Preface

The 41st annual conference of the Association for Consumer Research (ACR) was held in sunny Jacksonville, Florida, October 6 to October 9, 2010. This volume summarizes the research presented during the conference.

The theme of ACR 2010 was: “Think BIG. Big Ideas. Big Findings.” The conference showcased lots of “big picture” theories and “big” phenomena that are of real importance to consumers’ lives. In the grand scheme of things, the 2010 conference was pretty much like any other ACR Conference. That is probably a good thing. Lots of interesting talks, catching up with far-flung colleagues and friends, and meeting new ones are the constants that make ACR a central event in a consumer researcher’s year.

We did make some changes to the conference to promote big picture communication: (a) Every session had four, shorter talks (which necessitated doing away with the traditional role of discussant in Special Sessions), (b) We asked session chairs to kick-start discussion about big picture implications at the end of special and competitive paper sessions. (c) Abstracts in the program were shorter, encouraging authors to clearly communicate their big picture ideas.

We also made some other changes to encourage communication between junior and senior researchers, to green the conference, and to make the conference even more fun: (a) ACR newcomers could sign up on the registration form to meet ACR regulars for research chats during coffee breaks, (b) posters featuring working papers were kept up throughout the conference, (c) the conference was greened by using shorter program booklets, a build-your-own-program internet tool, and by offering participants the option of buying carbon offsets for travel to the conference, and (d) DJoy Srivastava rocked the beach at the Saturday night closing party. We have never seen so many of our peers have such a good time on the dance floor.

We are immensely grateful to the ACR community for presenting their work, asking constructive questions during talks, and doing a lot of reviewing. We would especially like to thank the Associate Editors and the members of the Program Committee for assessing many Competitive Papers and Special Session proposals. Many thanks go out to the Roundtables Chairs, Raj Ragunathan and Eduardo Andrade, to the Film Festival Chairs, Russ Belk and Rob Kozinets, to the Doctoral Consortium Chairs, Priya Raghubir and Patti Williams, and to the Working Paper Chairs, Jen Argo and Kristin Diehl. We thank Geeta Menon, the ACR President, for totally entrusting us with the whole enterprise. Finally, we thank the wonderful team of people who really did most of the work: Annette Bartels, Aleksey Cherfas, Phil Hamlin, Paula Rigling, Rajiv Vaidyanathan, the Phd student volunteers, and the folks at Omnipress.

You rock!

Darren Dahl, University of British Columbia

Table of Contents

ACR Presidential Address 2010

Navigating The PhD Waters: The Role of Advisors	1
<i>Geeta Menon, Abraham Krasnoff Professor of Global Business Stern School of Business, NYU, USA</i>	

Invited ACR 2010 Presidential Session

All My Children: Fostering Diverse Approaches to Consumer Well-Being Research	7
<i>Nidhi Agrawal, Northwestern University, USA</i>	
<i>Ellie Kyung, Dartmouth College, USA</i>	
On Indulgence as Sticky and Recurrent Desires Rather Than Weak Self-Control	
<i>Suresh Ramanathan, University of Chicago</i>	
Preventing One Disease, Promoting Another? Carry-Over Effects of Health Messages on Subsequent Self-Control	
<i>Nidhi Agrawal, Northwestern University</i>	
<i>Echo Wen Wan, University of Hong Kong</i>	
Credit Cards and Purchase of Unhealthy Food Products: The Roles of Impulsivity, Deprivation and Intrusive Desires	
<i>Manoj Thomas, Cornell University</i>	
<i>Kalpesh Desai, SUNY Buffalo</i>	
<i>Satheeshkumar Seenivasan, SUNY Buffalo</i>	
Loving, Feeling and Helping: The Impact of Mood, Self Esteem and Visibility of Consumption on Attitudes towards Ethical Products	
<i>Sucharita Chandran, Boston University</i>	
<i>Shuili Du, Simmons College</i>	
Is Profit Evil? Incentive Neglect and the Association of Profit with Social Harm	
<i>Amit Bhattacharjee, University of Pennsylvania</i>	
<i>Jason Dana, University of Pennsylvania</i>	
<i>Jonathan Baron, University of Pennsylvania</i>	
Success through Supplanting Sounds	
<i>Eric Yorkston, Texas Christian University</i>	
<i>Leonardo Nicolao, Texas Christian University</i>	
Examining the “Privacy Paradox”: The Role of Perceived Constraints	
<i>Ellie Kyung, Dartmouth College</i>	
People Say Happiness is the Ultimate Goal, But Do They Act Like They Mean This?	
<i>Raj Raghunathan, University of Texas, Austin</i>	
<i>Sunaina Chugani, University of Texas, Austin</i>	
<i>Ashesh Mukherjee, McGill University</i>	
Subjective Value of Money	
<i>Priya Raghubir, New York University</i>	
<i>Joydeep Srivastava, University of Maryland</i>	

ACR Fellows Addresses

Fellow’s Address: In Defense of Bumbling	9
<i>Joseph W. Alba, University of Florida, USA</i>	
Fellow’s Address: Substantive Consumer Research	15
<i>John G. Lynch, Jr., University of Colorado-Boulder, USA</i>	
Fellow’s Address: Three Silos and a Theory: Developing Nomological Networks to Explain Consumer Behavior.	19
<i>Brian Sternthal, Kellogg School of Management, Northwestern University, USA</i>	

Special Session Summaries

<p>Services as Social Structures: Consumer Collectives and Transformative Services Research. 24</p> <p><i>Laurel Anderson, Arizona State University, USA</i> <i>Amy Ostrom, Arizona State University, USA</i></p> <p style="padding-left: 20px;">“Conceptualizing Transformative Service Research” <i>Laurel Anderson, Arizona State University, USA</i> <i>Amy Ostrom, Arizona State University, USA</i></p> <p style="padding-left: 20px;">“There’s No Place Like Home...Or Is There?” <i>Stacey Menzel Baker, University of Wyoming, USA</i> <i>Jose Antonio Rosa, University of Wyoming, USA</i></p> <p style="padding-left: 20px;">“When Consumer Well-Being Meets Small Business Ownership: Transforming Financial Service Systems to Eradicate Disparate Treatment and Discrimination” <i>Sterling A. Navigating The PhD Waters: The Role of Advisors

Geeta Menon, Abraham Krasnoff Professor of Global Business Stern School of Business, NYU, USA

(This is a slightly expanded version of the talk.)

When I thought of today's talk over a year ago, it was crystal clear to me what the topic should be – PhD education. It is one part of our profession that gives me tremendous joy, and so it seemed like a perfect topic to focus on with a captive audience. However, having decided on the topic, the nuances of creating an impact by speaking about the less obvious was a challenge. After all there are several doctoral consortia, and many focus on the path to success for PhD students. So what could I speak about that was different, but still relevant? A topic discussed far less in these public forums is the nature of the Advisor-Student relationship itself: doctoral student training, our relationships with our students, and our presence in their lives for their continued success. So I will focus today on the role of Advisors in PhD education.

I joined the PhD program in Business Administration at the University of Illinois, Urbana-Champaign in 1986, or the time long before Google Scholar. Yes, o young ones, there was that time where the first name of an author could only be found after a visit to the stacks or on microfiche. I had applied to a PhD program, was admitted, and was now venturing forth, bravely and coldly, to the Midwest. And I got hooked on soap operas and used them to educate myself on American culture. I had no idea what I wanted to do or what I wanted to accomplish, but somehow I stumbled along, each year to something better. Now I realize that I wasn't really stumbling, but that my education was a process – a process shaped by my relationship with my Advisor, Seymour Sudman, and the other members of my committee (Carolyn Simmons, Thom Srull and Bob Wyer). As well as by my relationship with my peers in the PhD program – we supported each other, looked out for each other, and saw each through fairly hard times. It's a time when deep bonds are formed and one's world view is affected for life.

From a Student's perspective, PhD education is about learning new things, apprenticing with experts in the field, and eventually striving for independence and excellence in the profession. From an Advisor's perspective the education process is about creating a new generation of scholars who push the boundaries of knowledge, getting satisfaction from the process, and if some glory is reflected back on them, great! Additionally, there could also be a research synergy that is created for an Advisor across Students.

For students graduating with a behavioral focus in Marketing from a Business school, which tends to be true for most ACR attendees, the Marketing PhD is somewhat different in structure from a PhD in Psychology. For example, the Psychology PhD program typically consists of the "lab-model" where a group of students work with a faculty advisor who is the primary researcher. While the Advisor is a key player in this model, there also is an in-built mentorship or support system (or competition) from other students in the lab. This "lab" of students lives within a bigger doctoral student pool. On the other hand, when a student is working towards a PhD in Marketing in a Business School, s/he is typically working with a faculty advisor one-on-one. And the PhD student pools in a marketing PhD program are typically smaller than those in Psychology departments. Therefore, the Advisor-Student relationship is very central to the education process. Understanding what each group looks for in the other is important.

So my goals today are to help us:

- Understand the PhD landscape,
- Understand the critical Advisor-Student relationship better in terms of what we are doing right, what we are doing less well, and how we can improve.

So like any curious researcher, I collected data.

WHAT DO WE KNOW ABOUT THE PHD LANDSCAPE?

The first question that I asked myself was what is the size of the total Marketing PhD Student pool compared to the Marketing Faculty Advisor pool. Was there a dearth of one group versus the other?

I included a question in the most recent Marketing Academia Labor Market Survey regarding how many faculty members work with doctoral students in each of the schools surveyed.

- This survey was conducted using Qualtrics from mid-April to mid-May 2010 among 141 schools, out of which 117 responded.¹
- 16 schools responded that they do not have a PhD program, and of the remaining 101 schools, the average size of a department is 12.5 faculty members, and the average size of the PhD program in marketing is 6.6.
- Additionally, respondents reported that on average, 50% of their faculty work with doctoral students in some capacity, either supervising them on their thesis or working with them on projects with the intention of publishing papers.
- Simple math indicates that the student-faculty ratio is about 1:1, enough for a student to get plenty of attention from a faculty member! It's like pre-school or even better!

Thus, there is an ample supply of faculty members who could serve as potential Advisors to the market of PhD students who are ready to go forth and conquer. Of course, in reality we know that some faculty Advisors have clusters of students and therefore this simple math can only go so far, but at least it gives us an indication of the basic numbers.

The next step was to zoom in on the Advisor-Student relationship.

UNDERSTANDING THE ADVISOR-STUDENT RELATIONSHIP

In order to understand the Advisor-Student relationship, I surveyed both advisors and students. Additionally, I wanted to know whether the perspective of students changes once they become faculty members, so I also included a group that graduated a few years ago. Here's what I did:

After the AMA doctoral consortium in Texas Christian University this past June, I sent a survey to three groups of respondents:

1 The list of schools across Asia, Europe, North America, and Oceania was compiled using combinations of the UT-Dallas lists of the 100 most productive schools in the U.S. and the 100 most productive schools in the world, together with Chris Janiszewski's and my personal knowledge of schools that regularly interview at the AMA Summer Educators' Conference. Respondents were department chairs and area heads in Marketing.

2 / Navigating The PhD Waters: The Role of Advisors

- Faculty who were invited to the 2010 AMA Doctoral, and a handful of other faculty members; Of the 135 contacted, 82 responded, a response rate of 61%.
- PhD students who were Fellows at the 2010 Doctoral Consortium; Of the 97 contacted, 58 responded, a response rate of 60%; and,
- PhD students who were Fellows at the 2005 Doctoral Consortium at the University of Connecticut; Of the 81 contacted, 45 responded, a response rate of 56%.

The responses rates were much higher for behavioral (versus non-behavioral) faculty and students, and so I'm going to treat this sample as fairly indicative of the ACR audience.

I asked all three groups of respondents to evaluate the importance of 32 traits in Advisors and Students. Since all traits were positively framed, respondents were given specific instructions:

"Of course, you may be tempted to choose "7" on most of these options, but let's try to aim for a (normal or bi-modal, etc.) non-skewed distribution of your responses across these traits. In other words, skim through the traits first, and then use the scale discerningly."

Well, while the two Student groups used the scales more discerningly, faculty respondents just chose to disregard these instructions, and all 32 traits loaded onto one factor!

Despite such hiccups, the analyses revealed some interesting information that I have categorized into the following sections:

- A. "Seven Deadly Sins of an Advisor,"
- B. "Seven Deadly Sins of a Student,"
- C. "Are We All on the Same Page Regarding the Advisor's Role?" and
- D. "Guiding Light from Advisors Over the Years."

A general point of clarification – there wasn't much difference in the themes of the qualitative data obtained from Advisors and Students in the Seven Deadly Sins. However, when I present the Seven Deadly Sins of an Advisor, the verbatim I report are from Students, and vice versa.

A. SEVEN DEADLY SINS OF AN ADVISOR

I asked the 2010 Consortium faculty and student attendees what, in their opinion, were the top three traits an Advisor should and should not possess in an open-ended format. I did a content-analysis of these top-threes.

Positives

On the positive side, the most-mentioned traits were the Advisor's:

- Passion for research
- Productivity
- Ability to be a research role-model

All of these oft-mentioned positives have to do with the Advisor's research acumen. [At least that's what I called it till a colleague asked me why Indians speak in 18th century English, and so I changed this to "research talent and expertise."]

Negatives

On the negative side, the most mentioned traits are listed below. The main point is a numbered, paraphrased title, and the bullets within are reproduced verbatim from the responses as examples.

#1 Rigidity: My way or the highway

- "Controlling"
- "Dogmatic/strong ideas"
- "Stifling student creativity"

#2 Attitude^{Student}: I need therapy, but instead I choose to be...

- "Mean-spirited"
- "Verbally abusive"
- "Disrespectful"
- "Bossy"
- "Gossiping"

#3 Selfishness: How is this going to help me?

- "Focus on own productivity"
- "Believes in hierarchy and that students are minions"
- "Indifferent to student performance"

#4 Egotism: I reign supreme

- "God complex"
- "Infallible"
- "Dictates research agenda"

#5 Inaccessibility: "I am out of the office" auto-reply

- "MIA"/"Out of contact"
- "Non-responsive to phone calls and e-mails"
- "Overcommitted"/"tired"
- "Takes too long to give feedback"

And you can't have Accessibility without Diagnosticity!

#6 Non-diagnosticity: Feedback with little guidance

- "Shooting down ideas"
- "Too critical"
- "On the flip side, too much sugar-coating of comments"

#7 Unfortunately Unaware: La la la...

- "Not pushing student enough"
- "Not being wind beneath sails"

While the positives had to do with the Advisor's research talent, the negative traits had to do with the Advisor:

- a. Doing "bad" stuff (#1 and 2),
- b. Having personality issues (#3 and 4), or
- c. Doing nothing (#5, 6 and 7).

Bottom line

The good news is that as Advisors we at least know what we want to accomplish intellectually! But we can be in a better place by improving social dynamics with Students. Two recommendations emerge:

- a. To Advisors: Don't do bad stuff, self-regulate in interactions with Students when necessary, and try to do good stuff and advise;
- b. To Students: Either
 - i. Lower your expectations and accept that Advisors may sometimes be nasty/mean or lazy/alooof/absent (I know, this stinks), or
 - ii. Pick Advisors not just based on research talent but also based on personality and availability. Talk to other senior students. I think that it often comes down to a forecasting/selection problem from the point of view of the Student: they think that all that will matter is research talent so they pick the research star of the department (who happens to be nasty and absent... Just speculating – I do after all have Presidential license! ☺)

B. SEVEN DEADLY SINS OF A STUDENT

I also asked each respondent to list the top three traits that a Student should and should not possess in an open-ended question.

Positives

The three most-mentioned positives were:

- Intellectual curiosity
- Creativity
- Perseverance (hard-working, diligence, motivated)

Negatives

These same positive traits were also mentioned in the opposite valence as negatives, along with several others:

#1 Lack of intellectual curiosity

- “Not inquisitive”
- “Not passionate”
- “Not committed”

#2 Close-minded

- “Stubborn refusal to give up an idea”
- “Too narrow”
- “Inability to listen”

#3 Lazy or Passive

- “Procrastination”
- “Looking for the easy way”
- “Need for rapid closure”

#4 Perfectionist

- “Too detail-oriented”

#5 Thin-skinned

- “Emotionally fragile”
- “Can’t take criticism”

#6 Over-confidence

- “Sense of entitlement”
- “Arrogance”
- “Cocky”

#7 I not We

- “Not a good team player”
- “Overly competitive with other students in the program”
- “Doesn’t work well with others”

Bottom line

These overall results are not surprising: We want intellectually curious, open-minded, hardworking, thorough but not OCD, sensitive, humble, cooperative students!

But maybe not...

Interestingly, while there seemed to be an “ideal” Advisor (i.e., a good researcher, available, helpful, and nice), the data are more ambiguous regarding the “ideal” Student. For example, there is a conflict between #3 and #4 (do you want someone who works fast or is a perfectionist?) and between #5 and #6 (do you want someone humble or confident?). The data indicate greater heterogeneity of preferences when it comes to an ideal Student compared to an ideal Advisor. And one size does not fit all.

C. ARE WE ALL ON THE SAME PAGE REGARDING THE ADVISOR’S ROLE?

So far I have been focusing on the synergies of responses across groups of Advisors and Students. I would like to now focus on some interesting points of differences in perceptions between the groups

in terms of the evolving role of Advisors during a Student’s professional journey:

- a. As a student
- b. While on the job market, and
- c. Post-PhD

As an aside, I will be presenting some charts – All scales are 7-point scales, unless otherwise specified, and a higher number indicates more of whatever is being measured.

(a) While the Student is a Student

The time as a PhD student is a critical one in terms of both intellectual training, as well as in terms of developing and refining good “research habits.” But what Students think they want and what Advisors think they need to deliver maybe disjointed, and so I asked a few questions pertaining to Advising goals and the level of involvement.

(i) What could Advisors use more of?

Advisors say they wish they had more Time, Students say they wish Advisors had more Personality.

Faculty reported that the biggest problem they perceive in the advising environment is lack of time to advice. However, while Students did mention that Advisors are overcommitted, they reported the bigger issues are personality-related: rigid, selfish and egotistical. Students do believe that Advisors have the intellectual component (thank goodness!), but they would also like to receive respectful guidance.

However, Advisors don’t seem to realize this. They rated the importance of being Socially Aware (a measure that I am using as a surrogate for treating people with respect) as much less important a trait in an Advisor (3.8) compared to both groups of Students (4.8 and 5.6). Similarly, having a “Charming personality” was rated much lower by faculty (2.6) than the two groups of Students (4.0 and 4.2). While these traits are not the most important (given the overall middle-of-the range ratings on 7-point scales), we, as Advisors, should pay more attention to personality-related traits since there is a disparity in ratings between groups. Sensitivity to the way we interact with doctoral students is an important issue that we should keep in mind.

(ii) What specific activities should Advisors participate in to facilitate the PhD education process?

When asked this question, many faculty members mentioned:

1. Provide the big picture
2. Help with methodology and analyses
3. Keep abreast of the literature so that Students don’t go astray. These can be classified as the “intellectual” components of advising.

However, it turns out that Students don’t mention anything so sophisticated or highbrow in their responses. In fact, when asked to rate the traits of “Well read in the field” and “Has intellectual breadth” on importance in an Advisors, faculty rated these traits at 6.2 and 6.3. Students, both the 2005 and the 2010 samples, rated these traits between 5.1 and 5.3.

So what do Students want Advisors to do more of? They universally identified three sets of activities that they would like their Advisors to do more of:

1. Have regular meetings/provide constant feedback;
2. Make a schedule/check up on Student’s progress; and
3. Interact personally/have lunch together occasionally/and drinks!

All three have to do with “logistical details.” AKA, some form of hand-holding.

Thankfully, given the specific nature of the feedback from Students, these action items are simple to implement, if not already in place. However, Advisors, if you're not planning to check up on your students, you should make sure that students realize it is their task to chase you and harass you.

(iii) How directive should an Advisor be?

One of the scaled questions asked, "How directive do you think an Advisor should be as far as a Student's research is concerned?" Faculty expressed that they should be less directive (4.2) than recent graduates (5.6) and current students (5.1) desire.

What is the issue here? I have been involved in reviews of PhD programs and have given quite a lot of thought to different forms of advising that I have seen over the years. In general, at the two ends of a spectrum of advising, there is the "Apprenticeship" approach and the "Sink or Swim" approach. In general, I have been a fan of the Apprenticeship approach. A discussion with a colleague recently, though, made me rethink my stand. He pointed out that too much of an Apprenticeship approach may hinder the independence of the PhD student, making them less likely to succeed in a world where they need to struggle as Assistant Professors and get tenure. [Besides, we have scientific evidence that the Apprenticeship model may convert an Anakin Skywalker into a Darth Vader!]

I still do believe that Apprenticeship is important, and maybe there is a happy medium between this and the "Sink or Swim" approach in the role an Advisor plays in the Student's life.

(b) While the Student is on the Job Market

When on the job market, the set of demands on an Advisor is very different. The job market generally lasts for only a few months, but it has a lasting impact. So I wanted to gauge the levels of satisfaction with the role of the Advisor during this phase.

I asked respondents a hard-to-answer, ambiguous and complex question: "In your opinion, what percentage of PhD students in marketing are satisfied with the role that their advisor plays in their (a) overall PhD education; and (b) job placement?" In answering this question, respondents were asked to think about Students and Advisors around them to make the question slightly more tangible.

Regardless of the craziness of the question (and my Advisor's voice in my head saying, "I wrote Asking Questions! Did you not read it?"), the responses were indeed interesting. Faculty perceptions of themselves as Advisors are worse than student perceptions. Faculty reported on average that about 40% of students were satisfied with the role of their advisors in their overall PhD education. But the Student samples reported 60%. A similar pattern holds for job placement (40%, 54%, and 59% respectively).

Bottom line – Advisors, forgive yourselves! We are doing a lot better in the eyes of our Students than we give ourselves credit for. Yes, there is room for improvement (after all the satisfaction percentages are only a little over the half-way mark), but let's not try too hard to fix something that is only a little broken!

(c) After the Student gets a PhD

Once Students are gainfully employed, the question arises regarding the continuing role of Advisors. Anecdotally, I know several colleagues of mine who say that they wash their hands off their Students once that time comes, and yet others who continue to hover like helicopter parents. So I investigated this issue empirically.

(i) Mentoring after graduation

Respondents were asked: "How much (a) SHOULD, and (b) WILL an advisor continue to mentor their student after s/he graduates?"

- All three groups are equivalent in their beliefs regarding how much faculty members SHOULD mentor after graduation (Faculty = 5.7, Recent graduates = 5.5 and Current students = 5.8).
- However, Advisors believe they mentor Students after they graduate as much as they think they should (5.6); I call this group Idealists.
- Recent graduates (i.e., 2005 Doctoral Consortium students) do not believe that Advisors have continued involvement in mentoring after graduation (3.8); I call this group the Disappointed.
- Those that haven't yet graduated (i.e., 2010 Doctoral Consortium students) believe that their Advisors should continue to be involved, though they are not sure that they actually will be (4.6); I call this group the Pessimists, albeit not sufficiently so.

All three groups believe that Advisors should continue to be involved in their career, and yet according to the 2005 Students (who are probably the most recent beneficiaries of their Advisors' goodwill), Advisors are not as involved.

From an Advisor's viewpoint, however, consider issues of Promotion and Tenure down the road for our students. As good Advisors, we hopefully have internal compasses that tell us to what extent we should be involved (that is, till the student is flying on their own), and when to let go (that is, when students should establish an area of research of their own, and gain an independent reputation). Therefore, it is likely that Advisors are involved to the extent they believe that they should be involved, and that is just not the same amount as what Students expect. So again, it is up to us to either step it up or at least manage expectations.

(ii) How important is the Advisor-Student relationship to future success of the Student?

Both groups of "Students," the 2005 and the 2010 doctoral consortia attendees, rated this relationship as extremely important to their future success (6.5 and 6.6 out of 7). Faculty members, however, rated this relationship as less critical to success, albeit on the positive side of the 7-point scale (5.0). Since the Students that graduated a few years ago still think that the Advisor is critical to their success, Advisors need to acknowledge this more and need to: (a) either manage these expectations, or (b) work harder towards getting students to be more self-sufficient.

Bottom line

- Advisors need to be more attentive to personality issues when it comes to dealing with Students (maybe); and
- We need to revisit and manage the expectations of Students better in terms of:
 - Our role in their current PhD life (e.g., Schedule-keeper? Or idea-bouncer?)
 - Our role in their future academic life as young professors. Are we really that central to a Student's future success? I hope the answer is No.

An intriguing question is that given that all Advisors were Students at some point, why do these differences exist? I see four possibilities:

1. Advisors have moved on, forgotten, and now have a different perspective;
2. Times are different. Personality may have been considered irrelevant before (heck, it may even have been cool to be the crazy professor), but now Students want you to be nice;

3. There is a survival bias and the most successful academics are those that did not care whether their Advisor was charming; or
 4. Students are now a coddled bunch and expect to have a lot of hand-holding.
- You pick the poison(s)!

D. GUIDING LIGHT FROM ADVISORS OVER THE YEARS

Finally, I asked all respondents who have been in academia for as many as 40 years to as few as 2 years what was the best piece of advice they received from their Advisor. Here are the ones that resonated most with me and they are a reminder, in my opinion, of what we need to reinforce in our roles as Advisors:

(a) "It's a marathon, not a sprint."

It is important to think of the PhD education process as the antecedent to a life-long research adventure full of discoveries, akin to a life-long marathon. If these discoveries are packaged into synergistic research areas, a body of knowledge is generated. However, if we think of research as a bunch of publications, then the journey becomes more like a number of sprints strung together, rather than a marathon.

The kind of student that enters the PhD program is somewhat different today than 20 years ago, and some even join the PhD program with publications. Yet, doctoral programs now last 5 or 6 years instead of 3 or 4 because we hire junior faculty members for their record+potential, as opposed to the old days when we hired based on potential. All that is well and good, but I also fear that this change in our education system will slowly decompose the contributions of the next generation into a series of sprints if our focus shifts to publishing, rather than create an impact with a marathon.

So what can we do to encourage a marathon approach among Students? It is important to focus students on some of the basic characteristics that will maintain the excitement of research through the years ahead. Here's what some Advisors had to say:

Study something that excites you, not something that is "in".

Chris Janiszewski spoke about this last year in his Presidential address. Other Advisors have said:

"Follow your inspiration."

"Study what you are passionate about and academia ceases to be work."

"Don't follow the herd."

"Risky research is not all that risky – this is the work that garners the most attention and changes the way people think."

Try to explore the topic in various ways (width) and as well as you can (depth):

"Build a program of research."

"Work on multiple projects at once but don't spread yourself too thin."

"Publish in top journals."

(b) "When the going gets tough, the tough get going."

An aspect of research life is rejection, criticism and very often having to rework a project that you have already invested a year or two into (the Reject/Resubmit or the "new manuscript" syndrome). The key is perseverance! As many Advisors have noted, the correlation between smartness and perseverance is not perfect. Brilliant ideas are a dime a dozen, but brilliant ideas, done, redone and then disseminated are fewer and far between. One Advisor said:

"It's not the smartest people who succeed in our field, but it's the people who keep working and don't give up."

(c) "Take yourself seriously, but not too seriously."

I believe very strongly that everyone needs work-life balance, whatever that "life" component may be. So for those of us that need something beyond work, let's take our work seriously, but let's also try to find ways to incorporate other things that inject joy into our lives; who knows they may trigger a lot of creative thinking and produce impactful research as a side benefit!

I encourage my PhD students to enjoy whatever it is that rocks their boat: their kids, travel, cooking, gardening, drinking, bartending, karaoke, reading, working at the zoo, sky-diving, cross-dressing... you name it.

(d) "Personal issues come and go but you will always have your dissertation."

I have had several students over the years that joined the PhD program with families, or had a baby or two during the program. They balk at the age-old wisdom that the dissertation is like a baby. And while surfing the web and talking to colleagues, I found these compelling arguments about why a dissertation is harder than having a baby:

1. Unlike advisors, you can switch doctors without having to start over.
2. Conceiving a baby is WAY more fun than conceiving a topic.
3. Friends and relatives don't question the worth of a baby.
4. No one will complain if your baby is too similar to another one.
5. If you produce 8 dissertations, nobody will give you your own TV show.

So let's stop calling the dissertation a baby, and call it what it is – a big (though sometimes fulfilling) pain, which if doesn't kill you, makes you stronger.

(e) "Pass the torch."

As Advisors, we are role models setting an example for our Students, and much like our children, they pick up behaviors and attitudes that are both communicated deliberately as well as non-consciously. Have you ever noticed a child may end up a Phillies fan because one of the parents is a Phillies fan? PhD students tend to do the same thing. No, they may not become Phillies fans, but they mimic behaviors and attitudes. It is important to behave in a way that one is proud of when emulated. And as one Advisor said, "Whatever you get from me, pass it forward." We are, after all, creating the next generation of researchers.

ACKNOWLEDGEMENTS

I would now like to say a few words of thanks to ACR.

- a. In order to recognize the “marathon, not a sprint” thinking, ACR has instituted the annual Early Career Award for contributions to consumer research. This award will be presented for the first time at tomorrow’s luncheon.
- b. In today’s talk, I have focused on Advisor-Student relationships, but of course Advisors can spawn off a whole line of research with Students, and more interestingly (and very true in my case), can be influenced by their Students’ research. This is an extremely important aspect of an Advisor’s role in PhD education that I did not have the time to talk about.

As an illustration, there is a special session chaired by Nidhi Agrawal and Ellie Kyung that was invited by the three ACR co-chairs immediately following this luncheon. This session highlights synergy in research on Consumer Well-Being across several students I have been lucky enough to interact with during my twenty years as a faculty member. I have been influenced by their very intellectual minds in my own work.

- c. Finally, ACR is a forum that fosters mentorship both intellectually with cutting-edge research, and socially by bringing together different generations of scholar.

A few other acknowledgements...

Thanks to *The Bold and the Beautiful*: Darren Dahl, Gita V. Johar and Stijn van Ossalaer for an amazing conference and Priya Raghbir and Patti Williams for a thought-provoking doctoral symposium.

To *All My Children* who have enriched my life professionally and personally: Eric Yorkston, Suresh Ramanathan, Nidhi Agrawal, Manoj Thomas, Ellie Kyung, Amit Bhattacharjee and Rohaan Menon. (The last one is my biological child and my rock.) And to other students who I have had the pleasure of learning from over the years: Gita V. Johar, Priya Raghbir, Raj Raghunathan, Suchi Chandran and Cenk Bülbül.

To *The Young and the Restless*, each of who contributed in unique ways along the way and I am so grateful: Amitav Chakravarti, Rohit Deo, Ellie Kyung, Gavan Fitzsimons, Tom Meyvis, Vicki Morwitz, Priya Nair, Priya Raghbir, Akshay Rao, Sankar Sen and Nicole Verrochi.

DEDICATIONS

To Seymour Sudman,

Who set very high standards as an Advisor and ignited my enthusiasm for PhD Education.

To my parents

Who channeled my thirst for knowledge and taught me that the education process never ends.

THANK YOU!

Invited ACR 2010 Presidential Session

All My Children: Fostering Diverse Approaches to Consumer Well-Being Research

Co-chairs:

Nidhi Agrawal, Northwestern University, USA

Ellie Kyung, Dartmouth College, USA

In conjunction with her address which underscored the importance of doctoral education, ACR President Geeta Menon hosted an ACR session on an issue that has significantly influenced her work: consumer well-being. To that end, her past and present student collaborators presented on a broad range of topics related to improving consumer decision-making processes and their public policy implications.

GOAL

The goals of this session were two-fold. First, to showcase examples of theoretically grounded work in the realm of consumer well-being. And second, to promote further research in the realm of consumer well-being, while illustrating the importance of developing new scholars in our field through supporting doctoral education.

SESSION SUMMARY

With the proliferation of channels, firms, products, and services over time, the consumer world has become increasingly complex. Consumers are often faced with competing goals or objectives that can materially affect their well-being. Thus, there is a need to understand how to empower consumers through designing better messages, decision-making contexts, choice settings and behavioral motivations and aid them in achieving their well-being goals. Much attention has been drawn to this important, growing area of research in recent years, and this session showcased varied approaches to studying consumer well-being. **Geeta Menon** opened the session by discussing her interest in consumer health and well-being research and her work with doctoral students.

The first group of papers addressed novel issues related to impulsive behavior. **Suresh Ramanathan** presented his work suggesting that indulgence maybe viewed as sticky and recurrent desires rather than weak self-control. This implies a more 'active' and goal-directed view of self-control problems in domains of impulsive behavior. Following this, **Nidhi Agrawal** discussed when and why health messages designed with the good intention of promoting healthy behaviors might backfire on consumers' subsequent self-

control in unrelated domains. **Manoj Thomas** talked about how forms of payment used can influence impulsivity and the purchase of unhealthy food products.

The second group of papers examined the role that ethics can play in consumer choices. **Suchi Chandran** moved the discussion to a new domain of ethical consumption by asking how mood, self-esteem and consumption visibility influence attitudes towards ethical products. Then **Amit Bhattacharjee** took a different view of the evaluation of products from a social value perspective by discussing consumer perceptions of the relationship between firm profit generation and social value creation.

The final group of papers examined ways in which consumers can take control over their environment and decision making to improve their well-being. **Eric Yorkston** examined how consumers can use today's technologies to the counter background sounds – typically under the control of external agents – that might otherwise negatively affect their behavior. **Ellie Kyung** discussed why consumers treat their private information so lightly in the digital age and identify methods to encourage them to value and protect their personal information. Building on this question of how to encourage consumers to actually behave in ways that maximize their well-being, **Raj Raghunathan** examined the pursuit of happiness. His studies examined why consumers believe they should make choices to maximize happiness, but do not make choices consistent with this goal. Finally, **Priya Raghuram** discussed how consumers' subjective value of money can depend upon different payments forms, currencies and denomination, affecting critical saving and spending decisions. She discussed methods to improve financial decision-making.

Together, these papers presented a variety of perspectives to studying consumer well-being. Each showcased ideas that contribute to the understanding of consumer well-being while advancing existing theory. **Gita Johar** concluded the session by discussing the key points across these presentations and highlighting the commonalities across these papers. She presented an integrative view of the various papers and emphasized the importance of studying consumer well-being.

Short Abstracts

(Presenting authors in italics.)

On Indulgence as Sticky and Recurrent Desires Rather Than Weak Self-Control

Suresh Ramanathan, University of Chicago

Indulgence has often been ascribed to weakness in the ability to avoid temptations. Using a new Dynamical Systems approach, we will argue that indulgence is driven by desires that strengthen over time and recur more frequently for people who are impulsive. Further, such people get "stuck" in these states of desire for longer periods of time. Contrary to the prevailing view of indulgence, we find no diminution in avoidance reactions over time, suggesting that casting indulgence as a failure of self-control may not be always an accurate view of the phenomenon.

Preventing One Disease, Promoting Another? Carry-Over Effects of Health Messages on Subsequent Self-Control

Nidhi Agrawal, Northwestern University
Echo Wen Wan, University of Hong Kong

We examine the deleterious effects of health messages that communicate high risk of disease on consumers' subsequent self-control in other domains. Processing high- versus low-risk health messages impairs subsequent self-control via both motivational (e.g., depletion from trade-offs) and emotional (e.g., anxiety from risk perception) processes.

**Credit Cards and Purchase of Unhealthy Food Products:
The Roles of Impulsivity, Deprivation and Intrusive Desires**

Manoj Thomas, Cornell University
Kalpesh Desai, SUNY Buffalo
Satheeshkumar Seenivasan, SUNY Buffalo

Some food items that are commonly considered unhealthy also tend to elicit intrusive desires. Mode of payment can influence consumers' ability to control these intrusive desires. Paying by credit cards makes consumers more likely to buy such food items, and this effect is stronger when consumers are chronically impulsive or have been suppressing their desires.

**Loving, Feeling and Helping: The Impact of Mood,
Self Esteem and Visibility of Consumption on Attitudes
towards Ethical Products**

Sucharita Chandran, Boston University
Shuili Du, Simmons College

Research suggests that buying ethical products makes consumers feel good and that providing an 'ethical guarantee' can be impactful. Here, we investigate the role of self esteem, mood and visibility of consumption (private or public) on attitudes, intentions to buy and willingness to pay for ethical products.

**Is Profit Evil? Incentive Neglect and the Association of
Profit with Social Harm**

Amit Bhattacharjee, University of Pennsylvania
Jason Dana, University of Pennsylvania
Jonathan Baron, University of Pennsylvania

Multiple studies find a strong negative correlation between perceived profit and social value across both industries and specific firms, moderated only by perceived firm motives. Similarly, we find that hypothetical organizations are viewed as creating less social value when described as for-profit rather than non-profit. People report little faith in the power of markets to create and reward value, neglecting the incentive properties of profit and focusing instead on the perceived intentions of firms.

Success through Supplanting Sounds

Eric Yorkston, Texas Christian University
Leonardo Nicolao, Texas Christian University

Ancillary sounds, such as background music, can strongly effect consumers' behavior. These sounds are often determined by external agents and outside the control of individual consumers. We suggest that utilizing current technologies, consumers can take active control over environmental sounds and the behavioral consequences they have on their consumer welfare.

**Examining the "Privacy Paradox":
The Role of Perceived Constraints**

Ellie Kyung, Dartmouth College

In this digital age, it has become increasingly easy to solicit, collect, and disseminate personal information from consumers. Although consumers largely agree that privacy is important and that their information is valuable, they regularly share information in relatively unprotected forums in exchange for very little, if anything at all. We discuss reasons why consumers behave in this paradoxical manner and how to encourage them to protect their personal information.

**People Say Happiness is the Ultimate Goal,
But Do They Act Like They Mean This?**

Raj Raghunathan, University of Texas, Austin
Sunaina Chugani, University of Texas, Austin
Ashesh Mukherjee, McGill University

Although lay-people agree that life's ultimate goal is happiness maximization, our findings show they do not behave in a manner that is consistent with this goal. Our findings seem to suggest that, while people realize that they "should" select the intrinsically-motivating job, they can't help but select the extrinsically-motivating one.

Subjective Value of Money

Priya Raghubir, New York University
Joydeep Srivastava, University of Maryland

In our published and ongoing work we have shown that money is subjectively valued and is not fungible across forms, denominations, and currencies. People spend and save differently as a function of whether they are paying using legal tender versus credit cards, debit cards, and gift certificates. Further, the maximum price they are willing to pay for a product differs depending on whether it is in local or foreign currency, with the amount further contingent on whether the face value of the foreign currency is a multiple or fraction of the home currency. Finally, even when consumers are paying using legal tender in their home currency, the denomination of the bills they carry affects their likelihood of purchase.

ACR Fellows Addresses

Fellow's Address: In Defense of Bumbling

Joseph W. Alba, University of Florida, USA

As my comments may elicit little sympathy, I will begin on a note of widespread agreement: This honor is undeserved. It is undeserved for many reasons, but the foremost is that ACR has chosen to bestow it on someone who has experienced a continued inability to adapt to the culture of consumer research.

I began my career as an outsider to consumer research, ignorant of its substance and traditions. To acclimate, I delved into the leading consumer and marketing journals—an experience that was simultaneously stimulating and perplexing. I quickly apprehended many of the themes of the discipline but was bemused by some of its methods and philosophical leanings. For example, I was surprised to encounter in one of my first readings a section labeled “manipulation checks.” True to its title, the authors proceeded to report that they had successfully manipulated their independent variables. I was not particularly heartened by this outcome because my experience with experimental manipulations was that they required little confirmation. If a memory experiment varied the interval between stimulus presentation and recall, for instance, the manipulation could be checked with a watch or calendar, and there was little need to apprise the reader of its success. As I read further, it became clear why consumer articles contained manipulation checks. They were engaged in an alien practice that involved the manipulation and measurement of “constructs,” which I was further chagrined to learn were hypothetical.

