed effect between self-construal and innovation newness was mediated by perceived product benefits. The ANOVA of PI within the performance risks context shows that the independents and interdependents did not differ in their product adoption decisions, regardless of innovation newness of the product. Thus, H3 was also supported.

Adoption of Network Externality Products: The Interactive Influence of Self-construal, Branding Strategy, and Source of Information

Napatsorn Jiraporn, Binghamton University, SUNY
Kalpesh Kaushik Desai, Binghamton University, SUNY

EXTENDED ABSTRACT

Given the increasing importance of technological products in the current economy, this research examined the consumer, brand, and product factors on the adoption of network externality products. 'Network effect' or 'network externality' refers to a phenomenon where the utility of a product increases as the number of its adopters increases (Shapiro & Varian 1999). Standard competition is commonly present in the market with network effects (Chakravarti & Xie 2006). Some examples of such products and their competing standards are computer operating system (Windows vs. Mac OS) and DVD formats (Blue-ray vs. HD). In this market condition, consumers encounter a tradeoff between the differentiation of product features and the compatibility with current technology of other products in the market. We later showed that differentiation and compatibility are orthogonal constructs.

Using conceptual underpinnings from literatures in network externality, self-construal, and branding, this research proposes and finds that consumers exhibit different attitude and behavior towards non-network vs. network products. We first hypothesize that when facing non-network products, independent-self consumers, motivated by utility maximization (Aaker & Lee 2001), will prefer highly differentiated but incompatible products whereas interdependent-self consumers, motivated by preference for status quo (Chernev 2004), will prefer less differentiated but compatible products. Conversely, when facing network products, independent-self consumers, who define themselves as more separated from other consumers (Markus & Kitayama 1991), will be less confident in predicting adoption decision of other consumers. Hence, relative to interdependent-self consumers, independent-self consumers will seek compatibility in network products and will show greater preference for less differentiated but compatible network products. On the other hand, interdependent-self consumers who tend to define themselves in relation to others may feel more comfortable to predict behavior of other consumers. They are more experienced in adapting themselves to fit in a larger societal group, thus, should be more capable of coping with the issue of incompatibility. Therefore, interdependent-self consumers will show greater preference for highly differentiated but incompatible network products.

The second study is to further investigate the adoption decision of the highly differentiated but incompatible network products due to greater challenges it faces in the market. We hypothesize that when brand and information from trial users are simultaneously available; consumers consider information from trial users as more influential than brand information (Sheth & Venkatesan 1968). In contrast to the extant literature (Brown & Reingen 1987), the information provided by dissimilar (vs. similar) trial users may be more diagnostic for network product categories because it provides prediction about adoptions of other consumers whose opinions are less predictable. Hence, we anticipate that when consumers receive information from dissimilar trial users, consumers will be motivated to process more information and include brand in their decisions. In such cases, building on the prior literature in branding (Ng & Houston 2006), we hypothesize that independent-self consumers will prefer a brand with existence in multiple product categories (broad brand) whereas interdependent-self consumers will prefer a brand with existence in limited product categories

(narrow brand). In contrast, when similar trial users provide information, which is less diagnostic, consumers will be less likely to incorporate brand in their decision process. Therefore, the two selves will not differ in their preference between a broad vs. a narrow brand.

Two experiments tested these hypotheses. ANOVAs and planned comparisons were used when appropriate. Study 1 aims to establish evidence that consumers varying in self-construal differ in their responses to a network vs. non-network product. In exchange for extra credit, 122 students from a northeastern university participated in a 2 (self-construal: independent vs. interdependent) x 2 (product type: network vs. non-network) x 2 (product strategy: revolution vs. evolution) between-subject experiment. Note that a revolutionary product is highly differentiated but incompatible with current technology while an evolutionary product is less differentiated but compatible with current technology in the market. First, participants were primed into either an independent or an interdependent self. Participants were asked to read information about a new microwave oven vs. a new cell phone in the non-network vs. network condition, respectively. Then, participants rated their attitude towards the focal product. Results showed no difference in attitude scores between the two selves in the non-network condition for both product strategies ($p > .1$). However, consistent with the prediction, independent-self participants, relative to their interdependent-self counterpart, reported more positive attitude towards the less differentiated but compatible network product and reported less positive attitude towards the highly differentiated but incompatible network product ($p < .1$).

Study 2 aims to examine how consumers varying in self-construal rely on brand and information from trial users when encountering a revolutionary network product. 145 students from the same university with those in study 1 were randomly assigned into a 2 (self-construal: independent vs. interdependent) x 2 (brand breadth: broad vs. narrow) x 2 (trial users: similar vs. dissimilar) between-subject experiment. Participants, primed into either an independent or an interdependent self, were asked to read information about a new cell phone in the market with a highly differentiated feature but incompatible technology with other cell phone technologies in the market. Participants in the broad (*narrow*) brand condition read that this new cell phone was offered by Samsung (*Motorola*). Participants in the similar condition were shown feedback from trial users who are college students in New York, where the experiment was conducted. Those in the dissimilar condition were shown feedback from trial users who are college students in California. Then, participants rated their attitude, buying likelihood and willing-to-pay amount for the product. Results were significant and consistent across three dependent variables. When the similar trial users presented information about the new product, the two selves showed no difference in preference between a broad and a narrow brand ($p > .1$). When the dissimilar trial users presented the same information, independent-self participants showed greater preference for the new cell phone from a broad brand whereas interdependent-self participants showed greater preference for the new cell phone from a narrow brand ($p < .05$).

Along with managerial implications, this research has important theoretical contributions both to the self-construal literature

and to the network externality literature by providing evidence that independent-self consumers may avoid innovation when the incompatibility is a concern. The research contributes to the branding literature by identifying the boundary condition for the brand breadth effect— independent-self consumers prefer a broad brand while interdependent-self consumers prefer a narrow brand, only when the information is sufficiently diagnostic to reduce risk. Managerially, the research suggests that, under the influence of network effects, trial feedback from users who are dissimilar to the target consumers should be used for broad brands in the markets dominated by an independent culture and for narrow brands in the markets dominated by an interdependent culture.

Overlap and Dissociation of Mental Representations of Self and Brand

Rebecca Trump, University of Arizona, USA

Merrie Brucks, University of Arizona, USA

EXTENDED ABSTRACT

The pioneering psychologist William James posited that the self is comprised of many things including one's body, family, material possessions, and social relationships (James 1890). The present research investigates whether brands may also be a part of the self. Specifically, we propose that consumers go beyond connecting with brands (e.g., Escalas and Bettman 2003): Consumers may actually include loved brands into their psychological selves (self-brand overlap). Complementary to James' notion that the self is comprised of many things, people also define themselves in terms of what they are not (e.g., Tajfel and Turner 1979). It follows that people avoid brands with which they do not want to be identified (e.g., Escalas and Bettman 2005). Therefore, we further propose that disliked brands will be excluded from the psychological self (self-brand dissociation).

Brands are important to consumers' self-concepts (e.g., Escalas and Bettman 2003). If a brand is loved by consumers, it has been suggested that it may actually become integrated into their identities (Carroll and Ahuvia 2006; Oliver 1999). Complementary, beginning with Fournier's seminal paper in 1998, a growing stream of research views human relationships as a fruitful metaphor for consumer-brand relationships. This may be a result of consumers thinking of brands in human-like terms, attributing personality traits to them (Aaker 1997) and applying norms of social interactions to their relationships with brands (Aaker, Fournier, and Brasel 2004; Aggarwal 2004). At the same time, some argue that the personification of brands, and especially the notion of human-like relationships, stretches the anthropomorphic metaphor too far (Bengtsson 2003; Breivik and Thorbjørnsen 2008). By adapting theory and measurement techniques from interpersonal relationship research, the present research has the opportunity to provide credence to, or rebuff, the metaphor of consumer-brand relationships.

In addition to loved brands being important to consumers, disliked brands may have an impact on the consumer self. In fact, the noted anthropologist Richard Wilk has argued that what consumers choose not to consume is often more socially and personally significant to them than what they choose to consume (Wilk 1997). Empirical evidence documents that consumers may avoid brands that represent something with which they do not want to be associated, such as outgroups (Escalas and Bettman 2005; White and Dahl 2007). Here we examine the impact of disliked brands on consumers' psychological selves.

The present research applies social cognitive measurement techniques to examine the inclusion of the mental representations of loved brands into the psychological self and the exclusion of disliked brands from the psychological self. To do so, we utilize a response time methodology introduced in interpersonal relationship research, which demonstrates that people's mental representations of self overlap with their representations of close relationship partners (Aron et al. 1991; Aron and Fraley 1999; Smith, Coats, and Walling 1999). Applying this methodology to the study of consumer-brand bonds is appropriate since brands that are loved by consumers may be viewed as relationship partners and brands are inextricably linked to consumers' self-concepts. Therefore, the mental representations of brands may impact the mental representations of self, similarly to the impact close relationship partners have on the psychological self.

Aron et al. (1991) pioneered the testing of the inclusion of others in the self by finding that personality characteristics of close others impact the self. Specifically, they find that characteristics that are shared by the self and other are more accessible than characteristics that distinguish the self from the other. In two studies, we mirror that finding for loved brands. Specifically, in an initial study, we replicated the methodology used in the interpersonal relationship domain and find that, just like close relationship partners, the mental representations of loved brands overlap the psychological self (as evidenced by the greater accessibility of shared characteristics, compared to distinguishing characteristics). In a second study, we adapted the methodology to apply more directly to brand personality characteristics (Aaker 1997) and, again, find support for self-brand overlap.

Conversely, in both studies, we find that characteristics that are shared with disliked brands are less accessible than characteristics that distinguish the self from the disliked brand, providing support for self-brand dissociation. In sum, through two studies we find support for both the notion of self-brand overlap and self-brand dissociation. This adds to the accumulating body of evidence that consumers view brands similarly as they do other individuals and provides an implicit measure of the psychological relationship between consumers and both their loved and disliked brands.

Further, our finding of self-brand dissociation is the first evidence that we are aware of that the psychological self is dissociated from the mental representation of another entity. It is worth noting that this research investigated the extreme case of dissociation of the self and a disliked brand. It is possible that the psychological self may be dissociated from brands that are not disliked. For example, a woman may desire to dissociate from masculine brands, not because she dislikes the brand but, because it does not represent her feminine self. Future research should seek to determine the boundary conditions of both self-brand overlap and dissociation.

We are What We Drive: A SRM Analysis of Human-Brand Personality Associations

Maxim Polonsky, University of Connecticut, USA

Robin Coulter, University of Connecticut, USA

EXTENDED ABSTRACT

We draw upon self-congruity, symbolic interactionism, and interpersonal perception theories to model brand/human personality interdependence. We identified ten automobile brands for which consumers have some shared agreement about brand personality, and conducted a round-robin experiment with twenty three/four person limited acquaintance groups. Group members rated themselves and each other on seven personality characteristics, and answered: "How likely do you see yourself driving [brand]?" "How likely do you see [group member] driving [brand]?" and "How likely do you think that [group member] sees you driving [brand]?" Using the Social Relations Model, we assess the extent to which consumers perceive brands and consumers as sharing personality characteristics.

Nearly a half-century ago, Levy (1959) advanced the idea that brands are reflective symbols of the self. More recent work has considered how consumers use brands to create and communicate identity (Belk 1988; Escalas and Bettman 2005; Kleine, Kleine and Kernan 1993; Kleine, Kleine, and Allen 1995; Sirgy 1982; Solomon 1983), as well as to reinforce attitudes toward self (Escalas and Bettman 2003; McCracken 1988). Aaker's seminal work (1997) on the association of human personality characteristics to brands has been extremely influential in spurring the dialogue about how companies and customers anthropomorphize their brands. In the ensuing years, marketers and consumer researchers have focused on leveraging and understanding brand personality, that is, the set of human characteristics associated with a brand (Aaker 1999; Aaker, Benet-Martinez, and Garolera 2001; Johar, Sengupta, Aaker 2005). As a consequence, we are led to contemplate questions about consumers' brands and their personality characteristics, such as: "Do you infer an individual's personality based on his/her ownership of specific brands? Similarly, when you observe an individual's personality, do you associate that individual with a specific brand? Finally, are your opinions unique, or are they shared by others?"

Several theories of the self, individually and in a social context, are important to contemplate in the context of human-brand personality work. Briefly, self-congruity theory argues that consumers prefer brands with a symbolic function that is congruous with their self-identity (Sirgy 1982; Swann et al. 1992); symbolic interaction theory focuses on an individual's beliefs about how he is perceived by others (Cooley 1902, Mead, 1934; Solomon 1983); and interpersonal perception theory suggests that person perception consists of interdependent levels, but can be decomposed to understand an individual's perceptions of self, of another individual, and perceptions of how others see him (Malloy and Kenny 1986; Kenny 1994). In this paper, we draw upon these three theoretical perspectives, as well as the Social Relations Model (SRM; Kenny 1993, 1994; Kenny and Albright 1987; Kenny, Kashy, and Cook 2006) to further explicate and model brand and human personality interdependence. The SRM approach, using dyadic data, enables us to address questions such as: If Jane is seen to be extraverted, is she also associated with an extraverted brand? If Jane sees herself as being extraverted and prefers extraverted brands, do others also see her as extraverted and preferring those brands? If Jane sees herself using extraverted brands, does she see others using those brands?

Our research involved three data collections. As a basis for our experiment which focuses on the intersection of human and brand

personalities, we engaged in two preliminary studies to understand consumers' associations with automobile brands and personality characteristics. Our work focuses on the automobile product category because research in marketing and consumer behavior has documented that this product category includes brands that are associated with personality characteristics by groups of consumers (Bagozzi and Dholakia 2006; Muniz and O'Guinn 2001). We identified 23 brands and had 70 undergraduate students evaluate the brands on 34 semantic differential items with regard to the Big Five personality characteristics—Agreeableness, Extraversion, Conscientiousness, Emotional Stability, and Openness (Goldberg 1990) and two additional brand personality characteristics, Sophistication and Ruggedness (Aaker 1997). Additionally, we provided 40 MBA students with a definition of the seven personality characteristics and via a free association task asked participants to name one automobile brand that they associated with each personality characteristic. Based on these data collections, we identified ten brands (Jeep, Volvo, Toyota, Hummer, Jaguar, Mercedes, BMW, Audi, Honda, and VW) which had shared meaning for our main experiment.

Our focal study employs a round-robin experiment using 20 three or four person limited acquaintance groups, that is, groups in which the members were unfamiliar with one another. After a short (seven minute) introduction period, group members rated themselves and each group member on seven human-brand personality characteristics, including conscientiousness, extraversion, agreeableness, emotional stability, openness to experience, sophistication, and ruggedness (Aaker 1997). Then, participants answered the following brand use questions: 1) "How likely do you see yourself using brand X?" 2) "How likely do you see [group member] using the brand X?" and 3) "How likely do you think that [group member] sees you using brand X?" These data were analyzed using the Social Relations Model (Kenny 1988; Kenny et al. 2006) to assess the extent to which consumers perceive individual brands and consumers as sharing personality characteristics, and to determine if the Devil really wears Prada.

Our work demonstrates that even short interaction encounters enable participants to come to consensual conclusions regarding individual traits associated with specific brands. Moreover, for some brands we found perceiver-target accuracy so the ratings of participants correlated with target self-ratings. Both, consensus and accuracy speak to the existence of the socially shared meanings among individuals, as well as between personality traits and brands. Meta-accuracy further validates the symbolic-interactionism perspective: an individual thinking that others see her driving a Jaguar and being accurate in her perceptions indicates that a person is capable of understanding how others perceive her (table 3). The symbolic-interactionism perspective posits that people perceive and internalize others' attitudes to form the concept of self (Depaulo et al. 1987). Solomon (1983, 320) argued that people define themselves and social reality via product symbolism, relying "upon the social information inherent in products to shape self-image and to maximize the quality of role performance."

Our research on brands and their personalities provides evidence of symbolic interactionism in the context of consumption. We illustrate how the Social Relations Model decomposes the multiple levels of social interaction as related to brands, their users, and observers. In conclusion, our work demonstrates that consumer

and brand personalities are interdependent and points to a shared meaning system that is used to make inferences about individuals and products. Shared assumptions about physical appearance and shared interpretations of behaviors enable perceivers to come to consensual judgments about targets' personalities and brand use after seven-minute interaction periods. Moreover, such judgments can be accurate, reflecting targets' self-views.

Leader-focused Search: The Influence of an Emerging Preference on Information Selection

Kurt Carlson, Georgetown University, USA
Abhijit Guha, Wayne State University, USA

EXTENDED ABSTRACT

It is important to understand how consumers search for information in choices involving unfamiliar options, because search has the greatest impact on choice when consumers know very little about the options. In choices involving unfamiliar options, consumers develop an emerging preference for one of the options early in the choice process. Then, consumers support this leading option (or leader) throughout the remainder of the choice process by biasing new information to support the leader (Meloy and Russo 2004). Though Brownstein (2003) suggests that consumers may also seek information that supports their leader, the question of how exactly the leader influences information search remains unexplored.

This research considers two possibilities. The first possibility, leader-supporting search, involves the preference for information that is expected to support the leader over the trailer. The second possibility, leader-focused search, involves the preference for information that is expected to be about the leader, irrespective of whether such information is expected to support or denigrate the leader. By conditioning information search preferences on the leader, we examine the relative incidence of leader-supporting search versus leader-focused search.

Two elements are needed for this examination: (1) identification of each participant's leader, and (2) a choice that distinguishes between leader-supporting search and leader-focused search. To identify the leader, we use a horse race metaphor and ask each participant to reveal the current leader in the choice process (see Meloy and Russo 2004). With respect to information choice, we rely on the negative information choice condition, which requires a choice between two information sources, each of which is expected to provide negative information about one of the options. In this condition, leader-supporting search predicts that consumers prefer information about the trailer, because such information should help support the leader over the trailer. In contrast, leader-focused search predicts the exact opposite (i.e. that consumers prefer information about the leader, because such information allows consumers to focus on the leader). This distinction is not evident in positive information choice conditions, because then the two types of search make the same prediction, i.e. consumers prefer (positive) information about the leader over (positive) information about the trailer.

Across six studies, we examine the relative incidence of leader-supporting search versus leader-focused search. Studies 1 and 2 find that consumers are three times as likely to engage in leader-focused search (as leader-supporting search). Study 3 finds that consumers sacrifice source credibility to obtain information about their leader, suggesting that leader-focused search may undermine choice quality. Study 4 reveals finds that, all else equal, consumers prefer negative information about their leader from more credible sources—this suggests that consumers are not looking for information that they can conveniently counter argue. Studies 5 and 6 provide evidence of leader-focused search using methods that do not require informing consumers about the expected valence of the information. Also, Study 5 finds that consumers forgo learning about the trailer on a relatively important attribute, to learn about the leader on a less important attribute. And Study 6 finds that consumers prefer reading information about the leader before reading information about the trailer.

In sum, this research introduces a new information search phenomenon, leader-focused search. Ongoing research looks at

when exactly does leader-focused search give way to leader-supporting search, and also looks at how to make use of the propensity for leader-focused search to help predict consumers' hidden preferences.

Impression Evolution During Ad Exposure: Typicality Effects from 100 ms Onwards

Millie Elsen, Tilburg University, The Netherlands

Rik Pieters, Tilburg University, The Netherlands

Michel Wedel, University of Maryland, USA

EXTENDED ABSTRACT

In advertising theory and practice, atypicality is considered to be an effective creative strategy to break through the clutter, and to boost ad evaluations and memory for the ad and brand (Heckler and Childers 1992; Smith and Yang 2004). However, research on this issue is limited (Smith and Yang 2004). Moreover, most advertising research used long and forced ad exposures of up to thirty seconds or longer to investigate advertising processing and effectiveness (reviewed by Meyers-Levy and Malaviya 1999), whereas attention to ads is much shorter in practice, typically a few seconds or less (Pieters and Wedel 2004). It remains unclear whether the positive effects of atypicality carry over to these much shorter durations. In fact, considering people's basic need for certainty (Loewenstein 1994), there is reason to believe that the effects of atypicality may be different at shorter exposures.

The present research focuses on information processing within the first exposure to the ad, from 100 ms onwards. Motivated to identify the stimuli they are exposed to, people attempt to identify the ads that they encounter, i.e., what they are for. In three experiments, we show that, depending on the typicality of the ad, this identification process can take different forms over the course of a single exposure, which in turn influences how evaluations develop over time (experiment 1 and 2), the attention devoted to the ad (experiment 3), and subsequent memory (experiment 2).

Typical ads display objects and scenes that are expected for the advertised category (Mervis and Rosch 1981), such as a car in a car ad. The product category of these ads is rapidly identified and with certainty in 100 ms or even less ("Ha, it's a car ad"; Pieters and Wedel 2009), and this identification certainty contributes to an immediately positive ad evaluation (Loken and Ward 1990). Additional information that becomes available after the first glance confirms the immediate identification, leaving the ad evaluation at relatively high levels of positivity, until boredom eventually befalls these ads. We distinguish two types of atypical ads, hereafter referred to as "atypical" and "typical-other" ads. Atypical ads display objects and scenes that do not immediately bring up a product category, leading to identification uncertainty ("What is that ad for?"). This negatively affects the initial ad evaluation. When exposure to the ad continues, additional information and cognitive integration contribute to ad comprehension reducing identification uncertainty ("Aha, it's a car ad"). This increased certainty is appreciated, leading to a positive updating of the evaluation. Finally, typical-other ads display objects and scenes that are typical for another category, such as a lady misting her face in a car ad. These ads are initially identified with certainty ("Ha, it's a fragrance ad"), which is liked. However, new information that becomes available during exposure disconfirms the initial identification, which needs to be revised ("Oh no, it is a car ad"). This need to revise one's initial identification may lead to confusion and requires more cognitive effort, which is disliked and leads to a downward adjustment of the initially positive evaluation.

Thus, typicality determines the identification process—identification confirmation (typical), identification disconfirmation (typical-other) or uncertainty reduction (atypical)—which has predictable effects on how ad evaluations are updated within a single exposure. In addition, it influences attention and memory, and we predict different effects depending on whether recall or recognition

performance is assessed. Typical ads do not retain attention well, since they are immediately identified and additional processing does not provide much "new" information. However, because a connection between the ad and the advertised category is immediately established upon exposure, and the ad category serves as a useful retrieval cue (Goodman 1980), they are recalled well, even after brief exposures. Recall performance of atypical ads, in contrast, is relatively poor after brief exposures, but strongly improves when additional processing leads to ad comprehension (Bransford and Johnson 1982). Because atypical ads cannot be immediately identified, they retain attention longer, such that memory should be good. In case of typical-other ads, rapidly identified inconsistencies between the initial identification and newly processed information motivate people to prolong attention to the ad. However, recall performance remains relatively poor for these ads despite additional time attending, because of source-confusion (Roediger and McDermott 2000). Recognition performance, in contrast, is poor after very brief exposures for all three ad types, but strongly improves with additional time attending (Loftus and Bell 1975), except for typical ads, that remain relatively difficult to discriminate from other ads. Due to their typicality, these ads appear familiar regardless of whether they were presented or not, increasing false recognition (Silva, Groeger, and Bradshaw 2006).

We tested and found support for our predictions about the dynamic identification, evaluation and memory processes within a single exposure in experiments 1 and 2, where we systematically varied the exposure duration of ads between-conditions from 100 ms (which is less than a single eye fixation) up to 10 seconds (cf. Donders 1868). Finally, support for the prediction that atypical and typical-other ads retain attention longer than typical ads was provided in experiment 3, where participants freely viewed a large set of ads. These findings are the first to provide insights into the rapid advertising processes from 100 ms onwards. They reveal that the effects of typicality critically depend on the exposure duration, and require revision of the idea of atypicality as a universal creative strategy to improve advertising effectiveness. Although we observe the benefits of atypical ads, we also find that their effectiveness crucially depends on their ability to retain the consumer's attention. Typical ads, in contrast, do not require such sustained attention in order to develop positive ad evaluations and memory traces for the ad and brand. Moreover, we argue for careful consideration of the type of atypicality, since typical-other ads failed on almost all accounts in the present research. We believe that the proposed theory and methodology are applicable to other situations where initial feelings may be rapidly updated, and point to repeated ad exposures as a relevant area of future research.

Consumer Processing of Irrelevant Brand Associations

Claudiu V. Dimofte, Georgetown University, USA

Richard F. Yalch, University of Washington, USA

EXTENDED ABSTRACT

Researchers agree that environmental stimuli (e.g., words processed via the auditory route, objects perceived visually, and olfactory excitants) stimulate multiple thoughts, which often have only one thing in common. However, when the common element is activated, there might be confusion as to which of the many possible associations are relevant. When presented with ambiguous information in the form of concepts that share some associations, individuals may initially think about (retrieve) many possible references and rely on contextual cues to narrow their thoughts to the intended one. However, thought suppression is often difficult and frequently even counterproductive (Wenzlaff and Wegner 2000). Neuroimaging studies confirm that individuals frequently find themselves dealing with task-unrelated thoughts (Binder et al. 1999). Although these thoughts may not seem logically meaningful in context, they are generally linked to the target stimuli either semantically or perceptually.

Inspired by Bargh's (2002) review of automatic influences on consumer judgments, we focus on identifying conditions when simultaneous exposure to objects having minimal attributes in common leads to an illogical transfer of associations between them because of suppression failures. We show that such thoughts may be implicit but still have an effect on consumers' brand associations and evaluations of at least one of the objects. Borrowing from the extensive research on the mere exposure effect, we label the implicit transfer of meanings or affect from logically unrelated stimuli as the mere association effect (cf. Walther 2002) and propose that its underlying process is a failure to suppress unintended automatic associations.

Previous research has shown that mere or incidental exposure is sufficient to activate implicit associations of logically unrelated concepts (labeled a cognitive transfer), but mainly for those individuals familiar with the respective concepts. Among individuals familiar with the concepts involved, incidental priming with a common-node concept should activate nodes that result in the mere association of two concepts indirectly linked via the common-node concept (e.g., exposure to a John Deere lawn mower might create an implicit association between John and nature as well as strengthen the implicit association of deer and grass for outdoor enthusiasts). The presence and influence of these mere associations is captured via participants' explicit and implicit responses. In addition to the simple semantic linking of two concepts via a third concept to which both are related (i.e., cognitive transfer), it is proposed in a second case that the valence associated with these concepts can also be transferred via an indirect path (labeled an affective transfer). For example, exposure to Goodwill charity brochures might positively alter the implicit evaluation of one's last will and testament (and simultaneously make the inclusion of charitable donations in it more likely). Again, the effect is expected for those familiar enough with the concepts involved to be likely to activate these valenced associations.

Study 1 provides an illustration of the mere association effect based on cognitive transfer. Priming consumers with the slow terrapin concept was sufficient to influence participants in making an unconscious association between slowness and the track-and-field team of a university whose mascot is the terrapin. In study 2a, participants made more familiar with the Mayo clinic expressed

less favorable attitudes toward a prefix-sharing product (mayonnaise), without any explicit mention of the health concerns some consumers associate with eating mayo.

The mere association effects described above are not universal. As demonstrated in study 1 by group assignment based on measured familiarity and in studies 2a and 2b by direct manipulation, the mere association effect requires well-established associations between the concepts being incidentally linked. In studies 2a and 2b, only individuals exposed to information familiarizing them with the history and operations of the Mayo Clinic showed evidence of a transfer (explicit and implicit) of the less desirable aspects of health clinics to a food product. Apparently, individuals for whom the alternative conceptual meanings are likely to be easily accessed make the conceptual meaning transfer. Low familiarity individuals are less likely to activate associated meanings when exposed to the prime, limiting the meaning transfer.

Study 3 focused on the affective transfer base of the mere association effect. A wine bottle featuring a frog was chosen more often when participants were primed with frog or a proper name, Kermit, often positively associated with frogs but less often when primed with a negative associate—warts. This study extends previous literature findings by Labroo, Dhar, and Schwarz (2008) on conceptual and perceptual fluency by demonstrating how an implicit transitive association transfer related to a phonetical association (i.e., the valence of associated words) may counter any fluency effect attributable to prior exposures.

Finally, study 4 illustrates selectivity in the transfer of associations. When the two to-be-associated nodes belongs to the same semantic category, inhibition from one to the other occurs and the mere association effect is suppressed. Thus, a soft drinks brand explicitly associated with cold ice did not produce perceptions of a physically colder product, but did elicit colder emotional feelings toward the brand.

This investigation supports the increasing amount of consumer research looking at attitude formation as the result of consumers' own mental associations to specific brands or companies. Zaltman's Metaphor Elicitation Technique (Zaltman 1997) and Roedder et al.'s (2006) Brand Concept Mapping method are examples of this innovative work. Our results contribute by suggesting that qualitative research findings that discover linkages between brands and consumer thoughts that seem far removed from the product category (e.g., colors, shapes, flavors, animals) may reflect networks of mere associations that can influence product beliefs, attitudes and choices. On the other hand, it suggests that the associations activated in a particular context may vary from the usual ones because of the presence of entities not consciously recognized as being associated with the focal brand or product.

Doing a Good Thing or Just Doing It: The Effects of Attitude Priming and Procedural Priming on Consumer Behavior

Hao Shen, Chinese University of Hong Kong, Hong Kong
Fengyan Cai, Chinese University of Hong Kong, Hong Kong
Robert S. Wyer, Jr., University of Illinois at Urbana-Champaign, USA

EXTENDED ABSTRACT

Individuals form behavior-related concepts at different levels of generality. Thus, several different behaviors (walking slowly, eating slowly, etc.) may become associated with a more general concept (i.e., doing things slowly). Based on research on knowledge accessibility (Wyer 2008), it seems reasonable to suppose that performing a situation-specific behavior may activate a more general concept that it exemplifies. Furthermore, once this concept becomes accessible in memory, it may increase the likelihood that other exemplars of the concept are activated and employed under conditions in which they are applicable.

However, at least two quite different conceptualizations have implications for the above effect. One, Fishbein and Ajzen's (1976) theory of reasoned action, assumes that behavioral decisions are based on a conscious evaluation of the behavior's consequences or, alternatively, on the intrinsic pleasure that one expects to derive from performing it. The second conceptualization is based on Anderson's (1982, 1983) formulation of procedural knowledge, which assumes that previously acquired concepts and knowledge, along with features of the immediate stimulus situation, can elicit a behavior spontaneously with a minimum of cognitive mediation. In previous research, these two conceptualizations have normally been examined independently and the conditions in which process is likely to predominate in any given situation are unclear. In this paper, we are interested in the conditions that determine the relative impact of attitude-based and procedure-based processing on consumer behavior.

In experiment 1, participants were asked to shadow a speech that was either conveyed at a fast or slow speed. After that, they were asked to finish an unrelated marketing survey. We found that participants finished more questions in the survey if they had been induced to speak fast than slowly in the previous situation.

The objective of experiment 2 was to identify attitude-based and procedure-based processing on consumer behavior. Participants were again asked to shadow a speech that was delivered at either given at a fast or slow speed and then were asked to complete the marketing survey administered in experiment 1. Before doing so, however, they were asked to write down either positive or negative thoughts they had about shadowing a speech at the speed to which they were exposed. Furthermore, some participants were forewarned that they might not be able to finish all the questions within the time allotted, thus inducing them to think about the speed of answering the survey items. But this procedure was omitted for other participants.

We assumed that writing down positive or negative thoughts about the speed of speaking during the shadowing task would have implications for the desirability of doing things quickly or slowly in general. Therefore, these thoughts would provide the basis for the strategy they decided to employ in completing the survey when they were likely to make a conscious decision about how quickly they should complete it. When participants' attention was not called to their speed of completing the questionnaire, we expected that the speed of performing the first task would influence their speed of working on the marketing survey independently of their attitude toward working quickly or slowly. The results of experiment 2 supported these assumptions.

In experiment 2, participants were unaware of how quickly or slowly they completed the marketing survey unless it was called to their attention, and so their attitude toward this behavior had little effect. However, participants are typically conscious of *which* behavior they choose to perform and are more likely to use their attitude toward the behavior as a basis for their decision. In this case, increasing their cognitive load when making this decision should decrease the impact of attitude-based considerations, leading the effects of procedural knowledge to be evident.

Experiment 3 examined this possibility. Participants first completed a questionnaire in which they were asked to indicate whether or not they would participate in a number of activities. In one questionnaire form, the activities had socially desirable implications (e.g., supporting human rights, protecting the environment, etc.). In a second form, they had undesirable implications (harming the country, breaking the law, etc.). In responding to each question, however, some participants were asked to circle the option they favored ("join" vs. "not join") whereas others were asked to circle the option they opposed.

Participants were expected to have a positive attitude toward participating in socially desirable activities and a negative attitude toward participating in undesirable ones, and these attitudes were expected to be reflected in their responses. That is, if the activities in the questionnaire were desirable, they were expected to choose the "join" option when they are asked which option they favored and to choose the "not join" option when they are asked which option they oppose. When the activities were undesirable, they were expected to choose the "not join" opinion in the first case and the "join" option in the second. Thus, participants' responses to the opinion items ("join" or "not join") were manipulated independently of the attitude conveyed by these responses.

Participants after completing this survey were asked to decide whether to participate in an unrelated promotion for a soft drink being offered by a foreign country. While making this decision, however, they were either asked to remember a 12-digit number or 2-digit number.

The effects of completing the opinion questionnaire on participants' reactions to the promotion were expected to depend on their ability to think carefully about these reactions when making a decision. That is, priming a motor procedure of circling "join" or "not join" affected participants' decision to join a marketing promotion. This influence depended on their attitude toward this procedure when they had sufficient cognitive resources to compute this attitude. When participants were put under cognitive load, however, they were more likely to join a promotion if they had repeatedly circled "join" rather than "not join" in the priming task, independently of their attitude toward this behavior.

To summarize, our research is the first to demonstrate that performing a behavior can activate both attitude-based and procedure-based processing strategies, and to identify conditions that influence the relative impact of these strategies on behavior.

When Products Are Valued More but Sold for Less: The Impact of Waste Aversion on Disposal Behavior

Aaron R. Brough, Northwestern University, USA
Mathew S. Isaac, Northwestern University, USA

EXTENDED ABSTRACT

While purchasing, using, or disposing of products, consumers often judge a product's value. For example, when disposing of an unneeded product, consumers may consider the extent to which the product is still usable and estimate its worth. Products with greater residual value (e.g., newer products) generally command higher prices in the marketplace. Therefore, sellers with profit-maximization goals should be motivated to overestimate a product's value in order to increase its selling price.

In this research, however, we document the counterintuitive effects of a competing motivation—waste aversion—that decreases selling prices despite inflated value judgments. We characterize waste aversion as the desire to ensure that a product's residual value is fully exhausted before it is discarded, regardless of who benefits from the product's utilization. Because high selling prices can decrease the purchase likelihood of a used product, waste aversion should cause sellers to under-price a product to avoid the possibility that it will be discarded and its residual utility wasted. Prior research has examined consumers' aversion to purchase duplicate goods (Bolton & Alba, 2008) or to dispose of products without fully utilizing their value (Arkes 1996). We extend this work by examining how waste aversion influences value judgments, which provides additional insight into the processes that underlie disposal decisions. In particular, we argue that value judgments made by waste-averse consumers highlight a product's attractiveness even if such judgments result in financial loss.

Three empirical studies provide converging evidence that waste aversion, by shifting consumers from a profit-maximization to a product-utilization orientation, can bias value judgments.

Study 1. Study 1 shows that despite perceiving an owned product as newer, consumers primed with waste decrease its acceptable selling price. Online participants imagined either throwing away (waste condition) or moving (control condition) their favorite pair of shoes. Following this manipulation, participants indicated the minimum amount that they would be willing to accept in exchange for their shoes as well as the length of time they had owned the shoes. As predicted, participants in the waste (versus control) condition were willing to accept significantly less money as compensation for their shoes. However, this effect does not appear to be caused by devaluation; participants in the waste condition estimated their favorite shoes to be newer than participants in the control condition.

The results of study 1 are consistent with the notion that waste-aversion shifts sellers from a profit-maximization to a product-utilization orientation and influences value judgments. When primed with wasteful disposal, product owners appear motivated to make judgments about a product that increase its attractiveness to potential buyers and thereby diminish the possibility of needless waste. Offering a relatively new product at a relatively low price increases the likelihood that a product will be sold to an interested buyer and used rather than discarded and wasted. Given that consumers typically dispose of things that are no longer needed, asking people to imagine throwing away their favorite pair of shoes is admittedly unrealistic. In Study 2, we use a more realistic scenario and operationalize the wastefulness of disposal in a different way.

Study 2. The objective of study 2 was to manipulate wasteful disposal more realistically and examine its impact on value judgments. Online participants were assigned to either a wasteful or non-wasteful disposal condition. In the wasteful disposal condition, participants read the following scenario:

“John enjoys listening to music on his iPod each day as he exercises. Yesterday, John received a new iPod as a birthday present and is now trying to decide whether to *KEEP* or *THROW AWAY* his old iPod. John finally decided to keep his old iPod rather than throwing it away. Yesterday, someone offered to buy John's old iPod from him. What is the minimum amount you think the buyer would have to offer John to persuade him to sell his old iPod?”

In the non-wasteful disposal condition, participants read an identical scenario with one exception: the word “*THROW*” was replaced by “*GIVE*.” Giving is a disposal method that provides an opportunity for residual value to be consumed by someone else rather than wasted. As predicted, participants in the wasteful disposal condition provided a lower acceptable selling price than participants in the non-wasteful disposal condition. Although waste aversion can explain these results, it is possible that participants in the wasteful disposal method inferred that the iPod had low residual utility since John was considering throwing it in the trash. To address this concern, a follow-up experiment was conducted in which participants who read the first two sentences from the above stimuli and then estimated the number of times that John would use the old iPod over the next year if he decided to keep it as well as the likelihood that he would in fact keep it. Results indicated that participants who considered the wasteful disposal method estimated that John would use the old iPod more and be more likely to retain it. Thus, participants who considered a wasteful disposal method did not infer a lower product value, but in fact reacted by inflating the perceived value of the product.

Study 3. If waste aversion shifts sellers from a profit-maximization to a product-utilization orientation, the effect should not be observed when participants take the role of a buyer rather than a seller. Therefore, study 3 used a 2 (role: buyer vs. seller) x 2 (disposal: wasteful vs. non-wasteful) between-subjects design in which participants were assigned to take the role of either a buyer or a seller and respond to scenarios that involved wasteful or non-wasteful disposal. Consistent with the results of studies 1 and 2, results from study 3 indicate that sellers who consider wasteful (vs. non-wasteful) disposal judge products to be more valuable but are willing to accept a lower price for them. On the other hand, buyers who consider wasteful (vs. non-wasteful) disposal show a decrease in both perceived value and willingness to pay.

Across three studies, we show that the wastefulness of a disposal option influences value judgments. Economic theory assumes that sellers are motivated to maximize profit and are indifferent regarding the state of a sold product after the transaction has been completed. However, in this research we find that sellers primed with the notion of wastefulness perceive greater value in used products (as measured by newness, future usage, and retention

likelihood) while simultaneously agreeing to sell them for less money. These findings are consistent with our explanation that waste aversion causes sellers to be more concerned with product utilization than with financial gain.

Accounting for the Role of Habit in Regular Saving

Caezilia Loibl, Ohio State University, USA
David S. Kraybill, Ohio State University, USA
Sara W. DeMay, Ohio State University, USA

EXTENDED ABSTRACT

Conceptualization

What is the relationship between habit and saving? The many public calls for consumers to establishing a habit of saving indicate that it is a desired behavior, but, obviously, a difficult one to achieve. Savings habits are frequently practiced behaviors, done without a particular sense of awareness, with the goal of freeing up funds for saving or debt reduction. Automatically packing lunch for work, browsing supermarket shelves for discounted products, calling friends after 9 p.m. and on weekends when the phone rates are low are thrifty behaviors that appear to be habitual for many. Using the self-report habit index (Verplanken and Orbell 2003) and applying it to saving for the first time, survey data were collected to (1) validate the role of habits in regular savings; (2) test whether participation in a savings program aids in the formation of savings habits; and (3) examine the role of habits in the perception of financial strain.

Method

The treatment group included participants in a federally funded, multi-year savings program that provides incentives for low-income individuals to save toward purchasing a home, financing higher education, or capitalizing a small business. American Dream Demonstrations have documented the exceptional effectiveness of the program, based on mandatory deposits, matched savings, intensive financial education, and regular one-on-one counseling. In spring 2008, a paper survey was distributed to participants in this savings program who had enrolled with a program network in the U.S. Midwest; the response rate was 52% (n=94). The comparison group consisted of low-income individuals in the general population who lived in counties served by the network but who were not savings program participants. Addresses of 2,200 individuals were purchased to collect data by mail survey; the response rate was 15% (n=291). Nearest-neighbor matching without replacement was used to pair comparison group with treatment group observations to account for demographic differences (N=128).

Saving habits were measured with the Self-Report Habit Index (Verplanken and Orbell 2003), which was developed to reflect the different facets of habit, including the frequency, lack of awareness and control, and mental efficiency of behavior (Honkanen, Olsen, and Verplanken 2005). It compared well to other published measures of habit (Verplanken, Myrbakk, and Rudi 2004) and has been proved useful for a diverse number of common behaviors. The present study contributes to this literature by measuring habit formation during a behavioral intervention and applied to financial behaviors.

Major Findings

To validate the discriminant validity of the habit concept, the individual volume of savings deposits was regressed on attitude, subjective norm, perceived control and intention, past deposit frequency, and habit. Habit emerged as a significant predictor of savings deposits, confirming its role as an independent factor in explaining saving.

To examine the influence of program participation on habit formation, the length of participation was divided into six-month

intervals. Compared to non-participants, the savings habit of program participants increased over time, peaked at 19-24 months, and then flattened. There was no difference in savings habit between non-participants and new enrollees, thus supporting successful habit formation during savings program participation.

While habit tends to be associated with overt behavior, the habit literature notes its influence on mental processes (Verplanken 2006; Verplanken et al. 2007). Results of hierarchical regression analysis support the independent role of habit for reducing the perception of financial strain above the influence of household income and savings. This analysis parallels findings on the influence of mental habits on self-esteem (Hilton and Devall 1997).

Study findings document the role of habit for regular saving and the success of targeted educational and behavioral interventions on developing savings habits.

Choosing Your Future: Temporal Distance and the Balance Between Self-Control and Indulgence

Juliano Laran, University of Miami, USA

EXTENDED ABSTRACT

This project investigates how temporal distance influences consumers' self-control. We find evidence that self-control is dependent on the content of currently active information in decisions for the future. When indulgence information is currently active, decisions for the future tend to be oriented toward self-control. When self-control information is currently active, decisions for the future tend to be oriented toward indulgence. In a series of studies investigating two self-control domains (healthy eating and saving money), we find evidence for an information activation/inhibition account of the influence of temporal distance on self-control decisions.

Temporal distance has a wide array of implications (see Trope, Liberman, and Wakslak 2007). According to construal level theory (Trope and Liberman 2003), the greater the temporal distance the more likely it is that events will be represented in abstract terms (high-level construal) as opposed to concrete terms (low-level construal). Thinking about eating right now may be represented as preparing the food and eating it, while thinking about eating a year from now may be represented as trying to feel good and be healthy. According to time discounting theories (Frederick, Loewenstein, and O'Donoghue 2002 for a review), the greater the temporal distance to an outcome the smaller the perceived value of this outcome. A tasty, rewarding meal may not be perceived to be so rewarding if it will happen in the distant future. This paper proposes an additional way in which temporal distance can influence preferences in decisions requiring self-control. Based on research on the role of activation and inhibition processes in the representation of knowledge structures (Kruglanski et al. 2002), we propose that an increase in temporal distance may lead to inhibition of currently active information. Inhibition of currently active information may result in activation of competing information, which will in turn influence the value of objects. Therefore, when information about indulgence (regulation) is currently activated, people will make indulgent (regulatory) choices for the present, but regulatory (indulgent) choices for the future.

In study 1, we used a scrambled sentence task to prime information about indulgence, self-control, and neutral. Then, we asked participants to choose a snack for their participation in the study. They either chose a snack that they would receive at the end of the experimental session or at the end of the semester for their participation in the semester studies, manipulated between-subjects. A binary logistic regression indicated an interaction between the information prime and time frame factors ($Wald \chi^2(2)=18.83, p<.01$). In the indulgence information prime condition, participants were less likely to choose a healthy snack in the present time frame (22.8%) than in the future time frame condition (62.5%), ($\chi^2(1)=13.84, p<.01$). In the self-control information prime condition, participants were more likely to choose a healthy snack in the present time frame (58.9%) than in the future time frame condition (30.0%), ($\chi^2(1)=6.54, p=.01$). In the neutral information prime condition, participants were as likely to choose a healthy snack in the present time frame (50.0%) as they were in the future time frame condition (48.8%), ($\chi^2<1$).

In study 2, the same procedure was used with the exception that we measured implicit goal accessibility (i.e., latency of word recognition) after participants thought about snacks they would like to get in the present vs. in the future. A positive score indicates

activation of the self-control concept (i.e., faster reaction times for self-control-related words than for neutral words), while a negative score indicates inhibition of the self-control concept (i.e., slower reaction times for self-control-related words than for neutral words). There was again an interaction ($F(1, 209)=17.12, p<.01$). In the indulgence information prime condition, participants showed inhibition of the self-control concept in the present time frame condition ($M_{Present}=-75$ ms), but activation of the self-control concept in the future time frame condition ($M_{Future}=80$ ms; $F(1, 209)=9.22, p<.01$). In the self-control information prime condition, participants showed activation of the self-control concept in the present time frame condition ($M_{Present}=59$ ms), but inhibition of the self-control concept in the future time frame condition ($M_{Future}=-73$ ms; $F(1, 209)=7.90, p<.01$).

Study 3 asked participants how much money they were interested in donating to some local charities after information about saving or spending money was primed. We told participants that they could either spend money on shopping or save their money and donate it to charity (the more money they were willing to donate to charity, the more money they were willing to save). There was again an interaction ($F(2, 247)=4.44, p<.05$). There was an effect of time frame in the spending money information prime condition. Participants were willing to donate less money in the present than in the future ($M_{Present}=\$41.09, M_{Future}=\$81.98; F(1, 247)=4.45, p<.05$). There was an effect of time frame in the saving money information prime condition. Participants were willing to donate more money in the present than in the future ($M_{Present}=\$78.55, M_{Future}=\$34.24; F(1, 247)=4.41, p<.05$). There was not an effect of time frame in the neutral information prime condition. Participants were willing to donate the same amount of money in the present and in the future ($M_{Present}=\$63.50, M_{Future}=\$60.75; F<1$).

These results show that the content of currently active information can influence the construal of a situation in decisions for the future. In decisions involving a conflict between indulgence and regulation, information that is currently active tends to be inhibited as temporal distance increases. As a consequence of inhibition, this information content decreases in importance for the decision in hand. Marketers may be able to use the operations of these processes to their advantage. A retailer may use the store environment to make information about saving money currently active, but then motivate people to make purchases for a certain occasion (e.g., anniversary, child's birthday) in advance. A store environment that has information about saving money may attract more customers, but these customers may end up spending a lot of money rather than saving money when making purchases for the distant future.

Debiasing and Rebiasing the Illusion of Delayed Incentives

Dilip Soman, University of Toronto, Canada
Maggie Wenjing Liu, University of Toronto, Canada

EXTENDED ABSTRACT

Individuals often need to choose between options that trade off money with effort. For instance, a student could choose from two summer jobs, one which pays more but involves a lot of effort, and another which pays less but is relatively easy. A shopper could buy a do-it-yourself piece of furniture and assemble it at home, or purchase a fully assembled piece. Choices like these can be modeled in a multi-attribute context as a simple tradeoff between the extra effort required for one option and the additional cost of the other option (Payne, 1982). This trade-off approach not only applies to situations in which the choice and subsequent purchase are relatively concurrent, but also those purchase with a temporal delay after choice.

Past research shows that the evaluation of Effort–Money transactions (e.g., working in exchange for money) depends on whether the transaction is immediate or delayed (Lynch and Zauberman, 2005, Soman, 1998, 2004). Soman (2004) showed that receiving monetary reward conditioning on performing efforts might appear attractive when both the effort and money are in the future, but unattractive when both are imminent. Soman (1998) refers to the perceived attractiveness of the delayed transaction as an “illusion,” suggesting that it is a bias. He proposes that when the transaction is in the future, effort gets discounted to a greater degree than the monetary reward. Consequently, transactions that appear attractive from a temporal distance start appearing increasingly unattractive as the temporal distance decreases. Following Soman (1998), we refer to this phenomenon as the “illusion of delayed incentives.” Soman (2004) studied the problem in a multi-attribute product context and further suggested that the degree of discounting is the highest for the effort attribute, and lower for the quality and price attributes. He found preference reversals between such pairs of products as a function of the temporal perspective of the decision-maker.

Given the illusion of delayed rewards, what can individuals do to minimize this bias? In this research, we ask two questions: (1) How can the illusion of delayed incentives be corrected? (2) What debiasing and rebiasing mechanisms are involved in these corrections.

The extent to which cognitive strategies can improve reasoning and correct biases is a source of debate (Larrick, 2004). Although people recognize and correct their bias, some raise questions about whether people can truly debias themselves (Kahneman, 2003). One goal of studying biases is not only to demonstrate irrationality, but to help people make better decisions (Larrick, 2004). This paper offers a first step of corrective strategies for intertemporal preference reversals arising out of different discounting of effort and money.

The present research shows not only that people discount different attributes separately, but also that discounting of one attribute could be corrected singly. We show preference reversals using correcting strategies and proposed four potential reasons of such debiasing or rebiasing effects. Besides common debiasing and rebiasing strategies, we further suggest unbiasing strategies (changing an external factor which eliminates the bias) as an alternative correcting method applicable for bias intervention.

The More is Less Effect: How Adding Positive Arguments Can Undermine Attitude toward an Object

Kurt Carlson, Georgetown University, USA
Suzanne Shu, University of California at Los Angeles, USA

EXTENDED ABSTRACT

The number three is an important number in human learning (Tenenbaum and Xu, 2000), perception of streaks (Carlson and Shu 2007), and advertising (Belch and Belch 2001). In this article we posit and test a new role for the number three as the optimal number of arguments for message design. Thus, three positive claims should produce a more positive impression than one, two, or four positive claims. The surprising aspect of this prediction is that four positive claims should be less persuasive than three. We refer to this as the more is less (persuasive) effect. We draw from work on social intelligence, marketplace metacognition, and persuasion knowledge to propose that the more is less effect occurs because consumers, upon seeing a fourth positive claim, infer that something is amiss and that the set of claims is too good to be true, thus producing a lesser overall impression than would have occurred had the message contained just three positive claims. This article presents results from four studies that test for and explore this effect.

The first study used a 3 (target object: cereal, restaurant, friend's new partner) by 3 (number of arguments: 2, 3, 4) design, with target object as a within-participant factor and number of arguments a between-participant factor. Each participant read a description of the current target object with two, three, or four positive adjectives to operationalize the two, three, and four argument conditions. These adjectives were designed and pretested for importance and positivity. Participants then indicated their agreement with four statements about the object on a 7-point Likert scale to give an overall attitude toward the object. Higher average responses reflect a more positive attitude toward the object.

We analyzed overall attitudes toward the objects across all three domains simultaneously using a repeated measures ANOVA, with subject as a random factor and target object and number of arguments as fixed effects. The model revealed a significant effect of number of arguments ($F(2, 295)=3.33, p<.05$), as expected. Three arguments made for a slightly more positive attitude than did two, and four arguments produced a significantly less positive ($M=3.24$) attitude than did three arguments ($M=3.53; t(335)=2.78, p<.01$). In other words, these data reflect the more is less effect.

The second study explored if the more is less effect would be reduced or even eliminated if product improvement claims on a box of cereal were verified by a credible neutral party (e.g. Consumer Reports). Participants were assigned to one of four conditions created by crossing number of arguments (three versus four) with verification of the arguments (verified by Consumer Reports versus no mention of any attempt to verify the arguments). We find a significant interaction ($F(1, 218)=7.08, p<.01$). Planned contrasts revealed that attitude toward the cereal was more positive under four claims than it was under three claims when claims were verified ($t(53)=1.96, p=.055$), but it was less positive under four claims than it was under three claims when claims were unverified ($t(165)=2.13, p=.035$). In sum, the more is less effect replicated when the claims were not verified.

The third study tested if participants under cognitive load would exhibit the more is less effect. If inferences about the marketer's motives are at the heart of the more is less effect, then cognitive load should reduce and possibly even reverse the effect. We used the three argument and four argument cereal conditions

from Study 2, crossed with a cognitive load manipulation. Low cognitive load participants were required to remember a two-digit number, while those in the high load condition were required to remember a seven-digit number.

We find a significant interaction ($F(1, 124)=10.73, p<.001$); decomposition of this interaction revealed that the more is less effect occurred under low load ($t(57)=3.05, p<.01$) but did not occur under high cognitive load. Those under high load who received four positive descriptors of the cereal had a slightly more positive (though not statistically significant) attitude toward the cereal ($M=4.58$) than those who received three positive descriptors ($M=4.31; t(67)=1.32, p=.19$).

The final study was designed to determine if marketers could do anything to avoid the more is less effect. To this end, we examined whether admitting a weakness at the outset would insulate against the effect. The design was a 2 (number of positive arguments: three versus four) x 2 (negative argument added: yes versus no) between-participants design. Participants read a short description of a political candidate and answered three questions that were used to form a measure of overall attitude toward the politician.

An ANOVA with main effects for number of arguments and negative argument added and an interaction term revealed a significant interaction ($F(1, 129)=4.85, p<.05$). Decomposition of this interaction revealed that the more is less effect occurred in the condition where the unrelated negative feature was not mentioned. The politician was viewed marginally more positively after three positive claims ($M=3.70$) than after four positive claims ($M=3.23; t(64)=1.73, p=.08$) by participants in this condition. The effect was reversed directionally (i.e., four claims were more effective than three) when a negative feature was acknowledged at the outset ($t(65)=1.35, p=.18$).

Four studies found the more is less effect across a wide range of domains. It is eliminated when the claims are verified by a neutral party, when consumers are under cognitive load, and when the target revealed a single negative claim. Taken together these data suggest that the effect stems from an inference, due to use of persuasion knowledge, that the target is trying too hard to make the positive claims. Given its generality, we believe the more is less effect has important implications for nearly every aspect of marketing that is related to persuasion.

How Multiple Anchors Affect Judgment: Evidence from the Lab and eBay

Yan Zhang, National University of Singapore, Singapore

Ye Li, Columbia University, USA

Ting Zhu, University of Chicago, USA

EXTENDED ABSTRACT

People's estimates of uncertain quantities are systematically influenced by externally-provided or self-generated numbers, or "anchors" (Englich and Mussweiler 2005; Epley and Gilovich 2001; Tversky and Kahneman 1974). The anchoring effect is robust to many domains (Simonson and Drolet 2004; Wansink, Kent, and Hoch 1998). However, most of the research has focused on the case where only one anchor is provided. Less is known about how people make estimates when they encounter more than one anchor. In this research, we examined how multiple anchors affect estimates.

When there is only one anchor, research shows a positive correlation between anchor values and estimates: single extremely low anchors lead to lower estimates relative to less extreme ones (Chapman and Johnson 1994; Strack and Mussweiler 1997). We predict, however, that this effect can be reversed by adding a second, plausible anchor that is higher than the original first anchors: extremely low anchors paired with a plausible high anchor should instead lead to higher estimates. We suggest that this occurs because presenting multiple anchors together highlights the plausibility of each anchor and makes it easier to evaluate their plausibilities than when there is only one anchor present (Hsee 1996). As a result, when paired with a moderate anchor, extremely low anchors are judged as implausible and thus exert less influence on final estimates. The second, moderate anchor now has bigger influence on final estimates. Therefore, when paired with a moderate anchor, an extremely low anchor leads to a higher estimate than a less extremely low anchor.

We first demonstrate the basic effect in a laboratory experiment. As expected, across four different trivia questions, participants generated lower estimates for extremely low anchors than for less extremely low anchors. However, when the anchors were paired with a second, moderately high anchor, the pattern was reversed: extremely low anchors led to higher estimates than less extremely low anchors.

We tested the proposed mechanism in a second lab experiment. In this experiment, we held the anchor values constant but manipulated the contrast between the two anchors by changing the colors in which they were displayed. Using a manipulation adopted from Cheema and Soman (2008), we expected participants to pay more attention to the difference between the two anchors if they were presented in different colors. Consequently, participants should rely more on the more plausible anchor in making their estimates than when the two anchors were presented in the same color. As predicted, we found that participants who saw an extremely low anchor paired with a more plausible anchor in different colors rated the plausibility of the extremely low anchor even lower than those who saw the anchors in the same colors, and consequently gave higher final estimates. The opposite was true for extremely high anchors paired with a more plausible anchor: participants who saw the anchors in different colors generated lower final estimates.

We corroborated these experimental results with analysis using archival data from Buy-It-Now auctions on eBay. In Buy-It-Now auctions, bidders can either buy at the "Buy-It-Now" price or participate in the bidding process in order to try to pay less for the same item. Because the buy-it-now price disappears once anyone places a bid higher than the hidden reserve price set by the seller,

subsequent bidders in Buy-It-Now auctions in the United States only observe the starting bid price but not the Buy-It-Now price. However, this policy of removing the Buy-It-Now price is not implemented in China, so bidders there can observe both the starting bid price and the Buy-It-Now price throughout the auction. This difference between the two markets constitutes a natural experiment where bidders are affected by a single anchor (starting bid price) for transactions in the United States but are affected by two anchors (starting bid price and Buy-It-Now price) for transactions in China. After controlling for other variables known to affect final price such as number of bidders, number of bids, and buyer and seller ratings, etc, we found a pattern of results consistent with those found in the two laboratory experiments. In the United States, extremely low starting bid prices resulted in lower final prices than less extremely low starting bid prices. The reverse was true in China: extremely low starting bid prices resulted in higher final prices than less extremely low starting bid prices. In order to control for other between-country differences, we also examined pure auctions (with no Buy-It-Now option) in the two markets. In pure auctions, bidders only observe the starting bid price in both countries. The analysis shows no between-country difference in the effect of starting bid price on final prices for pure auctions, which suggests that the difference for Buy-It-Now auctions is due to the difference in number of anchors but not other between-country differences.

This research has important implications for pricing strategies. For instance, an extremely low historical sale price might lead to a higher willingness-to-pay when it is paired with the current market price, as consumers may infer that the low historical price is not relevant to the price that a buyer can possibly get in the present. In contrast, although providing a high "manufacturer suggested retail price" (MSRP) usually increases consumers' willingness-to-pay, this strategy may backfire when consumers compare the MSRP to the sale price (a plausible anchor since it is actually available at this price). If the MSRP is too high to be plausible, consumers may have a lower willingness to pay than if the MSRP is more reasonable.

When is Life Like a Box of Chocolates?: Providing Multiple Units of a Good Attenuates the Endowment Effect

Katherine Burson, University of Michigan, USA

David Faro, London Business School, UK

Yuval Rottenstreich, Stern School of Business, New York University, USA

EXTENDED ABSTRACT

The endowment effect is the well-known demonstration of loss aversion in which those endowed with an item value it more than a non-endowed group. Kahneman et al. (1990) demonstrated the robustness of the endowment effect in a series of studies in which half of participants were given an item that they might sell for some price (their willingness to accept, WTA) and the other half of participants were given the option to purchase the item for some price (their willingness to pay, WTP). Sellers and buyers rarely agreed in their offers. Another classic demonstration of the effect is with reluctance to trade (Knetsch 1989). Here, people are randomly endowed with one of two goods and are given the trade to trade their endowment for the other good. Trading proportions in these studies are typically much lower than would be predicted by distribution of preferences for the two goods.

The WTA-WTP gap and reluctance to trade follow from two fundamental findings of Tversky and Kahneman (1981; 1986): (i) reference-dependent preferences that (ii) reveal loss aversion, a heightened sensitivity to losses relative to gains. Thus, sellers feel greater pain of loss when they sell their endowed object than buyers feel giving up their money. Similarly, the pain of loss when an endowed object is traded for alternative object is greater than the joy of gaining that alternative.

Recent research has shown that patterns of attention and memory co-vary with the magnitude of the endowment effect (Carmon and Ariely 2000; Johnson, Haubl, and Keinan 2007). Specifically, the endowment effect is at least in part driven by asymmetric queries. Participants focus on the change that selling or trading would be from their reference point. A typical query for a chocolate owner might be: "should I give up a chocolate to get money?" Participants who are encouraged to think in a more symmetric way (e.g. "which do I prefer, chocolates or money?") show less of an endowment effect (Johnson, Haubl, and Keinan 2007).

We hypothesize that similar attenuation can be achieved by endowing participants with multiple units of a good. We suspect that multiple unit settings promote symmetric thinking: Rather than considering a query that focuses on entailed changes, a participant endowed with many chocolates may be prone to consider final outcomes. Intuitively, the offering of multiple units makes highly salient the issue of exchange rates. Thus, many participants, their attention drawn to exchange rates, might focus or dwell on this issue, essentially considering something akin to the symmetric question "is five dollars worth nine chocolates?" In essence, when attention is drawn to quantities and exchange rates, it might be drawn away from gains and losses, thereby blocking the operation of loss aversion and eliminating any chance of an endowment effect.

We test the attenuation of endowment effects for multiple units in two studies. One study examines endowment effects in a trading paradigm and the other in a pricing paradigm. We endow participants with either one unit of a good (e.g., one chocolate, one pen), several units of a good (e.g., nine chocolates, eleven pens), or nothing. Participants are given the opportunity to either sell (or trade) their entire endowment, or keep it. Note that no partial deals

were allowed. We then observe a three-fold pattern. First, when participants are given one unit of a good, we replicate the classic endowment effect in both pricing and trading contexts. Second, when participants are given several units of a good, we observe no endowment effect. Third, and finally, an endowment effect occurs whenever participants are presented with a single, well-defined unit, no matter how large or inclusive the unit. For instance, participants given one chocolate show an endowment effect, but so do participants given one box of chocolates. This is so, despite the fact that the box of chocolates we use packs together individual pieces, and that participants given the same number of individual pieces unboxed show no endowment effect.

These results not only suggest a straightforward solution to endowment-effect driven inefficiencies in the market (have marketers and consumers deal in multiple units), they shed light on the process underlying the effect, complementing a great deal of work that identifies factors that may attenuate or prevent the endowment effect.

Don't I Owe You? The Discrepancy Between Expected and Experienced Gratitude

Benjamin A. Converse, University of Chicago, USA

Ayelet Fishbach, University of Chicago, USA

EXTENDED ABSTRACT

Philosophers, religious leaders, and parents scolding young children have long extolled the virtues of gratitude. Psychologists point to intrapersonal benefits of gratitude such as improved well-being (Emmons and McCullough 2003) and to interpersonal benefits such as prosocial action and reciprocation (McCullough et al. 2001), and savvy marketing campaigns use rewards or free gifts to induce gratitude, thus generating loyalty and reciprocation (Cialdini 2001).

In this research we ask, when, over the course of a helpful encounter, do beneficiaries feel the strongest gratitude toward their helpers and when do the helpers expect the most gratitude in return? Specifically, we explore whether gratitude increases or decreases after help is provided.

We assume a motivational perspective to address this question. Helpers provide assistance to people in the midst of goal pursuit, and in doing so initiate helping goals of their own. From this perspective, gratitude may serve a functional role: to keep people on track while pursuing goals and to help them disengage from completed goals. The specific dynamics likely depend on one's role in the helping interaction.

We propose that receivers of help (beneficiaries) experience gratitude more strongly toward a person who is currently instrumental (i.e., when the beneficiaries have an active goal for which the other person is a viable means). This suggests that experienced gratitude will be higher before help is provided than after.