To understand how a construct could be unfamiliar to someone who by this time had read deeply (but obviously not broadly) about human behavior, one must appreciate the roots of cognitive psychology. As reflected in the verbal-learning paradigm, its associationistic accounts, and its functionalist orientation, much early work on memory occurred under the umbrella of behaviorism. Memory was taken to be a function of the learning environment and the individual's history (Watkins 1990), and in almost no instance did manipulation of these variables require verification.

It is no secret that consumer research has rarely aligned itself with the functionalist perspective. My personal affection for functionalism notwithstanding, I am disinclined to proselytize—a futile endeavor in any event. However, I would contend that functionalism is not a cult and that its current lack of popularity should be viewed as a matter of taste rather than scientific legitimacy.

Nonetheless, life in this non-functionalist world has been edifying, and the many issues we investigate, mostly with the aid of constructs, are interesting and important. If finding a comfort zone within consumer research required only that I relax my philosophical proclivities, I would have acclimated long ago. However, there is an additional word that has proven vexatious. It is a weighty word, but one that previously had failed to evoke a valenced response from me. That word is *theory*—a word that becomes even more ominous when used accusatorily in the sentence: “Where's your theory?” After nearly 30 years, I should accept the possibility that I may never come to terms with this question. However, if I am to maintain even a flicker of hope, I must first understand its intent.

WHAT IS THEORY?

I suspect that when people express a preference for theory, they are at various times using the term in at least one of three ways. The first is as a formalization, a view of theory that conforms most

closely to a textbook definition, as in “a statement of relations among concepts within a set of boundary assumptions and constraints” (Bacharach 1989, p. 498). One may quibble about the particulars, but such a definition is unlikely to generate much controversy. A second use of the term is as a synonym for process. That is, when asked to supply a theory, the researcher is really being asked to describe the cognitive (or affective) processes that underlie some reported effect. It is difficult to argue with this sense of theory, as well, insofar as it reflects intellectual curiosity. We wish to understand a phenomenon as well as it can be understood. Finally, request for theory can reflect a philosophical disposition that we commonly refer to as the hypothetico-deductive approach. The popularity of the approach is plainly evident in our literature in the form of explicit and extensively reasoned a priori hypotheses, which too suggests a lack of controversy.

Given the apparent reasonableness and general acceptance of each connotation of the word, there seems to be little reason to fear theory. However, one can acknowledge the validity of each view while also questioning the need to conform to any of them. I will try to make my case on substantive grounds, but I must also confess that the issue is personal. The simple fact is that I violate the prescription for theory in all of its senses. My empirical efforts typically focus on only one or two independent and dependent variables, thereby affording little opportunity to build a theory in the classic sense. I have an appreciation for process, and there are instances in which I seek to understand the process underlying an effect, but process rarely serves as my initial motivation. Finally, my favorite form of hypothesis barely qualifies as a hypothesis at all. I am drawn primarily to research questions that are two-tailed, which itself may be an overstatement. My favorite research questions begin with the words “I wonder” Formal hypotheses that have appeared in my published research have been inserted under protest.

Having failed at theory, I am sensitive to my outlier status. My self-esteem is further damaged by the realization that I fall into the category of investigators described by Wegner (1992) as “bumblers,” that is, people who go through life simply trying things. Worse yet, if I have accurately captured the multiple meanings of theory as used in our field, I am unlikely to ever escape bumbler status. The most obvious reason is that I lack the ability to do anything else. The other reason, however, is that my functionalist instincts prevent me from adhering to the theory orthodoxy. Fortunately, I am not alone, and I can take great comfort in the accomplishments of other bumlbers. It is not my original observation that some of the greatest achievements in the natural sciences were realized through induction and observation (see, e.g., Barwise 1995; Ehrenberg 1995; Peter 1991; Rozin 2001; Watkins 1990). Closer to home, it is Greenwald (2004, p.275) who has

“... long questioned the wisdom of a principle of proper method in psychology that is now widely advocated—the belief that empirical research is valuable only to the extent that it advances theory. ... Among the important works that have managed to achieve publication without advancing theory are some of the major works by Asch (conformity), Sherif (norm formation), Milgram (obedience), and Zajonc (mere exposure).”

WHY THE OBSESSION?

In trying to understand the emphasis on theory in consumer research, at least three explanations come to mind. Each has its own merits, but it is unclear that any one is completely valid.

Good Intentions

It is widely acknowledged that research in the fields of business, including marketing, was not highly developed 40 years ago. The stinging criticisms leveled by prestigious organizations prompted colleges of business to shift from a vocational to a scientific mode which, from a research perspective, translated into a shift from a descriptive to a theoretical orientation (see MacInnis and Folkes 2010 for a discussion).

Given the status quo, it is difficult to find fault with this shift, but there is much irony in the zeal—and narrowness—with which the theoretical approach has been promoted in our discipline. As a point of fact, theory testing is relatively rare in the so-called “hard” sciences that consumer research wishes to emulate. Emphasis on experimentation vies with an emphasis on description, and research is often motivated by a simple desire to probe the existence of a relationship between two variables (Rozin 2001, 2006). Graphs, which exhibit a strong relationship to the perceived hardness of a science, tend to be used toward descriptive rather than theoretical ends (Smith et al. 2002). These natural sciences recognize the evolutionary nature of science, embrace its multiple objectives, and are unembarrassed that a scientific paper can serve simply to report a set of empirical observations (Thomson 1994).

So, how is it that we have deviated from the practices of science while believing that we were conforming to them. Although our original intentions were laudable, we may have committed two errors in our execution. First, we may have over-interpreted the call for theory. Business research in previous generations was at its worst when its descriptions lacked generalizability and broad insight. However, neither generalizability nor profundity is isomorphic with theory. Phenomena, as I note later, are generalizable by their nature, and important phenomena spark the imagination.

Second, the consistent emphasis on theory in the ensuing years converted a notion into a rule, which is accompanied by the danger of mindless application (cf. Baron 1994; Langer 1989). Reflexive obedience to theory can be self-defeating and, in some contexts, immoral. We would question the values of a discipline that withheld publication of a welfare-enhancing discovery. We should care little about whether a discovery stems from the predictions of a formal theory, the meeting of a serendipitous outcome and a prepared mind, or simple luck. A cure is a cure, even when the mechanisms of the cure are not fully understood—and there has been no shortage of discoveries in the natural sciences that owe their existence to good fortune (Myers 2008).

Mature sciences exploit the multiple avenues to discovery. Consider Mukherjee's (2010, p. 45) characterization of cancer drug identification:

“Traditionally, three strategies have produced anticancer drugs. The first relies on serendipity: someone hears of a chemical that works on some cell, it is tested on cancer and—lo!—it is found to kill cancer cells while sparing normal stem cells. The second approach involves discovering a protein present or especially active in cancer cells—and relatively inactive in normal cells—and targeting that protein with a drug. ... The final strategy involves identifying some behavior of a cancer cell that renders it uniquely sensitive to a particular chemical.”

These “strategies” appear to map onto luck, deduction, and induction, respectively. Is consumer research more rigid simply because its discoveries lack import?

Confidence

Inexplicable empirical effects prompt skepticism, and therefore requests for a process explanation are not unreasonable. Confidence in the reliability and validity of a relationship between two variables can be enhanced by a plausible causal explanation (Alba and Hutchinson 2000). Again, however, our faith in the ability of theory to achieve our objective may be misplaced. In the social sciences we are fond of noting that no theory is likely to be correct and that a theory lasts until it is displaced by a superior theory. Hence, just as production of reasons for an outcome can lead to overconfidence in its likelihood, we should acknowledge that theory can provide a fall sense of security—if not mortification. As Steven Weinberg, Nobel prize winner, ruefully noted after devising a theory to explain the reported discovery of (nonexistent) trimuons, “I’ve always been embarrassed that we managed to come up with a theory” (Overbye 2007).

We might dismiss embarrassment as infrequent, but the same is not true of frustration, which can arise particularly when theories are abundant. Watkins (1990) identified a period in the history of memory research that he dubbed “an era of cheap theories,” an era that accompanied the ebb of functionalism and a growth in the popularity of memory constructs. Each of these theories was sophisticated, but clearly not all (or any) were correct. Those of us who were compelled to learn these theories are particularly sensitive to the havoc that can be wreaked by intelligent people armed with a large toolbox of constructs.

A final irony of the confidence-driven call for theory involves research from within our own field regarding the time at which a process explanation is offered. When process is articulated a priori, it conforms to our hypothetico-deductive instincts. When offered after the fact, the temptation is to view it as “mere” speculation. My fellow Fellows (Brinberg, Lynch, and Sawyer 1992; Sternthal, Tybout, and Calder 1987) have spoken eloquently about this misconception but with an apparent lack of persuasiveness. The implications are as significant pragmatically as they are conceptually. Researchers who speculate are frequently asked to go to great lengths to confirm their speculations within the same research report, a demand that I later suggest can be suffocating. Further, anticipating that the review process will demand a test of speculation, authors are understandably tempted to reframe their speculation as expectation—a weak form of fraud that is easy to rationalize.

In short, confidence has its costs. These costs are regrettable because they are avoidable. Those who earnestly seek confidence should explain their desire for process. If confidence is the goal, it can be achieved in the absence of theory via tests of robustness.

Direction

A third source of affection for theory is very pragmatic and is captured famously by Lewin's (1951, p. 169) assertion that “there is nothing so practical as a good theory.” When compared to random experimentation, theory does indeed convey advantage. However, for two obvious reasons, theory fails as a compelling directive if its benefit derives from practicality. First, pragmatics cannot be dictated. An important but inefficiently obtained discovery is a discovery nonetheless. With the possible exception of consumer researchers, it would be a rare patient who refused a remedy based on how it was discovered.

Second, it is not the case that scientists are faced with a binary choice between theory-based inspiration and random exploration. Bumpers in particular are familiar with the process of abduction—or “informed curiosity” (Rozin 2001). There is no reason to believe that research inspired by a hunch and then rigorously pursued is any less likely to shed light on consumer behavior than is research derived from a structured theory. In fact, as argued below, a reverse argument can plausibly be made.

Third, for those who rely on theory to confer scientific legitimacy on their efforts, abduction should not be viewed as having less serious philosophical underpinnings than the hypothetico-deductive approach or being any more detached from our ultimate scientific objectives (Haig 2005; *Stanford Encyclopedia of Philosophy* 2010).

NO FREE LUNCH

The theory imperative is more than a matter of philosophy. By uncritically accepting the advantages of theory, we ignore some very consequential tradeoffs. I will describe four.

Why Versus What

It has been argued that “The primary goal of a theory is to answer questions of *how*, *when*, and *why*, unlike the goal of description, which is to answer the question of *what*” (Bacharach 1989, p. 498). True enough, but it is bumpers who have a special appreciation for the fact that *what* precedes all other questions, and it amazes bumpers and functionalists (and this bumping functionalist) that such an assertion could be controversial.

It is notable that our colleagues on the non-behavioral side of marketing have debated the merits of an extreme form of *what*. We are reminded of this controversy by the recent passing of Andrew Ehrenberg, who advocated the Empirical-then-Theoretical (EtT) approach (Ehrenberg 1993), wherein one first establishes an empirical generalization and then develops a model to explain it. Although behavioral bumpers can relate to the spirit of this recommendation, we are less ambitious and less contentious. We believe neither that *what* needs to rise to the level of an empirical generalization or that a theory needs to be preceded by a well-established empirical generalization. We do agree with the general sentiment that data serve as the building blocks for theory and that some respect should be accorded an inductive (or abductive) approach to theory construction. To reprise an earlier irony, the hard sciences readily acknowledge this reality, such as when epidemiology provides a starting point for the investigation of an ultimately microbiological phenomenon.

If pursuit of *why* versus *what* reflected nothing more than idiosyncratic preferences, the issue would not preoccupy us. However, some have argued that theory can inhibit discovery—if for no other reason that resources are finite and effort devoted to hypothesis testing might come at the expense of hypothesis generation (McGuire 1989). A more extreme position contends that the theory orientation may actively stifle discovery:

“... theory is likely to obstruct research progress when the researcher’s primary goal is to test the theory. In testing a theory, the theory can dominate research in a way that blinds the researcher to potentially informative observations” (Greenwald et al. 1986, p. 217; see also Rozin 2001).

Mortensen and Cialdini (2010) make this point in a folksier manner by referring to the story of the drunk who searches for his car keys under the lamppost, not because the keys were lost under the lamppost but because the light is better there. As with EtT, it is curious that Mortensen and Cialdini would feel a need to promote a cyclical approach involving observation, theory, and experimenta-

tion. Given the rigors of the journal review process, it is less surprising that Cronbach (1986) felt the need to remind us that hypothesis testing follows a great deal of preparatory work and to urge tolerance of—and much patience with—the exploratory phase of the cycle, else good ideas be discarded prematurely. Indeed, Cronbach attributed dissatisfaction in the social sciences to “idolization of formal theory” and over-valuation of “theory-choice.”

Finally, it is important not to misconstrue abduction as a lowering of standards or a trading off against rigor. When an effect lacks a causal explanation, there is all the more reason to demonstrate its robustness and probe its boundaries. There is simply less of a need to provide an empirically grounded process explanation in the short term.

INCREMENTAL VERSUS ORIGINAL

With regard to the broader field of marketing, Rust (2006) has mused about outright hostility to original theory. I have not detected any such hostility, per se, in consumer research, but I join others in questioning the extent to which consumer research generates much original theory (MacInnis and Folkes 2010). Regardless of how one answers this question, it is undeniable that we have been unabashed borrowers of ideas developed elsewhere. The value of this strategy is a matter of opinion, but insofar as abduction is absent from our research, the risk of incrementalism lurks. Some go so far as to characterize abduction as a necessary condition for innovation (Martin 2010). Incrementalism has unfortunate negative connotations in that truth-finding can often be likened to a slow construction process. Insofar as the foundation for consumer research is provided by external disciplines, the larger question concerns the magnitude of our contribution. No metric exists, but my subjective impression is that consumer research frequently runs the risk of examining near-tautologies (Wallach and Wallach 1994), wherein the predicted outcome is a necessary consequence of the established premises. Near-tautologies appear in the literature, in part because they can add nuance to an outcome, including a demonstration of practical significance—and what could be more practical than consumption?

There are two additional dangers that accompany incrementalism. The first speaks to the legitimacy of our enterprise. Popper notwithstanding, it has been argued that psychological research is more apt to engage in confirmation than falsification of theory, and that such mis-testing of theories can forestall true understanding a phenomenon (Greenwald et al. 1986). Whatever the extent of this problem in the basic sciences, it is exacerbated in consumer research because we borrow theories for the express purpose of illustrating their relevance to consumer behavior. We have little scientific or personal incentive to borrow a theory in order to demonstrate its lack of relevance (for what journal would publish a paper about the irrelevance of a theory from another field). Worse yet, intolerance of messiness in the testing of a borrowed theory leads to sanitized confirmation of the theory (McGuire 1989).

The second danger is that dogged pursuit of any theory runs the risk of producing evanescent minutia. Research findings are produced at a prodigious rate. When the findings are produced in service to a theory, their practical contribution may evaporate with the nearly inevitable disconfirmation of the theory. In the present context, this problem may be understood via the distinction between data and phenomena. Haig (2005, p. 374) argues:

“Unlike phenomena, data are idiosyncratic to particular investigative contexts. Because data result from the interaction of a large number of causal factors, they are not as stable and general as phenomena, which are produced by a relatively small

12 / Fellow's Address: In Defense of Bumbling

number of causal factors. Data are ephemeral and pliable, whereas phenomena are robust and stubborn.”

Similarly, in criticizing the proliferation of memory theories, Watkins (1990, p. 332) argued:

“... research designed to address some person's individual theory is unlikely to be of any use once that person allows the theory to wither and die. ... Were we to shed mediationism, theorizing would in all likelihood become less labyrinthian, and research questions more straightforward. ... (T)he essential findings would be simpler. And simple findings, like simple items of furniture, can be used and reused. They would form a cumulative body of knowledge, and so would free future generations of researchers from the need to start anew.”

As a practical matter, we should also recognize the problem that esoterica poses for our community. As research questions become narrower, a field can become so balkanized that its members find topics outside their own area of interest to be arcane or incomprehensible (Reis and Stiller 1992). As a matter of science it is awkward to argue against deep understanding, but as a matter of influence it is less so. If we wish to understand consumers for the sake of understanding consumers, the deeper we will plunge. If we wish to speak to potential users of our findings, higher-order interactions will be a deterrent. Large main effects, whether accompanied by theory or not, are more likely to serve as an impetus for action—and appropriately so. Our friends in marketing science know this well, perhaps because they have a salient external constituency. Their ability to produce empirical generalizations about fundamental marketing phenomena has advanced understanding and practice, irrespective of underlying theory (Hanssens 2009). We, on the other hand, have historically shied away from managerial prescriptions, but policy makers constitute an appealing constituency that could benefit from fundamental and enduring truths we might offer (e.g., Johnson and Goldstein 2003; Thaler and Sunstein 2008).

Impossible Versus Possible

Intellectual curiosity is admirable, but it is fair to ask whether we place undue stress on scientists by raising the bar for an acceptable contribution to an unreasonable height (Sutton and Staw 1995). Consider the following observation that captures very well the view of our leading consumer journal:

“This focus on the underlying process is critical and something that tends to distinguish BDT articles that appear in JCR from BDT articles that appear in other journals. BDT researchers who submit to JCR are encouraged not only to illustrate the phenomenon but also to develop theory that specifies why phenomena occur, how they occur, and under what conditions” (Kahn, Luce, and Nowlis 2006, p. 131)

Such a policy is disturbing on multiple levels. First, some phenomena are not easily understood, and the importance of a phenomenon is not diminished by its mystery. For some widely appreciated phenomena, the record shows that a satisfactory understanding might await decades of effort rather than a manuscript's worth. Indeed, by one measure the most influential article ever published in JCR (Huber, Payne, and Puto 1982) continues to this day to inspire a search for understanding (Tsetsos, Usher, and Chater 2010). Second, some phenomena are not reducible, at least within the confines of our current state of knowledge and the collective intelligence of the community. Gravity was not reduced to a “process” until Einstein

tackled it. Looking forward, some decision phenomena (e.g., loss aversion) and some psychophysical phenomena (e.g., visual dominance) may ultimately find process explanations, but the work that uncovers the processes may vie for a Nobel Prize. Looking back, it is clear that a bar set at this level would have disqualified luminaries of decision research (including previous Nobel Prize winners) from publishing in consumer journals. We do not know how many consumer phenomena have gone undocumented as a consequence of our restrictive policy, but we can be grateful that the policy has not been monolithic. One might argue that Huber et al. were able to evade the theory police by demonstrating a violation of classic choice theory. If so, theirs is an exception that proves the rule. If an intriguing but mysterious phenomenon merits publication only if it addresses existing theory, we need to reassess.

Finally, we should not minimize the dispiriting effect our policy has on our research efforts more generally. It is all the more lamentable when considered in light of the tolerance other scientific fields exhibit with regard to the question of the possible:

“One reason researchers believe that heart disease and many cancers can be prevented is because of observational evidence that the incidence of these diseases differ greatly in different populations and in the same population over time. Breast cancer is not the scourge among Japanese women that it is among American women, but it takes only two generations in the United States before Japanese-Americans have the same breast cancer rates as any other ethnic group. This tells us that something about the American lifestyle or diet is a cause of breast cancer. Over the last 20 years, some two dozen large studies ... have so far failed to identify what that factor is. They may be inherently incapable of doing so. Nonetheless, we know that such a carcinogenic factor of diet or lifestyle exists, waiting to be found.” (Taubes 2007)

Yours Versus Mine

The preceding quote illustrates yet another disturbing aspect of an uncompromising stance on theory—one that is especially bothersome to researchers who take a cognitive perspective. Causality can be described at a variety of levels. The epidemiological finding regarding breast cancer is causal but devoid of process. The cause that is tractable at this juncture exists at the level of nature versus nurture. To identify the cause as one or the other is nontrivial, and this level of explanation may suffice depending on one's taste and objectives. Cognitive researchers, on the other hand, are held to cognitive explanations. The wisdom of this requirement grows more questionable by the day as research increasingly shows how physical cause competes with psychological cause to explain behavior (e.g., Iacoboni 2008). We would do well to abandon the conceit that we can identify true cause at this stage of development.

A more catholic view of theory is not novel within the philosophy of science. Cook and Campbell's (1979) primer on theory reminds us that different scientists may legitimately use theory in different ways. Not everyone is—or should be required to be—an essentialist. Positivists who appeal to theory as a convenience rather than a reflection of truth use a theory only insofar as it aids prediction. In other words, one's view of theory is a matter of taste and, to repeat myself, taste should not be dictated.

Finally, a recognition that different scholars might view theory differently would be a triumph of pluralism over orthodoxy, which in turn would eliminate the contradictions we conveniently ignore. As noted, our peers in marketing science enjoy greater freedom to approach market behavior from an engineering perspective (Moorthy 1993). Within consumer research, classic ethnography may be favor-

ably viewed as dustbowl empiricism in the sense of a being an exercise in uncontaminated induction. Insofar as cognitively oriented consumer researchers must account for process, our field should be held accountable for its double standard.

CONCLUSION

Theory has many virtues, but we should not regard theory as a defining feature of scholarship. Likewise, a request for pluralism should not be taken as radical (Simonson et al. 2001). The hypothetico-deductive approach is an esteemed mode of scientific practice, cause-effect relationships are desirable, and process explanations enrich our understanding. However, it is not illegitimate to engage in abduction, to pursue the truth via an effect-cause sequence (with a significant delay between effect and cause), or simply to acknowledge that an if-then statement can be valuable even if the intervening causal link has not or cannot be identified (Rozin 2009). When serendipity strikes, we should celebrate it rather than banish the discoverer to a hellish investigative journey. We should routinely strive for interestingness, robustness, and generalizability—but we can do so both within and beyond the confines of theory.

I noted the irony of using the theory-oriented approach to boost our self-image through emulation of real science. With the benefit of 40 years of hindsight, we can also ask whether theory has served its purpose (Hubbard and Lindsay 2002). The results from a very informal mental meta-analysis of addresses given by leading consumer researchers are not consistent with a self-confident field that can point with pride to its many important and novel discoveries. One is struck instead by the frequency with which we question the parameters and contribution of our field. I cannot prove that our obsession with theory is responsible for this state of affairs, but it seems that discovery might be more frequent if we relaxed the constraints a bit. To reference one more Nobel Prize winner, the words of E.O. Wilson (1998, p. 6-7) are sobering:

“Original discovery is everything.” ... “The true and final test of a scientific career is how well the following declarative sentence can be completed: He (or she) discovered that ...”

I suspect that Wilson would not be satisfied with a career in which the scientist “discovered” how a finding in a different discipline could be applied to one’s own. Wilson’s stringent criterion for a successful career is accompanied, however, by a less stringent road to success:

“Advice to the novice scientist: There is no fixed way to make and establish a scientific discovery. Throw everything you can at the subject, so long as the procedures can be duplicated by others.”

APPRECIATION

This recognition, undeserved as it is, would not have been possible without the support and understanding of many. My wife, Pat, and my daughters, Elli and Billie, have provided much needed affection and have exhibited a saintly degree of patience. My academic advisors guided the baby steps of my career as a parent guides a child. Lynn Hasher watched over me while simultaneously treating me as a colleague. Bob Weisberg was brilliant but approachable. In subsequent years I benefited from a stupendously talented group of graduate students who inspired many research projects and will always be a source of pride. Many colleagues provided support when it was most needed. Jim Bettman and Brian Sternthal, in particular, helped pave the path to this day. They did so at a time when neither had a personal connection to me. I have also benefited enormously

from the everyday assistance of my local colleagues. In particular, John Lynch and Wes Hutchinson have been an inspiration. They are paragons not only of scholarliness but also of virtue.

Fellow's Address: Substantive Consumer Research

John G. Lynch, Jr., University of Colorado-Boulder, USA

I'm humbled and honored to be added to the ranks of the Fellows of the Association for Consumer Research. It's a particular honor and delight to be recognized along with Brian Sternthal and Joe Alba, two of the people I most admire in our profession.

Joe and I were part of Brian's AE team when Brian was Editor of *JCR*, and I would say Brian was my favorite boss ever. We share a deep interest in philosophy of science and methodology, and it was a pure pleasure to exchange ideas with Brian about issues raised by manuscripts I handled for him. And I don't think he ever reversed one of my recommendations -- showing great insight and discernment on his part. Joe was my colleague at University of Florida, lifetime friend, and coauthor on two of my favorite papers on my vita. Joe declining my repeated lunch invitations extended over 15 years as colleagues. So he also showed impeccable discernment and wisdom, and batted 1.000 in his own way. All kidding aside, Joe is the scholar I most often tell my doctoral students to emulate. His simple experiments build on each other to create great insight, and his writing is a model of clarity.

KVETCHING

I want to go negative and talk with you today about what I see as a two unhealthy trends in our field. The first trend is the tendency for our best young scholars and reviewers to think that the goal of every paper must be primarily to make a theoretical contribution -- preferably with a mediation analysis. The second is our collective acceptance that our field is made up of multidisciplinary silos. Debbie MacInnis and Valerie Folkes (2010) make a compelling case that the original vision of *JCR* and *ACR* as homes for truly interdisciplinary work has long given way to a reality that we are a multi-disciplinary rather than an inter-disciplinary field. We nestle together in the pages of *JCR*, but we aren't really informing each other's work as much as we wish, and it is quite unusual for a given paper to draw strongly from ideas in two or more different disciplines --say psychology and economics.

Some people don't see either of these as problems, but I do. My thesis is that if we would more often look to the substantive domain as inspiration for our research, three good things would happen. Our work will be of interest to a wider public, we will have more vibrant mutual influence with adjacent social science disciplines, and in our dialogue within our field, consumer researchers of different primary disciplinary orientations will benefit more richly from each other's work.

BRINBERG AND MCGRATH'S VALIDITY NETWORK SCHEMA

Brinberg and McGrath developed their "Validity Network Schema" in a book and several articles in the 80s, and what I'm going to say in the rest of my remarks uses their foundation. The Figure below is from McGrath and Brinberg (1985). They pointed out that all research requires combining elements and relations from three domains: the conceptual domain, the methodological domain, and the substantive domain. Examples of concepts might be accessibility, diagnosticity, construal level, resource slack, or consideration set. Methods might be ethnography, meta-analysis, structural equation model of survey responses, mediation analysis, or 2 x 2 factorial design. Substantive phenomena might be price sensitivity

on the Internet, household budgeting, or "Yes...Damn" agreeing to future activities that one later regrets. Scholars have different priorities on these three domains that produce conflicts in judgments of what constitutes "good" research.

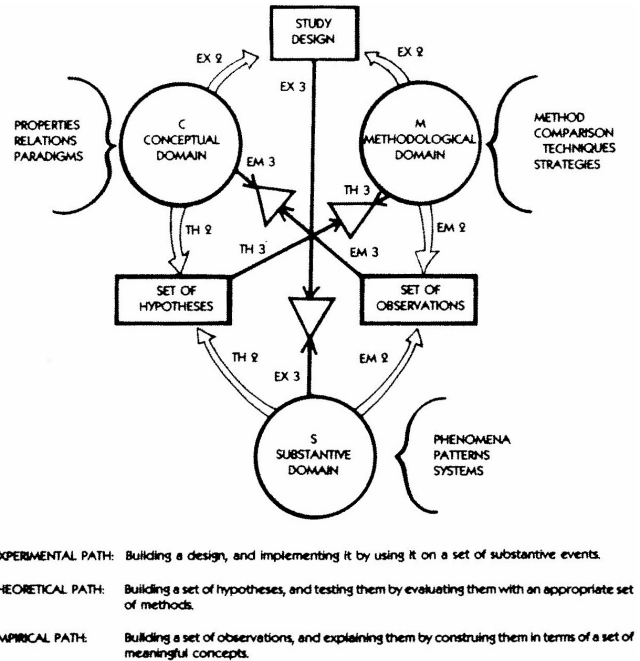

Figure: Validity Network Schema, from Brinberg and McGrath (1985, p. 22)

Brinberg and McGrath noted that researchers typically start with an interest in one domain, tie it to a second, and then choose elements from the remaining domain as a matter of convenience.

- In the "theoretical path", one builds a "set of hypotheses" by first combining elements and relations from the conceptual and substantive domains and then finding some convenient methodology to test them.
- In the "empirical path", one builds a "set of observations" by combining elements and relations from the substantive and methodological domains and then picks some convenient concepts to explain them.
- In the "experimental path", one creates a "study design" by first combining elements and relations from the conceptual and methodological domains and then picks some convenient substantive context as a way to operationalize the test of interest.

Brinberg and McGrath take pains to say that each of these paths is equally legitimate. But I was trained as an experimental social psychologist, and I made my reputation in this field in my first 15 years as a rigorous practitioner of the "experimental" path. I didn't place much value on "applied" research, and I got my ideas for my papers from the pages of journals, as in my work on the accessibility diagnosticity (e.g., Lynch, Marmorstein, and Weigold 1988; Simmons, Bickart, and Lynch 1993), or research explaining contrast effects

1. "Experimental" path may be a misleading term. It is not necessary for the concepts to be tied to *experimental* methods to be "experimental path" -- just that the substantive context for the research remains as a tertiary focus.

(e.g., Lynch, Chakravarti, and Mitra 1991). I see a lot of people with similar attitudes rising to positions of influence in our field.

But at my current stage of career, I think the “theoretical” path and the “empirical” path have gotten a bum rap. My beef is that the experimental path has become almost monolithic in the pages of *JCR* and *JCP*. The young scholars who I most respect seem to undervalue empirical path papers and to have an overly narrow view of what constitutes a good theoretical path project. Let me elaborate.

The Empirical Path

The “empirical path” is alive and well among our marketing science brethren, but not in consumer research. If one looks at the last 10 O'Dell Award winners, I'd classify half as “empirical path” marketing science -- e.g., Mela, Gupta, and Lehmann (1998) work showing how advertising makes people become less price sensitive in the long run and price promotion makes them more price sensitive. And there's a rich tradition of “empirical generalizations” papers that carefully show some facts about the marketplace.

In consumer research, reviewers make it tough to publish this kind of “atheoretical” empirical path research. That's a shame. I've found such papers to be particularly useful in my own work. They tell us what neglected topics in consumer research might prove to be truly important.

In the early 80s, I was slaving away with many others on models of multi-attribute combination rules. It was edifying to read primarily descriptive papers like Hoyer (1984). Hoyer showed that consumers engage in *very* low in-aisle search, and only 9% could give more than one reason for why they bought the brand of detergent they purchased. So much for multi-attribute combination rules. Papers like Wayne's made me conclude that I should shift my focus to *very* low-level consumer information processing, including processing below the level of conscious awareness (e.g., Lynch and Srull 1982; Feldman and Lynch 1988; Lynch Marmorstein and Weigold 1988; Alba, Hutchinson, and Lynch 1991).

Similarly, it was an eye-opener to read Hauser (1978) document that 78% of the explainable uncertainty in consumer choice outcomes is driven by what brands are considered at all, with only 22% of the explainable uncertainty tied to attribute-based preferences among considered brands. That led me and my colleagues and students to conclude that we should try to understand the workings of consideration sets (e.g., Lynch and Srull 1982; Alba and Chattopadhyay 1985; Nedungadi 1990; Alba et al. 1991; Hutchinson, Raman, and Mantrala 1994; Mitra and Lynch 1995; Alba et al. 1997; Diehl, Kornish, and Lynch 2003).

The Theoretical Path

A lot of people code research motivated by a problem in the world as “applied” and they think the task of a theorist is to identify construct-to-construct relations in some nomological net. Brinberg and McGrath remind us that the “theoretical path” is not just about construct-to-construct relations. It is also about relations between concepts and substantive phenomena. One can make important theoretical contributions either by starting with concepts and then linking to substantive phenomena or by starting with substantive phenomena then searching for concepts to explain the phenomena.

For readers who want to contribute to theory, I want to recommend this latter path to you -- start with the consumer phenomenon and then try to explain it rather than always starting with concepts in the literature and then thinking of where they might apply. Gal Zauberman and I were amused and frustrated by our own foibles -- apparently shared by others. We committed the “Yes...Damn!” effect, saying yes to attractive activities in a month that we would

say no to tomorrow because we believed we'd have more spare time in a month. At the same time, we persistently fooled ourselves into believing that next week would be the week that we would stop procrastinating on some important but not urgent task. These substantive facts led us to conceptualize those phenomena in terms of our resource slack theory of discounting (Zauberman and Lynch 2005).

Sometimes the theorist's task is not to conceptualize some individual behavior, but also some more macro consumption system. If the substantive phenomena are themselves really important, it is a real theoretical contribution to put structure on those phenomena. This almost always required combination of concepts from several disciplines. That is what we tried to do in our work on online shopping, first in the Alba et al. (1997) *Journal of Marketing* paper on interactive home shopping with our Florida colleagues, then with Dan Ariely in our (2000) wine online work, and then in Diehl, Kornish, and Lynch (2003) and Ariely, Lynch, and Aparicio (2004) about the role of screening agents. In all those cases, one of the major substantive questions was whether online shopping would lead to increased price sensitivity and ruinous price competition. My colleagues and I reasoned that retailers provide information similar to information provided by advertising. We used concepts from other literatures on the economic effects of advertising (Mitra and Lynch 1995, 1996) to make novel statements about when online shopping would or would not lead to increased price sensitivity and price competition.

THE SUBSTANTIVE DOMAIN AS A PLATFORM FOR CONVERSATION

What's Interesting?

Abelson (1995) said that research is “interesting” if it shifts one's beliefs about something that one cared about already. If I write about some topic that most people don't have any beliefs about, or if there's not a reason they'd care about their prior beliefs, it is harder for me to convince those people that my work is interesting. I liked my “experimental path” papers and early in my career, I considered it a badge of honor if only “in the know” could appreciate my papers. But later I came to realize that there were costs of being so specialized in my approach, and that I limited my audience in doing so. When I came into the field doing mathematical models of information integration, I found that behavioral people who understood the psychological issues couldn't follow the methods, and the people who understood the mathematical methods didn't understand the psychological literatures. So I switched what I studied.

If one's goal is to attract the interest of a broad rather than a narrow subset of colleagues, one can raise one's chances of success by choosing problems motivated by questions about the substantive domain. Think about how AMA interviewers perk up more when interviewees motivate their research with some real world behavior that the interviewers understand rather than leading with a literature-based motivation. When we lead with substantive phenomena, more in the audience have prior beliefs, and the topics are things they more readily care about. When we follow the “experimental” path, in contrast, it is common that a smaller set of people understands both the concepts and the methods.

I contend that substantively motivated research can a) attract broader interest among to lay people (as reflected in popular press coverage); b) stimulate greater interest and citations from scholars in adjacent social sciences; and c) inspire more vibrant within-field conversations among scholars with very different disciplinary orientations.

Influence on the Outside World

I would argue that substantive papers are especially likely to get significant press. People are interested in our work that illuminates some real world substantive phenomenon that people can see in themselves – more so than our papers that are primarily about constructs or methods.

Influence on Scholars in Adjacent Social Sciences

A more important measure of the success of our field is the degree to which scholars in other fields use our ideas and findings. Just individual scholars are judged less successful if they are the only ones citing their own work, we cannot judge ourselves to be successful as a field if our work is used only by others in our same field. Many have noted that we consumer researchers seem to import from other social sciences more than we export.

I contend that our prospects for export are greater for work that aims to make a contribution to the substantive domain. Substantive topics are inherently interdisciplinary, and that means I perceive that I learn a lot from work on the same topic from a scholar in another field and he or she might have the same perception.

Lately I've gotten into the field of consumer financial decision-making. This is a field where we consumer researchers can make important contributions to science and society. It's also a field that lends itself to learning from our colleagues in allied social sciences. Last year we at CU hosted the First Annual Boulder Summer Conference on Consumer Financial Decision Making. It was a remarkable conference because of the set of people in the room. We had scholars from Finance, Economics, Decision Sciences, Consumer Sciences, Marketing, Neuroscience, Psychology, and Behavioral Economics, learning from each other and from regulators, and consumer advocates in a common conversation. Candidly, I felt that I learned more from the average talk at this financial decision making conference than from the average talk I attend at ACR, where I feel there is more overlap between what I know and what the other attendees know. The benefit of interdisciplinary interchange is also what motivated Shlomo Benartzi, Stefano Della Vigna, George Loewenstein and me to propose and co-edit the *JMR* Special Interdisciplinary Issue on Consumer Financial Decision Making. We were very pleased with the 85 submissions we got from leading figures across those fields, and our hope is that this special issue will generate significant cross-field citation.

My conjecture is that interdisciplinary export and import is stronger for work that has a substantive focus than for most of what we do that starts in the conceptual or methodological domains. It's not just consumer financial decision-making, but other core topics we study. I was pleased to see Pierre Chandon and Brian Wansink (2007) win this year's *JCR* Award for their paper on health halos. Brian and then Pierre were pioneers in choosing a substantive topic of food consumption that was not "mainstream" consumer research when they started, though it has become mainstream due to their scholarly leadership. Their paper is the third most cited paper published in the 2007 issue of *JCR*, and almost 40% of those citations come from outside of consumer research and marketing. That's no accident; their own references came almost half from outside of consumer research and marketing, drawing from journals in economics, psychology, sociology, dietary science, medicine, judgment and decision-making, and nutrition.

Influence on Consumer Researchers with Different Disciplinary Orientations

If substantively motivated research gives stronger motivation for exchange with adjacent disciplines, it also gives us a stronger rea-

son to talk with each other and learn from fellow consumer researchers despite our different disciplinary orientations. I mentioned earlier the MacInnis and Folkes (2010) paper on the sociology of science of consumer research. It did a great job of documenting that the original vision of our field as an interdisciplinary social science had long given way to a multidisciplinary reality. Scholars (almost all housed in marketing departments) come from different disciplinary orientations that are rarely combined in a single paper.

This is an excellent and compelling paper, but I found it depressing. I know that there is truth to what Debbie and Valerie say because I see it in my role as ACR's representative to the *JCR* Policy Board. Two years ago the American Economic Association decided to drop its sponsorship of *JCR*, and we regularly have to provide help to the presidents of other sponsoring associations to identify appropriate representatives to that board. We have ceased to be relevant to them.

For my part, I think the original vision of the founders of *JCR* and ACR was inspiring. I don't want to let it go. I submit that we can find our way back to that interdisciplinary path with more substantively motivated consumer research. In the process, we can be a more influential field.

CONCLUSION

There is more than one path to contribute to consumer research. We do not always have to follow the "experimental" path of reading the journals to get ideas about construct-to-construct relations, then designing a study to test the ideas in some convenient substantive context. We can also follow Brinberg and McGrath's (1986) "theoretical" & "empirical" paths that prioritize understanding something new about the substantive domain.

A larger role for substantively motivated research can help our field in three ways. Substantively motivated consumer research can remove our paradigmatic blinders to help us see new topics for research that later scholars will recognize as truly central topics for consumer research. It can increase our influence in the public domain and among other social sciences. And it can increase our ability to learn from each other as an interdisciplinary field.