This dynamic of experienced gratitude would reflect a functional use of resources from the beneficiary's perspective. Gratitude is an interpersonal cost because it comes with aversive feelings of indebtedness and dependence (Greenberg and Westcott 1983). Recipients are therefore motivated to invest in helpers only as long as they are instrumental to current goals. Our proposal that gratitude fluctuates with goal activation is based on decades of work demonstrating that active goals increase the accessibility and evaluation of goal-related constructs, relative to goal-irrelevant constructs (for reviews, Fishbach and Ferguson 2007; Kruglanski 1996).

In contrast, we propose that helpers will expect more gratitude after providing help than before. For helpers, gratitude is the benefit they receive from pursuing a helping goal. By conditioning expected gratitude on task completion, helpers motivate themselves to continue helping. This analysis thus makes opposite predictions about the effects of goal pursuit on experienced versus expected gratitude. Whereas experienced gratitude should be strongest before help is finished, expected gratitude should be strongest afterwards.

Experiment 1 examined students' gratitude for academic help, using a 2(goal: active vs. completed) x 2(gratitude judgment: experienced vs. expected) mixed design. We approached undergraduates during the last week of the autumn academic term. They reflected on their experience working with a particular student in one of their current classes. We manipulated their perceived role in this instrumental relationship, casting them as beneficiaries by asking about help received, or as helpers by asking about help provided. Beneficiaries indicated experienced gratitude and helpers indicated expected gratitude. They repeated these evaluations at the beginning of the following academic term.

An ANOVA of gratitude ratings yielded the expected goal x judgment interaction. As expected, beneficiaries felt more grati-

tude in the autumn (for help in a class with a rapidly approaching exam) than in the winter (for help in a class finished last term). Although we predicted that helpers' ratings of expected gratitude would be higher in the winter than in the fall, we found no difference. Nonetheless, the predicted mismatch between experienced and expected gratitude emerged.

Experiment 2 examined gratitude in an economic-exchange game that modeled a business partnership. The experiment used a 2(instrumental: yes vs. no) x 2(gratitude judgment: experienced vs. expected) between-participants design. We endowed one participant, the investor, with \$1. He "invested" by sending it to the other player, the dictator, who "produced a return" of \$5. The dictator then faced a profit-sharing decision. She could keep as much as she wanted and give the rest. Thus, the dictator was instrumental to the investor's money-making goal. Both participants made gratitude judgments either immediately before the dictator's decision (instrumental condition) or immediately after (but before the decision was revealed; non-instrumental condition).

An ANOVA yielded the expected instrumentality x judgment interaction. Although dictators expected to be appreciated more after their decision than before, investors actually appreciated them more before than after the decision. Consistent with the proposed motivational account, we thus found support for the prediction that people would appreciate another person less right after (rather than before) that person decided to share some money with them.

In experiment 3, pairs of participants worked on an administrative task. We used a 2(goal: active vs. completed) x 2(gratitude judgment: experienced vs. expected) mixed design. A captain (beneficiary) and an assistant (helper) worked toward a monetary performance bonus in a task requiring joint contributions. Captains and assistants first made gratitude judgments during a break in the team task (active goal condition) and then again a few minutes later, after the task (completed goal condition).

An ANOVA revealed the expected goal x judgment interaction. Captains said they owed their assistants more during the administrative task than after. Assistants felt they were owed more after they finished helping than before.

Across three experiments, we find mismatches in expected and experienced gratitude. Beneficiaries felt more gratitude before rather than after help was delivered, but helpers expected more gratitude after rather than before they delivered that help. We believe this is consistent with a motivational account of gratitude whereby beneficiaries invest in their helpers more strongly when they are instrumental to current goals and helpers use expected gratitude as motivation to complete the task.

Marketers should take these goal-based evaluations into account when analyzing consumer feedback on goods and services. Our results suggest, for example, that consumers' purchasing intentions might be higher in response to an awaited-reward than to a delivered-reward. We believe these results also have important implications for potential conflict in social interactions. Without understanding the divergent role of motivation in "I owe you" versus "you owe me," people may exhibit inopportune timing when asking for favors or counting on grateful good-will.

Measurement of Emotions Elicited by Advertising

Andrea Groeppel-Klein, Saarland University, Germany

Oliver Hupp, GfK, Germany

Philipp Broeckelmann, Saarland University, Germany

Anja Dieckmann, GfK, Germany

EXTENDED ABSTRACT

Emotional experiences shape people's attitudes towards brands and products (Bagozzi et al., 1999) and also emotions elicited by advertising affect the advertising's success (Keller, 2008a, 2008b; McEwen, 2004; Percy & Rossiter, 2001). Thus, it is highly important to gain insights into consumers' emotional reactions to advertising and to measure them in a valid way. Until now, there has been no uniform, broadly accepted definition of emotions. Rather, most current definitions are confined to a list of characteristics (Scherer, 2005; Plutchik, 1991), according to which emotions are complex reactions to events that are relevant to a person's subjective wellbeing. They involve changes in physiology, behaviour (including facial expressions), and subjective experience. Emotions depend on the conscious or unconscious appraisal of the triggering event and are associated with certain behavioural responses, which are partly formed by evolution. They can be distinguished from other affective phenomena by their relatively fast onset, short duration and high intensity.

Basically, one can distinguish two different traditions in emotion theories: Appraisal theorists propose that emotions result from the comparison between a desirable or undesirable goal and the degree of goal attainment. Lazarus (e.g., 1982) considers cognitive activity a necessary precondition for emotions. According to his theory, emotional experience requires the understanding that an event can have positive or negative consequences for subjective wellbeing (Bagozzi, Baumgartner & Pieters, 1998). Also, people can anticipate and revive emotions by pure mental activity, which in turn can lead to physical reactions (Pham, 1998). According to biologically oriented emotion theorists, emotions are genetically programmed (e.g., Zajonc, 1980). They can be triggered automatically and without higher cognitive processing by innate or learned stimuli, even before one becomes conscious of these stimuli (e.g., LeDoux, 1996). With the help of modern brain-imaging technologies, neuroscientists have in recent years done impressive work in shedding light upon such automatic emotional processes. A series of studies now demonstrates that emotions can bias decisions in a certain direction before any conscious thought process occurs (Bechara et al., 2005; Damasio, 1996). Today, most current emotion researchers regard both theoretical accounts as legitimate. Emotions can occur automatically and unconsciously, facilitating fast reactions (e.g., "freezing", LeDoux, 1996). But they can also result from conscious assessments in cortical areas.

If emotions can be both, biologically pre-wired and arising from higher cognitive activity, their measurement in marketing and advertising effectiveness research becomes even more challenging (Scherer, 2005). Can emotions simply be captured by self-report or standardized verbal scales? Biologically oriented emotion researchers often apply neuroscientific methods to measure physiological indicators of emotions such as heart rate, electrodermal reaction, or regional brain responses. Observational methods for capturing emotional facial expressions are also popular, such as the Facial Action Coding System (FACS; Ekman & Friesen, 1975). These approaches have obvious advantages. They are highly objective and can capture emotions while they are occurring. But there are also disadvantages, especially when it comes to their application in marketing. For instance, not all emotions have a unique physiologi-

cal or mimic pattern. Especially secondary emotions can hardly be deduced in an unambiguous way. Additionally, application of these methods requires much time, effort and high levels of expertise, making them almost impracticable for large sample research.

Appraisal theorists mainly concentrate on capturing the conscious emotional experience by verbal methods, such as thinking-aloud techniques or questionnaires. Indeed, self-reports provide the only access to the subjective experience level of emotions, despite all the progress in the neurosciences. The variety of more complex secondary emotions cannot be revealed in any other way. Additionally, questionnaires are easy to apply and cost-effective, both in data-collection and in analysis (e.g. Pleasure/Arousal/Dominance-Scale (PAD) by Russell and Mehrabian (1977), Differential Emotional Scale (DES) by Izard (1977), Emotions Profile Index (EPI) by Plutchik (2003), Consumption Emotion Set (CES) by Richins (1997) or Watson and Tellegen's (1985) Two-Factor Structure of Affect). But they can lead to problems as well. Verbal methods are often criticised for inducing rationalizations in respondents and preventing intuitive responses. This raises serious concerns: Do respondents have sufficient insight into their emotions to be able to answer questions truthfully? Does the interview situation induce cognitive filtering of emotional experiences, thereby increasing the tendency to give socially desirable answers? Which unconscious or automatic components of the emotional reactions are missed by verbal measurement approaches?

Picture-based approaches (e.g. Desmet's (2003) PrEmo-Scale), unlike purely verbal questionnaires, are expected to facilitate intuitive access to emotions that are difficult to verbalize or which respondents are reluctant to talk about. At the same time, picture-based scales can give a fresh impetus to the interview and increase interest, motivation, and, ultimately, response rates. However, selection and validation of the pictures for such scales requires special care. It is very difficult to find truly unambiguous pictures that represent the same emotion for most people, especially if the scale is to be extended beyond the basic emotions. For instance, misinterpretations can result when the depicted emotional scene is not taken as metaphor for an emotion.

The number of emotions whose marketing relevance has been demonstrated in numerous studies extends far beyond the basic emotions (Bagozzi, Gopinath & Nyer, 1999). As mentioned above, both verbal and picture-based methodologies have pros and cons. The final decision for one approach—verbal or pictorial or a combination of both formats—will thus be based on an empirical comparison. To allow for a fair comparison, special attention needs to be paid to the selection of appropriate, unambiguous pictures. The development of the scale for capturing emotions can therefore be divided into different steps (identification of emotions, search for pictures and validation of pictures). This article summarizes the development of a picture-based scale and its validation in different steps. Finally, different scale variants (verbal, pictorial, and combinations of them) are used to capture emotional responses to TV ads and then evaluated on different performance criteria (scale validity, scale handling, ease of use, enjoyment of the survey and expert judgments). To sum up, the scale formats with "pictures/collages + labels" outperform the purely pictorial formats (pictures, collages) and "word only" on almost all comparison criteria. Assignments

that are solely due to similar motifs of pictures and TV-ads can thus be avoided. The comparison between the two labeled pictorial formats and the purely verbal format reveals several advantages of presenting a picture in addition to a verbal label. Labeled pictures lead to more pronounced differentiation across both emotions and TV spots. Socially desirable answers can be reduced, as indicated by higher selection rates for the negative emotions that a spot is expected to elicit in terms of the expert judgments. In general, labeled pictures produce higher levels of agreement with expert judgments and the scale handling gets better ratings compared to the other formats. Regarding the comparison between labeled single pictures and labeled collages no conclusive recommendation can be derived. In conclusion, we recommend using our labeled picture-scale for testing TV-ads for their emotional content.

(When) Does Choice Overload Occur? A Meta-Analysis

Benjamin Scheibehenne, Indiana University, USA
Rainer Greifeneder, University of Mannheim, Germany
Peter M. Todd, Indiana University, USA

EXTENDED ABSTRACT

In today's market democracies, people face an ever-increasing number of options to choose from. While individuals may often be attracted by this variety, some scholars argue that an overabundance of choice might eventually lead to a decrease in the motivation to choose and/or in a decrease of satisfaction with the finally chosen option. The possibility of a negative effect of large assortment sizes has important practical and theoretical implications. From a theoretical perspective, it challenges most choice models in marketing, psychology, and economics according to which expanding a choice set cannot make decision makers worse off, and it violates the regularity axiom, a cornerstone of classical choice theory (Savage 1954; Benartzi and Thaler 2001; Rieskamp, Busemeyer, and Mellers 2006). From an applied perspective, marketers and public policy makers would need to re-think their practice of providing ever-increasing assortments to choose from, since they could possibly boost their success by offering less variety.

Given these implications, it is important to learn how robust choice overload is, and to what extent it occurs in different situations. Therefore, in this paper we aim to thoroughly re-examine the too-much-choice effect by means of a meta-analysis across all experiments that we are aware of that investigated the influence of number of options on choice and satisfaction.

Data for the meta-analysis was collected via an extensive literature search, personal communication with scholars in the field, and a call for relevant studies (published or unpublished) that went out to several internet newsgroups covering the areas of consumer behavior, marketing, decision making, and social psychology. The meta-analytical integration of different studies requires that designs and research questions are comparable. Therefore, we only included data from randomized experiments in which participants were given a real or a hypothetical choice from an assortment of options, with the number of options being subject to experimental manipulation in a between- or a within-subject design. The dependent variable was either a continuous measure of self-reported satisfaction based on a Likert scale (usually requiring a forced-choice paradigm), or a measure of propensity to make an active choice. To enable meta-analytical integration across the dataset, we transformed the difference in the dependent variable between the small and the large assortment of each experiment into a Cohen's d effect size measure that expresses the difference between the experimental conditions in terms of the pooled standard deviations (Cohen 1977).

The total dataset consisted of 50 experiments, 26 of which stem from 12 published or in-press journal articles, 11 from 3 Master's or PhD theses, and 13 from 8 conference contributions or unpublished working papers which were made available by their respective authors. The dataset embraces a total of 5,036 participants. We integrated the results of all experiments by calculating a random effects model in which the effect sizes for each study are assumed to be randomly distributed around a grand mean effect size D .

The mean effect of size of choice overload across all 50 experiments was $D=0$ (CI_{95} -0.13 to 0.13). The between-study variance equaled $\tau^2=0.14$ (CI_{95} 0.089 to 0.317). The I^2 statistic that quantifies the proportion of variance due to non-random heteroge-

neity equaled 71% which indicates high heterogeneity. When the dataset was trimmed by 20% by excluding the 5 studies with the highest effect sizes and the 5 studies with the lowest, the mean effect size was unaffected ($D_{\text{trimmed}}=-.02$) but the unexplained variance fell to $I^2=28\%$. This indicates that most of the heterogeneity in the dataset is due to a few studies reporting large effect sizes.

To further explore how much of the variance can be explained by potential moderator variables, we extended the random effects model by a meta-regression in which the mean effect size D is predicted by a linear combination of a set of predictor variables. This analysis showed that a "more choice is better" effect is to be expected for studies that use consumption quantity as a dependent measure. Also, published articles are somewhat more likely to report an effect of choice overload as compared to unpublished manuscripts, which indicates a slight publication bias in favor of "positive" results. The degree of choice overload apparently does not depend on whether the dependent variable is satisfaction or choice. The data further indicates no difference in choice overload whether the choice task in the experiment is hypothetical or real. Likewise, there seems to be no difference between experiments conducted in Europe and the US, which questions cultural differences as an explanation for the effect, at least on this broad level. Within the tested range, the effect also does not depend on the difference in size between the small set and the large set. Likewise, we found no curvilinear relationship between assortment size and choice overload. With all moderators included, the unexplained variance drops to $I^2=60\%$, indicating that the identified moderators still leave some variance unexplained.

Together, our results indicate that the negative effect of choice overload is not as robust or widespread as previously thought. Still, our findings do not rule out the possibility that the too-much-choice effect can be reliably elicited with the presence of particular moderator variables, and a growing number of studies aim to identify such moderators. Towards this goal, it is essential to develop a more theory-driven understanding of the too-much-choice effect based on the interaction between the structure of assortments—beyond the mere number of options available—and the decision processes that people adopt.

Impact of Missed Opportunities on Subsequent Action Opportunities: A Functional Counterfactual Perspective

Partha Krishnamurthy, University of Houston at Texas, USA

Demetra Andrews, University of Houston, USA

Anu Sivaraman, University of Delaware, USA

ABSTRACT

According to the inaction inertia literature, the discrepancy between the missed and current opportunity induces counterfactual thinking which produces regret. As the attractiveness of the missed opportunity increases, the level of regret increases, thus reducing the likelihood of accepting the inferior opportunity. In this research we argue that this conclusion may be misleading because counterfactual thinking not only induces regret, it also helps prepare for future behavior. This suggests that as the attractiveness of the missed opportunity increases, the impetus to change course increases resulting in action rather than continued inaction. In two studies, we find that inaction leads to hyper-action when the decision-makers' past choices are facilitative of corrective functional counterfactuals.

Moderating Role of Parental Responsiveness in the Impact of Psychological Control on Youth Smoking: A Longitudinal Perspective

Zhiyong Yang, University of Texas at Arlington, USA
Charles M. Schaninger, University at Albany, USA

EXTENDED ABSTRACT

In public policy and marketing research, two parenting strategies—namely parental responsiveness and behavioral control—have long been regarded as two important inhibitors of consumer misbehavior among children and adolescents, such as credit card abuse (Palmer, Pinto, and Parente 2001), and risky sexual behavior (Tanner et al. 2008). Similarly, in the psychology and public health literatures, parental responsiveness and behavioral control are viewed as two important predictors of undesirable adolescent behaviors such as smoking cigarettes (Simons-Morton 2002; Tucker et al. 2003). These studies have yielded intriguing findings, but the impact of another key parenting strategy—psychological control—on child smoking initiation or progression is largely ignored. In addition, most studies on parenting-smoking linkages have mainly focused on the direct effect of parenting strategies on child smoking, ignoring their indirect effect through self-esteem. Exploring the role of self-esteem as the underlying mechanism through which parenting strategies affect child smoking may yield important new counter-marketing insights on how changing parenting strategies might be useful in avoiding or curbing youthful tobacco use.

This research intends to fill the gaps in the literature by developing an integrative model specifying that psychological control, and its interactions with parental responsiveness and behavioral control, drives self-esteem trajectories, which in turn drive smoking trajectories (initial level and slope). Self-esteem is the key focal mechanism because it is the single most important indicator of an individual's social well-being. Kaplan's (1982) self-derogation theory holds that adolescents low in self-esteem defend their egos by alienating themselves from conventional role models and rebelling against their standards. This leads to involvement with deviant peers and engaging in such delinquent behaviors as smoking, drinking, or taking illegal drugs. Because child self-esteem is influenced by extended interaction with parents (Hoelter and Harper 1987), we argue that psychological control influences child smoking development both directly and indirectly via influencing the changing pattern of child self-esteem.

We develop a series of latent growth modeling (LGM) analyses to examine the interactive impact of psychological control and other parenting strategies on self-esteem and smoking trajectories, using longitudinal data from ages 10 to 17. This coincides with transition to high school, puberty, and the development of an independent mature self-identity and ego. During this significant developmental period, self-esteem deteriorates over time and clearly has a negative slope (Blyth, Simmons and Carlton-Ford 1983; Simmons, Carlton-Ford, and Blyth 1987) through at least age 15. Correspondingly, smoking demonstrates a parallel but positive progression in frequency (Audrain-McGovern et al. 2004; Mayhew, Flay and Mott 2000).

To our knowledge, this research represents the first effort to examine the extent to which children's smoking initiation and progression is influenced by psychological control, or the extent to which the impact of psychological control is moderated by the other two parenting factors. In addition, we are among the first to examine trajectory-to-trajectory influences of self-esteem on smoking, and show that the indirect effects of parenting, through self-esteem, are stronger and more insightful than the direct effects. From a public

policy perspective, our findings suggest ways to improve the effectiveness of parent-oriented anti-smoking campaigns. Recent campaigns such as Tobacco Free Kids have recognized the importance of parenting by educating parents about conduct that is most likely to curtail teen smoking. Our findings suggest that the existing parent oriented anti-smoking campaigns have one major shortcoming. These campaigns have mainly focused on two parenting strategies—namely parental responsiveness and behavioral control—by emphasizing the importance of parental monitoring and open communication and problem solving discussions between parents and teenagers. In contrast, based on our findings, educating parents about the harmful effects of psychological control is even more important because psychologically controlling parenting can directly increase children's adoption of smoking and indirectly increase their adoption and progression of smoking through influencing their self-esteem.

Dealing with Anxiety: How Effective Health Messages Undermine Self-Control

Nidhi Agrawal, Northwestern University, USA

Echo Wen Wan, University of Hong Kong, Hong Kong, China

EXTENDED ABSTRACT

Health messages often attract consumers' attention by highlighting the high risk of their contracting a disease. Past research in marketing and health psychology has found that communicating health risk perceptions of a disease increases awareness and interest in that disease, and encourages preventative and healthy behaviors (Raghubir and Menon 1998; Raghunathan and Trope 2002). However, other research has also found that creating high perceptions of vulnerability to a disease might have negative repercussions such as leading consumers to avoid processing the health message or to counter-argue it (Block and Williams 2002; Keller, Lipkus, and Rimer 2003). The existing literature, however, has mainly focused on examining the effect of health risk perception about one disease (e.g., hepatitis) on behaviors related to this disease (e.g., getting tested for hepatitis virus). In this paper we go beyond previous research and examine the impact of processing high-risk health message on self-control behavior in general.

Recent research on health communication has suggested that the negative repercussion of processing high-risk health messages might be related to individuals' emotional deterioration in such contexts (Agrawal, Menon, and Aaker 2007; Raghunathan and Trope 2002). Reading messages describing symptoms and severe disease consequences will make individuals feel disturbed and uncomfortable (Agrawal et al. 2007). Moreover, the perception of high self-risk will challenge individuals' unrealistic optimism regarding their health (Menon and Raghubir 1998; Taylor et al. 2000), which will induce the feeling of uncertainty. Negative emotions with an uncertainty component are typically associated with anxiety (Tiedens and Linton 2001). Kahn and Luce (2003) found that participants who received false positive test results (perceiving at high risk) in the context of breast cancer, as compared with participants who did not receive such a false alarm, felt more stressful and consequently had lower intentions to comply with testing procedures.

Literature on emotion specificity and emotion regulation has suggested that coping with anxiety may consume self-regulation resources—resources involved in the deliberate regulation of responses (Muraven and Baumeister 2000). Anxiety signals to individuals that the situation is uncertain, which will make them feel lack of confidence about the situation and therefore prompt them to engage in effortful cognitive processes to change the state (Pelham and Wachsmuth 1995; Tiedens and Linton 2001). Previous studies have provided evidences that coping with anxiety requires regulatory resources. For example, Richeson and Trawalter (2005) argued that interacting with people of different race will cause anxiety that makes such interactions depleting in regulatory resources. Supporting this view, they found that 1) interracial interaction (vs. same-race interaction) led to poorer performance on Stroop task—an inhibitory task requires regulatory resources (Gailliot et al. 2007); and 2) the negative impact of interracial interaction on the Stroop performance was eliminated when participants' needs to regulate anxiety in their interracial interaction were reduced.

Research on regulatory depletion posits that self-regulation resources are limited in amount, and predicts a *depletion effect*: using regulatory resources in one task reduces the amount of resource available and thus will undermine performance on an

immediate subsequent self-regulation task (Muraven and Baumeister 2000). Depletion effects have been documented to affect a wide range of consumer behaviors involving self-regulation such as impulse purchase (Vohs and Faber 2007) and alcohol drinking (Muraven, Collins, and Nienhaus 2002).

By integrating research on health risk, emotion regulation, and regulatory depletion, we propose that processing high-risk health messages consumes self-regulatory resources and will impair subsequent self-control, whether such self-control is concerned with health or behaviors in general domains. Moreover, this detrimental effect on self-control occurs because of a depletion of resources in coping with anxiety resulting from high self-risk perceptions.

One laboratory experiment and two field studies examine the predicted effect, the underlying mechanism, and the boundary condition. In all studies the first task manipulates self-risk perception in health messages and the second task assessed subsequent self-control.

In Study 1 participants first read a message communicating a perception of being at high or low risk of getting Hepatitis C, a health risk manipulation adapted from past research (Menon, Block, and Ramanathan 2002). Next, participants were provided the opportunity to eat chocolate chip cookies. We found that participants who read the high-risk message ate more cookies than those who read the low-risk message.

Study 2 replicates the finding of Study 1 in a field study where participants firstly viewed advertisements about the consequence of second-hand smoking and then were provided the opportunity to eat cheese sticks. We found that second-hand smokers, perceived at higher self-risks of getting smoking-related diseases, ate more cheese sticks than non second-hand smokers. Moreover, we demonstrated that this effect was mediated by participants' anxiety after viewing the second-hand smoking ads.

Finally, Study 3 identifies the boundary condition for when anxiety from processing health risks has helpful versus harmful effects. We proposed that when individuals take a cognitive perspective to reduce the uncertainty, they will be more likely to engage in health practice because doing so will help them diminish their uncertainty about their health conditions. A typical context where individuals are likely to take a cognitive stance is when the subsequent behavior is obviously related to the focal disease causing the risk perception and anxiety. Supporting this view, Study 3 shows that participants who perceived at high (vs. low) self-risk of contracting Avian flu had greater intention to get tested for the avian flu virus but lower intention to do a check-up in a different health domain—dental health. Anxiety mediated the disease relevance x health risk interaction.

Our research enriches literature on health communication by documenting an unknown repercussion of using high-risk messages—processing high-risk messages impair performances on general self-control beyond health behavior related to the focal risky disease. It also adds to the literature on emotion and self-regulation by showing that coping with a specific emotion—*anxiety* involves depletion of regulatory resources and that taking a cognitive stance of coping with anxiety will overcome the depletion effect. Our findings also provide implication for marketing practice of health information communication.

Time-Inconsistent Preferences vs. Price Discrimination: How do Firms Increase Profits via Mail-in Rebate Promotions?

Beom Joon Choi, California State University, Sacramento, USA

Joseph Kissan, University of Kansas, USA

James Lemieux, University of Kansas, USA

EXTENDED ABSTRACT

Mail-in rebates are widely believed to be employed as a marketing tool because they motivate purchase, yet result in consumers failing to redeem the rebate offer (Bulkeley 1998). By some estimates, nearly 40 percent of all rebates never get redeemed because of such “breakage” (Grow 2005). Two streams of literature offer an explanation for this phenomenon. The first literature stream implies that consumer valuation of the costs and benefits of rebates changes over the time between purchase and redemption. Accordingly, a rebate that may initially appear worthwhile is perceived to be excessively costly to redeem after the purchase. Such time-inconsistent preferences are exemplified by several theories including: hyperbolic discounting (cf. O’Donoghue and Rabin 1999; Hoch and Loewenstein 1991; Soman 1998), time-construal theory (Trope and Liberman 2003), resource slack theory (Zauberman and Lynch 2005), procrastination (Silk 2005) and future optimism (Mowen and Mowen 1991). In contrast, the second literature stream implies that consumers self-select into groups characterized by their intention to redeem. Hence, rebates act as a price discrimination tool that attracts certain types of people who intend to redeem, but yet ensure that those who have no intention to redeem pay full price (Chen, Moorthy, and Zhang 2005; Lu and Moorth 2007). Thus, the appearance of ‘breakage’ may simply reflect the group of high-valuation consumers who never intended to redeem in the first place.

In light of these two explanations for breakage, the efficacy of time-inconsistent preferences and price discrimination to explain rebate profitability is tested using an actual rebate program with university students. In the experimental setting, subjects were given the choice of obtaining an immediate cash reward or the possibility of a greater cash reward upon completion of rebate offer. This is analogous to the situation where consumers choose between two products in the market place: one with a low price and another with a higher initial price but with a lower final price obtained via a mail-in rebate offer.

Since the greater cash reward was contingent upon completing the redemption requirements in the future, this choice represents the same type of forward decision making required in an actual rebate program. Since no accompanying product was offered for sale, this study design focuses exclusively on the rebate decision process.

A pretest determined the amount of cash reward and rebate effort that yielded a statistically significant number of redeemers. In the main experiment, the cash reward and rebate effort were manipulated at levels close to those used in the pre-test to ensure similar response rates. A follow-up questionnaire was conducted to measure subjects’ individual characteristics relevant to the study. In addition, rebate profitability was assessed by testing whether the observed redemption rate significantly exceeded the requisite ‘threshold’ for profitability. Finally, for those who accepted the rebate offer, an additional rebate offer was made to assess whether the subjects “learned” from their previous redemption experience.

This manuscript experimentally demonstrates that although both time-inconsistent preferences and the price discrimination mechanisms are present in a rebate program, the conditions which increase the occurrence of time-inconsistent preferences decreases the size of the intended redeemer segment and thereby limits rebate

profits. In addition, the ability of sellers to profit via this route is further limited to the extent that consumers have many opportunities to learn about their rebating propensity across many product categories (Hoch and Deighton 1989). In the follow-up study of those who participated in the experiment, subjects who had accepted the rebate offer were given the opportunity to make an additional choice between accepting an immediate cash reward and the possibility of greater reward in the future through a second rebate offer. In comparing the choice of the subsequent rebate offer between subjects who redeemed the first offer and those who did not redeem the first offer, it was found that prior success with rebates significantly increased the likelihood of choosing the subsequent rebate offer. Specifically, nearly 82% of those who had redeemed the first offer choose to accept the second rebate offer. In comparison, only 15% percent of those who failed at rebate redemption chose to accept the second rebate offer. This suggests that the subjects had learned substantially from their prior (failed) experiences in accepting a rebate. This finding further supports the main results that marketers are limited in their long-term ability to take advantage of time-inconsistent preferences to improve rebate profitability.

This study also finds substantial evidence for the premise that rebates serve as a price discrimination mechanism. Specifically, the construct of rebate involvement had a significant impact on rebate choice even after controlling for face value and redemption effort. Moreover, this trait is positively correlated with price consciousness and deal proneness, thereby providing evidence for the basic preference structure implicit in the price discrimination mechanism. The results here suggest that marketers may wish to employ rebates in markets characterized by heterogeneity in price elasticity. Furthermore, it may be premature to invoke regulation to curb the use of rebates if rebates simply act as another price discrimination tool.

The current experimental design did not allow us to consider the case where the rebate offers bring new low valuation customers into the market. If these customers are induced to purchase a product in the expectation of receiving rebates but fail to redeem, rebate profitability may indeed increase. However, given the situation where the low-valuation customers typically tend to claim rebates, the incremental sales may not guarantee higher profits. Nonetheless, we admit this is one of the limitations of the present study and leave this issue to future research.

Paying More but Choosing Less: How Input Factors Drive Preference Reversals in Consumer Decisions

Ritesh Saini, University of Texas at Arlington, USA
Fiona Sussan, George Mason University, USA
Anupam Jaju, George Mason University, USA

EXTENDED ABSTRACT

Previously it has been observed that input factors (like the amount of effort put in, direct costs, etc) which are likely to be non-diagnostic about the true utility derived from an item, significantly influence the preference for an item. In this paper we demonstrate that such non-diagnostic input factors have a greater influence on preference when consumers are asked to *price* items than when they are asked to *choose* from the same items. This leads to an input factors driven preference-reversal for consumer products. We demonstrate that this effect persists even when input factors are not monetary or quantifiable. In this manner we rule out scale compatibility hypothesis as a key driver for our results and instead propose a transaction fairness hypothesis.

Economics views individual decision makers as outcome-maximizers. This implies that all consumer decisions will be driven by the personal utility that an item provides to the consumer. However, consumer research has repeatedly shown that consumers invoke a variety of guiding principles and behavioral rules. Such rules can often undermine utility maximization. In this paper, we look at one such rule—consideration of input factors/ costs, and not just outcome utility, in constructing preferences for a consumption item.

In our first study, we asked respondents to express their preference for two paintings—one which was visually more appealing, while the other which had taken a longer time to finish. Participants who were asked to choose amidst the two chose the former more frequently. However, participants who were asked to price the paintings were willing to pay a higher price for the former.

In our second study we compared the pricing of the two products with the choice share of these two products. Products differ in terms of input factors. There were several pricing and choice conditions in the experiment. In some conditions, the products were priced separately (i.e. respondents who priced product A did not price product B and vice versa). This was done to more accurately reflect the reality in markets where consumers often focus on a singular item while pricing it, like bidding on eBay. In other conditions, products were priced jointly. In addition, in some conditions target products were chosen or priced when they were tied-in with other products. Our main hypothesis is that input factors influence pricing more than choice. Specifically, conditions 1-5 were pricing conditions while Conditions 6 & 7 were choice conditions. In the pricing conditions, participants were asked to state the maximum amount of money they are willing to pay to purchase a high (hardware) or low (software) input factor product with or without bundled (free) goods. In the choice condition, participants were asked to choose between high or low input factor product with or without bundled goods. The key findings of this experiment were that participants priced the high input factor more than the low input factor in the pricing condition. However this preference order was reversed when participants were asked to choose amidst these two options. Our main hypothesis was supported. We also found that input factors influence pricing more than choice for tie-in products, and even when prices are elicited in a joint-evaluation mode. Significantly, our choice and description of experimental stimuli was such that we rule out scale compatibility hypothesis as the key driver of our results.

The third experiment manipulated input costs within the same product category thereby controlling for any confounds. Again, in the pricing condition, participants valued the high input factors option (Restaurant B) more than the alternative; however in the choice condition participants chose the low input factors option more.

One of the most basic assumptions of the rational theory of preferences is the principle of extensionality (Arrow 1982) or invariance (Tversky & Kahneman 1986). This states that the preference ordering should not depend on the description of the options (description invariance) or on the method of elicitation (elicitation invariance). The present studies add to the evidence of elicitation invariance driven by a consumer's perception of the input costs and efforts involved in making a good. In this paper we have demonstrated that input bias significantly influences preferences, more in a pricing task than in a choice. This effect is not solely driven by scale compatibility, but continues to influence pricing even when input factors are not easily quantifiable. Also, we demonstrate that the pricing task primes the goal of transaction fairness which leads to higher pricing of the high input factors option. This hints at the possibility of such pricing-choice differences for all situations where non-diagnostic factors have been shown to influence preferences.

An Integrated Model of Reference Prices and their Impact on Satisfaction

Felix Tang, Hang Seng School of Commerce, Hong Kong
Jianmin Jia, The Chinese University of Hong Kong, Hong Kong

EXTENDED ABSTRACT

The Motivation

This article develops a satisfaction model that incorporates the concepts of the types of reference prices, perceived fairness, retrospective regret, and disappointment. Previous studies have examined *whether* reference prices lead to consumer satisfaction (e.g., Bolton and Lemon 1999; Fornell et al. 1996; Mittal, Ross, and Baldasare 1998; Varki and Colgate 2001; Voss et al. 1998); however, *how* reference prices lead to satisfaction remains unclear for two reasons. First, except for Voss et al. (1998), causality cannot be established when prices are not manipulated directly in the study. Second, except for Bolton and Lemon (1999), the underlying mechanism driving the relationship has not been examined.

The exploration of *how* reference prices influence satisfaction leads to two research questions. The first question concerns the relationships between different types of reference prices on the antecedent of satisfaction (i.e., fairness, regret, and disappointment). Inman, Dyer, and Jia (1997) define regret and disappointment according to the type of comparison. Their findings suggest that each antecedent is influenced by a specific type of reference prices. However, Bolton, Warlop, and Alba (2003) find that perceived fairness can be influenced by different types of reference prices, such as prices comparing across consumers and prices comparing across time. Their findings suggest that each antecedent may be influenced by multiple types of reference prices. Clarifying these contradicting predictions allows a better understanding of reference prices and satisfaction. The second question concerns the explanatory power of fairness, regret, and disappointment, and the robustness of existing model without one or more of these antecedents. Whether satisfaction can be adequately explained by one, two, or all of the antecedents is both theoretically and practically important.

The objective of this article is to develop an integrated model to capture the influence of how different types of reference prices influence consumer satisfaction. This article adopts Bolton et al.'s (2003) transaction space framework and proposes that the influence of reference prices on satisfaction can be separated into three types: across-time reference price, across-consumer reference price, and across-firm reference price. The levels of reference price are manipulated to draw causal inference. Furthermore, disappointment, fairness, and regret are included in the model to examine if they can moderate the effect of reference price on satisfaction.

The Conceptual Framework

An integrated model must be able to encompass the influence of different types of reference prices on satisfaction. This article transforms Bolton et al.'s (2003) transaction-space framework into a new reference price typology. Our model adopts the consumer (across-consumer reference price), firm (across-firm reference price), and time (across-time reference price) dimensions and relates them to fairness, regret, and disappointment.

Disappointment is a cognition-laden and psychological reaction to an outcome that falls below one's expectation (Bell 1985). Perceived fairness is a judgment that the distribution of resources is based on the principle of equity, equality, and needs according to the distributive justice theory (Deutsch 1975). Regret is an unpleasant, cognitively determined, backward-looking emotion

experienced when realizing or imagining that the present situation would have been better if actions had been done differently (Zeelenberg and Pieters 2007). The effects of disappointment, perceived fairness, and retrospective regret on consumer satisfaction have been independently demonstrated in previous studies (Bolton and Lemon 1999; Darke and Dahl 2003; Taylor 1997).

The relationship between fairness and regret and the relationship between fairness and disappointment were freed in the model estimation. The fairness-regret relationship was suggested by Tang and Jia (2007) that consumers are motivated to accept responsibility and such cognitive appraisal leads to the experience of regret. The fairness-disappointment relationship was hinted by Bell (1985) that one may feel disappointed at receiving such an unexpected, unfair outcome.

The Experiment

An experiment with a 3 (across-consumer reference price: favorable, same, unfavorable) x 3 (across-firm reference price: favorable, same, unfavorable) x 3 (across-time reference price: favorable, same, unfavorable) between-subjects factorial design was conducted to generate the price variations along different dimensions of reference price. The experiment was scenario-based, describing an Internet shopping experience of a DVD movie. Six-hundred-seventy undergraduate students participated in this study. All dependent variables were measured on a multi-item, seven-point Likert scale. The manipulations were successful.

The Findings

The proposed model is examined using structural equation modeling. Confirmatory factor analysis indicated excellent fit of the measurement model ($\chi^2=87.25$, $df=47$, $CFI=.99$, $RMSEA=.038$, $SRMR=.020$). Reliability of and discriminant validity among the constructs were also established. The proposed model fit the data well ($\chi^2=112.62$, $df=51$, $CFI=.97$, $RMSEA=.045$, $SRMR=.025$). The structural model suggests that perceived fairness, retrospective regret, and disappointment mediate the effect of reference price on satisfaction. Several nested models were also examined for model comparison. The findings in model comparison suggest that the impact of reference prices on satisfaction is type-dependent. That is, the influence of across-consumer reference price on customer satisfaction is larger than that of across-time or across-firm reference price. Our findings support Inman et al. (1997)'s conceptualization of regret and disappointment; however, the findings do not support their one-to-one mapping assumption from the types of reference prices to the antecedents of satisfaction.

The findings in the model comparison suggest that the model with all three antecedents of satisfaction, as well as the model with fairness and regret and the model with disappointment and regret, provide a good fit for the data. The other seven alternative models fit the data significantly worse and the estimators are directionally larger than the corresponding estimators in the proposed model. This observation hints that models ignoring one or more antecedents of satisfaction may have inflated the predictive power of other antecedents on satisfaction. Specifically, satisfaction models that ignore regret (e.g., Feinberg et al. 2002) and models that only measure regret (e.g., Tsiros and Mittal 2000) may have inflated estimators. The paths from regret or fairness to satisfaction in these models should be interpreted with caution.

Others Matter: The Effect of Peer Connectedness to Television Series on Product Placement Effectiveness

Valeria Noguti, University of Technology Sydney, Australia
Cristel A. Russell, University of Auckland, New Zealand

EXTENDED ABSTRACT

There is a growing body of research focusing on the impact on consumers of products and brands placed in the content of entertainment media such as movies, television series, and talk shows, a practice referred to as product placement (Auty and Lewis 2004; Babin and Carder 1996; d'Astous and Seguin 1999; Russell 2002; Russell and Stern 2006). Yet, surprisingly little research has addressed how the social environment affects product placement effectiveness. Drawing a parallel with research on self-connectedness, defined as the referential relationships that people develop with television series (Russell, Norman and Heckler, 2004), we introduce the construct of peer connectedness. We define peer connectedness to television series as the perceived referential influence of television series on others. In other words, peer connectedness reflects the degree to which others are perceived as having developed referential relationships with the series and its characters, and therefore as being influenced by its content, including the products placed in the series.

Consistent with the extant literature on interpersonal influences in many realms of behavior, we theoretically propose and demonstrate that peer connectedness contributes significant explanatory power to predictions of purchase intentions for placed products. As peer connectedness involves one's perceptions of what others think and do themselves, the construct of peer connectedness is akin to Cialdini and colleagues' notion of descriptive social norms, defined as individuals' perceptions of others' behaviors (Cialdini, Kallgren, and Reno 1991).

As peer connectedness effects on behavior inherently depend on the degree to which people care about others' opinions, we further propose that the effect of peer connectedness on behavior should be greater when the consumer is more concerned about the social environment. As such, we demonstrate that the effect of peer connectedness on purchase intentions is moderated by susceptibility to normative interpersonal influence.

One field study was conducted with consumers of a leather goods brand often placed in Brazilian soap operas. Participants responded to a two-page questionnaire involving brand attitudes, purchase intentions, perceived peer connectedness and self-connectedness to the series, susceptibility to normative influences, and demographics. We proposed that peer connectedness affects purchase intentions by moderating consumers' willingness to act upon their attitudes through their concerns with group norms. Indeed, the regression of consumers' purchase intentions (PI) on brand attitude, peer connectedness, susceptibility to normative influence (SNI), and the two-way and three-way interaction terms reveal the predicted three-way interaction. On the one hand, consumers who held strongly positive brand attitudes but were low in SNI still report considerably high PI, regardless of perceived peer connectedness. On the other hand, for consumers who had positive brand attitudes but were high in SNI, PI is affected by peer connectedness (i.e., higher when peer connectedness is high).

A follow-up experiment conducted with US college students investigated how the perception of peer connectedness is affected by self-connectedness, and ultimately, how the resulting perceived peer connectedness affects consumers' intentions to purchase brands placed in television series. Viewers of a popular television series participated in an experiment presented as a set of four separate

studies. Attitudes toward a series of brands, including brands placed in the series, were collected in the first section. After an unrelated study presented in the second section, the third section focused on participants' viewing history with the selected TV series and included a measure of self-connectedness. Participants were then randomly assigned to a majority or minority peer connectedness condition: explicit information was provided by stating that either a minority or a majority of other viewers are connected to that series. The participants' resulting perception of peer connectedness was then measured. In the final section, intentions to purchase a series of brands were collected, and SNI was measured. Regression results showed that, as predicted, the peer connectedness manipulation affected perceived peer connectedness. In turn, perceived peer connectedness mediated the effect of the peer connectedness manipulation on purchase intentions when SNI is low. When SNI is high, consumers have stronger pre-existing perceptions of peer connectedness and are less influenced by external peer connectedness information.

These two studies provide support for the proposition that peer connectedness to television series is an important factor in predicting consumers' intentions to purchase products placed in these series. The field study demonstrates that high perceived peer connectedness relates to higher purchase intentions for consumers who are more susceptible to normative influences. The laboratory experiment, in which peer connectedness was manipulated, demonstrates its causal effects on purchase intentions. Explicit information about peer connectedness creates a perception of peer connectedness that significantly predicts consumers' intentions to buy brands placed in the series. The resulting perceived peer connectedness mediates the effect when susceptibility to normative influences is low but not when high. Taken together, our results demonstrate the importance of incorporating peer connectedness when testing the effects on audiences of product placements in television series.

Stimulating Referral Behavior May Backfire: The Effect of Referral Failure on Susceptibility to Persuasion

Bart Claus, K. U. Leuven, Belgium

Kelly Geyskens, University of Maastricht, The Netherlands

Kobe Millet, K. U. Leuven, Belgium; Free University Amsterdam, The Netherlands

Siegfried Dewitte, K. U. Leuven, Belgium

EXTENDED ABSTRACT

Consumers often rely on vicarious experience information when deciding about a product or service (Herr, Kardes, and Kim 1991). The effects of WOM behavior on the receiver of the information conveyed have extensively been investigated. Amazingly, the field knows virtually nothing about the effect of WOM on the sender, although senders are crucial agents in the WOM process (Goldenberg et al. 2009), and may very well react differently depending on whether or not their recommendations are followed. We distinguish the situation in which the sender's recommendations were followed (what we call referral success), or ignored (what we call referral failure) and look at the sender's subsequent openness to new information.

A literature review suggests that referral failure may be more informative than referral success. People tend to overweigh negative information. This greater sensitivity of individuals to negative than to positive information has been called the negativity bias (Cacioppo and Berntson 1994). This allows us to predict that referral failure will have a more pronounced effect than referral success.

The act of subjecting oneself to the scrutiny of a receiver of information, allowing that receiver to evaluate the sender's information, is something that goes far beyond that information itself. To some extent, not following advice signals that the receiver may not value the sender's judgment or even doubt his or her expertise. Earlier research found that the mere act of exposing oneself to public evaluation boosts self-image as a way to compensate for the threat of failure (compensatory self-inflation) (Greenberg and Pyszczynski 1985). Additionally, Sherman, Presson, and Chassin (1984) state that when the self is threatened, perceptions of consensus may be increased by a motivation to seek normalization and support for one's own behavior. This latter might lead to an exaggerated belief in support for one's own opinions, leading to choices that might diverge from choices that were hinted at by an advising party. Steele (1988) stated that when the self is threatened in one domain, a normal coping mechanism is to boost the ego in a general way, a thesis denoted as the "fluid compensation" principle. Finally, Rudman, Dohn, and Fairchild (2007) show self-worth compensation in response to threats to the self involving identity and social rejection as subtle as losing a small football knowledge quiz, something quite comparable to being questioned about e.g. product knowledge through referral failure.

Earlier we predicted that the effects of referral outcome would be more pronounced when the outcome is negative. The literature about ego threat further develops this stance, and adds to it the notion that if referral failure indeed poses a threat to the ego, people will react with a boost in self-worth to compensate for this pending blow to their ego. Furthermore, any effects of referral failure will be moderated by the extent to which this ego boost adequately covers for the ego threat at hand. We tested the proposed effects of referral failure and self activation on subsequent susceptibility to persuasion in four studies.

In study 1 we tested the effect of referral outcome on subsequent susceptibility to advice originating from a third person. In this

first assessment of the effects of referral outcome on subsequent susceptibility to persuasion, we wanted to avoid effects of interaction between different genders. Therefore, we used only men for this study. The participants in this study were told they were testing a communication setup for online interactions between two consumer labs over the internet. The actual task involved recommending products to a person in the other lab, of whom they saw a photograph. This (preprogrammed) interaction partner then chose products from sets based on these recommendations. The preprogrammed interaction partner was set to follow the subject's recommendation either five out of six, or one out of six times, which comprises the manipulation of referral outcome. Subsequently the roles were reversed, but the participant was teamed up with another partner. The dependent measure was the number of times the subject followed the interaction partner's advice. The results were in line with our expectations, yielding less susceptibility to follow advice after referral failure in the first phase.

Study 2 was a replication of the first, but with minor adjustments to streamline the procedure. Also, this time, the sample included women. We replicated the results of study 1, generalizing the effect towards women.

Study 3 used a scenario to induce a feeling of referral failure, where participants were asked to imagine them being the child of a movie theater owner and their friends either always or seldom following up on their recommendations of movies. This study also included a baseline measure, where no recommendations had to be made. The dependent measure was ostensibly unrelated to this manipulation, as it consisted of reading an expert's report in a magazine, and then choosing combinations of products of which some were, and some were not, recommended in the report. Also in this study, participants were assessed for differences in activation of the self. Results were in line with studies 1 and 2. Additionally, we found that differences in activation of the self moderated the effect of referral outcome. By comparing the results within conditions with those in the baseline condition, we could establish that it is indeed referral failure that causes these effects, and that referral success corresponds to the baseline situation.

In a fourth study, participants had to choose their favorite movie poster and motivate their choice to another-preprogrammed-participant. This preprogrammed participant then either indicated that he or she would be unlikely or likely to switch his or her own choice towards that of the participant. The dependent measure was the same as in study 3, but used absolute measures. A measure of activation of the self was again included. The results replicated those of the previous studies.

Overall, these studies establish the referral backfire effect and show that this effect is moderated by differences in activation of the ego. Implications and recommendations for future research are discussed.

When Do Entertaining Promotions Trigger Caution?

Donnel A. Briley, University of Sydney, Australia

Shai Danziger, Ben-Gurion University, Israel

EXTENDED ABSTRACT

We propose that promotional efforts that attempt to entertain shoppers (e.g., “instant-win” games) can make deals less attractive for some consumers. In particular, such promotions can activate persuasion knowledge, triggering a cautious outlook and skepticism about the accompanying deal—but only for consumers who have a strong need to preserve their sense of self determination. Consistent with this persuasion knowledge conceptualization, we find in three studies that consumers who do not have strong needs for self determination find entertaining promotions more attractive than those who have strong needs, and that this difference disappears when all are prompted to adopt a cautious mindset.

Marketers use a variety of promotional vehicles to entice point of sale purchases, and sometimes these vehicles endeavor to entertain consumers. An example is the lottery-like *scratch-and-win* card that consumers must actively scratch to reveal possible deals. Presumably, the entertaining gaming experience increases the chances that shoppers will take advantage of the offered deal. In this research we test this assertion, suggesting that the effects can sometimes be negative. We propose that the attractiveness of deals delivered via a gaming experience is moderated by consumers’ self determination beliefs.

Lay theory suggests that infusing entertainment into purchase situations could be an effective tool in driving sales. The entertainment benefit, which applies to promotional games, giveaways and other events, encompasses the “active play” and “reactive aesthetic” values identified by Holbrook (1994). This benefit is yielded when shoppers have fun either engaging in promotional games or watching events and outcomes related to these promotions. Positive hedonic responses prompted by these entertaining experiences translate into more positive associations for the associated brand (Ward, Hill and Gardner 1987) and, consequently, increase purchase likelihood.

Other evidence indicates that games can be effective in improving deal sales. For example, coupons that shoppers unexpectedly receive in the store are 35% more effective in compelling purchases than off-the-shelf price discounts that offer the same monetary incentive (Dhar and Hoch, 1996). One might expect, then, that games could be similarly effective in converting deal purchase. Darke and Freedman (1995) suggest that promotional games might be particularly appealing because they “give each customer a chance to win a discount rather than giving everyone the same standard sale price”. The appeal of this approach, they suggest, could come from people’s desires to feel that they are lucky in obtaining the deal opportunity.

On the other hand, a case can be made that adding an entertaining aspect to promotions can hurt deal purchase rates. When consumers experience an entertaining event that is tied to a promotional deal, these relatively novel events might trigger a more cautious outlook in which the consumer becomes skeptical of the accompanying deal opportunity. More specifically, encountering the entertaining activity could activate consumers’ knowledge and beliefs regarding persuasion (Friestad and Wright, 1994), as they become sensitive to the fact that they are in the midst of a persuasive episode. This caution could lead to reactance (Brehm, 1966) and in so doing, increase the chances of deal rejection.

We propose that promotions that make a special attempt to entertain are more likely than more typical promotions to trigger

caution. Games are a relatively elaborate medium for offering deals, and this rather complex framing could sensitize consumers to the underlying purpose of the effort—influencing their selections.

When is Entertainment Effective?

Some people believe that they determine their own destinies, perceiving a strong degree of contingency between their own actions and the outcomes of events they encounter; though others perceive a lesser degree of influence, viewing forces outside of their control as principal determinants (Rotter, 1966). We suggest that deals offered through an entertaining promotional vehicle are more likely to be chosen by the latter type of people than the former. People who have strong beliefs in self determination should give high priority to protecting themselves against events and people who impede their autonomy, and people who do not have such beliefs should give lower priority to these protections. Each of these belief system types spawns knowledge structures that support and maintain the system: Different goals, motives and attitudes are likely to develop. In particular, differences in self determination priorities should be accompanied by difference in the accessibility of knowledge structures that pertain to sensing and fending off efforts to sway one’s attitudes and choices. People who believe strongly versus weakly in self determination are likely to access such knowledge more frequently. As a result, those strong rather than weak in self determination should have this knowledge more accessible in memory.

This difference in accessibility of persuasion-related knowledge might not influence decisions when the promotion of interest is typical, but could be important when a promotion involving features that could signal the efforts intention to influence consumers. We suggest that promotions that include entertainment, specifically games, should receive different responses depending on the self determination beliefs of the consumer. For those strong in self determination, entertaining promotions are expected to trigger persuasion knowledge, because this knowledge is relatively accessible. A more cautious outlook is likely to follow, leading to skepticism about the deal. But, people with relatively weak beliefs regarding self determination, because persuasion knowledge is less accessible, are not likely to have the same response. Persuasion knowledge is less likely to become salient in the mind, and the positive effects of entertaining promotions, discussed above, are possible in this case.

Overview of Studies

A pre-test confirmed that people infer greater influence intent from game-based promotions than more typical in-store promotions. In studies 1 and 2 we included Chinese, who tend to be low on self determination, and Americans, who tend to be high. We expected that differences in self determination needs across the two cultures would moderate choices of a promoted item delivered via “scratch and win” card. In study 1, Chinese participants were more likely to select a two-for-one tissue deal when it was offered via a “scratch-and-win” card than when offered as a regular store promotion. In contrast, the game based deal eroded selection among American participants. This pattern was replicated in study 2 for a golf umbrella deal. Again, the scratch-and-win delivery improved deal attractiveness among Chinese participants, but hurt it among American participants. Additionally, self-reported externality ten-

dencies mediated the effects of culture on deal selection when promotions were entertainment focused. Last, study 3 garnered evidence for our persuasion knowledge conceptualization whereby the attractiveness of an entertaining promotion delivery vehicle is moderated by whether it alerts shoppers to these promotions' intent to influence. Activating a "cautious" mindset by means of a priming manipulation, the study found that those low on self determination no longer found the entertaining promotion attractive. As predicted, the priming manipulation did not influence selection when the promotion was offered at an end of aisle display.

Roles of Food Consumption in the Experience of Homesickness among College Students

Elizabeth Crosby, University of Illinois at Urbana-Champaign, USA

Cele C. Otnes, University of Illinois at Urbana-Champaign, USA

EXTENDED ABSTRACT

Homesickness is described as a “complex cognitive-motivational-emotional state ... associated with ruminations about home, an intense desire to return home, depressed mood and somatic symptoms” (Fisher and Hood 1987, 426). This study explores how college students, a population that is specifically vulnerable to homesickness, experience this condition. In particular, we explore the ways food consumption shapes students’ experiences of homesickness, by examining how consumption both specifically triggers homesickness and enables students to cope with it. Focusing on food consumption within this cohort is important, both because of the increase in obesity among young people and because diet quality, eating habits, and weight control often are adversely affected in college (Conklin and Lambert 2005).

As part of a larger study on how homesickness influences consumption, we collected 209 narratives. We eliminated 12 of these due to poor quality, leaving us 197 narratives that yielded over 700 pages of data. Although we did not anticipate an overwhelming discussion of food consumption, 164 of 197 narratives mentioned food consumption as either a trigger and/or coping mechanism for homesickness.

In analyzing the text, we sought out emergent themes while engaging in dialectical tacking (Strauss and Corbin 1998), immersing ourselves in the interdisciplinary literature on homesickness, food consumption, and product symbolism to help illuminate our informants’ experiences. We read all narratives multiple times to identify salient and emergent themes (McCracken 1988). Although we did not initially intend to focus on how consumers use food consumption as a coping strategy for homesickness, the quantity of food discussions prompted us to concentrate on the construct.

In the consumer narratives, we find informants use food consumption in multiple ways to try to alleviate homesickness. Specifically, we describe six different food consumption patterns: (1) quintessential food consumption, (2) substitution, (3) channeling, (4) nationalistic or regional food consumption, (5) food ritual recreation, (6) binge or recreational eating.

Quintessential Food Consumption. Belk, Wallendorf, and Sherry (1989) describe quintessential goods as those that represent the ultimate in a product category. With quintessential food consumption, informants consume food to alleviate homesickness that they believe best represents the food they ate at home. Informants do so to immediately reconnect to their home of origin, and lessen their feelings of separation.

Substitution. Informants use substitution when they find they are unable to consume the quintessential food that would remind them of home. In substitution the informants replace the quintessential food item with something that is as similar as possible. Even if our informants cannot duplicate the exact types of foods that they would have consumed at home, substitute products allow them to transcend the limitations of space and reduce the sense of being separated from their homes (Otnes and Ruth 2008).

Channeling. With channeling, informants consume foods that are favorites of the people they have left behind at their home of origin. Interestingly, however, they themselves did not typically eat those foods. This strategy therefore reflects our informants’ use of food as a conduit to reconnect them to a particular person from their home.

Nationalistic or Regional Food Consumption. Many informants cope with their homesickness by consuming foods that they associate with their home country or region. Informants consume these types of foods even if they had never or rarely used these brands when they were at home.

Food Ritual Re-creation. Informants also may cope by attempting to recreate food rituals to preserve a connection to their home to decrease homesickness. Many informants discuss recreating special family dinner nights, such as Wednesday night barbecue or Friday night pizza. Reliving these family dinner nights help informants feel connected to their families and homes even though they cannot be with the people who originated these traditions.

Binge or Recreational Eating. Many of the informants engage in bingeing or recreational eating to try to alleviate their homesickness. In this case, they do not eat to establish a connection to home, but rather to take their minds off of their feelings of homesickness and to make themselves feel better. Although these foods do not remind our informants of some aspect of their home, they do help in terms of providing a short-term mood boost.

We also find three ways food consumption causes or increases homesickness. First, many informants report that the foods that reconnect them with home also increase their homesickness simply because they are such powerful reminders of home. In consuming these foods, informants often continue to dwell on their absence from these places, reinforcing the separation in their own minds. Second, food consumption can trigger homesickness even if our informants were not experiencing this condition prior to consuming these foods. In these cases, the food consumption provokes thoughts of home. Third, eating food that is not prepared in the same manner as food at home can also trigger or exacerbate homesickness. Many informants complain that the substandard quality of dining commons food serve to remind them of their home. The substandard food acts as a trigger because of the immediate comparison informants make the superior food that was prepared at home.

The relationship between homesickness and food consumption can have both physical and emotional negative consequences on consumer welfare. Using food consumption as a coping mechanism for homesickness can be counterproductive, as it can increase homesickness and along with it the feelings of loneliness, stress, anxiety, and depression. Furthermore, several informants report that they gained weight from using food as a coping mechanism which significantly affects their overall health. Others report a lack of energy and increased feelings of sluggishness.

The negative ramifications of using food consumption to cope with homesickness make it extremely important to assist college students in coping with this condition. By educating students about the psychological effects of homesickness, they will be better prepared to cope with it. Furthermore, we believe that public policy makers could use the findings in this study to help develop nutritional information and messages that are aimed at helping college students realize the deleterious effects of using food consumption as a coping strategy for homesickness.

Becoming a Mother: Negotiating Discourses Within the Life-Framing Identity Project of Motherhood

Emma N. Banister, Lancaster University, UK
Margaret K. Hogg, Lancaster University, UK
Mandy Dixon, Lancaster University, UK

EXTENDED ABSTRACT

Introduction

We explore women's experiences of identity conflicts and contradictions (Arnould and Thompson 2005) within the context of the consumption of discourses around motherhood. We particularly examine the intersection between the culturally pervasive discourse of self-management (Fischer et al. 2007) and more locally-bound discourses around women's identity framing projects as new mothers. We focus on the strategies women devise to allow them to negotiate the transition into new motherhood and integrate a variety of potentially conflicting possible selves in order to become relative experts. Drawing on three women's cases we identify how women variously reconcile themselves to discourses around good mothering, or resist or disengage from these discourses while developing viable mothering identities.

Identity projects, identity transitions and discourses

Motherhood requires the integration of different possible mothering selves which are informed by discourses that frame understandings of what it means to be a mother and reflect the conflicts, contradictions and ambivalence encountered. Discourses have been classified into two types: life-project framing and culturally pervasive (Fischer et al. 2007). "Life-project framing discourses are those that animate goals in a particular context" (Fischer et al. 2007:426). Miller (2007) argues that life-project framing discourses can leave women with unrealistic expectations of motherhood, partly through emphasizing mothers as natural and instinctive but also through failing to take account of women's diverse experiences and the relevance of individual differences. Culturally pervasive discourses are "those that are less germane to particular goals in a given context but that nonetheless inform consumers' thoughts and actions in particular contexts" (Fischer et al. 2007:426). The main culturally pervasive discourse that affects women's identity projects as new mothers relates to self-management (Fischer et al. 2007:433) and encourages individuals to develop their own understandings and knowledge in response to the diversity of expert (e.g. medical) discourses. Negotiating their way between culturally pervasive and life-framing discourses means new mothers have to reconcile their personal experiences and values with broader discourses. We examine identity work undertaken at the intersection between discourses by exploring the transition women make from pregnancy to new motherhood and the development of relative expertise. We therefore seek to understand how women respond to commonly held expectations of motherhood, which Miller (2007) argues are socially embedded and emphasized via prevailing discourses.

Research design

Our study focuses on three stories from a sample of first time mothers. Our depth interviews were loosely structured and informed by themes around mothering from earlier studies. We began with an over arching question: "tell me about your experiences of motherhood so far". Data analysis was ongoing throughout the data collection.

Findings

Drawing on three women's cases we identify how women respond to the discourses around mothering using three self management strategies: resisting the discourses; reconciling the discourses; or disengaging from the discourses. These strategies are used by women to make sense of their early mothering experiences and ultimately allow them to define their own version of the 'ideal' mothering self as they become more experienced and confident mothers. We reveal how women adopt these strategies within the context of prevailing (and often localized) discourses of ideal motherhood, to redefine their expectations of motherhood and to emerge in various ways, as becoming relative experts or 'good enough' mothers.

First, Olga's story revolves around resisting discourses of ideal motherhood. Olga's story reveals how some women resist what they perceive as normative discourses associated with mothering, such as the expectation to breastfeed, to have a particular physical appearance, and to purchase particular branded goods. Although at first women may struggle with resistance, over time expectations are reframed in the light of early mothering experiences, and women become more confident in their resistance and develop reframed expectations of the 'good enough' mothering self.

Second, Grace's story tells how she sought to reconcile potentially conflicting discourses. In her transition to motherhood, Grace struggles with, but eventually manages to reconcile, her initial expectations of her new mothering self versus the reality of her lived experience of new motherhood. Reconciliation involves a re-evaluation of initial possible selves and recognition of (prioritizing) what is important and feasible within the new mothering context.

Third, Nina's story exemplifies disengagement from ideal motherhood discourses. Nina chooses to ignore the discourses associated with 'pregnancy as (identity) project' (Brewis and Warren, 2001), which involves the assumption that women will inform themselves, attend classes, and make particular consumption decisions as part of the motherhood project. Although aware of these 'expert' discourses, some women prefer to ignore them, instead preferring to find their own way, through trial and error, developing an emerging confidence, expertise and belief in themselves as 'good enough mothers.'

Discussion

Arnould and Thompson argue that the marketplace provides a structuring influence and "produces certain kinds of consumer positions that consumers can choose to inhabit" (2005:871). However, consumers are faced with conflicts, contradictions and ambivalence which "frequently engender the use of myriad coping strategies, compensatory mechanisms, and juxtapositions of seemingly antithetical meanings and ideals" (2005:871). Our findings suggest that while these cultural scripts are prevalent and influential, some women do not feel able to align their identities with particular positions and others will consciously and purposefully resist elements that do not fit with their own understanding and experiences.

In addition to identifying the self management strategies that women adopt in response to discourses about motherhood, our research also reveals that the process of transition involved in becoming a (good) mother is somewhat more prolonged than might first be assumed. By interviewing women at different stages of new motherhood we have explored some of the ways in which women gradually accumulate the experience necessary to become a relative expert (Miller 2007). Despite pregnancy in itself representing a period of liminality, our findings suggest liminality continues after birth, as women develop “their own ways of knowing” (Miller 2007:351), which involves negotiating their path through a variety of life project framing discourses and the development of effective self-management strategies (Fischer et al. 2007) in order to cope with the often “seemingly antithetical meanings and ideals” (Arnould and Thompson 2005:871).