THANKS

Nobody receives such an honor as we received today without a lot of help. My wife Pat and my parents John and Bobby Gay are in my heart today. I'm the product of great colleagues and doctoral students at Florida, at Duke, and now at Colorado. But I particularly want to thank three people to whom I owe a deep debt of gratitude.

In my PhD program in social psychology at the University of Illinois, Bob Wyer taught me to get in the habit of generating testable research hypotheses. Thanks to Bob, I can't read a journal article without scribbling ideas in the margins. Bob remains my model for how I aspire to treat my students. I'm always telling them things Bob said to me that have some analogy to their situation – e.g., "word salad" to point out some particularly tortured prose, or Bob's famous line on the 6th draft of my thesis, "The need for excellence is beginning to be exceeded by the need for closure." Bob managed to be critical and so enthusiastic at the same time. That's a winning combination. His attitude about the excitement of research gave me the value system that has carried me through my career. I'll always be grateful that the Editor of *JESP*, one of the most productive authors in the history of social psychology and the most hotly sought advisor at the University of Illinois made time for a screw-up of a PhD student whenever I came knocking on his door.

Based on Bob's recommendation, Joel Cohen hired me at University of Florida when I knew nothing about consumer behavior

and marketing. Joel has been a lifetime mentor and friend. I wish I were as good a senior colleague to assistant professors at Florida, Duke, and CU as Joel was to me. When I didn't know anyone in the field, Joel introduced me around at ACR to big names like Jim Bettman, Carol Scott, Alice Tybout, and Peter Wright, and encouraged them to take me seriously. Joel stimulated my thinking. When I first arrived doing work on information integration, Joel needled me about its relevance to consumer decision making when inputs came from memory. I harrumphed, but eventually concluded that Joel's "irritating" question was a good one, leading me to collaborate with Thom Srull to develop distinctions among stimulus-based, memory-based, and mixed choice. Joel and Bill Wilkie hired five people in my assistant professor cohort went on to become ACR or SCP Presidents, making my early years assistant professor nirvana. I'm proud that along with those guys and others hired later, I was a part of the "Florida School" that produced a large body of research highlighting the role of memory, attention, and basic information processes in consumer decision-making.

When I moved to Duke, I was fortunate to have another set of outstanding colleagues and students whom I truly love. But I want to single out Jim Bettman. Jim has been like a brother to me – a smarter older brother who still has all his hair and great taste in music. Jim is a glue guy who created an exciting and collaborative culture at Duke. He is generous to a fault, and more *JCR* and *JCP* authors have thanked him than any other person in the field. He and I had the pleasure of co-chairing doctoral dissertations by many brilliant Duke students over the years, whose reflected glory I'm sure played a role in my receiving this honor today.

Fellow's Address: Three Silos and a Theory: Developing Nomological Networks to Explain Consumer Behavior

Brian Sternthal, Kellogg School of Management, Northwestern University, USA

Preparing for this talk prompted me to reflect on the evolution and direction of consumer research during the 40 years I have been in the field. When I started my career, there was an emphasis of developing a discipline base for studying consumer research, whether that discipline was economics, psychology, sociology, anthropology or home economics. There was also an emphasis on a multi-disciplinary approach to investigating consumer behavior. The first issue of *JCR*, published in June 1974, contained articles dealing with consumer economics, family decision making, statistical decision models and persuasive message effects. The *JCR* editorial board was represented by people from industry, as well as by academics trained in economics, home economics, human ecology, psychology and marketing.

Today, the multi-disciplinary focus remains and knowledge in the various domains has expanded dramatically. *JCR* annually publishes about twice as many articles as were published in 1974, and there are almost as many *JCR* Associate Editors as there were editorial board members when *JCR* was launched. The rapid accretion of knowledge in consumer research provides an opportunity that would not be possible without this development. It is to integrate knowledge that has been accumulated in disparate areas as a basis for developing a more general understanding of consumer behavior. Investigators in consumer research have an advantage in pursuing this analysis because the field is sufficiently small that integrating disparate theoretical views does not undermine a researchers' visibility, which often motivates a narrow focus by investigators in basic disciplines.

The opportunity to develop a more general understanding of consumer behavior emerges regardless of the domain in which this is done. For example, consumer culture research has provided rich descriptions of star trek fans (Kozinets 2001), mountain men (Belk and Costa 1998), Harley owners (Schouten and McAlexander 1995), and Burning Man (Kozinets, 2002). A more general understanding of these behaviors might be achieved by examining the factors that are common to these behavioral domains and that distinguish one from another. At issue is what explains the adoption of these unique behaviors and what prompts the choice of a specific alternative? Along the same lines, the demonstration of a variety of intriguing effects related to judgment and choice (e.g., attraction, compromise, compatibility, conjunction, contagion; cf., Gilovich, Griffin and Kahneman 2002) presents the opportunity to develop a more general understanding of consumer motivations by assessing when each of these decision strategies is likely to be invoked. Finally, investigations conducted under the rubric of information processing have reported the effects of a variety of factors related to resource allocation including repetition, involvement, and regulatory depletion. Each of these domains offers insight about how people make decisions. However, these insights have not been elevated to a level that informs understanding of how consumers make judgments beyond the variables investigated.

In this talk, I shall illustrate the development of a more general theory by examining how integrating disparate lines of inquiry pertaining to consumers' resource allocation accelerates the development of knowledge about consumer self-regulation in decision making. Three distinct areas of research will be examined as a basis for developing the more general theory: repetition, involvement, and regulatory depletion effects. The goal of this analysis is to develop converging inferences that offer a more general understanding of consumers regulate their resource allocation in rendering judgments than would be possible with a less encompassing analysis.

REPETITION EFFECTS

Investigations of repetition effects typically involve varying the number of exposures to a persuasive message and examining recipients' evaluation of the advocacy. A repeated finding is that repetition of a persuasive message is nonmonotonically related to persuasion (Anand and Sternthal 1991; Cacioppo and Petty 1979). In response to successive exposures to a persuasive message, recipients first process the message content. Once this information is learned, they either process their own message-relevant thoughts, other idiosyncratic thoughts, or simply stop thinking about the message (Greenwald 1968). Because the message is designed with the intent to influence judgment, thoughts that represent this content are more likely to be persuasive than the idiosyncratic ones generated by the message recipient. Thus, it is the rehearsal of message information that enhances persuasion, and the rehearsal of message recipients' idiosyncratic thoughts or the absence of thought generation that cause it to decline, a phenomenon that is referred to as wearout. At some point, additional exposures beyond those needed to produce wearout reverse this decline and enhance message persuasion. This outcome is thought to occur because the rehearsal of one's own thoughts makes message information less accessible and thus again informative to the message recipient (Anand and Sternthal 1991).

This account for repetition effects suggests that individuals regulate their resource allocation to the message content so as to help them make judicious decisions. As message exposures mount, the allocation is initially to the message, then to other thoughts and then to the message once again. This theorizing is supported by the demonstration that an increase in the number of exposures is accompanied by an initial increase and then a decrease and an increase once again in the number of arguments supporting the message, and the reverse for arguments that are counter the advocacy (counterarguments).

Although this account has survived 20 years of scrutiny, it is incomplete. It presents the notion that consumers self-regulate by changing the focus of their processing; but it does not indicate what prompts this shift beyond the fact that it occurs after a number of exposures to the same message. Some insight about what triggers the shift between processing the message and one's own thoughts is offered in a repetition study conducted by Smith and Dorfman (1975). Their stimuli were complex and abstract patterns composed of black and white rectangles rather than persuasive message content. Yet, the same pattern of responses was observed as those found when the stimulus was a persuasive message: Judgments became increasingly favorable on initial exposures, declined as exposures continued to mount, and then become more favorable again. Because of the abstract nature of the stimulus, these outcomes are not readily explained in terms of individuals' message and own thoughts, but they can be accounted for in terms of Berlyne's (1970) notion of positive habituation and tedium. According to this view, in response to initial exposures individuals experience habituation to the stimulus accompanied by a feeling of increased confidence about what the nature of the stimulus, which is reflected in enhanced persuasion. Further exposures to the stimulus prompt the onset of tedium, a feeling that results in less favorable assessments of the stimulus.

Applying Smith and Dorfman's findings to the repetition effects observed when the stimulus is a persuasive message suggests that a metacognitive process is responsible for the effects of repeating a persuasive message. Specifically, initial exposures to a persuasive

message enhance the feeling of confidence about the knowledge that has been acquired. At some point, however, message content is known and confidence asymptotes. It is supplanted by a feeling of tedium, which prompts either a scrutiny of the message by activating extra-communication thoughts such as counterarguments, or a cessation of thinking about the message. In either event, evaluation of the message advocacy declines. Continued repetition of the message activates the processing of its content anew because message recipients processing of their own thoughts reduces the tedium attendant to processing the message and lowers confidence that they have internalized message content.

Thus, the emerging view is that the effects of message repetition are guided by metacognitions in the form of confidence and tedium that serve an executive function in directing the amount and type of thought generation. As plausible as this account might be in explaining the effects of repetition on the activation of support and counterarguments and the attendant persuasive effects, the evidence favoring this view is incomplete. It would be bolstered by the evidence to document that the metacognitive processes hypothesized are operative in the context of persuasive message repetitions. It can also be bolstered by examining other contexts in which resource allocation is likely to be influenced by metacognitive processes similar those thought to be activated to regulate the processing of message repetitions.

MESSAGE INVOLVEMENT

Additional insight about the resource allocation process is provided by work on involvement. A seminal finding is that when experiencing a resource limitation, consumers use cues that accommodate this limitation to make a judgment. Along these lines is the observation that individuals who have low involvement in a message issue use the credibility of a message source, or the number of arguments made in favor of an advocacy, or some other so-called peripheral cue rather than message content as a basis for making a judgment (Cacioppo, Petty, and Schumann 1983). In contrast, those who are highly involved are more likely to rely on a central cue such as the message content in rendering their judgments. This suggests that decision makers select the cues that enable them to accommodate the resources they are willing to devote to a processing task to render a judgment about an object. However, it has also been demonstrated that highly involved individuals are willing to process source and message cues in circumstances when both inform their judgments (Petty and Cacioppo 1979). Apparently, what distinguishes which cues are central and peripheral depends on their perceived value in evaluating an object. Thus, highly involved individuals exhibit discretion in their resource allocation by processing source cues in instances when they are deemed useful and considering them peripheral to judgment when they are not.

Finally, there are demonstrations that the level of involvement can prompt regulation of how a particular cue is processed. When individuals are highly involved in a message issue, the color of an object presented in an ad serves as a cue to elaborate on the benefits of the advertised brand. However, when they allocate relatively few resources, this same color cue is processed heuristically as a basis for judgment (Meyers-Levy and Peracchio 1995).

Research on involvement thus suggests that individuals are judicious in their resource allocation. When they have interest in an issue, they allocate substantial resources to the processing of message information, whereas when the issue is peripheral to their interests they rely on cues that accommodate this resource allocation in making a judgment. In some cases, high involvement entails elaboration of a single cue such the message source, the color of an object

presented an ad, or message content, and in others it give rise to the processing of multiple cues such as the message and source. Under low involvement, individuals process cues that are less resource demanding or they process cues in a less elaborate manner.

These observations raise the question of how do those varying in involvement decide which cues to process as a basis for their judgments. As suggested for repetition effects, one possibility is that individuals select cues on the basis of metacognitions prompted by stimulus processing. Along these lines, individuals' level of issue involvement prompts the activation of a threshold for the onset of tedium, which guides both the selection of the cues that will serve as a basis for judgment and the depth at which cues are processed. As was the case for repetition effects, evidence documenting this process has not been reported. However, there is emerging evidence that implicates the coordination of cognitive and metacognitive processes in resource allocation. This research pertains to the effects of depletion on subsequent task resource expenditure.

RESOURCE ALLOCATION AND THE DEPLETION EFFECT

The depletion effect refers to the phenomenon where the resources allocated to the initial task affect those allocated to subsequent task: the greater the allocation to the initial task the fewer the resources devoted to a subsequent task. In most demonstrations of this phenomenon, the two tasks are not related. For example, as part of a food tasting study participants in the high depletion condition were asked to refrain from eating cookies, whereas this requirement was not imposed on those in the low depletion condition (Baumeister et al., 1998). All participants then performed a second task, which involved an attempt to complete an unsolvable puzzle. Those who refrained from eating cookies spent less time on the puzzle than those who did not have to engage in such initial self-regulation, thus providing evidence for the depletion effect. In everyday situations, the depletion effect is observed when regulation of some activity such as smoking or drinking results in the lack of regulation of a subsequent activity such as eating or shopping.

The initial explanation offered for the depletion effect was cast in terms of a resource limitation (Baumeister et al., 1998). To the extent that people allocate resources to an initial task, they have fewer resources to allocate to a subsequent task. This is based on the notion that there is a single pool of resources that can be consumed or significantly reduced by the performance of an arduous self-regulatory activity. Replenishment requires rest, consumption of food that provides energy (Gailliot et al., 2007), or practicing task performance (Muraven, Baumeister and Tice, 1999).

A substantial number of studies document that the depletion effect is unlikely to be attributable to a resource limitation. In these studies, individuals exhibit the same level of performance whether they are highly or less depleted when provided with the motivation to do so. This is achieved by paying depleted individuals for their performance on a persistence task (Baumeister et al., 2005), suggesting that persistence is warranted because the issue is important (Muraven and Slessareva, 2003), and informing participants of the time they have spent in performing a persistence task (Wan and Sternthal, 2008). In addition, there is growing evidence that the depletion effect can be reversed so that highly depleted individuals exhibit better performance on a subsequent task than those who are less depleted. This reversal has been documented by presenting two initial tasks prior to the critical task rather than a single initial task (Converse and DeShon, 2009), using two tasks that involve similar activities rather than the unrelated tasks typically employed in depletion research

(Dewitte, Bruyneel, and Geyskens, 2009), and by prompting participants to adopt a high level of construal (Agrawal and Wan, 2009).

These observations suggest that the depletion effect is better explained in terms of individuals' motivation to allocate resources they have rather than a resource limitation. A monitoring view offers such an explanation (Agrawal and Wan 2009; Baumeister et al. 2005; Baumeister 2002; Baumeister and Vohs 2007). According to this view, people set a goal and a standard that is necessary to achieve this goal, and continually adjust the allocation of resources needed to achieve this standard. For example, a consumer might consider \$200 an appropriate amount to spend on a pair of shoes and continue to search until an appropriate pair that is within this budget is found. However, when people are depleted, they abandon such goals and standards and focus on their fatigue as a basis for resource allocation: the more tired they feel, the less the effort allocated to the task. Because all participants in the typical two task procedure used to demonstrate the depletion effect typically experience some level of fatigue, their performance of a focal task would depend on the amount of fatigue experienced. In contrast, if a standard of performance were made salient, it would serve as a basis for resource allocation to the second task. And if the initial task served as a standard for performance of a subsequent task, those who set a high standard by engaging in an initially highly depleting task would exhibit better performance on the subsequent task than those who engaged in a less depleting initial task.

A critical assumption underlying these predictions is that the same cue can serve both as a means of interpreting a behavior (fatigue implies less performance) and as a standard for a behavior (fatigue implies a high standard for subsequent performance). Support for this assumption is found in research on context effects (Nam and Sternthal 2008). Experts and novices with regard to musical instruments were presented a persuasive message advocating the purchase of a musical system. The qualities of this product were ambiguous. This ad was presented in the context of an ad for a BMW, toward which message recipients were favorable, or Hyundai toward which they were unfavorable. Experts used this contextual information to interpret the target musical system and thus exhibited assimilation: they were more favorable when the context was BMW than when it was Hyundai. In contrast, novices used the contextual information as a standard and thus exhibited comparison contrast: they were more favorable when the context was Hyundai than when it was BMW.

Several studies identified earlier offer support for the monitoring prediction that more depleted individuals will exhibit superior second task performance than less depleted ones and that this outcome is likely when the resources allocated to the first task are viewed as a standard for subsequent task performance. For example, having people perform multiple initial tasks makes the initial task salient as a standard for performance (Converse and DeShon 2009), which leads more depleted people to set a higher standard. Along the same lines, when the initial and subsequent tasks are similar, the relationship between the tasks makes the initial task salient as a standard for subsequent performance. And prompting people to adopt a high level of construal enhances the connection between the unrelated initial and second tasks in a depletion procedure, which makes the initial task accessible as a standard. In contrast, a low level construal makes salient the fatigue produced by an initial task as the basis for subsequent performance, and thus the more resources allocated to the initial task, the fewer allocated to the subsequent task (Agrawal and Wan 2009).

Recent research that I have conducted with Echo Wen Wan and Alice Isen examining the moderating role of positive affect on deple-

tion offers additional evidence favoring the monitoring account. In these studies, participants were presented information that stimulates either positive or neutral affect immediately after being highly or less depleted by an initial task. Neutral affect was stimulated by having people consider an event with a neutral outcome, whereas positive affect involved having people think about an event that had a favorable outcome. Performance on the subsequent task by those in neutral affect provided evidence for a depletion effect: highly depleted individuals exhibited poorer performance on the subsequent task than those who were less depleted. In contrast, those experiencing positive affect performed better when the initial task had been highly depleting rather than less depleting. Apparently, positive affect activated between the two tasks stimulated the use of the effort induced by the initial task as a standard for the performance of the subsequent task. Moreover, the depletion effect found in the neutral affect condition was mediated by participants' feeling of fatigue, whereas for those experiencing positive affect, performance of the second task was mediated by the perception of effort required to perform this task. These findings thus support the view that those in the neutral affect condition used the fatigue induced by the initial task as a basis for subsequent performance, and those experiencing positive affect used the first task as a standard for performance of the second task.

The monitoring model not only suggests that prompting people to focus on their goal rather than their fatigue enhances performance on a subsequent task, but also predicts that the depletion effect should be moderated by the framing of the initial task. Given the premise that depletion effects occur because a feeling of fatigue serves as the basis for reducing the resource allocation to a subsequent task, altering how this feeling is experienced might be used to enhance the allocation of resources to a subsequent task and overcome the depletion effect. If the initial and subsequent tasks are framed as a single task, individuals should not have the opportunity to reflect on the experienced in performing the initial task when determining their allocation to the subsequent task, and this should eliminate the depletion effect. Alternatively, the depletion effect should be eliminated if the initial task is framed as one that facilitates the second task, or at least draws attention away from the fatigue resulting from first task performance.

These predictions are confirmed in several studies. In research conducted with Echo Wen Wan, participants were presented a two-task depletion procedure where the second task involved customizing products such as a suit or other clothing and accessories. When the two tasks were represented as a single task, the depletion effect found when the procedures were represented as two separate tasks was eliminated. This outcome occurred because the feeling of fatigue that mediated the depletion effect was not observed in the one task condition. Indeed, participants in the one task condition did not differ in their perception of fatigue whether the initial task was highly resource demanding or not.

There is also evidence that framing the initial task as enhancing subsequent performance eliminates the depletion effect. Martijn and colleagues (2002) found that individuals who were informed that working hard on a task enhances subsequent performance exhibited better performance on this latter task than either those who were highly depleted, but not informed about the effect of prior effort exertion, or those who were not initially depleted. Along similar lines, Clarkson et al. (2010) observed that those highly depleted by an initial task worked harder on a subsequent task when they were told that a feature of the initial task (i.e., the color of the paper on which the task was completed) was known to be exhausting than when this feature was described as replenishing. Apparently, the attribution of

the fatigue to a feature in the initial task that was not present in the subsequent task led to the inference that substantial resources were available for performing the latter task. However, when people felt that they were tired despite the presence of a replenishing feature, they inferred that fatigue induced by the initial task was indeed substantial, focused on this feeling of fatigue in determining resource allocation, and limited their allocation to the subsequent task.

The view emerging from depletion research is that the effect of initial task performance on the resources allocated to a subsequent task is guided by two factors. One is cognitive; the standard that the individual sets for task performance determines the resources allocated to it. The other factor is metacognitive; the feelings prompted by the performance of an initial task guide the subsequent resource allocation. The depletion occurs because the greater the resource allocation to an initial task, the greater the feeling of fatigue, and thus the fewer the resources allocated to a subsequent task. Stated another way, the metacognitive experience attendant to an initial task guides the resource allocation to a subsequent task. In accord with this interpretation, the depletion effect can be overcome by making salient cognitions related to the standard for performance of the second task, ignoring the metacognitive experience of fatigue attributable to the previous resource allocation, or by interpreting this experience in terms other than fatigue that stimulates substantial allocation to a subsequent task.

AN INTEGRATED VIEW

The repetition, involvement and depletion literatures reviewed not only offers insight about the processes that explain the effects of these variables, each of these literatures offers insight about some facet of the regulatory process. And collectively they suggest that the cognitive operations individuals engage in when performing an information processing task are dependent on the metacognitions they activate. Some metacognitions promote the allocation of resources to a task, whereas other metacognitions limit such an allocation.

The analysis of repetition effects described earlier suggests that individuals' willingness to sustain the processing of a repeated message depends on metacognitions related to confidence and tedium. Actions taken are influenced by whether a subjective feeling of confidence is evoked in responding to a stimulus, which promotes resource allocation, or a subjective experience of tedium is activated, which limits resource allocation.

Depletion effects can be explained using these same concepts, though the focus of these investigations is on metacognitions that limit resource allocation. Depletion research suggests that tedium or fatigue might prompt a reduction in resource allocation. Repetition research is informative about the mechanism underlying depletion effects; it suggests that metacognitions related to the feelings of confidence that emerge upon learning and mastering tasks are likely to propel the resource allocation observed under low depletion. This account explains the observation that when individuals are highly depleted, presenting an initial task as enhancing the performance of a subsequent task prompts a resource allocation that eliminates the depletion effect found in the absence of this motivation.

Depletion research also informs an understanding of repetition effects. Investigations of the depletion effect document that the feeling of fatigue can be managed by having people interpret the subjective experience of tedium in terms of goal attainment or to limit access to this feeling. These findings offer a starting point for managing wearout effects of repeated message exposures.

Investigations of involvement effects suggest that those under high involvement exhibit discretion in the allocation of their substantial resources. They engage in the processing of so-called peripheral

cues such as the message source based on an assessment of whether this information contributes to the judgment of a message advocacy. This observation suggests that regardless of involvement, there is a point at which the enhancement of confidence resulting from a resource allocation is offset by the tedium involved in processing additional information. The point at which this occurs differs between those who are highly and less involved. Applying this observation to depletion effects raises the possibility that non-depleted individuals will exhibit similar discretion and limit their resource allocation when this allocation is perceived to contribute more to fatigue than to confidence. Some evidence supporting this view is found in the demonstration that making salient an initial task as a standard for second task performance reduces the resource allocation that would otherwise occur. Demonstrations of naturally occurring social conditions when this outcome obtains awaits empirical demonstration.

ACKNOWLEDGEMENTS

The honor of being named an ACR Fellow is the result of a collaboration with mentors, colleagues and students. I am grateful to Jim Engel, whose passion for consumer research stimulated my interest in the area, to Tony Greenwald who taught me the how to think theoretically, to Roger Blackwell, who showed me how to advance research from ideas to outcomes, to Sid Levy who encouraged me to think abstractly, to Sam Craig who taught me how to make collaboration enjoyable, and to Alice Tybout whose wisdom about how to relate to people and ideas guided my personal and professional development.

I have benefitted from having intellectually stimulating colleagues. Collaborations with Bobby Calder enhanced my ability to situate research in a body of thought, and research conducted with Angela Lee has enhanced my experimental skills and provided insight about how to sustain research programs. I have learned from an affiliation and collaboration with doctoral students: Ruby Dholakia, Sue Jung Grant, Chris Janiszewski, Punam Keller, Durairaj Maheswaran, Joan Meyers-Levy, Prashant Malaviya, Michelle Roehm, Debbie Roedder John, Carol Scott, Echo Wen Wan and Richard Yalch. What is most gratifying is that these individuals exerted the effort to educate the next generation of scholars.

Finally, I want to acknowledge Joe Alba and John Lynch with whom I am sharing the honor of being inducted as an ACR Fellow and who served with me as editors of the *Journal of Consumer Research*. I benefited greatly from their skills, wisdom and passion for excellence.

Special Session Summaries

SPECIAL SESSION

Services as Social Structures: Consumer Collectives and Transformative Services Research

Laurel Anderson, Arizona State University, USA

Amy Ostrom, Arizona State University, USA

EXTENDED ABSTRACTS

“Conceptualizing Transformative Service Research”

Laurel Anderson, Arizona State University, USA

Amy Ostrom, Arizona State University, USA

In our presentation we seek to offer an alternate paradigm within which to consider the role of services and the service consumer within society. We pull especially from theories of social structure and ecosocial environments to frame our most dominant premises:

1. Services are so ubiquitous that they, to a large degree, structure the world within which consumers live, the ecosocial environment.
2. Reciprocally, other components of the ecosocial environment influence services and the success of services.
3. At times, there is a tension between these service social structures and the agency of individuals or groups of consumers.
4. In some sense, given services contribution to the social structure and ecosocial environment within which consumers live and their impact on consumer well-being, many services approach the level of a public good.
5. Services can be intentional, unconscious, or unintentional of their transformational impacts.

We utilize this paradigm to frame the area of transformative services research (TSR). In this conceptualization and theory building we both build on and add to the transformative consumer research stream. We define TSR as service research that strives to create uplifting changes and improvements in the well-being of both individuals and communities (Anderson, Ostrom, and Bitner 2010).

This transformative view is especially apt for looking at services because service consumers are often vulnerable (Baker, Gentry and Rittenburg 2005) in that they often lack a degree of control and agency, service consumers are often disadvantaged, most especially with regard to expertise and decreased knowledge in comparison to the service provider, and services are consumer-centric, experiential and co-created, thus more intimate than physical goods.

From this macro level view of services, it is apparent that services have the ability to uplift and transform individual consumers and communities. Conversely, “they also, often unwittingly, have the ability to marginalize, judge, and stigmatize citizens and communities and to compromise sustainability” (Anderson et al. 2010). If services create socio-cultural structures, they can be considered envirogenic (Jamner and Stokol 2000) and can act as stressors, as enablers of well-being or ill-being, as providers of resources and/or as sources of safety or danger. Furthermore, even though we are focused on the collective consumer, well-being is influenced not only by the environment, but also by personal attributes. There is a dynamic interplay between structure and person. The level of congruence

between the individual and the environment (structure) is connected to well-being. We will use research examples focused on consumer collectives to illustrate our above premises.

“There’s No Place Like Home...Or Is There?”

Stacey Menzel Baker, University of Wyoming, USA

Jose Antonio Rosa, University of Wyoming, USA

When Dorothy’s home is destroyed by a tornado in *The Wizard of Oz*, she sweetly declares, “There’s no place like home.” Her words resonate with viewers who have formed their own place attachments, which occur when individuals bond with particular physical spaces (Milligan 1998). Attachment to home or place develops over time and is formed through de-commodification and singularization processes (e.g., acquisition, decoration, ritual performance) that facilitate home becoming “me” or “mine” (Kleine and Baker 2004). Disruption of strong place attachments, such as those wrought by natural hazard events, leads to a profound sense of loss and necessitates renegotiation of self (Brown and Perkins 1992). In addition, when multiple displacements occur simultaneously, as they do in disaster, there is a loss of sense of *community*, and a desire to sustain community by keeping people *in* community. Such severe injuries create dependence and require the infusion of outside resources and services (shelter, food, clothing, financial assistance) into individuals’ lives and community for them to recover. Business, government, and non-profit services provide the resources which assist consumers in reconstituting the world in which they live.

The present research explores the tensions between community and individual identity reconstitution processes as housing (collective) versus home-creation (individual) needs are negotiated in disaster recovery. Qualitative, longitudinal data collected in a rural community in the Western United States impacted by a tornado inform our purpose. The tornado caused two deaths, rendered 100 homes uninhabitable, and left one-quarter of the community’s residents homeless. To understand how housing/home needs were negotiated, members of multiple constituent groups

were questioned about how recovery resources were garnered and distributed, as well as how resources were received and used.

Tensions between collective and individual identity reconstitution processes arose immediately after the tornado touched down, and continued throughout the entire data collection process (multiple site visits over the course of a year). Narratives reveal that the social and economic structure imposed by service providers supplying resources were at odds with survivors' familiar processes of home creation and the development of place attachment. We know that place attachments facilitate adaptation (Milligan 1998); yet our data show numerous impediments to reconstructing home: (1) recipients of burdens of costs versus the gift of benefits, (2) shared versus personal responsibility, (3) equality versus individuation motivations, and (4) personal privacy versus public transparency. Each constraint will be explored in the presentation.

Consider federal funds made possible the allocation of 60 identical trailers for displaced survivors. All were white on the exterior, all had the same floor plan, all had the same color of paint on the walls, and so forth. In other words, the behaviors, cognitions, and affect that typically lead to place attachment (e.g., freedom of choice over which home to inhabit and how to decorate it once occupied) were constrained by the commoditized state of the housing. The standardization of the trailers as well as rules against decorating trailers served to hinder positive adaptation by survivors. Though residents were displaced, they did not also want to feel misplaced. Survivors fought back and resisted the homogenizing forces of living in a commoditized home. Some broke the "rules" and hung things on the walls, while others viewed the housing as temporary and got out as quickly as possible, and still others had little choice and were forced to make the standardized housing their homes.

The presentation concludes with a discussion on (1) how transformative service research may play a role in community development or reconstitution and (2) the types of home-rebuilding services in disaster recovery that contribute to individual and community transformation. The data collection and analysis of this research is complete.

"When Consumer Well-Being Meets Small Business Ownership: Transforming Financial Service Systems to Eradicate Disparate Treatment and Discrimination"

Sterling A. Bone, Brigham Young University, USA

Glenn L. Christensen, Brigham Young University, USA

Jerome D. Williams, University of Texas at Austin, USA

Service systems are inherently complex because of the number and intricacy of the steps that construct them. This complexity creates a critical tension among service agents' abilities to follow formal procedures and structure to deliver desired service outcomes (Shostack 1987). The discretionary nature of many service systems requires employees to diverge from the normative to meet dueling demands of the firm and of their

customers (Bone and Mowen 2010). Bone and Mowen conclude that service agents in roles that require decision latitude may exert personal biases that result in disparate or discriminatory actions taken toward customers.

Complexity and divergence in service systems increases the risk that disparate, and even discriminatory actions will be taken by firms and their agents to achieve desired firm and employee outcomes. Prior research has argued that disparate or discriminatory actions are a threat to consumers that are in transitory states of vulnerability (Baker, Gentry, and Rittenburg 2005).

Particularly among immigrants, individuals, at an increasing rate, are starting small businesses in pursuit of their dreams in order to avoid barriers that come with traditional jobs (Kelleher 2008). Yet only two out of 10 small businesses succeed in the first year (Fairlie 2009). Stimulating growth and survival of small business is a pressing concern for federal, state, and economic stakeholders. Recent U.S. Senate hearings held on minority entrepreneurship call for transformative efforts to help minority-owned enterprises as service consumers overcome the "tremendous hurdles" that they "must face each day to gain fair and adequate access to venture capital, credit, and business and technical training" (Kerry 2008).

Census and economic research has reported that minority entrepreneurs are the most vulnerable to marketplace discrimination among consumer groups (Wainwright 2007). Where is discrimination among small business owners most likely to manifest its ugly head? A report from the U.S. Chamber of Commerce (2005) concludes that lack of access to capital and credit is the most common obstacle for African American and Hispanic business owners. Moreover, Wainwright (2007) reported finding quantitative evidence that minority-owned businesses are substantially and significantly more likely to be denied credit than are white-owned businesses. These consumers must maneuver complex service systems to garner the required resources.

In this paper we seek to disentangle the socio-cultural barriers in the small business bank lending service system. We argue that transformative service research can stimulate dialogue and intervention strategies to provide greater access to capital financing for racial/ethnic minority consumers, who out of necessity, start their own businesses. We employ an in-depth interview method to investigate the pilgrimage of consumers seeking to improve their quality of life through small business start-ups. The method chosen was the Zaltman Metaphor Elicitation Technique (ZMET) (Zaltman 1997), an in-depth interview format that focuses on uncovering the informants' emotions, beliefs, and values. We purposefully sampled small business owner informants to represent three racial/ethnic groups of small business owners: White/Caucasian, Hispanic, and African-American. Thirty-nine informants who owned a small U.S. business were recruited for this study. Sixteen were White, 13 were Hispanic, and 10 were African American. Informants were asked to prepare for their 90-minute interview by writing down at least five thoughts and feelings about seeking financing for their businesses. Informants were also asked to find a picture that represented each of their thoughts or feelings. The combination of the approaches elicited rich and descriptive insights into the informants' perceived vulnerability. Interviewers were matched to the informant based on their race and language of origin. This step was taken to enhance conversational flow and to ensure cultural sensitivity.

We contrast interviews conducted with the "White" majority to those conducted with minority consumers (African-American and Hispanic). Interpretive analyses use historical, political and sociological ideology perspectives to inform this comparison

of consumer experiences. We identify compelling differences in the barriers and conditions encountered in capital-seeking marketplace exchanges, factors that increase the likelihood of vulnerability in this service system, and in the coping mechanisms employed to protect from disparate treatment.

Our findings suggest that minorities perceive heightened restrictions of access to financial resources. Both minority and majority consumers describe their interactions with banks as a “financial pipeline.” Akin to water as an essential resource for survival, majority White informants describe their experiences seeking financial resources as embodied in the deep-metaphor of movement, where financial resources “flow” or “run” at their request. Minority consumers, however, describe the availability of resources as a “slow drip” a “dribble,” or a faucet or spicket that is “locked” or unavailable to them.

We also contrast the relationships that minority and majority consumers describe having with actors in the lending service system (e.g., loan officers, loan sharks). Drawing upon historical ideologies minority consumers describe their relationships as fettered, shackled, and oppressed (Crockett and Wallendorf 2004). Majority consumers, however, describe their relationships as emancipated, free and balanced.

We draw conclusions from these and other themes and suggest that consumer researchers and public policy stakeholders consider transformative efforts to protect minority consumers from disparate treatment. We propose an agenda for future transformative service research by outlining specific intervention strategies to reduce discriminatory and disparate treatment in service systems.

“From Patient to Agent: Collective Practices and Identity Work in an Emotional Community”

Susan Dunnett, University of Edinburgh, UK

Douglas Brownlie, University of Stirling, UK

Paul Hewer, University of Strathclyde, UK

This study unpacks the technology—in short, the practices—through which consumers transform themselves in a market context. It focuses on a site where selfhood has fallen under intense pressure—a community framed by the condition of serious illness. In a service setting, that of healthcare, which has undergone (and is still undergoing) a significant process of “marketisation” (Lupton 1997) it investigates an under-researched aspect of communal consumption—the sharing of social support resources in order to realise agency in service interactions.

Lupton has noted (1997) that where the patient as consumer is examined, the privileged representation is that of ‘dispassionate, thinking, calculating subject’. She argues that this depiction draws heavily on models of consumer behaviour where consumers are seen as rational economic decision-makers who benefit from sovereignty of choice. The conceptualisation of the patient as consumer of a healthcare system remains contentious. It has met with resistance from researchers and medical professionals alike, largely due to its perceived role in eroding the traditional power balance of the service encounter and thus creating the often undesired burden of consumer choice (Henwood et al 2003; Shankar et al 2006). The archetypal counterpart to the consumerist patient is the passive or dependent patient, a model of unquestioning compliance (Lupton 1997). The study at hand would suggest that beyond both of these simple conceptualisations, substantial emotional and social turmoil conditions a complex disempowerment in the diagnosed.

Taking its cue from previous consumer research into at-risk groups living with serious illnesses (eg. Kates, 2002; Wong and King, 2007), this study explores the lived experience of people suffering from multiple myeloma. Its context is a support group community, presented here as a form of Maffesoli’s emotional community (1996). Through a phenomenological approach (Thompson et al 1989), attention is drawn to an under-explored phenomenon, that of collective enablement of self-identity. The personal movement revealed is from a position of passivity, fear and objectification to one of *perceived* control, understanding and skilled navigation of healthcare services.

Further, it seeks to assert that community can be a technology which enables the consumer to make most effective use of the marketplace. The support groups under study are discursively positioned as receptacles of first-hand market information, with much of the narrative exchange within the group being concerned with navigating the healthcare, pharmaceutical and health insurance industries. Crucially this culture of information-exchange fosters a sense of belonging. The group provides a safe space for members to ‘forge new meanings and incorporate these meanings into changing self-conceptions’ (Kates 2002: 636). Carrying out this arduous business of *identity work*, informants make a journey from patient to agent that empowers them with a sense of self-confidence and a newly-found ability to negotiate and manipulate health care services.

The notion of patient as agent draws attention to the necessity of mediation of the marketplace. As the literature tells us, the consumption of goods and services is a transaction that offers

substantial opportunities for creative self-realisation (Arnould and Thompson 2005). However, to make the most effective use of marketplace services—as this study shows—requires much of the consumer: initiative, knowledge-gathering, energy and stamina, entrepreneurship and wise judgment are among the qualities that enable exploitation of its opportunities, as informant Marie's agentic narrative highlights:

Marie: So I met my oncologist, and he's trying to give me this drug, and I says, well how many milligrams you gonna give me? He says, two hundred. I says well that's too high. I said, I'm no way gonna take two hundred milligrams. So he dropped it down to a hundred.

The resources made available through support groups offer informants *access* to a new self—and in transforming into a skilled consumer, they are transforming the nature of the market itself. As such consumption communities can be conceptualised as a consumer-led solution to the dark side of empowerment—the burden of personal responsibility (eg. Lupton 1997; Shankar et al 2006). The extant literature has been slow to identify and explore helping behaviour in consumption communities. However, we answer Kozinets' (2002) call for consumption communities to be characterised as an 'ameliorative' to the effects of the marketplace (ibid: 34) by highlighting the emotional texture of exchange within such groups. In addition, conclusions are drawn about the incremental, complex nature of identity work, and the collective practices that empower it. Transformation is manifested in the newly-diagnosed patient's journey from dislocation and passivity to the empowered status of 'skilled consumer'.

Perhaps, too, we may draw on Price & Arnould's assertion (1999: 40) that 'buyer-seller or service provider-client relationships often pit the goals of one against those of the other' to conclude that the structural imperative of institutional medicine to make a profit (in the U.S.A. at least) inherently limits its ability to deliver the type of care desired by consumers. Nevertheless, this is still a market where the well-being of the consumer is the proclaimed mission of the service provider. Thus we can point to potential for improvement in the development of goods and services to fit better with the needs of the consumer. On this latter note, the study's findings have implications for patient information services, doctor/patient relations and the wider culture of institutional medicine. The planning of effective healthcare services would take account of the current deficit in acknowledgement of the consumer's involuntary renegotiation of self. As put by Frank (1995): 'The scope of modernist medi-

cine—defined in practices ranging from medical school curricula to billing categories—does not include helping patients learn to think differently about their post-illness worlds and construct new relationships to those worlds.' (ibid: 6). In practical terms, a deeper understanding of the processes of patienthood would seem to involve an acceptance that self-empowerment through narrative is key to the journey from passive suffering to agency. Data collection and analysis are complete.

The Effects of Incidental Cues on Goals and Motivation

Leonard Lee, Columbia University, USA

EXTENDED ABSTRACT

“From Physical Strength to Mental Resolve: Why Flexing Muscles Increases Willpower”

Iris W. Hung, National University of Singapore, Singapore
Aparna A. Labroo, University of Chicago, USA

“The mind commands the body and it obeys,” ~ St Augustine

To withstand physical pain and build resistance, to overcome tempting food when one is on a diet, to consume unpleasant medicine to become healthier, or to attend to disturbing but essential information are all activities that are immediately unpleasant but result in long term benefits and involve self-control dilemmas. Exerting self control during such dilemmas requires willpower—and people have to try to strengthen their resolve by employing thoughts that facilitate long term actions and suppress thoughts of succumbing to the temptation of avoiding pain or medicine or eating indulgent food. As a result of facing a self control dilemma, people sometimes clench their fists or jaws and stiffen their muscles as their mind commands their body to resist the temptation. But willpower is a limited resource and exerting willpower is difficult, it is likened metaphorically to a muscle that is easily depleted, resulting in people giving in to the temptation. The fact that the mind tries to and ultimately learns to control the body and it obeys has never been in question, but the current research examines the reverse—a role our bodies might play in strengthening our resolve or will power. If willpower is like a muscle, could simply flexing one’s muscles facilitate self control?

Recent findings in psychology are starting to establish that the relationship between the mind and the body is more complex than previously presumed. In particular, research is increasingly beginning to show that merely simulating many of the bodily actions that usually result from or accompany thought might also facilitate accessibility to those very thoughts, and in this manner our bodies might exert a powerful effect on our minds. For instance, standing upright rather than slouching not only results from feeling powerful or powerless, but also can result in people feeling powerful or powerless, respectively, and merely simulating the posture in an easy chair can evoke feelings of comfort and relaxation. Simulating motor approach toward a product that is being evaluated and results in increased preference because people usually associate positive feelings with approach, and writing with the dominant hand rather than the non dominant one can help validate ones thoughts. Adding to those findings, we propose that our bodies are instrumental in the recruitment of long range thoughts and in the suppression of immediate temptation thoughts and can therefore increase willpower and facilitate self control. Following the logic of other studies in embodied cognition, we argue that simulating the very actions that accompany or result when one is engaged in recruiting willpower—mentally pulling in long range thoughts and mentally banishing temptations—actions such as clenched fists and stiffened muscles, will also increase resolve and perceived willpower by helping recruit long range thoughts, banish temptation thoughts, and engage effectively in self control.

Across five experiments, we demonstrate that when participants contract their muscles, they feel more willpower and this enhanced perception of willpower mediates increased self control. Experiment

1 demonstrated that respondents have more long range healthfulness thoughts and are able to submerge their hand in an ice bucket (that presumably improves blood circulation but is painful to do) longer when they simultaneously contract finger muscles (vs. expanded it or do not do any muscle exercise). Experiment 2 demonstrated that contracting (vs. expanding) leg muscles also elicits willpower that enabled respondents to consume more of a bitter health drink (a vinegar concoction), but only among participants with health goals. When an irrelevant goal was primed, muscle contraction had no effect. Experiment 3 showed that participants are better able to resist tempting vice foods *while* they are contracting (vs. expanding) their biceps, rather than if they make the choice *after* they contract their muscles which results in depletion. Experiments 4a and 4b further examine the effect of muscle contraction in a field study to investigate whether participants are more willing to look at unpleasant charity materials (Experiment 4a) or purchase healthy food in a cafeteria (Experiment 4b) when contracting muscles.

Thus, our results demonstrate that muscle contraction elicits willpower and helps recruit thoughts that benefit long range actions. It is truly remarkable that small bodily actions can have big consequences. Of course, simply engaging in such actions is not a cure for all self control problems, but to the extent that these actions build the willpower muscle that is otherwise easily depleted from engaging in self control, a problem faced by most of us much of the time, has important consequences.

“Kindling the Motivational System: Impact of Incidental Hedonic Cues on Goal Pursuit”

Monica Wadhwa, INSEAD, France
Baba Shiv, Stanford University, USA

Our consumption environment is abundant in cues that are high in hedonic value (i.e., cues that are desirable). A whiff of a fragrance, a sample of a refreshing drink or an advertisement picturing romantic images are some such cues that we commonly experience in our everyday lives. While recent research on consumption motivation suggests that experiencing such high hedonic value consumption cues can lead to general reward-seeking behaviors (e.g., Wadhwa, Shiv and Nowlis 2008; Van den Bergh, Dewitte and Warlop 2008), relatively little is understood about whether and how experiencing such cues impact consumer’s subsequent goal related behaviors. Since most of consumer choices and behaviors are goal driven (Bettman, Luce and Payne 1998), investigating how such experiences with hedonic cues impact subsequent goal related behaviors is consequential both from the marketers’ and consumers’ perspectives. Drawing upon the synthesis of research on consumption motivation and recent evidence in neuroscience (Berridge 2007; Salamone 2007), in the present research, we propose that the motivational drive activated by brief experiences with hedonic cues can enhance pursuit of a subsequently adopted goal associated with a desirable outcome.

We test the aforementioned hypotheses, in a series of studies, across different consumer goals and different dependent variables. In study 1, we sought to examine the basic research question—whether or not a brief experience with a hedonic cue can enhance pursuit of a subsequently adopted goal. In line with the general-motivational drive hypothesis, our findings demonstrate that participants who had experienced a hedonic cue (romantic images) were more likely to persist on a subsequent goal involving unscrambling unsolvable

anagrams as compared to those who were exposed to a neutral cue (nature images).

In study 2, we sought to provide further support for the general motivational drive proposition. Specifically, we argue that when the motivational drive activated in response to experience with hedonic cues is satiated, impact of hedonic cues on subsequent goal pursuit behaviors should get attenuated. In this study, we carried out the motivational-drive manipulation by employing a sampling paradigm, whereby participants sampled either Hawaiian Punch (motivational drive-induced) or water (motivational drive-not induced). Subsequently, we carried out the motivational drive-satiation manipulation, which was adapted from Wadhwa et al. (2008). Specifically, participants who had experienced the hedonic cue either received a surprise reward (candy bar) after the hedonic cue experience but before the goal adoption (motivational drive-satiated), or they received the candy bar at the end of the study (motivational drive-induced). As in study-1, participants then worked on an intellectual goal that involved unscrambling unsolvable anagrams. Mirroring the results of study-1, study 2 results show that those who had experienced the hedonic cue persisted longer on the anagrams than those who had not experienced the hedonic cue. Further, in line with general motivational hypothesis, when the induced motivational drive was satiated, the impact of experiencing hedonic cue on subsequent goal persistence was attenuated.

Study 3 examines the role of individual differences related to behavioral activation system (BAS) in moderating the impact of brief exposure to hedonic cues on subsequent goal pursuit. The BAS system has been linked to appetitive motives and behaviors such that in the presence of rewarding cues, individuals with a high rather than low BAS sensitivity tend to exhibit an increased tendency to act on the rewarding impact of such hedonic cues (Carver and White 1994). Drawing upon this research, we argue that a brief experience with a hedonic cue will enhance subsequent goal pursuit for those who have a high sensitivity to BAS as compared to those who have low sensitivity to BAS. As in study, participants were either exposed to romantic images (motivational drive-induced) or nature images (motivational drive-not induced). Subsequently, participants worked on a persistence goal that required squeezing a hand dynamometer (a gauge that records force). As predicted, our results show that those high than those low on BAS sensitivity showed enhanced goal pursuit (as measured by persistence on the hand-dynamometer task) subsequent to a brief experience with the hedonic cue. These participants also persisted longer on the hand-dynamometer task as compared to those in the motivational drive-not induced condition.

The general-motivational drive conceptualization suggests that a brief exposure to a hedonic cue is likely to enhance pursuit of goals associated with a desirable outcome. In study-4, we explicitly test the role of goal desirability in moderating the general-motivational effects. Drawing upon research on goal systems, we manipulated goal desirability by making either the desirable or undesirable outcome contingency associated with the goal salient (adapted from Roney, Higgins and Shah 1995). Specifically, subsequent to the motivational drive manipulation, participants were told that they would be participating in another study on persistence, which comprises of two tasks. Participants were further informed that their performance on the initial persistence task would decide the persistence task they would subsequently work on. One of the alternatives for the second persistence task was a desirable outcome, while the other one was an undesirable outcome. All the participants were informed about both the alternatives for the second persistence task. However, for half of the participants, the desirable outcome contingency was emphasized, while for the other half, the undesirable outcome contingency was emphasized. In the first persistence task, participants'

goal was to squeeze the hand dynamometer for as long as they could at the level of force that was individually identified for them at the beginning of the experiment. Our results show that when the goal was framed such that the focus was on the desirable outcome, a brief experience with the hedonic cue enhanced persistence on the subsequent handgrip persistence task. However, when the goal was framed, such that emphasis was on the undesirable outcome, the impact of experiencing the hedonic cue on subsequent hand dynamometer persistence task was attenuated.

In sum, our findings suggest that a brief experience with a hedonic cue can enhance pursuit of a subsequently adopted goal that is unrelated to the experienced hedonic cue. Implications for marketers and policy makers are discussed.

“Climbing the Goal Ladder: How Upcoming Actions Increase Level of Aspiration”

*Minjung Koo, Sungkyunkwan University, Korea
Ayelet Fishbach, University of Chicago, USA*

People's goals often follow a “goal ladder” in which each goal is a step toward another, more challenging goal. For example, career paths often follow a goal ladder in which an entry-level position is a step toward a more advanced position in the organization. Even more mundane goals, such as playing a computer game, often include different levels in which a person can move up, for example, by advancing from “level 3” to “level 4.” Regardless of the specific features of the goal ladder, individuals face a dilemma between moving up to a more advanced level versus repeating the current level for their next pursuit. As such, we explore whether the way individuals monitor their current goal—either in terms of remaining or completed actions—influences their aspiration level for their next goal.

We position our theory in previous goal research, which explores the impact of discrepancies (i.e., remaining actions; Carver and Scheier 1998; Hull 1932), as well as successful past pursuits (Bandura 1991) on motivation to pursue a focal goal. In departure from previous research, we compare these foci against each other and explore their relative impact on the choice of what to do once the focal goal is achieved. Building on research by Fishbach and colleagues (Fishbach et al 2006; Koo and Fishbach 2008), we predict that an emphasis on remaining actions focuses individuals on making progress, leading to a desire to move up, whereas an emphasis on completed actions focuses individuals on their commitment to the current goal, leading to a desire to repeat the present goal level. That is, when the focus is on remaining actions, people consider their progress and wish to decrease the discrepancy between their current position and the state of goal completion; that is, people wish to move forward (Carver and Scheier 1998). In a goal ladder, a desire to move forward translates into not only greater motivation to complete the present goal level but into a greater level of aspiration, such that a person wishes to move up to the next level. In contrast, when the focus is on completed actions, the actions increase the sense of personal commitment to the goal. Because the goal appears more valuable and feasible (Atkinson 1957; Feather 1982), people wish to adhere to this goal at the next opportunity (Aronson 1997; Bem 1972).

Our results across five studies support these predictions. In Study 1 we asked undergraduate students to elaborate on their remaining versus completed academic tasks. As expected, we found that elaborating on remaining (vs. completed) academic tasks increased undergraduate participants' eagerness to begin their careers but decreased their satisfaction with their present college academic life. Furthermore, the satisfaction measure was negatively correlated with the desire to begin their career, implying a trade-off

exists between pursuing the goal for the sake of engagement and for the sake of moving up.

Study 2 extended these findings by separating the effect of time frame (past vs. future) from the focus on completed versus remaining actions. We asked students in beginner-level foreign language course to first consider what materials they had covered (in the past) versus would cover (in the future) in their current class. We then asked those in the remaining-actions conditions to consider either the topics they did not or would not cover in this class. Those in the completed-actions conditions considered either the topics they had covered or would cover in this class. As expected, regardless of the past and future frame, participants who focused on remaining actions aimed for a higher level as their ultimate goal in their language (among five levels) than those who focused on completed actions. This study also demonstrated more clearly that a focus on remaining (vs. completed) actions increase not only the desire to move to something else but the desire to move up to a more advanced goal as we assessed the ultimate level of mastery.

Study 3 built on the previous studies by testing the underlying inferences for these effects and including a control condition. Participants evaluated several unfamiliar musical pieces and their evaluation of each piece was followed by information on the portion they had completed, the portion of the task that remained, or the number of the next piece to be evaluated (control). After completing the initial task, participants indicated their enjoyment of the task and could choose a lower, a higher, or a similar task level for their next task. As expected, monitoring remaining (vs. completed) actions decreased participants' enjoyment of the initial task but increased their level of aspiration, as reflected in their choice of a higher-level review task. Those in the control condition fell in the middle on these measures, demonstrating unique effects for completed and remaining actions. In addition, as direct evidence for underlying inferences, we found they more likely inferred task value when they monitored completed (vs. remaining) actions, whereas they inferred higher need for progress when they monitored remaining (vs. completed) actions.

Study 4 was a field experiment involving employees at an advertising company. We found that when employees considered what they had yet to achieve (vs. what they had already achieved), they were motivated to move on to new, more challenging roles but experienced decreased satisfaction from their current roles. Finally, participants in Study 5 strategically sought information on the remaining (vs. completed) portion of the task when they expected to move to a more advanced level. Individuals appear to attend to information that matches their level of aspiration and that can best help them maintain their motivation to progress or not on a goal ladder.

Taken together, the current research sheds new light on the classic problem of what determines people's levels of aspiration (Dembo 1931) by showing that the focus on remaining actions and goal progress increase people's levels of aspiration beyond their present goal. In addition, it explores the motivational cost of the focus on making progress on a goal: It lowers the intrinsic value from engaging in a present goal.

“Crossing the Virtual Boundary: The Effect of Incidental Cues on Task Accomplishment”

Min Zhao, University of Toronto, Canada

Leonard Lee, Columbia University, USA

Dilip Soman, University of Toronto, Canada

Consumers' lifespans are filled with a large set of experiences that are task-oriented such as sending a package in the post office or getting a transaction done at a bank. Often times there are physi-

cal or temporal gaps between the point where the individual starts to engage in the activity and the actual activity itself, and these gaps may have multiple effects on individuals' queuing decision or their satisfaction.

Our research shows that in situations like these, an individual's approach towards the final activity might not be continuous, but rather is marked with a discontinuity. In particular, the incidental physical and informational cues in the context surrounding such tasks create discontinuities by serving as a virtual boundary which defines the starting point of the task system. These cues could be embedded within the physical context of the waiting environment such as whether people are inside a designated waiting area, an informational intervention such as an irrelevant sign-in form, or even appropriate semantic cues such as whether the term “wait inside” or “wait outside” is used to refer to the same waiting area. We argue that prior to this boundary, people are outside the system. However, once they pass this virtual boundary, they are inside the system and adopt an implemental *in-system* mindset which can increase their commitment to the task at hand (Gollwitzer 1999). Further, we propose that this increase in commitment is also characterized by a general increase in optimism and action orientation.

We conducted five experiments using a variety of incidental cues in different waiting environments to test our hypotheses.

In experiment 1, participants were asked to assume that they were waiting in the post office to send a small package. We manipulated an incidental physical cue (the presence and length of a queue-guide next to the queue) at three levels: no guide, short guide which excluded the participant, and long guide which included the participant; participants in all three conditions always stood in the same position of the queue. We found that participants in the long-guide condition (and had thus crossed the virtual boundary) were more likely to stay in the line rather than pay for immediate service, showing increased commitment to the task at hand.

In experiment 2, we investigated the interaction between two different informational cues in a visa-application scenario with a 2 (Waiting Time: Integrated vs. Segregated) x 2 (Immediate Start: Yes vs. No) between-subjects design, while holding the total waiting time for the visa application constant. The result showed that participants indicated a stronger commitment to the visa-application process when the waiting was segregated into three small waits which helped them cross the virtual boundary earlier, compared with a long integrated waiting. However, when an initial registration upon arrival was added to the beginning of the waiting such that participants perceived themselves to start immediately and thus increased their overall commitment, the difference between integrated and segregated waiting was attenuated.

In experiments 3–5, we employed real-waiting scenarios and tested the underlying mechanism through measuring participants' optimism and action orientation. In all three studies, participants were told that the experimental session was divided into two parts and they had to wait after the first part for the experimenter to set up the second part.

Experiment 3 used a 2 (Waiting Location: Old Room vs. New Room) x 2 (Timing of Consent for the Second Session: First vs. Last) between-subjects design, and the second part of the session was supposed to be in the new room in all conditions. We found that for participants who waited in the old room, signing the consent form first led to a more optimistic estimation of the time needed to complete the second part of the session, compared with signing the consent form after answering the time-prediction question. However, this effect was attenuated for participants who were already waiting in the new room and thus already had increased commitment.

In experiment 4, we adopted a 2 (Semantic Frame: Waiting vs. No Waiting) x 2 (Membership Badge: Yes vs. No) between-subjects design. The results showed that when we framed the time spent on the filler task before the focal study as waiting, wearing a member badge led to significantly more optimistic estimation for the time needed to complete the focal study compared with not wearing such a badge. However, if the time on the filler task was not framed as waiting, this effect was attenuated. Further, we observed the same result pattern for participants' CRT scores (Frederick 2005), showing that increased commitment was also characterized by increased cognitive effort and action orientation.

In experiment 5, we asked all participants to wait in the same waiting area for the second part of the study session to be ready, but framed it as "waiting *inside* the waiting area", or "waiting *outside* in the waiting area" (relative to the study room). The results showed that people who perceived themselves to be waiting "inside" (vs. "outside") were more optimistic in two unrelated tasks—they predicted a higher chance of hitting a golf ball into a hole, and preferred riskier gamble options. Further, people with an "inside" mindset were more likely to choose a computer from a given set compared to people with an "outside" mindset who were more likely to defer their choice. These results showed that people who crossed the virtual boundary adopt an in-system mindset, leading to greater action orientation and optimism in general, even in unrelated task domains.

Overall, the results in this work provided convergent evidence for the effect of incidental cues in the waiting environment on task commitment, optimism, and action orientation. These findings add to literature on the effect of incidental cues on judgment and behavior, the goal literature, as well as the queuing literature.

Do Consumers Get the Message? An Examination of How Consumers Respond to Health Information

Maura L. Scott, University of Kentucky, USA

Katherine E. Loveland, Arizona State University, USA

EXTENDED ABSTRACTS

“Effects of Decisional Status and Construal Level on the Persuasiveness of Health-Related Messages and Products”

Gergana Y. Nenkov, Boston College, USA

J. Jeffrey Inman, University of Pittsburgh, USA

Many products and messages in the marketplace emphasize important health-related goals that consumers might achieve by consuming them—e.g., nutrition, fitness, weight loss. Some products and messages, however, are described using high levels of construal, whereas others are described using low-levels. For instance, Kellogg’s *Smart Start*® line of cereals are all positioned as nutritional, but some are called *Healthy Heart*, emphasizing the reason for getting nutrition (high-level construal), while others are called *Antioxidants*, emphasizing the means of getting nutrition (low-level construal). An important question arises regarding which construal level will be more effective in persuading consumers to choose a particular product or perform a particular behavior (Lee, Keller, and Sternthal 2009). Building on construal level theory (e.g., Trope, Liberman, and Wakslak 2007), behavior identification theory (Vallacher and Wegner 1987), and the mindset theory of action phases (e.g., Gollwitzer 1990) we argue that the differential cognitive tuning created by pre- vs. post-decisional mindsets make consumers in the pre- vs. post-decisional action phase differentially receptive to messages framed using different construals.

Four studies examine the interactive effects of pre- and post-decisional status and construal level on the persuasiveness of health-related messages and products. We find that consumers in the pre-decisional action phase are more persuaded by health-related messages described using high-level construal, whereas consumers in the post-decisional phase are more persuaded by messages described using low-level construal. We test our thesis by manipulating construal level directly and indirectly, employing different targets, and examining several aspects of persuasion—choice (study 1), anticipated effortful goal pursuit (study 2), behavioral intentions (study 3), and actual behavior (study 4). We provide process evidence and show that consumers at the pre- vs. post-decisional action phase identify their goals and behaviors at different construal levels.

In study 1 (n=150) participants choose between two products promoting the same goal (i.e., nutrition), with one product stressing the abstract aspects of the goal—why one should obtain nutrition (i.e., “HEALTHY HEART: For a long and healthy life”), and the other stressing its concrete aspects—how one can obtain it (i.e., “ANTI-OXIDANTS: with Antioxidants A, C, and E, and Beta Carotene”). Participants in a deliberative (i.e., predecisional) mindset were more likely to choose the product positioned in terms of abstract construals; those in an implemental (i.e., post-decisional) mindset exhibited preference for the product positioned in concrete construals.

In study 2 (n=175) we extend previous findings by examining a different aspect of persuasion, a different construal manipulation, and a new dependent variable—anticipated effortful goal pursuit. Participants saw a brochure featuring a persuasive argument about weight control emphasizing either why one should control their weight or how one can control it. Results revealed that deliberative (implemental) mindset participants are more persuaded to pursue

the goal and anticipate more effortful goal pursuit in the high-level (low-level) construal condition.

In study 3 (n=103) we explore the effects of social distance construal framing on behavioral intentions, and test our proposition that consumers in the pre- vs. post-decisional action phases construe their goals and behaviors at different levels of construal. Participants evaluated one of two ads for a healthy product (orange juice), targeted at either a close (i.e., your family, low-level) or distant (i.e., families nationwide, high-level) construal. Participants in a predecision mindset were more persuaded to buy the product by the high-level construal ad, whereas those in the postdecision mindset were more persuaded by the low-level construal ad. Consumers in a predecisional, deliberative mindset are more likely to construe behaviors in abstract, high levels.

In study 4 (n=47) we employ temporal construal and examine whether its differential effect for people in a deliberative vs. implemental mindset would affect their behavior. Individuals participated in a study that purportedly examined decision making processes, whose purpose was to prime deliberative and implemental mindsets; in exchange, \$5 would be donated to a foundation in their name. One foundation was described using high-level (i.e., future) construals, and the other was described using low-level (i.e., present) construals. Participants in a deliberative (implemental) mindset allocated significantly more money to the foundation described using future (present) construal framing, providing convergent support for our predictions.

This paper contributes to two emerging streams in consumer research—one examining the effectiveness of messages and information represented at low- vs. high-levels of construal (Kim, Rao, and Lee 2009; Lee, Keller, and Sternthal 2009) and another studying the effects of action phase mindsets on consumer behavior (Chandran and Morwitz 2005; Cheema and Patrick 2008; Dhar, Huber, and Khan 2007). It also makes important contributions to the literature on action phase mindsets (see e.g., Gollwitzer 1990) by empirically demonstrating that predecisional consumers construe information at high level, whereas postdecisional ones construe information at low-levels. Finally, findings from the current set of studies offer important implications for the design and presentation of health-related products and persuasive messages, suggesting that products and messages should be framed at a different level of construal when targeting consumers at the different stages of their decision-making process.

“When 1-in-3 is Greater than 4-in-10: Why Lower Probability Events Can Be More Persuasive in Public Service Announcements”

Ann Schlosser, University of Washington, USA

Using ratios in public service announcements (PSAs) is a common tactic to persuade individuals of the seriousness of an issue and motivate them to act. I argue that the numbers used to represent a probability can influence consumers’ beliefs about the seriousness of a problem and their willingness to act. Specifically, I propose that when events are represented in ratios using very small numbers (denominators < 5), consumers perceive a problem to be more serious and are more willing to act than when ratios use large numbers (denominators ≥ 10). This is because ratios us-

ing small numbers (e.g., 1-in-4) are easier to visualize than larger ratios (e.g., 25-in-100).

People can process information using images or analytically (Epstein 1991; Green and Brock 2000). Imagery processing involves encoding information in the form of concrete, imagistic, and sensory representations, whereas discursive processing involves encoding information as abstract symbols, words, and numbers (MacInnis and Price 1987). Because of their different foci, they can lead to different outcomes (Schlosser 2003). People tend to perceive greater risk when ratios are in larger than smaller ratios (Pinto-Pradas et al. 2006; Yamagashi 1997). Although this may appear to contradict the predictions given here, the “small”-numbered ratios used previously had denominators of 10 or more. I propose that it is difficult to vividly imagine 10 or more people, hence people use discursive rather than imagery processing (i.e., focus on numbers). In the present studies, small-numbered ratios have denominators less than five.

In study 1, participants imagined a serious virus (worse than H1N1) that the Health Department wants to inform the public about. They were given three different pairs of ratios (in randomized order) and indicated which of the two made the incidence seem worse to them. The pairs were (1) 1-in-3 vs. 4-in-10 (or 6-in-15), (2) 1-in-3 vs. 35-in-100, and (3) 35-in-100 vs. 4-in-10 (or 6-in-15). If the paired comparison includes 1-in-3, which is easier to visualize and thus should seem more serious than large-numbered ratios, then more participants would select the 1-in-3 ratio as worse than 4-in-10, 6-in-15 and 35-in-100, although it represents a lower probability (i.e., 33% vs. 40% and 35%). For the third pair involving comparing two relatively large numbers, I expected that individuals would rely on discursive processing and thus more individuals would perceive the 35-in-100 ratio to be worse (because $35 > 4$ and 6). All participants were given three pairs of ratios and were randomly assigned to (1) the order of presentation for the three pairs of ratios, and (2) whether 40% was 4-in-10 or 6-in-15. The ratio for 40% was varied to examine whether the ease in comparing the ratios numerically would alter the results. It did not. As predicted, over 59% of participants found the 1-in-3 probability of illness to be worse than a 4-in-10, 6-in-15, and 35-in-100 chance of contracting the illness. In contrast, over 80% of participants chose the 4-in-10 and 6-in-15 options over the 35-in-100 option. It may be that processing large-numbered ratios discursively caused participants to correctly identify the higher-probability ratio.

In studies 2 and 3, participants received a single ratio in a PSA and then indicated how serious the problem seemed and their willingness to act. In study 2, participants were randomly assigned to one of four PSAs titled “Skin cancer affects X in Y Americans” where “X in Y” was a smaller- or larger- ratio reflecting 25% (1-in-4, 25-in-100) or 30% (3-in-10, 30-in-100). All other information was the same. I expected that by encouraging discursive processing and thus a focus upon the first number in the ratio, participants would perceive melanoma to be more serious and be more willing to take preventative actions in the 30-in-100 than 3-in-10 condition. In contrast, by encouraging imagery processing and thus a focus upon the few people *unaffected*, the 1-in-4 ad should persuade individuals of the seriousness of the problem and motivate them to act. Participants’ perceptions of the problem and willingness to act should be as high if not higher in the 1-in-4 than 25-in-100 and 3-in-10 conditions. The results support these predictions.

Study 3 extends the findings of the first two by testing the role of imagery processing in explaining the effects. Specifically, participants were presented with a drunk-driving PSA and told that either 3-in-10 or 30-in-100 cars will be involved in a drunk-driving accident. In addition they were either encouraged to visualize being in one of the 10 (vs. 100) cars or not. Replicating the results of

study 2, when imagery processing was *not* encouraged, perceptions of the problem and willingness to act were higher when the ratio was 30-in-100 than 3-in-10. In contrast, when imagery processing was encouraged, perceptions of the problem and willingness to act were higher when the ratio was 3-in-10 than 30-in-100.

Collectively, the results suggest that when designing PSAs with ratios, the numbers used have important implications for consumers’ beliefs about the seriousness of an issue and their willingness to act. The results also suggest that imagery processing plays an important role in whether smaller-numbered ratios will be more or less persuasive than larger-numbered ratios.

“The Effect of Model Size and Self-Awareness on Health Message Compliance”

Katherine E. Loveland, Arizona State University, USA

Elizabeth Gelfand Miller, Boston College, USA

Naomi Mandel, Arizona State University, USA

In recent years, obesity incidence has risen in the United States (cdc.gov). One way that the government has tried to address this issue is through the use of public service announcements (PSA) promoting a healthier lifestyle. We examine how external cues, such as these PSAs, interact with consumer characteristics to influence healthy food choices. We predict two factors are most likely to impact the effectiveness of a health message: the visual cue provided by the body type of the model that is paired with the message and the consumer’s level of self-awareness (SA) at the time of message exposure. Previous work is inconclusive regarding the impact of heavy vs. thin others on consumption. Campbell and Mohr (2009) demonstrated that exposure to an overweight prime, as compared to a normal weight prime, leads to increased consumption, suggesting that the use of a heavy model will lead to less healthful choices. Other work has demonstrated that exposure to thin primes, compared to neutral primes, can lead to increased consumption (e.g. Mills et al. 2002; Seddon and Berry 1996; Strauss et al. 1994). This suggests that the use of a thin model will lead to less healthful choices. We propose that one reason for these earlier contradictory findings is that the effect of model size on consumption decisions should vary based on SA level.

While previous work in the area of SA has demonstrated that compliance is generally higher when SA is high, as compared to low (c.f. Carver 2003), we predict that SA is likely to interact with model size, due to the automatic social comparison that occurs when individuals are exposed to a comparison standard. Additionally, since higher levels of SA lead to more accurate assessments of the self (Pryor et al. 1977), the social comparison information provided by a thin (or heavy) model will be interpreted differently depending on the level SA. Specifically, because college-aged females are often relatively thin, when SA is high, exposure to a thin (vs. heavy) model should allow participants to make a realistic assessment of how they are similar to the thin model, leading to higher body-esteem and consequently higher message compliance. On the other hand, because most young women feel constant pressure to be thinner, regardless of how thin they actually are, when SA is low, exposure to a thin (vs. heavy) model should lead consumers to judge themselves overly harshly by focusing on how they are different from the thin model, leading to lower body self-esteem and subsequently lower message compliance.

In study 1, 178 students participated for partial course credit. Participants were randomly assigned in a 2 (level of SA: high vs. low) x 4 (model size: thin, moderately heavy, obese, or no model) design. All participants viewed an ad with the same written content, emphasizing the importance of eating a healthful diet and giving specific tips on how to make healthful food decisions; the size

of the model paired with the message varied by condition. Next, participants selected snacks that they would like for the coming week from 10 pretested options, in which 5 were healthful (e.g. trail mix) and 5 were not (e.g. potato chips). In the low SA condition, participants selected the most healthful snacks when an obese model was depicted. In the high SA condition, participants selected the most healthful snacks when a thin model was depicted.

In study 2, 203 female students participated. The design was similar to study 1; however, SA was manipulated using mirrors and included an “escape” condition. We found a significant main effect for SA ($F(2, 191)=4.02, p<.05$), as well as a significant interaction between model size and level of SA ($F(6, 191)=2.54, p<.05$) on message compliance (as measured by plans to consume a healthful diet in the coming week). Planned comparison revealed several interesting findings. Self-awareness only affected responses when a thin model was present, suggesting that SA only plays a role in message compliance when there is a relevant social comparison standard present. When SA was high and a thin model was pictured, participants were significantly more likely to comply with the message compared to when SA was low and a thin model was pictured. These findings were fully mediated by Body Self-Esteem (BSE, Franzoi and Shields 1984).

Our results suggest that the way in which social comparison information is processed, and its subsequent impact on message compliance for PSAs, varies based on level of SA. When SA is high, using a thin model leads to assimilative processing, leading to higher BSE and subsequently higher message compliance in the form of more healthful food choices. When SA is low, using a thin model leads to contrastive processing, leading to lower BSE, and subsequently lower compliance. As the results from studies 1 and 2 show some discrepancies, we are collecting data in a third study in which BMI and weight locus of control are measured as possible moderators.

“The Effects of Vanity Sizing on Self-esteem and Shopping Behavior”

Darren Dahl, University of British Columbia, Canada

JoAndrea Hoegg, University of British Columbia, Canada

Andrea Morales, Arizona State University, USA

Maura L. Scott, University of Kentucky, USA

Consumers experience pressure to look thin from a variety of sources (Abramowitz 2007) and this can affect self-esteem (Smeesters and Mandel 2006). In a recent study, 89% of girls 13–17 indicated that the *fashion industry* placed “a lot of pressure on girls to be thin” and 75% stated fashion is very important to them (Salamond 2010). Consumers are also getting larger; 67% of Americans are overweight or obese (CDC 2008). In response, many retailers adapt clothing sizes (Kinley 2003). Vanity sizing refers to companies adjusting “the measurement specifications for each size [of a garment] to enable consumers to fit into smaller sizes” (Alexander et al. 2005).

“Fashion can be viewed as how one would like to be (the ideal self) vs. how one really is (the actual self)” (Kinley 2003); hence vanity sizing can be compared to the notion of an “ego size.” Consumers use the ego size as a reference point, which can be inconsistent from retailer to retailer, and deviations from this reference point can influence consumers differently depending on their self-esteem. Consumers with low body image self-esteem may be more aware of food/nutrition information, their own weight and size, and reflect a magnified response to the effects of clothing size variation. Awareness of their own size leads to a strong reference point from which to compare oneself and leads to expectancy disconfirmation (positive or negative) in the face of vanity sizing or inflated sizing

(e.g., clothing that is perceived to ‘run small’). In some cases, this heightens the consumer’s resolve to purchase something, namely a non-sized product. Individuals with high body image self-esteem have confidence in their appearance and are likely to be less tied to “numbers;” hence, they are not upset when sizes change.

Our research examines the benefits and drawbacks of varying clothing sizes. We examine the moderating effect of different types of self-esteem on consumers’ responses to clothing sizes. Four experiments demonstrate that consumers’ attitude toward the retailer, purchase intentions, and loyalty vary depending on clothing size variations and body-esteem. Study 1 establishes the basic effect that consumers are affected both positively and negatively by clothing size. Studies 2 and 3 demonstrate the moderating effects of different types of self-esteem on a consumer’s response to size variations. Study 4 demonstrates that vanity sizing may not be effective if people are suspicious of marketing tactics. Our findings both highlight the importance of using vanity sizing strategically as well as show the negative impact of “inflated” sizes.

Study 1 was a one-way (size: smaller, larger) between subjects experiment. Participants recorded six body measurements using a tape-measure and a mirror, and provided the measurements to the administrator. The administrator cross-checked each measurement with a fictitious size chart, then gave participants either a smaller or larger suit size. Participants in larger suit size conditions had a significantly less favorable impression of the retailer and lower purchase intention, relative to those in the smaller size condition. We demonstrate that the numeric clothing size label is important to consumers, beyond whether or not the clothing fits.

Study 2 was a 2(size: smaller, larger) x (body image–continuous) design. We found a significant interaction between body esteem and clothing size on impression of the retailer and the suit. In the larger size conditions, people with lower body esteem exhibited more negative attitudes toward the clothing and the retailer. We demonstrate the impact of clothing sizes on preferences, and show the moderating effect of body-esteem. Study 3 tests whether specifically body-esteem or any self-esteem boost would mitigate the effects of vanity sizing. Study 3 was a 2(size: smaller, larger) x 2(esteem: body, intelligence), between subjects experiment. We created a physical store with various products available. Participants tried on jeans labeled in their typical size (labels were adjusted, so the jeans would be larger or smaller) and other sizes. We find that only body-esteem, rather than any type of self esteem, can counter the effects of vanity sizing. Individuals primed with high body image self esteem were not affected by vanity sizing.

Study 4 was a 2(size: smaller, larger) x 2(suspicion: yes, no) between subjects experiment. To manipulate suspicion, participants either read a neutral article or one suggesting that marketers manipulate information to sell products. We find that suspicion reduces the influence of vanity sizing; suspicious participants were less affected by vanity- or inflated-sizing relative to their unsuspecting counterparts.

Our research contributes to the body-esteem and consumption behavior literature. Extant literature has examined dis-/confirmation from reference points such as the media (Smeesters et al. 2010) or others consumers (McFerran et al. 2009); we provide new knowledge on how consumers behave when the reference point is one’s own clothing

Standards and Construction of Hedonic Value

Meng Zhu, Carnegie Mellon University, USA
 Carey Morewedge, Carnegie Mellon University, USA

EXTENDED ABSTRACT

“The AB Identification Survey: Identifying Absolute versus Relative Determinants of Happiness”

Christopher K. Hsee, University of Chicago, USA

Adelle X. Yang, University of Chicago, USA

Some variables are inherently evaluable and others are inherently inevaluable. To say that a variable is inherently evaluable (for simplicity, call it a type A variable), we mean that human beings have an innate, shared and stable scale to assess which level of the variable is desirable and which is not (ambient temperature, amount of sleep, etc); to say that a variable is inherently inevaluable (type B), we mean that human beings have no innate scale to gauge its desirability and in order to evaluate its desirability one must rely on external reference information, such as social comparison (the size of a diamond, the horsepower of a car, etc).

The distinction between type A and type B variables carries important social implications. For instance, improving the value of a type A variable for all the members in a society will absolutely raise the happiness of all, whereas improving the value of a type B variable for all the members in a society is merely a zero sum game and will not raise the happiness of all. Therefore from a congregative point of view, policymakers should direct the resources to improving type A variables in order to increase happiness across time.

In this paper we propose the AB Identification Survey (ABIS), a simple and practical method to identify whether a given variable is type A or type B. The procedure of the ABIS is as follows. Suppose that we wish to identify whether a given variable X , say men's height, is type A or type B, assuming that greater X is more desirable and that the average X value in the given population is x_m , for example, the average height of men is 5'9". ABIS consists of two versions, the JE version and the simulated-SE version. Each version is simple and contains only two questions. The JE version reads as follows:

1. How tall are you? _____
2. As you may know, some men are tall and others are short, and men's average height is about 5'9". Given that, how do you feel about your height? Give a number between 1 (very unhappy) and 7 (very happy): _____

The simulated-SE version reads as follows:

1. How tall are you? _____
2. Suppose that you were living in a society where *every man were of your height*. Given that, how would you feel about your height? Give a number between 1 (very unhappy) and 7 (very happy): _____

Recruit a sample of men (whose height distribution should be representative of that of the target population) and ask half the sample to answer the JE version of ABIS and the other half the simulated-SE version.

After data are collected, run two regressions. One regresses the happiness ratings from the JE version of ABIS on the target variable X (e.g., height) and control variables, if any. The other regresses the happiness ratings from the Simulated-SE version of ABIS on X and

control variables, if any. Let β_{JE} and $\beta_{\text{Simulated-SE}}$ denote the estimated regression coefficients of X from the two models, respectively. Then we can simply use the following formula to identify whether X is type A or type B: AB coefficient = $\beta_{\text{Simulated-SE}} / \beta_{JE}$.

$\beta_{\text{Simulated-SE}}$ reflects the non-comparative effect of X , and β_{JE} reflects the total effect of X . Generally speaking, The AB coefficient reflects the size of the non-comparative effect relative to the total effect. The greater the AB coefficient, the more X is a type A variable; the smaller the AB coefficient, the more X is a type B variable.

We report three studies. The first study is a validation study. It compares the results of the ABIS with the results of a cleaner but less practical experimental method and shows that the two studies produce very similar results. In addition, we report two studies to show how to apply this method to identifying a series of naturally occurring variables as type A or type B. The first survey was conducted among 453 undergraduate students, the second among 352 business students with work experiences. Our surveys have revealed interesting findings. For undergraduate students, the two top type A variables are vacation time and winter dorm temperature; the two top type B variables are home size and height (meter). For business students, top type A variables were insomnia and vacation time, and top type B variables are income and car price.

The ABIS can be used to inform policymakers where to invest resources. From the perspective of an individual, improving either type A variables or type B variables will increase happiness: "I will be happier than you if I can afford more comfortable temperature or I can afford more expensive jewelry." For that individual, pursuing both type A and type B variables is rational. But from the perspective of a society, improving type B variables is a zero-sum game and only improving type A variables can improve the happiness of all. Since this distinction applies only at the societal level but not at the individual level, policymakers, rather than individuals, are better suited to distinguish type A and type B variables. ABIS is an instrument they can use in this endeavor.