Catch Me If You Can: Rethinking the Relationship of Body and Self through Pregnancy

Hyun Jeong Min, University of Utah, USA
Lisa Peñalosa, EDHEC Business School, France

EXTENDED ABSTRACT

The present study examines the relationship between body and self through the experiences of pregnancy and childbirth. Experiences related to pregnancy were considered an appropriate area to study due to four reasons. First, pregnancy is an epiphanic experience (Denzin 1989) that ruptures routines and lives, and provokes radical redefinitions of the self (Strauss 1959). Second, women tend to become more reflexive about their body when they are pregnant because they want to keep their body safe and healthy. In addition, they feel tension between their new self as a mother and the individual who is struggling to get a particular body and self back, and this makes them more reflexive about their body. Third, it should be noted that body changes accompanying pregnancy are not imposed by one's own self concept but are naturally occurring. Finally, pregnancy usually leads to changes in consumption behaviors.

Several researchers were interested in body related consumer practices such as plastic surgery (Schouten 1991; Sayre 1999; Askegaard, Gertsen, and Langer 2002), tattooing (Watson 1998; Kjeldgaard and Bengtsson 2005) and consumers' self-care practices (Thompson and Hirschman 1995). These studies have shed light on the dynamic relationship between body and self and showed the malleability of bodies to construct consumers' self-identity. What is common in these studies is that the researchers chose body modification practices as their empirical setting. Body modifications are usually based on a consumer's idea about ideal self. In other words, the consumer's mind is the starting point of the bodily changes, and this choice of research settings tends to leave out naturally occurring body changes (e.g., changes caused by pregnancy, childbirth, and aging) in the discussion. Unlike in body modification, consumers don't have a clear idea about what happens to their body during naturally occurring body changes. For instance, pregnant women expect that they will experience a certain amount of weight increase. However, they cannot know how much weight they will gain. Sometimes, unexpected changes happen in their body such as prenatal diabetes, which one of my informants had experienced during her pregnancy. So it would be natural to assume that naturally occurring body changes would evoke very different dynamics between body and self from those discovered in body modification practices.

Data was collected using in-depth ethnographic interviews (Spradley 1979) with six Korean women who experienced pregnancy in the U.S.. Analysis was based on extensive coding and memo writing (Lofland, Snow, Anderson, & Lofland 2006). For a guideline, the coding procedures of grounded theory (Glaser and Strauss 1967; Corbin and Strauss 1998) were used.

Through the analysis, three themes emerged: 1) Disavowal of changed body from self making effort; 2) A paired identity and body project; and 3) Korean women situated in the American culture. The most notable thing in the informants' experience of pregnancy was their refusal to accept their changed body into their self concept. They tended to think that their changed body was just temporary and could be restored to its condition before pregnancy. For this reason, most of them excluded their changed body from self construction efforts.

Second, the informants started to accept their changed body as inevitable emphasizing the importance of their baby and their identity as a mother. Their identity as an individual woman gave

way to the identity as a mother, which cannot exist without being a pair with a child. They showed many behaviors of self sacrifice for their children. When they were confronted with the conflict between their personal desires and maternal duties, they almost always chose the maternal duties over their own desires even if there was an alternate option for them to use.

Third, the importance of social context in body project and self making discovered again as seen in previous research of body modification. Informants said that they might have behaved differently in terms of their bodily consumption if they were situated in a different social context.

By examining women's pregnancy and childbirth experiences, this study complemented the research findings from body modification research. As consumers experience disturbing body changes, they did not accept these changes into their self concept due to their hope of getting back the body they had before changes. This disavowal of changed body led to delaying and degrading consumption showing the gap between ontological self and epistemological self. In addition, this study also illuminated the importance of relational self identity. Recognizing a new identity as a mother helped informants accept the body changes. Moreover, they sacrificed their desires and needs giving priorities to their child's needs and wants. The role of a situated context of consumers also shed light on the relational aspects of bodily consumption.

Guilt Appeals in Cause-Related Advertising: When Does a Guilt Appeal Backfire?

Chun-Tuan Chang, National Sun Yat-sen University, Taiwan

Ting-Ting Chen, National Sun Yat-sen University, Taiwan

EXTENDED ABSTRACT

Corporate social responsibility (CSR) has been prompted by companies because a good business should be perceived as socially responsible. Sharing the business ethics and value of “paying back to society”, CSR has become popularly recognized by industries or companies. One way to fulfill CSR is to partner a product with a cause, referred to strategically as cause-related marketing (CRM), where money is donated to a charity each time a consumer makes a purchase. Recent studies have begun to examine potential factors that might affect CRM effectiveness and how consumers respond to CRM initiatives (e.g., Strahilevitz, 1999; Strahilevitz and Myers, 1998; Subrahmanyam, 2004; Webb and Mohr, 1998). One influential variable that has been identified to determine the success of CRM is its advertising (Chang, 2008). A variety of advertising techniques are adopted to persuade consumers to buy products and services. Emotional appeals are widely used to “cut through the clutter” and arouse persuasive communication. Among them, guilt appeals are identified as popular, especially in contexts related to charitable donation (Hibbert et al., 2007).

Complementing previous research on the effects of guilt appeals in charitable giving contexts (Basil et al., 2006 and 2008; Bennett, 1998; Hibbert, Smith, and Ireland, 2007), this research shows how the guilt appeal can be relevant to CRM. This article contributes to this evolving stream of research by applying guilt appeals in CRM campaigns to demonstrate that guilt appeals might not be equally persuasive in all conditions, and could be moderated by product type and donation magnitude. This research also incorporates a product type combining both practical functions and hedonic rewards to examine how consumers perceive different product types and how these perceptions interact with CRM effects in a systematic way. The moderating roles of product type and donation magnitude on guilt appeals in CRM advertising effectiveness were explored in a 2 (guilt appeals: guilt vs. non-guilt) X 3 (product type: hedonic vs. practical vs. both) X 2 (donation magnitude: low vs. high) factorial design. In order to eliminate the effects of product-selection bias, two products were chosen for each product type based on a pre-test. Therefore, 24 experimental versions were produced. The experiment was conducted through the Internet. Participants were randomly assigned to one of the 24 conditions above. After successful manipulation checks, a series of analysis of variance controlling gender were conducted to examine proposed hypotheses.

The results support the general proposal that CRM effectiveness depends on complicated interrelationships among guilt appeal, product type, and donation magnitude. After the applying of guilt appeals in the CRM promotion business, the results show that a guilt appeal leads to higher persuasiveness than a non-guilt appeal. This confirms that guilt appeals can be an effective tool for influencing consumer behavior, notably in product purchase behaviors. From a practical point of view, the findings here should be considered encouraging companies who wish to employ guilt appeals in initiating CRM ads. The other goal of the present study was to extend earlier work on guilt appeals by identifying boundary conditions associated with the role of guilt appeals in consumer evaluations of CRM ads. In doing so, the study is capable of providing insight into the important, but previously unanswered question of “When does a guilt appeal backfire?” The results indicate that focusing on a comparison between guilt and non-guilt

appeals may be overly simplistic. Indeed, the findings presented here establish that the influence of guilt appeals on consumer response is relatively complex and contingent on product type and donation magnitude. Four observations are noteworthy.

First, in terms of the relative effects of different product types, this study shows systematic effects on consumer responses by comparing hedonic products, practical products, and those containing both values. When a non-guilt appeal is used to frame CRM promotion, the main effect of product type is observed. The advantage of perceived product hedonism resides in its ability to elicit more favorable consumer attitudes toward the company and toward the sponsoring firm. Products linked to the cause are most likely to be preferred when they are hedonic, followed by those products containing both hedonic and practical value. The results demonstrate the previously observed effects of product type on CRM by comparing practical and hedonic products (Chang, 2008; Strahilevitz, 1999; Strahilevitz and Myers, 1998). The current investigation provides guidance for practitioners to frame the nature of the product in CRM campaigns. Perceived product hedonism is an important element in CRM. Transforming a product with perceived practical value into one with clear hedonic value can be an important re-positioning strategy for a company using CRM to successfully promote the product.

Second, a boomerang effect of perceived product hedonism is found when the CRM message is framed with a guilt appeal. To be specific, when a guilt appeal is employed, a practical product or a product containing both practical and hedonic value is more effective than a hedonic product for promoting CRM. Experiencing guilt from hedonic product purchases can affect an individual’s willingness to contribute to charity. When consumers face a hedonic product with a guilt appeal, the guilt-appeal ad appears to be a deliberate attempt to seduce consumers into buying and makes consumers feel manipulated. The differences in participants’ maladaptive responses from the experimental results validate this argument. This study here echoes the idea that guilt can generate negative responses and disrupt the advertiser’s intended objectives as well (Cotte et al., 2005). Therefore, when consumers face a hedonic product, the CRM message in the guilt appeal reduces advertising effectiveness. These findings should be helpful to those seeking to use guilt appeals.

Third, a high donation magnitude presented in an ad would eliminate the CRM effectiveness of the guilt appeal. High donation magnitude could mean a large sacrifice for consumers since it involves a higher cost passed on to them. Consumers tend to become skeptical toward the CRM promotion and the company’s inferred motives. These unfavorable evaluations have been identified in previous research (Barone et al., 2007; Berglind and Nakata, 2005; Gupta and Pirsch, 2006; Smith and Stodgill, 1994; Webb and Mohr, 1998). The current study empirically indicates that, with the guilt appeal, the participants who viewed the CRM message with a high donation magnitude generated more maladaptive responses than those who viewed one with a low donation magnitude. On the contrary, when a donation magnitude is perceived as low, the guilt appeal can become an effective peripheral cue in CRM advertising allowing consumers to process favorably the promotion message.

Fourth, the interaction between guilt appeal and donation magnitude is significant when promoting hedonic products with CRM. When the donation magnitude is low, a non-guilt appeal is

more influential than a guilt appeal due to the boomerang effects of a product's hedonic nature. The results of the experiment indicated that when participants faced a guilt-appeal ad, they were likely to generate more maladaptive responses. Marketers need to use caution when employing a guilt appeal due to the negative effects of the donation magnitude on consumer responses, especially when promoting hedonic products.

Findings from this investigation are informative both theoretically and pragmatically. This study contributes to the academic literature and industry by increasing our understanding of guilt appeals in a CRM context by proposing product type and donation magnitude as factors that moderate the relationships between guilt appeals and consumer responses toward the promoted product and the sponsored company. Furthermore, maladaptive responses as the process measure are incorporated into the current study to provide evidence about potential drives behind how consumers process CRM messages. The findings underscore the importance for marketers to learn more about whether guilt appeals work, and in turn describe how practitioners can avoid negatively toward guilt appeals. The present research should serve a starting point for entry into this under-researched area.

The Impact of Anchors on Donors' Behavior: A Field Experiment

Sonja Prokopec, ESSEC Business School, France
Arnaud De Bruyn, ESSEC Business School, France

EXTENDED ABSTRACT

A recurring and important challenge facing managers working in the fundraising sector is how much they should ask for when soliciting donations. The effectiveness of any campaign to solicit donations depends upon compliance rates as well as the magnitude of the help. A standard practice in donation requests is to present a set of suggested amounts, hereafter referred to as a donation grid. As we will show in this paper, designing the appropriate donation grid requires strategic trade offs as the donation amounts that are too high might lead to relatively low compliance rates whereas those that are too low might negatively impact the average amount donated.

Anchoring is an extremely robust phenomenon that appears in many contexts, even among experts as well as with important decisions (cf. Wansink, Kent, and Hoch, 1998). Donation grids have been shown to act as de facto frames of reference, directly altering judgment (Schwarz et al. 1991). Fundraising organizations use donation grids to artificially influence donation amounts. When faced with a request for donation, one must decide whether to respond at all, followed by the decision about the amount to be donated. How a consumer makes a decision about the donation is affected partly by the way in which information is presented and partly by his/her own internal characteristics (Lynch, Chakravarti and Anuaree, 1991; Tversky and Kahneman, 1981). While several mechanisms have been identified to positively influence likelihood of donation as well as amounts donated, there is little research that has shown that some anchoring mechanisms might have adverse consequences on consumers' donation decisions.

The purpose of this study is to explore how different designs of donation grids affect the likelihood to donate and the magnitude of donations. In addition, we also explore how donors' individual characteristics impact their compliance with the donation grids. This study makes several contributions to the literature: we identify different donation grid designs that positively as well as negatively impact donation behavior, we show that donors with strong internal reference points are less influenced by the donation grids per se, and finally, our results have both internal and external validity by use of a controlled field experiment.

We ran a large field experiment in which a charity solicited 50,000 of its donors, and tailored suggested donation amounts based on their past behavior. The nonprofit organization and the research team manipulated donation grids to study their impact on actual donation behavior. The manipulations were twofold. First, we manipulated how the donor's internal reference point (i.e., her last donation amount) was embedded in the donation grid. The reference point (the first amount, or left end of the grid) was manipulated as follow:

- LOWER the first suggested amount (the left end of the grid) is actually lower than the donor's last gift;
- EQUAL the first suggested donation amount is equal to the donor's last gift;
- HIGHER the first suggested donation amount is higher than the donor's last gift.

Second, further suggested amounts were proportionally increased (influencing the right end of the grid), and the steepness of this increase was manipulated, as follow:

- Low suggested donation amounts were increasing at a 20% rate;
- MEDIUM suggested donation amounts were increasing at a 50% rate;
- HIGH amounts were increasing at an 80% rate.

Our final sample consisted of 50,208 donors. The summary of results is as follows: Increasing the left end of the donation grid seems to discourage donations, consistent with out theoretical development. Manipulating the steepness of the donation grid, however, does not affect the likelihood of donation, and none of the differences across conditions achieve statistical significance, consistent with our hypothesizing.

Of the 50,208 solicited donors, 4,539 (9.0%) made a donation. As expected, both anchoring mechanisms affect donation amounts, although changing the reference point (the left end of the grid) has the greatest effect.

Regarding the proposed moderating effects, we suggested that donors who have made in the past numerous donations to the charity might have developed a strong internal reference point, and that this reference point might counterbalance the influence of anchoring mechanisms, hence reducing their amplitude. Data confirm this hypothesis. Furthermore, it was hypothesized that for recent donors, the donation behavior would be more vivid in the memory, and would serve as a strong internal reference point which anchoring mechanisms might not be able to influence. This hypothesis is confirmed when it comes to likelihood of donation but not donation amounts. Finally, we found that the less generous donors were much more influenced by anchoring mechanisms, whether the manipulation was the reference point or the steepness of the donation grid than more generous donors.

While our results confirm that both anchors (manipulating the left end and the right end of the donation grid) increase donation amount, we showed that manipulating the left end of the donation grid also decreased the likelihood of donation, hence adversely affecting overall donations. We also showed that the amplitude of these effects predictably varied based on donors' characteristics. Donors who have strong internal reference points, either due to frequent donations or to large amounts donated, were not influenced by the donation grids. What our study results suggest is that fundraising managers should not only use donation grids to facilitate donations, but as an active tool to optimize them. For example, frequent and/or generous donors could be contacted with a donation grid that includes amounts at high as their previous donation amounts or higher. This paper is important both for academics and practitioners, demonstrating for the first time in a large-scale experiment the potentially adverse consequences of anchoring mechanisms on donation likelihood, and the need for future research in this area.

Causes at the Checkout: The Role of Temporal Construal in Consumer Reactions to Corporate Social Responsibility

Reetika Gupta, Lehigh University, USA
Sankar Sen, Baruch College, CUNY, USA

EXTENDED ABSTRACT

Marketplace polls today point to large and growing swaths of consumers who want to buy products and services that not only are good but also do good. For instance, according to a recent marketplace poll (Cone 2007), 87% consumers said that they are likely to switch from one brand to another (price and quality being about equal) if the other brand is associated with a good cause. At the same time, however, the advantage of CSR products at the checkout remains unsubstantiated.

We draw on temporal construal theory to examine why consumers express strong purchase intentions for brands associated with a cause in polls but balk at acting on their intentions at the point of purchase. According to the temporal construal theory, distant future events are represented in more abstract terms where desirability concerns guide preferences, whereas near future events are represented in more concrete terms, with preferences being guided largely by feasibility concerns (e.g., Liberman and Trope 1998). We predict that in a poll setting, the purchase intent expressed by consumers for the distant unspecified future is influenced significantly by the desirability aspect of the brand (i.e., a strong CSR record signaling a responsible company). In contrast, the CSR record has a more muted impact on imminent consumer purchase decisions (e.g., at the point of purchase); in these situations, the consumer is influenced more by the nitty-gritties (feasibility concerns), such as affordability of brand or the presence of functional attributes.

Moreover, we suggest that this interplay between effects of CSR actions and the time horizon for consumer purchases is likely to vary across consumer groups who differ on the extent to which they believe that a firm's CSR efforts, in general, detract (in terms of available resources) from, rather than reinforce, the companies' resources. Sen and Bhattacharya (2001) have shown that consumers' general beliefs about the trade-offs companies make to support CSR activities do influence consumer perceptions of CSR actions. Specifically, we demonstrate that the contribution of CSR to consumers' purchase intentions will be more susceptible to temporal construal among consumers who think CSR efforts detract from company resources; consumers who perceive that CSR efforts reinforce company resources will display their loyalty to CSR-based products, regardless of the purchase timeframe.

Three studies were conducted to test our research propositions. Study 1 had a between-subjects design with subjects asked to imagine a supermarket visit in one of the two purchase timeframes (near, far). As expected, subjects were more likely to buy products that were associated with a cause when their purchases were in the distant, rather than in the near, future. In Study 2, using a conjoint design where consumers had an opportunity to compare the ethical attributes with other functional attributes (price, style) across the two purchase timeframes (near, far), we provide evidence that the focus on ethical attributes do get heightened in the distant future, while it has a muted impact in the near future. In Study 3, we examined if the beliefs related to the trade-offs companies make to engage in CSR activities influence the pattern of relationships between CSR actions, timeframe and purchase intent. Study 3 had a between-subjects design with three factors: 2 (purchase timeframe: near future or distant future) X 2 (attribute: CSR record or DVD-

RW drive) X 2 (trade-off CSR beliefs: CSR activities detract, CSR activities reinforce). Participants were primed with a near or distant laptop purchase scenario. Half of the participants in each condition responded to a series of purchase decision questions about a brand that engaged in CSR activities and the other half responded to a series of purchase decision questions about a brand possessing a DVD-RW drive. To measure consumers' trade-off CSR beliefs, participants responded to a set of items that captured their beliefs about whether CSR activities detract or reinforce company resources (e.g., companies that engage in socially responsible behavior produce worse products than firms that do not worry about social responsibility). As expected, in the CSR condition, participants indicated a stronger intention to purchase the product if it is associated with a cause, when the purchase is in the distant future than in the near future. We found a moderating effect of trade-off CSR beliefs such that the temporal construal-based difference in the effects of CSR actions on purchase intent exist for those who, in general, believe that CSR activities detract from company resources but these differences are not observed among those who believe that CSR activities reinforce company resources. These results did not play out in the baseline DVD-RW drive condition, indicating the absence of temporal construal-based effects among functional attributes.

From a theoretical standpoint, the findings advance research in both CSR and temporal construal theory by demonstrating that consumers lay more emphasis on abstract aspirational features such as CSR records in the distant future than in the near future. In addition, this research reveals that these temporal construal-based effects are limited by the extent to which consumers think CSR actions detract from company resources.

The Reparation Effect: Indulgent Consumption Increases Donation Behavior

Promothesh Chatterjee, University of South Carolina, USA

Arul Mishra, University of Utah, USA

Himanshu Mishra, University of Utah, USA

EXTENDED ABSTRACT

Donations from the public constitute more than 75% of charitable contributions and thus are a major source of funds for charitable organizations (Giving USA 2007). Several ways have been researched to encourage charitable donations (Aunel and Basil 1994; Cialdini and Ascani 1976; Reingen 1978; Weyant and Smith 1987). This article proposes an unlikely prior act—food consumption—that could influence people's donation behavior. Specifically, we propose and find evidence that people who consumed an indulgent food (e.g., ice cream or chocolates, which are often considered vices) donate more money to charitable causes than those who consumed a non-indulgent food (e.g., sandwiches).

In this research, we posit that the guilt originating from indulgent consumption increases subsequent acts of donation. Contributing to a charitable cause provides people a means to alleviate their guilt. Therefore, people are likely to donate more money after consuming an indulgent food option than after consuming a non-indulgent food option. We call the phenomenon the “reparation effect”, in which prior consumption of an indulgent option produces guilt, and as reparation for the act of consumption, people engage in charitable activities to alleviate their guilt.

In the first study, we approached people exiting eateries which specialized in either chicken sandwiches or ice creams at a large public university campus for filling up questionnaires in lieu of a chance to win a coupon for free ice cream or chicken sandwich depending on the location of the encounter. After several filler questions, we informed the participant about the activities of Red Cross and asked them to indicate the amount of money they would be willing to donate. In a subsequent unrelated questionnaire, participants were asked questions intended to measure consumption guilt. The results of study 1 demonstrated that participants were willing to donate more money after indulgent consumption than after non-indulgent consumption, thereby demonstrating the reparation effect. Also, it generated support for our claim that guilt mediated this willingness to donate.

Study 2 had two objectives. The first was to use a choice versus no-choice task to provide further support for the proposed guilt-based mechanism underlying the reparation effect. The second objective was to rule out a demand artifact explanation (i.e., the possibility that the results of the previous studies may be explained by a self-selection procedure). A poster was put up which described that participation in a research study would enable the participants to get a meal coupon. One hundred and nineteen participants approached the table where one of the authors and two research assistants sat. The participants were told that they had to participate in a short survey and as a token of appreciation they would get a meal coupon. This survey took place in two stages; one part of the questionnaire was completed before consuming food and the other part after consuming. The participants were informed that there were two conditions in the survey, one where the participant gets to choose what to eat and the other where the experimenter decides what they should eat. If allocated the choice condition the participants will have to choose between an ice-cream coupon and a chicken sandwich coupon, otherwise the experimenter would determine whether participant receives an ice-cream or a sandwich coupon. The logic behind such a procedure was that participants who were in the experimenter allocated ice-cream condition could

have a justifiable reason for external attribution of indulgent consumption. We then randomly divided the participants into two groups. The participants in one group (choice group) were allowed to choose between two coupons entitling them to either a chicken sandwich or an ice-cream. The participants in the other group (no-choice group) were randomly allotted either the chicken sandwich or the ice-cream coupons. The participants then filled up the first part of the questionnaire which contained the demographic details and a question to assess their hunger state. The participants were then handed the coupons and proceeded with the research assistant to redeem their coupons. Once the participants had redeemed their coupons and consumed the product, immediately the research assistant then asked them to fill up the final part of the questionnaire which contained questions previously described in study 1. The results of study 2 replicate the findings of the reparation effect and also rule out self-selection bias as an alternate account since we randomly allocated participants to the ice-cream and chicken sandwich conditions. The results also find support for the proposed guilt-based mechanism.

In study 3, we wanted to lessen the impact of extraneous influences prevalent in field studies 1 and 2 by examining the reparation effect in a lab setting. Another objective was to investigate the influence of the quantity consumed on the reparation effect. If our conceptualization is true, then greater consumption of the indulgent food option should result in greater guilt and hence higher donation amounts. A final objective was to ensure that there were no differential influences due to the food items. It could be argued that ice cream and chicken sandwiches have different qualities (e.g., sugar vs. no sugar) and may be more or less filling. In order to address this concern we used the same chocolates for participant consumption but defined them as indulgent or non-indulgent. Participants were then asked to indicate the amount of money they would be willing to donate to such charitable institutions. The results of this study replicated the reparation effect and provided further evidence for our suggested account. We found an increased engagement in charity for those in the indulgent description condition compared to those in the non-indulgent description condition. Moreover, the effect was pronounced for those who consumed a higher number of indulgent chocolates.

The charity market is intensely competitive and guilt-appeals for donations are ubiquitous. Our findings suggest that charitable organizations will have a higher efficacy with donation appeals if they target post-indulgent behavior. Thus, the place at which an appeal is made is equally as important as when it is made.

It Takes the Chronic to Know the Prime: Understanding the True Benefits and Costs of Priming

Monika Lisjak, Northwestern University, USA
Daniel C. Molden, Northwestern University, USA
Angela Y. Lee, Northwestern University, USA

EXTENDED ABSTRACT

Priming is widely used in consumer research to systematically investigate how increased accessibility of cognitions and goals influence information processing and decision making (Higgins, Rholes and Jones 1977; Bargh, Lombardi and Higgins 1988). Researchers sometimes rely on priming and other times use chronic measures to provide convergent evidence for their hypotheses and ensure construct validity (e.g., Gardner, Gabriel and Lee 1999; Higgins, Shah and Friedman 1997). For example, Ramanathan and Menon (2006) either measured participants' chronic hedonic goals or primed them with hedonic goals to investigate impulsive behaviors. In this research, we argue that there are costs to priming. Across three studies, we show that priming individuals with a regulatory goal that is inconsistent with their chronic orientation creates a disruptive experience that is cognitively depleting.

The literature is replete with evidence showing that goals can be primed (Kruglanski et al. 2002; Fishbach and Ferguson 2007). Although there are individual differences in how people represent goals in memory, research shows that it is possible to override these chronic dispositions through priming. In fact, the current perspective is that priming a regulatory goal orientation has the same effects on people's judgments and behavior as having that orientation chronically accessible (see Shah and Higgins 1997; Shah, Higgins and Friedman 1998; Förster, Higgins and Bianco 2003).

In the current work, we examine the effects of priming a regulatory goal orientation on self-regulation. Regulatory focus theory suggests that people have two motivational systems: a promotion system that involves a concern for advancement and growth needs, and a prevention system that involves a concern for security and safety needs (Higgins 2000). When people pursue goals with strategies that fit their motivational orientation they experience regulatory fit, which leads to increased engagement and feelings of rightness (Hong and Lee 2008). We draw on and extend regulatory fit theory by hypothesizing that priming a regulatory goal orientation that is inconsistent with the chronic disposition disrupts people's chronic state; and this shift in regulatory goal orientation is cognitively depleting and impairs people's ability to self-regulate. We tested our hypothesis in three experiments.

In experiment 1, participants completed the regulatory focus questionnaire (RFQ) that measures chronic regulatory orientation. Then, participants were randomly assigned to describe their hopes and aspirations (promotion prime condition) or their duties and obligations (prevention prime condition) (Higgins, Roney, Crowe and Hymes 1994). Finally, participants were administered the color-naming Stroop task to assess their ability to resolve attentional conflict. Participants were asked to name the colors in which color words were printed. For example, the word "blue" may be presented in red, and the task is to identify the color red. On congruent trials, the color of the word matches the semantic meaning of the word, and hence, there is no conflict with the correct response. On incongruent trials, the color of the word mismatches its semantic meaning, creating a conflict with the correct response. Thus, participants have to inhibit their natural impulse to read the word, and focus instead on the color in which the word is printed (Kane and Engle 2003). The results showed that participants who were primed with a regulatory goal orientation that was inconsistent with their chronic orientation were slower at identifying the color in the

incongruent (vs. congruent) word trials as compared to participants who were primed with a consistent regulatory orientation.

In experiment 2, we demonstrated that inconsistent priming influences people's ability to exert attention. Participants first completed the RFQ and then went through the same priming manipulation as in experiment 1. Next, participants completed a lexical decision task. They were presented with a series of letter strings and had to decide as quickly as possible whether each letter string was a word or a non-word. The word stimuli were either neutral (e.g., table), promotion related (e.g., grow) or prevention related (e.g., guard) words. By design, non-words differed from actual words only by one letter (e.g., scangal instead of scandal), and hence required more cognitive resource to identify. Our results showed that participants were faster at recognizing words consistent with the primed regulatory orientation; whereas the chronic orientation did not matter. However, the chronic and the primed orientation interacted to influence the speed with which participants discriminated non-words. Participants primed with an inconsistent regulatory orientation were slower at discriminating non-words compared to participants primed with a consistent orientation.

In our final experiment, we explored whether inconsistent priming undermines people's ability to engage in logical reasoning. A different priming manipulation was used to provide convergent evidence for our results. Participants first completed the RFQ and then engaged in an ostensibly unrelated memory task that included a framing manipulation. We framed the contingency of the memory task to emphasize the objective of gaining points (promotion prime condition) or of not losing points (prevention prime condition) (adapted from Förster et al. 2003). Later, participants engaged in an ostensibly unrelated study in which they were asked to solve problems from the Analytical section of the GRE for seven minutes (adapted from Schmeichel, Vohs and Baumeister 2003). In line with our hypothesis, participants primed with an inconsistent regulatory orientation solved fewer problems than participants primed with a consistent orientation. To uncover the underlying process at work, we asked a separate group of participants to report the extent to which they felt motivated after the priming manipulation. Participants primed with an inconsistent regulatory orientation reported lower levels of motivation compared to participants primed with a consistent orientation.

These studies advance our understanding on priming. Extant literature suggests that it is the accessibility of people's regulatory goals that matter when it comes to people's attitudes and behavior; whether the goal is temporarily made salient or chronically accessible does not make a difference. This research shows that it may be important to distinguish between the two types of accessibility—chronic and temporarily enhanced—given the influence of their interplay on people's ability to self-regulate.

The Effect of Quasi Social Cue on Web Site Evaluation: Social Presence and Social Support Approach

Eun-Jung Lee, Kent State University, USA

EXTENDED ABSTRACT

Introduction

Store atmospheric qualities of online retailing are distinctive from those in offline retailing, often negatively affecting customer's shopping experiences within the context. In particular, as a fundamental characteristic of computer-mediated experience (Hoffman & Novak, 1996), the lack of social appeals in a cyber shopping space is often blamed as a main reason for low-level involvement and satisfaction of online customers (McCabe & Nowlis, 2003; Hoffman & Novak, 1996), as it generates psychological distance (Sroull & Kiesler, 1986). Given the combination of increasing attention to the importance of store environment in online customers' shopping experience (e.g., Eroglu, Machleit, & Davis, 2003) and the crucial role of positive social influence in retail contexts (e.g., Argo, Dahl, & Manchanda, 2005), more academic efforts should be made with regard to the dynamics of social factors in the online retail environment. Therefore, building on the social presence and the social support theories, this study investigates the viable impacts of quasi social cue on online customers' Web site evaluation, and the psychological dynamics underlying the impacts.

Conceptualization

Social presence and quasi social cue. Communication psychologists believe that the sense of other people's being is not solely based on physical presence ("to be together") but also on social presence ("the sense of others"). Social presence refers to "the degree of salience of the other person in the interaction and the consequent salience of an interpersonal relationship (Short, Williams, & Christie, 1976, p.65)," which is a subjective perception determined by the amount of (verbal and nonverbal) social cues available within the medium (Sroull & Kiesler, 1986). More recently, communication psychologists indicate that social presence does occur in computer mediated communication contexts (e.g., online learning, email or web survey) with no physical interpersonal presence, and this also determines effectiveness of the medium (e.g., Biocca et al., 2003). Extending this view into the electronic commerce contexts, it can be argued that intrinsic deputy of social interaction in a cyber store-as well as its negative consequences like low interest in products and low attachment to the Web store-could be alleviated by managing the amount and quality of available social cues within the contexts, and in overall, this would ultimately enhance the quality of shopping experiences that online customers have in their shopping. In the Internet retail environment there exist various types of quasi social cue that resemble in part the role of employee or other shoppers' presence within a traditional retail store. Increasing the amount of such quasi social cue would raise the perception of social presence, and in turn, heightens positive influences of social presence in the online retailing. Two fundamental types of quasi social cue in online retailing (i.e., seller's information, customer review) are tested in the current study.

Online social support. Social support theory is adapted in this study to gain an understanding of mediating psychological dynamics underlying the quasi social presence effects. In general, positive social interaction generates positive psychological consequences like social support, which in the social psychology discipline refers

to the psychological benefits that people receive from interpersonal contacts (Cohen & Wills, 1985). Applied to the context of retail surroundings, the study of social support focuses more on weak social ties occurring in a store setting (e.g., interaction with a salesperson) while the theory originally focuses on strong social ties in social interaction (e.g., Adelman, Ahuvia, & Goodwin, 1994; Rosenbaum, 2006; Rosenbaum & Massiah, 2007). Online social support refers to the psychological benefits that people gain from social presence in the Internet circumstances. Although no study has adapted social support theory into store environments of online retailing, it could be intuitively assumed that if a web store generates some positive social interaction during its transaction with shoppers, there could evoke social support which accordingly leads to positive shopping experiences of online customers. Building on the social presence and social support theories, it could be argued that if quasi social cue in an online store could be perceived as positive social interaction by customers, it would influence their evaluation on the Web store, with the mediation of their perception of online social support. Therefore, hypotheses are developed as follows:

- H1. Customers who shop at a Web site providing quasi social cue will perceive higher level of online social support than those who don't.
- H2. Customers who shop at a Web site providing quasi social cue will give higher Web site evaluation than those who don't.
- H3. Customers who perceive higher level of online social support will give higher Web site evaluation than those who perceive lower level of online social support.
- H4. The level of perceived online social support will mediate the positive influence of quasi social cue on Web site evaluation.

Method

A 2 (information vs. no information) x 2 (review vs. no review) experimental study was performed with one hundred and eighty four undergraduates. Independent variables were two common types of quasi social presence (i.e., service provider information and customer review) selected from the pre-test results, and determinant variables were i) Web site attitude, ii) overall service quality, and iii) loyalty intention. A fictitious, Web-based wine shop (Goodwine.com) was designed and used as the stimulus of this research, in order to control any past experience that participants may have. Subjects were randomly assigned to one of the four conditions and with two quasi social cues manipulated within the Web site: those for the information condition were exposed to a written company information, CEO greetings with a picture, and *sommelier's* recommendation on each wine (seller's information manipulation) and participants for the review condition are given customer reviews in addition to the basic wine information (customer review manipulation). After viewing all the contents of the Web site, participants were led to a Web-based survey, which involved measurements of online social support, Web site evaluations, basic demographics, and items for manipulation checks. A three-factor (i.e., emotional support, companionship, information support/affiliation) online social support measurement was used, referring to the social support scales in the psychology and consumer literature (e.g., Chronister et al., 2006; Rosenbaum, 2006).

Scales for Web site evaluation used the measurements suggested by prior work (Coyle & Thorson, 2001; Wolfinbarger & Gilly, 2003; Zeithaml et al., 1996).

Findings and Conclusion

MANOVAs were performed to test hypothesis 1 and 2. As hypothesized, results show significant main effect of providing service provider's information and customer review on the three dimensions of online social support (H1). The three variables of Web site evaluation were significantly different across the conditions with two types of quasi social cue, indicating significant main effects of service provider's information and customer reviews (H2). Also, results from a regression analysis revealed that perceived high level of online social support predicts higher Web site evaluation, supporting hypothesis 3. Finally, results of MANCOVA showed the mediating effect of perceived online social support in the social cues-Web site evaluation mechanism, supporting hypothesis 4.

This study examines the impact of quasi social cue in the context of online retailing and its underlying psychological dynamics. The results provide empirical supports to the hypothesized positive link between two common types of quasi social cue and Web site evaluations. In addition, positive mediating effects of online social support are empirically identified, providing a theoretical explanation of online customers' psychological reasons lying underneath the impact. This research contributes to a growing research stream on online retail store environments, by providing empirical supports on the effect of social factors online and new psychological explanations. Findings of the study indicate that social factors are crucial in the context of online retailing as they are in the traditional store atmosphere. Furthermore, findings of this study may present some useful empirical suggestions to managers, regarding how to implement quasi social cue in their Web site environments to provide richer shopping experiences to customers.

Mortality Salience and Brand Attitudes: The Moderating Role of Social Presence

Marieke L. Fransen, University of Amsterdam, The Netherlands

Dirk Smeesters, Erasmus University Rotterdam, The Netherlands

Bob M. Fennis, Utrecht University, The Netherlands

EXTENDED ABSTRACT

The fear of death is so fundamental to human beings that it pervades all aspects of life. People tend to cope with the aversive thought of one's own death in various ways. Several coping strategies have been identified and investigated, including self-esteem striving, in-group affiliations, and self-serving biases (see Pyszczynski et al. 2004 for a review). More recently another domain of human behavior has been added to this list, that of consumer behavior. Several studies have already provided empirical evidence for a relationship between mortality salience and consumer behavior. For example, it has been shown that individuals are more attracted to high status products (Heine, Harihara, and Niiya 2002; Mandel and Heine 1999), show a preference for domestic over foreign products (Fransen, Pruyn, Fennis, and Das 2008; Liu & Smeesters in press), evaluate their financial future more positive (Kasser and Sheldon 2000), intend to purchase and actually eat higher quantities of food products (Mandel and Smeesters 2008), and become more materialistic (Arndt et al. 2004) when they are reminded of their mortality.

The explanation for the relationship between mortality salience and various forms of consumer behavior has mainly been sought in 'distal' defense mechanisms (Terror Management Theory -TMT-; Greenberg, Pyszczynski, and Solomon 1986). These defense mechanisms are aimed at increasing self-esteem levels. Self-esteem is subsequently expected to serve as a buffer against mortality-related anxiety. It has been argued that consumerism and materialism are important values intrinsic to our contemporary western worldview (Arndt et al. 2004). Our current society turned into a consumer society in which the defining activity of individuals is consuming; money and possessions can therefore be seen as measures of self-worth (Bauman 1995). It is argued therefore that people can derive self-esteem by living up to these 'new' culturally valued norms of being wealthy, spending loads of money and live exorbitantly. Living up to these norms provides people with high levels of self-esteem functioning as a buffer against existential threat.

But are these coping strategies invariant across different consumption situations? We argue that they are not. Rather, the present paper will present evidence showing that consumption related terror management strategies are especially likely to unfold when consumption is public, and can be witnessed by others, rather than when consumption is private. More specifically, the present paper investigates the role of social presence in consumer-related mortality salience effects. As mentioned before, TMT states that individuals derive self-esteem from living up to culturally prescribed values and norms because meeting these norms allows people to feel like valuable persons in a valuable society. However, it remains unclear whether one directly derives self-esteem from looking at oneself and knowing that one behaves according to valued norms or that self-esteem is derived more indirectly from the fact that other society members witness how 'correctly' one behaves?

From research on Social Impact Theory (Latané 1981) we know that individuals desire to be viewed in a positive light by others (Baumeister 1982; Frey 1978; Leary and Kowalski 1990; Riordan, James, and Dunaway 2001), and therefore have the tendency to engage in impression management strategies when

other persons are present or only imagined to be present. For instance, consumers are more likely to purchase expensive luxury brands when others are present in a retail environment whereas consumers who are alone in a store opt more often for a cheaper brand (Argo et al. 2005). Consumers seem to be motivated to gain the approval of others, which can be achieved by behaving in ways that are approved within a situation or cultural worldview (Kallgren, Reno, and Cialdini 2000). But why do individuals need social approval? Research on Sociometer theory (e.g., Leary 2003; Leary, Baumeister, and Zanna 2000; Leary, Downs, and Kernis 1995; Leary, Haupt, Strausser, and Chokel 1998) demonstrated that social approval positively affects self-esteem, which according to TMT is essential for dealing with mortality-related thoughts. Therefore, we argue that not only behaving according to cultural norms but also the knowledge that others see and witness one's culturally approved behavior is essential in dealing with existential anxiety. Hence, social presence might be an important factor in explaining mortality salience effects. In accordance with TMT, we propose that individuals derive self-esteem from living up to cultural norms which makes them valuable persons in their society. In extension, we proffer that self-esteem will receive an even greater boost when others (can) witness their socially approved behavior. Hence, based on the notion that social approval leads to enhanced levels of self-esteem (e.g., Leary 2003; Leary, Downs, and Kernis 1995), we expect that people are especially prone to show culturally prescribed behavior (i.e., expressing favorable attitudes towards luxury brands and less favorable attitudes towards non-luxury brands) when other members of their cultural worldview can witness their behavior but less so when others are not present.

The results of Studies 1 and 2 indeed showed that the (imagined) presence of others increased the effects of mortality salience on brand evaluations. Individuals who were reminded of their mortality evaluated luxury brands more positive (Studies 1 and 2) and non-luxury brand more negative (Study 2) under conditions of social approval. This implies that self-esteem receives an extra boost when one knows that others are aware of one's culturally prescribed behavior.

In sum, the present research reveals that mortality salience effects are moderated by social presence in such way that these effects become stronger when people are pointed to the notion that others will observe their behavior. This implies that people experience an extra self-esteem boost when they know that others observe (and approve) their culturally prescribed behavior.

Consumer and Product Face-to-Face: Antecedents and Consequences of Spontaneous Face-Schema Activation

Linda Miesler, University of St. Gallen, Switzerland
Jan R. Landwehr, University of St. Gallen, Switzerland
Andreas Herrmann, University of St. Gallen, Switzerland
Ann L. McGill, University of Chicago, USA

EXTENDED ABSTRACT

The concept of anthropomorphism is gaining in popularity in marketing and product design. Particularly in automotive design, the trend to develop cars whose fronts look like the human face is increasing (e.g., VW Beetle, Mini). But, in striving for product success, whether the mere morphological shape of a product's design is sufficient to activate a human schema is, as yet, an unanswered question. In the context of marketing-mix activities, what specific contribution can anthropomorphic product design make to developing a product's personality? To answer these questions, evidence on the psychological process which underlies anthropomorphizing is needed. Aggarwal and McGill (2007) recently proposed the schema-congruity theory to explain how anthropomorphism works, but their experimental approach left it open if consumers anthropomorphize products spontaneously when they see a human-like product (i.e., according to an automatic bottom-up process) or whether it has to be triggered externally.

In our project, we were particularly interested in the tendency to anthropomorphize products due to their similarity to a human face. We chose real cars as objects of investigation and compared car fronts with car sides, since we assumed that the design of car fronts should resemble a human face, whereas the design of car sides should obviously not. To gain deeper insights into the cognitive mechanisms, we investigated in study 1 whether the activation of a face-schema in memory is an automatic, feature-driven process leading to anthropomorphizing car fronts but not car sides and, in study 2, we examined the effects of anthropomorphizing on explicit product evaluations.

Study 1: To investigate whether a car might be associated spontaneously with a human face solely due to its design features we settled on a lexical decision task (LDT) which was performed by 165 native German speakers. The participants' task was to categorize a target stimulus as a word versus a non-word ignoring a preceding picture prime. For all participants, words stemmed from two categories (face-words vs. car-words). With regard to the preceding picture primes, participants were randomly assigned to one of three priming conditions, so that they were primed either with pictures of cars presented in front view, cars presented in side view, or faces. Latency for participants' lexical decisions was recorded in milliseconds for each trial.

If the mere product design really accounts for the activation of a human schema, different response latencies to face- and car-words between the three priming conditions should occur. We hypothesized that average response patterns in the face condition should be similar to response patterns in the car front condition, but different from response patterns in the car side condition.

As expected, the priming condition (car front, car side, face) interacted significantly with the word target's category (face vs. car) ($F(2,162)=3.28, p=.040$). More precisely, participants who were primed with car fronts responded significantly faster to face-words than to car-words ($t(52)=1.69, p=.050$), whereas participants who were primed with car sides responded significantly faster to car-words than to face-words ($t(46)=-1.87, p=.030$). Further between-group comparisons showed that latency patterns did not differ between the car front and face condition ($t(116)=0.44, p=.660$), but both were significantly different from the car side

condition (face vs. side: $t(110)=-0.20, p=.044$; front vs. side: $t(98)=2.52, p=.013$) which was also congruent with our expectations.

Study 2: The same participants who performed the LDT were asked to rate pictures of cars on different scales (the pictures were identical to the pictures which were used in the LDT as primes). One group of participants rated cars shown in front view, the other group rated cars shown in side view. The scales assessed general marketing variables (e.g., liking, willingness to pay) and specific evaluative tendencies which should go together with anthropomorphizing (e.g., attribution of a human personality to the car). Furthermore, we also assessed the participants' personal disposition to anthropomorphize cars.

We assumed as explicit evaluative consequences of automatic face-schema activation and, therefore, anthropomorphizing that participants should rate car fronts higher than car sides on the anthropomorphism scales and, therefore, car fronts are maybe also evaluated better than car sides with regard to the marketing variables. As ratings on the anthropomorphism-related scales were highly correlated ($r=.74, p<.001$), we created a composite variable, named the anthropomorphism score. Overall, to our surprise, participants did not rate car fronts significantly higher on the anthropomorphism score than car sides ($F(1, 82)=2.45, p=.122$). However, when controlling for a participant's personal disposition to anthropomorphize, we found the expected main effect of the car view on the anthropomorphism score with fronts being more anthropomorphized than sides ($F(5, 71)=8.54, p=.005$). Likewise, participants were willing to pay more for cars seen in front vs. side views ($F(1, 71)=4.55, p=.036$) and general positive affect elicited by cars was higher for front than side views ($F(1, 71)=10.65, p=.002$), when controlling for personal disposition in both analyses.

General discussion: Our results support the assumption that consumers anthropomorphize products spontaneously solely due to anthropomorphic design features and provide insights into the relative priority of anthropomorphic thoughts. Specifically, findings show that car fronts not only bring to mind the human schema more so than car sides bring forth this schema, they bring to mind the human schema more than the actual product category schema. This remarkable, but maybe also non-intuitive effect could be explained by the growing evidence from neuropsychological studies indicating that face-selective responses have very short latencies what makes the processing of faces special compared to the processing of non-face objects (e.g., Farah et al. 1998; Seck and Grüsser 1992). Furthermore, spontaneous anthropomorphizing also seems to affect explicit product evaluations positively under certain conditions, for example, depending on personal variables. Our pattern of results suggests that future research is needed to examine the interplay and relative influence of implicit and explicit anthropomorphic thoughts on consumer behavior.

The Effect of Shipping Fee Structures on Consumer Evaluations of Online Offers

Nevena Koukova, Lehigh University, USA

Joydeep Srivastava, R. H. Smith School of Business, University of Maryland, USA

Martina Steul-Fischer, University of Erlangen-Nuremberg, Germany

EXTENDED ABSTRACT

According to Forrester Research, Inc. the online spending in US was \$141 billion in 2008 and is expected to reach \$156 billion in 2009 (Ranasinghe and Yee 2009). Given the large number of products ordered online, an important decision related to online and catalogue retailing is how to design and communicate shipping fees to potential customers. Shipping fees not only significantly influence order incidence rates and average expenditures (Lewis 2006), but are also considered a major reason for consumers to abandon their shopping cards and discontinue the purchase process (Schindler, Morrin and Bechwati 2005). The purpose of this research is to understand how consumers evaluate and respond to different shipping fee structures.

Online and catalogue retailers have a variety of options with regard to shipping fees. A common practice is to waive shipping fees for orders that reach a specific dollar amount threshold (Lewis, Singh and Fay 2006). For example, Staples and Office Depot offer free delivery for orders above \$50, and The Vitamin Shoppe offers free shipping for orders above \$99. Another commonly used policy is to charge a flat shipping fee independent of order value similar to what Swanson Health Products (\$4.99 for any size order) and Ann Taylor Loft (\$6.00 standard shipping for all orders) are doing. The flat shipping fee could also increase according to a step function as order size increases, for instance \$5.99 for orders below \$25, \$6.99 for orders \$25.01 to \$35.00 and so on. Given the variety of shipping practices in the marketplace and the level of experimentation occurring online (e.g., Amazon.com decreased its free shipping threshold from \$99 to \$25 in 2003, Lewis et al. 2006), there is a need to better understand consumers responses to different shipping fee structures, and provide guidelines to companies on how to communicate them to consumers.

In this paper we systematically investigate how consumers perceive and respond to two common shipping fee structures—flat fee shipping and free shipping threshold. We argue that the flat fee shipping and the free shipping threshold policies differ in the frame of reference from which evaluations and choices are made. Specifically, consumers being charged a flat shipping fee use as a reference point the expected shipping charge, whereas consumers facing a free shipping threshold policy use as a reference point the free shipping offered for orders exceeding the threshold. The flat shipping fee consumers are likely to consider the fee as a transaction cost that every consumer is incurring and evaluate it based on prior experiences and/or knowledge. The free shipping threshold consumers, however, are likely to think of the charge for offers below the threshold as a penalty or loss, and of the (lack of) charge for offers above the threshold as a bonus or quantity discount. Therefore, the two shipping fee structures are predicted to influence offer evaluations differentially based on whether the offer value exceeds the free shipping threshold or not. In addition, we propose that shopping goal concreteness and alternative reference price act as moderators of the effect of shipping fee structure on evaluations and choice.

We test our predictions in a series of three studies. Study 1a demonstrates that consumers evaluate the offer more negatively and are more likely to abort their purchase when a free shipping threshold is provided and they do not cross the threshold compared

to a flat shipping fee. For order values above the free shipping threshold, consumers evaluate the offer more positively and are less likely to abort the purchase when a free shipping threshold is provided compared to a flat shipping fee. Study 1b shows that when the shopping goals are less concrete, consumers evaluate the free shipping threshold offer more positively as compared to a flat shipping rate regardless of offer value. The free shipping threshold also acts as a goal for consumers, motivating them to buy additional product(s) to reach the threshold. Finally, study 2 suggests that the free shipping threshold serves as a reference point, and consumers evaluate the offer relative to this reference point. Importantly, when an alternative reference point is provided, the free shipping threshold does not play a role anymore.

Our results have important implications for the marketing theory and practice. From a theoretical point of view our study provides evidence about the differential effect of flat fee and free shipping threshold policies on evaluations and behavioral intentions, and clarifies the process driving the results. Regarding insights for practitioners, our results suggest that managers may provide alternative reference points to consumers to make free shipping thresholds (and the shipping charges in general) less salient. This motivates consumers to move to higher order values and evaluate the overall offer in a more positive way. When the average order value is below the optimal free shipping threshold, firms are better off by employing a flat fee shipping policy than a free shipping threshold policy.

Adding Promotions to Online Services: How Goal Relevance Ambiguity Shapes Consumer Response

S. Adam Brasel, Boston College, USA

EXTENDED ABSTRACT

Consumer services, from utility bill payments to concert ticket purchases, have increasingly moved online. While online consumer services offer increased convenience for many, there is also increased potential for confusion and service errors in an automated online environment where the traditional face-to-face rules of service do not necessarily apply. In fact, more than 9 out of 10 consumers have experienced online service failure (Deutschkron 2008), and over 80% of consumers are routinely frustrated by their online service experiences. Even given this consumer confusion, online services have begun to explore ways to increase revenue by embedding promotional elements into the service process. For example, concert ticket sites may offer free mp3s, while an address change service may offer moving-related coupons.

This research explores how adding promotional elements to online service transactions creates behavioral and affective responses in consumers, and how the goal-driven nature of online services and the goal-relevance ambiguity of service-embedded promotions drives these consumer reactions. The study shows that promotions within online services achieve higher response rates than identical promotions on other websites, but do so at the cost of consumer confusion, frustration, and anger.

One key difference between traditional web browsing and online service transactions are that service transactions are explicitly goal-driven in nature. Consumers using online services have a clear end-goal in mind for the web interaction, which makes online service transactions a more linear process than more free-form and exploratory traditional web browsing. Goal-directed online behavior appears different from exploratory web behavior (Sánchez-Franco & Roldan 2005), and goals create both cognitive and attentional pressures to focus on goal-relevant information and marginalize goal-irrelevant information (Desimone & Duncan 1995, Allport 1993). Goals also have a powerful impact on felt affect, and goal relevance can guide affect above and beyond contextual, interpersonal, and temporal cues (Fleeson & Cantor 1995).

Individuals use routinized heuristics or schema for navigating the web, generating personal scripts for online behavior. (Calisir & Karaali 2008, Wirth et al 2007) Service transactions also follow generalized scripts, and experienced consumers know the order in which various steps in service transactions will take place (Jenkins, Corritore & Weidenbeck 2003). Disrupting the consumer's script in a goal-directed service transaction by promotion insertions is a more serious issue in comparison to inserting promotions into more free-form web-browsing. In browsing, there is little penalty for delay or changing course through the website. But in a linear service transaction, unexpected elements can cause a consumer's script to 'derail' leading to confusion and frustration (Bessiere et al 2004). Even if the promotional element does not derail the service, it still represents a goal-delaying impediment, and goal-impeding stimuli are a key source of frustration (Lazarus 1991).

This suggests a system of four hypotheses:

1. Promotional messages in online services generate stronger negative affect than promotional messages in other forms of websites.
2. Consumers have difficulty determining the goal-relevance of promotional messages in goal-driven websites.

3. Participation rates will be higher for promotions embedded into online service transactions compared to promotions in other forms of websites.
4. Increased levels of goal-direction in the website create increased levels of negative affect towards promotional messages.

To explore whether consumers comprehend the goal-relevance of online service-embedded promotions and their potential negative affective consequences, an online study examined the insertion of promotions into linear service websites and freeform exploratory websites. The study design compared the effects of promotions in an online service environment (linear transactional) with three other common website styles; storefront (exploratory transactional), local blog (linear informational), and headline news page (exploratory informational). The linear sites contained 6 sequential pages of content, while the exploratory site contained a master page and 18 smaller sub-pages of content. Two versions of each site were created, one with two promotional pages included and one without promotions. 147 participants were randomly assigned to a website and explored it according to instructions. After using the website, a survey was collected where their perceived goal-direction, goal-relevance of the promotions, and negative affect (confusion, frustration, anger, annoyance, and distraction) was measured using various scales.

An ANOVA analysis revealed linear websites and transactional websites generated more goal-direction than exploratory and informational websites, and a significant interaction showed that linear transactional websites, the type of site exemplified by online services, experienced the strongest goal-direction overall. Not surprisingly, sites with promotions present generated more negative affect than sites without promotions, with the strongest negative affect created in the linear transactional service website. Promotions were also seen as highly goal-uncertain, with goal-uncertainty the highest in the service-style linear transactional website condition.

With respect to promotion compliance, linear and transactional sites significantly outperformed exploratory and informational sites. There was also a significant interaction, where the linear transactional service had the highest promotional compliance, over 15% higher than any other condition. This increased compliance comes at an affective cost, however. Interactions reveal that sites with increased goal-direction generate more negative affect when a promotion is inserted; and the highly goal-directed linear transactional service website with promotions generates considerably more confusion, frustration, and anger than its promotion-free counterpart.

In conclusion, online service transactions are linear and goal-directed tasks, and consumers have goal-relevance in mind as they move through the service process. As companies insert promotional elements into online services, there is a large risk of consumer confusion, frustration, and anger. Inserting promotions into online services does generate increased levels of consumer response, but also generates strong negative affect due to consumers having a difficult time discerning the goal-relevance of the promotional stimuli. While initial compliance with service-embedded promotions appears high, this compliance is inflated by consumers agree-

ing to participate for fear of non-compliance generating a service failure. This pattern of results suggests that companies need to be more active in declaring the goal-relevance of their promotions, and should explore new ways to ensure that promotions do not interfere with the service scripts that consumers use to navigate the online service process.

Promotional Bundles and Consumers' Price Judgments: When the Best Things in Life Aren't Free

Michael Kamins, Stony Brook University, USA
Valerie Folkes, University of Southern California, USA
Alexander (Sasha) Fedorikhin, Indiana University, USA

EXTENDED ABSTRACT.

The literature on pricing and promotions suggests that when a "free" product is bundled together with another product and offered for one price, consumers are willing to pay less for the "free" product when it is sold alone (Raghubir 2004). Our research shows that freebie also devalues the focal more expensive product in the bundle. With respect to the bundle as a whole, we show that the freebie devaluation effect does not occur unless the consumer is prompted to think about why a company would offer a product for free or the task is simplified by providing a bundle comprised of two identical items.

Because valuation of a bundle of two disparate products demands cognitive resources and consumers tend to conserve those resources, valuations of bundles with freebies can be similar to valuations of bundles that lack the "freebie" designation.

Our conceptual framework expands on previous pricing research by integrating recent insights about knowledge systems with the principles that the nature of the task and the consumers' cognitive resources influence judgments, and that shifts between knowledge systems are effortful. The valuation task can involve at least two systems of knowledge, a numerical system and an inferential system. Shifts from one system to another are effortful, which favors the numerical system since consumers focus on the numerical system when they need to generate a price. When the judgment task is difficult, consumers tend to conserve mental resources through information selectivity. The valuation of a bundle is more difficult than the valuation for each of the disparate individual products comprising the bundle. Hence, freebies can lower the amount a consumer is willing to pay (WTP) for the individual products comprising the bundle without lowering WTP for the overall bundle price.

Three experiments examined consumers' judgments about WTP for the focal product and for the overall bundle when the bundle included a freebie. The first study was conducted in the field with online auction bidders on eBay. The second and third studies were laboratory experiments that offered a more controlled setting in which to test effects of the free designation when the difficulty in arriving at a WTP judgment varies.

Study 1 conducted in the field showed that the final auction price for the focal product differed depending on the type of bundle sold concurrently. The focal product (the moderately expensive Indian penny coin) sold alone concurrently with a *free* bundle realized a lower price than when sold concurrently with a *non-free* bundle ($M_{\text{free}} = \$3.77$, $SD = 1.49$, $n = 25$, vs. $M_{\text{non-free}} = \$4.67$, $SD = 1.54$, $n = 25$), ($t_{(48)} = 2.09$, $p < .05$). Consistent with our theorizing, there was no difference between the final price realized at the end of the auction in the free versus non-free condition for the mixed bundle ($M_{\text{non-free}} = \$4.47$; $SD = 1.34$; $n = 45$, vs. $M_{\text{free}} = \$4.25$, $SD = 1.73$, $n = 45$, NS).

Study 2 conducted in the lab with shampoo and conditioner used as parts of a mixed bundle manipulated whether or not the supplemental item (conditioner) was free (free vs. no mention of free) and the type of judgment required (price for the focal product from the mixed bundle, price for the mixed bundle, and price for the homogeneous bundle consisting of two bottles of shampoo). The

results show freebie devaluation effect for the focal product and the homogeneous bundle, but not for the mixed bundle, suggesting that WTP for a bundle varies depending on the resources available for making inferences about the free offer. The lack of difference between the mixed bundle prices is consistent with our notion that the cognitive demands of the task deter respondents from taking into account negative inferences when arriving at the total bundle price. When the WTP task itself required fewer resources (e.g., as in a homogeneous bundle), describing one item as free reduced the price respondents were willing to pay for the bundle as a whole.

We conducted Study 3 in the lab with the same stimuli, manipulating motive salience for offering a free product (salience present vs. salience absent), the availability of resources for making judgments (time pressure vs. no time pressure), and the type of judgment required (focal product vs. overall bundle). Only freebie bundles were used in study 3. Consistent with our theorizing, making motives salient had no effect on focal product WTP when time was unlimited ($M_{\text{salience present}} = \2.95 vs. $M_{\text{salience absent}} = \3.03), but resulted in lower WTP when time was limited ($M_{\text{salience present}} = \3.30 vs. $M_{\text{salience absent}} = \4.16). Focal product valuation is a fairly simple task that does not require a lot of cognitive resources. Hence, consumers make inferences about company's motives for the freebie promotion, even when the motive is not made salient. Under time pressure, making the motive salient helps them incorporate it in their WTP.

Unlike focal product conditions, making motives salient lead to lower overall bundle WTP when time was unlimited ($M_{\text{salience present}} = \3.79 vs. $M_{\text{salience absent}} = \4.92). Salience had no effect on WTP when time was limited ($M_{\text{salience present}} = \5.03 vs. $M_{\text{salience absent}} = \4.87). Mixed bundle valuation is a relatively more difficult task, which means that making the motive salient only helps consumer incorporate this knowledge into their WTP if there is no time pressure. Under time pressure, the task becomes simply too difficult, and even making motive for the promotion salient is not sufficient to help consumers incorporate it into their judgments.

Consistent with our reasoning, the number of negative thoughts about the product mediated the effect of the three-way interaction on WTP.

Effects of Confusion on Resistance to Persuasion

Hélène Deval, University of Cincinnati, USA

Bruce E. Pfeiffer, University of New Hampshire, USA

Frank R. Kardes, University of Cincinnati, USA

Edward R. Hirt, Indiana University, Bloomington, USA

Samuel C. Karpen, Indiana University, Bloomington, USA

EXTENDED ABSTRACT

Most theories of persuasion focus on strategies that rely on clear, unambiguous reasoning to achieve compliance (e.g., Cialdini 2001). Hence, the idea of using confusing or negative information to enhance persuasion might seem counterintuitive. Yet, in some circumstances, the use of confusing information (Davis and Knowles 1999; Fennis, Das, and Pruyn 2004; Kardes et al. 2007) or acknowledging negatives (Ward and Brenner 2006) can be effective.

Instead of relying on strong reasoning to encourage compliance, these strategies operate by reducing resistance to persuasion (Knowles and Lin 2004). The Disrupt-Then-Reframe (DTR) technique (Davis and Knowles 1999) demonstrates how introducing a subtle disruption followed by an immediate reframing can increase compliance. Further, Ward and Brenner (2006) found that acknowledging a negative quality led perceivers to evaluate this quality less negatively than if no acknowledgement was provided. In two experiments, we investigate possible extensions and boundary conditions related to resistance to persuasion.

Although the DTR technique has been shown to be quite robust, all prior studies rely on a similar monetary manipulation to enhance persuasion. It still needs to be established if this technique is effective beyond this common manipulation. Experiment 1 used a personal sales simulation to investigate the generalizability of the DTR technique. Video recordings of a sales person describing the superior features of a plasma TV over an LCD TV were used in the simulation.

Participants were asked to imagine that they had planned to buy a new TV and were randomly assigned to one of three conditions: disrupt-then-reframe (DTR), disrupt only, or reframe only. In the DTR condition, participants were presented with technical information about a plasma TV (the disruption) followed by an explanation of the concrete benefits of the TV for the user (the reframe). The disrupt only condition consisted of only the first part of the sales presentation (the technical jargon). The reframe only condition consisted of only the second half of the presentation (the concrete benefits for the user).

Overall, the results replicate previous findings (Davis and Knowles 1999, Kardes et al., 2007) while successfully extending the DTR technique beyond the common monetary manipulation. Participants expressed greater preference for the Plasma TV in the DTR condition than they did in the two other conditions.

Experiment 2 used a technical manual to investigate the effectiveness of negative acknowledgement (Ward and Brenner 2006) while examining individual differences in the Need for Structure (NFS) (Neuberg, Judice, and West 1997) dimension of the Need for Cognitive Closure (NFCC) scale (Webster and Kruglanski 1994) as a potential boundary condition. It was predicted that the effects of negative acknowledgement may involve epistemic freezing on the acknowledgement.

Participants were asked to examine a technical manual about the features and installation of a digital sound system projector. The negative acknowledgement condition included a comment acknowledging some negative qualities of the manual (technical and confusing). In the control condition, participants only received a

small set of instructions describing the task. In addition to these two conditions, a mumble condition, that was not present in Ward and Brenner (2006), was included. It was adapted from Erikson (1964) and was designed to confuse the participants (similar to the disrupt only condition of experiment 1).

As expected, while the negative acknowledgement condition resulted in the highest product evaluations, the mumble condition behaved similarly to the disrupt only condition in experiment 1. It led to increased confusion resulting in the poorest product evaluations. Further, only individuals high in NFS were sensitive to the use of negative acknowledgement. This seems to indicate that negative acknowledgement works as a heuristic and that careful processing limits its effectiveness.

Again, although much of the research on persuasion focuses on strategies that rely on clear, unambiguous reasoning to achieve compliance, other methods focusing on reducing resistance to persuasion are also effective. Both of these experiments illustrate how the use of confusing information can be beneficial to persuasion. The DTR technique and negative acknowledgment leverage the persuasive power of what would usually be considered detrimental information.