“Social Standards and the Construction of Hedonic Value”

Meng Zhu, Carnegie Mellon University, USA

Carey Morewedge, Carnegie Mellon University, USA

Daniel Gilbert, Harvard University, USA

Kristian Myrseth, ESMT, Germany

Karim Kassam, Carnegie Mellon University, USA

Timothy Wilson, University of Virginia, USA

A contrast effect occurs when a standard of comparison influences judgment of a target stimulus, such that the target is considered less like the standard when in its presence than when judged in the absence of that standard. Contrast effects are prevalent in noetic (information based judgments) and psychophysics, yet the evidence for hedonic contrast effects has been mixed (Novemsky & Ratner 2003). We develop an attentional model to explain when and why comparative value influences hedonic value. Specifically, we propose that hedonic contrast effects are particularly elusive in experience because forecasters fail to account for (1) attentional requirements of comparison, as noticing the difference between a standard and a target requires considerable cognitive resources; (2) different attentional requirements of forecasting vs. experience—forecasters' mental representations of experiences consume fewer resources than having the forecasted experience. Thus, we predict that compara-

tive value will influence hedonic experiences when experiences are unengaging or when comparisons are easy to make. We report four experiments that tested our theory by examining how social comparison, which is automatic, well-practiced and often occurs without conscious awareness, influences hedonic value and decision making. We predict that social standards will evoke hedonic contrast effects in situations where nonsocial standard don't.

Study 1 tested whether social standards produce a greater influence on hedonic value and whether forecasters can correctly predict this difference. Participants were presented two food items, Lay's Potato Chips (target food) and another item (standard food), either Godiva Raspberry Chocolate (better standard) or King Oscar canned sardines (worse standard). We manipulated social comparison by telling half of the participants that they will be paired with another participant in the same experiment session and each of them will be randomly assigned to sample different food item (partner condition). The other half of the participants were simply assigned to evaluate one of the two food items (no-partner condition). All participants were then assigned by computer to evaluate the target food (potato chips). Experiencers reported how much they enjoyed eating chips and forecasted predicted how much they would enjoy eating chips. As predicted, experiencers in the partner condition rated chips more enjoyable when their partner was assigned to sardines as compared to chocolate, whereas in the no-partner condition, experiencers enjoyed chips the same no matter what the alternative food was. However, forecasters predicted that hedonic contrasts would occur in both the partner and no-partner conditions.

To test whether social standards are more influential because comparing to social standards requires fewer attentional resources, Study 2 employed a 2(cognitive load: low vs. high) x 2(standard food: chocolate vs. sardines) design. All participants were paired with another participant and assigned to evaluate chips. To manipulate cognitive load, participants were asked to remember a series of number and letter, either B4 (low load condition) or 8K3YW17L (high load condition) while performing the food evaluation task. In the low load condition, participants enjoyed chips more when their partner was assigned to sardines than chocolate. However, in the high load condition, enjoyment of chips was the same regardless of the standard. These results are consistent with our attention based explanation showing that hedonic contrasts are attenuated when experiencers don't have enough cognitive resource to pay attention to other people and compare their experiences. Study 3 examined whether hedonic contrast occurs because people compare their experience to the alternative enjoyed by another person or because they compare their imagined happiness to another person. In doing so, we manipulated the modality of standards. We predict that social standards of a different modality will have a weaker effect on the target experience, as it is more difficult to compare to standards of a different modality rather than standards of the same modality. All participants were assigned to eat potato chips and their partners were assigned to experience a superior or inferior alternative. Half of the participants were told that their partners were experiencing either chocolate or sardines (same modality condition); whereas others were told that their partners were listening to a sound clip of either jungle waterfall or vacuum cleaner (different modality condition), which was rated in a pre-test as being as pleasant as chocolate or sardines. We found that hedonic contrast occurred only when partners were experiencing easy-to compare same-modality alternatives, thus supporting our theorization that social standards produce a greater influence on hedonic value because social comparisons are easier not because they are fundamentally different.

Study 4 directly tested whether social comparison can lead to suboptimal decisions. We predict that a superior social standard

can lead people to choose a lower -value, difficult-to-compare option than a higher-value, easy-to-compare option. Upon arrival, participants were paired with another participant and completed an animal trivial. Participants were then asked to choose a prize from a set of four prizes—two from a superior category (chocolates: Godiva & Hershey's) and two from an inferior category (snack bars: Granola Bar & Power Bar). Results from a separate pretest indicated that Godiva was ranked as the best prize, Hershey's was ranked as the 2nd best, Granola Bar was ranked as the 3rd best, and Power Bar was ranked as the worst prize to get for participating in a psychology experiment. In the social comparison condition, participants were told that their partner was randomly assigned to choose first and Godiva was no longer available after being chosen by the partner. In the control, participants was simply asked to choose a prize and told that Godiva was out of stock. Consistent with our prediction, we found that participants in the social condition were more likely to choose the inferior Granola Bar instead of Hershey's than the control.

“Absolute and Relative Choices of Maximizers and Satisficers”

Kimberlee Weaver, Virginia Tech, USA

Norbert Schwarz, University of Michigan, USA

Kim Daniloski, Virginia Tech, USA

Keenan Cottone, University of Michigan USA

According to the theory of bounded rationality, cognitive and situational limitations can prevent individuals from optimizing or “maximizing” the outcome of many decisions (Simon 1955). Recently, Schwartz et al. (2002) extended these theoretical insights into an individual differences scale. “Maximizers” are consumers who exhaustively examine every possibility before deciding which choice is best, while “satisficers” are more likely to choose the first available option that meets a threshold of acceptability. In the current paper, we investigate a new question that past work has not considered: whether maximizers and satisficers not only differ in the amount of effort they put forth in trying to achieve their standards, but whether they also differ in the *type* of standard they choose to pursue in consumer choice situations. Past work has remained agnostic about which type of standard maximizers and satisficers emphasize when making decisions (Schwartz et al. 2002; Simon 1955). However, there has been an implicit assumption that maximizers and satisficers are aspiring toward the *same* standard, and that the major difference between the two types of decision makers is in the amount of effort they expend in trying to achieve it, with maximizers expending more effort and satisficers truncating the search process at an earlier point. In contrast to this implicit assumption, our major hypothesis in the current paper is that maximizers and satisficers may actually aspire toward different standards; with maximizers being more interested in pursuing the relative best, and satisficers more interested in pursuing the absolute best.

Generally speaking, there are two types of standards that consumers can use when judging what is “best”: *absolute* standards and *relative* standards. To illustrate this distinction, imagine that a consumer can choose to live in one of two possible worlds. In World A, she will drive a car that is a medium quality brand rated 7/10 in parts and performance by Automotive Weekly. Nearly all of her acquaintances will drive cars that are luxury models rated 9/10. In World B, she will drive a car that is a fair quality brand, rated 6/10 in parts and performance by Automotive Weekly. Nearly all of her acquaintances will drive cars that are low quality models rated 4/10. Consumers who aspire toward an *absolute* standard search for the objectively best outcome and would likely choose to live in World

A, since the car the consumer will have is rated more highly than the car they will have in World B (i.e., 7/10 in parts and performance versus 6/10). On the other hand, consumers who aspire toward a *relative* standard search for an outcome that is best in the relative sense that it exceeds what others have. They would thus prefer to live in World B since the car the consumer will have is better than the cars driven by others (i.e., 6/10 on parts and performance versus 4/10) (Solnick and Hemenway 2005).

Results from three studies confirmed hypotheses by showing that maximizers pursue relative standards more than satisficers. Specifically, study 1 showed that maximizers were more willing than satisficers to accept *objectively worse* products or outcomes when they were paired with superior social position (e.g., Option B above). Studies 2 and 3 sought to establish the psychological mechanism driving the effect by manipulating the public visibility of the decision outcome. If maximizers' emphasis on social comparison reflects a concern for information *about* the absolute standards as proposed by past work (Iyengar et al. 2006; Schwartz et al. 2002), then they should choose the same option regardless of whether the outcome of their decision will be publicly visible or not. In contrast, if maximizers are motivated by social rivalry, then the standards they use may shift from public to private contexts. Both studies showed interactions between the maximizer/satisficer variable and the public visibility variable, supporting the social rivalry explanation. Maximizers accepted objectively inferior products that were paired with superior social position more than satisficers in public (e.g., house, car). However, the two groups of decision makers were equally likely to maximize absolute quality when the outcome was private and known only to the decision maker (e.g., pajamas, brand of mattress). The final study also indicated that maximizers prefer counterfeit products—those that have low internal quality, but have the outside appearance of high quality items—more than satisficers.

In conclusion, the current results examine a new theoretical question that past work has not considered and show that maximizers and satisficers not only differ in the amount of effort they put forth in trying to achieve their standards, but also differ in the *type* of standard they choose to pursue in consumer choice situations, with maximizers emphasizing relative standards and satisficers emphasizing absolute standards. In examining this question we bridge two literatures, the first on maximizing and satisficing in decision making and the other on relative and absolute choices, which has been studied in the decision making, psychology and consumer behavior literatures (e.g., Easterlin, 1974; Huguet, 2009; Zhou & Soman 2003).

“Integrate or Separate Future Pain? The Impact of Current Pain”

Eduardo B. Andrade, University of California, Berkeley, USA
 Marco Aurelio Bianchini, Universidade Federal de Santa Catarina, Brazil
 Newton Lucchiari, Universidade Federal de Santa Catarina, Brazil

It is often the case that health-related treatments can take place either in one single, or in two or more, periods (e.g., extract two wisdom teeth). When no clinically dominant option is available, the doctor allows the patient to decide whether to undergo the unpleasant experience all at once or to separate it into multiple events. Although several considerations are at stake, the decision is in part a matter of one's ability to project and willingness to deal with the future painful experience. Interestingly, patients are often not experiencing any level of pain at the time of the decision (e.g., a teenager who, comfortably seated at the plastic surgeon's office, decides to undergo breast and nose surgeries all at once). Two

questions emerge from this type of scenario: (a) do patients prefer to integrate or to separate future painful treatments? And (b) does the current level of pain influence their preference?

In line with previous theoretical suggestions (Kahneman and Tversky 1979; Thaler 1985), we hypothesize that patients are more likely to integrate future pain. However, this preference, we argue, is partially due to the fact that they are often not experiencing any pain at the time of the decision. When pain is experienced at the time of the decision, patients might question their capacity to endure the future unpleasantness all at once (Linville and Fischer 1991). Thus, the preference for integration of pain could be reduced when a “sample” of pain is provided directly before patients make their choice.

We tested this possibility in a field experiment in a public dental clinic. Sixty-two patients with periodontal disease in both sides of the mouth (50% male) underwent a sequence of two standard and required dental examinations: one painless (i.e., general clinical exam) and one painful (i.e., pocketing and bleeding on probing exam). Our manipulation simply consisted of randomizing the order of examinations. Half of the patients were randomized to a painless-painful order whereas the order was reversed for the other half. After *each* dental examination, the patients were asked whether they preferred to have the future periodontal therapy (i.e., scaling and root planing in both sides of the mouth) in either one single intervention or in two interventions performed one week apart from one another. The results show that, in general, patients were more likely to integrate than to separate the future painful experience. However, the preference for integration diminished significantly when they experienced mild levels of pain at the time of the decision. Whereas patients, on average, preferred to integrate future pain after a painless examination, preference for integration did not differ from chance when the decision was made after a painful examination. The effect emerged when comparisons were made within and between subjects.

Given that patients' currently experienced pain can so easily influence their choice, health professionals should be aware of such effects when delegating the choice of future painful experiences to patients. Finally, it is an open question whether visceral information about pain at the time of decision can help patients make choices about integration versus separation with which they will, in retrospect, be more satisfied.

Constraining the Consumption Environment to Enhance Consumer Creativity

Anne-Laure Sellier, New York University, USA

EXTENDED ABSTRACTS

“The Influence of Ambient Noise on Creative Cognition and Behavior”

Ravi Mehta, *University of British Columbia, Canada*
Rui (Juliet) Zhu, *University of British Columbia, Canada*
Amar Cheema, *University of Virginia, USA*

Recent years have seen a rapid shift in consumer markets from being product- and firm- centric to one encouraging consumer involvement in mutual value creation by leveraging consumer creativity (Prahalad and Ramaswamy 2004). In parallel, there has been a surge in research studying various aspects of consumer creativity, such as consumer created content (e.g., Moreau and Herd 2010) and the effects of constraints on consumer creativity (Moreau and Dahl 2009). Our research builds on this research by exploring the effects of an important environmental variable on consumers’ creative performance. It is well accepted that consumers’ physical surroundings can significantly affect their decisions, whether it is color, aesthetics or ambient scents. We focus on one aspect of physical surroundings that has received less attention –ambient noise.

Although ambient noise is always present in consumption contexts, its effects on cognition and behavior are not well-understood. Our research contributes to this literature by exploring the underlying process through which noise may affect creative cognition. Specifically, we examine how different levels of background noise may affect consumer creativity and behavior.

We propose that moderate compared to low levels of noise can actually enhance creativity. Based on prior research (e.g., Nagar and Pandey 1987), we theorize that a higher noise level distracts individuals and increases processing difficulty, which causes individuals to process more abstractly (Alter and Oppenheimer 2008). Because empirical work on construal level has shown that abstract construal enhances creative performance (e.g., Smith 1995), we hypothesize that a moderate level of ambient noise may increase processing difficulty, activate an abstract construal level, which subsequently may enhance creativity. Our experiments provide systematic support to our theorizing.

In our research, we only use moderate (70 dB) and low (50 dB) levels of noise intensity. Although prior research has also used high noise levels (e.g., 95 dB, Nagar and Pandey 1987), such high intensity is (1) unlikely to be sustainable in a consumer environment and (2) has constantly shown negative effects across various studies and variety of tasks (e.g., Nagar and Pandey 1987). Consequently, high noise levels were excluded from our study. In addition to intensity, different types of noises have been used in past research, such as white noise, pink noise, jet engine noises, and incessant ringing of alarm clocks. In the present research, we blend a combination of different types of ambient noises to create a soundtrack of constantly varying background noise.

In Study 1, we test our main hypothesis that a moderate (vs. low) level of noise can enhance performance on a creative task. We used Remote Associates Tests as our focal task to measure creativity. Results showed that respondents in the moderate noise condition performed significantly better on Remote Associate Tests compared to respondents in the low noise condition. Study 2 tests our central thesis in a more consumer relevant context. It examines whether a moderate (vs. low) level of noise enhances persuasion when a persuasive message requires creative cognition to comprehend. Results again support our theorizing.

In Study 3 we test our proposition that alternative levels of noise affect the two key dimensions of creativity identified in prior research—novelty and appropriateness—such that a moderate level of noise would enhance both dimensions. In this study, we presented our participants with a dilemma problem and asked them to generate as many solutions as they could think of. In addition, to test the underlying process proposed earlier, we measured processing difficulty and construal level as participants completed the survey. All generated ideas were rated along the novelty and appropriateness dimensions by a separate set of 14 judges each. As hypothesized, ideas generated by those in the moderate (vs. low) noise condition were judged to be significantly higher on both the novelty and appropriateness dimensions. The multiple mediation analysis provided support to our theorizing by demonstrating that a moderate level of noise enhanced processing difficulty which in turn induced a higher construal level, consequently leading to higher ratings on both novelty and appropriateness.

In Study 4, we examine how noise affects individuals’ acceptance of creative, innovative products. In our first three studies, we manipulated noise at two levels. However, in real life, consumers come across a wide range of noise intensities. Thus, we conducted this study in a student lounge area and measured ambient noise level when the study sessions were run. Regression analysis revealed that as noise level increased, respondents reported a higher willingness-to-buy for innovative products, that is, they were more likely to accept these products.

“Restricting Choice of Inputs Increases Creativity for Experienced Consumers”

Anne-Laure Sellier, *New York University, USA*
Darren Dahl, *University of British Columbia, Canada*

Our research explores the influence of input choice set on both consumers’ self-perceptions and actual realization of creative output. It questions whether increasing choice of creative inputs (e.g., offering more choice of ingredients for a cook) leads to more creative outcomes.

Theoretically, because increasing choice of inputs offers increasing solution spaces, more choice should increase the likelihood that a more creative solution is produced. Previous investigations support this notion, finding that sufficient input choice plays a positive role in achieving creative outcomes (e.g., Amabile and Gitomer 1984). Consistent with such findings, suppliers of creative inputs (e.g., art stores) display choice options on entire walls; the implicit assumption being that more choice helps when people are selecting inputs for a creative task. Most consumers also believe that more choice is better (Schwartz 2004). It follows that consumers being provided with extensive rather than limited choice of creative inputs should feel more creative (H1).

Focusing on actual creativity, however, we challenge this lay belief to propose that increasing choice hurts creativity. In particular, we test the critical role of input choice in shaping creativity for consumers who are experienced in a creative task. In doing so, we primarily draw on the choice overload literature (e.g., Iyengar and Lepper 2000; Schwartz 2004) to test the prediction that input choice has a debilitating effect on experienced consumers’ actual creativity, when compared to consumers with limited experience in the creative task (H2). The more choice a consumer has, the less constrained s/he is, and the more likely it is that s/he will retrieve an existing solution to the problem under study (e.g., Park and Smith 1989), thereby sticking to the top-down process described

as the “path-of-least-resistance” (POLR, Ward 1994), which leads consumers to adopt a less rather than more creative solution. This adverse effect of choice should only apply to experienced consumers, since they have the domain-relevant skills allowing them to identify the vast number of possible creative solutions in the choice space (Amabile 1983). In contrast, inexperienced consumers are unlikely to be sensitive to a change in the input choice set, and should merely display a general tendency to stick to the POLR. In sum, restricting choice should positively affect creativity for experienced consumers, and have no impact on inexperienced consumers.

Further, we identify that a decrease in enjoyment with the creative process causes the debilitating effect of choice (H3). Too much choice has been linked to decision-making paralysis, and generally found to be detrimental to consumers’ emotional well-being, particularly when consumers do not know a priori exactly what they want (Schwartz 2004), as is the case with creative outcomes. Restricting choice in creative consumption contexts should be conducive to a more enjoyable and playful creative experience, which in turn should transcend into the creative outcome (e.g., Isen 1999). Again, this positive experience should only affect experienced consumers, for only they are affected by the daunting vastness of creative possibilities.

We tested our predictions in a field study, in which 76 experienced and inexperienced knitters (mean age=29.82 years) created a scarf over a week, after choosing yarn from a limited (6 colors) versus a relatively extensive (12 colors) choice set. At the end of the week, participants returned their completed scarf, reported how creative they thought their scarf was and assessed how pleasant the creative process had been. After all scarves were collected, two experts in creative knitting evaluated the creativity of the scarves (randomized order) through handling and inspection.

Our key findings are that, focusing on the knitters’ self-reported measure of creativity, knitters rated their own scarf as less creative under limited rather than extensive choice, in support of H1. In contrast, the averaged knitting experts’ creativity ratings (Pearson- $r=.66$, $p<.01$) revealed a very different pattern when it was subjected to a Choice x Knitting level ANOVA. As predicted, we found a significant Choice x Knitting level interaction, $F(1, 72)=7.75$, $p<.007$, $r^2=10$. In support of H2, the analysis of simple effects further revealed that scarves knit by experienced knitters under limited rather than extensive choice were significantly more creative. Scarves knit by inexperienced knitters were equally creative under limited and extensive choice, $t<1$. Finally, in support of H3, we found that the averaged measures of knitters’ enjoyment mediated the knitting experts’ creativity ratings. Of particular interest, a limited choice made the task more enjoyable for experienced knitters, and that enjoyment led to more objectively rated creativity. We discuss these key findings, as well as other measures further supporting our conceptualization.

“Designing Memories”

Kelly B. Herd, University of Colorado, USA

C. Page Moreau, University of Colorado, USA

While constraints can be beneficial, they also have the potential to diminish perceived autonomy during a creative activity. Finding the right balance between structure and freedom in any given creative activity is, therefore, challenging. This research examines an important factor likely to influence where that optimal balance lies. Specifically, we investigate how the purpose for which the creative task is performed influences consumers’ creative experiences and evaluations of the creative product. In two studies, we engage participants in creative tasks (customizing a storage box, creating a scrapbook page) during which we either manipulate (Study 1) or

measure (Study 2) the extent to which the created product is intended to hold/capture something special. Both studies demonstrate that constraints have a positive influence on participants’ experiences and product evaluations when the purpose of the product is less special. When the purpose is special, however, constraints do not have a positive influence on either measure.

In Study 1, 100 female participants were told that they would be choosing design options for a box, which would then be assembled to their specifications. Two factors were manipulated between-participants: (1) the purpose of the box (functional: “storage box” vs. special: “memory box”) and (2) the constraints operating (low vs. high). Upon arriving, participants in the “functional” condition were asked to think about and describe the items they would place in the storage box. Participants in the “special” condition did the same for the memory box.

All participants were given an order form showing a drawing of a plain box indicating all the choices they could make in the customization task. They were then given a packet containing the second manipulation. Participants made 7 design choices. In the “low constraint” condition, the options were arranged in the packet according to the choices they would have to make. (e.g., the wide ribbon on the lid was Option A, and this condition showed all the “A” options on one page). In the “high constraint” condition, the options were presented in eight coordinated arrangements in which all seven customization decisions had already been made. Participants were told that these were merely suggestions, but creating an entirely unique design in this condition required more effort as participants had to search across pages to see all of their options.

Results showed that participants designing storage boxes had a more positive experience than those designing memory boxes. We also found an interaction, such that under high constraints, participants designing storage boxes reported more positive experiences than those designing memory boxes. When low constraints were in place, participants’ experiences did not depend on the box’s purpose. There was also a main effect of the box’s purpose on expectations, such that participants designing storage boxes reported higher expectations than those designing memory boxes. An interaction also emerged: High constraints produced higher expectations for storage boxes than for memory boxes. Under low constraints, expectations did not depend on the box type.

Study 2 was a 2-part study, with 73 female participants. In the first session, participants were given a packet in which they were asked to either (1) think back 4 weeks (“past”) or (2) think forward 4 weeks (“future”) and to describe (on paper) an experience/event that was (or was expected to be) particularly meaningful, fun, or positive. Participants then indicated how special that event was (or was expected to be). Next, they were they asked to create a scrapbook page capturing that event. All scrapbooking materials were held constant. Participants evaluated their scrapbook pages and left them with us until the second session, 4 weeks later. At that time, participants in both conditions described and evaluated the event their scrapbook page again.

Participants scrapbooking an event that had already occurred were more constrained because the details of the event were fixed (e.g., pictures were or were not taken). Participants scrapbooking a future event could control, to some degree, the details of the event to come. Regression was used to assess the effects of the time manipulation and the measured specialness of the event on evaluations of the scrapbook page. An interaction emerged ($F(1, 73)=5.02$, $p<.05$), and a spotlight analysis was used to interpret the results. Those scrapbooking a past event (high constraints) reported higher evaluations of their pages when the event was less special. For those scrapbooking a future event (low constraints), the pattern

was reversed. These findings are similar to those observed in Study 1, demonstrating that the specialness of the purpose of a creative activity moderates the effectiveness of constraints.

“The Blank Page: How Constraining the Creative Task Influences Creative Processes and Outcomes”

Caneel K. Joyce, London School of Economics, UK

Freedom and choice are often associated with creativity. Findings from creativity research can be seen as supporting this association, showing that constraints on freedom such as surveillance and a lack of choice can decrease the intrinsic motivation to create (Amabile & Gitomer, 1984; Amabile, 1983). In seeming opposition, decision making research has revealed a “Paradox of Choice” (Schwartz, 2004) in that too much choice can be paralyzing and tends to undermine good judgment and intrinsic motivation (Iyengar & Lepper, 2000). Given that judgment and choice are important, but often-overlooked aspects of creativity, the extent of choice available to a creator regarding which problems to solve and which solutions to consider may have a major impact on the creative process and subsequent outcomes.

This research uses a multi-method approach to examine how constraining a creative task affects creative processes and outcomes. Creative tasks are characterized as more or less constrained, depending the size of the search space the creator is permitted or opts to explore. A search space is bound by constraints that limit the range of options available, and that direct the creator towards certain options over others. In practical terms, such constraints limit the range of problems that may be solved, as well as the range of solutions considered.

Three studies examined the effects of constraint on the creative task where constraint is conceptualized as a continuum. Study 1 was a laboratory experiment centered around a written product design task. First, participants were given a prompt instructing them to do internet research and then use their research to design a product to address some health-related problem. Constraint was manipulated by varying the degree of choice the participant had in defining that problem: The low constraint group could address any health-related issue; the low-moderate constraint group could address any one of five specific health-related issues, the high-moderate, one of three; and the high constraint group was given one specific issue to address. All four groups were given access to the same database of articles for their research, and their search behavior was tracked unobtrusively. All groups had 40 minutes to allocate as they wished between research and writing the product proposal. Proposal creativity was rated using the consensual assessment technique (Amabile, 1983).

Results showed a curvilinear effect of constraint on creativity, such that both the low-moderate and high-moderate constraint groups’ product proposals were rated as more creative than either the low or high constraint groups. These effects were not accounted for by alternative explanations such as time allocation during the task, or decreased intrinsic motivation. Analysis of the internet research data found differences in search behavior across groups in search behavior. Specifically, the two moderate constraint groups ran fewer unique searches in the database, spending more time with each search result than either the high or low constraint groups. This suggests that moderate constraint leads to a deeper engagement with new information, and greater certainty about the appropriateness of creative search strategies.

Studies 2 and 3 were field studies that examined the role of constraint in 43 new product development teams. In Study 2, constraint was measured rather than operationalized. Raters scored the limiting aspect of constraint by responding to the question, “What

percentage of possible ideas have been eliminated in solving the problem, or the types of solutions that address the problem” on a scale of 1-100%. Higher scores meant the project was more constrained (a greater percentage of all possible ideas being eliminated ex-ante) by virtue of the mission statement sentence. Inter-rater reliability was high (ICC=.80). Raters scored the directing aspect of constraint by responding to the question, “How constrained is the solution the team is trying to make” (ICC=.75). Each team submitted a mission statement for their new product, and two trained raters coded the content from these statements. Through quantitative analysis, Study 2 found that the degree of constraint that new product development teams voluntarily imposed on their projects at the beginning of the semester predicted the creativity of their product proposals more than ten weeks later. The results held up even when controlling for task conflict.

For Study 3, all 43 teams were ranked according to their constraint score as in Study 2 and sorted into high, moderate, and low constraint groups. One team was selected from each group based on the information richness of the data available, and was subjected to case study analysis using interview, observation, and archival data. We examined the data for these three teams. The result was a novel framework conceptualizing creativity as a hypothesis-testing activity.

These three studies suggest that while some amount of choice is important for encouraging creativity, too much can be counter-productive.

Effects of Choice Architecture and Menu Labeling on Food and Beverage Consumption

Jason Riis, Harvard Business School, USA

Janet Schwartz, Duke University, USA

EXTENDED ABSTRACTS

“Would You Like to Downsize that Meal? Prompting Self-control Is More Effective than Calorie Labeling in Reducing Calorie Consumption in Fast Food Meals”

Janet Schwartz, Duke University, USA

Jason Riis, Harvard Business School, USA

Brian Elbel, New York University, USA

Dan Ariely, Duke University, USA

Concern about rising obesity rates has led several jurisdictions to mandate calorie labeling of all items sold in fast food restaurant chains. Thus far however, such interventions have shown little evidence of influencing consumer choice. Much behavioral research suggests that self-control, and not lack of information, may be a more important contributor to problematic health behaviors such as overeating (Volpp, 2010; Thaler & Shefrin, 1981). This view is supported by recent Pew and Gallup surveys which show that most American consumers are 1) aware that they are overweight, 2) wish to lose weight, and 3) are aware that they should be eating less. In light of this, we tested an intervention that made a self control opportunity salient to customers at the point of purchase. In two field experiments conducted at a national fast food restaurant, this intervention proved effective in reducing average calories purchased per meal. In our second study, this intervention was compared a calorie labeling intervention—the portion control intervention was significantly more effective.

Both experiments were conducted at an Asian-style fast-food restaurant. Meal ordering during the studies worked using the restaurant's standard procedure, whereby customers first ordered a side dish (e.g., fried rice), and then ordered entrees (e.g., stir fried chicken). In Study 1 customers (N=238) were asked by restaurant staff if they wanted to “cut over 200 calories from their meal” by taking a half-portion of their side dish (which ranged in calories from 440-570). In one condition, on two consecutive days, restaurant customers were invited to take the half portion for no discount. In a second condition, on two different days, a nominal (25 cent) discount was offered for taking the half portion. Baseline data were collected on two consecutive days preceding each intervention. On these baseline days, the half portion offer was not made to customers. In all conditions, customers were unaware that a study was taking place and all data were recorded through individual cash register receipts.

While customers almost never spontaneously asked for a half portion side dish on the baseline days, 36% took the half portion when it was offered without a discount. Similarly, 30% took the half portion when offered with the nominal discount. These acceptance rates were not significantly different, suggesting that customers took the half portion because they wanted less food, not because they wanted to save money. Across the intervention conditions, store customers purchased an average of 71 fewer calories than customers on baseline days ($p < .05$). Furthermore, there was no evidence of compensation, that is, customers who opted for the half portion of their side dish did not go on to purchase higher calorie entrees.

In Study 2 we repeated the half portion intervention (with a younger, predominantly college, population; N=994). In this study, the offer always included the nominal 25 cent discount. (Although offer acceptance was just as high without the discount in Study 1, inclusion of the discount is more consistent with retail norms, and is

hence easier for employees who repeatedly make the verbal offer.) Calorie labeling was also introduced in this study to directly assess its relative impact compared to that of the half portion offer. The study was conducted in 2 three-week blocks. Calorie labels were added to menu items for the second block. During block 1 (pre-label), data were collected for a 3 day baseline period, then for a 4 day intervention, and then for another 3 day baseline period. The sequence during block 2 (post-label) was identical.

Seventeen percent of customers accepted the half portion offer (across labeling conditions), thus reducing the overall number of calories per meal served by 34 ($p < .05$). As in Study 1, customers did not compensate for these saved calories by ordering higher calorie entrees. While the half portion intervention did significantly reduce the average number of calories per meal, the labeling intervention did not. In fact, calories per meal went up slightly after labeling was introduced in the stores. The half portion intervention led to calorie savings both before and after labeling was introduced, but the savings were marginally smaller during the labeling period.

In sum, calorie labeling alone did not reduce the number of calories purchased per meal. However, a simple prompt to take a smaller portion (and thus fewer calories) significantly reduced calories purchased per meal.

We conclude that retailers who wish to help their customers eat less, can do so effectively by providing self control opportunities, such as smaller portion options. Such self control opportunities are more effective than simple calorie labels, and they may be cost-effective since many customers are eager to take smaller portions for no discount, or for a nominal discount.

“Simple Strategies for Communicating Health Information”

Julie S. Downs, Carnegie Mellon University, USA

Jessica Wisdom, Carnegie Mellon University, USA

George Loewenstein, Carnegie Mellon University, USA

This paper explores whether innovative strategies for providing nutrition information might work better than traditional, typically numerical approaches such as simple calorie labeling.

Participants were 735 passers by, recruited in public locations to complete a short survey in exchange for a free snack of their choosing. The sample was diverse on many dimensions: aged 18 to 87 (mean=31), 44% female, 68% white, 7% African American, 9% Asian, and 16% other or mixed ethnic heritage, reflecting the population in the neighborhoods where recruitment occurred.

Before completing the survey, participants were asked to choose their snack from a list of seven available options, which ranged from relatively healthful (a 40-calorie package of freeze-dried apple slices) to decadent (a 470-calorie, deep-fried, frosted apple pie). The manner in which these snacks were presented was manipulated to test different techniques for communicating health information, compared to a control condition (over-represented in randomization in order to power collapsed comparisons), which presented the seven snacks with no nutritional information, in an arbitrary (constant) order. The first category of information was numeric, based on calorie content (including a simple presentation of the number of calories in each option, and other alternatives providing guidance for caloric consumption or other aids to interpret the information). The second category did not provide explicit information about calorie content, but rather presented heuristic cues suggesting how healthful each option was (including letter grades and simple images). The third

category did not provide additional information, but rather ranked the items from least- to most-caloric, allowing satisficing behavior (finding an attractive option and then discontinuing the search) to default to a more healthful choice. This ascending order was also combined in one condition with simple calorie information, in order to look for possible interactions. Participants then completed the short survey, which included a short list of demographic questions.

Participants in the control condition selected snacks with the highest average number of calories compared to all other conditions, suggesting that any technique for communicating health information might have some benefit. An analysis of variance comparing controls to numeric information and heuristic cues found a statistically significant main effect between these three categories of communication, $F(2,591)=3.46$, $p=.03$; post-hoc tests found that the menus using heuristic cues led to significantly lower-calorie choices ($M=186$) compared to controls ($M=222$, $p=.03$), with numeric information falling in between ($M=200$), not statistically different from either of the other two groups. Interestingly, this pattern appears to be driven by overweight participants, with the difference between controls and those receiving heuristic cues being much larger among participants with a BMI of greater than 25 (237 vs. 165, $p<.01$) compared to those with a BMI in the normal-weight range (212 vs. 196, $p=.53$). Our comparison of ascending vs. arbitrary ordering of snacks found a marginally significant beneficial effect of presenting snacks in an ascending order, $F(1,302)=3.67$, $p=.056$, but no main effect of calorie information and no significant interaction between order and information.

This study includes several limitations, including an unrealistic setting, and that our participants may not have been seeking out a snack at that moment but may have merely taken the opportunity because it was free. Furthermore, we do not know whether they ate their snack at that time, or if the high- versus low-calorie snacks had differential effects on their consumption later in the day. Nonetheless, these preliminary results show promise for more intuitive approaches to presenting nutrition information, and suggest that eating behaviors may be malleable through information-only approaches. Further research is needed to assess whether these effects can carry over to more complex food choices in naturalistic settings, and whether aggregation problems in assessing calorie information can be attenuated by using simpler cues.

“Effectiveness of Menu Labeling and Choice Architecture on Food and Beverage Purchases at a Large Hospital Cafeteria”

Jason Riis, Harvard Business School, USA

Susan Barraclough, Massachusetts General Hospital, USA

Doug Levy, Massachusetts General Hospital, USA

Lillian Sonnenberg, Massachusetts General Hospital, USA

Anne Thorndike, Massachusetts General Hospital, USA

Although many public health and physician organizations agree that environmental interventions are needed to reverse the current trend of obesity, there are few studies of these types of interventions. The current study incorporates a two-phase environmental intervention in a large hospital cafeteria. In the first phase, a simplified menu labeling system was applied throughout the cafeteria. Since calorie labeling interventions have shown limited success in changing customer purchase behavior, this study implements a simpler and more meaningful labeling scheme whereby all foods in the cafeteria were labeled as red, yellow, or green (with green being the healthiest). The second phase of the study alters the choice architecture of the food and beverages in the cafeteria, making it easier for customers to make healthy choices. We will compare the purchase patterns made during these two 2-month intervention phases with purchase patterns during a 4-month baseline period.

The setting for the study is the main cafeteria at large hospital in Massachusetts. More than 5000 individuals visit the cafeteria during a typical weekday and daily revenues exceed \$20,000. Just over a quarter of the revenues come from employees who use a “meal card” which allows purchases to be directly deducted from their paychecks. The purchases of these individuals can hence be tracked over time.

The first phase of the intervention will be a point-of-purchase labeling intervention designed to educate the employees, patients, and visitors about the nutritional content of the foods and beverages of the cafeteria. All foods and beverages in the cafeteria will be labeled as red, yellow, or green to reflect the nutritional content based on the United States Department of Agriculture’s My Pyramid healthy eating recommendations. Displays around the cafeteria will inform customers that Red items should be consumed rarely, as they are high in calories or unhealthy fat while Green items, which feature fresh fruits and vegetables, whole grains, and healthy proteins, should be consumed often. Yellow items are intermediate. The red-yellow-green categories were developed by a team of nutritionists at the hospital.

Following the two months of Phase 1, the second phase of the cafeteria intervention will begin. The labeling scheme will not change from Phase 1; food and beverages will continue to be labeled red, yellow, and green; but choice architecture changes will be made.

The intervention at Phase 2 will involve a series of changes to the layout of the cafeteria and the standard servings of some items. These changes are designed to increase the purchase rates of green items by making them more convenient to select, and by making them the default choice whenever possible. Two such interventions involve beverages and side salads. Water and diet soda (both green items) will appear at many more locations around the cafeteria, including several prominent, easy-access baskets near each food service station. Side salads will become be the default side dish. Currently, customers who want a side salad must make a separate trip to the salad bar. Now, customers will be offered a side salad with every entrée (including pizza, burgers, and sandwiches).

Cash registers have been programmed to record individual food items and their associated red-yellow-green label. Baseline data have been collected since November of 2009. Phase 1 began on March 1, 2010 when green-yellow-red labels were placed on all menu boards in the cafeteria. The convenience and default interventions of Phase 2 will begin on May 1, 2010. Data analysis will begin in early July and results will be ready for reporting by the beginning of August.

In addition to analyzing cafeteria-wide purchase trends, we are following a cohort of several hundred meal card users. For each user in the cohort, we will be able to determine their age, sex, race/ethnicity, and job type. We will collect data on all of their purchases at baseline and during the intervention phases, allowing us to assess how the interventions affect individual-level behavioral changes and to identify the characteristics of purchasers most likely to change their behavior in response to the intervention.

Our principal outcomes are total daily and weekly cafeteria revenues for green or red labeled foods, as well as the proportion of daily revenues that are from green or red labeled foods. Analyses of meal card user purchases will be based on similar measures of spending, using time series analysis.

“Does Calorie Labeling at Restaurants Affect Consumers’ Decisions of Where to Dine?”

Brian Elbel, New York University, USA

Courtney Abrams, New York University, USA

Previous investigations of the effectiveness of calorie labeling interventions have relied on analyses of point-of-purchase surveys and receipts. However, customers may alter their behavior in ways that would not be evidenced in point-of-purchase studies. After seeing the calorie content of the generally energy-dense offerings at fast food restaurants, customers may stop going to fast food restaurants, may limit the frequency of their fast food restaurant visits, and may substitute other types of (non-labeling) restaurants. On the other hand, health-conscious diners may welcome the transparency of information and increase the frequency with which they eat at chain fast food restaurants, versus non-labeling restaurants. In this study we examine whether mandatory, city-wide calorie labeling policies influenced the restaurant choices of adults; establish why mandatory, city-wide calorie labeling do or do not influence restaurant choices; and determine to what extent individual- and community-level factors interact with the influence of calorie labeling on restaurant choice.

In order to include individuals who may have stopped going to restaurants, reduced frequency, or substituted other types of restaurants as a result of calorie labeling, we conducted a random digit dial telephone survey. We employ a difference-in-difference design, examining changes in the data from pre- to post in a large northeastern city where mandatory menu labeling was enacted in January 2010, and compare with changes from pre- to post in a control (non-labeling) city. The difference-in-difference design allows us to isolate the impact of the policy change and net out any possible non-treatment related trends that may influence food choice, such as food pricing, the growth or change in the fast food industry, or health information diffusions. The telephone survey was fielded simultaneously in both cities.

Pre-labeling data was collected in both cities December 7th-24th, 2009. A total of 1,542 telephone surveys were conducted; 755 from the labeling city and 787 from the non-labeling city. All data has been coded and entered into SAS, cleaned, and weighted. Labeling laws in the city of interest went into effect January 1, 2010 and were fully implemented by February 1, 2010. Post-labeling phone surveying will begin in both cities May 3rd, 2010. Approximately 1,500 post-labeling surveys will be conducted. All data will be coded, entered, cleaned, weighted, and analyzed by August, 2010.

We examine changes in frequency of eating at (or getting take-out from) restaurants affected by the labeling law. Individuals reported the number of times they ate breakfast, lunch, dinner, and snacks from a big chain fast food restaurant in the past week. They also reported the number of times they ate breakfast, lunch, dinner, and snacks from a big chain casual dining restaurant in the past week.

Individuals were also asked whether they had changed the frequency of eating fast food in the past three months (and whether it increased or decreased). Those who did make changes provided the reason(s), including: nearby restaurants opening or closing, seeing calorie or nutrition information in a fast food restaurant, seeing calorie or nutrition information in another type of restaurant, wanting to eat healthier food, changes in financial situation or food budget, wanting to eat or cook more at home, or other.

Respondents were also asked whether they had noticed calorie or nutrition information at a restaurant. All consumers who noticed calorie or nutrition information on a menu at any type of restaurant were asked to describe its impact on their restaurant-going behavior. Specifically, they were asked to recall in what type(s) of restaurant they saw the information, whether seeing the information changed their eating, and if so, how. The answers pertaining to restaurant-

related behavior included eating fast food less often, stopping eating fast food, eating at non-fast food restaurants more often, and eating at non-fast food restaurants less often.

Factors including gender, age, race/ethnicity and income are all related to food choice. Income is expected to be highly relevant to calorie labeling and restaurant choice. Because fast foods are generally cheaper than most other foods (Darmon et al. 2004; Drewnowski 2004; Monsivais and Drewnowski 2007), consumers with lower income may be less likely to be able to substitute away from fast food in response to calorie labeling. Moreover, controlling for income, those who even perceive price to be a barrier to purchasing foods have been shown to have a less healthy diet (Beydoun and Wang 2008; Beydoun et al. 2008). We will examine differences across gender, age, race/ethnicity, educational achievement, employment status, household income, health status and weight status.

Results from this study will substantially increase our knowledge of how consumers are responding to mandatory calorie labeling. Additionally, the rich data we have collected will provide insight as to why consumers are responding as they do, and how we might make labeling and other policies more effective. Given the rate at which labeling policies are increasingly being adopted, and the need for more effective obesity policies, these insights will substantially inform this debate.

Influence of Social Norms on Consumption: Psychology, Biology, and Behavior

Vladas Griskevicius, University of Minnesota Carlson School of Management, USA

Noah J. Goldstein, UCLA Anderson School of Management, USA

EXTENDED ABSTRACT**“Reciprocity by Proxy: Expanding the Boundaries of the Norm of Reciprocity to Induce Environmental Action”**

Noah J. Goldstein, UCLA, USA

Vladas Griskevicius, University of Minnesota, USA

Robert B. Cialdini, Arizona State University, USA

The central goals of the current investigation were to challenge the wisdom of a motivational strategy commonly used in cause-related marketing campaigns (Varadarajan, Rajan, and Menon 1988), and to explore whether a seemingly small—but theoretically crucial—change to that strategy would prove more psychologically powerful and behaviorally compelling. We suggested that rather than offering to perform a favor for causes, organizations, and people that the target individuals value on the condition that the targets takes the first step (which we call an *Incentive-by-Proxy* approach), a more effective strategy—one that harnessed the obligating force of the norm of reciprocity (Gouldner 1960) to the fullest extent—would be to deliver the favor first on their behalf and then ask those individuals to repay the already completed favor via the desired behavior (which we call a *Reciprocity-by-Proxy* approach).

We argue that the effectiveness of the Reciprocity-by-Proxy normative approach lies in its ability to produce a strong sense of obligation toward the favor-doing proxy. Although the focus of his work was on gifts and favors that were mostly direct in nature, the anthropologist Marcel Mauss (1954) argued that three different normative obligations influence gift-giving and favor-doing processes in all human cultures: an obligation to give, an obligation to receive, and an obligation to repay. We contend that the Reciprocity-by-Proxy strategy should be an especially effective motivational tool because it is the only reciprocation-based influence strategy that we know that utilizes all three obligations simultaneously. That is, in a sense, targets have received in the process of giving to the valued cause (via the favor-doing proxy), and as a consequence, they are obligated to repay the favor-doer. Consequently, the individual should feel a sense of indebtedness toward the favor-doer, which will lead them to reciprocate the gesture by complying with the request.

A large field experiment in a hotel produced two findings. First, in-room signs explaining that if guests reused their towels, the hotel would donate money to a pro-environmental organization (the Incentive-by-Proxy sign) were not any more successful than a standard environmental control sign at motivating the desired behavior. Second, the Reciprocity-by-Proxy sign indicating that the hotel had already made the donation and asking guests to pitch in for that donation—a message we have never seen employed in any hotel—was the most effective.

These findings are noteworthy in that the Incentive-by-Proxy and Reciprocity-by-Proxy appeals carried similar content (in the form of monetary donations to a worthy cause) but differentially activated a crucial psychological motivation. The results of the field experiment and a follow-up pilot study strongly suggest that the superior level of prosocial conduct observed in the Reciprocity-by-Proxy condition was due to participants' greater sense of obligation to the hotel and not to potential alternative motivations. Specifically, participants who viewed the Reciprocity-by-Proxy messages were more likely to feel they would owe it to the hotel management to reuse their towels than were all other participants. Moreover, *only*

for Reciprocity-by-Proxy participants did we find a significant positive correlation between their personal endorsement of the reciprocation norm and the extent to which they felt they owed it to the hotel management to reuse their towels.

We conducted three additional experiments to replicate the findings, rule out any remaining potential alternative explanations, reveal in greater detail the psychological mechanism driving the phenomenon, and explore possible boundary conditions for the effect. Specifically, Experiment 2 replicated the field experiment in a different context and with a different behavior (i.e. volunteering time and effort to complete a task), and showed that Reciprocity-by-Proxy approaches need not explicitly portray a target's compliance with the request as helping to recover the costs of their actions. In Experiment 3, we examined the effectiveness of these approaches in yet a different context and with yet a different behavior—gift-giving. In conjunction with the findings of the survey study that was paired with the field experiment, the results of Experiment 3 yielded strong support for our contention that the Reciprocity-by-Proxy approach's effectiveness is mediated by the perception of indebtedness and obligation that the norm of reciprocation elicits in the target individual. Finally, Experiment 4 provided further support for our reciprocation-based account and revealed an important boundary condition for the effect by demonstrating that the approach is only effective when the favor to the third party has been performed on behalf of the target individuals—an approach that makes clear to the targets that the favor-doer was attempting to support his or her interests and goals when performing the favor.

“Using Space as a Weapon: The Effects on Social Norm Violations on Consumer Territorial Defense”

Lily Lin, University of British Columbia, Canada

Darren W. Dahl, University of British Columbia, Canada

Jennifer J. Argo, University of Alberta, Canada

There are numerous examples in the consumer context of social scripts and norms people are expected to follow. In a restaurant setting, for example, people are expected to arrive on time for their reservations so they would not hold up other people's tables. Additionally, there is an implicit norm among many societies that people's personal space should be respected. Therefore, hovering over someone's space while they enjoyed their meal or browsed for books at the bookstore is often seen as inappropriate. While prior research in the social norms domain had focused mainly on identifying what norms are and how one could change behavior through the promotion of norms (e.g., Goldstein, Cialdini and Griskevicius 2008; Joly, Stapel and Lindenberg 2008), no research in the consumer context has examined consumers' reactions toward those who are the violators of these well-established norms. Hence,

the purpose of the current research is to examine whether and how individuals would punish another consumer who had violated a social norm. Importantly, the aim of the research is to explore the conditions under which people would be willing to engage in punishing another at a cost to oneself.

According to the research on altruistic punishment and human cooperation, individuals often punish violators of social norms as a way to restore order in society. Importantly, punishment will often take place even when it is not in the best interest for the punisher. For example, when norm violators are detected in the form of selfish behaviors in economic games, other players in the game were willing to punish these defectors even if it was costly and did not lead to any material gains (Fehr and Fischbacher 2004).

The present research extended the research in altruistic punishment by testing actions taken against norm violators in two contexts. In our studies, the degree of punishment was operationalized through the level of territorial defense shown. Territorial defense, or the tendency to occupy one's territory or space for a prolonged period of time, is an interesting phenomenon that has been demonstrated in real-life contexts such as parking lots and public pay phones (e.g., Ruback and Juieng 1997). Specifically, the researchers observed that individuals were especially likely to protect and spend more time at their space when they recognized that others were waiting to occupy the same space. By employing territorial defense as the measure of punishment, our research was not only able to demonstrate altruistic punishment in a subtle, but interesting way, but we were also able to gain a better understanding of the thought processes and consumption experiences of those who chose to punish the norm violators.

Study 1 examined consumers' actions against another individual who had violated a norm against the self (i.e., invasion of personal space) in a 2 (norm violation: hovering vs. no hovering) by 2 (wait time: short vs. long) between-subjects design. To manipulate norm violation, a confederate either hovered over the participant or waited in a designated waiting area as the participant completed a food sampling task. To manipulate wait time, the participant had to wait for either a short or long amount of time before s/he could begin the task. The purpose of this manipulation was to ensure that the amount of time spent by the participant at their space was not simply driven by the anchor and adjustment effect. Results showed that those who did not have to wait for a long time themselves demonstrated more territorial defense when the confederate was a norm violator. Additionally, the results from the level of enjoyment felt during the task revealed that participants chose to spend more time on the task even though it did not provide them with a more positive consumption experience.

In Study 2, a 2 (norm violation: late vs. on time) by 2 (wait time: short vs. long) between-subjects design was utilized to examine consumers' actions toward another consumer who had violated a norm against the system (i.e., being late for an appointment). Replicating the patterns of results from the previous study, participants in the norm violation condition demonstrated more territorial defense than those in the no violation condition. Importantly, participants who spent more time at their space were not more involved with the task, and did not enjoy the task more than those who spent less time at their space. Overall, participants in the study engaged in altruistic punishment through the protection of their territory.

 Rebecca Dyer, Yale University, USA
- The iconic Lacoste green crocodile logo—initially created in honor of the 1920's French tennis star Rene Lacoste—has waxed and waned in popularity over the years, enjoying enormous popularity in the United States in the late 1970's and early 1980's while nearly disappearing from sight in the 1990's, only to reemerge in this decade as a desired status symbol. One reason to buy clothing featuring this crocodile might be to emulate Lacoste himself, of course, but we would be surprised if American teenagers have any awareness of the origins of the logo. Instead, such trends are often driven by the adoption—and rejection—of products by others: The value of little green crocodiles depends critically on the value that others attach to that symbol (Berger & Heath, 2007; Cialdini & Goldstein, 2004).
- In this paper, we model the process by which social norms impact preferences in a one-hour experimental session, using a paradigm in which we train participants to see symbols as socially valued or not by providing them with feedback about the preferences of others. We then examine the impact of this social feedback on the brain activity that participants exhibit while viewing objects that have been endorsed or rejected by their peers, exploring the neural processes underlying changes in valuation due to social normative influence.
- We first exposed participants to information about others' preferences for abstract symbols in a "social norms" phase. During this phase, participants learned that some abstract symbols were "popular" (preferred by others on 90% of trials) while others were "unpopular" (preferred on just 10% of trials). To confirm that our social tagging manipulation impacted liking for the stimuli, we conducted a behavioral version of this social influence phase, in which participants ($N=32$) rated all symbols on a 5-point scale both before and after the social influence task. As expected, popular symbols were rated significantly higher after the social norms phase than before, while attitudes towards unpopular symbols showed a marginally significant decrease.
- In the fMRI experiment, we assessed brain activity when participants ($N=12$) were exposed to these socially tagged (popular and unpopular) symbols, as well as new symbols about which they had not been provided normative information. As expected, mPFC, a brain region involved in thinking about the attitudes and preferences of others (Amodio and Frith 2006), was more active when participants viewed symbols that had been socially tagged than symbols for which they had no prior social information, suggesting a possible index of normative influence at the level of the brain. Also as predicted, we found that a region involved in the experience of reward—the caudate, part of the striatum—exhibited greater activity in response to popular symbols, providing a possible neural index of informational influence.

These results suggest that predicting whether a symbol is socially valued may require integrating data from both the mPFC and the caudate. Looking solely at the mPFC reveals only whether a symbol is socially tagged or not, while looking solely at the caudate reveals only whether a symbol is liked or disliked; only by looking at both regions together can we identify those symbols that have become valued as a result of social normative influence.

“Going Against the Grain: The Evolutionary Roots of Normative Influence”

Vladas Griskevicius, University of Minnesota, USA

Noah J. Goldstein, UCLA, USA

Joseph Redden, University of Minnesota, USA

Much research shows that people are strongly influenced by social norms. Consumers, for example, are more likely to purchase a product upon learning that many others have bought it, and hotel guests are more likely to reuse a towel when informed that many other guests reuse their towels (e.g., Goldstein, Cialdini, and Griskevicius 2008). Social norms often influence behavior in a heuristic manner, whereby people are often unaware that their actions are being influenced by the norms in the situation. The automaticity of normative influence is consistent with the evolutionary underpinning of heuristic attunement to norms. Across social species, for example, individuals who follow the crowd gain an adaptive survival advantage because following the herd decreases the likelihood that a given individual will be eaten by prey.

Although people are heuristically influenced by social norms, an evolutionary perspective suggests that organisms generally do not evolve domain-general heuristics. Instead, organisms manifest different biases in different evolutionary recurring domains (e.g., survival, reproduction, etc.) (Sundie et al. 2006). We suggest that whereas following social norms is adaptive in the evolutionary critical domain of survival, blindly following the herd is unlikely to be adaptive in the domain of mating. Thus, whereas susceptibility to social norms should be exacerbated when survival-related motives are active, people might not follow norms when mating motives are activated (Griskevicius et al. 2009).

In Study 1, we activated either self-protection, mating, or control motives by having participants read a short pre-tested story. Then, participants entered a multi-person chat room in which they were asked to indicate their preferences for various works of art. Before participants could indicate their like or dislike for the artworks, they were able to see the preferences of their peers in the chat room, which were designed to either create a social norm for liking *or* a norm against liking a given piece of art.

In the control motive condition, participants were moderately influenced by the norm, whereby preferences for liking or disliking the art were swayed in the direction of the norm. Consistent with predictions, when self-protection motives were active, people were significantly more influenced by the norm, being especially susceptible to following the herd when self-protection motives were active. However, when mating motives were active, participants

responded in a drastically different manner: People, especially men, went against the norm. Mating motives led people to flout norms, doing the opposite of what everyone else was doing.

Study 2 examined an important boundary condition for when mating motives influenced susceptibility to social norms: whether the topic was *subjective* (e.g., preference for a product in a category in which there are multiple products of relatively equal quality) versus *objective* (e.g., preference for a product within a category in which one of the products is verifiably superior). After eliciting a mating or a neutral motive, participants responded to a survey in which they could see the responses of previous individuals. Half of the survey questions were relatively subjective (e.g., do you prefer a Mercedes-Benz or a BMW), and half were objective (e.g., do you think it's more expensive to live in New York or San Francisco). As in Study 1, findings showed that when choices were subjective, mating motives led people, especially men, to go against the group. However, mating motives did not influence choices for objective items.

Because mating motives likely motivate individuals to want to stand out from the crowd in a new way, Study 3 examined whether mating motives would lead people to desire products that were “new” and, thus, uncommon. Control or mating motives were activated. Then, participants chose among products that were labeled “new”, “classic”, or had no label. Findings showed that mating motives led people to choose a product significantly more when it was labeled as “new” compared to having no label or being labeled as “classic.” Overall, consistent with evolutionary considerations of the adaptive functions of following social norms, we found that mating motives can consistently lead people to go against the prevailing social norm.

Consumer Motivation: When Initial Consumption Influences Subsequent Actions

Stacey Finkelstein, University of Chicago, USA

Ying Zhang, University of Texas at Austin, USA

EXTENDED ABSTRACTS**“Motivational Consequences of Perceived Velocity in Goal Pursuit”***Szu-Chi Huang, University of Texas at Austin, USA**Ying Zhang, University of Texas at Austin, USA*

A large body of research has documented that as people make progress and move closer to the end point, their motivation increases and they exert more effort in the pursuit (Hull 1932; Kivetz, Urminsky, and Zheng 2006). However, because movement toward goal attainment is a dynamic process, trying to understand the motivational consequences of progress by focusing on the level of progress alone would neglect the temporal aspect of movement and miss out on the rate of progress, a psychological equivalent of velocity (Carver and Scheier 1998). For companies that try to encourage repeat purchases, should they design a loyalty program that allows consumers to experience a fast or slow rate of progress? Should companies use the same point structure to motivate customers who just joined a loyalty program as the one used to motivate those who are getting close to redemption?

In order to address these questions, we build on the research on the dynamics of self-regulation (Fishbach and Dhar 2005), and posit that people are concerned about different questions as they move from earlier stages to later stages of goal pursuit, and the velocity in goal pursuit allows them to make different inferences. Specifically, when people start pursuing a goal and the progress level is low, the perceived attainability of the goal is relatively low and people's commitment to goal is ambiguous. In this situation, individuals' motivation in further pursuit is determined by whether the goal is perceived to be attainable.

Consumers are less likely to commit to goals that are beyond their reach (Bandura 1997). Thus, high (vs. low) perceived velocity suggests that one is moving toward the ideal state at a faster rate, and signals higher attainability of the goal, thus motivating the person to persist in the pursuit. On the other hand, when the progress level on the goal is relatively high, people feel more confident about achieving the goal (Wood and Bandura 1989). Thus, low (vs. high) velocity of goal pursuit suggests that more effort will be needed and thus increases one's motivation in the pursuit.

Four studies tested present predictions. The first study tested the hypothesis in the context of public goal pursuit through conducting a field study. We launched a campus campaign with the Relief Nursery of Central Texas, a social-profit organization dedicated to the cause of preventing child abuse, and created different flyers to solicit volunteer hours for the organization. The results showed that when the progress on volunteer recruitment was low, information of high (vs. low) velocity was more motivating and led to higher percentage of people willing to volunteer as well as more hours people were willing to volunteer for; in contrast, information of low (vs. high) velocity was more motivating when the progress on recruitment was high.

In Study 2 and Study 3, participants took computer-based tasks and were offered the chance to accumulate 700 points to win cash rewards. We manipulated participants' progress and perceived velocity by offering them feedback on their performances. In Study 2, we gave them three extremely difficult questions and measured the amount of time participants spent on these questions as the

indicator of their motivation for the reward. We found that when the progress level was low, the participants who thought they were gaining points fast (vs. slow) persisted longer in the task, while the reverse was true when the progress level on the goal was high.

In Study 3 we asked participants about their perceived attainability of the goal and their concern about reducing the discrepancy, in addition to their persistence in trying to reach the goal. We found that low (vs. high) speed led to lower perceived attainability of the goal when the progress was low, but not when the progress was high. Also, we found that low (vs. high) speed led to higher concern about closing the gap when the progress was high, but not when the progress was low. In addition, when the progress on the goal was low, perceived attainability of the goal significantly predicted one's persistence, but when the progress was high, the concern for reducing the gap predicted their motivation for the pursuit.

In Study 4, we collaborated with a local coffee shop and distributed two versions of loyalty cards to their customers: the “uniform velocity” card that allowed customers to get a fixed number of points for purchases made at all stages of the program, and the “variable velocity” card that allowed customers to accumulate points at a faster rate at the initial stage of the program and at a slower rate when they approached the redemption point. We found that, compared with the uniform velocity program, the variable velocity program effectively enhanced customers' motivation for redemption and increased their purchase frequency at the shop.

“Exposure to Healthy Food Increases the Appetite”*Stacey Finkelstein, University of Chicago, USA**Ayelet Fishbach, University of Chicago, USA*

Consumers often experience a conflict between the health goal and the motive to satisfy their appetite (Geyskens et al. 2008; Herman & Polivy 1975; Scott et al. 2008; Vohs & Faber, 2008). Further, consumers generally believe that healthy food is less fulfilling than unhealthy alternatives, further increasing this conflict (Chandon & Wansink, 2007; Raghunathan, Naylor, and Hoyer, 2006).

To explore this conflict, we use a goal analysis (Kruglanski et al. 2002). In particular, we draw on research on the Dynamics of Self-Regulation (Fishbach and Dhar, 2005), which suggests that whether consumers infer commitment to their goals (versus progress towards their goal) influences the course of self-regulation over time. While an experience of commitment encourages goal-congruent actions due to an increased sense that the goal is valuable and attainable, an experience of progress on one goal will result in relaxing one's effort and moving away to another, competing motivation, which is presumably somewhat neglected.

In 3 studies, we test whether exposure to healthy food cues increases the strength of the motive to satisfy one's appetite as manifested by a stronger hunger experience and increased food consumption. This effect is driven by a perception of progress towards a person's goal of being a healthy individual as a result of exposure to healthy food cues. Consequently, consumers feel that the competing motivation of satisfying their hunger was neglected and increase food consumption. Further, we propose that this effect is stronger for less committed individuals who are more likely to infer progress on the health goal without an increase in commitment to the health goal.

Three studies manipulate exposure to healthy products and product labels (versus tasty products or regular product labels) and show a boost in experienced hunger, perceived progress towards the health goal, and actual food consumption as well as moderation by importance of watching one's weight. In study 1, we measured participants' experience of hunger over time. First, participants rated their hunger at the present moment. After, they tasted a sample of a protein bar that was either described as healthy or tasty or they did not taste a sample (control condition). After sampling and completing a distracter task (sampling conditions) or just completing the distracter task (control condition), participants rated their hunger a second time. In support of our hypothesis, those who sampled the item framed as healthy grew hungrier over time while those who did not taste a sample showed no difference in hunger and those who tasted the item framed as tasty were less hungry after sampling.

In study 2, we explored whether merely viewing low-fat food (e.g., fat-free cheese) versus regular (e.g., regular cheese) labels would lead participants to infer they have made progress towards their health goal. Consequently, after viewing low-fat labels, people should consume more of a neutral snack to satisfy their hunger. As predicted, participants who viewed low-fat labels reported having made more progress towards their health goal, thus activating the conflicting measure to satisfy their appetite as measured by an increase in consumption.

Clearly, there are individual differences in importance of weight-watching. For consumers who are less concerned with watching their weight, viewing low-fat labels leads to (often illusionary) progress towards one's health goal. However, for those whom weight-watching is a high priority, viewing low-fat labels and seeing that these items are pervasive in one's environment reflects that the items are common as well as that one searches for these items. Study 3 tests these predictions. Participants were exposed to either low-fat or regular labels and given a chance to consume a snack that was unrelated to the initial exposure during a presumably unrelated task. After completing this task, participants also rated how important it was for them to watch their weight using items from the restrained eater's scale (Polivy & Herman, 1975). We find that those who are less concerned with watching their weight consume more of a neutral snack when they view low-fat versus regular labels. However, those who were highly concerned with watching their weight, viewing low-fat labels did not increase consumption compared to those who viewed regular labels.

These findings have implications for marketers who use sampling to promote their product, especially in the food categories (e.g., Wadhwa, Shiv, and Nowlis, 2008). The drawback in giving away samples is that these samples can potentially make consumers feel less hungry and therefore reduce subsequent purchases and consumption. For example, grocery shoppers might satisfy their hunger with food samples and subsequently buy less food in the store. As the above findings suggest, one factor that influences the direction of impact is the perceived healthfulness of the sample.

“Too Much of A Different Thing? The (De)motivating effects of Variety on Goal Pursuit.”

Jordan Etkin, University of Maryland, USA

Rebecca Ratner, University of Maryland, USA

In the course of goal pursuit, consumers must make a series of choices about the products they use to help them maximize their likelihood of goal attainment. These chosen products, or means of goal attainment, will likely vary in many ways. How might the variety among chosen means affect subsequent motivation to pursue the goal?

The tendency for consumers to seek variety and change in choice over time has been construed as a goal-directed phenomenon (Ariely and Levav 2000; Kahn and Ratner 2005; Ratner, Kahn, and Kahneman 1999). Indeed, previous research has explored some of the inferences consumers make based on the perceived variety among products (Berger et al. 2007). Interpreting this finding from a goal systems perspective, if consumers make inferences about the “focus” of the means to their goal based on the relative similarity of the products that they choose, then this inference of “focus” may transfer from the products themselves to their associated goal. As a result, consumers may perceive themselves as more focused on a particular goal when they choose similar (vs. dissimilar) means of goal attainment, consequently affecting their motivation to pursue that goal.

We propose that the similarity of means chosen in the course of goal pursuit will affect subsequent motivation to pursue the goal, due to the inferences of focus on goal pursuit that consumers draw from the focus of the means set. Further, we propose that the amount of progress consumers feel that they have made towards attaining their goal will moderate the effect of means similarity on motivation, such that similar (vs. dissimilar) means will increase motivation when people feel that they have made high progress toward their goal.

Three studies were conducted to test these predictions. Each study used fitness goals as the target goal and followed the same basic procedure. All participants were shown a series of protein supplements and were asked to choose the three that they would most like to try after their next three workouts. Perceived goal progress was either measured or manipulated, followed by the key dependent measures of interest (motivation, perceived focus, etc.). In study 1, means similarity was manipulated by varying the set of protein supplements between participants, such that half of participants saw a set of six PowerBar protein bars (similar set) and half saw a set of six assorted protein supplements, such as a protein powder, a protein bar, etc. (dissimilar set). Participants were either surveyed before beginning a workout (low progress) or after finishing a workout (high progress). In study 2, all participants saw the same set of PowerBar protein supplements and means similarity was manipulated in a separate priming task, holding actual similarity constant; perceived progress was measured across participants and treated as a continuous variable in subsequent analyses. In study 3, means similarity was manipulated as in study 1 and perceived goal progress was manipulated in a separate priming task, holding actual progress constant.

Across all studies we found consistent support for our predictions: means similarity had a systematic affect on motivation to pursue the associated goal. Specifically, choosing from a set of similar (vs. dissimilar) means to a goal increased motivation, but only when consumers inferred that they had made high progress toward their goal. Further, in all three studies the effect of means similarity on motivation was mediated by perceived focus on goal pursuit in the high progress condition. These results persisted regardless of how means similarity was manipulated and whether perceived goal progress was measured or manipulated separately.

This research demonstrates that in addition to motivation affecting the amount variety chosen among means, the variety among means themselves may also affect subsequent motivation. In particular, the relative focus of a set of means chosen in the course of goal pursuit (similarity vs. dissimilarity) leads consumers to draw inferences about their own focus on goal pursuit, increasing motivation when perceived goal progress was already high.

“The Dynamics of Goal Revision: Updating the Discrepancy-Reducing Model of Self-Regulation.”

Chen Wang, *University of British Columbia, Canada*
Anirban Mukhopadhyay, *Hong Kong University of Science and Technology, China*

Existing research on goal-directed behaviors has largely focused on striving towards static goals (e.g., Carver and Scheier 1981), with relatively little attention directed towards dynamic goal-setting and updating. However, as Fishbach and colleagues have demonstrated (Fishbach and Dhar 2005), goals are not always static. Rather, people frequently revise their goals upward or downward based on the discrepancies between their initial goals and subsequent achievements.

In this research, we generalize this model to goals that are dynamic, and propose that goals are updated every period based on the extent of achievement in the previous period. Based on this proposition, we incorporate an additional element—a “calibrator”—into Carver and Scheier’s model. In our revised model, the goal-performance discrepancy serves not only as an input to the system as suggested by the original model, but also as the input to the goal calibrator. This goal calibrator is directed by an S-shaped response function which generates an updated goal for the next time period. This S-shaped function predicts the properties of *proportionality* and *diminishing sensitivity* for all goal-discrepancies, *failure aversion* for intrinsically motivated goals, and *satisficing* for extrinsically motivated goals.

Four experiments provide empirical support for our model. In Study 1, we manipulated discrepancy valence to be positive or negative, and provided hypothetical feedback for five successive time periods. Participants were to write down a savings goal and were then presented with a hypothetical performance outcome (e.g., you saved 15% more vs. less than your goal). Based on the feedback, they set their financial goal for the next month, and the next feedback was then presented. These procedures were repeated for five iterations. The performance outcomes ranged from 15% to 19%, always either positive or negative based on feedback condition. In support of our predictions, positive discrepancies resulted in continuous upward goal revision—savings targets for each month were higher than in the previous month. In contrast, negative discrepancies led to the maintenance of the original goal—savings targets stayed flat from month to month. Taken together, this experiment demonstrates (a) the existence of goal revision for self-set goals, and (b) the property of *failure aversion*.

Study 2 investigated effort exertion for positive versus negative discrepancies. We used a similar design, in the context of working out on the treadmill. Consistent with our hypotheses, we find that participants having positive discrepancies indicated the same amount of effort for each trial, whereas those with negative discrepancies indicated increasingly more effort to strive for the goal.

Study 3 further tested the characteristics of the S-shaped function by exploring the following features: proportionality, diminishing sensitivity, and failure aversion. Participants were presented a scenario in which they had a goal of burning 200 calories on the treadmill. The discrepancy was manipulated by giving hypothetical outcomes (burning 10 vs. 110 calories more vs. less). Next, participants established their calorie goal for the next day based on their performance. As predicted, consistent with the *proportionality* feature, large discrepancies resulted in greater goal revision than small discrepancies of the same valence. Further, discrepancies had a smaller marginal impact when they were more distant from the origin, demonstrating *diminishing sensitivity*. Finally, positive discrepancies led to larger goal revision than negative discrepancies of the same magnitude, highlighting *failure aversion*.

Study 4 tested *satisficing* for extrinsically motivated goals. In this study, we utilized a computerized anagram task. Participants were asked to set a goal for the first anagram (i.e., “to find ___% of the possible solutions”). Manipulated feedback was presented after participants submitted their answers (i.e., 5% more vs. less than your goal). As predicted, participants with positive discrepancies initially maintained the original goal, but revised the goal upward as they kept receiving positive feedback. In contrast, those with negative discrepancies revised the goal downward based on the negative feedback. In sum, these experiments contribute to a greater understanding of multi-period consumer goal-directed behavior.

Consumer Disposal Behavior: Retaining, Selling, Discarding, or Donating Used Products

Aaron Brough, Kellogg School of Management, Northwestern University, USA

EXTENDED ABSTRACTS

“To Have and To Hold? Marketing Implications of Consumers’ Product Retention Tendency”

Kelly L. Haws, Texas A&M, USA

Rebecca Walker Naylor, Ohio State, USA

Robin A. Coulter, University of Connecticut, USA

William O. Bearden, University of South Carolina, USA

In this research, we introduce the concept of product retention tendency, defined as an individual’s propensity to retain physical possessions. Per our conceptualization, consumers can fall anywhere on a continuum ranging from those who have no desire to “hang on to” their possessions and who therefore frequently dispose of things, to those who keep nearly all of their possessions and who do not like to discard anything. We argue that an individual’s general tendency to retain physical possessions impacts not only their retention/disposal decisions, but also their acquisition- and consumption-related behaviors. We propose that consumers with a stronger product retention tendency are driven by the desire to avoid waste (reflected in their greater frugality, interest in creative reuse, and concern for the environment) and by their attachment to physical goods (including possession attachment and materialism). These characteristics influence how individuals with a strong (vs. weak) product retention tendency differentially respond to various marketing tactics (e.g., product/packaging design decisions and specific promotional strategies).

We draw upon relevant literature in marketing, consumer behavior, and psychology (e.g., Coulter and Ligas 2003; Frost et al. 2004; Lastovicka et al. 1999) to provide theoretical grounding for a nomological network for product retention tendency and related constructs, including compulsive hoarding. We then detail six studies (studies 1a-f) conducted to (1) develop a valid and reliable measure of product retention tendency (PRT), (2) establish discriminant validity between our construct of interest and clinical compulsive hoarding, and (3) assess the proposed relationships between the constructs in the nomological network. In accordance with our conceptualization, these studies also demonstrate that product retention tendency is associated with avoiding waste due to frugality, an interest in creative reuse, and concern for the environment, as well as with feeling connected to one’s possessions because of possession attachment and materialism.

We then build upon insights from the nomological network of product retention tendency to discuss and hypothesize the influence of product retention tendency on consumers’ acquisition- and consumption-related behaviors. We focus on waste avoidance motivations and reuse of product packaging in study 2 and on attachment motivations and the response to promotional offers in study 3.

In study 2 we expect that individuals who have a stronger (vs. weaker) product retention tendency will consider more alternative uses for product packaging because of their desire to avoid being wasteful. More specifically, we expect that the waste avoidance motivations of frugality, creative reuse, and environmental concern are the drivers of this behavior. As expected, a regression model with PRT as a continuous predictor variable revealed that participants with a stronger product retention tendency reported significantly more ways to reuse a glass mayonnaise jar ($F(1, 398)=6.80, p<.01$). Creative reuse fully mediates the relationship between PRT and the number of uses generated. Frugality and concern for the environment both partially mediate the relationship, as confirmed by significant

Sobel tests. Study 2 therefore demonstrates that the waste avoidance motivations in the nomological network help explain why consumers with a stronger (vs. weaker) product retention tendency respond differently to an opportunity to reuse product packaging. The results of study 2 suggest that managers can successfully target consumers with a stronger product retention tendency by using product packaging that is specifically designed to be reused by the consumer, perhaps even touting the potential for reuse as an added benefit of their offering.

In study 3, we draw on Okada’s (2001) work on trade-ins to examine how differences in product retention tendency can impact response to two equally-valued promotional offers (i.e., a trade-in offer, in which a used good is “traded in” for a discount on a new good, vs. an equally-valued sale price offer on a new good). We predict that product retention tendency will moderate Okada’s (2001) findings, which show an overall preference for the trade-in offer. Consistent with our expectations, we found a significant interaction between product retention tendency and camera offer condition ($F(1, 201)=3.93, p<.05$). Follow-up analyses revealed that participants with a weaker product retention tendency reported a greater likelihood of buying the camera because of the deal in the trade-in offer condition compared to the sale price offer condition ($F(1, 201)=10.08, p<.01$). In contrast, participants with a stronger product retention tendency, regardless of whether they were in the trade-in or the sale price condition, were equally likely to report that they would buy the camera because of the deal ($F(1, 201)=.26, p>.10$). We also found that the difference in response to trade-in versus sale price offers for consumers with a stronger versus weaker product retention tendency is mediated by consumers’ emotional attachment to their possessions and their materialism. Our results suggest that Okada’s (2001) findings may have been driven by consumers with moderate or weak levels of product retention tendency. For those with a stronger product retention tendency, both types of offer are attractive because of the motivating factors we identify, attachment to possessions and materialism.

Overall, our research seeks to draw attention to the area of product disposal and how such tendencies impact consumer responses to marketing tactics. Our studies provide examples of the many ways in which a consumer’s attitude toward retention can affect their decision making behaviors through the waste avoidance and product attachment motivations.

“When Low Bids Win: Non-Price Competition among Buyers in Secondary Markets”

Aaron R. Brough, Northwestern University, USA

Mathew S. Isaac, Northwestern University, USA

A central aspect of marketing is how sellers compete for customers. Although price competition among sellers is prevalent, marketers recognized many years ago that customers also care about non-monetary factors. As a result, marketing literature has focused extensively on how sellers may successfully compete without lowering prices by differentiating themselves on dimensions such as location, brand, service, context, etc.

An area that has received less attention in the literature is how buyers compete for scarce goods. This neglect may be due to the assumption that sellers' pricing decisions are based on an aim to maximize profit (Monroe and Della Bitta 1978), and that therefore buyers compete exclusively on the basis of price (i.e., the highest bidder wins). Such an assumption may be particularly prevalent in the context of secondary markets, where sellers reveal a profit-motive by deciding to sell rather than keep, discard, or donate a used product. Furthermore, many second-hand exchanges are one-time transactions among relatively anonymous buyers, which incentivizes sellers to focus on profit-maximization.

In this research, we challenge the assumption that sellers of used goods are concerned exclusively with profit and argue that they may also care about non-monetary factors. We therefore predict that buyers of used goods may successfully compete with higher bidders by differentiating themselves on non-monetary dimensions. In particular, we focus on one non-monetary factor—buyer usage intent—and investigate how sellers' pricing decisions are influenced when prospective buyers communicate how they intend to use a product following a transaction. Building on diverse literatures which suggest a connection between a product and its owner (Argo, Dahl, and Morales 2008; Belk 1988; Thaler 1980), we attribute sellers' preferences regarding post-transactional product usage to a sense of product attachment that sellers feel towards their used goods. We test these predictions across three empirical studies.

Study 1 examines how sellers choose among two buyers who intend to use a product differently. 89 online participants were presented with a scenario in which they received offers from two buyers interested in purchasing a used piano. Buyer A planned to play the piano, but Buyer B planned to use the piano strictly for decoration. Participants were then presented with eleven pairs of offers from these two buyers in which the monetary amounts differed, and participants indicated for each pair to whom they would sell the piano. Results indicated that even for pairs where Buyer B offered a substantially higher amount (ranging from \$500 to \$4,000), many participants nevertheless preferred to sell to Buyer A. Whereas Study 1 demonstrates the effect of buyer usage intent on seller pricing decisions; Study 2 examines the role of product attachment intensity in driving this effect.

In Study 2, 100 online participants indicated the maximum amount they would be willing to accept (WTA) from each of two buyers with different usage intents. Participants were told that they originally intended to ask \$500 for a wedding ring they were selling. After learning that a potential buyer planned to wear the ring to a costume party rather than use it for a marriage proposal, participants indicated WTA. They then encountered a second buyer who planned to use the ring for a marriage proposal and again indicated WTA. Finally, participants indicated their level of attachment to the ring using a scale which depicted differing degrees of overlap between themselves and the ring. Results showed that WTA of participants who felt weakly attached to the ring did not differ based on buyer usage intent. However, participants who felt

strongly attached to the ring indicated a lower WTA from the buyer who planned to use the ring for a marriage proposal and a higher WTA from the buyer who planned to wear the ring to a costume party. These results are consistent with the notion that attachment influences the impact of buyer usage intent on seller pricing decisions. The next study examines the extent to which sellers regret a transaction after learning that actual product usage violated the seller's post-transactional preferences.

The objective of Study 3 was to provide additional evidence for the role of attachment by manipulating rather than measuring it. This was done by using hedonic versus utilitarian products, with the idea that participants would feel greater attachment to hedonic products than to utilitarian products. 142 undergraduates imagined that after selling a VHS tape which was originally purchased either for pleasure (hedonic) or for use in writing a term paper (utilitarian), they learned that the buyer had either watched the tape multiple times (proper usage intent) or recorded over its original content (improper usage intent). Participants were also informed that subsequent bidders had offered more money for the tape than the buyer to whom they sold it. Participants then indicated the extent to which they regretted selling to this buyer. Results showed that participants experienced greater regret after learning that a buyer had recorded over the VHS tape rather than watching it, but only when the tape was perceived to be a hedonic product.

Overall, this research contributes to the marketing literature by examining buyer-side competition. In particular, we suggest that like sellers, buyers may successfully engage in non-price competition. This insight has important implications for the pricing literature, which has focused primarily on how firms set prices and how consumers perceive and respond to those prices. In contrast, our work focuses on how consumers generate prices when selling used goods, and we identify product attachment as an important factor that influences seller pricing decisions in secondary markets.