Negative Effects of Event Sponsoring and Ambushing: The Case of Consumer Confusion

Manuela Sachse, Chemnitz University of Technology, Germany

Jan Drengner, Chemnitz University of Technology, Germany

Steffen Jahn, Chemnitz University of Technology, Germany

EXTENDED ABSTRACT

Event sponsorship is one important marketing tool for companies to favorably influence brand awareness, attitudes or purchase intention. Since numerous sponsors use different leveraging techniques to promote their event engagement, these companies create a cluttered environment (Cornwell et al. 2000; Séguin and O'Reilly 2008). In the case of major events, this effect will be increased by several ambushers that actively try to confuse people about who is official sponsor of an event and who is not (Dalakas, Madrigal, and Burton 2004). As a result, memory for sponsors might be reduced, diminishing the goal of awareness enhancement (Cornwell et al. 2006; Johar and Pham 1999). Such a consumer failure to develop a correct interpretation of various facets of a stimulus during the information processing procedure has been described as consumer confusion (Turnbull, Leek, and Ying 2000). The aim of the present study is to develop a theoretically sound conceptualization of consumer confusion and relate it to dark-side effects of sponsorship.

Drawing on Turnbull et al. (2000), we define consumer confusion as interfered information processing which impedes consumers' ability to select and interpret relevant stimuli. We argue that this 'core' of the construct should be separated from the following antecedents (Mitchell and Papavassiliou 1999; Mitchell, Walsh and Yamin 2005):

- Perceived stimuli overload, resulting from the accumulated effects of many messages by a large number of sponsors and ambushers during an event.
- Perceived stimuli similarity, evolving from sponsors' and ambushers' similar communication content and formal similarity (e.g., slogan, pictures), especially in situations of high similarity of the advertised products.
- Perceived stimuli ambiguity as ambiguous, misleading, inadequate, and conflicting information, reflecting a typical side effect in information-rich environments (e.g., different sponsor categories during mega sports events).

Consequently, we derive a first set of hypotheses to test this conceptualization.

H1a: The higher the stimuli ambiguity, the higher the consumer confusion.

H1b: The higher the stimuli similarity, the higher the consumer confusion.

H1c: The higher the stimuli overload, the higher the consumer confusion.

According to Bijmolt et al. (1998), we argue that the quantitative overload is upstream of the antecedents that refer to qualitative stimuli (i.e., ambiguity, similarity).

H2a: The higher the stimuli overload, the higher the stimuli ambiguity.

H2b: The higher the stimuli overload, the higher the stimuli similarity.

Since sponsorship aims at influencing brand awareness (Johar and Pham 1999), the following hypotheses link consumer confusion with this outcome (Mitchell and Papavassiliou 1999).

H3a: The higher the consumer confusion, the less the correct classification (recall) of sponsoring brands as sponsors.

H3b: The higher the consumer confusion, the higher the misclassification of ambushing brands as sponsors.

Besides multiple sponsorships and ambusher activities, danger of mix-ups exists with regard to brands that have been sponsors of similar events. In such situations, retrieval of the correct sponsor is more difficult (Cornwell et al. 2006). We suppose that due to carryover effects the 'other-event sponsors' are perceived as being official sponsors.

H3c: The higher the consumer confusion, the higher the misclassification of other-event sponsors as sponsors.

In addition to memory interference, research shows that consumers feel annoyed by confusion (Dalakas et al. 2004). Annoyance, in turn, is likely to influence the attitude toward the company's sponsorship activities.

H4: The higher the consumer confusion, the more negative the attitude toward the sponsorship.

A further reaction could be opposite buying behavior to punish companies using the event for their communication (Séguin and O'Reilly 2008). Such opposite behavior might be expressed by so-called reactant behavioral intentions (Brehm and Brehm 1981).

H5: The higher the consumer confusion, the stronger the reactant behavioral intention.

Furthermore, research indicates that attitude toward sponsorship positively affects the purchase of sponsors' products (Madrigal 2001). Hence, negative attitudes should lead to reactant intentions.

H6: The more negative the attitude toward the sponsorship, the stronger the reactant behavioral intentions.

To test the new conceptualization, 465 German participants completed an online survey during UEFA EURO 2008 ($M=25.4$ years, 44.3% female). We measured confusion, overload, ambiguity, and similarity with items generated by two focus group discussions and two quantitative pretests. Measuring attitude toward the sponsorship and reactant intentions, we modified existing scales (Hong and Page 1989; MacKenzie and Lutz 1989). Awareness was measured by aided recall. The list for this task included 11 main sponsors (42.45% correctly identified as sponsors), 11 ambushers (93.0% correctly rejected as sponsors), 4 brands that were sponsors of the FIFA Soccer World Cup 2006 (89.5% rejected), and 5 foils (96.4% rejected). That the five foils were detected as non-sponsors by almost all respondents implies that respondents were not lead astray.

Using structural equation modeling (LISREL 8) to test the hypotheses, the measurement models exhibit high reliability, convergent and discriminant validity (Fornell and Larcker 1981). Fit indexes ($\chi^2(181)=457.74$, $p<.01$; $RMSEA=.057$; $CFI=.97$, and $NNFI=.96$) suggest that the hypothesized model fits the data well.

All but two hypotheses are supported. Consumer confusion is influenced by ambiguity (H1a; .56), but not similarity (H1b; .05) and overload (H1c; .08). Perceived stimuli overload impacts on both ambiguity (H2a; .38) and similarity (H2b; .68). Consumer confusion reduces memory for sponsors (H3a; -.41) and increases the likelihood that ambushers (H3b; .10) and other-event sponsors (H3c; .11) are perceived as official sponsors. Furthermore, confused consumers have a worse attitude toward the sponsorship engagement (H4; -.13) and show reactant intentions (H5; .15). Reactant intentions are higher the more negative the attitude toward the sponsorship (H6; -.43).

Concluding, we show that confused consumers have less memory of sponsors and are more likely to perceive ambushers and sponsors of other events as official sponsors. The most influential antecedent of consumer confusion is perceived stimuli ambiguity, which in turn is influenced by perceived stimuli overload. Thus, it is the combination of multiple sponsorships and ambusher activities that confuses consumers. Furthermore, we provide evidence that high levels of confusion negatively impact on the attitude toward the sponsorship and evoke reactant intentions. Ironically, this effect particularly impacts both sponsors and ambushers which were successful in linking their companies or brands to the event.

Determinants of Sponsorship Fit: A Multilevel Analysis

David M. Woisetschläger, TU Dortmund University, Germany
Christof Backhaus, TU Dortmund University, Germany
Heiner Evanschitzky, Strathclyde University, Scotland, UK
Manuel Michaelis, TU Dortmund University, Germany

EXTENDED ABSTRACT

Sponsorship fit is frequently mentioned and empirically examined as a success factor of sponsorship (e.g. Becker-Olsen and Hill 2006; Cornwell, Weeks, and Roy 2005; Simmons and Becker-Olsen 2006; Speed and Thompson 2000). Sponsors that are perceived as congruent with the sponsored object have been found to benefit more from their sponsorship engagements in terms of increasing brand equity (Becker-Olsen and Hill 2006; Gwinner and Eaton 1999; Simmons and Becker-Olsen 2006) and purchase intentions (Speed and Thompson 2000) than incongruent sponsors. From a theoretical point of view, a low sponsorship fit is equivalent to incongruence between sponsor and sponsored object. Such incongruence causes psychological tensions in the consumer's mind and forces to reestablish congruence (Festinger 1957). Hence, a perceived miss-fit is often related to a negative evaluation of the sponsor, and, therefore causes lower brand equity and purchase intentions.

While sponsorship fit has been considered as a determinant of sponsorship success, little knowledge exists about the antecedents of sponsorship fit. Commonly, sponsorship fit is conceptualized as "fit in a general sense" (e.g., Speed and Thompson 2000). From a managerial point of view and especially for sponsors that are in a particular situation of low fit, identifying antecedents of (in)congruence is highly relevant for improving the effectiveness of sponsorships. On the one hand, sponsorship fit can be seen as a result of a cognitive process including different antecedents which is different for each individual. On the other hand, sponsorship fit is likely to be different between brands, i.e. the group level as a result of different sponsorship policies and other influencing factors. While previous research provides insights on individual drivers of sponsorship fit, explaining differences resulting from varying sponsorship policies (i.e., sponsorship deal characteristics) is mentioned as a noteworthy area of research (Cornwell 2008).

Hence, the present paper contributes to the literature by examining the individual and sponsor-level antecedents of sponsorship fit. To test our hypotheses, we draw on (1) a sample of 1,579 soccer fans from 18 clubs of the first German league to obtain individual drivers of sponsorship fit and (2) objective characteristics of the shirt sponsorship deals of these clubs to explain between-group differences. Given the hierarchical structure of the data, hierarchical linear modelling (HLM) is an adequate method for analysis and hence applied in this study.

Individual Fan Perceptions as Determinants of Sponsorship Fit

Several factors have been mentioned in previous studies that are proposed to contribute positively to sponsorship fit or sponsorship related outcomes. Functional similarity (Gwinner and Eaton 1999), relatedness to the sponsored activity, perceived benefits of the partnership (Woisetschläger and Haselhoff 2009), regional identification of the sponsor (Woisetschläger and Haselhoff 2009), the sponsors sincerity (Speed and Thompson 2000), dominance in the partnership, and the ubiquity of the sponsorship (Speed and Thompson 2000) are potential determinants of sponsorship fit.

Sponsorship Characteristics as Determinants of Sponsorship Fit

Besides determinants of sponsorship fit that are perceived differently by individual fans, characteristics of the sponsorship partnership are proposed to affect sponsorship fit. Typically, sponsorship contracts can be characterized by the contract value (i.e., the amount paid by the sponsor per year), and the duration of the contract. These objective measures indicate the firm's commitment (Farrelly and Quester 2005) in terms of budget and timeline. Differences in contract value and contract length are expected to partially explain differences of the level of sponsorship fit over different sponsor-partnerships.

Methodology

Sample. To test the hypotheses, consumer-level data was collected via an internet survey among fans of the 18 clubs of the first German soccer league. A total of 1,579 respondents participated in the survey and fully answered all questions.

Measures. Our study comprises two levels of analysis: the individual fan-level and the sponsor-level. All measures are adapted from the literature. Sponsorship fit is measured with seven items using the scale employed by Simmons and Becker-Olsen (2006). Items to measure functional similarity are taken from Gwinner and Eaton (1999). Relatedness to the sponsored activity is operationalized using items by Speed and Thompson (2000). Scales to measure perceived benefits and regional identification of the sponsor are adopted from Woisetschläger and Haselhoff (2009). Sincerity and ubiquity of the sponsor are measured with items from Speed and Thompson (2000). Situation specific reactance (Wendlandt and Schrader 2007) is adopted to measure the degree of sponsor dominance.

On the second level (sponsor-level), we measure key characteristics of the sponsor partnerships from secondary sources. More specifically, contract value is measured by the total yearly amount spent by a particular firm for the actual sponsorship contract. Past contract length is measured by the number of years that a particular firm has been a sponsor of the particular club. Future contract length is the contract duration in number of years starting from today.

Results, Implications, and Future Research

Our findings reveal that, on the individual fan level, perceived benefits are the strongest determinant of sponsorship fit. Sponsors should therefore actively communicate the benefits of their engagement. Regional identification is also an important antecedent of sponsorship fit. Firms that show their belongingness to the region of the club are perceived as in-group members, and therefore as congruent to the club. Perceived sincerity of the sponsor is also a positive determinant of sponsorship fit. Therefore, firms should communicate that they are reliable partners of the particular club but should avoid to be perceived as a dominator of the club. Relatedness to other sports activities is also positively contributing to sponsorship fit. Contrary to our propositions, functional similarity and perceived ubiquity are not significantly related to sponsor-

ship fit. The individual-level determinants explain about 45 % of the variance in sponsorship fit.

On a sponsor-level, results show that past and future contract lengths contribute positively to sponsorship fit and explain 41 % of the variance between the 18 groups. Sponsors that strive for short-term impact are evaluated less favorable. Contrary to our expectations, contract value is not significantly related to sponsorship fit. Hence, firms should invest in long-term sponsorship relations instead of spending more of their budget over a shorter time period.

The model is limited to a few—yet central—proxy variables to characterize sponsorship deals. Results show that a good part of the variance of sponsorship fit between the 18 sponsor partnerships is explained by these variables. The remaining part could be explained by including additional variables that characterize sponsorship deals and the nature of the sponsoring brand.

Sport Sponsorship Effects on Spectators' Consideration Sets: Impact With and Without Brand-event Link Recognition

Jean-Luc Herrmann, Paul Verlaine Metz University CEREFIGE, France
Björn Walliser, Nancy University CEREFIGE, France
Mathieu Kacha, Paul Verlaine Metz University CEREFIGE, France

EXTENDED ABSTRACT

Sponsorship effectiveness' evaluation relies heavily and mainly on recall and recognition tests (Cornwell, Weeks, and Roy 2005; Walliser, 2003). The legitimacy of these tests lies in the assumption that brand-event recognition is a necessary condition for sponsorship success (Sandler and Shani 1989). Such an assumption can however be challenged on at least two points. First, sponsorship messages can be considered peripheral elements (Ydewalle and Tasmin 1993) for the spectator and may not be retrievable during a direct memory search (Shapiro, MacInnis, and Heckler 1997). Second, recall and recognition tests focus more on the control of the brand-event association, than on the perception of the sponsor brand per se (Holden and Vanhuele 1999).

Authors investigating incidental exposure effects in marketing (Acar 2007; Holden and Vanhuele 1999; Janiszewski 1988) postulate that the effect of exposure without memory of the exposure itself operates through familiarity or perceptual fluency. Among the effects that appear to be mediated by perceptual fluency or familiarity, the mere exposure effect indicates that repeated exposure to a stimulus increases stimulus' likability even in the absence of stimulus' recognition (Zajonc 1968). Fang, Singh, and Ahluwalia (2007) consider affect as a key process underlying the mere exposure effect and deduct a strengthening of these effects under resource-constrained decision-making situations characterizing many marketplace environments. It is thus expected that spectator exposure to a sponsor brand during an event increases the likelihood of the brand to be included in the spectator's stimulus-based consideration set, even if the spectator does not recognize the brand as sponsor (H1).

Stipulating a non-conscious sponsor effect does not exclude the existence of a conscious sponsorship effect which may become manifest in the spectator's ability to recognize the sponsor brand. Most major concepts and mechanisms identified in the literature to explain sponsorship effects (Cornwell et al., 2005)—such as for example perceived congruency and its articulation to “create fit” (Becker-Olsen and Simmons 2002), Heider's balance theory (1958), meaning transfer (McCracken 1989), social identification (Gwinners and Swanson 2003), and attribution theory (Dean 2002; Rifon, Choi, and Trimble 2004)—rely on the consciousness of the brand-event link. Even if sponsorship is characterized by numerous incidental exposure occasions, there are moments when the spectator is less absorbed by the “primary task”. An arrival on site before the (sport) action starts as well as interruptions at halftime are examples of occasions favouring the unconsciousness and a semantic processing of the brand-event link. It is thus expected that spectator exposure to a sponsor brand during an event increases the likelihood of the brand to be included in the spectator's stimulus-based consideration set, through the recognition of the brand as sponsor (H2).

Data collection took place over four days of a one-week international tennis tournament. Face-to-face interviews were conducted before the spectators entered the stadium (control group) as well as inside the arena after spectators had assisted to one or several matches (experimental group). No significant differences between both groups are observed.

In order to determine the stimulus-based consideration set, respondents were given a list of 16 brand/company names within the target product category, including the sponsor name (Shapiro et al. 1997), and were asked which of these brands/companies they would consider for personal use or recommend to a friend. Subsequently, sponsor recognition was tested on a list of 16 brands including four “dummy” brands.

Following a series of successive (logistic) regressions analyses recommended to test for the existence of mediating effects (Baron and Kenny 1986), a significant positive effect of exposure (Expo) on the target brand's likelihood (Cset) to be included in the consideration set ($p=.02$, odds ratio $\text{Exp}(\beta)=3.6$), as well as on the presumed mediator process ($p=.002$) are observed. Exposure simultaneously multiplies the likelihood of the target brand to be included in the stimulus-based consideration set by a factor close to 3.5 and the chances to recognize the sponsor brand by a factor greater than five.

The presumed mediating variable Reco (recognition) is found to have a significant influence ($p<.001$, odds ratio $\text{Exp}(\beta)=6.4$) on the variable Cset when controlling for the influence of exposure. Thus, the target brand's recognition appears to mediate the influence of exposure on the target brand's likelihood to be included in the stimulus-based consideration set, supporting H2. Concerning the partial vs. complete mediation test, a significant positive effect ($p=.029$) of brand exposure on the likelihood of the sponsor brand to be included in the consideration set is observed if the sponsor brand is not recognized. Compared to the control group, the likelihood for the sponsor brand to be part of the consideration set under conditions of exposure without recognition is multiplied by a factor greater than four, supporting H1.

A dual route of sponsorship impact seems to exist. Sponsorship increases the chances of a brand to be part of the stimulus-based consideration set of spectators, both for persons conscious and unconscious about the brand-event link. Since most previous studies on sponsorship effectiveness concentrated on conscious effects only, sponsorship impact may have been underestimated in the past. In advertising, improved perceptual fluidity of brands as a consequence of increased (unconscious) exposure is found to positively influence stimulus-based brand choice (Lee 2002). If the same was true for sponsorship, sponsors whose products or services are typically chosen based on cues available in the physical purchase environment (Reilly and Parkinson 1985) would greatly benefit from their sponsorship investment. Furthermore, the results of this study call for a change of sponsorship measurement approaches. If conscious and unconscious sponsorship effects occur simultaneously, both have to be taken into account.

Affect-Gating

Dan King, University of Florida, USA
Chris Janiszewski, University of Florida, USA

EXTENDED ABSTRACT

Extant theories of affective networks (e.g., Bower 1981) assume that affect is a unitary construct. This article integrates emerging findings in the neuroscience literature to show that there are, in fact, two major types of affect: *state* affect and *hedonic* affect (Barbano and Cador 2007), and that state affect can influence the experience of hedonic affect in surprising ways. First, positive affect can come in the form of positive *state* affect and positive *hedonic* affect. Positive *state* affect is mediated by dopaminergic activation and generates a light, airy feeling that makes people feel upbeat (Sacks et al. 1972). In contrast, positive *hedonic* affect is mediated by opioidergic activation and generates a pleasurable feeling that causes people to like a specific stimulus (Pecina, Smith, and Berridge 2006). Similarly, negative affect can come in the form of negative *state* affect and negative *hedonic* affect. Negative *state* affect is mediated by corticotrophin-releasing factor (CRF), and generates a heavy feeling that makes people feel downcast (Panksepp 1998). In contrast, negative *hedonic* affect is mediated by inhibition of orbitofrontal cortex firing, and generates a feeling of satiation or even aversion for the stimulus (Rolls 2004, 2005). Because there is significant pathway interaction in the affective circuits for both types of affect, state affect can influence the experience of hedonic affect in surprising ways. Negative *state* affect, for example, can lead to more intense positive hedonic affect, leading to a result that is surprising from the standpoint of mood-congruent models of affective influence on perception (e.g., Bower 1981; Isen 1989). Likewise, positive *state* affect can lead to less intense positive hedonic affect.

Animal research in mammals (who share a similar neural architecture with humans in terms of affective circuits) suggests how state affect can influence hedonic affect. Neurological research demonstrates that organisms are more attuned to different sensory channels during different affective states (Martel et al. 1993). In the process of natural selection (Darwin 1859), the relative value of information in different sensory channels changes as a function of the affective state. For example, mammals under negative affect are more attuned to tactile stimulation, because negative affect indicates separation from the mother, and tactile stimulation indicates reunion with the mother (Keverne, Martensz, and Tuite 1989). In contrast, mammals under positive affect are more attuned to visual stimulation, because positive affect indicates self-sufficiency and the organism's ability to search for rewards (Panksepp 1998). Affective states thus perform a gating function for the sensory-perceptual system (hence "Affect Gating"), in which information from different sensory channels are overweighted or underweighted as a function of the affective state. Marketers who understand the affective gating process will thus benefit from knowing which attributes to focus on for particular product categories and segments. Consumers who are using a product to comfort themselves (e.g., lotions, comfort food) will be more sensitive to tactile information, whereas consumers who are using a product to celebrate will be more sensitive to visual information.

Experiment 1 suggests that consumers are more attuned to tactile attributes of a product during a negative affective state. Consumers under negative affect generated more perceptions of the lotion's tactile qualities, such as its creaminess and moisturizing properties. In contrast, consumers under positive affect generated more perceptions of the lotion's visual qualities, such as its blue

color. Experiment 2 suggests that consumers under negative affect were more attuned to the product's tactile qualities, and experienced more hedonic pleasure, than consumers under positive and neutral affect. Mediation analyses suggest that greater attunement to tactile qualities led to hypervaluation of the product (greater willingness-to-pay). Experiment 3 suggests that consumers under negative affect were more sensitive to changes in the veridical tactile quality of the product, whereas consumers under positive and neutral affect could not perceive changes in tactile quality. Experiment 4 aims to show that blocking the visual channel amplifies the information coursing through the tactile channel, hence amplifying the hedonic experience for consumers in negative affect. This may explain the phenomenon of why people close their eyes when they receive a massage. Experiment 5 shows that negative affect induces a physiological response of coldness (to induce organisms to seek social support under negative states), and experiment 6 shows that adding warming agents to lotions amplifies the tactile experience, hence improving the hedonic experience of consumers under negative affect. The article discusses conceptual implications of the "two affects" view and the gating process.

Differential Reliance on Feelings in the Present vs. the Future (or Past): Affect as a Decision Making System of the Present

Hannah H. Chang, Singapore Management University, Singapore
Michel Tuan Pham, Columbia University, USA

EXTENDED ABSTRACT

Consumer judgments and decisions can be made either in a more cognitive, reason-based manner (by assessing, weighing, and combining attribute information into an overall evaluative judgment) or in a more affective, feeling-based manner (by inspecting one's momentary feelings toward the options). An emerging body of evidence suggests that the two modes of judgment and decision may tap into two separate systems: a reason-based, analytical system and a feeling-based affective system. However, the conditions under which either system dominates are still unclear.

The present research suggests that, everything else equal, the affective, feeling-based system is more likely to be engaged in judgments and decisions that are set in the present than in similar judgments and decisions that are set in the future or in the past. This broad proposition generalizes the established finding that compared to reason-based decisions, affect-based decisions tend to be more myopic (Loewenstein 1996; Metcalfe and Mischel 1999; Ariely and Loewenstein 2006). Previous explanations of this myopia have focused on the differential accessibility of affective feelings across time perspectives. Because the immediate feelings that one experiences in relation to a present stimulus are more accessible than those that one can only imagine in relation to a future state of the world, the reliance on feelings in judgments and decisions steers preferences toward myopic options that are immediately rewarding compared to farsighted options that are superior in the long-run (e.g., Mischel et al. 1989; Loewenstein 1996; Metcalfe and Mischel 1999; Shiv and Fedorikhin 1999; Loewenstein et al. 2001).

We agree that the differential accessibility of feelings is a major contributor to the myopic tendencies of affect-based decisions. However, we suggest that this phenomenon is only one facet of a more general property of the affective system. We propose that the affective system is inherently a decision-making system of the present (Pham 2004; 2007). We derive this proposition from the rationale that, as a remnant of our distant evolutionary past (Epstein 1994; Lieberman et al. 2002), the affective system was originally meant to guide behavioral choices that our ancestors faced in their immediate (i.e., present) environment (see Cosmides and Tooby 2000, Pham 2007). Because of its original emphasis on immediate behavioral choices, the affective system has retained a distinctive orientation toward the present. Our general thesis is thus that the entire affective system of decision-making is more likely to be engaged in judgments and decisions that are set in the present than in similar judgments and decisions that are set in a more distant time, whether in the future or in the past.

As an initial test of this general proposition, the present set of studies tests the more specific hypothesis that, holding accessibility of feelings constant, affective feelings are weighted more heavily in consumers' judgments and decisions that are set in the present than in equivalent judgments and decisions that are set in the future or in the past. The effect of time perspectives on consumers' reliance on the feeling-based vs. reason-based system in judgment and decision making was tested in three separate marketing contexts, including apartment choices, video game evaluations, and evaluations of past vacations. In the first experiment, we demonstrate that—when given a choice between two apartments, one that is superior on the affective dimensions (e.g., breathtaking views) and

one that is superior on the cognitive dimensions (e.g., bigger rooms)—consumers deciding for the immediate future tend to choose the apartment that is superior on the affective characteristics, whereas consumers deciding for the distant future tend to choose the apartment that is superior on the cognitive characteristics. To further demonstrate that consumers are more likely to use their feelings as inputs in deciding about present events rather than about distant events, we show in Experiment 2 that consumers' incidental moods (positive vs. negative) are more likely to influence their decisions to rent a particular apartment when these decisions are imminent than when the same decisions are remote. Hence, even though their incidental feelings were equally accessible, consumers are more likely to use their feelings as information under a present orientation than a future orientation.

Providing more process-related evidence, Experiment 3 shows that consumers find the reliance on feelings (as opposed to reasons) more "natural" in decisions set in a near future than in decisions set in a more distant future. These three experiments thus far have focused on contrasting the influence of feelings on decisions for the present vs. for the future. In the fourth and fifth studies, we also demonstrate that consumers are more likely to rely on their feelings in their evaluation for video games and their evaluation of past vacation when prompted to think about the recent past than about the distant past. Specifically, in Experiment 4, we conceptually replicated Experiment 2 using past perspectives—we show that consumers' incidental moods (positive vs. negative) are more likely to influence their evaluations of video games when these games were produced recently than when the same games were produced in the distant past. In Experiment 5, we found that students' incidental moods were also more likely to influence their evaluations of a recent spring break (recent past) than evaluations of spring break two years ago (distant past). Importantly, results from these studies emerge holding the affective experience constant and outside of the delay of gratification and self-control domains.

These findings suggest that—given two systems available for decision making—consumers seem to shift the relative weights they place on their affective vs. cognitive systems in assessing value in judgments and decisions, using their feelings selectively depending on the time perspectives. In another related work, we examine indirectly the relative engagement of the affective system under present orientation through a well-known characteristic of the affective system in valuation—the scope-insensitivity bias—in the context of charitable donation, willingness-to-pay for music CDs, and evaluations of past video games. This finding is further evidence that affect is inherently a decision-making system of the present.

Negative Affect and Choice: The Moderating Effect of Procedural and Outcome Accountability

Nitika Garg, University of Mississippi, USA

Vikas Mittal, Rice University, USA

J. Jeffrey Inman, University of Pittsburgh, USA

EXTENDED ABSTRACT

Negative affect in decision making has captured the interest of researchers for quite some time in both psychology and marketing. Incidental affect, also known as ambient affect, is affect that a consumer may imbue from her environment in isolation to the decision on hand. More recently, the focus has shifted away from simple emotion valence (positive, negative) to more specific, discrete affective states such as sadness, anger and fear (Desteno et al. 2000; Lerner and Keltner 2000, 2001; Tiedens and Linton 2001; Raghunathan and Pham 1999). Researchers have found differences not only between negative and positive affect but also between different discrete emotions having the same valence (e.g., anger/sadness, pride/happiness). Lerner and Keltner (2000, 2001) proposed the 'appraisal-tendency' approach, which hypothesizes that 'each emotion activates a predisposition to appraise future events in line with the central appraisal dimension that triggers the emotion'. For example, they find that fearful people make pessimistic risk assessments and future events judgments whereas angry people make optimistic assessments in the same scenarios.

Research has also shown that while incidental affect influences many aspects of judgment and decision making, there are moderating factors that successfully attenuate the effect of emotions. For example, Desteno et al. (2000) find that making subjects aware of the source of their affect wipes out the influence of affect. Another factor that has been consistently shown to moderate the effect of emotions is accountability. Accountability refers to the implicit or explicit expectation that one may be called on to justify one's beliefs, feelings and/or actions to others (Lerner and Tetlock 1999). Past research has shown that increasing the level of accountability makes the decision process more elaborate and effortful (Chaiken 1980; Thompson et al. 1994). It has also been found to lead to attenuation of the effect of incidental emotions on unrelated judgments (Bodenhausen, Kramer and Susser 1994; Lerner, Goldberg and Tetlock 1998). Lerner et al. (1998) found that the tendency of anger to elicit punitive attributions of responsibility was reduced when subjects were accountable. However, more recent research in accountability has revealed that there are two forms of accountability—process and outcome based—that can have differential influence on decision making (Simonson and Staw 1992; Zhang and Mittal 2005). Under process accountability (PA) decision makers are accountable for the procedure used to arrive at a decision whereas under outcome accountability (OA) they are accountable only for the quality of the outcome, with no evaluation of their decision process (Escalas and Luce 2004). This research also shows that PA and OA differentially influence the perceived difficulty of a decision and that decision biases are relatively lower under PA than under OA. However, the few empirical studies comparing PA and OA have not examined how the influence of a contextual factor such as incidental affect on consumer choice is moderated by these two types of accountability.

The objective of this research then, is to examine the interactive effect of incidental negative affect with the accountability degree (low vs. high) and type (PA vs. OA). Specifically, we examine the differential impact of two discrete, negative emotions—anger and fear—on consumer choice with accountability degree (study 1) and type (study 2) as the moderating factors. We hypoth-

esize that consumers experiencing different negative emotions will display differential reliance on the avoidance choice strategies such as delaying the decision, and that this effect will be moderated by accountability. Our reasoning for the above hypothesis is that anger versus fear differentially impacts subject's degree of certainty. Previous research has shown anger to have a higher degree of certainty associated with it as compared to fear (Smith and Ellsworth 1985). Garg, Inman and Mittal (2005) have further, shown that this difference in certainty can lead to angry individuals choosing the avoidance option more than sad (fear is close to sad in terms of 'certainty') individuals when faced with a difficult decision. On the other hand, we predict that fearful individuals should exhibit similar choice patterns under both types of accountability and under low versus high accountability as their lack of certainty should lead them to make the decision more deliberately, irrespective of the accountability degree and type.

Study 1 finds that making people accountable for their decision (i.e., manipulating degree) actually amplifies the decision bias in angry condition which results in angry individuals choosing to defer choice, an avoidance response. As expected, fearful individuals do not exhibit any difference in avoidance choice across the two accountability conditions. Study 2 manipulates accountability type. We expect that under OA which has higher perceived difficulty (Zhang and Mittal 2005), angry individuals will choose the avoidance option more than fearful or neutral individuals will and also, more than angry individuals will under PA. Thus, we predict that unlike OA, PA will negate the influence of incidental affect on choice and lead to more balanced choice process, highlighting the differences across the two types of accountability.

Study 2 supports these predictions. The two studies together, highlight an interesting insight into the nature of accountability—accountability degree implicitly manipulates outcome accountability. That is, when no accountability type is specified, accountable people assume outcome accountability. This is evident when we compare results for high accountability and those for OA across Study 1 and 2. The final study (study 3) seeks to not only replicate the results from Study 2 but also, examine the role of optimism in so far, as emotions with varying levels of certainty are linked to differential levels of optimism (Lerner and Keltner 2001). Examining optimism should provide a greater understanding of the underlying mechanisms that might be implicated in this phenomenon. The implications of the findings for academics as well as managers, are discussed.

Pride: A License to Indulge or a Cue for Greater Self-Control?

Keith Wilcox, Babson College, USA
Thomas Kramer, Baruch College, CUNY, USA
Sankar Sen, Baruch College, CUNY, USA

EXTENDED ABSTRACT

Consumers frequently face choices in which personal goals of long-term importance conflict with indulgent pursuits that are inconsistent with their long-term objectives. When faced with such decisions, most consumers try to exercise self-control, but they often fail and make indulgent choices that undermine their long-term goals. Recent research has linked emotions to indulgence. However, much of this research has focused on the effect of incidental happiness (versus sadness) on consumption (Garg et al. 2007). Thus, we know very little about how other incidental positive emotions, such as pride, affect consumers' long-term goal pursuit and their preference for indulgent options that undermine such goals.

When consumers face indulgent decisions, self-regulatory processes facilitate their ability to act in accordance with their long-term goals (Baumeister 2002). A central component of successful self-regulation is that the person must have the capacity to monitor her behavior to ensure that it is consistent with her goal. Carver and Scheier (1998) propose that when people are consciously monitoring their behavior relative to a goal, negative emotions signal goal failure, which leads them to try harder to reach their goal. Positive emotions, however, signal goal attainment, which licenses them to reduce subsequent effort in the domain.

Interestingly, this suggests that positive emotions may reduce a person's effort toward a long-term goal, which, in turn, should increase his or her preference for indulgent options that undermine such goals. Yet, this appears counter to what we already know about the motivational properties of emotions since happiness has been shown to reduce indulgent behavior compared to sadness (Garg et al. 2007). We suggest, however, that because pride is experienced in response to the successful pursuit of long-term goals, upon experiencing pride, consumers are likely to infer that they have achieved or have made satisfactory progress toward a long-term goal. Consequently, when consumers face an indulgent choice and they begin to monitor their behavior relative to a long-term goal, they should misattribute the experience of pride as having temporarily satisfied the goal, which, in turn, should license indulgence.

Recent evidence suggests that specific emotions may also influence goal pursuit beyond that of the information providing during the monitoring process. When individuals experience an emotion or are primed with an emotion, it activates cognitions and action tendencies that are linked to that emotion in memory (Lang et al. 1998). These concepts can lead individuals to perform emotion appropriate behavior (Zemack-Rugar et al. 2006). Because pride is experienced in response to the achievement of long-term goals, it is linked in memory to cognitions associated with the successful pursuit of long-term goals (Eyal and Fishbach 2009). Thus, the experience of pride should activate these concepts, which, in turn, should serve as salient cues to guide behavior. Consequently, pride may decrease consumers' preference for indulgent options by serving as a behavioral cue through an automatic process.

In sum, we argue that the experience of pride influences consumers' pursuit of long-term goals through dual pathways that predict different outcomes in terms of their preference for indulgent products. When consumers are consciously monitoring their behavior, pride serves as a source of information that licenses indul-

gence. Otherwise, the experience of pride will decrease consumers' preference for indulgent products through an automatic process by cueing behaviors consistent with the successful pursuit of long-term goals. We demonstrate the dual pathways in two studies. First, we show that pride licenses indulgence, unless a) individuals are unable to monitor their behavior or b) the experience of pride is discredited as a source of information. Second, we demonstrate that another positive emotion (i.e., happiness) does not have a similar influence on behavior.

In study 1, we presented respondents with an indulgent decision in the health domain that involved a choice between french fries or salad as a side dish with their lunch entrée. Prior to making their decision, respondents were primed to experience pride, happiness or no emotion (control group). The extent to which individuals were able to monitor their behavior was manipulated using a cognitive load manipulation. Consistent with our prediction, when respondents were able to monitor their behavior (high cognitive load), those that were primed with pride were more likely to make an indulgent choice compared to the control group. When individuals were unable to monitor their behavior (low cognitive load), those that were primed with pride were less likely to make an indulgent choice compared to the control group. Additionally, no difference was observed between the happiness and control conditions at high and low levels of cognitive load.

In the second study, respondents were given an indulgence decision in the money domain that involved a choice between two \$25 gift certificates where one could be used for entertainment products (indulgent option) and the other could be used for school supplies. Prior to making their decision, respondents were primed to experience pride or no emotion (control group). For half of the respondents, the experience of pride was discredited by having them focus on the source of their feelings prior to making their decision. As expected, when the source of their feeling was not discredited, respondents that experienced pride were more likely to make an indulgent choice compared to the control group. However, when the experience of pride was discredited, respondents were less likely to make an indulgent choice compared to the control group. Thus, the results of the second study demonstrate the dual pathways even where individuals have the capacity to monitor their behavior.

This research makes an important contribution to the literature on the motivational properties of emotions by a) identifying the process through which pride affects goal pursuit and b) demonstrating the effect of its experience on consumer preference. Our findings also contribute to the decision-making literature, which has focused primarily on discrete negative emotions (Raghunathan, Pham and Corfman 2006), by demonstrating that distinct positive emotions (pride versus happiness) can have unique effects on consumer choice.

Impact of Age on Repeat Choice and Attitude Certainty

Raphaëlle Lambert-Pandraud, ESCP-Europe, France

Gilles Laurent, HEC Paris, France

David Dubois, Northwestern University, USA

Derek Rucker, Northwestern University, USA

Etienne Mullet, Ecole pratique des Hautes Etudes, France

EXTENDED ABSTRACT

We investigate the impact of age on repeat choice and attitude certainty. This research is motivated by the apparent contradiction between two series of previous results on the impact of age: impact on attitude strength, impact on repeat purchase.

Visser and Krosnick (1998) study attitude strength in the context of a new topic (e.g., a fictitious foreign conflict), for which respondents, by definition, have to develop online, during the interview, a new attitude (for or against a US intervention in the conflict), and to take a position on the spot. Researchers then supply additional "information:" Each respondent is told that the United Nations have a position opposite to the one s/he has just taken, and asked whether s/he holds to her/his first attitude or changes it. Visser and Krosnick find an inverted U-shape impact of age on attitude strength. Attitude stability is at its maximum for mature persons (between 40 and 60), while both younger and older respondents are more likely to change their position.

This seems to contradict results on age-related differences in brand choice. For example, Lambert-Pandraud, Laurent, and Lapersonne (2005) find that choice stability increases monotonically across age ranges: Older car buyers are more likely to consider and repeat purchase the previous car brand, and less likely to explore alternative choices.

Could this apparent contradiction be due to the type of attitude under investigation? Visser and Krosnick investigate, after a few minutes, the stability of a rootless attitude: Since the foreign conflict is fictitious, the respondent does not bring a previous attitude, let alone a network of related attitudes, to the survey. In contrast, Lambert-Pandraud et al. investigate stability towards the previous car brand, for which consumers have likely developed a rooted attitude, based on daily usage over several years, and on their lifelong experience with cars.

Besides, are attitude stability and attitude certainty correlated?

Study One

In contrast with Visser and Krosnick, we therefore analyze a domain in which respondents have had lifetime opportunities to develop rooted attitudes: A presidential election. We perform a secondary analysis of survey data collected in the two months preceding the French 2007 presidential election (n=17,622). We analyze respondents' certainty about their planned vote (a binary answer to "Is your choice final or can it still change?") in relationship with choice stability (whether the planned 2007 vote is the same as at the previous [2002] presidential election, coded by the authors on the basis of separate questions on the planned 2007 vote and on the previous 2002 vote).

Age has a very significant positive impact on choice stability. The probability of a repeat vote increases linearly across age ranges.

Attitude stability and certainty are correlated. At any age, respondents who plan to vote in 2007 as they voted in 2002 are more likely to be certain about their future vote ("My choice is final") than respondents who plan to change their vote.

However, we find contrasted age-related patterns: There is indeed a monotonic growth in certainty among respondents who

plan to vote in 2007 as they voted in 2002, but an inverted U-shape relationship for respondents who plan to change their vote.

This suggests a possible avenue to reconcile the apparent contradiction described above. One may distinguish the impact of age on attitude certainty, depending on whether the current attitude remains consistent with the attitude held in the past (in our case, with the 2002 vote), or the current attitude is new, in the sense of either differing from the attitude held in the past (in our case, changing the vote) or being formed online, in answer to a new topic (as in Visser and Krosnick).

Study Two

Study One and the Visser and Krosnick study (1998) are not comparable: different subjects in different countries, under different circumstances, using different questions to measure attitude certainty. In Study Two, we therefore obtain more comparable data on rootless and rooted attitudes by comparing answers provided by the same respondents in the same study, using the same questions to measure certainty.

We interview US respondents (n=245 respondents in an Internet survey) about one week before the 2008 presidential election. For the rooted attitude, we replicate Study One by asking their voting intentions. For the rootless attitudes, we ask for their online attitudes towards two minor fictitious stimuli (a healthcare program about a benign Mediterranean skin disease, and a program by Volkswagen to develop an environment-friendly car in France). On each of the three attitudes, we measure respondent confidence with the same question.

As in Study One, older respondents have a higher likelihood of planning to vote for the same party at the 2008 presidential election as at the 2004 presidential election. Also, older respondents have a higher confidence in their planned vote, and the increase is monotonic. However, we find no significant correlation of confidence with the intention to vote for the same party as in 2004.

In contrast, in agreement with Visser and Krosnick, we observe, for each of the two online attitudes, an inverted U-shaped impact of age on confidence. The highest average confidence in their attitude is obtained among mature respondents (between 55 and 60 years of age). Older respondents display a lower average confidence.

Discussion

Combining both studies, we find that respondent age has a significant impact on consumer confidence, but that the shape of the relationship differs, depending on the attitude under study. For voting intentions, which are rooted in the respondents' political attitudes developed over their lifetime, we find that average consumer confidence (measured on a confidence scale, or by the likelihood of stating "My choice is final") increases monotonically across older age ranges. For online attitudes, in contrast, we replicate Visser and Krosnick (1998) finding that, for respondent confidence in an online attitude just developed about a previously unknown topic, the impact of age on confidence follows an inverted U-shaped relationship.

Further research could replicate these findings for other consumer decision domains, and investigate mediating variables between age and observed results.

The Effect of Referent Age on Interpersonal Influence in Domains Related to Factual Information, Values, and Style

Todd Pezzuti, University of California, Irvine, USA
Cornelia Pechmann, University of California, Irvine, USA
Dante Pirouz, University of California, Irvine, USA
Adilson Borges, Reims Management School, France
Carolina Werle, Grenoble Ecole de Management, France

EXTENDED ABSTRACT

The effect of referent age on interpersonal influence is explored in a series of studies. Researchers commonly assume that individuals are more influenced by someone who is of the same gender, race, and age than by those who are different on these dimensions (Chang 2008; Tajfel and Turner 1986). However, a critical evaluation of age as a construct reveals that in some situations this characteristic may have a unique effect on influence that is not well understood. Chronological age may be especially relevant when assessing persuasive messages since this characteristic is easily inferred and age-related features likely act as environmental cues that guide socially and biologically functional behavior (Montepare and Zebrowitz 1998).

Despite the logical connection between referent age and influence, very little is known about this subject beyond the work on similarity. One study that explored this topic found that advertisements featuring elderly models negatively affected retail patronage intentions for young adults for conspicuous services, but not inconspicuous services (Day and Stafford 1998). Though these findings are informative, much more research is needed in order to develop a deep and insightful understanding of how an important and pervasive social cue such as age affects interpersonal influence.

Although the effect of age on interpersonal influence has been largely neglected, some insight is offered by research that focuses on how trait inferences that are indirectly linked to age affect judgments and decisions. Research on inferences of competence stands out as particularly relevant to how people may respond when faced with messages that pertain to factual information or values since inferences of competence emerges as a universal dimension of social cognition that influences important decisions and social judgments (Fiske, Cuddy, and Glick 2007). Importantly, researchers draw a connection between inferences of competence and facial maturity (Zebrowitz and Montepare 2005) and the positive consequences of facial maturity and competence have been observed in numerous contexts including the public image of chief executive officers (Gorn et al. 2008).

A connection between chronological age and judgments of competence and facial maturity exists because older individuals are generally perceived as more competent with more mature features than younger individuals; however older individuals can possess more babyish features and be perceived as less competent as well. Nevertheless, differences in these trait inferences are likely to be ascribed to different age groups which should affect how people respond to messages pertaining to factual information and values. Influence in matters pertaining to factual information was first assessed in Study 1 by asking participants to rate whether they would consider the opinions of referents in regards to facts and statistics (referents varied on age; children of 10 years, teen-ages of 17 years, young adults of 25, and mid-aged adults of 45 years). Study 2 evaluated the effect of referent age on messages related to values and ethics in a consumer context. In this study participants selected a brand based on value-related recommendations. The effect of referent age on messages related to factual information was

also assessed in a consumer context. In study 3 participants evaluated brands of enhanced bottled water based on referent claims related to technical aspects of the water (e.g., antioxidants). In each study, the older referents were more influential than younger referents and this effect was mediated by judgments related to competence and facial maturity.

When messages relate to style, characteristics other than competence and facial maturity are likely to be relevant since style is about appearance and looks. In this domain, creating an appearance that is highly valued in society is socially and biologically functional and according to sexual selection theory and empirical evidence, society values physical attributes that signal high reproductive value (Jones 1996). Importantly, reproductive health and fertility largely depend on age and the key features of physical attractiveness reflect fertility which peaks in young adulthood around 25 years of age (e.g., ideal waist-to-hip ratios and facial proportions) (Jones 1996). The reproductive status of this age group is also connected to their heightened concern over appearance and fashion, and, as a result, young adults may make good sources for determining what is stylish and fashionable (Berger 2008; Biddle and Mutrie 2001). With this in mind, people should be more open to messages related to style and taste when the source is a young adult since creating an image and appearance like these individuals is functional. This reasoning extends to teens as well since the teen years are also marked by high levels of reproductive value, albeit to a lesser extent than young adults (Jones 1996). To test the assumption that age and sexual appeal relate to style-related influence, participants were asked to choose a brand based on referent recommendations in terms of what is stylish and unique (Study 2). As hypothesized, young adults were most influential, followed by teens, then middle age adults and children and this effect was mediated by sexual appeal.

These results indicate that individuals use the perceived age of a referent as a proxy for expertise when evaluating information even in situations in which there is no direct connection between a referent's age and actual expertise and all referents state precisely the same product claim. The findings are substantively useful as marketing practitioners can use this information to choose a spokesperson or model that best fits the desired message. The findings are also theoretically important as they illustrate how fundamental environmental cues influence judgments and decisions.

Trust, Commitment, and the Elderly: Exploring Age Differences in Consumer-Brand Relationships

Steffen Jahn, Chemnitz University of Technology, Germany
Hansjoerg Gaus, Saarland University, Germany
Tina Kiessling, Chemnitz University of Technology, Germany

EXTENDED ABSTRACT

In industrialized Western countries, the population is rapidly aging. Companies took a long time to realize that this fact is relevant for their businesses and often responded with inappropriate marketing activities (Moschis 2003, Weijters and Geuens 2006). Thus, in order to improve strategies aimed at mature consumers, we have to understand their behavior, investigate their consumption needs, and identify whether the older consumer market should be treated as homogeneous or further subdivided (Moschis, Lee, and Mathur 1997). Psychological and consumer research indicates that there are indeed differences within the segment of consumers older than 50 years (e.g., Carstensen, Isaacowitz, and Charles 1999; Helson and Soto 2005) and that consumers boycott brands that mistakenly treat the elderly as being all equal (Tepper 1994; Weijters and Geuens 2006). In this vein, changes in emotion regulation that come along with aging (Carstensen, Isaacowitz, and Charles 1999) might influence consumer behavior through differences in brand attachment. Thus, we argue that there are differences in consumer-brand relationships (Fournier 1998) across age segments. Despite the widely accepted importance of a brand relationship perspective and the need for research incorporating older consumers, we are aware of only one study that connects these perspectives (Olsen 1999). However, in this qualitative research the five women all were around the age of fifty and no age-specific differences could be analyzed.

So far, extant age-related research mainly focused on declining cognitive abilities of older people (Yoon 1997; Yoon, Cole, and Lee 2009). There is growing evidence, however, that not all older adults exhibit marked declines in performance of executive function tasks (Yoon and Cole 2008). More important for changing behavior might be changes in motivation across the life span (Carstensen, Fung, and Charles 2003). Thus, we draw on socioemotional selectivity theory which suggests changes in emotion regulation due to perception of time as limited (Carstensen, Isaacowitz, and Charles 1999). Supporting this view, Williams and Drolet (2005) show that consumers older than 65 years have higher liking and recall of emotional appeals in advertisements. In contrast, young adults have higher liking and recall of rational appeals. While, on average, people older than 50 years give more importance to emotional goals than younger adults, research suggests a further increase around the age of 65 (Carstensen, Fung, and Charles 2003; Carstensen, Isaacowitz, and Charles 1999; Williams and Drolet 2005). Thus, consumers' emotional attachment to brands is likely to differ between groups of 50-65 year olds and older people. More precisely, relationships among important marketing variables like self-concept connection, partner quality, brand trust, and affective commitment are assumed to differ across what we call "younger elderly" and "older elderly" consumers.

Following prior studies, trust was considered to be a determinant of relationship commitment (Chaudhuri and Holbrook 2001; Morgan and Hunt 1994). In addition, self-concept connection and partner quality were seen as determinants of trust and commitment (Breivik and Thorbjørnsen 2008; Escalas 2004; Kressmann et al. 2006; Laurenceau, Barrett, and Pietromonaco 1998). Regarding differences between both age groups, the effect of trust on commit-

ment is assumed to be higher for the younger elderly, relative to the older ones (Charles, Mather, and Carstensen 2003; Williams and Drolet 2005). In contrast, the effects of partner quality on commitment and trust are expected to be higher for the older elderly (Carstensen, Fung, and Charles 2003; Carstensen, Isaacowitz, and Charles 1999; Helson and Soto 2005; Williams and Drolet 2005). In addition, self-concept connection is supposed to impact on commitment to a higher extent within the group of older elderly consumers (Carstensen, Fung, and Charles 2003; Carstensen, Isaacowitz, and Charles 1999). Due to common heuristics in the identification-trust link (Butler 1991; Dunn and Schweitzer 2005), we expect only low if any age-group differences in the effect of self-concept connection on trust (Yoon and Cole 2008).

We empirically tested the hypotheses in a survey among 341 women over the age of 50. Coffee as a frequently purchased packaged good was chosen because here strong brand relationships may continue to impact on buying behavior even into old age. Moderator analyses with LISREL reveal significant path differences between the younger elderly and the older elderly groups for the influences of partner quality on commitment and trust. In addition, the path from trust on commitment is higher for the younger elderly. However, two results are counter-intuitive. The path from self-concept connection on commitment did not differ across groups. Its influence on trust differed, being stronger within the younger elderly group. A reason might be that this link is more cognitively driven than expected. Hence, the younger elderly process the information more deeply and form their trust judgments on the basis of identification. While trust represents the major determinant of commitment for the younger elderly, commitment is not affected by trust within the older senior segment. For the latter, commitment heavily depends on perceived partner quality. Self-concept connection has little impact on commitment in the entire sample with no difference across both age groups. Older elderly's trust process is determined by partner quality, while both partner quality and self-concept connection affect trust judgments within the group of younger elderly.

Overall, the findings support the theoretically derived assumption of shifts in brand relationships with respect to consumers' life cycle. Socioemotional selectivity theory (Carstensen et al. 1999) has been successfully used to describe these shifts. In general, for younger elderly it seems to be important how the brand is, expressed by the links between self-concept connection, trust, and commitment. For the older elderly it appears to be more relevant what the brand does. Consequently, a high partner quality drives their brand trust and affective commitment. "What a brand does" seems to fit older people's needs and generate positive emotions. In line with socioemotional selectivity theory, this affects motivation and behavior. Younger elderly appear to be more able or willing to put cognitive effort in the brand relationship process. Concluding, this study contributes to the understanding of the 50+ market by analyzing differences in consumer-brand relationships between two groups of elderly consumers, namely those between 50 and 65 and those above 65 years of age. In addition, we demonstrate that chronological age is a valuable segmentation criterion for both consumer researchers and marketing managers. The findings chal-

lenge prior research that generally devaluated chronological age in favor for other measures such as cognitive age.

Threat Perception in Product Harm Crises: Do Older Consumers Feel More Vulnerable?

David H. Silvera, University of Texas at San Antonio, USA

EXTENDED ABSTRACT

Age-related declines in physical and cognitive abilities are well-documented (Schneider and Rowe 1991). These declines result in older adults having a reduced ability to actively cope with problems and being more susceptible to potential threats than younger consumers (Heckhausen 1997). Although there is ample evidence that older adults experience an increase in real susceptibility to threat, there is relatively little evidence indicating whether perceptions of susceptibility to threat increase similarly with age. The present research attempts to examine this question within a marketing context by (a) examining how older consumers evaluate potential threats in relation to negative marketing events in the form of product harm crises, and (b) studying how threat perceptions influence marketing outcomes for involved companies.

The existing literature provides two competing predictions regarding how age will relate to perceived threat. The most straightforward prediction is that real increases in susceptibility to threat in older adults should be paralleled by increases in perceived susceptibility to threat. There is substantial research indicating not only that older adults experience real decline in many domains, but also that people of all ages are aware that mental, physiological, and psychological decline is associated with old age. Furthermore, these declines are most prominent in the physical domain, which has been the focus of most research on product harm crises.

However, more recent research suggests that this common sense hypothesis might not be correct and that instead older adults might view themselves as less susceptible to threat than younger adults. This alternative hypothesis is based on Heckhausen and Schulz' (1995) proposition that there are age-related differences in primary versus secondary control processes. Primary control processes are typically active and outwardly directed, and represent an effort to change the present or future environment to fit one's needs or desires (e.g., by avoiding threatening circumstances, for example by not purchasing a dangerous product); secondary control processes are primarily cognitive and inwardly directed and involve psychological adjustment to accept existing circumstances as they are (e.g., altering perceptions to perceive a situation as less threatening, for example by viewing the danger associated with a product harm crisis as being exaggerated by the media). Research suggests that, whereas the ability to engage in primary control declines across the adult lifespan, secondary control becomes more prevalent with age. Secondary control involves altering one's own perceptions so that a problem (which typically can't be resolved via primary control processes) is viewed as less threatening and thus more acceptable to the individual. Protection Motivation Theory (Rogers 1975) describes threat perception as being derived from the perceived severity of a negative event and perceptions of personal vulnerability to negative outcomes associated with that event. Thus, reductions in perceptions of severity and personal vulnerability would be evidence for a stronger impact of secondary control processes on judgments related to a product harm crisis.

Based on the proposition that older adults have a reduced ability to engage in threat protection via primary control and thus compensate with increased secondary control, our hypotheses are that, compared to younger adults: (1) Older adults will engage in

less primary control, meaning that they will have stronger intentions to purchase or recommend a product associated with a product harm crisis; (2) older adults will engage in more secondary control, meaning that they will perceive themselves as less personally vulnerable and a product harm crisis as less severe; and (3) older adults will place less blame on the company involved in a product harm crisis due to lower threat perceptions based on the defensive attribution hypothesis (Robbennolt 2000). A theoretical model is also proposed in which age predicts secondary control (perceived severity and vulnerability), secondary control predicts blame to the company, and blame to the company predicts purchase and recommendation intentions toward the company's products.

Two studies were conducted to test these hypotheses. In each study, older versus younger consumers were presented with a scenario describing a product harm crisis (involving televisions in study 1 and coffee in study 2). After reading the scenario, participants completed measures of their perceptions of the severity of the product harm crisis, their perceptions of their own vulnerability in relation to the crisis, the degree to which they blamed the company for the crisis, and their intentions to purchase and recommend the involved company's products in the future.

In both studies, the hypotheses were fully supported: Compared to younger adults, older adults had lower perceptions of severity and vulnerability in association with the product harm crisis, blamed the company less, and had stronger intentions to purchase and recommend the company's products. The theoretical model was also supported in both studies, with one exception: For the television crisis (study 1), blame to the company was predicted by perceived severity but not by perceived personal vulnerability. For the coffee crisis (study 2), however, perceived personal vulnerability was a stronger predictor of company blame than perceived severity. Thus, although older participants exhibited stronger secondary control processes with regard to both aspects of threat perception in both studies, this result suggests that different aspects of secondary control might be more relevant under different circumstances.

In conclusion, we find evidence that, contrary to the perceptions of many in the general public regarding the elderly, real increases in susceptibility to a threat due to aging are not associated with increases in consumers' perceptions of the danger posed by that threat. In fact, the present results suggest that perceptions of threat related to a product harm crisis actually decrease with age. Older adults appear to focus less on the negative information associated with a crisis, and are thus less likely to incorporate this negative information into their attitudes and preferences. This research provides unique insights to marketers relative to a growing and under-researched segment of the world population.

Examining Structural Relationships among Environmental, Behavioral Factors, and Childhood Obesity

Myoung Kim, University of Wisconsin-Madison, USA
Nancy Wong, University of Wisconsin-Madison, USA

EXTENDED ABSTRACT

The startling growth in the obesity epidemic facing American children has been a leading public health concern over the past several decades. It is becoming clear that the consequences of this dramatic growth in childhood obesity are severe. The childhood obesity epidemic results in not only severe health consequences, but also the attendant medical, psychological, and social costs (Allison, Fontaine, and Naraya 1999; Rippe and Aronne 1998). A considerable body of research has focused on understanding various factors associated with childhood obesity. Past research has identified two main factors associated with childhood obesity: behavioral and environmental factors. Behavioral factors include a sedentary lifestyle and consumption of excess calories, which lead to low energy expenditure and high energy intake, while environmental factors consist of (1) family factors, (2) school factors, (3) community factors, and (4) media factors.

However, these relationships have often been examined individually without consideration for how these factors could jointly contribute or mitigate the effects of each other. Furthermore, due to the limitations of past study samples, it was often not possible to account for the child's psychological traits in these studies. In order to develop more effective intervention programs, we must consider these factors jointly (Davison and Birch 2001) and also test for possible moderating effects of certain key psychological factors. With that in mind, the goal of this study is to develop and test a comprehensive model on factors influencing childhood obesity. By applying the theory of consumer socialization (Moschis and Churchill 1978), we postulate that children's behaviors related to obesity-prevention such as (un)healthy eating patterns and physical activities are (1) learned "consumer skills" through the socialization process and are (2) influenced by social agents (i.e., family, school, community, and media). We further examine the potential moderating role of the child's psychological traits, such as self-control and internalizing problems, in the relationship among environmental, behavioral factors and children's weight status.

We analyze data on fifth graders from the Early Childhood Longitudinal Study (ECLS-K) conducted by the National Center for Educational Statistics. The longitudinal survey was performed in the fall and the spring of kindergarten (1998-99), the fall and spring of 1st grade (1999-2000), the spring of 3rd grade (2002), 5th grade (2004), and 8th (2007) grade. The ECLS-K used the nationally representative sample of a cohort of children who entered kindergarten in the fall of 1998 from approximately 1000 schools. A multistage probability sample design was employed to select the ECLS-K sample. Information about children was obtained from parents (through CATI interview), teachers (through paper survey) and students (through in-person interview and paper survey). However, we focused on the 5th grade data (2004) because the ECLS-K started to include information on children's food consumption since 5th grade; furthermore, the 7th grade data are not yet available to the public. Among a total of 11,820 students from the 5th grade data, our sample was limited to 9,019 students who attended public schools and provided information on BMI.

For the purpose of testing the proposed model by incorporating multiple factors simultaneously, we use the structural equation modeling (SEM) approach. We first tested the measurement model to examine whether the measurement items have the appropriate

properties to represent each construct included in the model. We then evaluated the structural model by examining overall model fit and structural relationships specified in the model. LISREL 8 (Joreskog and Sorbom 1993) was used for evaluating both the measurement and structural models.

The results from this study provide empirical support of identifying relative importance among multiple factors contributing to childhood obesity. The major findings from our study are: (1) When family, school, community, and media factors are considered jointly, the family factors appear to be the most significant determinants of a child's involvement with (un)healthy eating patterns and physical activities, (2) especially, mothers' working hours more than 35 hours and children's TV viewing time have a significant and direct impact on children's weight status, (3) while the school factors and community factors have relatively less significant impact on children's behaviors related to obesity-prevention, and (4) children's psychological traits such as self-control and internalizing problems moderate the relationships among environmental, behavioral factors and children's weight status.

The findings from our study are important in several ways. First, it might be the one of the first studies to look at the relationship between childhood obesity and multiple factors including both environmental and behavioral factors simultaneously. In so doing, we overcome conflicting past findings based on largely bivariate relationships. Second, the relative importance of family or parental factors contributing to childhood obesity leads to a re-examination of the current intervention programs. More effective education materials and health communication tools targeting parents are critical in improving children's healthy eating and increased physical activities. Third, the moderating effect of children's self-control confirms that school records regarding children's test scores for psychological traits can be used as a tool to evaluate children at being risk of obesity. Political support that aids systematic intervention programs is needed.

While findings from this study may offer vital implications on the prevention of childhood obesity, we acknowledge several limitations of this study and offer possible directions for future research: (1) perform a longitudinal analysis of the models developed in this study, (2) include other potential environmental variables from the comprehensive model, (3) improve the measurements used in our study, and (4) incorporate qualitative insights from parents and children.

Empty Pockets Full Stomachs: How Monetary Scarcity and Monetary Primes Lead to Caloric Desire

Barbara Briers, Tilburg University, The Netherlands
Sandra Laporte, HEC Paris, France

EXTENDED ABSTRACT

Briers et al. (2006) showed that desire for monetary resources motivates people to acquire or maintain resources in the food domain. Their study demonstrates that people eat more candy in a taste test when they desire money than when their desire for money is lower. In this research, we set out to investigate how monetary scarcity might lead to higher food intake. We identify and test two ways in which money, a commodity that has no biological significance in itself, can become a strong motivator for gathering food. Specifically, we test whether the effect of monetary scarcity on food consumption results from the instrumental, secondary reinforcer value of money rather than its primary rewarding qualities. In line with the value heuristic (Dai, Wertenbroch, and Brendl 2008), we also assume that monetarily deprived people perceive food items as less caloric because they value calories more. Accordingly, this perception can lead to a preference for more caloric food and/or bigger portions.

Money represents an instrument to obtain natural incentives (e.g., food) but is not directly consumable. According to operant psychology, money therefore is a conditioned (or secondary) reinforcer that gains its motivational property only because of its repetitive pairing with unconditioned (or primary) reinforcers (Skinner 1953). Similarly, standard economic theory posits that money is an instrument or tool for obtaining biologically relevant incentives (Lea and Webley 2005). Once a Pavlovian association exists, the conditioned stimulus (e.g., money) can trigger a motivation (desire) for an unconditioned reward (e.g., food) (Berridge and Robinson 2003). Because of its instrumental quality, money might be conditioned to different types of primary incentives. According to Skinner (1953), if a single kind of conditioned reinforcer gets paired with many different kinds of unconditioned reinforcers, the reinforcing effect will become independent of the deprivation of any of them. Thus, money would have the same motivational properties as natural incentives or primary rewards.

Recent consumer research offers evidence that induced appetites can instigate a greater urgency to consume anything rewarding (Li 2008; Van den Bergh, Dewitte, and Warlop 2008; Wadhwa, Shiv, and Nowlis 2008). Appetitive stimuli (e.g., rich desserts, sex cues, food samples) can prompt people to seek anything that offers a high incentive value (e.g., money, candy bars, a massage) and thus affect subsequent consumption across domains. Both Van den Bergh and colleagues (2008) and Wadhwa and colleagues (2008) suggest that a general reward system gives rise to this effect. That is, if money alone can instigate an increase in appetitive motivation, just as a primary reward does, it also may induce people to desire more food, as well as other kinds of reward. The effect of monetary scarcity on caloric intake thus may be driven by the activation of a general reward system.

As far as we know, money cues have not been used as the independent variable in this stream of research. Moreover, recent advances in parsing rewards into specific psychological components might challenge a view of money as a primary reward. Berridge and Robinson (2003) distinguish between “liking” and “wanting,” though both are necessary for rewards to occur in the fullest sense. Yet wanting may occur without liking: Drug addicts crave drugs, such as nicotine, even when they do not derive much

pleasure from them. It is the attribution of wanting that makes a conditioned stimulus an object of desire. As an instrument, money may be conditioned on food rewards but is not directly consumable; money is “wanted” but not “liked,” in which case it may not be a reward with appetitive properties. Building on the distinction between wanting and liking, we posit that the association between money and food may be driven by the instrumental, secondary reinforcer value of money rather than by its primary rewarding qualities.

In four experiments, we consider both explanations and thereby obtain more evidence that suggests the effect derives from the instrumental value of money, that is, money as a conditioned stimulus of food. In study 1, we show that the effect of monetary scarcity differs for food versus nonfood rewards. The results also suggest that participants’ sensitivity to rewards does not moderate the effect of monetary scarcity on subsequent food choices. In study 2, we pit the two possible explanations against each other by investigating the role of symbolic meanings of money (Rose and Orr 2007). Specifically, in study 2a, we find that the effect of monetary scarcity on caloric desire is greater for persons who view money as an instrument, and in study 2b, we establish a link between desire for calories and money as an instrument more directly by manipulating, instead of measuring, the meaning of money. To follow up on the idea of money as a conditioned stimulus strongly associated with food, in study 3, we investigate whether priming people with money (i.e., priming as an unconscious reminder of the concept of money) produces the same results. In a 2 (money vs. fish screensavers; Vohs et al. 2006) X 2 (monetary satiation vs. control) between subjects design, participants primed with money on average choose a larger brownie, but only when money is scarce. Furthermore, study 2 and 3 also imply that calorie (under)estimation is mediating the effect of monetary scarcity and money primes on subsequent food choices.

In sum, this research illustrates how money scarcity, as well as money primes, can induce people to consume more (caloric) food. We also demonstrate that money can lead people to underestimate the caloric content of food, which prompts them to choose larger food portions or more caloric dishes. This effect of money (scarcity and primes) on food consumption stems from the Pavlovian association that results from a pairing of money and food, in which money represents a secondary reinforcer or instrument to acquire food. Although this series of experiments contributes to a growing body of research that shows out-of-domain effects of appetitive stimuli (Li 2008; Van den Bergh et al. 2008; Wadhwa et al. 2008), we do not believe a general reward system gives rise to this effect.

Investigating the money–food association further might help explain why poor people appear especially vulnerable to overeating and its poor health effects (Drewnowski and Specter 2004). Although reduced physical activity and specific food manufacturing and marketing practices might be (partly) responsible for the societal correlation between obesity and poverty, no research attempts to understand why, for example, food manufacturing and marketing practices have a stronger impact on poor people than on rich people. Perhaps in modern societies, the attraction to money is so powerful that (all-pervading) monetary cues can tempt money-deprived people easily to eat more (caloric) food. That is, this series

of experiments might render a proximal account for the well-documented societal link between obesity and poverty, based on individual experiences of money deprivation.

Place, Prosocial Activity, and Unhealthy Consumption

Brennan Davis, Baylor University, USA

Connie Pechmann, University of California at Irvine, USA

EXTENDED ABSTRACT

The academic literature increasingly recognizes a relationship between retail placement and unhealthy consumption in adolescents (Lu et al. 2007; Patel et al. 2007; Powell et al. 2006; Novak et al. 2006; Weitzman et al. 2003; Scribner, Cohen and Fisher 2000). At the same time, there is an emerging literature showing that youth prosocial activity is associated with unhealthy consumption (Xue, Zimmerman and Caldwell 2007; Eitle, Turner and Eitle 2003; Elder et al. 2000; Cooley et al. 1995). Prosocial activity means involvement in group functions like sports teams, religious groups and clubs (Duncan et al. 2002). It is surprising that these streams have not been brought into consumer research, given the wealth of studies on retail placement as a marketing strategy (Fox and Hoch 2005; Mittal, Kamakura and Govind 2004) in marketing and on prosocial behavior (Small and Simonsohn 2008; Bagozzi and Moore 1994) in consumer research. We study unhealthy consumption as a function of both place and prosocial activity.

Our study offers an empirical examination of hypotheses related to Third Place Theory (Oldenburg 1983), which says that people frequent public places outside of home and work to gather for prosocial activity. Past work on Third Place Theory has been primarily theoretical and qualitative (Rosenbaum 2006; Cheang 2002; Oldenburg 1982), leaving a gap for quantitative tests. We examine hypotheses supporting Third Place Theory on a large sample of students with varying levels of prosocial activity.

We consider rival hypotheses to the traditional ones about place and prosocial activity. The traditional hypothesis about place says that nearby fast food is associated with unhealthy consumption and obesity. The traditional hypothesis about prosocial activity says that prosocial activity is negatively related to unhealthy consumption and obesity. Third Place Theory says that people frequent public places outside home and work for the purpose of prosocial activity and consumption. They are both geographically accessible to consumers and spatially commodious for social activity. Hence, Third Place Theory describes an interaction of place and prosocial activity.

In our study, we expect fast-food restaurants around schools to serve as Third Places for students seeking social interaction with other students. Research has shown that fast-food venues are places for social gathering, leading to unhealthy consumption for those who are socializing there (Cheang 2002; Rosenbaum 2006). If fast food serves as a Third Place for youth with greater prosocial activity, then access to nearby fast food may lead to an increase in unhealthy consumption and obesity among those with greater prosocial activity. Our study offers the first empirical tests of Third Place Theory to our knowledge. Past work on Third Place Theory has been theoretical or qualitative, leaving a gap for quantitative tests (Cheang 2002; Oldenburg 1982; Rosenbaum 2006).

Specifically, we posit that prosocial activity moderates the effect of place on unhealthy consumption and obesity. We predict that students with greater prosocial activity will be affected by their exposure to fast-food placement around schools. Students with lesser prosocial activity will not be affected by nearby fast food. Because fast-food restaurants host prosocial activity, we predict that the nearby fast food will be associated with unhealthy consumption and obesity for students with greater prosocial activity.

Some may argue that prosocial activity is a moderator merely because of the activity rather than prosocial nature of prosocial activity. Activities are time consuming, increasing the need for

convenient food options that nearby fast food provides. If this were true, then for students with greater participation in activities that are not prosocial, nearby fast food should also be associated with unhealthy consumption. However, in support of Third Place as the main theory behind place effects in fast food, we predict that non-social activity will fail to moderate the role of place on unhealthy consumption because fast food is acting as a third place for prosocial gathering. For increasing non-social activity, nearby fast food will not increase its association with unhealthy consumption and obesity.

Our methodological approach uses geographic information systems (GIS) data, which are site addresses linked spatially to the earth's latitude and longitude coordinates. We link GIS data with survey results from individual consumers. First, we collect GIS data on a student's school and on the fast-food sites around a student's school. Then, we link the GIS data with survey data on a student's prosocial activity, consumption habits and body weight. Last, we compare the unhealthy consumption and obesity of students whose schools are near versus not near fast food. We make this comparison across two student segments: those with greater versus lesser prosocial activity.

We use GIS data and survey results on almost 500,000 youths from 2002-2005 with multivariate regression models to estimate associations among fast food around schools; student measures of prosocial activity; consumption of soda and fried potato foods; and youth obesity. The measures of fast-food placement around schools come from Microsoft Streets and Trips, the California Department of Education, and Technomic, a food industry consultant. The measures of prosocial activity, consumption and obesity come from the California Healthy Kids Survey. We control for individual, school, and environment variables like grade, race/ethnicity, school enrollment, county, and urbanicity.

Our results demonstrate that, for students with greater prosocial activity, those exposed to nearby fast food around their schools: 1) consume more servings of soda and fried potato foods; and 2) are more likely to be obese relative to similarly situated youths whose schools are not near fast food. However, the presence of fast food does not affect students with lesser prosocial activity. We also find that, for students with greater non-social activity, nearby fast food does not increase its association with unhealthy consumption and obesity, as hypothesized. The results provide evidence for fast food as third places that attract youths looking for prosocial activity. Our results bridge the research on place and prosocial activity, empirically test formal hypotheses about Third Place Theory, and inform public policy.

When Flippers Flop: Goal Reversion in Consumer Choice

Kurt Carlson, Georgetown University, USA

Meg Meloy, Penn State University, USA

Liz Miller, Boston College, USA

EXTENDED ABSTRACT

Imagine choosing between two restaurants (A and B), one which has tastier food and one which has healthier food. Suppose you first learn that Restaurant A has very decadent food, which is good because it fits one of your goals—to have a delicious meal. Next, you learn that Restaurant B uses fresh, local ingredients, which fits another of your goals—to eat healthfully. Though you were leaning towards Restaurant A originally, this new information causes you to switch your preference to Restaurant B (i.e. you flip from A to B). Suppose you then encounter additional neutral information about the two restaurants. How does your prior decision process, particularly the inhibition of the initial goal, influence your final restaurant choice?

We argue that because the two choice options align with different goals (to eat tasty food and to eat healthy), a consumer's restaurant preference at any point during the choice process can be used to infer which goal is more active at that point. Further, when a consumer switches preference from one option to another (as in the example above), he must inhibit one goal to pursue the other. This inhibition of the original goal should cause it to increase in activation (Atkinson and Birch 1970; Bargh et al. 2001). Therefore, we predict that when a consumer inhibits one goal to pursue another (by switching his preference from A to B), the original goal should increase in activation, leading the individual to be more likely to switch back to the original option when given the opportunity (i.e., upon encountering additional information). We refer to this as the *goal reversion hypothesis*. In this paper we report findings from three experiments designed to test this hypothesis.

Participants in experiment 1 chose between two unfamiliar restaurants based on four attributes that they read in sequence. The initial two attributes revealed that one of the restaurants had food that was more decadent and tasty. The third attribute revealed that the other restaurant had food that was healthier. We expected that this ordering of the information would establish the more decadent restaurant as preferred after the first two attributes, and that many participants would switch to the healthier restaurant after reading the third attribute (to pursue the competing goal). This subset of participants constitutes our focal sample, because these participants have inhibited one goal in pursuit of another. Our main interest is what happens to preferences of participants in the focal sample upon reading an additional attribute that is uncorrelated with tastiness or healthiness of the food. The goal reversion hypothesis predicts that a greater proportion of subjects should be expected to flop back to the more decadent option than would be normatively expected. Our results support this hypothesis. Forty-six percent of participants in the focal sample reverted back to the initial choice option after viewing the final attribute. This proportion was significantly greater than predicted by normative standards ($\chi^2=6.47$, $p<.01$).

Experiment 2 attempts to replicate the findings from experiment 1, and to examine whether those for whom the goal to eat tasty is most important are most likely to revert. Goal reversion is also observed in this experiment, and reversion is most prevalent among those who place the greatest importance on the goal to eat tasty food. As expected, this indicates that self impeding an important goal causes greater activation than self impeding a less important goal.

The third and final experiment examines whether goal reversion is symmetric for different goal types. In addition, the experiment examines Need for Decisiveness as a possible moderator of the effect. Participants again read four attributes about two restaurants. Based on the ordering of the information, half the participants were led to favor the healthy option first, while the other half were led to favor the tasty option. Reversion rates for both groups were significantly higher than that predicted by normative standards (both $ps<.01$). In addition, participants who started with a taste goal were marginally more likely to revert to the original goal than those who started with a health goal. This result fits with the idea that the goal to eat tasty is more desirable and so is more goal-like than the goal to eat healthy. An examination of various individual difference measures revealed that reversion is not a function of self-control or preference for consistency, but is related to an individual's Need for Decisiveness. Specifically, those high in Need for Decisiveness are less likely to exhibit goal reversion.

These findings provide support for the goal reversion hypothesis, and increase our understanding of the role goals play in the earliest stages of preference construction. In addition, our methodology illustrates a new technique for tracking which goal is most active at any point of a choice process. Specifically, we examine which option is leading in a choice process with competing goals and use these preferences to infer which goal is active at a particular time. The advantage of this procedure is that it can be used to study the effects of self-inhibition of goals and how consumers switch between goals during a choice process with minimal interference of the choice process itself. Our findings highlight the importance of understanding order effects and preference reversals during choice processes and suggest that managers may want to consider the timing of information that could help an initial goal re-emerge.

Contextual Cues and Descriptive Norms: Do People Stick to Context When They Know What Others Choose?

Alessandra Zammit, University of Bologna, Italy
Elisa Montaguti, University of Bologna, Italy

EXTENDED ABSTRACT

Retailers are likely to influence consumers' shopping behavior though featuring, display and other marketing instruments. Increasingly this implies providing information on the behavior of other customers. Companies like Amazon.com and Barnes and Nobles regularly provide customers with a list of items previously selected by consumers similar to the prospects. Their behavior is driven by the belief that consumers are influenced by those around them (Asch 1955; Burnkrant and Cousineau 1975). Additionally, the same companies often manipulate their assortment to favor one or another product alternative. They can use specific comparison among products to influence potential buyers as the selection of an alternative is influenced by the other alternatives included in the same choice set (Hamilton 2003; Shocker et al. 1991). Increasingly, companies both in online and offline contexts try to jointly generate these effects by simultaneously presenting socially relevant information and constructing assortments that favor a specific alternative.

Literature in marketing and consumer behavior document that the choice set composition can favor the selection of the intermediate option in a ternary choice set (Simonson 1989; Simonson and Tversky 1992), because most consumers are extreme averse. The compromise alternative is often selected because individuals compare themselves with the information on the products presented and they chose the alternative that best matches their own preferences and the context-based information (Burson 2007; Prelec, Wernerfelt, and Zettelmeyer 1997).

There is ample evidence that individuals' both judgments and choices can be shifted when the judgment and the choices of others are known (Ariely and Levav 2000; Nemeth and Markowski 1972). When consumers observe or learn that others have opted for a specific alternative they are getting information on descriptive norms (how most people have acted in a specific circumstance). This suggests that norms alter consumers' assessment of the context-based information as knowledge on the most popular alternative modifies their inferences on the underlying distribution of other consumers' preferences and choices.

Our work posits that the effectiveness of strategies based on social norms (Cialdini and Goldstein 2004; Griskevicious et al. 2009) varies with the nature of the popularity they choose to emphasize. In particular, the gain associated to the intermediate position is modified by the likelihood of the extreme alternative to be the most frequently purchased in a overall market or in a smaller group of consumers who share some basis for social identification (Shang, Reed, and Cronson 2008). These kinds of norms could influence the ability of the compromise heuristic to identify the safe and easy to justify alternative in two ways. First, consumers may engage in an identification process with an extreme-positioned alternative that is popular with their reference group and move away from the compromise alternative which is considered more suitable for the majority of the consumers. Second, when an extreme-positioned alternative is popular among the majority of the consumers, both the extreme popular and the compromise alternatives appear safe and easy to justify. This will diminish the share of the compromise alternative, but not vanish the compromise effect as

two options can now match the needs of the average customer: the most popular-extreme option and the compromise option.

To test our predictions we run five studies. Study 1 analyzes the role played by social information in moderating the compromise effect. Our results show that social norms can diminish the total share of the middle option but cannot vanish the compromise effect itself. Study 2 aims at ruling out the possibility that social information, acting upon the attribute-importance balance, might change the structure of the choice context needed to identify an option as extreme and/or compromise. Our results are consistent with the findings of Study 1. Studies 3A and 3B further investigate the influence exerted by social information on compromise effect while examining how differences in the degree of social identification can lead to different context-based inferences and perception of self-extremeness. Our results show that that social norms shift people preferences away from compromise alternatives, but this happens only when the social norm is held by a reference group. In particular, in Study 3A we find that consumers update the information embedded in the context with the social information cue and this leads to a shift in the match between the inferred product ranking and their own relative rank. Interestingly, this process does not mitigate the compromise effect per se, but determines a reduction in the absolute share of the intermediate alternative. This process also increases the level of uncertainty associated with the choice and modifies the perceived extremeness of the extreme alternative. By contrast, Study 3B shows that social information related to a reference group can vanish the compromise effect, but does not affect the structure of the contest (the perception of extremeness).

Finally, in Study 4 we show that the reduction on the compromise effect due to the social cue is attenuated when context is more uncertain. When the presented products outline a market characterized by a large dispersion in the product array, consumers rely on the context to make inferences about their position in the market. As a consequences, social information does not influences preferences and compromise effect is still present.

This article contributes to extant literature in several ways. First, we provide evidence as to how the advantage related to the compromise position can be overcome by extreme alternatives in a choice set. Second, drawing on research on the informational content of context (Prelec et al. 1997) we show that social norms can act on both the shape of the market distribution of preferences (when social information refers to market behavior) or on the matching consumers make between themselves and the best product choice in the context (when social information refers to reference group behavior). Finally, this article documents how and when social norms interact with context-generated inferences in modifying either consumers' perception of the self without altering the structure of choice context or in changing consumers' perception of preferences of others without affecting the perception of the self.

Ellard John, University of Calgary, Canada

EXTENDED ABSTRACT

While a large body of research has examined consumers' perceptions of fairness as they pertain to their own experiences and outcomes (e.g., Smith, Bolton, and Wagner 1999), research has not examined consumers' fairness beliefs as they relate to concerns for justice for others. We examine consumers' perceptions of fairness for others in the context of fair trade. Fair trade refers to a social movement that encourages the payment of a fair price for products, while aiming to alleviate poverty, promote sustainable development, and assist producers marginalized by the traditional economic model (De Pelsmacker and Janssens 2007). Researchers have recently lamented the fact that it is often difficult to encourage consumers to actually choose and purchase products that are fair trade (Chatzidakis, Andreas, and Smith 2007). We utilize a just world framework (Lerner 1970) to investigate what factors make consumers more likely to support and choose fair trade products when they learn about marginalized coffee and tea producers.

Just World Theory proposes that people are motivated to construe the world as a just place in which individuals get what they deserve and deserve what they get. Further, when evidence is provided that the world is not fair (e.g., learning of an innocent victim's suffering), this threatens just world beliefs. To reconcile evidence that the world is not just, people demonstrate varied reactions, which can range from rationalizing the victim's situation, to engaging in helping behaviors (Hafer and Begue 2005; Lerner and Simmons 1966). We show that the tendency to assist others in need through supporting and choosing fair trade coffees (pilot study, study 1, and study 2) and teas (study 3) can be decreased (increased) by varying factors that heighten (reduce) defensive reactions to just world threat.

One commonly held view among marketing practitioners and researchers is that, when appealing to consumers to engage in prosocial behaviors, highlighting a high degree of perceived need should enhance helping (Bendapudi, et al. 1996; Fisher and Ackerman 1998). However, a just world framework predicts that, in the absence of alternative avenues for ameliorating just world threat, a high degree of need may decrease willingness to engage in prosocial behaviors (Hafer 2000). We tested for this possibility in a pilot study. Participants read about a situation for coffee producers in Malawi that either depicted a high or moderate degree of need. Participants then reported their behavioral intentions towards purchasing a fair trade product—Karma Coffee, which was described as a fair trade coffee that would support coffee producers in Malawi. Consistent with predictions, participants were significantly more inclined to help by purchasing fair trade products when perceived severity of need was moderate versus high ($p < .01$). Following from this study, we set out to test for a series of moderating and mediating variables to elucidate the role that justice concerns play in determining the consumption of fair trade products.

In Study 1, we examined the role of duration of suffering. We predicted that if the situation for marginalized coffee producers is described as being a long-term, chronic issue this should increase just world threat (particularly under high need), whereas if it is more

acute in nature this will be less threatening. Participants took part in a 2(Severity of Need: moderate vs. high) x 2(Duration of Suffering: short-term vs. long-term) design. As anticipated, under conditions long-term suffering, participants reported a lesser willingness to purchase fair trade products when perceived need was high rather than moderate ($p < .001$). These effects were mediated by beliefs about victim deservingness.

In Study 2, we examine a condition under which helping will be more likely when need is high versus moderate—ability to impact justice is high (vs. low). When helping has a larger impact on the ability to restore justice for coffee producers (i.e., a high percentage of the fair trade purchase goes to producers), defensive reactions under conditions of high need should be mitigated. Participants took part in a 2(Degree of Need: moderate need vs. high need) x 2(Ability to Impact Justice: low vs. high) design. Among those who believed that ability to impact justice was low, people were less inclined to purchase fair trade products when need was high versus moderate ($p < .05$). However, when the ability to impact justice was high the reverse effect was found, whereby those in the high need condition were more likely to help than were those in the moderate need condition ($p < .01$). These effects were mediated by justice restoration beliefs.

In study 3, we examine actual choices of fair trade (vs. non-fair trade) teas. In addition, we elucidate the underlying role of justice concerns by directly manipulating whether or not the purchase of fair trade leads to positive justice outcomes (restored justice vs. unrestored justice vs. control) and by examining the moderating role of BJW. A just world framework would predict that when the notion that justice can be restored via choosing fair trade is highlighted, those high in BJW (who are particularly sensitive to fairness information) should be more likely to choose fair trade products (Hafer and Begue 2005). Those high in BJW were more likely to select fair trade teas when justice was restored versus unrestored, or in the control condition ($p < .01$), but no significant differences emerged for those low in BJW.

This research demonstrates that novel factors such as the duration of suffering, ability to restore justice, and justice outcomes predict inclinations towards purchasing fair trade and actually choosing fair trade products. We find that factors that heighten (reduce) defensive reactions to just world threat can decrease (increase) helping responses. This research also has practical implications for marketers. Although a common assumption is that increasing perceived need should enhance helping, the current work suggests that, under certain conditions, highlighting a high degree of severity of need or injustice for others can be detrimental. Further, highlighting severity of need works best when accompanied with information that efficacy of helping is high and that justice can be restored.

When Knowledge is De-motivating: Consumer Knowledge and Assortment Size

Hadar Liat, IDC Herzliya, Israel

Sanjay Sood, UCLA Anderson School of Management, USA

EXTENDED ABSTRACT

Marketers have long been trying to determine how much choice to offer consumers. Evidence from consumer research as well as psychological research has shown that consumers prefer choice over no choice: when offered choice participants are more motivated to make a good decision and are more satisfied with the product. However, recent studies have indicated that too much choice can be motivating. In particular, it was shown that consumers who were offering over 20 options were less likely to purchase the product than consumers who were offered about 6 options (Iyengar and Lepper 2000). We suggest that the impact of choice set size on choice is mediated by consumer knowledge. We rely on previous findings, showing that knowledgeable consumers limit the amount of information search and the number of options considered, whereas less knowledgeable search for more information and consider more options (Johnson and Russo 1981; 1984). We hypothesize that knowledgeable consumers are more likely to purchase a product with small choice sets because they are not interested in considering many options; however, we conjecture that ignorant consumers are more likely to purchase a product with large choice sets because large assortments offer more options and afford more learning opportunities about the product category. Our hypothesis was supported in three studies.

In the first study participants were presented with a list of 5 or 25 red wines. They were asked to choose their favorite bottle and to indicate whether they would prefer receiving the chosen bottle or an equivalent amount of \$20. Half of the participants were presented with a list of Chilean wines (ignorance group) and half were presented with a mixed list of wines (control group). A manipulation check verified that participants knew less about Chilean wines than about the mixed list of wines. Replicating previous results, we found that in the control group, the proportion of participants who preferred the wine over the \$ amount was higher among those who were presented with a small choice set (5 wines) than a large choice set (25 wines). An opposite pattern emerged among participants who were presented with Chilean wines: the proportion of participants who preferred the wine over the \$ amount was lower among those who were presented with a small choice set (5 wines) than a large choice set (25 wines). The results of study 1 thus supported our hypothesis, showing that assortment size can have both negative and positive impact on choice, depending on whether consumers are knowledgeable about the product category or not.

The knowledge manipulation employed in study 1 was based on familiarity with the product, and thus different experimental groups were presented with different stimuli (different wine lists). Study 2 was designed to replicate the results using a comparative knowledge manipulation, in which all participants were presented with the same stimuli, and knowledge was manipulated by presenting comparison groups that are more/less knowledgeable than the participant pool. Participants were asked to choose a video game from a list of five or 25 games, and to indicate whether they would prefer \$5 or the chosen video game. They were informed of the general participant population, which was either similar to them in terms of knowledge about video games (undergraduate students—control condition) or more knowledgeable (undergraduate students and professional video game programmers—comparative ignorance condition). The results indicated that participants in the control were more likely to prefer the video game over the cash

when presented with five games than 25 games, but that participants in the comparative ignorance condition revealed the reversed pattern. In addition, we found that the interactive impact of comparative knowledge and assortment size on choice was mediated by the degree of self-reported knowledge of video games.

A third study examined the impact of comparative ignorance as well as comparative competence on consumer choice. Participants were asked to choose their favorite body lotion from a list of five or 25 lotions. Then, they were asked to indicate whether they would prefer \$5 or the chosen body lotion. Participants were informed of the general participant population, which was either similar to them in terms of knowledge about video games (undergraduate students—control condition), more knowledgeable (undergraduate students and dermatologists—comparative ignorance condition), or less knowledgeable (undergraduate students and elementary school students—comparative competence condition). The results showed that participants in the control group were more likely to prefer the body lotion over the cash when presented with five rather than 25 games; participants in the comparative competence condition revealed a similar yet stronger pattern; participants in the comparative ignorance condition revealed the reversed pattern: they were more likely to prefer the video game over the cash when presented with 25 games. Moreover, as in study 2, this choice pattern was mediated by self-reported knowledge.

The results presented in this paper reconcile two different, well established, schools of thought in consumer research—one suggesting that marketers should offer consumers as much choice as possible, and the other suggesting that limited assortments are preferred because excessive choice may be de-motivating, by showing that choice set size should depend on consumer knowledge. We conclude that marketers should consider an estimate of consumer knowledge about the product category when deciding how much choice to offer. Extensive choice may increase sales when consumers are believed to have limited knowledge about the product category, whereas limited choice may increase sales when consumers are believed to be knowledgeable about the product category.

EXTENDED ABSTRACT

With the purpose of catching and holding consumers' attention advertisers often make use of sexually provocative images (Dahl, Sengupta, and Vohs 2009). Given that provocative images often are of no or little relevance to the advertised product (Reichert and Lambiasi 2003) advertisers thus seem to assume that consumers can be influenced by sexual cues. This assumption is based on the well-known male preference for young, attractive mates (Maner et al. 2003). It appears that this insight is extensively applied in advertising practices (Colarelli and Dettmann 2003) in order to draw consumers' attention and to increase sales.

The current research examines how variation in goal motivation affects men's interest in high-status products in a mating environment. The two studies presented in this paper demonstrate that exposing men to cues of women in sexy attire leads the single-but not the committed-men to automatically pay attention to and to long for high-status products. In Study 1, single men ($N=24$) and men in committed relationships ($N=39$) were exposed to 15 pictures of women. In the mating cue condition, the models were dressed in a sexually appealing manner (e.g. wearing lingerie or a bikini). In the control condition, the models wore unrevealing clothing. After exposure, participants filled in the prestige sensitivity scale (Lichtenstein, Ridgway, and Netemeyer 1993). Participants indicated higher interest in high-status goods in the mating cue condition ($M = -.68, SD=1.02$) than in the control condition ($M = -.98, SD=.64$). Single men indicated higher interest in high-status goods in the mating cue condition ($M = -.33, SD=1.08$) than in the control condition ($M = -1.20, SD=.68$), ($t(59)=2.52, p=.01$). For committed men, no differences were obtained between the mating cue condition ($M = -.95, SD=.91$) and the control condition ($M = -.88, SD=.61$), ($t(59)=.25, NS$). Study 1 suggests that exposure to mating cues increases men's interest in high-status products. Based on Markman and Brendl (2000), we predicted and demonstrated that the value of high-status products increases because these products may enhance and facilitate reaching the mate attraction goal.

In Study 2, single men ($N=72$) and men in committed relationships ($N=61$) were shown ten visual displays on a computer screen. Each display consisted of the pictures of six different products: five functional products (e.g. a desk lamp) and one high-status product (e.g. a Breitling watch). Each display remained on screen for one second. After a display disappeared, participants had 20 seconds to write down as many products as they had seen on the screen. Before engaging in this visual display task, we exposed the participants to a female experimenter who either wore sexy clothing (mating cue condition) or plain clothing (control condition). Sexy clothing should temporarily trigger the goal of displaying social status. In turn, this heightened goal of displaying social status should render high-status goods in the visual display more salient than functional products (Moskowitz 2002). We therefore hypothesized that men in the mating cue condition would notice the high-status goods more

than men in the control condition. In addition, we expected this difference to be obtained for single men only.

Overall, a higher proportion of high-status goods ($M=.36, SD=.16$) than of functional products ($M=.32, SD=.05$), ($F(1, 129)=6.91, p=.01$) was remembered. However, participants in the mating cue condition ($M=.38, SD=.15$) recalled a higher proportion, but not significantly so, of the high-status products than participants in the control condition ($M=.34, SD=.16$), ($t(131)=-1.60, NS$). The pattern for functional products was reversed ($M_{\text{mating cue}}=.31, SD=.06$ vs. $M_{\text{control}}=.33, SD=.05$), ($t(131)=2.34, p=.02$). The elevated attention for high-status products was obtained for single men only ($F(1, 129)=4.42, p=.04$). Single men recalled a higher proportion of the high-status products in the mating cue condition ($M=.43, SD=.17$) than in the control condition ($M=.33, SD=.15$), ($t(129)=-2.80, p<.01$). In contrast, committed participants recalled almost the same proportion of high-status products in both conditions ($M_{\text{mating cue}}=.33, SD=.13$ vs. $M_{\text{control}}=.35, SD=.17$), ($t(129)=.43, NS$). Conversely, single men recalled more of the functional products when exposed to the control condition ($M=.34, SD=.06$) than to the mating cue condition ($M=.31, SD=.06$), ($t(129)=1.92, p=.06$). Participants with committed relationships recalled not significantly more of the functional products in the control condition ($M=.33, SD=.04$) than in the mating cue condition ($M=.31, SD=.05$), ($t(129)=-1.31, NS$). Study 2 suggests that exposure to mating cues may automatically increase interest in conspicuous consumption. Exposure to mating cues increased men's attention to high-status products in a task where this was irrelevant. Apparently, the presence of a sexily dressed female set off a process of heightened automatic attention for luxury and status-evoking products in single men.

A host of studies already suggest that images of attractive models in advertising may elicit positive feelings that are transferred to the advertised brand (Kim, Allen, and Kardes 1996). Moreover, when endorsing high-status products targeted at men, attractive models may not only function as a heuristic cue, influencing brand attitudes through affect transfer, but also as a central argument: "This is the brand that may increase your mating chances!" (Kang and Herr 2006). Presumably, mate attraction cues in the shopping environment may lure men into purchasing a more expensive brand than they had planned. So, the mere presence of a sexy woman may suffice to increase sales of high-ticket items. These effects, however, may be limited to single men.

To Defend or To Improve, That Is a Question: Self Views and Evaluations of Self Improvement Products

Fang Wan, University of Manitoba, Canada

Pingping Qiu, University of Manitoba, Canada

Darren Dahl, University of British Columbia, Canada

EXTENDED ABSTRACT

Body aesthetics industry is one of the major subcomponents of the Self-Improvement Product (SIP) industry, promoting hope of personal betterment or promise improvement in various domains of a person's life: appearance, body shape, relationship satisfaction, career achievement and self-esteem (MacInnis & De Mello 2005). One of the advertising strategies for body aesthetics SIPs is to employ super-slim and super-fit models, with the intended outcome to induce consumers' want (vs. need) of the product to minimize the discrepancy between the real and an ideal state (MacInnis & De Mello 2005). However, whether these idealized images facilitate or obstruct the effectiveness of SIP advertisements has rarely been studied. Moreover, previous research has dealt with the impact of idealized images on female consumers' self-evaluations and psychological health (e.g., Richins 1991; Stice & Shaw 1994; Smeesters & Mandel 2006), but little has been done to further investigate whether and how consumers' attitude toward and choice of SIPs are affected by the self-image goals activated in the viewing contexts.

In the present research, we put forth a conceptual framework for studying the impact of self-image goals activated by contextual information (e.g., idealized images presented within advertisement viewing context or in focal SIP advertisements) on consumers' evaluation of SIPs and the effectiveness of SIP advertisements. Drawing research from social and cognitive psychology (Bargh 1982; Bargh 2002; Vohs & Heatherton 2001), consumer research and advertising studies (e.g., Dunning 2007; Richins 1991; MacInnis & De Mello 2005; Escalas & Luce 2004), we propose that consumers' attitude toward SIPs is influenced by self-image goals—the goals of presenting and maintaining positive self beliefs (Dunning 2007), which can be triggered in the advertisement viewing process or by other contextual information. How consumers cope with the self-deficiency may determine what self-image goal (whether a self-defending or a self-improvement goal) is activated. If consumers cope with self-deficiency in a defensive manner, they will adopt strategies such as reappraisal (e.g., Gross 2002) to restore a positive self belief, as well as counter-arguing and dismissal of product or endorser credibility (Duke 2002). As a result, SIPs will be evaluated negatively. However, if self-deficiency is moderately triggered, or the focal advertisement invites consumers to contemplate on the possibility of enhancing the current state and reaching an ideal state, a self-improvement goal will be activated. In this case, SIPs will be viewed as a means to reach the ideal state. As a result, SIPs will be evaluated positively. We report three experiments conducted to examine the major propositions.

Study 1 intended to investigate the working of self-defending goal in SIP evaluations. Specifically, we explored consumers' evaluations of a dietary supplement product after a prior exposure to idealized images in a preceding and seemingly unrelated advertisement evaluation task. We expected to find that subjects whose self-deficiency is activated by the exposure to idealized images are more likely to evaluate the product less favorably and demonstrate lower purchase intention. As the negative effect of idealized images in media is mostly observed among female consumers (Rodin, Silberstein & Striegel-Moore 1985), we expected to observe the effects to emerge among females but not males.

Results of a 2 (self-deficiency activation) x 2 (gender) between-subjects experiment supported our hypotheses. A follow-up Study 1b further evidenced the defensive mechanism among males when threatening information came from a domain (intelligence) which is more crucial for men's self-esteem.

In Study 2 we tried to uncover whether the negative SIP evaluations in Study 1 were the results of the activation of a self-defending goal among the female subjects. Adopting research from self-affirmation (Spencer et al. 1998; Schwinghammer, Stapel & Blanto 2006), we inferred that dismissing the value of SIPs or denying a need to improve is indicative of a self-defending goal, which can be directly tested by adding a self-affirmation task between the priming task and the SIP evaluation task. We hypothesize that if a self-defending goal is activated, self-affirmation task (receiving bogus positive feedbacks) can deactivate the goal. In addition, we intend to study the moderating effect of self-esteem on the relationship between self-affirmation and product evaluation. Research on threats to self-esteem has demonstrated that individuals with different trait self-esteem (high vs. low) respond differently in information seeking once being threatened. After receiving an ego threat, high self-esteem (HSE) individuals, compared to the low self-esteem (LSE) individuals, tend to be more sensitive to competency feedback (Vohs & Heatherton 2001). In our research context, we expected that the self-affirmation task will be more effective at deactivating self-defending goal, i.e., enhancing evaluations of self-improvement products, for HSE individuals than for low LSE individuals. Hypotheses were supported by results of Study 2.

The first two studies demonstrated that self-deficiency activated by the idealized images lowered consumers' intention to purchase SIPs. This effect was however alleviated by a self-affirmation task among HSE individuals. This research finding seems to run contradictory to the intended outcome of most SIP advertisements. The intention of Study 3 was to explore how to activate a self-improvement goal. Based on limited research in this area, we argue that advertisements focusing on inspiration and hope, rather than self-deficiency (which triggers self-defense, as what was studied in Study 1 and 2), are the keys to activate people's desire to improve (MacInnis & De Mello 2005). We manipulated the hope appeal by different headlines of the advertisements as well as different instructions for viewing the ads (Escalas & Luce 2004). Results of Study 3 evidenced that SIP can be evaluated positively if the SIP advertisement emphasizes the possibilities of attaining an ideal state, instead of making the gap between ideal and current state more salient (as what was implicitly done in our previous studies).

Put together, we discovered from Study 1 and 2 the negative impact of idealized image priming on SIP evaluations could be due to the activation of a self-defending goal. Consumers are motivated to restore a self-worth once their self-image is threatened and they tend to penalize the SIP made available to them right after the ego threat. Findings in Study 3 provided some hope for SIP advertisements. In spite of self-deficiency activated by exposure to idealized images, consumers can evaluate SIPs positively and consider purchasing them if the SIP advertisements contain messages of hope and inspiration.

Disposable People: Commoditization and Redefinition of Self as Rubbish

Angela Hausman, Howard University, USA

Chris Manolis, Xavier University, USA

EXTENDED ABSTRACT

We investigate disposable people thrown away as a consequence of extensive abuse of alcohol and/or drugs. Building on theories of commoditization, disposal, and rubbish, we pose the following questions: Can people become rubbish, and, if so, how does this process work? How does addiction affect users' relationships with self and others and their tendencies to treat others as rubbish? What happens when an individual internalizes the rubbish label and redefines self as such? Finally, we propose means by which such understanding might be used in rehabilitating users.

According to a recent report, 8.3 % of the US population reported illicit drug use within the last month (Office of Applied Statistics 2007). Alcohol abuse is nearly as high and has increased over 53 % between 1992 and 2002. The individual and societal consequences of this abuse are dire (National Institute on Drug Abuse 2006). Of those who get treatment, between 27 and 82 % fail to finish rehab programs (Wickizer 1994), and, of those who do finish, less than 20 % are addiction-free four years later (Simpson and Sells 1982). Unfortunately, drug and alcohol abuse is far from victimless and it may be the involvement of innocent bystanders that contributes to society's desire to discard abusers.

There are various theoretical perspectives that contribute to the concept of disposable people. These include human commoditization and consumer disposition, which have been used extensively in consumer behavior, as well as rubbish theory, which has yet to be systematically incorporated. Human commoditization begins with the eroding of consumer choice, which transforms decisions that were once considered trivial into life and death situations. It is this absence of meaningful choice that eliminates personal identity and makes maintenance of self difficult (Hirschman and Hill 2000). Next, people are stripped of clothing, material artifacts, and even personal identifiers, such as hair, becoming non-differentiated units (Hirschman and Hill 2000). The final stage of the process enforces invariant patterns of behavior so that commoditized individuals not only look the same, but act the same. Decent into rubbish involves commoditization and subsequent negative attitudes toward the object (person in this case) and its means of disposition. Dispossessed rubbish is temporally linked with a lack of desire for the object (Lucas 2002).

In order to begin understanding the construction of people as rubbish, we interviewed individuals addicted to drugs and/or alcohol. Informants came from three sources: a residential treatment facility, a detox center, and a non-residential treatment facility. These facilities were not the spa-type rehab centers frequented by celebrities or even more modest, insurance-supported treatment facilities, but public and charity supported facilities that serve vast numbers of low income and indigent abusers who are often sent by court order or as a condition of parole. Residents of the various facilities shared, among other things, diminished consumer choice and behavioral control, as well as a devalued sense of self.

Within the theme of disposable people, several sub-themes were detected: 1) the process of commoditization and decent into rubbish; 2) how relationships with others were constructed and contributed to definitions of self; 3) dispossession; and, 4) events leading to internalization and maintenance of self as rubbish. Through the voices of these informants, we see the progression from having control (as a non-commoditized person) to being out-of-control. Consistent with commoditized persons, informants of-

ten found themselves living on the streets, being cast out or disposed of by family and friends, and possessing few of the niceties, if not necessities of life, such as nutritious food and clean clothing. Not only do we find an absence of consumer choice, but evidence of a break with conventions of behavior (stealing and cheating) that reflects the final step toward communization. They also begin to sell their bodies, perhaps the last vestige of self, to become truly commoditized.

We also see evidence of the weakening relationship between the commoditized individual and his/her friends and family who normally form an important support system for the non-commoditized individual. Substance abuse becomes a driving force, reducing or eliminating the addicts' engagement with society and its norms, as well as free will and choice. The defining characteristic that moves commoditized people into the category of rubbish is their diminished level of societal value, a strong theme reflected by our informants (Thompson 1979). Through abusers' stories, we see the de-evolution from commoditization to rubbish is complete when the individual is living surrounded by other rubbish (trash, etc.), including other de-valued people who often engaged in non-constructive activities, such as stealing.

The preceding discussion suggests that people do, in fact, transition to commodities then rubbish as they increasingly lose value through their substance abuse. They also commoditize those around them, both other addicts and family and friends. Rubbish people have also lost everything of value in their lives; material possessions, close relationships, and, possibly most important, their sense of self. This suggests that transforming the rubbish person back into something durable, something society recognizes for its inherent value, may be an important part of the recovery process.

Unfortunately, our informants reflected on the difficulties encountered in regaining this value. For instance, one informant talked about the near impossibility of finding a job with a drug conviction on his record. Therefore, in his mid-twenties, he had already given up trying to find a job. Reconnecting with family and friends is also difficult, as some of the informants implied. One male resident lamented he had never met his grandchildren because of his addiction. Others have been abandoned by family who are disillusioned after being treated badly by the addict. The rubbish person seems to develop a certain inertia, potentially remaining rubbish for an extended period of time, which makes recovery problematic.

Preference Reversal in Risky Choices under Time Pressure

Najam Saqib, Ryerson University, Canada
Eugene Chan, University of Toronto, Canada

EXTENDED ABSTRACT

One pervasive aspect of decision-making under time pressure is the salience of negative information. Research has repeatedly concluded that “the harassed decision maker” tends to weigh the possible negative consequences of his or her action heavily to the relative disregard of the possible positive rewards of those same actions. In this paper, we propose that the salience of negative information under time pressure not merely leads to risk-aversion, but that it may reverse an individual’s usual preferences.

Individuals are typically either risk-seeking or risk-averse. Research outside the time pressure domain has shown that, when negative information becomes salient, risk-seeking individuals perceive little room for further gains but large likelihood of accruing losses, causing them to adopt risk-averse behaviours. In a choice between a modest-but-certain and greater-but-uncertain gamble, risk-seeking individuals tend to adopt risk-averse behaviours whereas risk-averse individuals tend to adopt risk-seeking ones. Meanwhile, for risk-averse individuals, the salience of negative information only adds to the extant negativity, causing them to adopt risk-seeking behaviours with the hopes of removing the negative state. We extend these findings to the time pressure domain and suspect that time pressure would likewise be one instance where individuals would reverse their usual risk preferences to adapt to the salience of negative information. We examine this possibility in three studies.

In Study 1, participants with positive (negative) affect chose a riskier (certain) lottery to a NHL hockey game when there was no time pressure, but adopted the certain (riskier) approach under time pressure. We thus demonstrated the basic outline of our hypothesis.

In Study 2, we used a gambling task in which participants stated their willingness to gamble for specific dollar amounts. We also added a thought protocol to assess the participants’ emphases on positive versus negative outcomes during the gambling process. Under no time pressure, risk-seeking (risk-averse) individuals focused more on positive (negative) outcomes than negative (positive) ones. Under time pressure, however, risk-seeking (risk-averse) individuals focused more on negative (positive) outcomes than positive (negative) ones. The focus on positive versus negative information for risk-seeking and risk-averse individuals reversed under time pressure. These differences in foci on positive versus negative outcomes mediated the preference reversal.

In Study 3, we explored a similar preference reversal in regulatory orientation using a consumer choice task involving toothpaste and grape juice brands as well as investment choices. Under no time pressure, promotion- (prevention-) focused individuals preferred promotion- (prevention-) framed and risk-seeking (risk-averse) brands and choices. Under time pressure, however, promotion- (prevention-) focused individuals preferred prevention- (promotion-) framed and risk-averse (risk-seeking) brands and choices.

Taken together, the three studies suggest that individuals tend to reverse their preference for risky choices under time pressure compared to situations under no such constraint. It is important to note, however, that preference reversals in risky choices do not occur because risk-seeking individuals want to avoid risks or that risk-averse individuals want to take risks, but that they need to. Risk-seeking individuals adopt risk-averse behaviours when negative information becomes salient because such an approach can

secure gains, in line with the goals of risk-seeking. Conversely, risk-averse individuals adopt risk-seeking behaviours when negative information becomes salient because such an approach can avoid further losses, in line with the goals of risk-aversion. Thus, preference reversals are not in innate risk preferences, but in the perception and adoption of the behaviours that best serve their objectives given the circumstance. Our findings have important marketing implications since consumers often face decision-making tasks under time pressure in everyday life.

Examining the Paradoxical Effects of Counterfactual Generation in Negative Consumption

Candy K. Y. Ho, Hong Kong Baptist University, Hong Kong

Jessica Y. Y. Kwong, The Chinese University of Hong Kong, Hong Kong

EXTENDED ABSTRACT

After a negative consumption experience (e.g., missed a flight), consumers often muse about how their consumption might have turned out better (e.g., "If I had taken another transport to the airport, I might have caught the flight," or "I would have been enjoying my vacation if I had caught the flight.") The generation of these imaginations, called counterfactual thoughts, has been viewed to pose paradoxical effects on people's responses to these experiences. On one hand, counterfactual thoughts are functional because they provide corrective information that helps solve problems associated with the consumption (Epstude and Roesse 2008; Markman et al. 1993; Roesse 1994). On the other hand, they are painful to consumers because they accentuate negative feelings about the consumption (Gleicher et al. 1990; Markman et al. 1993). In this research, we attempt to tease out these paradoxical effects and argue that a counterfactual thought is not likely to exert both problem-solving and affect accentuation effects. Rather, these effects are more likely to be independently induced by counterfactual thoughts that have different structural contents.

In this research, we first propose two new types of counterfactuals, namely, process- and outcome-focused counterfactuals. Then, this classification becomes the means to tease out the two effects of counterfactual generation. We argue that while process-focused (vs. outcome-focused) counterfactuals pose a stronger problem-solving effect; outcome-focused (vs. process-focused) counterfactuals exert stronger affect accentuation effect. This implies that consumers may enjoy the problem-solving function of counterfactual generation without hurting their feelings.

To start with, this research proposes thought focus as a new dimension to classify counterfactuals into process- and outcome-focused counterfactuals. Process-focused counterfactuals focus on the process of how an imagined outcome might have been brought about (e.g., If I had taken another transport to the airport, I might have caught the flight). They mentally construct the actions (e.g., taking another transport) that, had they been taken, might have led people to the imagined outcome (e.g., had caught the flight). Outcome-focused counterfactuals, however, focus on the benefits the imagined outcome, had it been obtained, would have provided (e.g., I would have been enjoying the vacation if I had caught the flight).

We further argue that process- and outcome-focused counterfactuals have differential consequences to consumers who experienced negative consumption. First, process-focused (vs. outcome-focused) counterfactuals are more effective in promoting corrective actions for better consumption outcomes. This is because process-focused counterfactuals highlight the most promising actions (e.g., taking another transport to the airport) that, had they been taken, might have improved the consumption outcome (e.g., had caught the flight). Outcome-focused counterfactuals, however, elaborate only on how much better off consumers would have been (e.g., enjoying vacation) had they received a better-off outcome. They give no information on *how* this better-off outcome might have been obtained. Hence, consumers who generated process-focused (vs. outcome-focused) counterfactuals are more likely to identify the appropriate corrective actions that solve problems associated with the consumption, such that they will have an increased chance of yielding better consumption outcomes in subsequent encounters.

Second, it is argued that outcome-focused (vs. process-focused) counterfactuals are more likely to accentuate consumers' negative feelings (e.g., disappointment and sorrow) about a negative consumption outcome. Outcome-focused counterfactuals highlight the benefits brought by the better-off imagined outcome, which contrast with the reality and induce consumers to feel worse about the factual outcome than when these benefits are not highlighted (Schwarz and Bless 1992).

We tested our contentions in a scenario-based experiment. The scenario described a situation where the participants went through some job assessments. To begin with, the participants were provided two computer programs, which were superior in different aspects, to work on in an assessment task. They were told they selected either one of the two programs and completed the task. Regardless of their program choice, however, they failed in the assessment. At this point, the participants were prompted to generate different types of counterfactuals in relations to their assessment result. The participants were then told that they were now given a second chance to complete another similar assessment using either one of the two different programs. They reported their intention to switch to another program in the second assessment and their negative feelings about their first assessment result.

We predicted that the process-focused (vs. outcome-focused) participants would have a lower switching intention, because the process-focused counterfactuals they generated helped them identify how they might have made use of the computer program they used in the first assessment to increase their chance of success. They should therefore have increased confidence in using the program again in the second assessment and hence reduced switching intention. We also predicted that outcome-focused (vs. process-focused) participants would report more negative feelings about their first assessment result.

Supporting the idea that process- and outcome-focused counterfactuals are distinct, analysis on the participants' open-end thoughts indicated that (1) the classification on what types of counterfactuals these thoughts were had a high inter-rater agreement (.97); and (2) the two types of counterfactuals were independently manipulated. In addition, the process-focused participants, who imagined what actions, had they been taken, might have made them pass the assessment, were found to have a lower switching intention than the control and the outcome-focused participants. The outcome-focused participants, who imagined how much better off they would have been had they passed the assessment, felt more negatively about their first assessment result than did the control and the process-focused participants.

To conclude, this research not only contributes to the existing literature by showing that process- and outcome-focused counterfactuals are distinct, but it also advances our understanding on the paradoxical effects of counterfactual generation in negative consumption. It teases out these effects and demonstrates that they are independently induced by these two types of counterfactuals. The findings suggest that consumers who experienced negative consumption should (1) focus their attention on the *process* leading to a better-off imagined outcome, and (2) draw their attention away from how better off their consumption might have been. This will increase their chance of having better future consumption outcomes at no incremental psychological cost.

Does Thinking Make It So? The Effect of Counterfactual Thinking on Product Evaluations

Kai-Yu Wang, Brock University, Canada

Minli Liang, University of Wisconsin-Milwaukee, USA

Laura Peracchio, University of Wisconsin-Milwaukee, USA

EXTENDED ABSTRACT

Counterfactual thinking (CFT) refers to the process of reflecting on past events and simulating alternative possible outcomes. People engage in CFT in their everyday life at home, school, work, and shopping. Consumer researchers have explored related issues, such as how anticipation of counterfactual regret influences decision-making and behavior (Hetsts, Boninger, Armor, Gleicher, and Nathanson 2000) as well as how CFT affects information processing (Krishnamurthy and Sivaraman 2002). Previous studies provide evidence that CFT may be the cognitive mechanism underlying the generation of regret (Tsiros and Mittal 2000). Unlike previous research on CFT, the present research focuses on the impact of counterfactual thinking on product evaluations and uses the direction of counterfactual thinking, upward or downward, to explain the process underlying such evaluations. This research also explores a factor that seems likely to qualify the impact of counterfactual thinking on product evaluations, namely, the level of consumers' processing extensiveness.

We present three studies demonstrating the impact of counterfactual thinking on product evaluations. In study one, we explore the effect of counterfactual thinking on product evaluations after people experience either a positive or a negative purchase outcome. Experiment 2 provides an extension of experiment 1 and establishes the robustness of the documented findings. In study 2, a follow-up customer survey, instead of a counterfactual thinking instruction, was used to induce participants to engage in CFT. Experiment 3 examines how such post-purchase marketing efforts, customer surveys, may influence the direction of CFT and product evaluations.

Recent research by Roese, Sanna, and Galinsky (2005) has explored the relationship between CFT and outcome valence. In response to a positive outcome, people generate more downward than upward counterfactual thoughts, simulating more outcomes that are worse than actuality. By contrast, in response to a negative outcome, people generate more upward than downward counterfactuals, producing a greater number of outcomes that are better than actuality. Previous studies (e.g., Schwarz and Bless, 1992) indicate that downward counterfactuals induce positive affect while upward counterfactuals induce negative affect. Further, Markman et al. (1993) finds that the direction of counterfactual thought also influences satisfaction. That is, a positive outcome induces not only relatively more downward counterfactuals but also greater feelings of satisfaction, whereas a negative outcome evokes not only relatively more upward counterfactuals but also greater feelings of dissatisfaction.

According to this view, satisfied consumers engaging in downward counterfactual thinking may become more satisfied. By contrast, dissatisfied consumers engaging in upward counterfactual thinking may become more dissatisfied. The latter situation, in particular, is thought to create a reciprocal cycle (Sanna, Turley-Ames, and Meier 1999). In this research, we investigate the possibility that consumers can break the cycle of dissatisfaction and upward CFT and instead enhance their product evaluations via counterfactual thinking.

We propose that the extensiveness of information processing, whether such cognitive resources are ample or in short supply, may

provide a potential boundary condition for the reciprocal cycle of upward counterfactual thinking.

In experiment 1, as anticipated, after experiencing a negative purchase outcome, higher Need for Cognition individuals generated more favorable product evaluations than lower Need for Cognition individuals when given a counterfactual thinking instruction. By contrast, absent instructions to think counterfactually, lower NFC individuals generated more favorable product evaluations than higher NFC individuals after experiencing a negative purchase outcome. In the positive purchase outcome condition, there were no effects of either counterfactual thinking instructions or individuals' level of Need for Cognition.

The protocols reinforce our theorizing that, in a negative outcome condition, if a CFT instruction is provided, higher NFC individuals generate fewer upward counterfactual thoughts than lower NFC individuals. By contrast, in a negative outcome condition, when offered instructions to think counterfactually, higher NFC individuals generate a greater proportion of downward counterfactuals than lower NFC individuals. If instruction to think counterfactually is not provided, higher NFC individuals, as compared to lower NFC individuals, produce more thoughts focused on comparing the two possible alternatives. Such thoughts appear to result in less positive product evaluations.

Experiment 2 successfully replicated experiment 1's findings with a different manipulation of counterfactual thinking and an alternative procedure for varying information processing extensivity. The results from experiment 2 are important in advancing our understanding of the effects that underlie respondents' processing in negative purchase outcome conditions. The findings from experiment 2 demonstrated that after experiencing a negative purchase outcome and receiving a follow-up customer survey, higher motivation respondents generated more downward counterfactuals and fewer upward counterfactuals than lower motivation respondents. And, the respondents in the higher motivation condition evaluated the product more favorably than those respondents in the less processing extensiveness condition. When they do not receive a follow-up survey, respondents with higher motivation produced more comparison thoughts and evaluated the product less favorably than respondents in the lower motivation condition.

The purpose of experiment 3 was to examine whether the direction of CFT could be influenced by post-purchase marketing efforts via customer surveys. In experiment 3, we added two additional surveys with directional questions, asking customers to comment on satisfying or dissatisfying aspects of the purchased product. As expected, we found that the former design (satisfying) induced respondents to engage in more downward CFT whereas the latter design (dissatisfying) generated greater upward CFT.

Together, the three studies support our proposed theorizing regarding how counterfactual thinking can affect people's product evaluations after a positive or a negative purchase experience. The studies reveal that when instructions to think counterfactually are given following a negative product outcome, individuals engaging in more extensive processing generate higher product evaluations and more downward than upward counterfactual thoughts as compared to when instructions to think counterfactually are not available. This conclusion does not hold true for individuals engaging in

less extensive processing whose product evaluations were equivalent across conditions.

Order In Choice: Effects of Serial Position on Preferences

Antonia Mantonakis, Brock University, Canada

Pauline Rodero, Brock University, Canada

Isabelle Lesschaeve, Vineland Research and Innovation Centre, Canada

Reid Hastie, University of Chicago, USA

EXTENDED ABSTRACT

Our primary interest is to determine if there are biases in a final choice simply as a function of the location of each option in the temporal sequence—what we call order effects on choice. Notice that we are assuming that on-line evaluation is taking place (Hastie and Park 1986) and that the chooser has a goal of making a relative assessment of personal preferences for the options throughout the task.

We distinguish this task from closely related tasks that are associated with some well-known serial position or sequence effects. Although there are several prior studies of the effects of location in a sequence on end-of-sequence choices, there is still no clear answer to the question: Which location in a sequence is most advantageous? Several researchers have concluded that there are “primacy effects”: (Carney and Banaji 2008) and many descriptive studies of consumer choice find primacy (Berg et al. 1955). But, some researchers predict and observe “recency effects” (de Bruin 2005). We conjecture that there are both primacy and recency effects under certain conditions.

We propose that when participants sample the options, knowing they will be asked to make a choice, they repeatedly compare each new option with their current favorite. Such a pair-wise competitive evaluation strategy will produce an advantage for later items, especially in longer sequences, where an early option has to beat more options to become the overall favorite. Also, we expect a primacy advantage for early options driven by high levels of attention, lower levels of proactive interference, and the common habit of satisficing (Simon 1955). Thus, our basic hypothesis is that we will observe primacy effects, especially pronounced for short sequences, and recency effects as well in longer sequences. We speculate that this pattern may be moderated by participants’ sophistication about the options. Since the pair-wise comparison strategy is demanding of cognitive resources, we predict that participants who are more interested and knowledgeable about the choice options will be more persistent in making pair-wise comparisons and hence are likelier to show recency effects. We report an experimental study of serial position effects on choice and then return to a discussion of the serial evaluation process.

Participants were instructed that they would taste several samples of locally produced wines and then were randomly assigned to taste one sequence with a length of two, three, four, or five samples. At the end of the tasting sequence each participant was asked, “Which ONE of ALL the wines that you have tasted today is your favorite?” Finally, participants completed various questions including a test of wine expertise (Hughson and Boakes 2001).

Each preference serial position curve shows a primacy effect with the first wine preferred more than the second and third in every sequence length. Longer sequences also show a recency effect with the last wine preferred more than the previous two or three wines. When examining high-knowledge versus low-knowledge participants, it is apparent that a simple primacy effect pattern best describes the low-knowledge participants’ choices in only the five-wine condition; while the primacy plus recency pattern in the combined data set is only clearly apparent for the high-knowledge participants.

Taken together, globally we have a primacy advantage for all conditions; and a recency effect for four-option and five-option choice sets. Second, the global pattern is qualified by the expertise moderator: There is a primacy advantage for all sets for both low- and high-knowledge participants, and there is also a recency effect for the high-knowledge participants (only for four-option and five-option choice sets). Finally, the primacy effect is larger for the high-knowledge participants in the two-option and three-option choice sets.

Participants expected to be asked for evaluations. This means they were evaluating each wine as they tasted it. Also, all the wines tasted “good” and would get positive evaluations if sampled by themselves. Finally, the wines were difficult to discriminate between for our participants. Thus, our first assumption is that the participants were engaged in a “competitive” evaluation process for each pair of wines sampled. When they sampled the first wine, it became their favorite. When they sampled the second wine they compared their memory of the first wine’s goodness to the second wine and concluded with a current favorite; and so on.

We propose that two biases operated within that sequential competitive evaluation process. First, there is a first-is-best bias that accounts for our consistent primacy advantage. Second, we propose that the high-knowledge participants tried harder (than the low-knowledge participants) to discern differences between the wines. Compared to low-knowledge participants, high-knowledge participants were more persistently looking for a better wine, later in the sequence, if there was one.

This means, for high-knowledge participants there is a substantial chance that the new wine in each competition might surpass the current favorite and this habit produces the pronounced recency effect in longer sequences for high-knowledge participants. For example, suppose each new wine has a .30 chance of beating the “current favorite” and the “current favorite” remains favorite with a .70 probability. The pair-wise model provides an almost perfect fit to the data if we add one more assumption about the comparison process. In the original model, we assume that all current favorites have a .70 versus .30 advantage in all pair-wise comparisons. If we suppose that the “current favorite advantage” increases for later favorites (e.g., if the third option wins its pair-wise competition its advantage increases .75 versus .25), then the model almost perfectly fits the data.

The pair-wise comparison process model is a hybrid of the two major psychological explanations for sequence effects in the extant literature. The primary contribution of this research is a clear answer to the question of which serial position locations in a sequentially-presented choice set have an advantage in the final choice of a single option. The answer is that primacy is always an advantage and that recency has an advantage in longer sequences and especially when the choosers are knowledgeable about the choice options.

Restrained Pursuit of Luxury: Wealthy Shanghainese Attitudes towards Upscale Consumption

Junko Kimura, Hosei University, Japan
Hiroshi Tanaka, Chuo University, Japan

EXTENDED ABSTRACT

Although Chinese economy is in full bloom, at this point we cannot necessarily claim that we know sufficiently about Chinese consumers. Our knowledge on the Chinese consumer is often limited just like a patchwork of fragmented images. We were interested in their perception towards consumption, as it may be an only recently formed concept among newly rich Chinese consumers. More specifically, our research agenda was the following: How do the Chinese consumers perceive the concept of consumption? How is their notion of upscale consumption similar or dissimilar to that of US or Japan?

This time our research focus was wealthy Chinese' perception of luxury, as they may hold distinctive notions of luxury with their unique background of society and culture, and at the same time they are nouveau riche in the uprising Chinese economy. Our previous studies about luxury revealed that four different types of values are included in the notion of luxury among Japan and US female consumers: Distinctive, Relevant, Conspicuous, and Superfluous. We expected Chinese consumers may have different ideas on luxury or on upscale consumption.

Four Shanghainese female homemakers with annual income of more than 100,000 US dollars were recruited for video interview. All of the interviewees lived in Shanghai City area and owners of their own apartments. These female informants lived with her family with three members of their core family; husband, wife, and a child.

Before we actually visited these families, we had imagined their apartments must be splendid condominiums: What we saw, however, were unexpectedly modest apartments. Four informants expressed their perceptions of luxury during the interview. Their perceptions were categorized as follows:

1. Spiritual luxury: pursuant of luxury of attaining the spiritual satisfaction instead of materialistic satisfaction.

This notion was brought to us by an informant woman who was a devout Buddhist, and she is engaged in the marketing of mandala drawings.

2. Socially acceptable luxury: Setting one's level of luxury according to the standard of the society.

This idea of luxury was from an internationalized woman who had an experience of attending a hotel management school in Switzerland. She is currently in charge of sales in a manufacturer, and is an independent person who is willing to earn her own money.

3. Socially balanced luxury: Enjoying the luxury that does not deviate from the social norm and that is, therefore, socially tolerable.

The informant was an ambitious housewife who launched her own trading company in Shanghai, taking advantage of human networks that she had cultivated during her study in Japan, and she became quite successful within a few years.

4. Disciplined luxury: Enjoying the luxury within a boundary of certain standard shared by the peer.

The informant who gave us this notion of luxury was the most rich among the four informants. Her husband, a successful realtor, was born in Taiwan and he holds the U.S. citizenship. Her family hires a maid who, among others, goes to the grocery shopping for the family. The entire family goes out for shopping and entertainment every week.

What these four types commonly seem to reveal is that luxury in modern Shanghai is not at all uninhibited; Shanghainese luxury is firstly restricted by the traditional Confucian values. It also has to be within the boundary of socially acceptable norm. Furthermore, Shanghainese housewives in their 30s and 40s are still under the strong influence of consumption ethics of their parents' generation which had undergone the atrocious hardship during the Great Cultural Revolution. Observing the rapid growth of the Chinese economy, it appears that, deep down, these Chinese homemakers might well have been convinced that they should prepare for the ever-changing society. It might be concluded that the the modern wealthy Shanghainese' perception towards upscale consumption can be characterized as "restrained luxury". This notion may have been generated in a country in transition from a developing economy to a more advanced economy.

Doing the Right Things and Doing the Things Right-Endorsers in Retail Store Flyer Advertising

Bernhard Swoboda, University of Trier, Germany

Stefan Elsner, University of Trier, Germany

Thomas Foscht, University of Graz, Austria

Hanna Schramm-Klein, University of Siegen, Germany

EXTENDED ABSTRACT

Store flyer advertising is a medium that is well accepted by consumers and also popular among retailers. Nevertheless, the body of research available on the effectiveness of store flyer advertising is very small (Arnold, Kozinets and Handelman 2001, 245). Of course, findings on print advertising could be transferred to store flyer advertising in some cases, but there are some distinct differences such as available advertising space. Unlike printed ads, for example, store flyers usually consist of more than four pages. Thus, retailers are able to promote more products or can use the advertising space available for other design elements, such as endorsers. Some retailers, for example Wal-Mart, use photos of the entrepreneurs with their associates as endorsers to build up a retail image on the basis of trustworthiness and honesty (Arnold et al. 2001). Other retailers, particularly large retail chains, use physically attractive endorsers on the basis of the “What-is-beautiful-is-good” hypothesis to apply persuasiveness in advertising (DeShields, Kara, and Kaynak 1996). Indeed, the extensive use of endorsers in advertising is not a recent phenomenon, as the vast endorser literature indicates. However, the impact of depicting entrepreneurs with their associates on advertising effectiveness has been less analyzed (Reidenbach and Pitts 1986).