“Curb Your “Wastism”: Interplay between the Abundance Mindset and Non-abundance Cues on Waste”

Meng Zhu, Carnegie Mellon University, USA

Ajay Kalra, Rice University, USA

Managing how much consumers waste has become an essential issue in maintaining sustainability of our society. Existing literature on waste holds the viewpoint that consumers are averse to waste due to their motivation to fully exhaust a product's residual value (e.g., Arkes 1996). We propose an additional “Wastism” perspective to examine consumer waste behavior at a non-conscious level. Specifically, we theorize that as mass production has become increasingly mastered by society (Riesman, 1950; Côté, 1993, 1996) people are in a default “abundance” mindset that emphasizes the need to seek convenience rather than conservation in consumption, which consequently leads to increased waste.

Building on the passive goal activation literature (e.g., Bargh et al. 2001; Laran and Janiszewski, 2008), we posit that subtle cues that highlight the non-abundance of resources (e.g., half-length pencil in a writing task) can trigger the goal to conserve. These cues can cause a shift away from the default abundance mindset and the tendency to seek convenience, therefore leading people to waste less in subsequent consumption, even when the consumption takes place in unrelated domains and utilizes different types of resources. Consistent with the passive goal-activation account, we find that this decrease in waste induced by non-abundance cues is attenuated when participants get a chance to conserve before the resource is provided (e.g., giving them a chance to help with an environmental-based charity as compared to an education charity). We also find that people with a chronic conservation goal are less susceptible to the influences of non-abundance vs. abundance cues.

Study 1 tests for the presence of a default abundance mindset and whether non-abundance cues can lead people to waste less resources in unrelated domains. Participants completed two purportedly unrelated tasks. In the first soft-drink sampling task, the experimenter poured the same quantity of drink into a sampling cup, but either took the bottle away after pouring the drink (non-abundance condition) or left the bottle on the desk (abundance condition). In the second task, participants were given a roll of wrapping paper and asked to gift wrap a box. In a third, control condition, participants proceeded to the second task directly. The length of wrapping paper utilized served as the dependent measure for the relative waste amount. Consistently with our prediction, the non-abundance cue lead subjects to waste relatively less resource (i.e., wrapping paper) in a subsequent unrelated task. Importantly, the length of wrapping paper utilized in the control condition was similar to that in the abundance condition, suggesting that people are naturally in an abundance mindset. Additionally, in support of our theorization, we found (with another group of participants) that participants in the control condition reacted to abundance words as quickly as those in the abundance condition, whereas participants in the non-abundance condition reacted more slowly.

Study 2 disentangles the effect of non-abundances cues on consumption quantity and waste quantity. In the first task, participants completed a figure drawing task, which randomly assigned them to either a non-abundance condition in which they were provided only a half-length pencil, or an abundance condition in which they were given a penholder holding a stack of regular pencils. In the second task, participants sampled three snacks and were told to rinse their mouth with water before each tasting. They were instructed to go to another desk in the room to get the water and then come back to their seat to finish the sampling task. The amount of water poured (i.e., the total amount of resource taken), the amount of water left in the cup (i.e., the waste amount) and the difference of the two (i.e., the consumption amount) were measured. The amount of water consumed was the same in both conditions, but as compared to the abundance condition, participants in the non-abundance condition took less water and wasted less. These results provide support for the proposed convenience-based explanation by demonstrating that non-abundance cues decreased waste because they reduced the amount of resource taken, rather than increasing the amount of resource consumed.

The last two studies seek support for the proposed goal-activation account. In both studies, we asked participants to evaluate the smell and color of a new detergent and provided them with a crystal cup. The amount of detergent subjects poured into the cup served as our waste measure as only a minimal amount is needed for evaluation. Specifically, Study 3 investigates whether people with a chronic conservation goal (high on the frugality scale) are

insensitive to the influence of non-abundance vs. abundance cues. As predicted, we found that a non-abundance cue as compared to an abundance cue (manipulated by offering participants a small or large quantity of ketchup in a prior sampling task) lead low frugality participants to pour less detergent; whereas high frugality participants poured very low amounts in both the abundance and non-abundance conditions. Finally, Study 4 tests whether giving people a chance to satisfy the activated conservation goal (manipulated by giving them a chance to help with an environmental charity vs. an education charity) influences the relationship between non-abundance vs. abundance cues (manipulated as in Study 1 by leaving or not leaving the bottle of a sample drink) and waste. Consistent with the goal-activation account, we found that the decrease in waste induced by the non-abundance cue disappeared only when participants got the chance to conserve in the environmental charity.

In contrast to the prevailing literature that people are averse to waste, we propose an additional “wastism” perspective to study consumer waste behavior at a non-conscious level. Our findings indicate the presence of a default abundance mindset. This default abundant mindset accentuates the need for convenience, which in turn increases waste of resources. Non-abundance cues in the environment can passively activate a conservation goal thereby decreasing waste even in unrelated domains. In support of this theorization, we find that giving participants a chance to conserve before the resource is provided can diminish the beneficial impact of non-abundance cues on conservation.

“Please, Accept My Kidney: Kidney Donors in African American Families”

Naja Williams Boyd, Anka Behavioral Health, Inc., USA
Tonya Williams Bradford, Notre Dame, USA

The gift of an organ represents a sacrifice (Mauss 1967) and typically is requested, highly specified, extensively investigated, and tightly managed by several members of the healthcare system. Kidney transplantation is the only solid organ transplant performed in which an individual is able to gift an organ to another human being and continue to live a healthy and substantially normal life. Kidney donation is a gift exchange that is extensively controlled, monitored, and managed by the market. A gift of a kidney may be desired by the donor, the recipient, and the recipient’s loved ones, yet there are required intermediaries who make the final determina-

tion for the gifting process—a departure from our understanding of gifting in consumer research.

Through five extended case studies, we explore the experience of living African American kidney donors who have successfully donated a kidney to a loved one. Through the experiences of these donors, we seek to understand consumer gifting behavior in complex market-necessitated circumstances. We purposively study experiences of African American kidney donors because they are in high demand for African Americans End Stage Renal Disease patients who are less likely to be referred, placed on the national waiting list, or receive a transplant (Gadegbeku 2002).

As symbols, gifts represent relational ties and communicate expectations from the giver to the recipient (Belk, Wallendorf, and Sherry 1989; Caplow 1984). Gifts establish and maintain roles in social relationships (Otnes, Lowrey, and Kim 1993), fortify social bonds (Mauss 1967), alter relationships (Cheal 1988), and serve higher-order needs of love, self-esteem or self-actualization (Belk 1996; Offer 1997). For our organ donor informants, the desire to enable the health of their loved ones is a tangible—life-giving—symbol which is mediated and managed through the healthcare market. The trinity of giving, receiving, and reciprocating constitutes an exchange cycle that attracts others into an intimate, involved relationship with one another. Receiving an organ from a relative places the recipient in a state of owing a gift of comparable magnitude. In general, the recipient will never be able to repay the debt, a circumstance described as the “the tyranny of the gift (Fox and Swazey 2002),” though it may be the role of the market that obviates the very need for reciprocity in this form of gifting (Marcoux 2009). We find organ donation to loved ones may not always result in a process devoid of reciprocity, as the organ donor may be engaged in self-gifting.

In the complex gifting circumstance of kidney organ donation within African American families, we find six themes that reflect significant decision drivers for our informants: loss and abandonment; recipient’s health; recipient resistance and reluctance; family support; healthcare provider optimism; and organ donation education. Themes of abandonment and loss resulted from experiences of previous losses in their respective families. One participant said she was aware of her own “selfishness” and another did not want to lose another parent if she could make the difference. Was the gift of the kidney an actual gift to the recipient or was it a self gift to the donor? The two may actually be one and the same.

Each informant stated that the health of the recipient was of paramount concern in their decision to donate: “It was devastating for me to see him on dialysis.” Recipient reluctance was prevalent as donors sought to give their organ. Not all recipients are interested in receiving kidneys from loved ones, because they “didn’t want to put them [the donors] through that...” One informant stated that he felt “it may be difficult for a sibling to ask another to donate because it’s a sacrifice” and that his brother would feel responsible if something were to happen to him. Family support plays a significant role in the gifting decision process. One donor shares responses to her decision to donate: “Oh girl, are you out of your mind?!” “Do you realize that you are going under the knife?” Her perspective was that “most Black people do not give up their organs.”

The role of the market is crucial to the successful culmination of organ donation. Once one donor made the decision to donate and the recipient’s approval, they made a conscious choice to wait until a new transplant team was in place. The donor had not been impressed with the transplant surgeon on staff because of the way he handled the recipient’s first transplant surgery. The gift-giver and recipient decided to wait until the existing team retired and the new team was in place. It was her belief that “you have to have a connection with whoever is going to be working with you.” The

market also is involved in the education process. Donors became educated about the process from their work environments, medical providers, and websites. All gift-givers were willing to donate because they had knowledge and had become educated about living kidney donation.

A kidney is an extraordinary gift. People who give gifts want to know whether their gifts are appreciated and used for their intended purpose (Sherry 1983). Such expectations have a quality of self-interest and may develop into enmeshed relationships created by the donor toward the recipient. This leads to complications in the relationship for both parties, particularly for the recipient. Post-donation behavior will depend on the expectations of the donor when they made the decision to gift the kidney. Recipients may anticipate these feelings of obligation from the beginning; that may be the reason they prefer not ask a living relative to be a donor. Thus, relationships may be altered as a result of kidney donation (Ruth, Otnes, and Brunel 1999).

From the experiences of our informants, we find kidney organ donors may experience the gift of their kidney to a relative as a puritanic self-gift (Mick 1996) with the hopes of continuing a cherished relationship. As such, the gift of the kidney is both a gift and a self-gift which is reciprocated by the recipient through a continued affective relationship, and embraced by the donor as either reward or stress relief through the same which truly encapsulates the notion of the extended self (Belk 1988). We expand the notion of puritanic self gifts to encompass those where the task completion is the reinstatement of the desired status. In the case of kidney transplantation, task completion is that the kidney recipient engages in life fully without the constraints and limitations of end stage renal disease and the donor goes along, with one less kidney, for the ride!

The ‘Nature’ Of Life: How the Physical World Colors Impressions, Informs Decisions, and Shapes Who We Are

Joshua M. Ackerman, MIT Sloan School of Management, USA

Lawrence E. Williams, University of Colorado at Boulder, USA

EXTENDED ABSTRACT

“Haptic Experiences: A Touching Story of Impression Formation and Decision-Making”

Joshua Ackerman, MIT Sloan School of Management, USA

Christopher C. Nocera, Harvard University, USA

John A. Bargh, Yale University, USA

Touch serves a critical means of learning, communication, and developing social bonds, yet, despite the fact that tactile sensations are critical to both our intra- and interpersonal lives, touch remains perhaps the most underappreciated sense in behavioral research. Several researchers have begun to highlight the importance of touch within consumer domains (e.g., Peck and Childers 2003). Tactile cues can influence our conceptions about products, even when those cues are nondiagnostic for the actual qualities of the item (e.g., water seems to taste better from a firm bottle versus a flimsy bottle; Krishna and Morrin 2008). Why might our sense of touch direct our impressions about untouched (or untouchable) things?

One possibility is that sensorimotor experiences in early life form a scaffold for the development of conceptual knowledge, which is subsequently applied to novel events, situations and objects. This conceptual information is reflected in the use of particular psychological constructs such as metaphors. For example, grasping motions and feelings of warmth elicited by interpersonal touch may give rise to beliefs about holding and caring as expressed in the aphorism “the world is in our hands.”

Building off work on metaphor priming, we propose that experiences with specific, object-related tactile qualities activate a haptic mindset such that touching objects triggers increased accessibility and application of associated concepts, even for unrelated impressions and decisions. We present 6 studies testing the role of 3 touch dimensions—weight, texture and hardness—in impression formation and decision-making.

Weight: The experience of weight, or heaviness, is metaphorically associated with concepts of seriousness and importance (e.g., “thinking about *weighty* matters;”). The physical experience of weight was manipulated by having participants hold either heavy or light clipboards. In Study 1, participants holding the heavy clipboard judged an academic job candidate as more serious about and better qualified for the position, but not as more likable. In Study 2, participants holding the heavy clipboard decided that important issues (e.g., air pollution standards), but not idiosyncratic issues (e.g., creation of universal electrical plug outlets), should receive more funding.

Texture: The experience of texture, or roughness, is metaphorically associated with the concepts of difficulty and harshness (e.g., “having a *rough* day;”). The physical experience of texture was manipulated by having participants complete either a rough or smooth puzzle prior to the main study DVs. In Study 3, participants completing a rough puzzle judged two people in an ambiguously-valenced interaction as displaying less coordinated (i.e., more difficult and harsh) behavior, but not less relationship familiarity. In Study 4, participants in an Ultimatum game offered lottery tickets to a 2nd person who could accept or reject the offer. Those completing the rough puzzle gave more tickets, which further analysis suggested

was compensatory behavior for perceptions of low coordination and not due to more cooperative inclinations.

Malleability: The experience of malleability, or hardness, is metaphorically associated with concepts of stability, rigidity and strictness (e.g., “*hard*-hearted”). The physical experience of hardness was manipulated both actively (Study 5) and passively (Study 6). In Study 5, participants examined one of two objects to be used in a magic act—a hard block of wood or a soft blanket—and then evaluated the personality of an ambiguously described employee. Participants who touched the hard wood judged the employee to be more rigid/strict, but not more or less positive on other traits (e.g., trusting, kind). In Study 6, participants sat in either hard wooden chairs or soft cushioned chairs while making two offers in a car-buying negotiation task. Participants sitting in the hard chair exhibited less change in price from 1st to 2nd offer, indicating reduced decision malleability.

In summary, six experiments showed that heavy objects trigger conceptions of importance, rough objects trigger conceptions of difficulty, and hard objects trigger conceptions of rigidity. First impressions are liable to be influenced by one’s tactile surroundings, and control over these surroundings may be especially important for negotiators, pollsters, job seekers, and those interested in interpersonal communication.

“Washing Away the Past with Cleaning Products: Of Dirty Mouths, Dirty Hands, and Post-Decisional Dissonance”

Spike W. S. Lee, University of Michigan, USA

Norbert Schwarz, University of Michigan, USA

Brushing our teeth, washing our hands, and taking showers are part of our daily routine. Their psychological effect goes far beyond cleaning our bodies. As a growing number of studies indicates, cleaning products remove more than stains, microbes, and contaminants—they also remove the guilt of past misdeeds, weaken the urge to engage in compensatory behavior (Zhong and Liljenquist 2006), and attenuate the impact of disgust on moral judgment (Schnall, Benton and Harvey 2008). These findings are usually conceptualized in terms of a “moral purity” metaphor that grounds abstract thought about morality in more concrete experiences of physical cleanliness. In natural language use, this metaphor is associated with the specific body parts involved in an immoral act, prompting speakers to refer, for example, to “dirty hands” or a “dirty mouth.” This suggests that the specific motor-modality involved in an immoral act may figure prominently in the embodiment of the moral purity metaphor, potentially prompting people to purify the specific body part involved in the act. While this conjecture is compatible with the general canon of embodiment, the implied motor-modality specificity has not received attention and the embodiment of the moral purity metaphor has been treated as generic in previous research: washing one’s hands (the only cleaning manipulation used to date) is assumed to restore purity independent of the specific body part involved in the “dirty” act.

Therefore, we conducted two experiments in which a transgression involved either only the hands (“manual modality”) or only the mouth (“oral modality”). Experiment 1 coded for motor-modality in autobiographic memories of moral transgressions and Experiment 2 induced participants to lie on voicemail (involving

the mouth) or email (involving the hands). As predicted, doing bad things with one's mouth increased the appeal (desire and willingness to pay) of mouthwash but not of hand-sanitizer; conversely, doing bad things with one's hands increased the appeal of hand-sanitizer but not of mouthwash. These converging findings indicate that the morality-purity link is specific to the motor-modality involved in moral transgressions.

Note, however, that metaphors involving physical cleanliness extend beyond moral issues. We may say, for example, that we "wipe our slate clean" to convey that we are ready to move on to new endeavors. If so, the use of cleaning products may not only restore moral purity but may metaphorically "wash away" traces of past behaviors that may have no particular moral implications. We tested whether physical cleansing can more generally reduce the impact of past actions, even actions without moral implications. Using a classic dissonance paradigm, we gave people a free choice between two similarly attractive music albums. After selecting one, they participated in a "product evaluation survey" that involved either simply examining a bottle of hand soap or actually washing one's hands with it. Finally, they provided another rating of the albums. Replicating the usual dissonance findings, the attractiveness of the chosen album increased, and the attractiveness of the rejected album decreased, after the choice. However, this was *only* observed when participants merely examined the soap. When participants tested the soap by washing their hands, their post-choice ratings were unaffected by the decision made, indicating that dissonance was "washed away."

In combination, these findings extend earlier research in several ways. First, they highlight that the metaphorical link between moral and physical purity is specific to the motor-modality used: if given a choice, consumers want to clean the tainted body part. Second, our findings highlight that the impact of physical cleansing extends beyond the domain of morality as has been previously assumed. Ongoing research addresses whether such cleansing effects are limited to past negative events (e.g., moral transgressions, poor choices) or also extend to the positive glow of competent and noble acts (e.g., being an eloquent salesperson, raising awareness of support to Haiti).

"Embodied Real Estate: North-South Location Biases Housing Preference and Pricing"

Brian P. Meier, Gettysburg College, USA

Julie J. Chen, Gettysburg College, USA

Arlen C. Moller, Northwestern University, USA

People link abstract concepts to sensory experiences in metaphors to express preferences. One metaphor describes good and bad in terms of space. For example, good things are described as high ("her career is on the rise") while bad things are described as low ("he's on the bottom rung"). Research shows that when evaluating things, people unwittingly activate vertical perceptions in a metaphor-consistent manner (good=up; bad=down; Meier and Robinson 2004).

We examined an under-explored metaphor, north-south as up-down. Maps are typically constructed such that north is up and south is down despite the fact that north and south do not physically relate to vertical space. Frequent exposure to this representation may contribute to the tendency to describe north and south in vertical terms (e.g., "we're headed up north"; see Nelson and Simmons 2009). A consequence is that directions may have developed affective connotations (i.e., north represents "good"). For example, in some areas of the U.S., terms like "southie" or "movin' on up" suggest that northern areas of cities are more attractive than southern areas.

We predicted that a north-south affective bias has implications for an important decision context—real estate judgments. We hypothesized that people will perceive higher house prices and income among residents in northern areas of a city, and that people will prefer to live in northern areas as well.

Study 1. Sixty-six undergraduates (41 males) chose where to live in a fictional city. We created a city map that included lines around the city limits. Distances between north-south limits and west-east limits were equal. We told participants the map represents a city and the lines indicate the city limits. We asked them to imagine that they were moving to this city and could live anywhere, and to select a location on the map. We converted choices to a score that represented the distance from the north-south mid-point. Analyses revealed that participants' average choice was significantly north of the mid-point, $t(65)=2.15, p=.035, d=.27$.

Study 2. We hypothesize that people prefer to live in the north because they believe northern areas of a city have higher socioeconomic status (SES). The map from Study 1 was presented on paper. We randomly assigned 87 undergraduates (30 males) to one of two conditions in which we described either a High SES (wealthy) or Low SES (poor and unemployed) individual named Mr. Bennett. Participants drew an "x" on the map to indicate where they thought "Bennett" lived. We calculated position of the estimates for north-south and west-east locations and converted these into scores that indicated the distance from the mid-point. An ANCOVA examined the impact of condition on north-south estimate while controlling for west-east estimates. Estimates for the High SES person were further north than estimates for the Low SES person, $F(1, 84)=32.75, p<.001, \text{partial } \eta^2=.28$.

Study 3. We sought to determine if a north-south bias influences house prices. We collected data on house prices and locations for the 25 most populous cities in the U.S. We used a real estate website (Trulia.com) to find 50 houses in each city. We selected the first 50 listings for each city that included address, price, and square footage (1,250 data points). We found the latitude (north-south) and longitude (west-east) for each address using Geocoder.us. A partial correlation for each city was calculated between price and latitude (controlling for the quadratic, square footage, and longitude). The average Fisher's Z was .13, which was significantly greater than zero, $t(24)=1.96, p=.031, d=.40$, one-tailed. On average, housing prices support the north-south bias.

Our results reveal a surprising impact of north-south location on real estate preference and valuation. Embodied metaphor theory and research has revealed that cognition is grounded in metaphor, but the current findings move beyond laboratory-based social cognition by revealing the potential for such representations to influence behavior in contexts of significant financial importance.

"I Am Where I Am: Physical Distance Fractures the Self"

Alexandra Sedlovskaya, Yale University, USA

John A. Bargh, Yale University, USA

Lawrence E. Williams, University of Colorado at Boulder, USA

Valerie Purdie-Vaughns, Columbia University, USA

Given the rapid pace of technological advances in telecommunication and transportation over the past century, people's lives commonly span large distances. Within the U.S., family networks extend across state boundaries, business is conducted in an increasingly global fashion, and students travel well beyond local confines to attend college. The boundaries of the average life space, defined as the sum of a person's intrapersonal, interpersonal, and ecological experiences (Lewin 1943), are arguably at their widest point in human history. What are the consequences of this heightened capability to live lives spanning large distances?

We propose that physical distance promotes fracturing of the self into distinct self-aspects. Support for this proposition stems from an emerging tradition that grounds people's psychological states in their physical environment (Williams, Huang and Bargh 2009). In this view, people's early childhood understanding of fundamental physical concepts, such as physical distance, facilitates the development of abstract concepts, such as interpersonal distance (Williams and Bargh 2008). Since the distinction between self-aspects involves psychological distance, greater physical distance should increase this distinction. For example, greater physical distance that students travel to attend university should increase the distinction they experience between school and home identities.

To examine this physical-self relationship, 46 university students were primed with either physical closeness or physical distance by plotting coordinates that appeared either close together or far apart on a Cartesian plane, thus allowing participants to perceive and engage in relevant motor actions (Williams and Bargh, 2008). To examine whether this physical distance cue altered the psychological distinction that students experience between their school and home identities, we next measured the speed with which participants indicated whether a series of traits best described them at school or at home, while controlling for their general speed of response. If people experience difficulty distinguishing between their school and home identities, then they should take more time to respond. We predicted that participants primed with physical distance would experience greater distinction between school and home identities and would thus be faster on this measure, compared to participants primed with physical closeness. Our results supported this prediction [$F(1, 41)=5.57, P=.02$], suggesting that physical distance strengthens the psychological distinction people draw between aspects of their identities.

Study 2 extended this finding by using a more ecologically valid operationalization of physical distance and by examining reported stress as a potential downstream consequence of self-fracturing. Study 2 employed the same response latency measure used in our first study, as well as the Perceived Stress Scale to measure stress at school. Physical distance was operationalized as the number of miles between students' university and their hometowns. Consistent with Study 1, data from 38 university students revealed that greater geographical distance was associated with shorter response latencies, indicating greater distinction between school and home identities [$r=-.38, t(33)=-2.69, P=.01$], which was in turn associated with higher reported stress at school [$r=-.40, t(33)=-2.23, P=.03$].

In summary, the simple perception of and motor actions associated with physical distance increased the psychological bifurcation of the self into distinct self-aspects. This effect echoes recent demonstrations of how environmental cues can meaningfully affect people's judgments and decisions. Practically, this work suggests a psychological benefit of thinking locally (less identity fracturing, less stress), and encourages practitioners to recognize the power of local environs in shaping consumer identities.

SPECIAL SESSION
Moral Flexibility in Consumer Judgment and Choice

Dan Bartels, University of Chicago, USA
A. Peter McGraw, University of Colorado, Boulder, USA

EXTENDED ABSTRACTS

**“Slam the Good Guys: Guilt Over Less Ethical Behavior
Results in Denigration of Ethical Consumers”**

Julie R. Irwin, University of Texas, Austin, USA

Szu-Chi Huang, University of Texas, Austin, USA

It has been suggested that observing others behaving ethically inspires admiration and “other-praising” (Algoe and Haidt 2009; Haidt 2001). We explore a less positive response to ethical others, especially among consumers who themselves have not behaved ethically. We examine the process by which behaving less ethically can result in “slamming” people who behave more ethically than we do, with the goal of preserving self-esteem.

Individuals gain self-esteem from thinking of themselves as moral and that they reconcile conflicts between their perceived morality and actual behavior in the direction of preserving self-esteem (Batson et al. 1999). Despite the motivation to perceive the self as highly moral, individuals frequently fail to carry out ethical behaviors in the market place. Many motivations, such as the desire to avoid reading about uncomfortable information (e.g., Ehrich and Irwin 2005) or the beliefs about moral tradeoffs (Luchs, Naylor, Irwin and Raghunathan in press), often lead consumers to avoid ethical information even when they care about the underlying issues.

Our project focuses on what happens after a consumer fails to act ethically (e.g., fails to seek out ethical information in order to make an informed ethical choice) in the market. We propose that after behaving less ethically, consumers denigrate other consumers who would have acted more ethically than they did. We show that guilt underlies these judgments, and that reducing guilt reduces the denigration. Furthermore, we show that the denigration reduces future ethical behavior.

In Study 1, participants chose between four pairs of jeans that differed on: style, price, manufacturer size and either manufacturers’ labor practices (i.e., whether their factories employed children, the ethical condition) or manufacturers’ delivery time (control condition). All of the attribute information was initially hidden and participants could choose to view the contents for two out of the four attributes before making their product choices. Thus, participants overwhelmingly chose to view price and style, not the fourth piece of information (labor practice or delivery time). We expected that only the participants in the ethical attribute condition would feel that their ethical self-view had been threatened from not choosing the fourth attribute. After choosing the attributes and the jeans, participants rated consumers who “ask about the labor practices used to produce their clothes (i.e., whether child labor was used) before buying them”. Only a few participants viewed the fourth attribute; they were eliminated from the analysis. Our results supported our hypothesis of “slamming” the good guys: not viewing information about manufacturers’ labor practices (vs. delivery time) resulted in significantly more unfavorable ratings of ethical others on both positive (e.g., fashionable and attractive) and negative (e.g., boring and preachy) characteristics.

In Study 2, participants could view the attribute value information for either one, two, or four (i.e., all) attributes before making product choices. We expected the two attribute condition to produce more threat than the other two conditions. Indeed, the denigration and self-esteem was statistically equivalent in the one and four/all

attribute conditions. In addition, we measured self-esteem either right before or right after the (possible) denigration. Participants in the threatening two-attribute condition had significantly lower self-esteem prior to denigration, and were significantly more likely to denigrate ethical others. After denigrating others, self-esteem and ethical self-view were restored to the same level as groups who did not feel threatened, indicating that the denigration served its psychological purpose.

Study 3 tested our hypothesis using backpacks and a different ethical attribute (recycled content of materials). Participants could view information about one, two, or four (material, price, function, and recycled content) attributes. Participants made product choices and either evaluated ethical others or did not. In this study, in the “chance to denigrate” condition we allowed them to both rate others and to provide open-ended evaluation of “people who might check the recycling practices of the firms that make their backpacks”. Also, at the end of the task all participants were invited to take a “Think Green” online pledge to sign up for e-newsletters about easy ways to be green. Both the open-ended responses and the ratings scales replicated the denigration results (i.e., more denigration in the threat condition). In addition, we also found that participants who were threatened (i.e., who were in the two-attribute condition) showed a significant difference in future ethical behavior depending on whether they were given the opportunity to denigrate. The more they denigrated others, the less likely they were to take the environmental pledge. In other words, denigration restored self-esteem to such an extent that it actually reduced future moral behavior.

Thus, consumers do not, at least in our context, respond with admiration to ethical behavior. Instead, they denigrate ethical consumers. We suggest that awe and other positive emotions may be more likely when guilt is absent; it may be easier to avoid denigration when self-esteem is not threatened.

**“Sweatshop Labor is Wrong Unless the Jeans are Really
Cute: Motivated Moral Disengagement”**

Neeru Paharia, Harvard Business School, USA

Rohit Deshpandé, Harvard Business School, USA

Kathleen Vohs, University of Minnesota, USA

We examine whether people may be motivated to morally disengage (Bandura 1991, 1999) in the presence of harmful attributes such as sweatshop labor when desire for a product is high. We show that moral disengagement can be driven by affective desire for a product. Mechanisms of moral disengagement may allow consumers to perceive their desire for products made with sweatshop labor to be consistent with their moral standards (Tsang 2002) enabling them to avoid dissonance (Festinger 1957). We demonstrate that levels of moral disengagement can be motivated by one’s level of desire for a product made with sweatshop labor. Furthermore, we show a full mediated moderation where beliefs about sweatshop labor use moderates the impact of desirability on purchase intention, and moral disengagement mediates this process.

In experiment 1 participants were told about a hypothetical pair of jeans where sweatshop labor was either present or not. Participants were then asked about their desire for the jeans and answered questions on moral disengagement. We predicted that when sweatshop labor was present, there would be a stronger positive association between desire for a product and moral disen-

agement than when no sweatshop labor was present. In the *high sweatshop labor* condition participants first read: *Imagine that you are shopping and found the perfect pair of jeans. They look good on you and fit great. [A large amount of sweatshop labor was used to produce these jeans.]* In the *no sweatshop labor* condition the text in brackets was replaced by the following: *No sweatshop labor was used to produce these jeans.* Participants were first asked about their desirability for the jeans and then asked about moral disengagement. The moral disengagement measures were adapted from Bandura et al.'s (1996) original scale, and participants were asked to indicate how much they agreed or disagreed with the following four statements: 1. *The use of sweatshop labor is okay because otherwise those workers would not have jobs;* 2. *Without sweatshops poorer countries couldn't develop;* 3. *Buying clothes that are made with sweatshop labor is okay if it saves the consumer money because clothes are not affordable.;* and: 4. *The use of sweatshop labor is okay because companies must remain competitive and all other companies do it.* We found levels of moral disengagement to be significantly higher when desirability for a product was high and sweatshop labor was present. In the case where sweatshop labor was not present, there was no significant association between desirability and moral disengagement. Experiment 1 gives us cause to believe that moral disengagement may be motivated by one's desirability for a product.

In experiment 2, (in a 2X2 between subjects design) participants first read about the desirability of a hypothetical pair of Nike shoes. In the *high desirability* condition participants read: *Imagine that you own a pair of Nike running shoes. [The shoes retail for \$175.00 and you got them at a 75% discount. You are extremely happy with these shoes.]* In the *low desirability* condition the text in brackets was replaced by the following: *The shoes retail for \$175.00 and you got them at a 5% discount. You are satisfied with these shoes.* After answering this initial set of questions on desirability participants clicked through to the next page and were told about Nike's labor practices. In the *high sweatshop labor* condition participants read: *Imagine that you've just read an article that suggests that Nike [uses] sweatshop labor to make their shoes.* In the *no sweatshop labor* condition the text in brackets was replaced by: *does not use.* Participants then answered questions on moral disengagement, and asked about their beliefs about Nike's true use of sweatshop labor. Participants then answered a second set desirability questions that were identical to the first set. Finally participants were asked about purchase intention. We found that measures of moral disengagement were higher for *high desirability* products than for *low desirability* products when sweatshop labor was present; however we did not find this effect in the *no sweatshop labor* condition. Furthermore, we show a full mediated moderation where beliefs about high sweatshop labor use are associated with an *increased* purchase intention for high desirability products; however this effect does not hold for low desirability products.

In a follow up study we demonstrate the effects of moral disengagement can be attenuated when participants are put under cognitive load. More specifically, a positive association between one's desire for a product and level of moral disengagement disappears once participants are put under load. Such finding suggests that limiting one's cognitive resources may reduce desire-driven moral disengagement.

As we are confronted with conflicts between our desires, and our moral standards on nearly a daily basis it behooves us to carefully consider how our desires, in particular, drive us to morally disengage from harmful behavior. If our moral judgments vary based on our affective desires, any moral standards we may hold ourselves to are dubious at best, and desire-driven moral disengage-

ment may broadly contribute towards the tolerance of harm in our social and economic systems.

“Choosing For the Right Reasons: Value-driven Reasoning in Consumer Choice”

David Tannenbaum, University of California-Irvine, USA

Daniel M. Bartels, University of Chicago, USA

Even if consumers do not always succeed in choosing outcomes that make them happier, healthier, or wealthier, they usually try their best to do so. In this way, most choices consumers make reflect a desire to maximize consequences. Some moral choices involving protected values, however, are more driven by proscriptions than by consequences (e.g., “do not allow companies to pollute for a fee, even if the fee helps reduce pollution”). In four studies, we examine how thinking about proscriptions and consequences may depend on the decision maker's initial preferences and on the situational context. We find that when presented with ethically-relevant information, consumers with a ‘protected value’ are both more *and* less consequentialist in their choices than consumers without protected values. Because PV consumers care deeply about the issue at hand, their choices vary based on what information they attend to (Bartels 2008) and what reasons are available for the choice (Shafir 1993).

In the first three studies, we presented participants with descriptions of each option's non-ethical attributes (e.g., workmanship and comfort ratings) and collected desirability ratings. Later, we presented them with ethically-relevant information (e.g., whether a desk used unsustainable rainforest wood) and assessed preferences for one option over the other.

Study 1 pitted an attractive product that used rainforest wood against a less attractive product that did not. The more attractive desk was described, depending upon condition, as constructed from rainforest wood that caused unmitigated harm to the environment (“Impoverished Harm”) or from rainforest wood whose harm was mitigated through the planting of trees that resulted in a net gain for the environment (“Enriched Harm”). Only participants with a PV were likely to choose the more unattractive desk, and this was the case in both the Impoverished Harm and Enriched Harm conditions. When the choice context allows for one to honor a PV—with at least one option not causing harm to the rainforest—then subjects with PVs tend to choose on this basis, regardless of the consequences entailed and regardless of their initial preferences.

Study 2 was similar to Study 1, except now participants could choose only between the Impoverished and Enriched Harm conditions. Now, participants with a PV were most likely to choose the Enriched Harm option. When the choice context did not allow for honoring a PV—with both options caused some degree of harm—then subjects with a PV made more consequentialist choices than subjects without a PV, regardless of their initial preferences.

Study 3 examined if the previous two findings—that subjects with a PV can be both more and less consequentialist depending on the choice context—is the result of moral posturing or value-driven choice. A moral posturing account would explain this pattern by arguing that participants with a PV still wish to choose the more attractive desk (even if it causes more harm), but only have a reasonable excuse to do so in Study 2. A value-driven choice account would argue that participants with a PV will choose to not actively cause harm so long as they have the ability to do so (when they do not have that option, they will instead choose to maximize consequences). Study 3 was designed to pit these two accounts against each other. Participants now chose between three options: (i) a less attractive, No Harm option, (ii) a more attractive, Enriched Harm option, and (iii) a symmetrically-dominated very unattractive, very harmful option. Consistent with the value-driven choice account,

participants with a PV tended to choose the No Harm option that honored their protected value even though they could justify choosing the more attractive, Enriched Harm option because it was both more attractive and caused less harm than the dominated option.

Our final study explored the role of reasons in explaining how participants made a value-driven decision. For Study 4, participants judged which of two companies was (depending upon condition) either more moral or more immoral. Similar to Study 2, one company's actions embodied Impoverished Harm and the other Enriched Harm. Subjects with a PV were more likely than non-PV subjects to both accept the enriched option as morally superior and reject it as morally inferior.

In sum, consumers with a PV are more likely than consumers without a PV to make use of ethical attribute information when presented with such information. If one or more options satisfies the proscription to do no harm—even if it is unattractive or other options might maximize consequences—they opt for the No Harm choice. If all available options cause some degree of harm, however, consumers with PVs maximize ethically-relevant consequences, regardless of their initial preferences. Consumers without a PV, however, choose according to their initial preferences.

“Commercial Marketing with Communal Sentiments: Reframing Taboo Trade-offs in Religious Marketing”

A. Peter McGraw, *University of Colorado, Boulder, USA*

Janet Schwartz, *Duke University, USA*

Philip E. Tetlock, *University of California, Berkeley, USA*

While consumers typically expect businesses to profit from the marketing of goods and services, they believe that some organizations should be more focused on accomplishing communal goals than making a profit. When communally-focused organizations do use commercial marketing strategies, consumers react as though a taboo has been breached (Tetlock 2002). For example, consumers find it morally distressing to see churches using steadfast commercial-marketing strategies like advertising, rebranding, and outsourcing (e.g., McDaniel 1996). People will respond with a mix of moral outrage (condemn the perpetrators) and moral cleansing (distance oneself from the transgressors; Tetlock et al. 2000; McGraw, Tetlock, and Kristel 2003). This creates negative consequences for the organization; people stop using services or they spread negative word-of-mouth.

We investigate the ability of organizations to conceal or assuage taboo trade-offs. As a case study, we examine people's reactions to the use of marketing techniques by religious organizations. Churches compete with the secular world for the allegiance of worshippers, and churches are increasingly resorting to the same marketing techniques that corporations use to recruit, retain, and serve customers (e.g., Schlesinger and Mellado 1991, Symonds 2005). But not everyone finds these techniques acceptable; people can be horrified when churches use violent video games to recruit young people (Richtel 2007).

The project draws on work by McGraw and Tetlock (2005) that examines how rhetorical redefinitions (i.e., relational framing) change the perceived normative 'rules' at work for a strategy in order to assuage the unsettling nature of a taboo trade-off. We test the effectiveness of organizational justifications that reframe market interventions to have a communal focused (i.e., priorities and offerings based on cooperative and relationship-building principles; see Fiske 1991). If marketing techniques are rhetorically disguised through communal-focused endeavors, the church gets both market efficiency and loyalty. But if rhetorical disguises fail, market-based techniques may compromise the moral branding and sanctity of the church.

In Study 1a, we presented participants twelve marketing strategies that an organization was considering using. The strategies were pretested to vary along a continuum from communally-focused (e.g., provide child care for members) to market-focused (e.g., institute a rebranding strategy). We find that neither communal nor market focused strategies affected the judged acceptability of the marketing strategies used by a credit union, a secular market-driven organization. For a religious organization, however, judgments of acceptability were strongly influenced by the focus of the strategy. As the strategy became more communally focused as opposed to market focused the strategy was viewed as increasingly more acceptable. In Study 1b, we show that negative reactions to commercial marketing techniques by a church mediate people's desire to affiliate with the organization.

Study 2 investigated the effect of presenting communal-sharing justifications for market interventions conducted by a church. We found that distress with the Catholic Church's practice of outsourcing prayers to India due to a shortage of U.S. Priests was mitigated by invoking the shared world-wide communality of Priests, a justification that emphasizes the communal nature of the church across national boundaries. Reported distress in a market-pricing justification condition (“matching supply and demand in the market for prayer service, thus maximizing prayers and revenue generation”) was no different than that of a control condition that featured no justification, which indicated that respondents spontaneously assumed and rebuffed the church's market-based intervention.

Study 2 also investigated who is most affected by communal justifications. We hypothesized that those who have the greatest moral stake in the organization would be most motivated to seize on the communal justification and thus show the greatest reduction in distress. We found that consumers who most regularly attend religious services were most persuaded by communal reframing justification.