Against this background, our study has two objectives. Firstly, we propose to investigate for the first time in a field setting the efficiency of showing entrepreneurs with their associates and of using physically attractive models in terms of consumer perception and purchasing behavior, i.e. which endorser type is better. Furthermore, in order to assess whether the use of endorsers is generally justified, we propose investigating the effectiveness of endorsers, i.e. is it better to depict entrepreneurs with their associates or physically attractive models rather than no endorsers at all?

We have, therefore, developed a conceptual framework based on the dual mediation hypothesis. In order to test these hypotheses, we conducted our survey in a field setting. For this purpose we printed three original store flyers, differing only in the endorser groups and one flyer without any endorser, in cooperation with a local medium-sized retailer and a professional advertising agency. The impact of the endorsers on consumer perceptions was then evaluated in 300 face-to-face interviews using a standardized questionnaire. We measured attitude toward the ad (A_{AD}), perceived corporate credibility, store image perceptions, and visit intention on established, seven-point semantic differential scales. Subsequently, we analyzed the impact of different endorser types on purchasing behavior. We divided the trading area of the retailer advertised into three regions with the same statistical distribution of the corresponding population in terms of age, gender and number of households. Then 90,000 store flyers (30,000 of each type of flyer) were disseminated evenly throughout the regions on a Sunday by a local newspaper. A baseline approach was employed to measure the purchasing behavior for each region. Thus, we recorded the number of customers making a purchase of the advertised product category two weeks before (control weeks) and two weeks after distribution (experimental weeks) and aligned them to the region of origin.

In the analysis of consumer perceptions, our conceptual framework indicates partial mediation and provides strong support for the dual mediation hypothesis. We conclude that the A_{AD} mediates the store image perceptions directly as well as indirectly by means of the perceived corporate credibility, whereas the indirect effect is even stronger, meaning that the perceived corporate credibility strengthens the impact. Hence, our findings underline the notion that the perceived corporate credibility plays an important role in advertising persuasiveness.

In order to investigate the moderating effect, the results of the mean value comparison and the path strength comparison show ambiguous results. The mean value comparisons indicate that depicting of entrepreneurs with their associates leads to a more positive effect in terms of A_{AD} , perceived corporate credibility, and store image perceptions compared to use of physically attractive models. This result is in accordance with Goldsmith et al. (2000), who also identified highly credible endorsers as an efficient advertising instrument. Moreover, our results demonstrate that depicting of entrepreneurs with their associates also outperforms the store flyer with no endorsers at all in terms of perceived corporate credibility and store image perceptions. On the other hand, the flyer using physically attractive models is ranked even lower in terms of corporate credibility than the control flyer with no endorsers. In summary, we conclude that depicting of entrepreneurs with their associates is more efficient than depicting physically attractive models and also more effective than no endorser at all for non-attraction-related products in store flyer advertising, while depicting of physically attractive models is even detrimental. However, the results of the path analysis demonstrate no significant differences. Thus, we conclude according to MacKenzie and Spreng (1992) that the moderating effect of different endorser types influences the extent, but not the nature of information processing.

The analysis of purchasing behavior does not show the same results. This can be explained by several factors. Firstly, we can assume that there is an attitudinal behavior gap. Chandon, Morwitz, and Reinartz (2005) stated that attitude could be overestimated in such a way that behavior could not be measured. Secondly, by analyzing purchasing behavior shortly after flyer distribution we only take the direct effect into consideration. However, in order to improve store image perception in particular, a certain time period must be allowed to elapse. Nevertheless, the analysis of purchasing behavior reveals interesting findings for retailers. Firstly, according to Burton, Lichtenstein, and Netemeyer (1999), we identified a strong direct effect by store flyer advertising on sales, with an increase of nearly 19%. This underlines the considerable importance of this advertising medium. Secondly, the baseline approach applied offers retailers an easy-to-handle means of measuring the performance of their store flyer advertising.

As with all empirical studies, this study has limitations. A major limitation is the single product setting of our study, which limits the extent to which our findings can be generalized. Thus, additional multi-product studies are needed to establish whether the effects are also stable for attraction-related products.

Positive Affect, Intertemporal Choice, and Levels of Thinking: Increasing Consumers' Willingness to Wait

Jin Seok Pyone, Cornell University, USA
Alice M. Isen, Cornell University, USA

EXTENDED ABSTRACT

Individuals frequently make choices requiring self-control, some of which involve a trade-off between taking an immediate small gain, versus taking a delayed larger gain. Although the basic principles that may underlie the effect that we study apply to many kinds of self-control, in this article we address the phenomenon of intertemporal choice—perceived differences in the value of rewards over time.

How to reduce impulsivity and increase self-control has been of interest to researchers in several fields. The literature shows that self-control can be enhanced through cognitive processes that relate to ways of thinking about situations and options. For example, thinking about one's action at a higher level, in terms of its consequences and implications, can enhance self-control (Fujita et al. 2006; Vallacher and Wegner 1989). Also, research has shown that focusing on other, non-consumatory, aspects of tempting stimuli can increase delay-of-gratification in children (e.g., Mischel, Shoda, and Rodriguez 1989).

Interestingly, the affect literature suggests that positive affect has an influence on thinking that is compatible with what has just been described as conducive to improved self-control—increased cognitive flexibility, resulting multiple ways of thinking about stimuli and situations, and broadened scope of cognition (e.g., Fredrickson and Branigan 2005; Isen and Daubman 1984; Kahn and Isen 1993; Staw and Barsade 1993; Isen 2007 for discussion). For example, a series of studies shows that positive affect leads to more flexible categorization—multiple aspects of situations and ways of categorizing considered—but at the same time with more typical ways of categorizing not lost. In addition, research has shown that positive affect improves problem solving, including medical decision making (e.g., Estrada, Isen, and Young 1997), by facilitating flexible and integrative thinking. Additionally, positive affect has been shown to influence the way people construe present and future rewards. For example, individuals in a positive state are able to see how present situations are linked to possible future outcomes, and to their own effort (Erez and Isen 2002). Thus, when there is a trade-off between short-term rewards and long-term gains, they are willing to forgo present enjoyment in favor of long-term gains (e.g., Isen and Reeve 2005; Gervy, Igou, and Trope 2005).

Concerning intertemporal choices, researchers interpret a person's loss of self-control or impulsive behavior as based on a human tendency to value immediate rewards over delayed future rewards (i.e., “present-biased preferences” or “hyperbolic discounting”). That is, people discount the value of rewards set to take place in the future, and the discounting rate is greater for shorter time horizons than for longer time horizons (e.g., Frederick, Loewenstein, and O'Donoghue 2002). Recent research suggests that an individual's mindset or level of construal influences these present-biased preferences, such that construing a situation at a high level (or an abstract mindset) leads to long-term thinking and greater self-control, and thus to a decreased level of present bias (Fujita et al. 2006; Malkoc, Zauberman, and Bettman 2007).

Because positive affect has been shown to facilitate flexible thinking and the ability to conceptualize situations in such high-level ways, and thus to facilitate self-control, we propose that positive affect will influence self-control in the specific domain of

intertemporal choices. We test this idea using a delay-of-gratification paradigm suited to adult consumers, and temporal-discounting paradigms that assess change in value with delay, and willingness-to-pay to expedite delivery. Specifically, we propose that people in positive affect will be more likely than those in neutral affect to think of the intertemporal choice situation with a long-term perspective, and thus to be more willing to wait for more desirable later outcomes that are at least moderately better than the available immediate outcome, and to show decreased present bias. In addition, we examine some possible underlying mechanisms by which positive affect influences consumers' self-control in such intertemporal choices.

Studies 1 and 2 investigated the impact of positive affect, induced in two different ways, on participants' choices between an instant rebate returning a smaller amount of money and a mail-in rebate returning a larger amount of money. The results revealed that individuals in the positive-affect conditions were more likely than those in the neutral-affect conditions to choose the mail-in rebate, especially when the difference between the instant and mail-in rebates was moderately large (but not when the difference was small). In addition, for people in whom positive affect had been induced, compared to controls, the rebates appeared to be cognitively represented in a less vivid (“cooler”) way.

Studies 3 and 4 tested whether positive affect leads to decreased present-biased preference, by examining participants' willingness to pay. In Study 3, participants indicated how much they would pay for a product if they received it immediately versus one month later. Overall, participants were willing to pay less for the delayed product than for the product immediately (i.e., present bias), but the willingness-to-pay decreased less in the positive-affect condition than in the neutral. In Study 4, participants were asked how much they would pay for expediting delivery of their product by 3 or 10 days. Again, overall, participants were willing to pay more per day to expedite the delivery over a shorter delay than over a longer delay, showing present bias, but the decrease in daily premiums was less in the positive-affect condition.

Studies 5 and 6 investigated some possible cognitive processes involved in this effect. Study 5, using the Behavior Identification Form developed by Vallacher and Wegner (1989), to examine whether induced positive affect can foster a higher level of thinking, found that individuals in positive affect, compared to control-affect participants, were more likely to think of behaviors at a high level. Study 6 investigated the level of thinking in terms of time perspective orientation. Past research suggests that a future-oriented time perspective is related to pursuing future, long-term, rather than short-term, present-oriented, goals. Time orientation, as reflected by the Future-Time-Perspective scale (Carstensen and Lang 1996), was more future-oriented among people in the positive-affect condition than among people in neutral affect.

The Inhibition Effects of Repetition on Non-target Ad Recall: The Role of Affect Valence

Hieu P. Nguyen, California State University–Long Beach, USA

James M. Munch, Wright State University, USA

Meryl P. Gardner, University of Delaware, USA

EXTENDED ABSTRACT

Repeat advertising exposure is often used to strengthen top-of-mind awareness and recall. The effects of ad repetition on attitude and recall in cluttered and uncluttered/isolated contexts have been researched extensively (e.g., Burke and Srull 1988, Campbell and Keller 2003, D'Souza and Rao 1995, Kirmani 1997, Lane 2000, Malaviya, Meyers-Levy, and Sternthal 1999, Malaviya 2007). However, little is known about how repetition of some ads may affect consumers' memory for the *remaining* ads in the exposure set. Specifically, we have three main research questions: (1) Does exposure to a subset of previously viewed print advertisements strengthen or inhibit recall of the remaining ads? (2) Are the effects specific to a particular affective valence? Does exposure to positive ad cues inhibit only recall of positive ads and not negative ads? Does exposure to negative ad cues inhibit only recall of negative ads and not positive ads? (3) What are the boundary conditions of any observed effects? Does exposure to neutrally valenced ads inhibit recall of only neutrally valenced ads and not emotionally valenced ads? Does exposure to emotionally valenced ads inhibit recall of only emotionally valenced ads and not neutrally valenced ads?

We draw on findings in the psychology literature on part-list cuing inhibition effects to construct our theoretical foundation. Part-list cuing inhibition refers to the observation that the presentation of a subset of previously learned items as retrieval cues often inhibits recall of the remaining noncue items (Aslan, Bauml, and Grundgeiger 2007). The earliest and most predominant theoretical account is the retrieval competition hypothesis (Rundus 1973). It suggests that exposure to cue words strengthen their memory traces compared to those of noncue words. When individuals attempt to recall noncue items at test, the higher retrievability of the cue items decreases the probability of accessing noncue items directly (Bauml 2007, Nickerson 1984). Based on the retrieval competition hypothesis, we predict that compared to uncued participants, cued participants will show poorer recall of ads (H1). However, this effect is also affect-specific. Bower's associative network theory (1981) suggests that the affect node is connected by associative pointers to other aspects of the emotion. Activation of a node is accomplished either by presentation of the corresponding stimulus pattern or by prior activation of an associated thought. Bower also suggests that "each emotion may reciprocally inhibit an emotion of opposing quality, as fear inhibits joy and sexual arousal." (p. 135). We follow Bower's theory and argue that exposure to positive ad cues should activate the positively valenced node, which can transmit excitation to other positive nodes but not negative nodes, eventually helping retrieval of positive ads. Therefore, when participants see positive ad cues, they should be able to recall other positive ads. However, the covert retrieval of the positive *ad cues* at recall inhibits the retrieval of *uncued* positive ads. Compared to uncued participants, positive cue participants will show poorer recall of the remaining positive ads while recall of negative ads will not differ (H2). Similarly, compared to uncued participants, negative cue participants will show poorer recall of the remaining negative ads while recall of positive ads will not differ (H3). For neutral ads, emotion is not a salient aspect. Exposure to emotional ad cues should only result in inhibition for emotional ads but not neutral ads, because these ads are not associatively linked to emotional ads in memory structure. Neutral ad recall will not differ significantly between

uncued and emotionally cued participants (H4). Neutral valence is not a salient aspect of one's experience. Ads which are not emotional are unlikely to be remembered for their neutral moods, and are not expected to be organized by emotional valence. Drawing from Bower's associative network theory, exposure to neutral cues should not inhibit recall of neutral ads only (because neutral ads are not an affective category in memory, therefore neutral nodes are not linked to other neutral nodes in the same fashion that positive and negative nodes are linked to positive and negative nodes, respectively). In line with the retrieval competition hypothesis, we predict that exposure to neutral ads as cues will inhibit recall of positive, negative, and neutral ads alike (H5).

One hundred forty seven undergraduate students participated in the experiment for partial course credit. Participants were randomly assigned to one of four cue conditions (no cue, positive cue, negative cue, neutral cue). Each participant viewed 26 ads (eight per affective valence type plus two buffer ads). After that, those in the experimental conditions were shown four randomly selected and ordered ads from the slideshow they had just seen. These four cue ads matched the valence type of the participants' assigned condition. Participants in the control condition solved some simple reasoning tasks. We found support for all hypotheses. Our findings indicate that exposure to ad cues inhibits recall of uncued ads, and more importantly, this inhibition effect is affect-specific. Our research makes an important contribution to the ad repetition literature because it sheds light on the effect of repetition of target ads on non-target ads. For advertisers, using the same affective valence in all of their ads might result in situations where some of the ads will be forgotten because of exposure to other ads of the same affective tone.

Not All Products are Placed Equal: A Quasi-Experimental Approach to the Integration Effects of Conspicuous Product Placement on Affective Brand Attitude

Sukki Yoon, Bryant University, USA
Yung Kyun Choi, Dongguk University, South Korea
Sujin Song, University of Rhode Island, USA

EXTENDED ABSTRACT

Imagine two consumers, Jason and Sarah, watching movies on TV. Jason, viewing a scene from *Runaway Bride*, sees Julia Roberts jump on a truck that conspicuously displays the FedEx logo. Sarah, watching *The Thomas Crown Affair*, sees Rene Russo march to a vending machine, pull out a can of Pepsi, with its logo prominent, and guzzle it down. In both scenes the brands are noticeably displayed; the actors touch or consume the products. Jason and Sarah instantly recognize that the products have been placed with obvious, persuasive intent. Who will feel more positively toward the product featured? Jason or Sarah? Will they feel differently if they are cognitively busy while viewing these scenes, if they are, say, speaking on the phone or browsing the Internet? And will their feelings toward brands that are not shown—UPS and Coke—be influenced as well? How Jason and Sarah respond may vary, depending on, among other things, how well the product has been integrated into the storyline.

As the practice of product placement is becoming more overt and blatant, marketers and consumers alike are increasingly accepting this “in-your-face” practice. Because costs associated with the placement and the centrality (e.g., close-ups) of the placement are directly linked, marketing practitioners have a heightened need to understand how and when such conspicuously placed placements help or damage the brand. Previous research has compared prominent placement and subtle placement as a primary construct responsible for effects on cognitive variables. However, few studies have yet to focus on how conspicuous placements in themselves—arguably the most common form of product placements in today’s media—can differently affect consumers’ feelings toward the brand. The present research aims to fill this gap.

Today’s discerning consumers seem to see both gratifying and disturbing aspects of product placement. They acknowledge that a well-placed product enriches the plot, heightens realism, and adds enjoyment to their entertainment experience, but when the product placement is poorly done, they see it as an intrusive and unwelcome distraction. According to one survey, 80 percent of American consumers have positive views toward conspicuous product placements, but 46 percent agree that it “depends on how it’s done”. Academics share this view. Some researchers have argued that well-integrated placement increases persuasion, but poorly integrated placement has the opposite effect. Using real movie scenes as stimuli, this paper focuses therefore on the factor that makes the difference between persuasion and dissuasion—integration.

The objectives of this research are to (1) identify exemplar scenes of conspicuous placement, well-integrated and poorly integrated, from current films (Pretests 1-4), (2) test whether a well-integrated placement indeed enhances a brand’s image, whereas a poorly integrated placement damages a brand’s image (Study 1), (3) examine how consumers’ cognitive busyness moderates the placement integration effects (Study 2), and (4) explore whether a consumer’s exposure to a conspicuous brand placement (e.g., Pepsi) influences the consumer’s evaluation of the apparent competitor that is not shown (e.g., Coke; Study 2).

First, through a series of extensive pretests we selected two real movie scenes with conspicuous product placements that represent contrasting sides of placement-plot integration: well

integrated product placement and poorly integrated product placement. These two scenes were further validated for conspicuousness, integratedness, and relevancy. In addition, we quasi-experimentally controlled for program length, brand-exposure duration, and program liking.

Second, in Study 1, we tested a rather straightforward but yet-to-be-experimentally tested effect: A well-integrated conspicuous brand placement will evoke a higher affective evaluation than will a poorly integrated conspicuous placement (H1).

Third, in Study 2, we tested the following hypothesis: For a well-integrated conspicuous placement, cognitively busy participants will have lower affective evaluation of the placed brand than will cognitively non-busy participants, but for a poorly integrated conspicuous placement, cognitively busy participants will have higher affective evaluation of the placed brand than will cognitively non-busy participants (H2).

Fourth, in Study 2, we tested two additional hypotheses: 1) For the poorly integrated conspicuous placement, cognitively non-busy participants will have a lower affective evaluation of the placed brand than of the not-shown competing brand (boomerang effect), but cognitively busy participants will have a higher affective evaluation of the placed brand than of the not-shown competing brand (H3.1). 2) However, for the well-integrated product placement, the two-way interaction effect specified in H3.1 will be absent (H3.2).

In sum, using real movie scenes as stimuli, this paper demonstrates that consumer feelings toward the placed brand improve when the product is seamlessly integrated, but deteriorate when the product is intrusively integrated. We also identified the boundary condition under which such integration effects are altered: that is, poor integration’s brand-damaging effect can be reversed to a brand-enhancing effect if viewers are cognitively preoccupied with another task. In addition, the results suggest that poor integration’s reactance-induced boomerang effect might not only decrease the affective evaluation of the placed brand, but might also increase the affective evaluation of the not-shown competitor.

Power and Choice: Do Powerful Consumers Prefer Bold Options?

Mehdi Mourali, University of Calgary, Canada

Frank Pons, Laval University, Canada

EXTENDED ABSTRACT

Power is a basic feature of social life (Russell 1938). Most societies are organized in a hierarchical fashion, with some members enjoying more power than others. Even so, people regularly experience feelings of being both powerful and powerless, regardless of where they stand in the social hierarchy. Being asked for one's expert advice, for example, may induce a psychological state of feeling powerful, whereas being evaluated by one's peers may evoke a sense of powerlessness. The evident ubiquity of power in our everyday life prompts a critical question: Do people make different consumption decisions when feeling powerful versus powerless? Although the role of power in consumer behavior has received relatively little attention (Rucker and Galinsky 2008; Dwyer 1984), recent developments in psychological research suggest that possessing versus lacking power can have a significant influence on how people think, feel, and act in a variety of social situations (Fiske 1993; Guinote 2007; Keltner, Gruenfeld, and Anderson 2003; Overbeck and Park 2001; Smith and Trope 2006).

The approach/inhibition theory of power (Keltner et al. 2003) posits that power influences the relative activation of the behavioral approach and inhibition systems—the two fundamental action tendencies that regulate behavior associated with rewards and threats respectively. The theory holds that elevated power activates the behavioral approach system, whereas reduced power activates the behavioral inhibition system. Building on the approach/inhibition theory of power, this paper proposes that power significantly and predictably influences consumer preferences in a number of decision contexts. In particular, we focus on decision contexts in which consumers choose between extreme versus compromise options (Simonson 1989), hedonic versus utilitarian options (Dhar and Wertenbroch 2000), enriched versus impoverished options (Shafir 1993), and unique versus standard options (Maimaran and Wheeler, forthcoming). These four types of decisions share a common characteristic: they all involve a choice between bold and timid options (Maimaran and Simonson 2008). Bold options (i.e., extreme, hedonic, enriched, and unique options) are defined as less conventional, more distinctive, and more self expressive, whereas timid options (i.e., compromise, utilitarian, impoverished, and standard options) are more conventional and less self-expressive. We propose that a heightened sense of power increases consumers' tendency to make bold choices. Furthermore, power often comes with a sense of responsibility (Overbeck and Park 2001). This sense of responsibility can raise the perceived constraints that a powerful individual feels (Smith and Bargh 2008), and lead to reduced approach-related tendencies. Thus, we expect that the effect of power on choice of bold versus timid options would disappear under conditions of high responsibility.

Studies 1 and 2 tested the main effect of power on choice of bold versus timid options. Power was manipulated using a scrambled sentence task (Smith and Trope 2006) in study 1 and a writing task (Galinsky et al. 2003) in study 2. Using different types of choice problems, these studies offered converging evidence that when consumers' sense of power is elevated, they are more likely to choose bold options over timid ones. However, reducing consumer's sense of power did not increase their preference for timid options. Moreover, the observed effects were not mediated by consumers' mood.

Study 3 tested the moderating role of responsibility. Power was manipulated using a role-based procedure adapted from

(Galinsky et al. 2003), and responsibility was manipulated by telling a group of respondents that they were highly responsible for the outcome of the project and the wellbeing of others. As expected, power had a significant effect on choice of bold versus timid options in the low responsibility condition but not in the high responsibility condition.

Choice Facilitating Effects of Online Shopping Agents in the Face of Missed Opportunities

Demetra Andrews, University of Houston, USA

EXTENDED ABSTRACT

To date, research on the influence of missed opportunities has largely focused on “offline” purchases in which a decision-maker evaluates the available alternatives without external assistance or information (see Kumar (2004) for an exception in which the purchase behavior of a referent other is available to the decision maker). However, consumer use of the Internet to facilitate purchase decisions is rapidly increasing (Haubl and Trifts 2000). In a recent study by comScore, Inc. (Fuglioni and Abraham 2008), nearly three-fourths of respondents stated that the Internet affords them better pricing information and almost 25% indicated its particular value in identifying sales and special offers. Of specific relevance to the current research, the comScore report indicated that, from 2007 to 2008, the number of unique users of online search and comparison tools increased by 7% to 67MM, providing vivid evidence of consumers’ increasing reliance on these tools.

The purpose of the current research is to enhance our understanding of the influence that one type of Internet-based interactive decision aid, online shopping agents (OSAs), exerts on two consequential reactions to missed opportunities that have been noted in the literature, increased likelihood of choice deferral (Arkes, Kung and Hutzel 2002; Tykocinski and Pittman 1998; Tykocinski, Pittman and Tuttle 1995) and brand switching (Zeelenberg and van Putten 2005). Findings from three studies demonstrate the efficacy of OSAs in reducing the likelihood of both choice deferral and brand switching and offer ideas regarding possible drivers of this positive influence. Thus, the current research extends the current literature by addressing the question of whether the influence of OSAs can dissipate the shadows of missed opportunities.

Popular examples of such OSAs include MySimon.com, pricegrabber.com, and shopping.com. OSAs scour the Internet to identify alternatives that match consumer-input preference information. At the conclusion of their search and filtering activity, they return a list of available alternatives ranked according to those preferences. Prior research has shown that OSAs exert a strong influence on consumer behavior. Among the noted effects are changes in price sensitivity (Diehl, Kornish, and Lynch 2003), reduced search effort (Haubl and Trifts 2000; Ratchford, Talukdar, and Lee 2007), and improved decision quality (Haubl and Trifts 2000).

One of the core behaviors observed in prior research on missed opportunities is an increased incidence of choice deferral such that missing out on a good opportunity reduces the likelihood that a lesser opportunity will be accepted, even if it is better than the standard offer (Tykocinski et al. 1995). This finding has been consistent in multiple studies and proposes an unattractive prospect for marketers that employ hi-lo pricing strategies or promotional offers. However, the question of whether this pattern would hold in the presence of online shopping agent influences is yet unanswered. Thus, the current body of research was undertaken.

In Study 1, I manipulated whether the missed opportunity was caused by an OSA or the decision-maker and whether the information on the currently-available offer was discovered by the OSA or the decision-maker. Findings showed that use of an OSA significantly reduced the likelihood of choice deferral over conditions where no OSA was employed. Moreover, when the information on the currently-available offer came from an OSA, the deferral rate held constant (at approximately 30%), but when the decision-maker

was the source of the new information the likelihood of choice deferral varied as a function of the cause of the missed opportunity (Self or OSA).

Choice deferral is but one troublesome response to a missed opportunity. Research by Zeelenberg and van Putten (2005) and Tsiros (2009) suggests that, rather than go without a desired item, people may switch to another brand to avoid purchasing an item on which a special offer was missed. Such a negative influence on brand loyalty is unattractive to marketers, thus I undertook studies 2 and 3 in order to evaluate the efficacy of OSAs in mitigating brand switching. Studies 2 and 3 followed a design similar to that of Study 1, but rather than evaluate whether a choice was made or not, the key dependent variable was whether the originally desired brand was selected vs. another available brand.

In Study 2, the “currently-available” choice set included a brand that was identical to the one for which a sale was missed. The results showed the lowest likelihood of brand-switching when an OSA was both the cause of the initial missed opportunity and the source of information on the current offer. In Study 3, the currently-available choice set included a brand that was highly similar to the one for which a sale was missed, rather than identical to it. Thus, the study was likely more reflective of real life choices. Under this condition, the results showed that an OSA-caused missed opportunity generated less brand-switching behavior than did a self-caused miss. In particular, the lowest likelihood of brand-switching was observed when an OSA caused the initial miss but the decision-maker discovered the information about the current offer. When this finding is compared to that observed in Study 2, the difference suggests that the use of OSA to aid choice may be beneficial to brand loyalty even if the decision-maker decides not to use a faulty OSA in the second stage of the choice process.

Taken together, findings from these three studies suggest that the increasing usage of online shopping agents in consumer choice may bode well for marketers in that OSA usage may reduce the likelihood of both choice deferral and brand-switching in response to missed opportunities.

Effects of Resource Availability on Consumer Decisions on Counterfeit Products: Role of Justification

Jungkeun Kim, Auckland University of Technology, New Zealand

Jae-Eun Kim, Auckland University of Technology, New Zealand

Jongwon Park, Korea University, Korea

EXTENDED ABSTRACT

People consider counterfeit products to be unethical, yet sometimes engage in counterfeit purchases. Previous research has identified various determinants of counterfeit purchases, including price benefits, perceived risks, demographic factors, and personality variables. For example, it has been shown that the most important motive for purchasing counterfeit products over genuine ones is their functional quality and physical appearance comparable to that of originals (Wee, Tan, and Check, 1995). It has also been shown that consumers' risk perceptions about counterfeits and their moral beliefs against them decrease purchases for counterfeit products (Logsdon, Thompson, and Reid, 1994; Moores and Chang 2006). However, most of these findings are generally descriptive and based on correlational analyses. In addition, situational influences and cognitive processes underlying these influences have rarely been investigated.

The present research investigated the effect of resource availability on the consumption of counterfeit products. We contend that to the extent that counterfeit purchases being considered as unethical behavior, people need to be able to justify their decisions in order to engage in counterfeit purchases. However, the justification process requires considerable amount of cognitive resources. Consequently, people are more likely to consider purchasing counterfeits when they have cognitive resources than when they do not. This effect is more likely to occur among people who have strong moral beliefs against unethical consumption behaviors in general. If people do not consider the counterfeit purchase as unethical, however, they may feel no need to justify their purchases, thus are likely to consider purchasing counterfeit products regardless of whether their cognitive resource is non-limited or limited. On the other hand, if people are required to explain and justify their purchase decisions to others, they may not be able to generate sufficient justification for counterfeit purchase, thus unlikely to consider counterfeit purchase regardless of resource availability.

These possibilities were examined in four studies. In experiment 1, participants were asked to perform either a resource-depleting task or a control task, which was to manipulate the amount of cognitive resources available for a subsequent task (limited resource vs. non-limited resource). Then, participants were introduced to a purchase situation for knit sweaters and were asked to decide whether they would like to buy counterfeits over genuine products. As expected, participants reported a higher level of purchase intentions for counterfeits when their cognitive resource was non-limited rather than limited. In addition, this effect was mediated by the effect of resource availability on participants' perceptions of justifiability about the counterfeit purchase. Finally, a follow-up study replicated these results in a different product category and in addition, eliminated a mood-based alternative explanation for the effect.

Experiment 2 replicated results from experiment 1 in another different product category and in addition, identified consumers' moral beliefs against unethical consumptions as a moderator for the effect. To do so, participants' moral beliefs were assessed. In addition, resource availability was manipulated by a distraction task during the counterfeit purchase situation rather than by a depletion task prior to the purchase situation for generalizability of

results. As expected and consistent with experiment 1, resource availability increased counterfeit purchase intentions. As also expected, however, this effect was restricted to individuals who have high moral beliefs, whereas participants with low moral beliefs exhibited high purchase intentions for counterfeits regardless of resource availability conditions. This difference was evidenced by a significant interaction of moral beliefs and resource availability, and was mediated by participants' justification perceptions about the counterfeit purchase.

Experiment 3 identified accountability of decisions as another moderator for the effect. When participants were required to account for their decisions to others and thus found it difficult to fully justify their decisions, their purchase intentions for counterfeits was low, regardless of people's resource availability.

In sum, these and other results suggest that people intend to purchase counterfeits if they can justify their decision, but that such justification requires cognitive resources. Theoretical and managerial implications are discussed.

When Unique (Nonalignable) Differences Acquire Greater Importance than Shared (Alignable) Ones: The Role of Noncomparison-Based Choice Processes

Amitav Chakravarti, New York University, USA
Suzanne A. Nasco, Southern Illinois University, USA

EXTENDED ABSTRACT

Choices are often a function of the shared (i.e., alignable) and the unique (i.e., nonalignable) attributes of the options under consideration. Past research in a variety of areas has shown that alignable attributes tend to have a greater impact on choice than nonalignable attributes. This is marked by a well-documented tendency for decision makers to choose options that are superior on the alignable attributes (i.e., the alignable-better brand) over options that are superior on the nonalignable attributes (i.e., the nonalignable-better brand). We refer to this robust and well-documented phenomenon as the alignable superiority effect (ASE).

In this paper, across five studies, we show that several individual-level, contextual, and situational factors are capable of either attenuating or enhancing this effect. More importantly, the studies presented collectively provide strong evidence that the degree of noncomparison-based processing is a critical factor in determining the relative influence of alignable and nonalignable attributes in choice tasks. Alignables dominate in decisions involving extensive comparisons; however, nonalignables loom larger when decision makers are encouraged to engage in non-comparison based processing. This conceptual rubric not only explains the moderators we present in this paper, but it might also explain moderators that have been documented in the past. In fact, we believe that the dominance of alignability found in consumer behavior studies so far, is in part due to the fact that most of the experimental tasks encouraged extensive, attribute-by-attribute, comparison-based processing of choice alternatives. In fact, as we later demonstrate, small changes to these often-used experiment features can have important consequences for the alignable superiority effect.

The preceding discussion naturally begets the question, what is noncomparison based processing? The details regarding the theoretical underpinnings of our argument regarding the impact of noncomparison-based processing on the ASE are provided in the main body of the paper. However, to provide a nutshell summary, we essentially propose that anything that dampens the comparison processes that are usually ubiquitous in choice decisions, either directly (e.g., by reducing the number of attribute-by-attribute comparisons), or indirectly (e.g., by increasing holistic, alternative-based processing), should significantly weaken the ASE. We conducted five studies to investigate this basic proposition. Studies 1-4 were designed to investigate the impact of reduced comparisons on the ASE, and study 5 was designed to look at the joint effects of reduced comparisons and increased holistic processing on the ASE.

We first show that individual-level predispositions to not engage in comparisons mitigate the ASE (study 1). More specifically, we showed that the ASE is prominent among individuals predisposed to engage in comparative behavior (e.g., those who score high on the Comparison Orientation scale), but that the ASE is significantly attenuated among individuals predisposed to not engage in such comparisons (e.g., those who score low on the Comparison Orientation scale).

We then manipulate the contextual descriptions of product features and show that if contextual characteristics discourage extensive comparison of the choice options, then reliance on the

nonalignable attributes increases significantly and the ASE is eliminated (study 2). We find that a relatively simple manipulation of the information presentation format suffices in reducing the ASE, in keeping with past research (e.g., Bettman and Kakkar 1977, and Painton and Gentry 1985) that has shown that relative to a tabular format, a paragraph presentation format tends to inhibit a decision maker's ability to make comparisons. Thus, study 2 showed that a paragraph (tabular) information presentation format inhibited (facilitated) comparisons and attenuated (bolstered) the ASE.

In study 3 we extended the generalizability of our research by replicating our findings in three different product replicates, each with a varied set of attributes. We also varied the kind of attribute descriptions that were used as alignable or nonalignable attributes by "rotating" the attributes that were used as alignables with the ones that were used as nonalignables.

As a more complete test of our proposed relationship between the ASE and comparisons, we not only show that discouraging comparisons weakens the ASE (like in studies 1-3), but also demonstrate that encouraging comparison-based processing actually strengthens the ASE (study 4). To situationally induce a more comparative mindset we used Mussweiler's (2003) procedural priming method, that has been successfully used in a wide variety of domains, from classic anchoring-adjustment tasks (Keil, Mussweiler, and Epstein 2006) to financial decisions regarding stocks (Mussweiler and Schneller 2003). To induce a less comparative mindset we used Shiv and Huber's (2000) intervention, in which participants are asked to anticipate satisfaction with the options prior to making a choice. Thus, by simultaneously showing both that noncomparison-based processing favors the nonalignable-better brand, and that encouraging comparison-based processing has an effect that is opposite to that of noncomparison-based processing, these results provide stronger support for the central claims of our research. In addition, given the description of the manipulations above, this study also showed that unrelated situational factors, like the comparative mindset induced in an independent and unrelated preceding task, could also significantly affect the ASE.

Finally, study 5 addresses one missing piece of the puzzle. We had claimed that there were two possible routes to dampening the ASE. So far, in looking at personality (study 1), contextual (studies 2-3), and situational (study 4) factors that dampen or augment the ASE, we have always implicated either a reduction, or an increase, in comparative processing as the key driving force behind our results. Study 5 provides strong support for the second route, and shows that greater holistic processing can, independently, dampen the primacy of the alignables that has been observed in the past.

The issue of comparability is central to structural alignment theory, since it is only through comparisons that alignment is established. Logically, therefore, comparisons should play a big role in the dominance of alignable attributes that has been observed in past work. Up to now, however, this comparison process that should be so central to the dominance of alignables over nonalignables, has gone relatively unexamined. We try to address this gap through this research.

Does Cultural Orientation Influence Consumers' Propensity to Trust?

Yinlong Zhang, University of Texas at San Antonio, USA

EXTENDED ABSTRACT

Consumer trust is essential to all kinds of modern exchanges; the very concept of marketing (Bagozzi 1975), from buying a used car, purchasing on-line, deciding on a relationship partner, to choosing among different careers. The importance of consumer trust has been further enhanced by the development of E-commerce and globalization (Doney, Cannon, and Mullen 1998), as more and more transactions and marketing operations take place in a global scale. With the increasing pace of globalization, it is important to understand the role of cultural orientation on consumer trust, for example, what is the role of individualism/collectivism orientation on consumer trust?

Empirical findings on the relationship between cultural orientation and trust are very inconsistent in the literature. For example, through surveys, Yamagishi and his colleagues (1994) found that U.S. participants showed higher level of trust than their Japanese counterparts. Through a 20-year analysis of economic development, Putnam (1993) found the similar pattern of results that U.S. participants showed higher level of trusting tendency than those from Asia such as Korea, China and Japan. More recently, while comparing seven-markets (China, Hong Kong, Japan, Korea, Malaysia, Taiwan and U.S. Hawaii and Illinois), Huff and Kelley (2003) found extremely strong evidence showing that individualistic American show much higher trusting tendency than collectivistic Asians. In the contrast, using an investment game, Buchan and her colleagues (Buchan, Croson and Dawes 2002; Buchan and Croson 2004) found that collectivistic Chinese showed higher trusting tendency than individualistic Americans. This pattern of results has been obtained by other researchers. For example, in the World Values Survey, Inglehart, Basanez, and Moreno (1998) found participants from Asian countries such as China, Japan and South Korea showed higher level of trusting tendency than those from U.S. (see Buchan et al. 2002 for a detailed review).

As Oyserman, Coon, and Kimmelmeier (2002) have noted, countries differ on many cultural dimensions other than individualism. Because many studies have divided countries into groups based on only one variable (individualism) and assumed that differences in the dependent variable are caused by individualism, researchers actually have no way of knowing whether it is that predictor variable, or perhaps some other cultural variables, that influences the correlation between individualism and trust. As discussed by Camerer (2003), cross-cultural comparisons are interesting but need to address the potential confound such as income differences. Additionally, most of the existing studies have not even measured the construct of individualism/collectivism in their cross-country comparisons. This further compounded the problem in the cross-country comparison. The current research aims to address these concerns.

Four studies are reported to investigate the impact of cultural orientation on consumers' propensity to trust. A cross-country comparison of trust tendency across 59 countries from World Value Surveys (study 1) indicated that an individualism orientation is associated with greater trust tendency than a collectivism orientation. An individual level of survey confirmed this country-level relationship. One additional experiment that manipulated self-construal provided causal evidence on this relationship. In the fourth study, we used investment game to test our hypothesis. We found that the self-construal effect on consumer trust held for the

friend not for stranger condition. Divergent operationalization of cultural orientation and measurement of trust indicates this relationship is robust.

Social Inertia: Ignoring my Benefits for the Community

Dominic Thomas, Monash University, Australia

Adam Finn, University of Alberta, Canada

EXTENDED ABSTRACT

Social change drives social marketing practice (Andreasen, 2002). Whether a campaign discourages smoking or promotes vaccination against the HPV virus, the marketer's goal is to discern societal perceptions of desirable behavior and then persuade consumers to act in certain ways. However, the consumer may experience *social inertia*—the tendency to maintain current patterns of behavior—possibly resulting from the perception of community consensus regarding that product or service. In certain contexts, the consumer's perception of community attitudes may strongly influence the evaluation and subsequent acceptance or rejection of a product or service. To date, no research has examined how an individual's perception of the community's tendency to sustain current patterns of behavior in relation to particular products or services affects evaluation of the product or service in question. Such research is necessary if we are to expand our understanding of social exchange (Blau, 1964).

The existing literature focuses primarily on acceptance of a good or service as influenced by the physical presence of the group. A two-fold rationale supports the need for research directed at acceptance as influenced by the imagined or implied presence of the community. First, when people experience conflict with their social group, they are as likely to comply with the group's attitudes and practices as to act upon their own felt needs and desires. Second, when individuals feel that they are functioning as representatives of a community, their perception of the community's general acceptance and continued use of the product and/or service will determine their evaluation of it.

We propose that this effect of the group will be greater for individuals with higher collectivistic orientation. A defining attribute for collectivism states that collectivists will give priority to the group goals, and a complementary defining attribute for individualism states that individualists will give priority to the personal goals (Triandis, 1995). We extend the discussion of collectivist and individualist priorities to the evaluation of new products and services. We contend that individual participants who regard themselves as functioning in a representative capacity will be more influenced by perceived community wants than by their own personal wants. The individual's social identity as a member of the group supersedes the sense of unique identity, so that a perception of community consensus becomes salient. Given their importance in shaping individual choice, perceived community desires are quite likely to become deeply ingrained in the individual psyche, making the individual subject to them not only when the group is physically present but also when it is absent.

Using two experimental studies, we demonstrate that consumers with higher collectivistic orientation are more likely to be influenced by the salience of their social identity so as to lower their willingness to pay for new electronic services when they perceive their community wants to continue with the existing services. We demonstrate the underlying role of the dynamic nature of self in explaining this effect. Unlike individualist consumers, collectivist consumers are influenced when social identity is made salient, and lower their willingness to pay for new electronic services if they perceive that their community prefers the existing service. In addition, this effect is dominant in case of social goods in comparison to private goods.

Our research makes three important contributions to the theoretical literature. First, this study enlarges the literature on the

dynamic nature of self. Self-categorization theory (Oakes, Haslam & Turner 1994) proposes that the salience of social identity is context-dependent. We provide evidence to support our prediction: when the context makes social identity salient, the SCT fails to hold true for people low on collectivism, although it does hold true for people high on collectivism. Second, we demonstrate the influence of an individual's perception of the community's reluctance to accept a product on his/her own evaluation of a new service, that is, the concept of social inertia. Social inertia occurs even without the direct, physical presence of community members. Finally, we also show the influence of the salience of social identity on the evaluation of new services. This finding is relevant to the literature on valuation of public goods. In this stream of literature, researchers have the tough task of associating a monetary value to public goods. Public policy makers, environmentalists, and others use methods such as contingent valuation and choice experiment to associate a monetary value with a particular public good. Our research could prompt questions concerning their valuation process. Researchers generally describe a public good (either real or hypothetical) and then ask respondents to value these services based on the description. Our paper raises the question of how the particular ways in which these descriptions are construed might influence the participants' responses. It becomes important whether these descriptions have been stated so as to make personal identity salient or social identity salient, or to leave the situation neutral.

Forewarned is Forearmed: Conserving Self-Control Strength to Resist Social Influence

Loes Janssen, Tilburg University, The Netherlands

Bob M. Fennis, Utrecht University, The Netherlands

Ad Th. H. Pruyn, University of Twente, The Netherlands

EXTENDED ABSTRACT

As consumers, it is often difficult to resist (unsolicited) influence attempts of advertisers, fundraisers, and other compliance professionals. As recent research has shown, resisting persuasion is frequently a costly process involving active self-regulation. Resisting an influence attempt consumes self-regulatory resources, with the inevitable consequence that when these resources are low, one's attempts at resistance are more likely to fail (Burkley 2008; Fennis, Janssen, and Vohs 2009; Janssen et al. 2008; Wheeler, Briñol, and Hermann 2007). Hence, resisting (unwanted) influence is more successful when self-regulatory resources are high rather than low, but the present research demonstrates that all is not lost for consumers in a state of self-regulatory resource depletion.

According to the limited-resource model of self-control (for a review, Baumeister, Vohs, and Tice 2007) any act of deliberate and regulated responding by the self draws on a limited intrapsychic resource which, akin to strength or energy, becomes depleted with use. Recently, research started to test the notion that resisting persuasion is an activity which also draws on this resource. Indeed, a state of self-regulatory resource depletion weakens resistance to temptations and (unwanted) influence attempts (Baumeister 2002; Burkley 2008; Vohs and Faber 2007; Wheeler et al. 2007). More specifically, Fennis et al. (2009) and Janssen et al. (2008) forwarded resource depletion as an important underlying factor mediating the effectiveness of sequential request social influence techniques, such as a foot-in-the-door (Freedman and Fraser 1966). They showed that actively responding to the initial request of such a technique depleted self-control resources, resulting in increased compliance with a subsequent (charitable) target request, such as freely donating time, effort or money. Importantly, depleted participants were not susceptible to influence by default, but rather because they relied more on compliance-promoting heuristics that were present in the persuasion context, such as authority, reciprocity, or likeability (cf. Cialdini's [1993] principles of influence).

In sum, and in line with dual-process models of persuasion (Petty and Wegener 1999), a state of self-regulatory resource depletion appears to reduce systematic or central-route processing, and enhances the weight on heuristic processing in consumer judgment and decision making. A key means to encourage more systematic processing could be to increase consumers' awareness of an upcoming influence attempt in advance. Multiple studies have suggested that forewarning people of an upcoming persuasive communication motivates them to counterargue the message in order to reassert their attitudinal freedom, and thereby inhibit subsequent persuasion (see Wood and Quinn 2003 for a review).

But what if the motivation to counterargue is present, but the ability to engage in counterargumentation is lacking because of previous depletion of regulatory resources? We argue that in these conditions, forewarning motivates people to conserve their remaining resources and mobilize them in the service of this counterargumentation. This presupposes that a depleted state does not reflect a complete exhaustion of resources but merely a temporary deficit, a notion that was recently supported by Muraven, Shmueli, and Burkley (2006). They suggested that individuals are (at either a conscious or an unconscious level) motivated and able to conserve their current regulatory energy when the benefits of using the resource in the future apparently outweigh the benefits of using it right now. We expect that forewarning consumers of an

upcoming influence attempt will motivate them to conserve self-control strength in the service of resisting the impending influence attempt. We expect this especially to be the case when there is a clear rationale for doing so, that is when they previously suffered a loss of self-control resources.

A first experiment tested whether forewarning increases resistance to persuasion among depleted individuals, using a 2 (self-regulatory resource depletion condition: depletion vs. no depletion) x 2 (forewarning: forewarning of an influence attempt vs. no forewarning) between-subjects design. Resource depletion was induced with a self-control task adopted from Muraven et al. (2006). Participants retyped a paragraph as quickly as they could, yet participants in the resource depletion condition were instructed to retype the paragraph without using the letter "e" or the space bar. Next, half the participants were forewarned about an upcoming encounter with a representative of the 'Campus Clean' student project, who was actively looking for volunteers to clean-up the lecture halls of the campus buildings. After performing a filler task, all participants were asked to indicate how much time they would be willing to volunteer for 'Campus Clean'. Results indeed show that when initially depleted, forewarned participants complied far less with the request (they were willing to volunteer less time) to clean-up their lecture halls as compared to their not forewarned counterparts, and resisted as much as non-depleted participants.

A second study was performed to uncover the assumed underlying psychological process: is it indeed a matter of conserving self-control strength that drives this effect? To test this notion, we included a validated measure of self-control performance after the depletion and forewarning manipulations, before compliance was measured. For most part, the design and procedure parallel that of study 1. As expected, results show that a forewarning of an impending influence attempt motivates depleted people to conserve their resources; they performed worse than participants in any other condition on the intermediate measure of self-control performance. Conserving resources appeared to be beneficial: as in study 1, when subsequently confronted with a request, initially depleted participants resisted as much as non-depleted participants.

Although the forewarning itself may or may not accompany an influence attempt in commercial settings, advanced awareness of the upcoming persuasion attempt may well be a default mode for consumers when they enter marketing spheres, such as shopping malls, or commercial websites. Indeed, work on the persuasion knowledge model (Friestad and Wright 1994) supports the notion that consumers are typically prone to infer the (self-serving) motives of marketers and advertisers, and this knowledge could function as a source of self-generated forewarnings. Hence, as consumers, we should be comforted by the present results which imply that we are still proficient in defending ourselves despite a general increase in susceptibility to influence. Even in these instances we will not always end up with products and services that we do not want or need.

Cognitive Structure Complexity in Social Cognition and Its Effect on Interpersonal Preference Prediction

Yu Hu, Salem State College, USA

EXTENDED ABSTRACT

Consumers frequently purchase products or services that are intended to be consumed by their social partners. Decisions like buying birthday gifts or Christmas presents often involve predictions of other people's preferences, a task that most consumers are not very good at, as suggested by academic researchers (e.g., Davis, Hoch, and Ragsdale 1986; Lerouge and Warlop 2006). What makes it so difficult for us to correctly predict our partners' preferences? Past research has identified important antecedents (e.g., Kenny and Acitelli 2001; Swann and Gill 1997) but paid little attention to the cognitive mechanisms that could explain the effects of social relation on judgment and decision-making.

The present paper intends to close this empirical gap: borrowing the social cognitive view of the seminal Construal Level Theory (CLT, Trope and Liberman 2003), I propose that a mediating role played social relations is that it affects the cognitive structures that people use to process social information. Specifically, as I contend, the complexity level of cognitive structures that individuals employ to process and store their partners' information, such as product preferences, is a function of the social distances between them and their partners: people are more likely to use a complex, detailed category structure, as manifested as of greater number and/or narrower breadth of categories, to process information that pertains to their close social partners (e.g., spouses or best friends); whereas people are more likely to use a simple, abstract category structure, as manifested as of fewer number and/or wider breath of categories, to process information that pertains to distant social partners (e.g., co-workers or casual acquaintances). Furthermore, a diluting effect of this structure complexity in close relation is that it might lead people to spend unnecessary efforts on and assign unnecessary weights to evaluatively non-diagnostic, secondary (vs. primary) information, which could affect people's memory and subsequent judgments of their partners.

Two experiments were conducted to test these propositions. Study 1 examined the category structures used to process information related to other people. Participants were first primed with a target person of different social relationship (best friend vs. stranger) and then acted on behalf of that person to sort objects into groups (i.e., categories). As predicted, greater number of groups and smaller group size were used to categorize objects that were allegedly to be used by their best friends (vs. strangers). Study 2 examined how category structure affects information processing and its evaluative consequences. After the relationship priming used in Study 1, participants were given the opportunity to request job information that might assist them to better predict the target person's job preference. Both evaluatively diagnostic (i.e., primary attributes) and non-diagnostic (i.e., secondary attributes) job information were available to be requested. As expected, participants requested more non-diagnostic job information for best friends than for strangers, whereas no difference was found in the amount of diagnostic information requested. Two days later, the same participants reviewed a similar job position that contained positive secondary attributes but ambiguous primary attributes. They were instructed either to predict the target person's preference for the job or express their own attitudes toward the job. Results showed that while participants' own judgment of the job did not differ between the two experimental groups, those in the best friend group gave

significantly higher preference ratings to the job when judging on behalf of the target person than for their own. This result not only provided direct evidence of the effect of categorization on the delayed prediction accuracy of other people's preference, it also interestingly revealed individuals' strategic, selective use of category knowledge in forming preferences for the self and for others.

To conclude, this paper examined the effect of social relation on people's processing of information pertaining to their partners and the subsequent memory-based judgment about their partners. Past research has already shown that non-diagnostic, secondary information could impair prediction accuracy in close relations (e.g., Kenny and Acitelli 2001). The current study demonstrated the potential cause of the accumulation of secondary information: individuals tend to use more complex cognitive structures to process their partners' information as the relationship becomes closer and the expanded category structure not only enables the accumulation of less-important information, it also consequently affects how individuals search, categorize, and remember that information, and how they use the information to make subsequent decisions or judgments about their partners.

From a managerial perspective and for future research, notice that this paper mainly focuses on the negative effects of category structure on judgments and evaluations in close relationship. However, perhaps a more important role of the expanded category structures is to assist individuals to accommodate complex social information generated from long, intimate interactions with their close relationship partners. The resultant greater number of, and narrower breadth of categories used by people to classify partner-related information might affect the formation of a consideration set when making a surrogate purchase and it might also give marketers a chance to fine-tune their segmentation strategies when there is a product offering targeted at consumers' gift-buying needs. A great deal of research is needed in this area.

Motivated Valuation: A Motivational Perspective on the Disparity between Willingness-to-Accepted and Willingness-to-Pay

Francine Espinoza, ESMT Berlin, Germany
Joydeep Srivastava, University of Maryland, USA

EXTENDED ABSTRACT

The disparity between willingness-to-accepted (WTA) and willingness-to-pay (WTP) refers to the finding that individuals tend to ask for a higher price when they are giving up an item as opposed to when they are acquiring it (Thaler 1980). Descriptive economic explanations derived from prospect theory (Kahneman and Tversky 1979) state that this disparity rests largely on notions of reference dependence and loss aversion. Thereby sellers, when they become endowed with an object, experience loss aversion, and because losses loom larger than gains, the discrepancy in valuation of the object emerges (Kahneman, Knetsch, and Thaler 1990). Loss aversion is perhaps the most accepted explanation for the effect (Brenner et al. 2007). Current interpretations of loss aversion in the WTA/WTP disparity build on the notion that it is sellers' concern with losing an object and buyers' concern with losing their money that are equally responsible for the effect (Zhang and Fishbach 2005). Despite the enlightening conceptualizations (e.g., Carmon and Ariely 2000, Nayakankuppam and Mishra 2005), it appears that explanations solely based on loss aversion fail to capture some aspects of the valuation process (Brenner et al. 2007; Horowitz and McConnell 2003; Novemsky and Kahneman 2005; Sayman and Öncüler 2005), perhaps because of its primary focus on what is being foregone or given up while what one is getting is relatively ignored.

This research proposes an alternative explanation for the disparity between WTA and WTP. We argue that a seller and a buyer differ primarily in their intrinsic motivational orientation, and the different motivations underlying the valuation process lead to the disparity between WTA and WTP. Our basic premise is that the role of a seller and a buyer activates different intrinsic motivations predisposing individuals in each role to behave accordingly (Buss 1995). Giving up a good is an intrinsic part of being a seller as is acquiring a good an intrinsic part of being a buyer. Given that in most transactions, the good being exchanged is identical and constant for both parties, the motivational orientation of both the seller and the buyer is likely to center on the mutable aspects of the transaction (e.g., monetary valuation of the non-mutable good). Because of the different motivational orientations, sellers and buyers differ in terms of the aspects of the transaction that they primarily attend to in the valuation process. Specifically, when individuals adopt the role of a seller or a buyer, the intrinsic motivations and cognitions associated with each role are activated (Ferguson, Hassin, and Bargh 2008) such that sellers are primarily concerned with what they are getting and are motivated to maximize that, and buyers are primarily concerned with they are giving up and are motivated to minimize that. The conflicting motivational orientation of the seller and the buyer leads to the disparity between WTA and WTP. Note that loss aversion would account only for buyers' motivation of minimizing what they are giving up, but not sellers' motivation of maximizing what they are getting.

We adopt a motivation-as-cognition approach (e.g., Kruglanski et al. 2002), which treats motivation as a dynamic construct and allows us to investigate goal pursuit of buyers and sellers in five studies. Studies 1-3 test the prediction that the role of a seller is associated with the goal of maximizing what they are getting whereas the role of a buyer is associated with the goal of minimizing

what they are giving up. Study 1 suggests that sellers approach transactions with a "make money" mindset and buyers approach transactions with a "save money" mindset. Study 2 examines participants' reaction time to words related to the proposed goals of sellers and buyers and show that sellers respond faster to words related to maximization (e.g., maximize, high, increase) and buyers respond faster to words related to minimization (e.g., minimize, low, reduce). Study 3 shows that priming the goal of selling or buying to neutral traders produces the same disparity between WTA and WTP. Studies 4 and 5 investigate conditions under which goal pursuit of buyers and sellers might change and, consequently, buyers may be willing to pay more for a product, and sellers may be willing to accept less for the same product. We manipulate two factors that are expected to moderate goal pursuit in a systematic way, namely the pursuit of multiple goals (Shah, Friedman, Kruglanski 2002; Shah and Kruglanski 2008) and goal fluency (Avnet and Higgins 2006; Labroo and Lee 2006). Study 4 primes the alternative goals of competition or cooperation and shows that when participants are primed with a competition goal, the price disparity effect is observed, and when participants are primed with a cooperation goal, buyers are willing to pay more and sellers are willing to accept less. Study 5 shows that goal fluency moderates the effect such that the disparity between WTA and WTP was eliminated in the low goal fluency (versus the high goal fluency) condition.

Taken together, the five studies build on goal theory to provide support for the motivated valuation explanation. The basic premise is that sellers' primary motivation is to maximize what they are getting whereas buyers' primary motivation is to minimize what they are foregoing or giving up. Understanding of the motivations that underlie the valuation process provides deeper insights into the factors that affect the valuation process and the conditions under which the WTA-WTP disparity exists.

Scope Neglect in Spending Time

Ritesh Saini, University of Texas at Arlington, USA

EXTENDED ABSTRACT

People are quite rationally willing to pay more money for obtaining more quantities of a desirable good or outcome. However this relationship is not always linear and usually the monetary willingness to pay exhibits a concave relationship with increasing quantity. In this paper we explore what kind of a relationship exists when people have to pay in time, instead of money, for increasing quantities of a desirable outcome.

Scope (or magnitude) neglect is the tendency to ignore higher utility derived by higher amounts of a desired good or outcome. An expected value-maximizing individual should display a linear relationship between utility and an economically desirable resource. However descriptive models have proposed that for virtually any resource, we have marginally diminishing utility. Psychology and economics have explained this phenomenon using the concepts of satiation, diminishing sensitivity, and affect. While these factors have been known to enhance scope neglect, we investigate whether the currency of payment itself can influence this effect. In most studies showing scope neglect, the willingness-to-pay has always been elicited using monetary currency. What will happen to the evinced nonlinear relationship between stimulus scope and willingness to pay when the method of payment is something other than money? This is the primary research question of our paper.

People often spend time, instead of money, to acquire desirable outcomes. The default economic assumption is that spending time is similar to spending money (Becker 1965, Graham 1981) and therefore both are mutually tradable using a linear economic exchange rate. However, recent research has demonstrated several ways in which consumer's monetary decisions are different from their temporal spending decisions (Okada and Hoch 2004, Leclerc, Schmitt, and Dube 1995, Soman 2001, Zauberman and Lynch 2005, Saini and Monga 2008). Specifically, Saini & Monga (2008) have demonstrated greater susceptibility to heuristic people when spend time. This is primarily because time is more ambiguous, and less fungible, than money and therefore temporal (vs. monetary) information is more difficult to process. In such situations, instead of continuing efforts to utilize this relevant information, people make a qualitative shift to a different form of decision making in which they rely on heuristics (Payne, Bettman, and Johnson 1993). From engaging in more reasoned, deliberative processing, people regress to a more heuristic-based processing mode where they make judgments based on simple, accessible cues, oftentimes ignoring other relevant information. Previously Hsee and Rottenstreich (2004) have explained the concavity of the value function using very similar information processing mechanisms. Simply put, we propose that temporal decisions cause greater heuristic-use thereby leading to diminished scope sensitivity.

In the first experiment, we demonstrate that consumers' willingness to pay is more sensitive to changes in the magnitude of the outcome when they are paying in money than in time. In a between-subjects setting consumers have to pay in time/money for 2/10 music CDs. In both time and money conditions, participants were willing to pay more for 10 CDs (vs. 2 CDs). However the difference was much larger in the case of money (\$49.7 vs. \$ 14.5, i.e. 242% increase), than time (55.2 min. vs. 48.8 min., i.e. 13% increase). In support of our underlying psychological mechanism, we also demonstrate that consumers found temporal decisions to be more

difficult than monetary spending decisions. In the second experiment, we again test this time-money difference in both between- and within-subject settings and find that scope neglect breaks down for both time and money in the latter settings. In the third experiment, we extend this phenomenon to the domain of qualitatively different outcomes and demonstrate that when paying in time, consumers ignore not just the (quantitative) magnitude of the stimulus but also the qualitative variation between one stimulus versus another. Instead of changing the number of items at stake, we had two qualitatively different items as stimuli—an indoor grill & a digital tire gauge. In both time and money conditions, participants were willing to pay more for the indoor grill. However the difference was much larger in the case of money (\$48.27 vs. \$ 17.42, i.e. 177% increase), than time (28.70 min. vs. 19.56 min., i.e. 47% increase). In the fourth experiment we find that, when asked to put a monetary value to an item before deciding how much time to spend to procure it, some of the scope neglect diminishes. The final experiment investigates scope neglect for non-market outcomes, and finds a similar time-money difference, thereby also ruling out any congruency effects. When asked to donate time/money for helping save one/four panda bears, participants were more sensitive to scope when donating in money.

A Meta-Analytic Review of Just Below Pricing Effects

Traci Freling, University of Texas at Arlington, USA

Leslie Vincent, University of Kentucky, USA

Robert Schindler, Rutgers University-Camden, USA

David Hardesty, University of Kentucky, USA

Jason Rowe, University of Kentucky, USA

EXTENDED ABSTRACT

Just-below prices—prices that are expressed so their endings fall just below a round number—have been a prominent feature of the retailing landscape for decades (Gabor and Granger 1964; Knauth 1949). However, research on just-below pricing dating back to the 1930s (Bader and Weinland 1932; Ginzberg 1936) offers disparate viewpoints and ambiguous empirical results. While some published studies show just-below pricing can significantly improve sales (Anderson and Simester 2003; Kalyanam and Shively 1998), others demonstrate that such effects are product-specific or situational (Blattberg and Wisniewski 1987; Schindler and Kibarian 1996). Still other researchers report finding *no* just-below pricing-related effects (Dodds and Monroe 1985; Holdershaw 1995). Despite marketplace endorsement of just-below pricing and 70 years of research investigating the efficacy of this tactic, the body of work examining just-below pricing effects seems to yield inconclusive findings.

In addition to the equivocal nature of the empirical research findings regarding just-below pricing, *how* just-below pricing may operate is not well understood. The *association hypothesis* suggests consumers construe meaning from price endings through incidental or low involvement learning (Postman 1964; Hawkins and Hoch 1992), which may lead to: (1) a *low-price image effect*, wherein the consumer comes to associate a just-below price with a low, decreased, or discount price, which generally leads to higher sales for products carrying a just-below price because the consumer is likely to see the product as being a bargain or perceive it as being on sale; or, (2) a *low-quality image effect*, which results from an association of a just-below price with inferior product quality and encourages consumers to regard just-below-priced products less favorably because they are viewed as possessing lower quality. The *underestimation hypothesis* suggests consumers routinely distort their perceptions of just-below prices, mentally transforming them into perceptually lower prices than their actual value and thus interpreting them more favorably than round-number prices (Lambert 1975; Nagle and Holden 1995). This is believed to occur due to: *rounding down* of just-below prices, since rounding up to a whole number requires more cognitive effort (Gabor and Granger 1964; Schindler and Kirby 1997); *left-to-right processing* of pricing information and relative inattention to a price's rightmost digits (which causes consumers to perceive just-below prices as lower than they actually are) (Poltrick and Schwartz 1984; Thomas and Morwitz 2005); or, humans' innately limited *memory capacity* (Schindler and Kibarian 1993; Schindler and Wiman 1989).

Pricing theorists have failed to converge on a unifying theoretical framework that cogently and comprehensively explains just-below pricing effects. Extant explanations are not mutually exclusive (Coulter 2001), and evidence for both the association and underestimation hypotheses has been found across and within research studies (Stiving and Winer 1997).

Methodology

We followed the procedures for conducting a meta-analysis described by Hunter and Schmidt (2004). We identified 25 papers containing 106 independent samples that reported both the Pearson

correlation between just-below-ending prices and other constructs and the sample size (Janiszewski, Noel, and Sawyer 2003). The sample size for the meta-analysis across all retained samples was 130,139 observations. The average and median sample sizes were 1228 and 202 observations, respectively.

In addition to investigating six depending variables (i.e., *choice, sales, recall, low-price image, low-quality image, and value*), we also examined the impact of the following variables identified in the literature that have theoretical justification as potential moderating factors and could be coded from the extant studies and analyzed using a generalized least squares regression (GLS) approach (Geyskens, Steenkamp, and Kumar 1998): *price-ending manipulation*; *price magnitude*; *nature of the product*; *product durability*; *product realism*; *research design*; *research setting*; and *sample characteristics*.

Major Findings

The results of this meta-analysis suggest that, on average, products bearing a just-below price are associated with (1) more frequent product choice, (2) higher sales levels, (3) less attention to the rightmost digits of prices in recall tasks (and greater accuracy in recalling the leftmost pricing digits), (4) perceptions of a more discounted price, (5) a lower quality image, and (6) more favorable perceptions of value. So, just-below pricing does appear to consumers in a variety of ways.

However, our results indicate that the impact of just-below pricing on choice, sales, underestimation due to inaccurate recall of just-below prices, and low-price image perceptions is contingent upon important price- and product-related contextual variables. We found no significant differences in the size of just-below pricing effects for 5-ending just-below prices versus 9-ending just-below prices on any of the outcome variables. This result suggests that retailers who use just-below pricing should choose prices with 9 instead of 5 as the rightmost digit, and benefit from the extra four cents revenue on each sale. Results relating to price magnitude imply that just-below pricing will be most effective for high-priced products when the objective is to stimulate demand, impair memory of pricing information for more expensive products, or communicate favorable low-price-image perceptions.

We found just-below pricing to be more effective for actual brands in terms of low-price image and recall, suggesting it may be used to communicate a discount or bargain image for well-established brands in the marketplace. Conversely, because consumer choice is more favorably influenced by just-below pricing for unknown or hypothetical brands, it may also be used to induce trial and purchase of new or less dominant brands. Other interesting product related findings relate to the nature of the good and durability of products that have been investigated in just-below pricing research. While just-below pricing is likely to stimulate choice and communicate favorable price image associations for services, just-below pricing appears to favorably impact choice, price image, and recall of pricing information for durable goods.

Finally, this meta-analysis uncovers some discrepancies across empirical efforts and highlights methodological issues relating to research design, setting, and subjects that qualify just-below pricing

ing effects. This indicates a need for programmatic research in this area, that seeks to reproduce results obtained in diverse settings with different methodologies, stimulus products, and pricing manipulations, and a variety of samples.

Multi-Unit Discounting and Discount Size: Getting More Out of Less

Devon DeVecchio, Miami University, USA
Timothy Heath, Miami University of Ohio, USA

EXTENDED ABSTRACT

Despite their widespread use, only three published studies have investigated the effects of multi-unit discounts (Blattberg and Neslin 1990; Manning and Sprott 2007; Wansink, Kent, and Hoch 1998). These studies indicate that multi-unit discounts stimulate higher purchase quantities; an effect that appears to arise from anchoring processes. However, three important issues remain unresolved. First, whereas Manning and Sprott (2007) find that “2 for” deals do not result in greater unit sales than a single-unit discount, Wansink et al. (1998) report a significant increase in purchase quantities most “two for” deals. Thus, the first issue we consider is the effectiveness of small unit quantity deals. Second, although the size of multi-unit discounts has not been studied systematically, prior results suggest that discount size may matter. Our second focus, therefore, is the possibility that discount size moderates the effectiveness of multi-unit discounts. Third, Manning and Sprott (2007) speculate that high-quantity anchors “may generate negative deal perceptions” (p. 420). This implies that a mechanism other than anchoring and adjustment may affect the efficacy of multi-unit discounts. Together, these issues lead to our research question: How does the value of a multi-unit discount affect consumer deal evaluations and resulting choice quantities?

First, we assessed 2,383 discounted purchases in a store located in a Midwestern city. ANCOVA results indicate that, consistent with expectations, increasing the number of units associated with the discount increased purchase quantities ($F(2, 2382)=46.90, p<.001$). Mean purchase quantities were greater when discounts were offered as “2 for” ($M=1.70; F(2, 2382)=65.76, p<.001$) or “3 or more for” ($M=1.78; F(2, 2382)=45.74, p<.001$) deals than when offered as a single-unit deal ($M=1.23$). In addition, the number-of-units in the deal moderated the effect of discount size ($F(2, 2382)=3.75, p<.05$). Larger discounts increased purchase quantities in the context of single-item deals ($F(1, 2382)=3.57, p<.05$) and for the two-for deals ($F(1, 2382)=4.17, p<.05$), but had no effect in the context of 3+-for deals ($F(1, 2382)=1.05, ns$).

Next, student participants ($n=243$) completed a simulated shopping experiment in which they selected between brands including a brand offering the focal promotion. The base design was a 3 (promotional units: 1, 2, 6) x 2 (discount size: 15%, 33%) between-subjects factorial. Participants also indicated the reason they would purchase the indicated quantity, responded to three positive affect and three negative affect items from the positive and negative affect schedule (PANAS, Watson, Clark, and Tellegen 1988) to identify deal-derived affect, and completed a five-item scale of deal value (e.g., Lichtenstein, Burton, and Karson 1991).

ANCOVA results indicate that purchase quantity intentions increased as deal units increased ($F(2, 242)=6.41, p<.01$). Mean purchase quantity intentions were greater for the “6 for” deals ($M=2.22$) than for the “2 for” deals ($M=1.51, F(2, 242)=4.53, p<.05$) and the single-item deals ($M=1.08, F(2, 242)=12.55, p<.001$). Purchase quantities did not differ for “2 for” and single-item deals ($F(2, 242)=2.08, p=.15$).

Number-of-units in the deal also interacts with the value of the discount ($F(2, 242)=3.25, p<.05$) such that discount size affects purchase quantity intentions to a lesser extent as the number of units in the promotion increases. Purchase quantities are significantly greater for the 33% discount ($M=1.64$) than the 15% discount ($M=0.51$) in the single-item condition ($F(1, 242)=6.40, p<.05$). The 33% discount performs marginally better in terms of purchase

quantity intentions ($M=1.86$) than the 15% discount ($M=1.11$) in the “2 for” condition ($F(1, 242)=2.66, p=.10$). Purchase quantity intentions did not differ across the 33% ($M=2.22$) and 15% ($M=2.25$) discount values in the “6 for” conditions ($F(1, 242)=0.81, ns$).

Regarding the process variables, perceived deal value exhibited a main effect of discount size ($F(1, 242)=11.99, p=.001$) and a main effect of deal units ($F(2, 242)=3.30, p<.05$). However, controlling for perceived deal value does not eliminate the interactive effect of deal units and deal value on purchase quantity intentions ($F(2, 242)=3.22, p<.05$).

Consistent with an anchoring explanation of multi-unit deal effects, the number of usage-related thoughts indicated in the open-ended question regarding purchase quantity rationale was positively related to the number of items in the deal ($F(2, 242)=2.98, p=.05$). However, usage thoughts were not a function of the deal unit by deal value interaction ($F(2, 242)=0.53, ns$) and controlling for usage thoughts had little mediating effect on the deal unit by deal value interaction on purchase quantity intentions ($F(2, 242)=2.94, p=.055$).

Finally, net affect (positive affect minus negative affect) exhibited was (at least marginally) a function of deal units ($F(2, 242)=7.21, p<.01$), discount value ($F(1, 242)=3.41, p=.07$), and the deal unit by discount value interaction ($F(2, 242)=2.51, p=.08$). Furthermore, controlling for net affect eliminated the deal unit by discount value interaction on purchase quantity intentions ($F(2, 242)=2.14, p>.10$).

The results indicate that multi-unit discounts lead to greater purchase quantities than single unit discounts of equivalent value. In both studies there were instances (statistically in Study 1, directionally in Study 2) in which multi-unit discounts led to greater purchase quantities than did single unit discounts of greater value. Thus, retailers may be able to get greater sales at higher margins by employing multi-unit discounts. The results of Study 2 indicate that, consistent with an anchoring process, multi-unit discounting does lead to greater usage-related thoughts but this outcome, and the resulting purchase quantity, is tempered by the less positive affect stemming from larger unit deals.

Breaking through Complexity: How the Interplay between Visual and Conceptual Complexity Affects Logo Evaluation across Repeated Exposures

Irene Scopelliti, Bocconi University, Italy
Gaetano 'Nino' Miceli, University of Calabria, Italy
Maria Antonietta Raimondo, University of Calabria, Italy

EXTENDED ABSTRACT

According to experimental aesthetics (e.g., Berlyne 1971) and consumer research (e.g., Janiszewski and Meyvis 2001), the level of complexity of a visual stimulus has steady effects on consumer evaluations. Complexity, however, appears to be a multi-faceted construct that concerns both perceptual and conceptual aspects whose joint effect on consumer reactions is not yet clear.

In this paper, we analyze the effects of both visual complexity (VC—the amount and variety of visual information inherent in a stimulus) and conceptual complexity (CC—the number of different meanings associated with a stimulus), in the context of brand logos, using single and repeated exposures. Specifically, we propose arguments and hypotheses on how the main and interaction effects of visual and conceptual complexity depend on the number of previous exposures to the logo.

Based on experimental aesthetics (Berlyne 1971), we hypothesize that, at a single exposure, logo VC has an inverted U-shaped effect on attitude (H1). Based on studies on conceptual fluency, which propose that the ease with which the meaning of a stimulus comes to mind (Hamann 1990; Lee 2002) positively influences stimulus evaluations, we expect that, at a single exposure, high levels of CC lower attitude toward the logo (H2).

Crossing VC and CC, we define four basic types of logos. One might expect that high-VC/low-CC logos (do induce arousal and learning, and are clear in their meaning hence easily interpretable) will show the most favorable evaluations; low-VC/high-CC logos (do not induce arousal and learning, and are vague and unclear in their meaning) will show the lowest evaluations; low-VC/low-CC, and high-VC/high-CC logos will show intermediate evaluations. These expected results suggest the absence of interaction between VC and CC at a single exposure.

This pattern, however, may change over multiple exposures. Although it is difficult to formulate predictions for all the four of VC/CC combinations, we expect that evaluations of high-VC/low-CC logos will suffer a decline as the number of exposures increases. Such a prediction lies in the idea that perceptual elements are quickly elaborated and exhausted in terms of arousal potential. Moreover, high VC is likely to be related to multiple perceptual dimensions thus being unlikely to generate fluency (Janiszewski and Meyvis 2001), while low CC implies quick habituation and boredom. Based on similar arguments, one may expect that evaluations of low-VC/high-CC logos will increase across exposures due to the generation of perceptual fluency (low VC is more likely related to a uniform perceptual dimension), as well as to the relevant potential for elaboration and learning. Conceptual fluency is, indeed, sensitive to time and to opportunity for elaboration. Eventually, evaluations of low-VC/high-CC logos may decline as additional increases in the number of exposures make the source of fluency too salient to be misattributed to the stimulus. Low-VC/low-CC and high-VC/high-CC logos stimulate similar mechanisms but in opposite directions. It is therefore difficult to predict a specific pattern for these types of logos. Overall, expected changes in evaluations of high-VC/low-CC and low-VC/high-CC logos across number of exposures suggest the hypothesis of a three-way interaction between VC, CC, and number of exposures (H3).

Our conceptual analysis also suggests that the independent two-way interactions of VC and CC with the number of exposures qualify this three-way interaction. We expect that low-VC logos will initially show low evaluations (see H1). An increase the number of exposures might instill perceptual fluency, as low-VC logos tend to manifest a uniform perceptual dimension. Therefore, we predict that, across exposures, evaluations of these logos will increase, but only up to a certain threshold, when boredom intervenes causing the logo wear-out (H4a). A high-VC logo starts with an average or high evaluation depending on the inflection point of the quadratic effect (see H1). Apparently, the arousal and learning potential of such a logo should cause an improvement in the evaluations over repeated exposures. However, we also expect absence of or little perceptual fluency, as high-VC logos tend to refer to multiple perceptual dimensions. Moreover, perceptual information is elaborated very quickly, particularly in stimuli as small as logos, therefore dampening any arousal and learning potential. Hence, we expect a slight fall in high-VC logos evaluations over repeated exposures (H4b).

We expect that low-CC logos initially show high evaluations due to stimulus-driven conceptual fluency (see H2). However, one might expect a decrease in evaluations over repeated exposures due to quick habituation (H5a). High-CC logos will initially show low evaluations (see H2). Since conceptual fluency is sensitive to the opportunity to elaborate the stimulus, we expect that increasing the number of exposures will boost evaluations of high-CC logos. Further increases in the number of exposures may eventually dampen the learning potential. These arguments suggest a reverse U-shaped pattern of attitude toward high-CC logos (H5b).

Results of a survey (Study 1) with multiple respondents (cf. Henderson and Cote 1998) support H1 and H2, and also show that VC and CC do not interact with each other in shaping attitude at one exposure. Findings from an experiment (Study 2) offer general support to H3, H4a, H4b, H5a, and H5b.

From a theoretical perspective, we integrate within a unified conceptual framework the effects of two forms of complexity across repeated exposures on attitude toward a logo. Our analysis allows understanding the processes that co-occur to explain consumer preference for hybrid logos, such as those high in VC and low in CC, which may reflect the concept of “simplicity in complexity” proposed by Reber et al. (2004). Furthermore, our findings propose that VC and CC affect attitude following different patterns across the multiple exposures. Finally, our research suggests, therefore, that ignoring either VC or CC in the analysis of consumers’ reactions to the complexity of visual stimuli may hide relevant mechanisms and processes.

Consumer Responses to the Mass Customization of Product Aesthetics

Ruth Mugge, Delft University of Technology, The Netherlands

Frédéric Brunel, Boston University, USA

Jan Schoormans, Delft University of Technology, The Netherlands

EXTENDED ABSTRACT

Mass-customization strategies allow consumers to create individualized products that match their personal needs. Although mass-customization can appeal to broad audiences and is becoming more available in the marketplace, research on this topic has been somewhat limited (Hauser, Tellis, and Griffin 2006). Specifically, we have an emerging body of evidence on the processes that determine consumers' evaluation of the mass-customization of functional elements (e.g., Dellaert and Stremersch 2005), but lack a complementary understanding regarding the mass-customization of product aesthetics. Although there are some similarities between mass-customization of functional features and aesthetics, we believe that there are unique aspects to aesthetic mass-customization as well. An important difference is that aesthetic mass-customization has a strong affective and symbolic nature. Hence, different constructs might drive consumers' reactions to these mass-customization configurators. This paper explores the value of aesthetic mass-customization for self-expression and identity management. Specifically, we investigate the importance of the extent of mass-customization and the public consumption of the mass-customized product for realizing the full potential of aesthetic mass-customization.

Mass-customization configurators differ in the extent of customization that is offered. In some configurators, the extent of mass-customization is narrow, because consumers are only offered a small number of choices, whereas in others they can make selections amongst an immense number of options. Research on functional mass-customization demonstrated that increasing the extent of functional mass-customization allows consumers to achieve greater functional value, because the product can be better customized to fit one's technical requirements (Dellaert and Stremersch 2005). Similarly, to match consumers' individual aesthetic preferences, consumers should be offered a great extent of aesthetic mass-customization. Then, the product can be aesthetically customized to fit one's unique taste and reflect one's identity. In contrast, the importance of functional mass-customization for self-expression will be limited, because functional components are often internal, and therefore, less visible than aesthetic elements. Furthermore, consumers' aesthetic preferences are heterogeneous, whereas functional preferences are often uniformed within consumer segments, and thus, less effective in supporting one's unique identity. Accordingly, we hypothesize that the extent of aesthetic mass-customization positively impacts the mass-customized product's self-expressive value (H_{1a}), whereas the extent of functional mass-customization positively affects its functional value (H_{2a}).

Increasing the extent of functional and/or aesthetic mass-customization may also have a negative effect on consumer responses. Consumers may become overwhelmed by the great number of possibilities at their disposal (Huffman and Kahn 1998). Accordingly, we hypothesize that the perceived complexity of the mass-customization process is positively affected by the extent of aesthetic (H_{1b}) and functional (H_{2b}) mass-customization.

Based on the former, two opposing effects are expected for consumers' purchase intention of mass-customized products. Whereas the mass-customized product's functional (H_{3a}) and self-expressive value (H_{3b}) will enhance purchase intentions, perceived complexity (H_4) will reduce these.

Nevertheless, we expect that consumers' perceptions of the self-expressive value of mass-customized products are impacted by more than just the extent of aesthetic mass-customization. People derive their identity more from social interactions with others than from internal, psychological forces (Kleine, Kleine, and Kernan 1993). Consequently, a product's self-expressive value depends on its visibility to others. Accordingly, we propose that for aesthetic mass-customization the benefit of self-expressiveness is enhanced if the mass-customized product is publicly consumed (H_5). Because the value of functional mass-customization for self-expression is limited, public consumption will not affect this type of mass-customization.

In Study 1, 364 undergraduate students were presented with one of the eight generated mass-customization configurators for a laptop. For the manipulation of functional mass-customization, the breadth (4 vs. 8 technical aspects) and depth (2 vs. 4-6 options for each aspect) of functional mass-customization choices was varied. Extent of aesthetic mass-customization was manipulated by offering a choice among four colors or the possibility to personally create the motif for the laptop's appearance. For the manipulation of public/private consumption, we primed the respondents by telling them that they are interested in purchasing a new laptop to replace their current desktop, because it is portable and allows the user to work anywhere they want (public) or because it takes less space in their bedroom (private). Each condition was explained in text and by showing pictures of the mass-customization configurator. Next, responses to several multi-item measures were obtained.

To test our hypotheses, we performed a structural equation model with latent variables in LISREL. The fit statistics for the model indicated a good fit and only the hypothesized relationships were significant. These results confirmed past findings on functional mass-customization and supported our hypotheses on the different processes that are involved with aesthetic mass-customization.

In Study 2, we investigated the robustness and generalizability of our findings. Specifically, we stepped outside the laboratory setting and tested our theory amongst a heterogeneous group of consumers, using a home cordless telephone as a product category, and a different manipulation of public/private consumption. Public/private consumption was manipulated by varying the customized elements of the telephone. The configurator allowed the consumers to customize an aspect of the telephone that would be more (shell) or less (display) visible to others. By varying the number of aesthetic options, three conditions were generated to manipulate the extent of aesthetic mass-customization. Members of a consumer panel ($n=218$) were asked to evaluate one of the six different configurators. After conducting several steps in the data analysis, this model resulted in a good fit and replicated all effects regarding aesthetic mass-customization as found in Study 1.

In conclusion, our research shows that aesthetic mass-customization is different from functional mass-customization, because it provides symbolic value through the product's ability for self-expression. In contrast, functional mass-customization is valued because it provides a better fit to individual technical requirements. Consequently, different antecedents may drive the two types of mass-customization, which is supported by the effect of public/private consumption on the evaluation of aesthetic mass-

customization. Finally, our findings show that increasing the extent of aesthetic mass-customization has a positive (through the self-expressive value) as well as a negative (through perceived complexity) effect on the intention to purchase the mass-customized product. These opposing effects have to be carefully managed when offering mass-customization configurators.

Effects of Exaggerated Priming and Fluent Processing on the Evaluation of Design

Irene Scopelliti, Bocconi University, Italy

Paola Cillo, Bocconi University, Italy

David Mazursky, The Hebrew University of Jerusalem, Israel

EXTENDED ABSTRACT

In several industries competition is based on the continuous proposal of new styles, in a sort of dynamic innovation process based mostly, if not exclusively, on product design and on a planned obsolescence of that design. This process is called stylistic innovation, and refers to all changes in design that are not purely the results of engineering advances (Robinson 1958; Cappetta et al. 2006). Apparel, cars, furniture and home appliances are just some instances of industries featuring competition based on stylistic innovation, for which success is strictly dependent on consumers' fast and rapid adoption of the new design.

In some design-based industries, the launch of a new design is realized by means of showpieces featuring in an exaggerated way, i.e., by emphasizing the central features of the design up to the point of appearing wacky, the same design that will be then delivered to the market in a more moderate form. This launch strategy is widely adopted in the apparel industry, but also elsewhere (e.g., new car models are often presented as concept cars during trade shows). Exposure to exaggerated showpieces might shock consumers since such exemplars are typically disruptive, and they are often perceived as bizarre or extravagant. However, exposure to showpieces could help improving consumers' attitude toward a moderate form of the new design: the visual exaggeration of the distinctive features of a design may enable a more fluent processing of the same features in subsequent encounters with other exemplars of the same design (Reber et al. 2004), by leaving a deeper trace in consumers' implicit memory than a moderate form of the design would do.

This article examines whether the strategy of introduction of novel designs used in some fashion-based industries (i.e., introduction with exposure to an exaggerated showpiece) is more effective in terms of favorability than a standard launch strategy in which consumers are exposed directly to a moderate marketable form of the design. Differences in the effectiveness of such a strategy of introduction between consumers holding different levels of prior knowledge of the product category, and between showpieces with different levels of structural redundancy with respect to the target design, are also examined.

Experiment 1 shows that initial exposure to exaggerated showpieces generates a more favorable evaluation of a moderate target design than initial exposure to moderate exemplars or no initial exposure, with this effect being driven by the evaluations of experts (measured expertise). We argue that experts' advantage is the outcome of highly effective encoding of the visual information contained in the exaggerated showpiece, and of a more fluent processing of the target design favored by the trace left by the showpiece in subjects' implicit memory. Experiment 2 adds external validity to Experiment 1, and replicates the results of the previous experiment by making use of a group of real experts (fashion design students and young fashion professionals) compared to a group of non-experts (management students). This effect could be explained by the fact that experts, compared to non-experts, are able to process and to learn the structure of the design in a more effective way upon exposure to exaggerated exemplars, and are able to elaborate more fluently the same structural elements of the showpiece featured in the target design. The greater shifts in the evaluation of the target design on behalf of experts should signal such higher fluency, because of the positive valence associated to

processing fluency—the so called hedonic marking of fluency (Winkielman et al. 2003) that is misattributed to the target stimulus. This idea is explored in Experiment 3, where we test the hypothesis that experts' stronger shift in the evaluation of the target design is not a function of expertise per se, but of higher processing fluency, by manipulating a visual feature of the design able to make processing more fluent, i.e., the redundancy (Reber et al. 2004; Garner 1974) between the exemplars shown in initial exposures and the target design. Redundancy is a variable that makes the structural alignment between the two stimuli (exaggerated showpiece and moderate target design) more salient, and therefore improves the processing of the visual information contained in the target design (Markman and Gentner 1997). Experiment 3 indicates that experts' advantage is eliminated when redundancy increases, resulting in comparable evaluations of the target design by experts and non-experts in the case of high redundancy: all subjects evaluate the target more favorably when exposed to exaggerated and highly redundant exemplars, whereas experts evaluate the target significantly more favorably than non-experts when exposed to exaggerated but low-redundancy exemplars.

Results generally support the idea that exposure to exaggerated showpieces is able to improve the evaluation of a moderate target design, shedding light on the effects of exaggeration in the domain of visual information. Exaggerated stimuli, despite less attractive than prototypical stimuli (Rhodes and Tremewan 1996), have a great potential in terms of emphasis on the most relevant elements of a message, and of impact on the encoding of information. Our findings suggest that exaggeration is a visual feature able to affect the ease of processing visual information, i.e., perceptual fluency, as hypothesized by Reber et al. (2004). We also find that greater structural alignment, as favored by visual redundancy within the set of stimuli, is able to affect evaluation of the target design upon exposure to an exaggerated exemplar, by again improving the fluency experienced in the elaboration of visual information.

Some relevant implications for managerial practice can be drawn from our results. Firms competing in design-based industries engage in a process of dynamically continuous innovation that sees each new design competing with others to overcome the previous design in consumers' preferences. The comparison of alternative strategies that could be easily managed by firms when presenting a new design in terms of impact on consumers' evaluation might help them to launch their new designs in the most effective way.

The Interpersonal Hot Hand Fallacy: How Similarity with Previous Winners Increases Subjective Probability of Winning

Sandra Laporte, HEC Paris, France
Gilles Laurent, HEC Paris, France

EXTENDED ABSTRACT

This paper tries to explain a prevailing advertising practice for promotional and state lotteries. Organizers often showcase a photograph of a recent winner together with some personal information (e.g. name, age, place of living, occupation). Further, the profile of the featured winner is similar to the typical profile of potential participants. The repeated use of this technique by multiple lotteries in different countries suggests it must be an efficient tool to increase participation in the next drawing. We propose that the underlying mechanism is based on what we call the “interpersonal hot hand” fallacy. In the hot hand fallacy, basketball fans believe (contrary to objective evidence) that a specific player has a higher chance to hit the basket if he was successful in his previous attempt (Gilovich et al. 1985). In the Interpersonal Hot Hand Fallacy, consumers believe that they have higher odds of winning the next drawing if they are similar to the previous winner than if they are dissimilar. This effect induces a greater participation intention.

The entry decision is made under uncertainty since most of the real-life advertisements for these lotteries do not state explicitly the probability of winning. Moreover, the entry decision is likely to be low-involving because of the minimal costs at stake. As a consequence, consumers may rely on heuristics to estimate their probability of winning. A highly accessible heuristic attribute appears in the similarity information that the advertisement implicitly offers by providing very basic, general demographic information about previous winners. Regarding the direction of the similarity effect, we propose that advertisements, by showcasing “lucky” previous winners, focus on a potential human cause, while they overlook the inanimate random character of the lottery by not mentioning the probability of winning. According to the literature about the antecedents of the hot hand and the gambler’s fallacies (Ayton and Fischer 2004, Burn and Corpus 2004, Sundali and Croson 2006), we hypothesize that this focus leads potential participants to attribute the outcome of the drawing to the previous winners’ luck and, in the absence of objective information about their chances to win, estimate they have higher chances if they feel similar to these “lucky” previous winners.

Study 1 aims at testing the impact of the similarity with previous winners on the intention to participate in a sweepstake, and at contrasting it with the effect of the number of prizes to win. We manipulate both factors in a 2x2 between-subject design. In the similar condition, the advertisement for the sweepstake shows the picture of a couple of previous winners with about the same age as the respondents (college students), while in the dissimilar condition, featured previous winners are much older. In the ‘high number of prizes’ condition, ten week-ends are offered as prizes, while there is only one week-end to win in the ‘small number of prizes’ condition. Age similarity has a significant positive effect on how much time respondents are willing to spend to enter the sweepstake measured by a 7-point scale ($F(1,113)=5.02, p<.03$), while multiplying the number of prizes by ten has no significant impact.

In Study 2, we test directly the interpersonal hot hand fallacy by manipulating interpersonal similarity using gender to rule out an attractiveness alternative explanation. The scenario indicates that a social network website for students regularly organizes a random drawing among its members, and features two previous winners with their photographs and verbal legends. Respondents estimate

their probability to win the impending drawing (open-ended answer) to be higher when the last two winners have the same gender as them rather than the opposite gender ($t(48)=1.817, p(\text{one-tailed})<.05$). We also rule out the simulation heuristic (Kahneman and Tversky 1982) as an alternative explanation.

Study 3 replicates this result with educational background as a new similarity manipulation: participants evaluate their chances of winning to be higher when the two previous winners pursue the same kind of academic studies as they do ($t(60)=2.643 ; p(\text{one-tailed})<.05$).

In Study 4, we show that featuring a similar winner is particularly effective for people who are not particularly attracted by promotional games. Respondents with a high sweepstakes proneness (Lichtenstein et al. 1995) have the same high probability to participate whatever their similarity with previous winners ($\beta=-.557; t=-1.265; p(\text{one-tailed})>.10$), while respondents with a low sweepstakes proneness will be more likely to participate if they are similar to previous winners ($\beta=.861; t=1.934; p(\text{one-tailed})<.05$). Most importantly, the estimated probability of winning mediates the impact of similarity on participation likelihood, while the similarity has no impact on the attitude towards the organizing brand ruling out another alternative possible mechanism.

If the impact of similarity with the previous winner on the respondent’s intention to participate is mediated by the respondent’s estimated probability to win, the effect of similarity should disappear if respondents benefit from objective information on their probability to win. In Study 5, we compare two conditions: One in which respondents are only given (as in real life) indications on the number of prizes to be won, and one in which they are also given indications on the number of participants, allowing them to do an objective estimation of the probability to win. Indeed, in the first condition, we replicate the preceding results on the impact of similarity on participation intention ($F(1,52)=8.227; p<.01$), while, in the second condition, there is no impact of similarity on intention to participate.

The main contribution of this research is to show a new kind of hot hand fallacy caused by a similarity judgment. This explains why the widespread technique consisting in presenting a recent winner may boost the participation of similar consumers. It also adds a new result to the vast literature on interpersonal similarity that has already emphasized how similarity with others can affect our attitudes, beliefs and behaviours. This paper shows that, when making judgments under uncertainty, what just happened to similar others can impact our estimated probability of benefiting from the same random positive outcome.

The Role of Seed Money and Threshold Size in Optimizing Fundraising Campaigns: Past Behavior Matters!

Griet Verhaert, Ghent University, Belgium
Dirk Van den Poel, Ghent University, Belgium

EXTENDED ABSTRACT

Fundraising appeals often announce seed money by showing the audience that some funds have already been raised in order to reach the threshold. The technique is based on the theory of charitable fundraising proposed by Andreoni (1998). His theory predicts that publicly announced seed contributions will increase charitable donations. Seeking to contribute to the existing debate on the use of seed money, we investigated the role of seed money in combination with the threshold size and de type of the audience.

Academics attach more and more importance to the investigation of charitable behavior outside the laboratory because of the benefit of measuring real donation behavior instead of intentions. Recently, two studies on the use of seed money in direct-mail campaigns were examined in the field. First, List and Lucking-Reily (2002) tested three different levels of seed money based on a cold list of prospects. They found that 67% seed is the optimal level considering a threshold of \$3,000. On the other hand, Rondeau and List (2008) found a 50% seed level as optimal with a threshold of \$5,000 soliciting from a relatively warm list of contributors. The role of the threshold size in combination with the seed percentage however, is never examined. Therefore, based on a field experiment, we test both optimal seed levels in combination with different threshold sizes for a cold list as well as a warm list of contributors.

Moreover, various authors identified moderating effects of past behavior on the effectiveness of different types of direct-mail campaigns (e.g., Rust and Verhoef 2005). Therefore, we do not only distinguish between prospects and past contributors but we also want to separate the more loyal donors from the less loyal ones based on transactional data. Knowing that past behavior could play a crucial role in the effectiveness of direct-mail campaigns, we would like to investigate the use of seed money in combination with the threshold size across real donor segments.

Taking the previous into account, we set up a 2x3x3 between-subjects design in a real charity context. Our design manipulates the level of the threshold (low versus high) and the percentage of seed money (no seed, 50% and 67%). Based on previous research, we expect differences between donors depending on their past behavior. Therefore, based on the charity database, we include three groups in the experiment. The first segment consists of prospects (i.e., the cold list), whereas the second group incorporates current donors with a lower loyalty score, and the last considers existing donors with a higher loyalty score. We calculated this score based on historical giving behavior. Starting from the original campaign, we created several smaller campaigns, each representing one of the six versions. The final campaign was sent to 25,617 households.

For each donor segment, we examined the persuasiveness of the different appeals on participation rate, gift size and overall revenue. In general we only found effects on the response of the campaigns and no effects on the size of individual contributions. Consequently the overall revenue was driven by the participation rate. We found that the use of seed money, regardless of the size of the threshold, is a good strategy in direct-mail appeals targeted at prospects and donors with a lower loyalty score. These results are in agreement with those reported by List and Lucking-Reily (2002) and Rondeau and List (2008). Moreover, we can conclude that the proposed optimal level in both studies, respectively 50% and 67%, are equally successful.

By contrast, when analyzing the most behaviorally loyal contributors, we neither found a main effect of seed money nor a main effect of the size of the threshold. Interestingly, we revealed a predominating interaction effect between the use of seed money and the size of the threshold. More specifically, when announcing a relatively low threshold, it is pernicious to announce seed contributions. On the other hand, seed money remains a good technique when the threshold is rather high. This finding appears to be somewhat in contrast with previous authors who consistently found that seed money is generally a valuable strategy. However, we want to remark that previous studies reached response rates much lower (i.e., below 5%) than we obtained in our loyal segment (i.e., around 15%) which suggests that this type of loyal segment is never studied before. Our finding suggests that the still required residual money should be set high enough to encourage the best donors. At the same time, we showed the need for incorporating past behavior as input for a differentiated communication approach across donor segments.

Our study has important implications on the academic literature of seed money in charity appeals. Especially when focusing on loyal contributors of the charity, we recommend considering the size of the threshold when investigating the role of seed contributions. Moreover, research on the effectiveness of fundraising campaigns should take into account past behavior of the target audience. The findings also have many practical implications. We demonstrate different effects according to the donor segment indicating a need for differentiation in the communication strategy as well as the importance of using the database. In general, announcing seed money is always a valuable strategy except when raising funds for a relatively low threshold. In this latter situation, it is more efficient not to announce seed money in appeals towards the best donors because of its detrimental effect.

Exploring other distinctions between donor segments (e.g., previous donation size and frequency) on the warm list would undoubtedly be a fruitful area for further research as would be to incorporate reactivation campaigns. Finally, it would be worthwhile to further explore additional levels of seed money and threshold sizes. In conclusion, this research is the first to demonstrate the effect of both seed money and size of the threshold on charitable contributions across donor segments. It reveals an important restriction of the announcement of seed contributions. Finally, it clearly shows the necessity of a differentiation in direct-mail appeals by considering past behavior of the contributors.

The Role of Activation in Advertising

Yael Steinhart, University of Haifa, Israel

EXTENDED ABSTRACT

The current research explores the relationships between action, advertisement evaluation, and attitudes toward the product presented in the advertisement.

Actions in the context of advertising can be considered a “foot in the door” technique, in which the advertiser initially promotes the viewer to attend to the advertisement, although the advertiser’s ultimate goal is to generate a favorable attitude toward the product. Therefore, the present research examines direct and indirect effects of actions on attitudes toward the product via the mediating variable of advertisement evaluation.

The proposed research examines physical activities that are strongly associated with the advertisement message. This type of action is labeled as the Activation technique. The activation technique includes a physical action, which can be executed immediately upon viewing the ad, and the action’s results highlight the message conveyed in the advertisement.

The effect of activation on advertisement and product evaluations is proposed to be based on the extent of compatibility between the type of action and the content of the message conveyed in the advertisement. When the physical action is congruent with the content message, activation is proposed to enhance not only the evaluation of the advertisement but also generate a favorable attitude toward the product. On the other hand, when the physical action is not congruent with the content of the message, activation is anticipated to indirectly elicit a negative attitude toward the advertised product.

The underlying mechanism for the activation effect is proposed to rely on the advertisement processing fluency. That is, ease of processing contributes to the formation of an overall impression of an advertisement. In the case of compatible activation, the action is expected to facilitate advertisement processing since the performance of the action bolsters the punch-line of the advertisement. In this situation, it is proposed, activation will increase the overall advertisement evaluation. On the other hand, in the case of a less compatible action, the action is expected to increase processing difficulty. That is, it will be harder to form an impression of the advertisement, leading to lower advertisement evaluations compared to a condition in which the same ad does not instigate an action.

The research comprises three studies all of which focus on a single physical action (i.e. turning a page upside-down) that was related either to a call to reverse the situation of the needy by donating the cost of meals, or a call to reverse the viewer’s situation by purchasing a dinner card that constitutes a routine breaker.

The first study examines the compatibility between the action and the advertisement message. Its results support the fluency of processing mechanism, which either facilitates or inhibits advertisement comprehension and consequently influences overall advertisement evaluation. The second study explores the direct effect of activation on advertisement evaluation as a function of action compatibility. The final study investigates the direct and indirect effects of action compatibility on the attitude toward the advertised product via the mediating variable of advertisement evaluation. Its findings pointed out the direct effect on attitude formation in the case of action and message compatibility. When activation was less compatible with the message, activation influenced the attitude toward the advertised product indirectly via the advertisement evaluation.

To sum, this research highlights the possible “cost” of implementing the activation technique in advertising as a function of its compatibility to the messages conveyed in the advertisement. Specifically, the effect of activation on both advertisement evaluation and attitude formation was found to be contingent upon the messages of the advertisement.

Future research may examine the compatibility between different types of actions (such as scratching or folding a page) and different types of messages. This would enable to further generalize the phenomenon.

The Experiential Information Exchange in Electronic Word-of-Mouth Communications

Lei Huang, Dalhousie University, Canada

EXTENDED ABSTRACT

Word-of-mouth (WOM) is usually viewed as a credible and objective diffusion mechanism for information (e.g., Gilly et al. 1998). While WOM has been traditionally spread among acquaintances through personal “contagions” (Barlas and Huang 2009), the Internet has dramatically increased the scale of WOM communication (Dellarocas 2003). Examples of such electronic word-of-mouth (e-WOM) communications include online product review forums, internet discussion groups, instant messaging, chat rooms, mailing lists and Web logs. As an important format of e-WOM, Bulletin Board Systems (BBS) can easily facilitate individuals in their communication with people who have similar interests, experiences, or attitudes, regardless of differences in location, socioeconomic background, or personal relationships (e.g., friends, acquaintances). One major purpose of this paper is to investigate participants’ information exchange behavior that has no basis in an existing (or trusted) relationship.

A very large percentage of the consumers who post their consumption experiences on BBS do so with little deliberate intention of “evangelizing” or “persuading” others. These consumer-generated-messages (CGMs) may or may not have an intended “target” within his or her trusted social network, yet his or her archived opinions may have a lasting impact on the awareness, trial, and purchase behavior of other consumers. Some of the CGMs can be very insightful and initiate a passionate response to the focus topic. Therefore, BBS are much more than just the buzzword-of-the-week sites, because they cannot be forced and are often a natural process. Furthermore, evidence from both marketing and social psychology has supported the role of experiential processing in decision-making and behavior. According to the cognitive-experiential self-theory (CEST) (Epstein et al. 1996), people process information by two parallel but interactive systems: one operates by context-specific, heuristic rules; whereas, the other operates by abstract, general rules guided by analysis and logic. The former deals with information that is affective in nature, and is associated with crude and emotional aspects; the latter processes information that is cognitive in nature, and is associated with refined and rational aspects. WOM is usually generated by cues that serve both systems. In accordance with CEST, this paper defines experiential information as imprecise emotional or sensual reactions to subjective characteristics drawn from the consumption of products or services. Cognitive information, however, concerns the objective features, utilitarian functions and economic values of the product or service.

Specifically, this paper argues that the experiential versus cognitive aspects of the information communicated are similar to some extent to the characteristics of goods in consumption. It crystallizes as “goods” entities, the meaning of which crucially depends on the context and on irreducibly subjective elements, such as a pleasant message, a joke that makes everyone laugh, or a story centered around the course of consuming a product or service. The idea of social exchange in WOM (and e-WOM) depicts communicators entering an interaction as having an endowment of resources that are, subsequently, transferred to the other parties. This obscures the fact that WOM communication generates something that did not exist before, and that communicators act as co-producers of this something—*recreational consumption information*. The normative significance of the correspondence of experiential information may help to explain why recreational consumption information

is important for our sense of well-being (Barlas and Huang 2009; Huang and Barlas 2009).

In addition, the advent of the Internet has made it possible to increase the experiential processes with browsers, including viral marketing, online advergaming, and interactive advertising (Fong and Burton 2006; Porter and Golan 2006; Winkler and Buckner 2006). Indeed, the information contained in CGMs on BBS underlies both experiential and cognitive processes. By using the social relationship matrix and multilevel modeling methods to study individuals’ CGMs on an online travel forum, this paper aims to answer the question of how the experiential versus cognitive CGM influences online information exchange behavior. Different from previous research on the topic of information search and Internet that mostly used “review” websites (e.g., the review section of Amazon, Rotten Tomato, etc.), the context of BBS adopted in this paper appears to be less structured than “review” websites, which creates a different information exchange dynamic. Also, BBS is more prone to an actual discussion than “review” websites (though people sometimes reply to each other in a review section of a website), which creates a more natural setting.

This study employed publicly available data from a major online travel forum for independent travelers, Travelblog.org. The data downloaded in this research were from the “Oceania Travel Forum” that contained 205 threads and 497 posts. There were 119 participants involved in discussions during the period of 2004-11-26 to 2007-11-19. Results from aggregated analysis suggest that, compared with cognitive posts, experiential posts generally had a higher proportion at the beginning of the discussion ($M_{t1}=.54$), and this advantage enjoyed a systematic increase as time went by ($M_{t2}=.63$, $\chi^2=9.48$, $p<.002$). In other words, the more experiential posts a thread had, the more discussion on the topic under this thread occurred. Further analysis from the multilevel model illustrates that the more positive posts a thread contained, the more likely this thread had higher ratings on the experiential contents of its posts ($t=2.21$, $p<.05$). Interestingly, opinion leaders’ participation led to a significant increase of experiential information in discussions, especially among those positive posts ($t=3.08$, $p<.01$).

One major contribution of this research is to demonstrate that people exchange experiential more than cognitive information on BBS. Jointly, according to experiential information transmission characteristics and the incidental variances in the BBS, marketers can make use of this “recreational consumption information” to create favorable e-WOM communication for both customer acquisition and retention. Moreover, aspects of the Internet also lend themselves well to e-WOM communication. We may not know that person, but we relate to—and often trust—posts originated from their *experiences*, especially for those virtual participants viewed as opinion leaders or “mavens.” Consequently, an extensive implication of this paper is to help marketers generate proactive WOM contents in order to unleash advocacy among enthusiasts (or opinion leaders) who will exercise influence or social-currency among certain networks and communities.

The “Name-Ease” Effect and its Dual Impact on Importance Judgments

Aparna Labroo, University of Chicago, USA
Soraya Lambotte, University of Chicago, USA
Yan Zhang, University of Chicago, USA

EXPANDED ABSTRACT

Existing research has established that subjective feelings of ease can arise while processing a target stimulus. For instance, prior exposures to a target stimulus or improved clarity of visual features of the stimulus can result in the perceptual features of the stimulus being processed more easily, and increased expectancy of seeing the stimulus can make processing of its meaning feel easy (Lee and Labroo 2004; Reber et al. 1998; Zajonc 1980). It has further been argued that because things that are personally relevant and important are processed more easily, once feelings of ease arise people mistakenly make a reverse inference that ease must equal personal relevance and importance. Thus, feelings of ease can increase perceived importance of a target stimulus, its perceived relevance, and liking towards the stimulus.

In the current research we argue that merely naming (vs. not naming) a finding also elicits subjective feelings of ease. But in contrast to existing studies, we further show that the impact of ease on perceived importance of the finding can depend on whether people are making inferences about how understandable or how memorable the finding is. In particular we suggest that feelings of ease that arise from merely naming a finding, might be associated with how memorable or how understandable the presented information is. If people associate ease with how memorable the information is, the finding appears more important. This is because things that are important are usually recalled more easily, but people also mistakenly reverse this inference. Thus, information that feels easy-to-recall is also judged more important. However, if alternatively, ease is associated with understanding the information, the finding appears unduly simplistic, less novel, and unimportant. This is because usually people exert more effort to understand information they think is important, and they thus equate importance with effort-to-understand. But when trying to understand information, people also invert this relationship and infer that feelings-of-effort imply importance. In this case, feelings of subjective difficulty, not ease, increases the perceived importance, and naming a finding makes it feel easy-to-understand and trivial. We test these effects across five experiments.

Across five experiments, participants evaluate a popular research finding: a psychological effect, an economic principle, a jury decision, or a medical condition. In experiment 1, we established people’s natural inference in evaluating a finding’s importance. Participants evaluated a psychological effect or an economic theorem that was named or not named, and endorsed which strategy they had used in evaluating importance afterwards. We found that naming a finding always increased feelings of ease, but its effects on importance were driven by the extent to which participants reported having judged the finding for memory or understanding.

In the subsequent experiments, we manipulated ease of processing by either associating a name with the finding or not, and attributed those feelings of ease either to recalling or understanding the information. Specifically, experiments 2a-b examined the presence of a name (vs. no name) atop the descriptions of a jury decision or a psychological effect, and resulted in participants finding the information more important when making a memory-based evaluation in which participants were primed to focus on recall but less important when making a stimulus-based one in which they were primed to focus on understanding. A post-test revealed that includ-

ing the name increased the perceived ease-of-processing. However, depending on whether ease was associated with recalling or understanding the information, ease increased or decreased, respectively, the perceived importance of the findings. In experiment 2b, we further explored this interaction and found that ease of processing mediated the effect such that ease-of-recall was positively correlated with importance, while ease-of-understanding was negatively correlated with importance.

Finally, in experiments 3a-3b we extended these findings to judgments pertaining to the importance of funding research for a medical condition. We additionally investigated who is more likely to fall prey to such reverse inference rules: people who pay more or less attention to information. We predicted that although low attention people usually fall prey to heuristics, in the case of these particular inference rules it is people high in attention who will more likely fall prey to such rules. This is because people who pay more (vs. less) attention to information are also those people who are more likely to put effort to understand information that is important. Thus, they will be more likely to associate effort-to-understand with importance. Also, ironically, it is these high attention people who will be more likely to recall important information more easily, because they probably attended to the important information more carefully when they came across it. Thus, for them, ease of recall is also more likely to be associated with perceived importance of information. We found that this is indeed the case.

As a set, these studies thus demonstrate that merely naming a finding always increases ease of processing the information, but ease can increase or decrease perceived importance of that finding depending on whether decision makers associate ease with memory or with understanding. Thus, the direction of impact of naming a finding on its perceived importance is moderated by the inference rule people use (memorable or understandable) and the extent of influence of naming a finding on its perceived importance is mediated by the feelings of ease that result from naming the finding.

Buyer Beware of Your Shadow: A Dual Process Explanation of Name Letter Branding and Avoidance

Luke Kachersky, Fordham University, USA
Sankar Sen, Baruch College/CUNY, USA

EXPANDED ABSTRACT

According to the work on implicit egotism (Pelham, Carvallo and Jones 2005) and name letter branding, people subconsciously gravitate toward others, professions, and brands (Brendl et al. 2005) with names that ever so slightly resemble their own. For example, Denise has a propensity to fall in love with Dennis, become a Dentist, and prefer Dove chocolate. These tendencies are in line with many other effects in which people prefer things associated with the self (e.g., mere ownership; Beggan 1992). What is counter-intuitive is that these tendencies extend to negative performance outcomes (Nelson and Simmons 2007). In other words, Denise is also likely to earn more *D* grades. It has been proposed that this paradox arises because preference for name letter objects is an automatic effect. Can consumers defend against their own vanity?

As with other automatic effects, we suggest there are boundaries to name letter branding and implicit egotism. Building on the idea that these effects are automatic, we propose that a reversal is possible when people are motivated to protect their feelings about themselves. Specifically, people should be motivated to protect their self-concepts from associations that reflect poorly on the self (Snyder, Lassegard and Ford 1986). When an association with a negative product is established via a shared name letter, people should be motivated to distance themselves from that association. But, self-protective action requires cognitive resources even if the contents of the process are not consciously accessible (Murray et al. 2008). We propose that when Denise's cognitive resources are being utilized on academic exams, for instance, it depletes the resources required for self-protective activity (i.e., distancing from *D* grades). But if those resources were available, we predict that people would prefer name letter objects *less* when it comes to negative stimuli. This effect, called *name letter avoidance*, fits with name letter branding within the context of the heuristic-systematic model (Chaiken 1980). In name letter branding, name letters are processed heuristically and consumers automatically prefer the brand to identical, non-name letter brands. In name letter avoidance, the inconsistency between one's positive self-beliefs and the presence of one's name letters on a negative product results in systematic but still subconscious processing that enables distancing (Giner-Sorolla and Chaiken 1997; Murray et al. 2008).

We first tested these ideas in an experiment with a 2 (product valence: positive, negative) x 2 (cognitive load: high, low) mixed design, in which participants assigned brand names to a series of products. Participants first received a cognitive load manipulation in which they were asked to hold either a one-digit (low load condition) or an eight-digit (high load condition) number in memory (Gilbert and Osborne 1989). They then assigned one of two brand name choices to several products. Included were one product that was pre-tested to be positively valenced (flat screen television) and one product that was pre-tested to be negatively valenced (rifle). The television names were constructed as XXXyvia, where XXX represents the first three letters of the participant's own name for the name letter (NL) choice, but represents the first three letters of a fellow participant's name for the non-name letter (NNL) choice. Similarly, the rifle brand name choices were constructed as XXXylok. Results showed that under high cognitive load, people chose the NL name at a rate greater than chance for both the television ($N_{NL}=59$,

$N_{NNL}=39$; $\chi^2(1, n=98)=4.08, p<.05$) and the rifle ($N_{NL}=59$, $N_{NNL}=39$; $\chi^2(1, n=98)=4.08, p<.05$). However, under low cognitive load, people chose the NL name at a rate less than chance for the rifle ($N_{NL}=38$, $N_{NNL}=58$; $\chi^2(1, n=96)=4.17, p<.05$), but still chose the NL name at a rate greater than chance for the television ($N_{NL}=61$, $N_{NNL}=35$; $\chi^2(1, n=96)=7.04, p<.01$).

To identify the scope of name letter avoidance and test the affective underpinnings of the distancing mechanism, we also tested our framework using risk in lieu of product valence, as risk has been linked to self-protective behavior (Josephs et al. 1992). This study employed an Internet auction scenario and used a 2 (cognitive load: high, low) x 2 (risk: high, low) x 2 (seller name: name-lettered (NL), non-name-lettered (NNL)) between subjects design. Participants first read a passage stating that either 80% (high risk condition) or 5% (low-risk condition) of Internet auction participants encountered fraud. Following the passage, cognitive load was manipulated as in the first study. Participants then evaluated an Internet auction listing for a calculator. The seller's name was constructed as XX_Math, where XX represents the first two letters of the participant's own name in the NL condition or the first two letters of a fellow participant's name in the NNL condition. They then rated their purchase intent, attitude toward the seller, and perceived risk. Under high cognitive load, participants demonstrated greater purchase intent for the NL seller in both the high-risk ($M_{NL}=2.97$ vs. $M_{NNL}=2.08, p<.05$) and low-risk conditions ($M_{NL}=2.70$ vs. $M_{NNL}=2.03, p<.05$). Under low load, participants had *lower* purchase intent for the NL seller under high risk ($M_{NL}=1.79$ vs. $M_{NNL}=2.60, p<.05$), but still had *higher* purchase intentions for the NL seller under low risk ($M_{NL}=3.05$ vs. $M_{NNL}=2.06, p<.05$). Under high risk the influence of name letters on purchase intent was mediated by attitude toward the seller, suggesting that derogation is the mechanism for distancing in name letter avoidance.

Name letter avoidance is different from name letter branding in that it has a motivated component in the form of self-protection. In turn, the self-protection system requires some degree of mental resources to enable distancing. The framework tested here demonstrates that name letter branding can be automatic, but that people are capable of correcting its maladaptive effects and distancing themselves from potentially damaging associations.

Illusionary Progress in Loyalty Programs: Moderating Role of Perceived Ease of Estimation and Medium's Magnitude on Consumer Perceptions

Rajesh Bagchi, Virginia Tech, USA

Xingbo Li, Virginia Tech, USA

EXPANDED ABSTRACT

Compare the following promotions—"Earn a free lunch after accumulating 10,000 points. Get 1,000 points with every lunch purchase." versus "Earn a free lunch after accumulating 100 points. Get 10 points with every lunch purchase." In both cases (10,000-high magnitude and 100-low magnitude), consumers need to purchase 10 lunches to avail the 11th lunch for free. Thus, perceptions of the promotion (e.g., attractiveness, ease of attainability) and progress (e.g., time and money needed to redeem the reward) should not be differentially influenced. However, we believe that the magnitude of the medium in which the judgment is elicited will influence consumers' perceptions, even when the effort and expense incurred in earning these rewards remain the same. Specifically, we posit that the perceived ease with which consumers think they can estimate redemption costs (hard vs. easy) will influence how the medium's magnitude affects perceptions and study these contingent on consumers' distance from the reward (far vs. near).

When costs associated with points accruals are made more ambiguous (e.g., "Get 100 points with every lunch purchase that costs \$5 or more"), the true costs are harder to discern (a lunch could cost \$5 or \$10). In such instances, consumers may use the only other cue available to them, that is, the medium's magnitude, to make inferences about the program. However, when costs are made more obvious (e.g., "Get 100 points with every \$1 spent"), consumers may believe that the redemption costs will be easier to estimate and may make an attempt to infer them. To do so, however, consumers will first need to attend to the rate of return in the medium (i.e., number of points earned per dollar) and then divide the number of required points by this rate. Given the complexity involved in the second step, we do not expect consumers to follow through with the computation and instead (fallibly) use the rate of return as a proxy for making program inferences. Thus, participants may overweight the rate of return and adjust insufficiently for the influence of the number of points. We draw from research in marketing and psychology to develop our hypotheses and report findings from four scenario-based studies.

In study 1A we only focus on the hard to estimate costs condition. We manipulate magnitude (high vs. low) and reward-distance (far, near) and study contingent effects on program attractiveness and progress. In this study participants learn that they can earn a free lunch after accumulating a certain number of points in a restaurant. Every lunch costing \$5 or more will result in a fixed number of redeemable points, for example, 150 points in the high magnitude condition and 7.5 points in the low magnitude condition. Participants need to earn 1,500 points and 75 points respectively in the high- and the low- magnitude conditions to redeem the reward. We manipulate reward-distance by informing participants how many points they have already earned. Because the real rate of return is unclear (\$5 or more per lunch), the true redemption costs are harder to discern. In such a situation, we expect consumers to use the medium's magnitude and reward-distance to make inferences. In the high magnitude conditions the distances appear larger. Thus, consumers in the far condition feel that they have to travel a much larger distance to earn the reward relative to those in the near condition. In contrast, in the low magnitude condition, where distances appear much smaller, consumers' perceptions of progress are not influenced by reward-distance. Correspondingly, judg-

ments of program attractiveness and attainability are influenced by reward-distance in the high magnitude condition but not so in the low magnitude condition. We also find that attainability perceptions mediate the relationship between magnitude and reward-distance on program attractiveness. Study 1B replicates the results of Study 1A.

In study 2A we focus on the easy to estimate costs condition in a credit card context where points could be redeemed for an \$8 gas card. As in the earlier studies, we also manipulate magnitude (high vs. low) and reward-distance (far, near) and study contingent effects on program attractiveness and progress. However, in this study we make the rate of return more explicit. Participants learn that every dollar that they spent would fetch a certain number of redeemable points. In the high magnitude condition the rate of return is higher relative to the low magnitude condition, but participants need to accumulate more points to earn the reward. We manipulate reward-distance by informing participants the number of points that they have already earned. Because the rate of return is specified clearly, participants feel that they will be able to easily estimate the redemption costs and pay attention to the rate of return. However, in reality, the cost computations are harder than they appear. Consequently, instead of using this rate to compute redemption costs, participants use this rate as a cue to make program inferences. In the high magnitude condition, the rate of return is higher and so consumers are not influenced by reward-distance. In contrast, in the low magnitude condition, the rate of return is significantly lower and participants who have to traverse a longer distance to earn the reward may feel that they have made less progress relative to those who are closer to earning the reward.

Therefore, in direct contrast to the findings of studies 1A and 1B, program attractiveness and attainability perceptions are influenced by reward-distance only in the low magnitude condition, but not in the high magnitude condition. Consistent with findings from study 1A, we also find that attainability perceptions mediate the relationship between magnitude and reward-distance on program attractiveness. In study 2B, we use the same procedures as in study 2A, but ask participants to calculate redemption costs before responding to all the other measures. Calculating redemption costs requires paying attention to both the rate of return as well the points required and as expected, this attenuates the influence of magnitude and reward-distance on attractiveness and attainability. These findings suggest that individuals may not have calculated redemption costs in study 2A, or for that matter in studies 1A and 1B, and may have anchored on other factors (e.g., rate of return in study 2A), which led to perceptions of illusionary progress. We discuss theoretical and managerial implications and suggest avenues for future research.

The Simple (and Complex) Effects of Scent on Retail Shoppers: Processing Fluency and Ambient Olfactory Stimuli

Friederike Haberland, University of St. Gallen, Switzerland

David Sprott, Washington State University, USA

EXTENDED ABSTRACT

Research in marketing suggests that customers within a retail store can be influenced by ambient scents. Unfortunately, there have been few theoretical explanations offered for observed effects. The major goal of this paper is to explore how ambient scent impacts expenditures and the extent to which specific characteristics of the olfactory cue itself plays a role. In particular, we propose that the ease with which olfactory cues are processed (i.e., processing fluency) will affect how such cues influence customer behavior. According to processing fluency, stimuli that are easier processing will trigger positive affect, which in turn will result in greater liking of a stimulus and other positive outcomes (e.g., increased spending in the presence of such a cue). In this research, we examine the perceived ease of processing of a simple versus complex olfactory cue, such that ease of processing effects are significantly stronger for simple, rather than for complex, scents (stimulus complexity is a traditional manipulation of processing fluency). To provide insights in the underlying process and support a processing fluency explanation, we explore the mediating role of affective responses on the observed effects.

In this research, two pretests were conducted for stimuli selection, followed by two experiments designed to explore the major issues of interest. In pretest 1 (N=208), we tested different scents varying in terms of complexity (or processing fluency), but that did not differ along other theoretically relevant dimensions. In cooperation with a commercial scent supplier, experimental stimuli contained only one a single scent for the simple scent condition or multiple scents for the complex condition. Participants rated scents (provided in an opaque vial) regarding stimuli complexity, pleasantness and congruency with the retail store. A significant complexity by scent interaction emerged for the selected scents but, as intended, no interactions emerged with regard to perceived congruency or pleasantness of the scent. In pretest 2 (N=156), the complexity of scents selected from the first pretest were examined in a real-world setting by diffusing the scents in a retail store. Shoppers were stopped randomly and asked to fill out a questionnaire. Using the same measures as first pretest, we obtained a significant effect on perceived complexity as expected.

In study 1 (N=186), customers were exposed to simple and complex ambient scents diffused within a retail store, or to no scent at all (in the control condition). After passing the cash register, customers were asked to indicate their spending and complete a short survey. As expected, results indicated a significant impact of ambient scent on sales, but only for simple scents. In particular, shoppers spent more money when exposed to a simple ambient scent, as compared to a complex ambient scent or no scent at all. Sales between the complex and no scent conditions did not differ. To understand the postulated underlying processes of fluency, we explore in study 2 the psychological process underlying observed effects.

In study 2 (N=220), customers were exposed to simple or complex scents, or no scent at all, within a retail store. Additionally,

we assessed customers' affective response. Results of this experiment were nearly identical to those of study 1. Given the similar result, the mediating role of affective reactions was tested via OLS regression. These results showed that the direct effect of the simple ambient scent on spending was significantly mediated by consumers affective responses, such that when consumers' affective reactions are included in the model, the relationship weakens to non significance.

Nearly all prior research on scent has applied the S-O-R model to explain the effects of scent on customers. In our research, we demonstrate the theoretical importance of processing fluency by demonstrating stronger effects for simple (versus complex) ambient scents on sales. One of the most intriguing findings of the current research concerns our demonstration that processing fluency can be applied to olfactory stimuli, something that has yet to be shown in the fluency literature. The results of the current research are not only of theoretical interest to those in marketing and psychology, but also have important managerial implications by indicating the nature of scents that should be employed by firms and marketing managers. In particular, firms would be well served to consider the actual nature of scents and to consider employing scents that are simpler and therefore easier to process by consumers.

Verbalizing or Visualizing Metaphors? The Moderating Effects of Processing Mode and Temporal Orientation

Yi He, California State University–East Bay, USA
Qimei Chen, University of Hawaii, USA
Dana L. Alden, University of Hawaii, USA

EXTENDED ABSTRACT

The Internet, with its “seemingly endless opportunities to inform, teach, and connect” (Silberg et al. 1997, p. 1244), has become one of the most important channels for pro-healthful persuasive communications. Central to many of these communications is the use of metaphor. Despite this, understanding of metaphor processing mechanisms remains limited. For example, theory has yet to incorporate mental imaging as mediator of metaphor’s enhanced persuasiveness. This is the case despite the centrality of imagery processes to metaphor comprehension (Marschark, Katz, and Paivio 1983; Gibbs and Bogdonovich 1999). The extent to which processing mechanisms differ by type of metaphor also remains unknown. To address these gaps, the first objective of this research is to identify underlying processing mechanisms for alternative metaphor formats (i.e., abstract versus concrete metaphors).

A second objective is to extend current theory regarding relationships between metaphor message strategies and “processing fluency.” Processing fluency refers to the ease with which message content is evaluated and understood (Petrova and Cialdini 2005; Thompson and Hamilton 2006; Lee and Aaker 2004). Enhanced processing fluency has been associated with the use of imagery appeals (Petrova and Cialdini 2005), comparative advertising (Thompson and Hamilton 2006), and certain message frames (Lee and Aaker 2004). However, researchers have yet to test the impact of metaphor (e.g., abstract versus concrete metaphors) in conjunction with other communication tactics (e.g., processing goals or temporal orientation priming) on processing fluency as a mediator of message effectiveness. Closing these theoretical gaps, this research further examines ways that congruency between metaphor format (i.e., abstract versus concrete metaphors) and processing instructions (i.e., low- versus high-imagery instructions) impacts persuasion by enhancing processing fluency. Similar congruency effects between metaphor format (i.e., abstract versus concrete metaphors) and temporal orientation priming (i.e., long-term versus short-term priming) are also investigated.

Experiment 1 examines the processing mechanism of abstract versus concrete metaphor. Although imagery has yet to be incorporated into the metaphor processing mechanism, prior research has consistently underscored the role of imagery in comprehending metaphoric messages (Bottini et al. 1994; Burgess and Chiarello 1996). In addition, the level of mental imagery may vary by type of metaphor. For example, Gibbs and Bogdonovich (1999) demonstrated that concrete metaphors were usually processed through higher imagery mode than abstract metaphors. In addition, as imagery processing is believed to have superiority over discursive processing, concrete metaphors may be expected to be more persuasive than abstract metaphors. Experiment 1 tested the information processing mode of abstract versus concrete metaphors and the effect of metaphor format on message persuasion. Experiment 1 features a 2 metaphor format (abstract metaphor versus concrete metaphor) one-factor between-subject experimental design. Experiment 1 reveals that concrete (versus abstract) metaphors activate higher levels of imagery processing, and increase message effectiveness.

Experiment 2 investigates the effect of congruency between metaphor format and processing mode on persuasion. Congruency between message format and processing mode is believed to positively affect persuasion. Such effect is expected based on processing fluency theory (Winkielman and Cacioppo 2001). Processing fluency is defined as the experienced ease or fluency of ongoing processing (Unkelbach 2007). Processing fluency may also result from congruency between 1) the information and organization of information, and 2) the type of processing being done (Bettman et al. 1986). As found in Experiment 1, abstract (concrete) metaphors are more compatible with lower (higher) imagery processing. Then it can be predicted that compared with concrete (abstract) metaphors, abstract (concrete) metaphors lead to greater persuasion when low-imagery (high-imagery) processing was made salient. To test these hypotheses, Experiment 2 features a 2 metaphor format (abstract metaphor versus concrete metaphor) X 2 processing instructions (low- versus high-imagery instructions) factorial design. Experiment 2 shows that congruency between metaphor format and processing goals facilitates processing fluency, and thereafter enhances message effectiveness.

Experiment 3 extends the same analogy and tested similar congruency effects between metaphor format (i.e., abstract versus concrete metaphor) and temporal orientation priming (i.e., long-versus short-term priming). Temporal orientation priming was selected due to its close associations with health related behaviors (Orbell and Hagger 2006). Prior research revealed that an individual can be primed to either focused on the long-term, the pursuit of distant rewards and achievement, or alternatively focused on the short-term, the pursuit of immediate gains and returns (Liu and Aaker 2007). According to the Temporal Construal Theory (Trope and Liberman 2003), abstract (concrete) metaphors are congruent with long-term (short-term) temporal orientation. Following the regulatory fit hypothesis (e.g., Lee and Aaker 2004; Aaker and Lee 2006), one may expect that when there is congruency between an individual’s regulatory orientation (e.g., long- versus short-term) and communication message (e.g., abstract versus concrete metaphor), the ideas conveyed in the message are conceptually more fluent, and hence are more effective. To test these hypotheses, Experiment 3 features a 2 metaphor format (abstract metaphor versus concrete metaphor) X 2 temporal orientation priming (long-versus short-term priming) factorial design. Experiment 3 reveals the positive effects of congruency between metaphor format (i.e., abstract versus concrete metaphors) and temporal orientation priming (i.e., long-term versus short-term priming) on message effectiveness due to increased processing fluency.

This research contributes to the collective knowledge of marketing in the following aspects. First, by developing a more precise model of the processing mechanism related to metaphors, this research advances the collective knowledge concerning how to effectively deliver metaphoric marketing appeals. Second, by examining the match or mismatch of different kinds of metaphors to other communication tactics (e.g., processing goals or temporal orientation priming), the present research may help identify ways to optimize the blending of linguistic and non-linguistic advertising elements. These analyses should assist marketers in answering

important strategic questions in today's highly competitive global marketplace.

Unleashing the Imagination through Priming: Prompting and Facilitating Effects of the Imagery Mindset

Massimiliano Ostinelli, University of Wisconsin-Milwaukee, USA
Ulf Bockenholt, McGill University, Canada

EXPANDED ABSTRACT

Imagery-evoking advertisements (i.e., ads that prompt and/or facilitate the generation of mental images) are often used to promote products and services. The widespread use of these advertisements is justified by empirical evidence suggesting that imagining consumption-related behaviors can lead to favorable product evaluations (e.g., MacInnis & Price, 1987; Petrova & Cialdini, 2005, 2007; Thompson & Hamilton, 2006) and increase purchase behavior (Gregory, Cialdini, & Carpenter, 1982).

Imagery-evoking ads, however, are not always effective. Their persuasiveness depends on both a consumer's propensity to imagine and ability to generate vivid mental images (e.g., Keller & McGill, 1994; Petrova & Cialdini, 2005; Thompson & Hamilton, 2006). Propensity to imagine can be increased through imagery instructions (Keller & McGill, 1994; Thompson & Hamilton, 2006), whereas one's ability to imagine is influenced by individual differences and, in particular, by one's dispositional imagery vividness (Petrova & Cialdini, 2005). Since the persuasiveness of imagery-evoking advertisements is ultimately determined by the information processing mode used by consumers and their dispositional imagery vividness, these types of ads may be a risky option from an advertiser's point of view: Asking to imagine the content of an imagery-evoking ad may be an effective means of persuasion when dispositional imagery vividness is high, but it may backfire when dispositional imagery vividness is low (Petrova and Cialdini 2005).

We propose that the persuasiveness of an imagery-evoking ad also depends on the tasks a consumer performs before encountering the ad and, in particular, on the amount of mental imagery these tasks elicit. We draw on the literature on procedural priming (e.g., Kolers & Perkins, 1975; Kolers & Roediger III, 1984; Shen & Wyer, 2007; Xu & Wyer, 2008) to suggest that tasks evoking mental imagery (e.g., reading a narrative) may prime an imagery mindset—defined as a state of enhanced accessibility of an imagery processing mode—which affects the evaluation of advertisements subsequently presented.¹ More specifically, we suggest that priming an imagery mindset may simultaneously prompt a consumer to imagine—we call this effect prompting effect—and facilitate imagery processing—we call this effect facilitating effect. The prompting effect activates an imagery processing mode, as imagery instructions do, whereas the facilitating effect increases the ease of imagery processing, as dispositional imagery vividness does. Thus, the combined effect of the prompting effect and the facilitating

effect may increase the persuasiveness of imagery-evoking advertisements.

The first two studies supported this proposition by showing that performing a task that elicits mental imagery can increase the persuasiveness of imagery-evoking advertisements subsequently presented. In Study 1, participants who read imagery-evoking, as opposed to abstract, descriptions of an apartment and a restaurant had higher (lower) purchase intentions toward a tropical resort whose description was imagery-evoking (abstract). In Study 2, participants who made 20 size judgments (e.g., select the item that is larger in real life: Camel/Cow)—a task that evokes mental imagery (Paivio, 1975)—as opposed to 20 vowel judgments (e.g., select the word with more vowels: Camel/Cow)—a task that does not elicit mental imagery—, had more favorable evaluations of a tropical resort described in an imagery-evoking way.

We also propose that the impact of an imagery mindset on persuasion may be moderated by both the presence of imagery instructions and a person's dispositional imagery vividness. In the absence of imagery instructions, the prompting effect activates an imagery processing mode that may increase the persuasiveness of imagery-evoking ads for individuals high in dispositional imagery vividness—who can easily generate mental images—, but it may decrease the persuasiveness of imagery-evoking ads for individuals low in dispositional imagery vividness (Petrova & Cialdini, 2005)—who cannot easily generate mental images. The facilitating effect, on the other hand, may have a null impact for individuals high in dispositional imagery vividness—who can easily generate mental images regardless of the activation of an imagery mindset—and a positive impact for individuals low in dispositional imagery vividness—who otherwise would not easily generate mental images. Thus, in the absence of imagery instructions, priming an imagery mindset may have a positive net effect on the persuasiveness of imagery-evoking messages for individuals high in dispositional imagery vividness and a null effect for individuals low in dispositional imagery vividness (since the positive facilitating effect may neutralize the negative prompting effect). Study 3 supported this prediction by showing that, in the absence of imagery instructions, priming an imagery mindset through size judgments increased preferences toward a cell phone with positive vivid attributes (i.e., imagery-evoking product option), as opposed to positive abstract attributes, but only for participants high in dispositional imagery vividness. As expected, priming an imagery mindset had no significant effect on preferences when participants were low in dispositional imagery vividness.

In the presence of imagery instructions, consumers' propensity to imagine is high regardless of the activation of an imagery mindset. Therefore, the prompting effect may be influential. The facilitating effect, however, may increase the ease of imagination for individuals low in dispositional imagery vividness and, in turn, the persuasiveness of imagery-evoking messages. On the other hand, the facilitating effect may have a null effect for individuals high in dispositional imagery vividness—who can easily generate mental images regardless of the activation of an imagery mindset. Thus, in the presence of imagery instructions, priming an imagery mindset may have a positive net effect on the persuasiveness of imagery-evoking messages for individuals low in dispositional imagery and a null effect for individuals high in dispositional

¹Preliminary evidence in favor of the existence of an imagery mindset has been provided by Adavel and Wyer (1998) who, unexpectedly, found that evaluating an imagery-evoking (i.e., a narrative), as opposed to an abstract (i.e., a bullet-style description), brochure of a vacation destination led to more favorable evaluations of a second vacation destination described in an imagery-evoking format. In a post-hoc explanation of these findings, the authors suggested that evaluating an imagery-evoking message might activate an information processing mode that affects the evaluation of successive messages. Despite this evidence and the compelling explanation, no formal account of the notion of an imagery mindset has been provided yet.

imagery. Study 4 supported this prediction by showing that activating an imagery mindset by memorizing and retrieving a series of pictures, as opposed to performing a numerical task, increased attitudes toward an imagery-evoking restaurant review preceded by imagery instructions for individuals low in dispositional imagery vividness, but it had no significant effect on individuals high in dispositional imagery vividness.

From a managerial point of view, this work suggests implications of interest for the placement of print advertisements. For example, an advertisement that asks consumers to imagine enjoying a Caribbean vacation may be more persuasive when presented after an imagery-evoking narrative than after, for example, a Sudoku puzzle (a low imagery-evoking task).

Uncovering the Coexistence of Assimilation and Contrast Effects in Hedonic Sequences

Tanuka Ghoshal, Carnegie Mellon University, USA
Eric Yorkston, Texas Christian University, USA
Joseph C. Nunes, University of Southern California, USA
Peter Boatwright, Carnegie Mellon University, USA

EXTENDED ABSTRACT

Most judgments that consumers make everyday are part of sequences and hence unlikely to be context-free. Whether test driving cars, evaluating courses of a menu, dating (in particular, speed-dating), tasting wines or completing a customer satisfaction survey, it is difficult to imagine how the results from one evaluation would not affect the next. The literature in marketing is replete with examples of how the context in which a stimulus is embedded can have a significant impact on people's judgment of that stimulus. The two context effects that have been most reliably demonstrated in psychology and marketing are assimilation and contrast. Assimilation refers to a positive relationship between the value people place on the contextual stimuli surrounding a target and the value they place on that target itself. Contrast refers to a negative relationship between these two values (Martin, Seta, and Crelia 1990).

What has been consistent across previous research on assimilation and contrast across sequences of experiences is that these are two opposing and mutually exclusive effects. It is assumed that one or the other takes place and that characteristics of the context, such as domain match (Meyers-Levy and Sternthal 1993, Raghunathan and Irwin 2001), product knowledge (Bickart 1993), availability of cognitive resources (Meyers-Levy and Tybout 1997), or context set range (Lynch, Chakravarti, and Mitra 1991) dictate which one occurs. We propose that within a sequence of comparative evaluations, both assimilation and contrast can co-occur and that previous analyses focusing and thus testing for one or the other exclusively may have failed to pick up one or the other. More specifically, if these effects coexist, controlling for one (e.g. assimilation) may reveal the other (contrast) where it was not observed before, which is the main contribution of this work.

A relatively recent stream of research in this domain focuses on characterizing context effects in sequences of hedonic experiences (i.e., incidents of pleasure or pain). The findings have been mixed. For example, Raghunathan and Irwin (2001) document contrast effects in respondents' prospective evaluations of descriptions of vacation spots and cars when there is a domain match but assimilation effects in cases of a domain mismatch. Novemsky and Ratner (2003) find that although individuals expect and predict contrast effects, evaluations provided at the time of the actual experience of consuming jellybeans provide no evidence of contrast effects. Even today researchers (Morewedge et al 2009) are searching for empirical evidence for contrast effects in actual experience, which is another important contribution of this work.

We obtained eight years of judging data from a national beer brewing competition. All entries are grouped into sequences or "flights" ranging from five to 13 beers. All beers within a flight belong to the same broad category (example: Pilsner), but could belong to different subcategories (example: American or German Pilsner). Each flight is rated by two independent certified (expert) judges who sample all the beers within the flight in the same order. Each beer is scored out of 50 points, and each score is recorded while tasting the specific beer and written down prior to moving on to the next beer in the flight, ensuring that the evaluations in our sample are actual real-time experience data and not recalled experience or retrospective evaluation data.

For our hypotheses we draw on literature in order effects and sequential evaluation, and context effects. We propose the following hypotheses regarding context effects in sequential evaluation:

- H₁: Ratings of the stimulus in the first position will be higher on average than ratings of subsequent stimuli.
- H₂: Across a sequence of trials, ratings assimilate to one another.
- H₃: Ratings within a sequence contrast to extreme stimuli.
- H_{4a}: Ratings will contrast more strongly with stimuli within the same subcategory.
- H_{4b}: Ratings of the stimulus in the first position of a new subcategory will be higher on average compared to the ratings of subsequent stimuli.

Unlike previous work in this area that has documented these effects utilizing separate tests, we test for these effects simultaneously using a multilevel modeling approach. Our first estimation establishes significant assimilation effects at the level of the flight. Scores of the focal beer assimilate to the score of the beer immediately preceding it, and to the running maximum and minimum scores (extremes) of the flight. However, we are unable to detect contrast effects in this model. In the second stage, we "adjust" for the variation in scores across flights by incorporating individual flight dummies. We now find contrast effects against extreme scores as hypothesized. Statistical testing reveals that the flight coefficients are significantly different from each other, indicating that assimilation effects at the level of the flight cause beers to anchor to one other, and influence between-flight variation. Once flight differences are accounted for, the effects of beers within a flight being pitted (directly compared to) against each other are visible and hence contrast effects emerge. In terms of the other results, we find that stimuli in the first position of the flight and sub-flight score higher on average compared to the rest of the stimuli, however, subcategories within a flight do not impact (either enhance or attenuate) contrast effects. In summary, we find support for hypotheses 1, 2, 3 and 4b, but not for hypothesis 4a.

In conclusion, with our multilevel estimation approach, we were able to control for assimilation and simultaneously isolate contrast effects that had previously been masked by assimilation. We posit that assimilation drives the overall evaluation or impression of a sequence or group, while contrast effects influences within-group evaluations. Thus the two effects occur simultaneously, but they operate at different levels within the same sequence of hedonic experiences. Contrary to other researchers (Novemsky and Ratner 2003), we are also able to document contrast effects in real-time sequential hedonic evaluations. By documenting how two seemingly opposing effects such as assimilation and contrast effects can coexist, and how controlling for one reveals the other, our work contributes to numerous research streams including work on sequential evaluation, taste, and the evaluation of hedonic experiences.

Haptic Product Information and Consumers' Recall of Haptic Imagery Information

Shannon B. Rinaldo, Texas Tech University, USA

Terry L. Childers, Iowa State University, USA

EXPANDED ABSTRACT

Although the role of haptic processing within marketing has been increasingly studied, haptic imagery use has not received the same level of attention. Imagery is a mental representation similar to the initial phases of perception but occurs without actual perception of a stimulus (Kosslyn, Thompson, and Ganis 2006). The nature of imagery consists of an experience to the individual that may appear as real as perception, where no perception is taking place.

Imagery is said to be functionally equivalent to perception in that similar behavioral and physiological responses have been observed during imagery as are observed during perception within a perceptual modality (Finke 1989). This phenomenon was first published in the marketing literature by Unnava, Agarwal, and Haugtvedt (1996), who studied the effects of perceptual modality on participants' ability to recall imagery information from an advertisement. Auditory signals were detected more slowly when participants were holding auditory images in their minds than when they were holding visual images. Similar interference for detection of visual signals was shown when visual images were being held. Other studies investigating perception and imagery interaction have found imagery to facilitate perception in that imagery appears to improve a person's ability to perceive stimuli (Finke 1989). This is the first study to investigate the interaction of haptic imagery and haptic perception in this way. Following the path laid by the two literatures, shape perception should differentially interfere with or facilitate the ability to recall shape imagery information, while texture perception should differentially interfere with or facilitate the recall of texture imagery information.

Evidence in the behavioral and neurological literatures indicates that the visually impaired have unique abilities in the haptic modality (Davidson 1976). Not only is this population well practiced in both haptic perception and imagery, but evidence is growing that shows that their brains react differently to haptic stimuli and memories than do the brains of their sighted counterparts (Röder et al. 1997; Sadato et al. 2002). These facts allow for a unique comparison for the study of haptic imagery's use in consumer product evaluation. The researchers predicted, therefore, that blind consumers would differ in their results.

Sixty-two sighted and sixty-four blind consumers were recruited to participate in an experiment. Participants listened to auditory advertisements that were embedded with texture and shape salient imagery. Participants then evaluated textured or shape salient products while recalling information from the advertisement. Additional variables were collected via self report questionnaire: extent and type of imagery evoked by the advertisement; attitude toward the advertisement; attitude toward the product; frustration with the task; and confidence with the task. The Communication Evoked Imagery Scale was also used to measure the nature and extent of mental imagery evoked (Babin and Burns 1998).

A general linear model revealed that visual status (i.e., sighted versus blind) was significant ($F=2.218$, $p<.05$), supporting the prediction that blind and sighted participants would differ in their results. Visual status was significantly related to the number of non-imagery statements ($M_{\text{sighted}}=1.98$ vs. $M_{\text{blind}}=2.48$), ($F=4.0$, $p<.05$), quantity of imagery evoked by the target ad ($M_{\text{sighted}}=3.28$ vs. $M_{\text{blind}}=3.93$), ($F=3.202$, $p=.076$), attitude toward the target ad

($M_{\text{sighted}}=4.4$ vs. $M_{\text{blind}}=5.1$), ($F=6.610$, $p<.05$), confidence in recall ($M_{\text{sighted}}=3.52$ vs. $M_{\text{blind}}=4.52$), ($F=14.847$, $p<.0001$), overall rating of the ad ($M_{\text{sighted}}=3.51$ vs. $M_{\text{blind}}=4.37$), ($F=12.83$, $p<.001$), overall rating of the product ($M_{\text{sighted}}=3.85$ vs. $M_{\text{blind}}=4.73$), ($F=8.778$, $p<.01$), and haptic imagery evoked by the ad ($M_{\text{sighted}}=4.63$ vs. $M_{\text{blind}}=5.36$), ($F=4.342$, $p<.05$).

The research question stated that when participants were evaluating stimuli while recalling imagery elements from an advertisement, properties of the stimulus touched would interact with the nature of the imagery advertisement content recalled. Because visual status was significant in the overall GLM, the data were split by visual status and an overall test of effect was conducted. In line with Unnava et al. (1996), a t-test was performed to test the overall effects of match/mismatch of stimulus evaluated with imagery statements. This is essentially a contrast of recall means when stimulus quality matched the recall statement modality (Texture/Texture or Shape/Shape) versus when modalities did not match (Texture/Shape or Shape/Texture). Results indicated that there was a significant difference in both groups. The sighted participants recalled significantly more imagery statements when there was a modality match ($M=1.57$ vs. $M=1.04$), ($t=11.306$, $p<.0001$). Blind participants results followed the same trend where a modality match resulted in more imagery recall statements ($M=1.55$ vs. $M=.88$), ($t=8.826$, $p<.0001$). These results indicate that in this case modality match resulted in the facilitation of matched imagery recall.

Participants who reported having both visual imagery and haptic imagery from the target ad had significantly better overall attitudes toward the ad itself ($F=25.595$, $p<.0001$, $SS=64.307$). A hierarchical regression removed variance attributable to the visual imagery item in the haptic imagery item (Cohen and Cohen 1983). The residual variance of the haptic imagery item was regressed on attitude toward the ad and the relationship was significant apart from the portion attributable to the visual imagery question ($F=8.847$, $p<.01$, $SS=206.608$). The same was true for likelihood of purchase ($F=6.82$, $p=.01$, $SS=401.869$) and for attitude toward the product ($F=7.409$, $p<.01$, $SS=315.077$).

The utility of non-visual imagery use in advertising and other consumer marketing has yet to be fully realized (Unnava et al. 1996). This study is the first to offer evidence that the use of haptic imagery in advertising is likely to be effective. Participants in this study who reported experiencing haptic imagery while listening to the advertisement also indicated a more positive attitude toward the advertisement, more positive attitude toward the product, and higher likelihood of purchase. This study is also the first to show how product properties can affect recall of imagery statements from an advertisement upon product evaluation. The study specifically showed that when evaluating a shape salient product, participants were more likely to recall shape imagery and when evaluating a texture salient product, participants were more likely to recall texture imagery statements.

Sizing Up Package Size Effects

Natalina Zlatevska, Bond University, Australia

Marilyn Y. Jones, Bond University, Australia

EXPANDED ABSTRACT

Repackaging food into smaller servings has become a popular strategy among food marketers but recent research surprisingly suggests that smaller packs may lead to more food consumed (Coelho de vale et al. 2008). Studies have found that, when comparing dieters with non-dieters, dieters were more likely to over-consume from smaller packs (Scott et al. 2008). These results are unexpected as smaller sized portions are typically used as a dietary aid (Wansink et al 2005). The aim of the present research is to explore the usefulness of using smaller package sizes as a tool for monitoring consumption. In particular, we explore this in situations where distractions are present.

The main prediction of the present study is that small package sizes are beneficial for dieters, though usage needs to be in circumstances where no distractions are present. It is expected that restrained eaters (dieters) will consume more from smaller package sizes when distracted than when not distracted. This is because dieting individuals will be unable to monitor the visual consumption cues or benchmarks offered by a smaller package and will therefore believe that they have consumed less, because the portions are smaller, than what they actually have. Moreover, because consumption volume is proportionate to package and serving size, the more that is placed in front of a distracted dieter, the more they will eat, it is expected that dieters will consume more from larger packages when distracted than when not distracted.

The design of the study was a 2x2x2 mixed design with one measured variable, dietary restraint (restrained, unrestrained) and two manipulated variables, serving size (small, large), and distraction (TV on, TV off). The main dependent variable of the study was the amount of candy consumed during the experiment. Depending on the condition, participants were either given a number of small packs (5 x 20g) or one large pack (1 x 100g) of chocolate rocks confectionery. Participants in the distraction condition were shown an episode of a popular television show during the study. The amount of candy consumed during the experiment was weighed once participants completed a final, short questionnaire.

The results reveal that as expected, restrained eaters consume more from smaller packages when distracted than when not distracted. This is because for restrained eaters, the visual cues of package size are used as a consumption monitoring device. Distracting environments distort a dieter's ability to accurately monitor consumption. The findings illustrate this point further, with respondents stating that when distracted they found it much more difficult to regulate consumption behaviour than when not distracted.

Somewhat surprisingly, although distraction has a negative effect on consumption for restrained eaters consuming from smaller packages, distraction has an overall positive effect on consumption from larger packages and on the consumption patterns of unrestrained eaters. The results reveal that, restrained eaters consume more from large packets when not distracted than when distracted. They also consume more from large packets when not distracted than they do from small packets when distracted. A possible explanation for the unexpected results is that, although visual contact with food and close attention to consumption cues is extremely important in providing dietary benchmarks when monitoring intake of smaller sized portions, visual contact and attention also creates increased tension and exposes dieters to greater temptation when faced with larger sized servings. Because restrained

eatiers rely heavily on consumption cues and norms, when not distracted and focused solely on the large serving of food placed in front of them, they are more likely to consume more.

In summation, repackaging bulk snack food into smaller sized servings is beneficial for individuals, though only when the repackaged food is consumed in environments where distractions are not present. Distractions distort an individual's impression of dietary intake. Conversely, larger serving sizes under conditions of no distraction may create increased cognitive tension and temptation. When distracted some of the internal conflict and stress, of being faced with a large serving size is removed. This finding is consistent with popular dieting wisdom suggesting that those who absorb themselves in activities that do not relate to food are more successful at keeping temptations at bay.

Although smaller package sizes are beneficial for dieters, consumption needs to be in situations where distractions are not present, a scenario that is quite difficult to replicate in everyday circumstances. Rarely does an individual consume food in situations where no children, television, radio, co-workers or friends are present. Consistent with the conclusions drawn by Scott et al (2008) and Coelho de vale et al. (2008), dieters should opt for traditional larger package sizes over smaller package sizes in circumstances where they might lose track of the number of smaller packets consumed.

Is What You See What You Get? Consumer Responses to Product Packaging Transparency

Rishtee Batra, Indian School of Business, India
Benjamin Lawrence, Boston University, USA
Sucharita Chandran, Boston University, USA

EXTENDED ABSTRACT

As much as 73% of all purchases are made at the point of sale, with packaging heavily influencing not only what products are included in consumers' consideration sets but also which of those are ultimately selected (Rettie and Brewer 2000). While product packaging encompasses several different dimensions, research in visual aesthetics has focused most prominently on package shapes, colors, and proportions (Orth and Malkewitz 2008; Raghurir and Greenleaf 2006) while largely neglecting other characteristics of packaging such as its transparency. This finding is curious, given a recent trend in the marketplace toward using packaging transparency as a means of innovation and differentiation. While intuitively this seems to be a good way to differentiate products in a cluttered market, we currently lack a theoretical understanding of the impact of transparency in consumers' judgments of product packaging.

In this research we examine the relationship between the transparency of packaging and consumers' product evaluations for a variety of product categories that vary in levels of sensory attributes. Using a series of three experiments we propose and test three hypotheses that predict transparency preference and find that both product specific factors and product packaging cues can moderate the relationship between transparency and perceptions of performance.

We find that for those products that are high on sensory attributes such as turkey and cotton tips, participants show a clear preference for transparent packaging while they are indifferent to packaging for those products low on sensory attributes (DVDs, highlighters; Study 1). However it is possible to mitigate this transparency advantage, through the provision of other relevant market information which can be visual (picture of cotton tips) or verbal (claim that opaque packaging prevents freezer burn of Turkey; Study 2). Finally there are instances where this transparency advantage not only does not manifest but that there is in fact an opacity advantage—i.e. opaque packaging is preferred (nausea medicine; study 3). Such contexts represent boundary conditions to the transparency advantage and are likely to manifest when transparency of packaging may instantiatate negative emotional reactions (such as disgust, fear, embarrassment) to the problems that the product serve as solutions for.

We support the notion here that given the primacy of firsthand experience in product evaluation, marketers have the ability to shape this firsthand experience through the transparency of packaging. To a great degree, allowing visual inspection of contents of the package through transparent packaging provides sensory information not only related to sight but may also serve as a proxy for other sensory information such as taste, touch and smell. In absence of the ability to provide such a direct visual inspection it is possible through other means to mitigate the opacity disadvantage. Marketers can transform the way an indirect, secondhand experience occurs by changing the way in which the sensory attribute is framed. This can occur through some kind of a proxy of firsthand sensory experience by the use of market information such as a salient product image on the package and/or a relevant product claim.

In this research we have focused solely on the impact of visual inspection through transparent packaging. However we still lack an understanding of how such a visual examination helps or falls short of serving other sensory evaluations—such as smell, touch, taste,

Also, it would be interesting to examine how opaque packaging with some other sensory dimension, such as scent, may serve as an indirect diagnostic visual experience. An orange scented opaque package for orange juice may invoke visual images of fresh oranges and may perform adequately or even better than a transparent package. Our findings also suggest that other relevant cues may provide diagnostic information that acts as a proxy to mitigate the absence of visual information in evaluation. Such a transformation may change either the relative weights attached to the associated sensory and cognitive attributes or may in fact change their relative value. The precise mechanism of the transformation between the impact of sensory and cognitive cues in determining the effect of transparency of packaging is also an interesting question for future investigation.

More generally, this is an area of substantive interest because of the important implications of packaging in marketing strategy. Not only does packaging have the ability to influence purchase decisions (Creusen and Schoormans 2005), it also holds the power to damage consumer relationships if not thought out carefully, as in the recent case of Pepsico's redesign of Tropicana Orange Juice. The packaging of a product can be thought to "do the talking" for its contents and therefore it is necessary to ensure that the packaging is communicating the right message. It is therefore important to understand how consumers react to and process package-related information so that marketers might align their packaging's message to consumer needs.

Not as Big as it Looks: Attribution Errors in the Perceptual Domain

Zachariah Sharek, Carnegie Mellon University, USA

Sam Swift, Carnegie Mellon University, USA

Francesca Gino, University of North Carolina at Chapel Hill, USA

Don Moore, Carnegie Mellon University, USA

EXTENDED ABSTRACT

People routinely assume correspondence between acts and dispositions, a systematic error prior research has labeled “correspondence bias.” Three laboratory studies investigate the robustness and generality of this tendency, and suggest that it may be even more fundamental than prior theories have supposed. Most of the research documenting the correspondence bias uses paradigms in which the behavior is more salient and easier to assess than is the situation. Our studies employ a new paradigm in which people have perfect information about both the situation and the behavior. Using this paradigm across different settings, we find that the correspondence bias generalizes to inanimate objects.

Participants in our first study evaluated the height of ten target individuals, some of whom happened to be standing on cinderblocks. The height of the cinderblock was common knowledge. Using this setting, we were interested in testing whether people made correspondent inferences and reported believing that those standing on cinderblocks were taller than those who did not. Such an effect could not easily be explained by the theories offered previously to explain the correspondence bias.

Consistent with the correspondence bias, participants were more likely to select candidates on blocks as among the five tallest candidates. Had participants always chosen the five tallest candidates, then, on average, 2.5 of the five candidates they chose would have been standing on cinderblocks. In fact, 2.8 of those chosen were standing on cinderblocks, a significant difference, $t(78)=3.37$, $p=.001$.

To examine the effect of the cinderblock on each candidate’s rated height, we conducted a mixed model analysis of the ten repeated measures from each participant, including the candidate’s actual height and the presence of a cinderblock as covariates. The results reveal that each inch of actual height increased a candidate’s rated height by .26 units ($t[652]=25.02$, $p<.001$) and that the eight inches contributed by the cinderblock contributed an additional .15 units ($t[90]=2.3$, $p=.02$).

In this study, both the outcome of interest (height) and the situational effect (standing on a cinderblock) were obvious and quantifiable. Unlike so many prior studies of the correspondence bias, the situational was visible. Nevertheless, the correspondence bias persists. Its effect is modest in size but still robust. We wondered, however, whether the effect we obtained in Study 1 was somehow due to the fact that we had used a subjective response scale, and whether people might be able to arrive at more accurate numerical judgments when forced to estimate the exact height in feet and inches. Study 2 replicates Study 1 and varies the response scale participants used. Given our interest in the quantifiability of judgments, we also wanted to know how important the presence of the ruler was in the pictures participants saw in Study 1.

Like most research on the correspondence bias, our focus thus far has been on attributions about people. But we wonder whether the correspondence bias might be more basic and more general than these explanations suggest. This experiment put participants in the role of a shopper who has to choose from a selection of products that vary in both packaging weight and net weight of the product. Complicating the judgment was a significant variance in the weight of the product packaging. This is a task which should put participants on guard against the ulterior motives and potential manipula-

tion of vendors for whom it is less costly to provide packaging than product (see Fein, 1996; Fein, Hilton, & Miller, 1990). We used as stimulus materials a set of similarly sized pint glasses of different weights, covered with colored construction paper and lids, and filled with various quantities of M&Ms. The M&Ms were the focal product, while the pint glasses of varying weights provided a situational influence.

Participants each made nine estimates of the net weight of the contents of the nine products they were given. The 60 participants generated a total of 540 estimates, from which we created a repeated measures mixed model with container weight and content weight predicting participants’ estimates of content weight with random effects modeled on the participant level. Both container weight and content weight were highly significant. A one gram increase in the weight of the container led to a .206 gram increase in the estimated weight of its contents, $t(179)=8.49$, $p<.001$, and a one gram increase in the weight of the cup’s contents led to an increase of .467 grams in its estimated weight, $t(198)=9.99$, $p<.001$. Recall that an accurate estimate of the contents’ weight requires that one completely factor out the weight of the container. The highly significant predictive value of container weight suggests that participants failed to factor out the weight of the container.

Gilbert and Malone’s (1995) analysis of the correspondence bias suggested four contributing causes: (a) lack of awareness of the situation, (b) unrealistic expectations for behavior, (c) improper categorizations of behavior, and (d) incomplete corrections. None of the first three offer plausible explanations for the data we present in this paper. While each of these may undoubtedly contribute to the correspondence bias in some contexts, none of them appear to be necessary conditions for the presence of the effect.

It appears that our participants were committing a far more basic and rudimentary error, one that Kahneman and Tversky (1972) attributed to a “representativeness heuristic” in human judgment. The representativeness heuristic leads us to want the cause to look like—to be representative of—the effect. The world is more orderly when smart people perform better on quizzes, when tall people appear tall, and when heavy things feel heavy. Assuming that a smart person will perform well on quizzes is reasonable, but the representativeness bias can lead people to mistakenly assume the converse: that someone who performs well on a quiz is smart. This does not follow, because even unintelligent people can perform well on easy quizzes.

Our results do, however, underscore the robustness and generality of the correspondence bias. We found that the bias generalized to inanimate objects and persisted even in situations where avoiding it amounted to a simple subtraction problem. We are prompted to remember that in 1990, Ned Jones proposed the correspondence bias as “a candidate for the most robust and repeatable finding in social psychology” (p. 138). We would tend to agree.

Not Just Gustation: The Cognitive Effects of Multi-Sensory Advertising on Taste Perceptions

Ryan S. Elder, University of Michigan, USA
Aradhna Krishna, University of Michigan, USA

EXTENDED ABSTRACT

Food advertising is big business. Kraft Foods spent \$1.5 billion in 2007 on advertising in the U.S. alone, whereas PepsiCo spent \$1.31 billion, and McDonalds spent \$1.14 billion (Advertising Age Data Center 2008). Not surprisingly, most of these advertisements focus on increasing awareness, purchase intentions, and overall brand attitudes. However, few ads focus on the actual taste of the product, and those that do fail to incorporate the multi-sensory determinants of taste (i.e., smell, touch, vision, sound). This research utilizes prior literature in consumer behavior and physiology to posit that cognitions directed by ads can have an impact on sensory perceptions, and that taste is affected more positively by multiple-sense ads than ads that focus on taste alone. Across three studies we show that advertisements focusing on multi-sensory components of taste result in higher taste perceptions than ads focusing on taste alone. These effects are mediated by sensory cognitions (study 1), and as such are attenuated when cognitive resources are constrained (study 2). Further, the individual's ability to sensorially imagine consumption experiences interacts with the ad and product familiarity to reverse the effect of multiple-sense ads (study 3).

Despite our seemingly constant exposure to food, we have remarkable difficulty in discerning one taste from another. Part of this ineptitude stems from the limited number of distinct tastes that we can detect. Our taste buds alone (pure gustation) detect only sweet, sour, salty, bitter, and umami tastes. This leads to a general ambiguity in taste experiences that is reduced in large part by our ability to incorporate multiple sensory inputs into our ultimate taste perceptions. The primary accompanying sense for taste is olfaction (how the food smells). Taste is further affected by vision (how the product looks), as well as audition (the sound the item makes when chewed). The convergence of these sensory inputs occurs in the orbitofrontal cortex, labeled as a secondary taste cortex (Rolls 2005) and leads to a complete composition of taste.

In addition to a reliance on other senses, the ambiguity of taste experiences also leads to a reliance on external cues (Hoch and Ha 1986). Within the present context, the ambiguity of a taste experience would then lead to more susceptibility to, and increased utilization of advertising and verbal descriptions. Prior literature in marketing has shown that verbal labels can affect product preferences (Allison and Uhl 1964; Levin and Gaeth 1988, Raghunathan, Naylor, and Hoyer 2006), taste discrimination (Hoegg and Alba 2007), as well as altering the taste experience itself (Lee, Frederick, and Ariely 2006). We build on this literature to show that sensory cognitions created by ads will impact taste perceptions, and thus contribute to both the sensory marketing literature and general perception literature.

In study 1, we test the basic effect of multiple-sense ads on taste perceptions. The ads created were pretested to be equal on informativeness, complexity, and overall attitudes toward the ad. The ads either listed three sensory components aside from taste (e.g., texture, smell) or listed three distinct taste components. Individuals were randomly assigned to either the multiple-sense or single-sense ad conditions and, upon reading the ad, were given a cup of potato chips. Participants then listed their thoughts regarding the consumption experience and rated the taste of the potato chips. Thoughts were coded for valence and sensory nature. The results from study 1 show that the multiple-sense ad leads to significantly

higher taste perceptions than the single-sense ad, and that the excess of positive over negative sensory thoughts mediates the effect of ads on taste.

Study 2 was designed to further explore the cognitive process of ads on taste. We used a 2 (cognitive load: yes, no) x 2 (ad: multiple-sense, single-sense) design with the experimental procedure following closely that of study 1. Cognitive load was imposed by having participants memorize a class roster of first and last names. We conducted an ANOVA with taste perception as the dependent variable and ad and cognitive load as independent variables. There was a significant main effect of ad on taste perceptions with the multiple-sense ad leading to higher taste perceptions than the single-sense ad. This main effect was qualified by the hypothesized two-way interaction of load and ad on overall taste perception. Simple effect tests revealed a significant difference between the multiple- and single-sense ads in the no load conditions, with taste perceptions in the multiple-sense ad condition being significantly higher; however, there was no significant difference between the multiple- and single-sense ads in the load condition. Thus, the effects of the multiple-sense ad (vs. single-sense ad) are reduced when participants were restricted in their cognitive ability.

Study 3 explored additional moderators of the ad-taste effect, namely sensory imagery ability and product familiarity, creating a 2 (ad: multiple-, single-sense) x 2 (product: familiar, unfamiliar) design with sensory imagery ability used as a measured third factor. We chose popcorn as the familiar food, with soy popcorn as the unfamiliar food. With an unfamiliar food, we expect individuals who are less able to imagine sensory experiences on their own will rely more heavily on the ad for the image generated. In contrast, those who are high in imagery ability should rely on their own imagination of the experience and less on the ad and its positive direction for sensory thoughts. Indeed, we find that for an unfamiliar food, sensory imagery interacts with the ad so that a multiple-sense (vs. single-sense) ad leads to better taste for low imagers (vs. high imagers). Interestingly, for high imagers taste perceptions are significantly lower in the multiple-sense condition than in the single-sense condition, showing a backfire effect of multiple-sense ads. This may stem from previously reported negative perceptions of soy as an ingredient (Wansink et al. 2000). For a familiar food we replicate our findings from studies 1 and 2, leading to a three way interaction with familiarity, ad, and imagery ability.

Our results across these three studies exhibit the cognitive effects of ads on sensory perceptions and contribute both theoretically and substantively to the perception and marketing literature.

The Intersectionality Paradigm and Consumer Culture Theory

Ahir Gopaldas, York University, Canada

EXTENDED ABSTRACT

This article offers a paradigmatic view of intersectionality organized into the following sections: (1) grammarology, (2) ontology, (3) epistemology, (4) methodology, and (5) axiology. Thereafter, to explore the scope of intersectionality's value to consumer culture theory (CCT; for a review, see Arnould and Thompson 2005), the article analyzes exemplars of social taxonomy research in the CCT canon and develops avenues for intersectionality research in marketplace contexts.

Intersectionality as paradigm. Intersectionality is an interdisciplinary field of social studies whose shared objective is to explicate social phenomena in terms of multiple identity systems (e.g., race, class, gender, education, marital status, sexuality, religion, nationality, immigration status, disability, *et cetera*). Intersectionality has been diversely described as an analytical tool (e.g., Collins 1998), buzzword (e.g., Davis 2008), concept (e.g., Crenshaw 1989), perspective (e.g., Shields 2008), paradigm (e.g., Hancock 2007), *et cetera*. Hence, our choice to present intersectionality as a paradigm, which subsumes the other descriptors, warrants explanation.

In knowledge production cycles, a set of ideas often begins as a perspective, gains acceptance, undergoes formalization, and yields a paradigm (Denzin and Lincoln 2005). In this progressive sense, our use of paradigm is meant to signal a maturing set of ideas. However, far from ending scholarly conversation, a paradigm (Kuhn 1962) is a worldview that precedes the empirical research process; in other words, paradigms make theorizing possible. Paradigms stimulate theoretical conversations by proposing (1) a grammarology: propositions on the representation of phenomena using language, (2) an ontology: propositions on the nature of being or the constitution of phenomena, (3) an epistemology: propositions on the legitimation of knowledge, (4) a methodology: propositions on data collection and analysis, and (5) an axiology: propositions on the purpose or value of empirical research and emergent knowledge.

In Kuhn's (1962) sociology of knowledge, science is argued to evolve sporadically on account of 'revolutions'—social competitions between incommensurable emergent and extant paradigms. By contrast, in subsequent assessments (Denzin and Lincoln 2005; Feyerabend 1975; Laudan 1977), science, especially social science, is argued to evolve continually on account of researcher bricolage—creative configurations of paradigms, methods, and theories to solve substantive problems. The latter model better explains the development of intersectionality. In our assessment, the intersectionality literature has assimilated select tenets from constructivism, critical theory, feminism, neo-positivism, post-colonialism, post-modernism, post-structuralism, and structuration to inform research on social taxonomy.

In the intersectionality purview, identity categories (e.g., "black" and "white"; "working class" and "middle class"; "man" and "woman") are not mere verbal representations of inevitable distinctions so much as powerful tools that construct social distinctions and economic implications. Intersectionality is "the interaction [among] categories of difference in individual lives, social practices, institutional arrangements, and cultural ideologies and the outcomes of these interactions in terms of power" (Davis 2008: p.68).

Intersectionality and CCT. Three studies published in recent volumes of the *Journal of Consumer Research* (Crockett and Wallendorf 2004; Henry 2005; Thompson 2004) are among the

more intersectional analyses of social taxonomy in the CCT canon. These articles are not directly informed by current intersectionality literature, but are sensitized to some of its logics via precursory and parallel literatures: men's and women's studies, feminist and post-structuralist theories, and Bourdieulian thought. We review aspects of these studies through the lens of intersectionality. Our purpose in doing so is to enliven the logics of intersectional research and highlight best practices among consumer culture theorists. Viewing CCT through the lens of the intersectionality paradigm also illuminates several avenues for future research.

One promising avenue of research is to examine the emerging identity categories and systems in marketscapes. Marketscapes, especially virtual and transnational marketscapes, are marked by a high degree of semantic flux (Kozinets 2008) because such scapes connect people across traditional geopolitical and sociocultural boundaries (Muniz Jr. and O'Guinn 2001), for example, via online networking (e.g., *Facebook*) or matchmaking (e.g., *eHarmony*) services. What novel identity categories and systems do these marketscapes produce and which historical identity systems of (dis)advantage do they reproduce? In marketscapes, where a temporary emancipation from identity categorization (a.k.a. anonymity) is technologically feasible, how do consumers' and producers' interventions thwart such emancipation? Which identity markers are prerequisites for participation and which are optional?

Another promising avenue of research is to compare and contrast historical and emerging identity categories. An example of a market-mediated context where both types of categories predominate is the transnational news media (e.g., *CNN International*), wherein news anchors, celebrities, and experts reproduce historical identity categories and reify emerging ones simply by repeated invocation of them. Such comparative studies might confirm whether emerging categories are indeed more fluid than historical ones (Firat and Venkatesh 1995) and, if so, whether encouraging continual re-categorization of identities might be one strategy for weakening social structures and strengthening individual agency. After all, intersectionality research is undertaken not merely to identify structural (dis)advantages, but primarily to alleviate them.

Consumer Culture Plots in Television Advertising: Consequences of Globalization in Emerging Markets

Adesegun Oyedele, St. Cloud State University, USA

EXTENDED ABSTRACT

In the marketing and advertising literature, researchers have employed several methods including content analysis of commercial ads to explicate the impact of Western cultural values on the promotion of goods and services in the global marketplace (e.g., Lin 1993; Tse, Belk and Zhou 1989; Mueller 1987). However, in recent years, researchers have problematized the use of content analysis technique by suggesting that the outcome of this technique lacks the required rigor for developing theory.

In response to the call by these researchers (e.g., Zhao and Belk 2008; Ger and Belk 1996) for more studies about the cultural complexity of globalization in advertising, the current study employs a semiotic approach in addressing the following research questions: 1) What are the plots used in promoting consumer culture in television advertising from Nigeria? 2) Are there signals of global and local contention in television advertising in Nigeria? 3) Is there any evidence to suggest that the symbolic elements of the local traditional culture are transformed to promote a culture of consumption or global consumer culture?

The development of global consumer culture in Nigeria can be linked to: 1) the colonization activities of the British and other European super powers; 2) the missionary activities of the British and Europeans in Nigeria; 3) the activities of newly emerging Christian evangelist churches in Nigeria and 4) the availability of cable network programs (e.g., CNN, MTV)

The methodology used in this study is based on the theoretical frameworks of semiotics (Mick 1986), visual rhetoric (Barthes 1977; Goldman and Papson 1996; Scott 1994), the theories of dramatic performance in advertising, and motion picture narrative structure (e.g., Boller and Olson 1991; Wright 1975). These techniques are appropriate when the underlying objective is to evaluate the content (e.g., visual, sound imagery, settings, story lines, characters) of the advertisement beyond the obvious message implied by the advertisement (Zhao and Belk 2008).

A non-probability convenience sampling technique was used in collecting the sample advertisements. The advertisements (N=196) were recorded from two popular national channels (National Television Authority Channel 7 and Channel 5). The advertisements included in the final sample were selected based on three criteria. First, the ad must promote a consumer product; all non-consumer product ads were excluded from the final sample. Second, the ads must have human characters must be over 10 seconds long. The final requirement was the conceptual richness of the narrative plot. This form of selective sampling is common in studies using semiotic analysis (e.g., Mick and Oswald 2006). The evaluation and interpretation of the advertisements from Nigeria was conducted by the author and a linguistic graduate who is a native of Nigeria

The initial analysis revealed seven main plots. However, a closer examination of these initial plots and more iteration resulted in the identification of three unique plots: 1) Male breadwinner 2) The Big man plot and 3) Masqueradization of Western Ideals.

Male breadwinner. The Male breadwinner (MBW) plot usually begins in a family house or the breadwinner's place of work. If the setting is a family house, the housewife is usually busy with housekeeping activities such as cooking and bringing food to the family. In this plot, the male breadwinner is either at work, coming home from work, or on his way to work. If his coming back home from work, his arrival at the house tends to coincide with dinner

time. For this plot to be complete, the product or service must be useful to the housewife in appeasing the husband.

The big man plot. The protagonist in this plot is the big man (TBM). The big man (TBM) is well informed and eager to provide advice for resolving problems. The big man exhibits contradictory traits; he's endowed with both altruistic and egoistic traits. For example, if someone is ill or distressed, TBM will offer product information that can help cure the illness. In some cases, TBM will offer a free trial of the product, but not without openly rebuking the person needing assistance. TBM ideal in Nigeria, or Oga mentality, is synonymous with hegemonic masculinity (Linsay 2003). TBM is the man who spreads resources to his family members, extended family members and networks outside his family (Linsay 2003). TBM ethos is the most dominant male aspiration in Nigeria (Falola 1999; Linsay 2003). TBM plot also provides some clues about the dynamics of leadership, power relations, and social hierarchy in Nigeria.

Masqueradization of Western Ideals. The general gist of the plot is that people can derive hedonic experiences (happiness, enjoyment, pleasure) by constructing identity that mimics Western ideals. The *masquerading* concept is underscored because the context always involves dancing, festivities, enjoyment and fun. Additionally, the notion of masquerading is an analogy for illustrating the three dominant themes associated with the plot. The dominant themes associated with the masqueradization plot are: 1) masquerading Western aesthetics (e.g., Western bodily beauty, Western music and Western architecture), 2) masquerading classical Western theatrical performance (expressing Western rock star-like personality, mimicking Western romantic motifs) and 3) Appreciating modern products and showcasing traditional fashion.

Overall, the results showed that advertisers in Nigeria highlight the global through the overwhelming display of Western aesthetic attributes (e.g., Western music, Western-style design—furnishing, images of Western cities, architecture). The presentation of the global is not modified or re-signed to fit the local. The local is relegated and suppressed via wholesale presentation of Western aesthetic attributes. Occasionally, the use of traditional-style fashion may be used to legitimize the overwhelming display of Western aesthetic attributes. The findings concerning the interplay between the local and the global suggests that the global is more powerful in transforming the aesthetic of the local but less powerful in transforming social order attributes associated with the local.

Consumer Culture Theory: Constitution and Production

Ahir Gopaldas, York University, Canada

EXTENDED ABSTRACT

Consumer culture theory (CCT) is a continually evolving field of social science that extends methods and theories from various disciplines to the domain of consumption and marketing. This essay offers (1) an inventory of the elements that compose the field (major influences, frequently examined phenomena, common contexts of investigation, theoretical foci, data collection and analysis methods, conceptions of the consumer, focal stages of the consumption life cycle, *et cetera*) and (2) a dialectical model of interdisciplinary knowledge production.

Constitution. CCT is an interdisciplinary field of social science that encompasses explanatory, interpretive, critical, and transformative analyses of the experiential, ideological, material, and praxeological dimensions of marketing and consuming in their myriad manifestations since modernity (for a review, see Arnould and Thompson 2005). Several sibling fields examine terrain similar to that of CCT; some of them are: comparative media studies (for a review, see Jenkins, McPherson, and Shattuc 2002); consumption anthropology (for a review, see Miller 1995); consumption sociology (for a review, see Zukin and Maguire 2004); critical marketing studies (for a review, see Saren et al. 2007); cultural studies (for a review, see Grossberg 2006); and interpretive consumer research (for a review, see Cova and Elliott 2008). Though much Western social theory on production and consumption in the 20th century can be traced back to Adam Smith's (1776) *Wealth of Nations*, Karl Marx's (1867) *Capital*, and Thorstein Veblen's (1899) *Theory of the Leisure Class*, more recent theorists such as Bourdieu (e.g., 1984), Foucault (e.g., 1970), and Giddens (e.g., 1984) have had more direct and visible impact on CCT. Furthermore, CCT draws on numerous social science disciplines such as anthropology, cultural studies, media studies, social psychology, and sociology.

Among CCT's most frequently examined phenomena of investigation are consumption-related actants such as consumers, producers, brands, products, and markets; consumption-related discourses such as consumerism (Zhao and Belk 2008) and materialism (Belk 1985); and market-motivated variants of enduring human logics such as (brand) communities (Muniz and O'Guinn 2001) and (marketplace) mythologies (Thompson 2004). Consumer culture theorists often select long-term, high-stakes, interrelated, multi-service, consumption contexts such as healthcare (e.g., Fischer, Otnes, and Tuncay 2007; Wong and King 2008), leisure activities (e.g., Arnould and Price 1993; Celsi, Rose, and Leigh 1993), and technology (e.g., Kozinets 2001; Mick and Fournier 1998). The theoretical goal of many CCT studies is to explain cultural and structural processes and to extrapolate sociological or anthropological models of consumer-consumer relations (e.g., Epp and Price 2008; Mathwick, Wiertz, and de Ruyter 2008; Wooten 2006), consumer-consumable interactions (e.g., Chen 2009; Coupland 2005; Lastovicka and Fernandez 2005), and marketplace reconfigurations (e.g., Giesler 2008; Thompson and Tian 2008; Zhao and Belk 2008). Consumer culture theorists often collect data using observation, participation, interviews, surveys, projection techniques, or historical archives and analyze data using critical discourse analysis, grounded theory, multidimensional scaling, or semiotics. Cova and Elliot (2008) suggest that CCT is the domain of theories while interpretive consumer research (ICR) is the corresponding domain of methods.

No single metaphor encapsulates CCT's conception of the consumer, which is an important point of distinction. The philosophic orientation of consumer information processing (CIP) and

consumer decision making (CDM), namely positivism, necessitates a singular and stable metaphor of the consumer to sustain theoretical development in each field. The metaphors (of the consumer as an information processor and consumer as a decision maker) form the foundations (rather than the frontiers) of CIP's and CDM's theoretical programs (Newell and Broder 2008). By contrast, we observe that metaphors of the consumer are plural and evolving in CCT research because they are the frontiers (rather than the foundations) of research attention. CCT's conceptions of the consumer include: meaning-maker (Mick and Buhl 1992; Thompson 1996); (dis)empowered reproducer of class stratification (Allen 2002; Henry 2005); identity bricoleur (Holt 2002; Kates 2002); dynamic self concept extending to possessions (Belk 1988; Tian and Belk 2005); market-incentivized tribesperson (for a review, see Cova, Kozinets, and Shankar 2007); dramatic performer of marketplace scripts (Deighton 1992; Giesler 2008); *et cetera*. Historically, CCT has distinguished itself from other fields of consumer research by focusing on the consumption (i.e., engagement or experience) stage of the consumption life-cycle (e.g., Goulding et al. 2009; Muniz Jr. and Schau 2005; Rose and Wood 2005; Ustuner and Holt 2007), though some studies have also examined the acquisition (e.g., Fischer and Arnold 1990; Sherry 1990) and disposition (e.g., Lastovicka and Fernandez 2005; Price, Arnould, and Curasi 2000) stages.

Production. Arguably, one of the most important transdisciplinary questions in the social sciences is: how does science progress (Feyerabend 1975: anything goes; Kuhn 1962: paradigm shifts/scientific revolutions)? Or more broadly, how does knowledge evolve (Foucault 1970, 1972)? Over the course of the 20th century, these questions provoked numerous debates. While these debates continue among philosophers of science, academic fields often have their preferred philosophic approach to knowledge production. Denzin and Lincoln (2005) have proposed bricolage as a metaphor for interdisciplinary knowledge production in the social sciences. For them, bricolage is the mixing and matching of ontologies, epistemologies, methodologies, axiologies, and theories from multiple disciplines to solve the research problems at hand. Adapting Denzin and Lincoln's metaphor of bricolage, we supplement Kuhn and Feyerabend's canonic models of scientific progress with a recognition that paradigmatic pluralism in an interdisciplinary field of social science, such as CCT, can foster a pair of contrasting ideologies that we term intellectual bureaucracy and bricolage. The ideology of bureaucracy favors tradition, conformity, and essentiality, thrives in authoritarian environs, and permits incremental intra-disciplinary research developments, but hinders breakthrough and inter-disciplinary progress. By contrast, the ideology of bricolage favors novelty, multiplicity, and hybridity, thrives in anarchic environs, and encourages the forging of new theoretical linkages across disciplinary divides, but disregards the origins of ideas and the situated intentions of their creators. Within this dialectical model, exemplary interdisciplinary research is conceived of as reasoned ideological compromise between bureaucracy and bricolage.

Leave Your Mark: Afterlife Belief Strength's Effect on Durability Focus in Creative Consumption

Huimin Xu, SUNY Oneonta, USA
Merrie L. Brucks, University of Arizona, USA

EXTENDED ABSTRACT

Consumers participate in various types of creative consumption. Some types of creative consumption leave long-lasting products (e.g., photography) whereas others do not (e.g., cooking and karaoke improvisation). When do consumers place more emphasis on producing tangible, durable creative outcomes and when are they content with short-lived creative experiences? In this research, we conceptualize creative consumption as a way of coping with threats to the self's very existence and identify afterlife belief strength as a driver of the durability focus placed on creative outcomes.

Terror Management Theory posits that unconscious anxiety over one's mortality is a basic driver of human behavior. To manage such anxiety, humans have developed a number of coping strategies including belief in an afterlife (Dechesne et al. 2003) and engagement in creative pursuits for self-esteem enhancement. Rank (1932) argues that creative pursuit is essentially the externalization and preservation of personality and soul. By lending concrete, presumably indestructible existence to the abstract ideas of the soul, creative work imbues the creator with a sense of immortality. To render the creator's ideas truly immortal, however, the creative product must also be durable. Thus, individuals who are existentially threatened prefer creative activities that leave durable outcomes. To the extent that afterlife belief and creative activities both relieve existential anxiety, they may be negatively related. Rank (1932) states that "Art was at first, and for a long time to come, the handmaid of religion" and observes that art rises in the wane of religious faith.

We explore the link between durability focus in creative consumption and afterlife belief in four experimental studies. We hypothesize that experimentally weakened afterlife belief should increase durability focus in creative consumption while experimentally strengthened afterlife belief should reduce it.

In experiment 1, we induced mortality salience in all respondents. Afterwards respondents read either an article that argued for the validity of afterlife (i.e., the "stronger" condition) or an article that argued against it (i.e., the "weaker" condition). From a list of pre-tested durable creative activities, respondents selected an activity and indicated their current interest in engaging in it. Respondents also rated their interest in participating in a non-durable creative activity: ice sculpting. We found that while weakened afterlife belief increased interest in the chosen durable creative activity, it had no effect on interest in the non-durable creative activity. Using the difference between interest in the durable and non-durable activities as a measure of durability focus, we found a marginally higher level of durability focus in the weakened belief condition. Interestingly, the afterlife belief manipulation had no effect on intention to attend a workshop to improve creative skills for (and presumably the outcome quality of) the chosen creative activity. The effect of mood as an alternative mechanism (as gauged with the PANAS) was ruled out in experiment 1 and the following 3 studies.

Experiment 2 used a 2 (mortality salience vs. control) x 2 (weaker vs. stronger afterlife belief manipulation) between-subjects design. We employed a different measure of durability focus in this study. Prior to the manipulations, respondents selected an activity from each of 3 categories: durable creative activities (e.g.,

photography), non-durable creative activities (e.g., cooking), and non-creative activities (e.g., watching TV). After the two manipulations, respondents allocated 100 points among the three activities based on their current levels of interest. Durability focus was operationalized as the ratio of points allocated to the durable creative activity relative to the total points allocated to both durable and non-durable creative activities combined. Results showed that strengthened afterlife belief reduced durability focus and that this effect was not moderated by mortality salience—that is, the baseline level of existential anxiety was sufficient for the hypothesized effect to hold. Again, the afterlife belief manipulation had no effect on interest in improving creative skills.

The first two studies were conducted in the U.S. where a large population strongly believes in an afterlife and where an individualistic culture promotes leaving a personal mark. We ran experiment 3 in China to test whether the effects are particular to certain cultures or reflect a more pervasive motive. We chose China because it is a largely secular, collectivist society. The 2 x 2 between-subjects design and dependent measure of experiment 3 are similar to that of experiment 2. Again, our hypothesis was supported and the effect was not moderated by mortality salience. Interestingly, whereas the U.S. respondents in the previous two studies reacted to a weaker afterlife belief by beefing up interest in durable creative consumption, the Chinese respondents coped by curbing interest in non-durable creative consumption.

Research has suggested that individuals in collective cultures tend to be more prevention-focused whereas individuals in more individualistic cultures tend to be more promotion-focused. To explore whether the cross-cultural differences observed in experiment 3 arose from differences in self-regulatory focus, experiment 4, conducted in the U.S., used a 2 (weaker vs. stronger afterlife belief manipulation) x 2 (promotion vs. prevention regulatory focus manipulation) between-subjects design. When prevention focus was primed, we found a greater loss of interest in non-durable creativity as affected by a weaker afterlife belief relative to when promotion focus was primed. As in the previous studies, strengthened afterlife belief again reduced durability focus and the belief manipulation did not have an effect on interest in improving creative skills.

Overall, our research identifies a hydraulic relation between creative consumption and a basic belief system component—afterlife belief—in coping with existential threat. Apart from its business implications, our findings more importantly point out one particular attribute of creative consumption that can render this seemingly ordinary activity more potent at ameliorating a fundamental source of anxiety: a threat to the self's very existence.

After The Box Has Been Opened: Goal Orientation as the Driver of New Product Usage and the Moderating Effects of Product Knowledge and Perceived Newness

Qing Wang, University of Warwick, UK

David Alexander, University of St. Thomas, USA

John G. Lynch Jr., University of Colorado at Boulder, USA

EXTENDED ABSTRACT

The success of an innovation ultimately depends on consumers' acceptance and sustained use of that innovation—not necessarily the easiest thing for firms to ensure. Customers who buy a product and use it less than expected will be less inclined to invest further in the technology (Farley et al. 1987). Given the importance of understanding the processes driving consumers' continued product use, it is surprising how little attention the subject has traditionally drawn from researchers (Rogers 2003); Especially for technological products where consumers initial usage experiences are quite complex (Mick and Fournier 1998). Some recent research has, however, begun to examine the effect of usage on successful adoption (e.g., Shih and Venkatesh 2004; Wood and Moreau 2007).

The extant literature has tended to examine product usage in isolation from motivational factors and, in particular, in isolation from consumers' goals, even though goals are central to consumer decision making (Bettman, Luce, and Payne 1998; Higgins 2002). In a three wave, longitudinal field study with real consumers reporting their usage of new communication and entertainment products, we combine goal orientation theory (e.g. Dweck 1986; Nicholls 1984; Elliot and Sheldon 1997) with recent studies of consumer cognitive and emotional responses to new technological products to examine the drivers and consequences of new product usage. We ask why some new product purchases are followed by rapidly increasing use, while others are followed by little or no use. We examine the attainment of long-term product usage as a function of consumers' goal orientation. Goal orientation consists of two dimensions: approach goal orientation and avoidance goal orientation. We find that consumers' goal orientation has a strong self-reinforcing effect throughout the three waves.

Next we are interested to know how the perceived newness of a product will moderate the relationship between goal orientation and usage. Linking perceived newness to goal orientation theory, we reason that, because individuals with approach goal orientation perceive the achievement setting as a challenge, the newer the product is perceived by these individuals, the greater the challenge product use is perceived to be. This construal in turn is likely to generate more excitement, encourage more affective and cognitive investment, and facilitate greater concentration and task absorption. In contrast, people with avoidance goal orientation perceive the achievement setting as a threat; the newer the product is perceived to be, the greater the threat product use is perceived to be. This construal in turn elicits more anxiety and encourages greater self-protective withdrawal of affective and cognitive resources. Additionally, new consumer tech products are characterized by innovative and often complex features (Thompson, Hamilton, and Rust 2005) that deliver superior customer benefits (Zhao, Meyer, and Han 2006). To extract high utility from such products requires consumers' investments in time and money and, more importantly in knowledge acquisition. The empirical results of our fieldwork support our conceptualization that approach goal orientation acts as the key driver for long term usage particularly when combined with perceived product newness and product knowledge. In contrast, avoidance goal orientation has a negative effect on product usage that is resilient; it is unaffected by product knowledge but is reinforced by perceived product newness.

We also reason in our framework that for consumers, new and technologically complex products are characterized by high uncertainty about the value of new benefits and the appropriate cost-benefit trade-offs to use in evaluating the products (Hoeffler 2003; Alexander, Lynch and Wang 2008). Since this uncertainty is particularly high before actual use of the product, consumers likely encounter unexpected joys or frustrations which lead to experienced emotions (i.e., surprises) when they start using the product. We argue that individuals with avoidance goal orientations tend to focus on negative aspects of product relevant information, likely generating negative emotional responses. Individuals with approach goal orientations, on the other hand, focus on positive aspects of product relevant information, likely generating positive emotional responses. Additionally, surprises experienced during the initial period of product use partially mediate the reinforcing effect of initial goal orientation on subsequent goal orientation.

In sum, in a three wave, longitudinal field study we empirically tested our conceptual framework. Using structural equation modeling (i.e. Amos 7.0) to analyze the data, we find support for our hypotheses. Most importantly, we find that the reinforcing effect of goal orientation results in two distinct paths of consumption: consumers either use the new product more and more (i.e. the approach goal orientation path) or less and less (i.e. the avoidance goal orientation path). In addition, we find that consumers on the approach goal orientation path are more likely to spread positive word of mouth than consumers on the avoidance goal oriented path. We discuss the implications of these findings for marketers of technological consumer products and for managing customer relationship and providing service.

EXTENDED ABSTRACT

We suggest in a series of studies that subtle indicators pointing to the originality of a product might increase its attractiveness. This may explain why brands often communicate to consumers when they originated. For example, Heinz states that its tomato ketchup dates back from 1869. Heinz' label "since 1869" might not only indicate that Heinz has been around for a long time, but might also suggest that it was first, and thus original, in the ketchup category. Bolton (2006) proposes that people might have a kind of "folk wisdom" that being first (e.g., in invention, arts) is better and that "folk wisdom" leads to a positive evaluation of pioneers as they are "first" and therefore better. Swinyard, Rinne and Keng Kau (1990) note that Western societies have a preoccupation with the protection of original work which finally led to copyright, patent, and trade-secret legislation. In contrast, copyright and other legislation to protect original work may strongly go against the grain of Asian cultures. In fact, Asian cultures seem to support the concept of sharing of individual creative work, instead of protecting the creator of the original work. In support of this view, software piracy rates appear to be higher in Asian than in Western economies (Ding & Liu 2009), and it turns out that these rates are not only a function of the level of poverty in a given society, but also of the societal degree of collectivism (Moore 2003 and 2008). Summarized the originality of a product may not matter in collectivistic cultures, while it may have a special status in individualistic cultures. We argue in the present manuscript that (1) perceptions of (un)originality are important in consumers' evaluation and (2) that this especially holds for the individualistic consumer.

In study 1 we test the hypothesis that originality indicators have a beneficial effect on preferences, which leads to a preference for the original or "first" object among similar objects (hypothesis 1). In study 1a, we presented abstract paintings in different rotations and found that seemingly original rotations (0° & 360°) were preferred over any other rotation (although 90° was actually the real original orientation). Study 1b shows that participants rate an 'original' picture more favorably than other participants who were led to believe that that same picture was photoshopped. This is consistent with the idea that digit alteration harms the perceived originality of a picture. Summarized, study 1 demonstrates that perceived originality affects consumer evaluations.

It is important to note that originality has an all-or-none character (i.e., only one object can be the first and thus original): The presumed effect of originality differs from an effect in which earlier objects are preferred to later objects. In study 2, we test the hypothesis that in a set of similar objects the first, "original" product will be preferred, but not earlier to later objects (hypothesis 2). In study 2a, participants indicated their preference for one of two movies after seeing the two movie trailers. The movie trailers were labeled "Life on Earth I" and "Life on Earth II" ("originality" condition) or "Life on Earth II" and "Life on Earth III" ("earlier" condition). Participants preferred "Life on Earth I" to "Life on Earth II" but did not prefer "Life on Earth II" to "Life on Earth III" (hypothesis 2). We made use of nature documentaries to rule out the alternative explanation that one would need to watch the movies in proper order to understand 'the plot'. Study 2b eliminates an interpretation in terms of preference for earlier stimuli entirely.