In a third study, we demonstrate that moral outrage with outsourcing prayer was linked to moral contamination and not socially desirable responding. To do so, we drew on the Lady Macbeth effect, whereby people feel physically tainted by morally upsetting information and seek physical cleansing opportunities to symbolically cleanse themselves (Zhong and Liljenquist 2006). Indeed, respondents exposed to the outsourcing decision without a communal justification showed the greatest preference for cleaning products (e.g., Tide detergent) relative to non-cleaning products (e.g., post-it notes).

Marketing is commonly used to add value to consumer experience and build brand relationships. However, certain categories of marketing tactics appear to be disturbing to consumers when they believe the organization ought to be acting in communal ways. We show that distress with religious marketing is assuaged by simple rhetorical tactics that transform market actions into communal actions.

Self-Identity Amplification: When (and How) Situations Promote Identity Congruent Behavior

Keri Kettle, University of Alberta, Canada

EXTENDED ABSTRACTS

“When do Consumers Bolster Their Preferences in the Face of Threat? The Role of Self-Construal and Collective Identity Activation”

Katherine White, University of Calgary, Canada

Jennifer J. Argo, University of Alberta, Canada

Jaideep Sengupta, HKUST, China

Marketers often link their brand with an aspect of consumer social identity. Pepsi attempts to link Pepsi Max with male gender-identity: “Maximum Taste, No Sugar, and Maybe Scorpion Venom. Pepsi Max, the First Diet Cola for Men,” whereas Secret links its brand with female gender-identity: “Strong Like a Woman.” Although marketers can link products with various aspects of consumer identity, the effectiveness of such a strategy may depend on other contextual factors. Recent research suggests that when consumers experience threat to one aspect of social identity (e.g., their gender identity or nationality), they sometimes avoid products associated with that identity (White and Argo 2009). The present research extends this previous work by identifying instances where consumers will strengthen their connection to, rather than avoid, the identity-linked product in response to social identity threat.

Drawing on social identity theory (Tajfel and Turner 1986) and self-construal theory (Singelis 1994), we predict that the impact of identity threat on product preferences is moderated by self-construal. The independent self is viewed as being autonomous, unique, and separate from other, whereas the interdependent self is viewed as more collectivistic, communal, and relational (Markus and Kitayama 1991). We propose and find that people with interdependent self-construals demonstrate more positive evaluations of identity-linked products when that social identity is threatened versus not threatened. Our framework proposes that this arises because people who are highly interdependent are particularly attuned to their social identities, and that identity threat primes/activates these multiple social identities. Interdependents are then able to draw on this repertoire of identities as a resource, and feel more positively about their multiple group memberships when under threat. In contrast, those with independent self-construals do not activate their identities in response to threat, but instead are motivated to enhance their individual self (Heine 2001). Consequently, independent people tend to avoid an identity-linked product when their social identity becomes threatened.

In study 1, we examined differences in self-construal by investigating differences between Asian (i.e., interdependent) and Caucasian (i.e., independent) Canadians. We exposed participants to negative (threat condition) or neutral information (neutral condition) regarding their university. Participants then completed the twenty statements task (“I am _____,”) which was coded for statements related to social identities in general and university-identity in particular. The number of different reported identities were totaled and served as a measure for the degree to which multiple identities were activated. Participants then evaluated products that were matched for price and pretested as being related to university-identity or neutral (university book store vs. a restaurant gift certificate). Asian Canadians evaluated an identity-linked product more positively when threatened versus not threatened. In contrast, Caucasian Canadians evaluated identity-linked products more negatively when threatened

(vs. not threatened). These effects were mediated by the differential activation of multiple identities.

In study 2, we used a similar method to study 1, except that we assessed individual differences in self-construal (Singelis 1991) and measured the degree to which participants felt a sense of identification with their multiple social identities. Once again, interdependents (independents) evaluated an identity-linked product more positively (negatively) when threatened versus not threatened. These findings were mediated by feelings of identification to multiple social identities.

Study 3 investigated primed differences in self-construal (Brewer and Gardner 1996). The results support our framework by demonstrating that—in addition to demonstrating more positive evaluations of the focal identity when threatened—interdependents also show this bolstering effect for another aspect of identity, suggesting that multiple identities have been activated for more interdependent people (under threat).

Finally, in study 4 we further examined the underlying process by using a cross-national sample (Hong Kong vs. Canada, to represent interdependents vs. independents) and investigated the moderating role of affirmation type (self-affirmation, group affirmation, or no affirmation). The results show that, overall, interdependents demonstrate identity bolstering responses, whereas independents are more likely to show identity dissociating responses when the particular identity is threatened. Further, Hong Kong participants made more positive evaluations of the university identity-linked products under conditions of group affirmation as compared to conditions of no affirmation or self-affirmation. This suggests that for interdependents, group-affirmation enhances the ability to feel positively about a threatened group membership. Among independents, however, when under threat self-affirmation led to more positive university product evaluations as compared to no affirmation and group-affirmation. Thus, when under threat, independents are only able to evaluate the identity-linked product positively by affirming the individual self.

Taken together, the results across 4 studies highlight the conditions under which identity bolstering can occur and provide support for the notion that among interdependents, identity threat primes multiple identities which can have a buffering effect on social identity threat.

“A Unified Theory of Consumer Response to Self-Threat”

Justin Angle, University of Washington, USA

Mark Forehand, University of Washington, USA

The self-concept—and its constituent associations—has powerful effects on behavior. Because consumers respond strongly when aspects of their self-concept are threatened, marketers routinely challenge components of the self-concept by introducing new negative information about a self-related group, or suggesting the consumer is an inadequate member of such a group. For example, Apple’s “I’m a Mac, and I’m a PC” ads link computer choice to identity and suggest that PCs—and their owners—are dull, slow, complicated, and trouble-prone. We propose that consumer response to such identity threats depends on whether the threat targets the association of the self with the identity, or the association of the identity with positive valence. In addition, the strength of threat response is moderated by initial consumer self-esteem.

Recent work has shown that threats to the self can produce both identity-approach and identity-avoid behaviors. Consumers threatened with negative information about their social category tend to avoid products associated with that category (White & Argo 2009), avoid threatening social comparisons (Argo et al. 2006) and distance themselves from products related to dissociative outgroups (White & Dahl 2007). On the other hand, when a consumer's strength of association with a particular identity is threatened, an approach response is more likely as the consumer takes action to rectify threat (DeMarrée et al. 2007; Tetlock et al. 2000) and restore that self association (Gao et al. 2009).

Although these distinct research streams generate contrasting results, they identify processes that are less contradictory than they first appear. The negative information threats employed by White & Argo (2009) target a group associated with the consumer, and such group affiliations often act as resources protecting consumers from threat (Correll & Park 2005; Knowles & Gardner 2008). Although White & Argo provided evidence of this self-protection strategy in consumers for which group affiliation was important, they did not investigate how the negative information affects group associations or the importance of the group to one's self-concept. Similarly, the self-concept threats employed by Gao et al. (2009) are posited to shake the association of one's self with a group or attribute, yet these associations and any changes in them were not measured.

The present research develops a single theoretical framework to explain the apparently divergent findings of prior work, and offers predictions about how a variety of self-threat situations will influence consumer behavior. Building on the Unified Theory of Implicit Social Cognition (Greenwald et al. 2002), threat response is explained in terms of three types of implicit associations: self-esteem, self-group, and group-valence. Although prior investigations occasionally reference the importance of one or more of these associations, none of the research to date has actually measured them and assessed their influence on the self-threat response. We hypothesize that initial implicit self-esteem will predict strength of response to self-threat, such that people higher in self-esteem will exhibit stronger approach and avoidance tendencies.

The results of two experiments demonstrate this framework. Using a series of Brief Implicit Association Tests (BIATs), we show that consumers respond very differently to self-concept threats that target the association of the self with a given identity, as compared to threats that target the association of the identity with positivity. When the latter type of threat was encountered, the resultant avoidance effect was mediated by a weakening of the association of the threatened identity with positive valence. By contrast, when the former type of threat was encountered a weakening of the self-identity association mediated the expected approach response.

Together, these findings shed critical light on the processes driving consumer response to self-threat. In addition, the methodology employed in this research can contribute to a better understanding of relationships between the self, social groups, stereotypical attributes, and valence.

“The Moderating Role of Self-Construal in Selective Self-Stereotyping”

Linyun W. Yang, Duke University, USA

Tanya L. Chartrand, Duke University, USA

Gavan J. Fitzsimons, Duke University, USA

Does it matter if someone stereotypes you? When a stereotyper inflicts harm on a target (e.g., denying a promotion, excluding from a social group), the answer is an obvious yes. Prior work has shown that individuals are selective in applying specific stereotypical traits to themselves in order to reconcile the conflicting goals of self-en-

hancement and group identification (Biernat et al. 1996; Pronin et al. 2004). Research has also shown that the effects of being stereotyped extend to domains where no overt harm occurs, such as by changing how the stereotyped individual views him or herself (Sinclair et al. 2006). The present research investigates the role that self-construal plays in determining individuals' self-evaluative response to being negatively stereotyped. We propose that self-construal moderates the way individuals address the stereotype and their motivation toward the stereotyper. These responses are reflected in targets' self-views in the form of selective self-stereotyping (assimilating toward the stereotype) or counter-self-stereotyping (contrasting away from the stereotype).

As stereotypes are multidimensional and contain numerous characteristics associated with a social group, individuals' self-views do not necessarily have to shift on all aspects of the stereotype. We posit that targets' self-evaluations change in a selective manner consistent with their self-construal orientations. That is, stereotype targets engage in selective self-stereotyping and leverage the multidimensionality of stereotypes in order to remain consistent with their attitudes toward the stereotyper. Rather than embracing or rejecting a stereotype in its entirety, stereotype targets alter their self-views on subsets of the stereotype. Targets' responses stem from their self-construals and thus determine whether they selectively assimilate toward or contrast away from the stereotype.

Self-construal refers to how individuals understand and define themselves in relation to the social environment (Markus & Kitayama 1991). People with interdependent self-construals see themselves as closely connected to the people in their social environment, whereas those with independent self-construals see themselves as distinct and separate from others. Research suggests that independent individuals are likely to contrast their self-evaluations away from stereotypes (Bry et al. 2007; Keller & Molix 2008; Stapel & Koomen 2001) and tend to respond in a hostile manner towards those who stereotype them (Pinel 2002; Wout et al. 2009). By contrast, interdependent individuals tend to assimilate their self-evaluations toward stereotypes and compensate for the stereotyper's negative expectations. In the present work, we find that one's response to the stereotype and the stereotyper shape how their self-evaluations shift in terms of stereotype-relevant traits.

In Study 1, we examined how interacting with a sexist male supervisor influenced interdependent and independent female participants. As independence increased, participants rated themselves lower on positive feminine traits and higher on negative masculine traits to contrast away from the female stereotype and to remain consistent with hostile feelings toward the supervisor. As interdependence increased, however, participants adopted the opposite strategy and rated themselves higher on positive feminine traits and lower on negative masculine traits. This served the dual purpose of remaining likeable to the supervisor but conforming to his stereotypical views of women.

In Study 2, using the self-evaluations of female participants, we examined whether the traits interdependent participants wish to embody are specific to the affiliation target. As predicted, we found that interdependent participants' self-evaluations changed depending on the affiliation target. When they imagined interacting with a colleague, interdependent participants increased their self-evaluations on feminine traits valued by the colleague, even though the traits were stereotype consistent. With a supervisor, interdependent participants did not decrease their self-evaluation ratings on masculine traits valued by the supervisor because doing so would compromise their self-image as it pertains to the supervisor. Independent individuals' self-evaluations, on the other hand, were not influenced by the interaction partner because they are less

motivated to affiliate and less sensitive to the specific preferences of their interaction partners.

Our theory of selective self-stereotyping takes into account how individual differences in self-construal influence self-stereotyping in contrasting interpersonal contexts. This focus departs from previous research, which has generally focused on selective self-stereotyping where stereotype targets view themselves in a positive light. Furthermore, we contribute by examining selective counter self-stereotyping where individuals view themselves more negatively in order to respond to the stereotyper in a hostile manner.

“The Signature Effect: Merely Signing One’s Name Promotes Identity-Congruent Behavior”

Keri Kettle, University of Alberta, Canada

Gerald Häubl, University of Alberta, Canada

Your signature—the distinctive way in which you write your name—plays a vital role in your life. By simply signing your name on a document, you can commit to marriage, years of mortgage payments, or military service. Despite the importance of signatures, however, the influence of signing one’s name on subsequent behavior has not been examined to date.

People associate their signature with their identity. They craft a signature that is unique (and thus difficult to forge) which they use to represent their identity in writing. We propose that signing one’s name acts as a general self-identity prime, and thus promotes behavior congruent with the specific aspect of that self-identity that is afforded by the individual’s current situation (Gibson 1977). We predict and demonstrate this phenomenon in five studies. In each study, participants were randomly assigned to either sign or print their own name on a blank piece of paper (ostensibly for a separate study about hand-writing) before entering into the focal situation.

The first two studies examine a domain with divergent schemas for women and men—food. As compared to men, women perceive that they are more prone to impulsive food consumption (Fredrickson et al. 1998). We hypothesized, therefore, that signing their name would promote impulsive food consumption among women, but would have no such effect on men. In Study 1, participants were given the opportunity to buy chocolates. Women who had signed their name bought more chocolate than those who had printed their name. By contrast, the amount of chocolate purchased by male participants was not affected by this manipulation. In Study 2, participants were offered free snack foods (carrots and pretzels) during a brief waiting period. As predicted, women who had provided a signature consumed more snacks than those who had printed their name, but male participants’ snacking was not affected by whether they had signed or printed their name. Thus, the first two studies show that people who sign their name behave in a manner congruent with their gender identity.

Studies 3 and 4 investigate the relationship between how closely consumers associate their identity with a product domain and their engagement while shopping in that domain. Consumers who closely associate a product domain with their self-identity are engaged in that domain. Therefore, we hypothesized that signing their name would induce consumers who identify more (less) closely with a product domain to be more (less) behaviorally engaged when shopping in that domain. In study 3, participants searched for product attribute information prior to choosing from a set of products (cameras or dishwashers). As predicted, signing their name led participants who identify more (less) closely with the product domain to examine more (less) product information. In study 4, participants went to a retail store to choose a pair of running shoes. Signing their name induced participants who identify more (less)

closely with running to spend more (less) time in the store and to try on more (fewer) pairs of shoes.

The final study tested our theoretical account by examining the effect of signing one’s name on identity-signaling. After signing or printing their own name, participants identified a social group to which they either belonged (in-group condition) or did not belong (out-group condition), and then made choices in 19 product domains (Berger & Heath 2007). As predicted, signing their name promoted greater divergence from out-groups—and greater conformity with in-groups—in identity-relevant domains.

The present research is the first to show that merely signing one’s name influences subsequent behavior in a predictable manner. Because consumers are often required to provide a signature (e.g., in a retail setting), our findings have important implications for both consumers and retailers.

Globalcityscapes: Re-Reading Ethnicity in Movement

Eric Ping Hung Li, Qatar University, Qatar

Bernardo Figueiredo, University of New South Wales, Australia

EXTENDED ABSTRACTS

“Cityscapes and Migration: Encapsulating Acculturation in the Urban Collective Space”

Luca M. Visconti, Università Bocconi, Italy

Migration is structurally connected with the idea of movement. People leave a country, their houses, family members, and beloved objects to start elsewhere a new life and thus redefine their extended self (Belk 1988). Also, the employers in the countries of destination frequently appreciate migrant workers for their openness to geographical mobility given their weaker ties to a given place (Visconti 2007). Such flexibility better fits companies' territorial fast-moving needs and grants competitive advantage.

Despite the centrality of space in the construction of the migration experience, consumer acculturation studies have mostly interrogated migration in static fashion. The country of origin and of destination, as well as the cultures embedded in such loci, are crystallized, frozen, captured in a Polaroid snapshot, where they can be contrasted, scrutinized, mixed (Laroche, Kim, and Tomiuk 1998; Padilla 1980; Peñaloza 1994; Wallendorf and Reilly 1983).

From this perspective, it is arguable that migration studies have been so far dominated by the category of *time*. Time is surely a relevant dimension to capture the ongoing processes of cultural adaptation (Berry 1980), the learning of new languages and their symbolic nuances, the establishment of new social linkages, consumption practices, and meaningful experiences (Peñaloza and Gilly 1999).

Nonetheless, migration can be fruitfully understood also in the light of the category of *space*. Migrants enter territories, homes, marketplaces. They cross regions to settle down and reconnect with family members. The relevance of space in understanding culture and the relationships migrants establish with it are crystal clear in a world where cultural dynamicity and its deterritorialization are increasing (Craig and Douglas 2006).

However, a bunch of consumer studies dealing with migration and space is noteworthy. Transnationalism has come to the edge (Portes, Guarnizo, and Landolt 1999). Sometimes, transnational consumption experiences are mediated by the brands and remain within the sphere of imagination (Cayla and Eckhardt 2008). Other times, and more easily, transnationalism relates to real migration paths (Basch, Glick Schiller, and Szanton Blanc 1994) and openly interrogates the issue of place (Gupta and Ferguson 1997; Hanerz 1992).

Second, consumer researchers have documented the impact of globalization on the shaping of consumers' global identity (Üçök and Kjeldgaard 2006). Among others, Thompson and Tambyah (1999) highlight the tensions expatriates meet during their migratory process, in which nomadism and cultural adaptability contrast their loss of home.

In this paper, I look at space as *collective space*. Immigrants reach a new country, and their encounter is objectified through the encounter with a new city. Also, the city is a “shared land” in which migrants overcome the invisibility that the market and media sometimes generate. Being visible, they can reclaim a subject position and become active agents in/of their context of living. As noted by Kostof (1992, 123), public space is actually “a destination, a purpose-built stage for ritual and interaction.” The city is a

collector of rival ideologies about the role that different dwellers have to express (Visconti et al., forthcoming).

From this viewpoint, understanding the way migrants live the city holds a terrific explanatory power about the processes of social inclusion, justice and equity, market and civic legitimization, and the power migrants have to cope with the contradictory stances posed by migration and the hosting culture.

This research is an ethnographic inquiry conducted in the city of Milan, Italy. The project is at an early stage of data collection. Three main typologies of neighbourhoods have been selected: i) areas dominated by migrant's dwellers belonging to a single ethnicity (mono-ethnic ghettos); ii) areas appropriated by a prevalence of migrants from different ethnicities (multi-ethnic ghettos); and, iii) areas of coexistence between autochthonous dwellers and migrants (dialogical areas). Sites of investigation span from citizens' dwellings (homes) to commercial spaces, and from profane recreational areas (e.g., parks, gardens, etc.) to sacred religious sites. Informants are involved both individually and jointly, in the form of families, religious communities, or associational groups.

This project aims at answering to a list of relevant questions. Do migrants feel part of the city they inhabit? How do they establish geographical, symbolic and emotional rooting in their cities? How do they feel about ethnic ghettos or dialogical areas? Do they get involved in confrontations with other members of their neighbourhood? But also, how do they envision urban changes and to what extent do they feel legitimized to or interested in being part of this change?

Overall, my work extends our understanding of acculturation by reading it through the lens of collective space since the city should not be meant as a physical space only but also as a mental space (Park and Burgess 1984). As such, the city and the way dwellers live it mirror the existing social tensions, the identity projects of its inhabitants (Minowa, Visconti, and Maclaran, 2010), and the very fabric of acculturative practices.

“Mobile Ethnicities In Global Cities”

Bernardo Figueiredo, University of New South Wales, Australia

Eric Ping Hung Li, Qatar University, Qatar

Moving beyond the traditional concept of ethnic migration and acculturation, our study aims to highlight the fluidity and mobility of ethnic representation in global cities (Bauman 2000). New forms of governance and market competition, along with the ever-increasing interaction between ethnic groups and ideologies alter the concept of nation and cities under the globalization discourse (Bhabha 1994; Appadurai 1996). The de-territorialization and re-territorialization of culturally diverse migrants not only challenges the traditional conceptualization of ethnicity which is associated with its geographic origin and historical roots, but also create a new order of global cities such as Toronto, New York, London, and Sydney (Sassen 1991). The construction of ethnic ghettos and expatriate regions illustrate the concept of multiplicity, diversity and complexity of the global city landscape. The co-existence of different groups from different ethnic and cultural backgrounds not only problematizes the form of and space for ethnic representations, but also forces different policy makers and cultural agents to create new strategies to ensure and maintain the harmony of the marketplace. Through comparing the commonalities and differences

among mobile groups' experiences in different socio-cultural settings (expatriates in Sydney and immigrants in Toronto) our current study seeks to answer two research questions: (1) what is the role of global cities in organizing market-mediated ethnic relations and (2) how do ethnicities become resources for mobile consumers' identity projects in culturally diverse global cities? In other words, we are interested in studying the power relationships among different cultural agents in the construction of the "imagined" global cities (Anderson 1983; Pieterse 2007) and how individuals re-perform ethnicities within the global cultural supermarket (Mathews 2000).

Prior research on the movement of ethnic groups primarily focuses on acculturation and identity negotiation issues (e.g., Peñaloza 1994, Oswald 1999, Askegaard, Arnould and Kjeldgaard 2005; Üstüner and Holt 2007) but the impact of the mobilized group on the local cultures as well as the power relationships in facilitating the ethnic relations have been under-researched. The movement of ethnic groups, in many cases, challenges the structure and order of the city in a different way than they do in other contexts. In addition, the multiplicity and friction (Tsing 2005) of the various populations generate issues that related to market representation, ethnic identification and public policy. Also, literature on acculturation overlooks the creative and productive aspect of adaptation and representation in culturally diverse landscapes and the power of these landscapes in shaping consumption. Therefore research on the mutually constitutive inter-relationships between cultural practices in the construction of global cities and mobile identities is necessary.

In this study we adopted the multi-sited ethnographic method (Marcus 1998) to extend our understanding of the construction of "global cities" and the pattern of identity projects among mobile consumers (immigrants and expatriates) in two multi-ethnic global cities: Sydney and Toronto. The choice of cities was based on the fact that both rank among the top ten in ethnic diversity and welcome factor (Florida 2008). Moreover, both share public policies that openly aim to attract skilled labor (Salt 1997). By comparing the historical and socio-cultural development of these global cities we identified how a colonial past and government policies shape the construction of global city markets, and how different waves of immigration and migration re-construct the order and dynamic of the city. We also conducted participation observations, photographs and long interviews in order to have a better understanding of the identity projects and ethnic-related consumption practices among mobile groups in a naturalistic setting (Belk, Sherry and Wallendorf 1988). The multicultural background of the researchers together with the diversified cultural experiences of our informants allows us to triangulate our data from multiple sources and points of view.

Both Sydney and Toronto have experienced British colonial rule as well as successive waves of immigration in the past century, and the significant population changes underway in each means there is no numerically "dominant" group in either city. Our findings suggest that global cities provide a "stage" for performing multiplicity and diversity. Under the influence of multicultural policies and the organization of ethnicized space as well as the encouragement in preserving cultural uniqueness and mutual accommodation, consumers in Sydney and Toronto learn tolerance and open themselves to diversity, and are encouraged to preserve, display and exhibit their cultural practices. Ethnic-themed festivals, public policies that celebrate special ethnic holidays, the organization of neighborhoods, and ethnic-themed businesses highlight cultural differences within global city spaces and our findings demonstrate that the very meaning of ethnicity also undergoes a series of preservation, authentication, transformation and reinvention processes. As a result, ethnicity itself becomes a dynamic resource for mobile members

of all ethnic backgrounds. At the same time, different motilities use these resources in different ways according to their intention to stay and cultural knowledge. In other words, the structure and order of global cities, although different from one another, embody ideologies of mobility, of difference, and of multiple identities. This ideology becomes an important enabler of alternative identities (e.g. cosmopolitans) and alternative representations of the existing ones (e.g. diverse market-mediated representations of Chineseness).

This article supports a conceptualization of ethnicity and locality not in opposition to the global, but in relation to social, political, and cultural relationships that operate within and beyond these particular spaces. More specifically, our research extends current understanding on the role of global cities not only as culturally diverse landscapes, but as enablers of ethnic negotiations. It suggests that global cities are important arenas for revising and reinventing ethnic relations and ethnic symbols. Moreover, the history and organization of the city play defining roles in the identity construction of mobile ethnic groups. Thus, in an important extension to the consumer acculturation literature, this article shows that global cities are structured in a way that highlights mobility and integration and downplays assimilation.

"The Role Of The Marketplace In The Immigrant Women's Negotiation Of Place Within The Dominated Space"

Zuzana Chytkova, University of Pisa, Italy

Most of the research regarding immigrant consumer acculturation has been carried out in environments with a long history and experience with immigration, such as the United States (Peñaloza 1994, Oswald 1999), United Kingdom (Jamal 2000, Lindridge, Hogg and Shah 2004), or Denmark (Askegaard, Arnould and Kjeldgaard 2005). However influential and important these studies, they concentrated on the immigrants' creative ethnic identity construction through the marketplace offerings in the contexts, in which the studied minority's culture was, in one way or another, commodified and marketed also to the mainstream. Such situation, then, creates a specific climate, in which there are certain legitimate ethnic identity positions created for the immigrants in and by the marketplace. It was, in fact, illustrated how, with time, the same marketers become influenced and changed by marketing to the ethnic minorities (and therefore more receptive and open towards the catered ethnic group), and how, for instance, English/Spanish bilingual advertisement legitimizes the Hispanics' presence in the American marketplace (Peñaloza and Gilly 1999). In such contexts, therefore, the space of the multicultural city can be seen as co-created by the dominant group and the ethnic minorities.

However, the immigration phenomenon is not confined to countries with a long tradition of accommodating differences. On the contrary, with the process of globalization, more First World countries become the destination of migrants from developing parts of the world. Given this premise, it becomes crucial to study the underlying conditions that allow for the accommodation of differences and the minimization of "otherness" within the multicultural spaces. One possible way to advance such knowledge is to study contexts in which the construction of such spaces is in its embryonic stage. In empirical contexts, in fact, in which the marketplace (and the society) is immature due to the recency of the immigration phenomenon, legitimate ethnic identity positions may not be offered. The common space, then, is not co-constructed, but rather constituted by the dominant group, as is the immigrants' place within the space. It is a question, then, if the immigrants in such setting still use the marketplace offerings to construct their hybrid ethnic identities, or if they are constrained to their "place"

by the dominating discourses in a similar manner as proposed by Üstüner and Holt (2007).

The empirical context of the current study mirrors the above considerations, as it focuses on the Romanian female immigrants to Italy. Italy, traditionally a country of emigration and the source of workers for other European economies has not yet quite recovered from the “shock” of becoming the country of immigration some twenty years ago. As a result, multiculturalism or ethnic marketplace is still in diapers, especially outside the few big cities that could be considered as global. Italian companies, convinced by the media representation of immigrants as victims or delinquents (more than eighty percent of television and newspaper coverage on immigration in 2002) (Napolitano and Visconti 2007), do not consider them as feasible market segments. As a consequence, certain subjectivities are constructed in and by the marketplace. In the specific case of the food market serving the Romanian immigrants in Italy, for instance, the same organization of the marketplace where it is the small shops of Romanian propriety that cater to the Romanian community, but none of the mainstream distribution channels, creates a sort of subjectivity that evidently favors the self-perception of an “immigrant”, rather than an integrated part of a multiethnic culture.

Yet, through the marketplace, the immigrant women also come into contact with the consumer culture representation of the modern woman, a woman that, through her consumption choices, can be whoever she wants to be (McDonald 2000). The representation of women in the consumer culture can be seen, and indeed has been criticized, as another discursive apparatus that constitutes female subjectivity in a certain way, more precisely as a gendered version of the neoliberal “enterprising consumer” (Catterall, Maclaren and Stevens 2005). The notion of the “enterprising self” is based on the economic and political liberalism that sees in a subject a self-defined, self-motivated individual that is free and able to decide what he wants and does what he can to reach it, assuming the responsibility for his own life (Slater 1997).

Based on depth interviews and video-registered cooking sessions with Romanian immigrants, I studied the way immigrant women use marketplace-originated symbolic resources to negotiate the subjectivities (places) ascribed to them within the dominant spaces. I concentrated on the practices of everyday life, namely cooking, as a means of resistance. Drawing on De Certeau’s notion of consumption practices as “tactics” through which the “weak” appropriate the dominant “spaces” much as the reader appropriates the written text with his/her own imagination, I show how the immigrant women draw on the discourse of the “enterprising consumer” in its gendered alternative of the “modern just-do-it woman” and by doing so, they re-interpret the subject position of immigrant assigned to them.

The research shows that even when the “space” and the immigrants’ “place” within it are constituted as a hegemonic structure by the dominating group, consumers are still able to make use of the symbolic resources offered by the marketplace to negotiate such identity positions. Further, it is illustrated how, with a growing cultural capital based on consumer culture knowledge and education, the immigrants make benefit of the marketplace symbolic resources in a more nuanced way, primarily by making use of what little multiethnic offerings the market provides in the construction of a cosmopolitan identity that allows them to take a reflexive distance from the dominated subjectivity assigned to them.

“Ethnic Entrepreneurs: The Identity-Enhancing Tactics of Global City Consumption”

Ela Veresiu, Witten/Herdecke University, Witten, Germany

Markus Giesler, York University, Canada

How has consumer culture theory constructed migrant consumers? Below is a short collection of voices. Following the standard view, migrant consumers must

“not only cope with foreign languages, diverging cultural habits, and alternative markets, but also with multiple “ascriptive identities” (Horowitz 1975) and multifaceted national discourses and practices” (Luedicke and Giesler 2009)

“live in a society that undermines the building blocks of their identities: their ethnicities” (Özçaglar-Toulouse and Üstüner 2009)

“grapple with an alien mass-produced culture” (Üstüner and Holt 2007)

“struggle to extract a sense of real identity from acculturative experiences that are often anxiety provoking” (Askegaard, Arnould, and Kjeldgaard 2005)

“[be] fearful of being pigeonholed into stereotypes or fetishized into objects of curiosity” (Oswald 1999)

“confront a myriad of frustrating and seemingly intractable sociocultural barriers to getting inside the local culture” (Thompson and Tambyah 1999)

“[deal with] conflict and pressure to adjust to the way of life in the United States” (Peñaloza 1994)

Furthermore, migrant consumers are

“unable to engage with, let alone negotiate through the use of product consumption, daily interactions between South Asian and British White cultures (Lindridge and Dhillon 2005)

To conclude, migration is

“the emergency situation (economical crisis or the experience of the unknown upon arrival) (Chytkova and Özçaglar-Toulouse, 2010)

“not a simple process of integration but one that is highly contested and characterized by conflict” (Wamwara-Mbugua and Cornwell 2006)

“disempowering” (Chytkova and Özçaglar-Toulouse, 2010)

The existing theoretical picture on migrant consumption can be summarized as follows: Migrant consumers are suffering from adverse social circumstances due to the overwhelming challenge of negotiating competing identities and cultural practices in an unfamiliar sociocultural and market environment. Sedentary consumers, on the other hand, are generally more empowered due to their familiarity with the national context’s sociocultural norms and market system. We characterize this view as the “struggling migrant” model.

To engage this dominant theoretical perspective, we studied migrant consumers of Roma ethnicity in three global cities. The Roma are commonly portrayed as a victimized ethnicity whose culture has been under constant threat by nation-state norms through centuries of official persecution, slavery, forced assimilation and attempted integration in all the countries that they migrated to (Belton 2005; Liégeois 1994; Petrova 2003). As a consequence, these migrant consumers should struggle the most.

As we interviewed the Roma consumers, we came to believe that the “struggling migrant” model fails to capture some of the most powerful identity-enhancing consumer tactics that are enabled in the context of global cities. Sociologist Saskia Sassen (2006, 316) has argued that “current conditions in global cities are creating not only new structurations of power but also operational and rhetorical openings for new types of political actors that may have been submerged, invisible, or without voice.” Unlike other cities, the global city consists of a complicated and powerful nexus of economic, political, sociocultural, and infrastructural resources and structures that, when used effectively, enables citizens to establish a meaningful presence. Our consumer cultural addendum to this definition is that these resources and structures become the subject of consumption, and that this agentic consumption takes the shape of what we define as ethnic entrepreneurship.

To reveal ethnic entrepreneurship, we illustrate how our Roma migrants consume the available structures and resources of the global city in creative and often unexpected ways in order to support and enhance their ethnic identities. For example, the informants use the cities’ advanced resources to create Roma organizations and community centers that provide an internal network of assistance, cultural solidarity and information exchange exclusively for Roma citizens. Similar to Belk and Paun’s findings (1995, 2001) that “[Roma] survive by cleverness in adaptation, by finding viable economic niches,” all of our informants pride themselves on being crafty businessmen, as well as highly flexible in their consumption of food, religion and clothing. However, upon closer inspection this seeming flexibility is a rhetorical device used to protect their core cultural identity from outsiders (the non-Roma), including us in the role of researchers. Furthermore they creatively integrate themselves in the global city’s network in order to optimize their consumption of all available social services. We discuss these findings in detail and establish important interpretive boundary conditions by comparing Roma consumption and ethnic entrepreneurship in three different global cities.

In terms of methodological details, our study is part of a larger ethnographic and netnographic (Kozinets 2002) investigation of Roma consumers in Toronto, Pisa and Berlin. Our collection of ethnographic and consumer interview data was completed in the summer of 2009 and subsequently analyzed. The study intentionally spans three cities for the purpose of interpretive triangulation. Roma informants were solicited through Roma and activist websites, as well as Roma organizations. We conducted in-depth, semi-structured interviews with 29 Roma consumers, where everyday activities (e.g. housing, working, education, dress, religion, cooking, family and traveling) were discussed. In order to better understand the overall sociocultural and political environment of the respective global cities, we also interviewed national citizens, which were mainly solicited from anti-Roma websites and online discussion forums, as well as public officials across the social services, immigration, child welfare, and education sectors. The complete data set included 65 in-depth, semi-structured interviews, which ranged from 30 minutes to four hours in length, as well as 140 pages of online material, historical data, and media reports. A hermeneutic approach was used to analyze the data (Thompson 1997).

In conclusion, we combine our empirical findings with extant sociological research to trace the genealogy of the “struggling migrant” thesis in consumer culture research. We find that the “struggling migrant” thesis is an example of methodological nationalism. Critical sociologists define methodological nationalism as the assumption that the nation-state is the natural and necessary form of social, political and geographic organization in modernity (Beck 2000; Chernilo 2006; Wimmer and Schiller 2002). According to these scholars contemporary mainstream social theory has generally taken nationally bounded spaces and societies for granted, which overlooks other important human realities. For this reason, consumer theories on migration would not have predicted the important role of the global city as a strategic consumption resource in migrant consumers identity work. Our results offer new and important theoretical insights by presenting the empowered ethnic entrepreneur that creatively consumes the global city in order to reinforce his/her ethnic identity.

SPECIAL SESSION

“How Close or How Far?” The Role of Perceived Goal Progress in Consumer Goal Pursuit

Minjung Koo, Sungkyunkwan University, Korea

Oleg Urminsky, University of Chicago, USA

EXTENDED ABSTRACT

“Stuck in the Middle: The Psychophysics of Goal Pursuit”

Andrea Bonezzi, Northwestern, USA

Miguel Brendl, Northwestern, USA

Matteo De Angelis, Luiss University, Italy

Achieving a goal often requires engaging in goal-consistent actions for a prolonged period of time. For example, losing weight requires sticking to a diet and resisting temptations to indulge for many months. The classic goal-gradient hypothesis (Hull 1932; see also Kivetz, Urminsky and Zheng 2006; Nunes and Dreze 2006) posits that motivation to reach a goal increases monotonically with proximity to the desired end-state.

In this research, we posit that motivation to reach a goal is not always a monotonic function of distance from the desired end-state. Specifically, we show that motivation to reach a desired end-state is higher when either far from the goal or close to the goal, and lower when halfway toward reaching the goal. We propose a psychophysical explanation that accounts both for this tendency to get “stuck in the middle” and for the classic goal-gradient pattern. In particular, we argue that motivation to engage in goal-consistent behavior is influenced by the perceived marginal value of progress granted by such behavior (Heath, Larrick and Wu 1999).

According to previous research, people monitor progress toward a goal in terms of distance from a standard of reference (Carver and Scheier 1998). Specifically, they can either use their initial state (i.e., their starting point) as the standard of reference, hence consider what they have achieved so far (e.g., to-date frame), or they can adopt the desired end-state as their standard of reference, hence consider what they still need to achieve (e.g., to-go frame), (Koo and Fishbach 2008). We suggest that people tend to adopt the initial state as the standard of reference when far from the goal and the final state as the standard of reference when close to the goal. Furthermore, consistent with the psychophysical power law (Stevens 2000), and the principle of diminishing sensitivity (Kahneman and Tversky 1979; Tversky and Kahneman 1991), we suggest that the value of the same unit of progress decreases as the distance from the standard of reference adopted increases. For example, if the goal is to collect 100,000 frequent flier miles, flying 4,000 miles seems a lot when the account shows 5,000 miles (the standard) or when the account shows 95,000 miles (the standard being 5,000 miles to go). The same 4,000 miles, however, seem little when the account shows 50,000 miles because either standard yields a ratio of 4,000 to 50,000. Thus, “in the middle”, when both standards of reference are far, an additional unit of progress is perceived to have less value, compared to when either close to the initial or to the final state.

Study One tested the hypothesis that motivation to engage in goal-consistent behavior is lower when about halfway toward reaching a goal. Participants read a scenario about a dieter, specifying her weight when she began dieting (200 lbs), the desired weight goal (140 lbs), and her current weight, varying between-subjects (190 lbs vs. 170 lbs vs. 150 lbs). Then they were told to imagine that the dieter was ordering from a restaurant menu offering many options, ranging from a very healthy but less tasty dinner (salad and fruit) to a very tasty but less healthy dinner (cheeseburger and cake). Participants then indicated on a scale from 1 (tasty dinner) to 9 (healthy dinner) which alternative they expected the

dieter to choose. Participants predicted the dieter would choose a less healthy (i.e. goal-inconsistent) dinner when halfway toward reaching her desired weight, compared to when she was either far from or close to her goal.

Study Two aimed at assessing how motivating an incremental unit of progress is perceived to be, as a function of the distance from the desired end-state. Respondents read a scenario describing a runner with a goal to run 10 miles. After running a certain distance, varying between-subjects (2 miles vs. 5 miles vs. 8 miles), he feels tired and feels he has the energy to run only about one more mile. Participants indicated on a scale from 1 (not motivated) to 9 (highly motivated) how motivated the runner would feel to keep running about one more mile. Participants thought the runner would feel less motivated to run an extra mile when halfway toward reaching his goal, compared to when he was either close to the beginning or close to the goal.

Study Three tested our theoretical explanation by explicitly manipulating the standard of reference used to monitor progress. Participants imagined they were enrolled in the frequent flyer program of Airline X, in which they could earn a free ticket after accumulating 25,000 miles. We manipulated the standard of reference adopted to monitor progress by informing participants of either how many miles they had already accumulated (4,000 vs. 12,000 vs. 21,000), or how many miles they still needed to reach the reward (21,000 vs. 12,000 vs. 4,000). Respondents then indicated the premium they would be willing to pay for an Airline X ticket that would earn them 3,000 miles, versus a \$300 ticket from another airline that would earn them no miles. Specifically, they indicated how much more than \$300 they would be willing to pay to fly with Airline X, thus adding 3,000 miles to those already accumulated (to-date), or deducting 3,000 miles from those they still needed (to-go). Respondents who were informed of how many miles they still needed to reach the reward were willing to pay most when close to the goal, less when halfway, and even less when far from the goal. Respondents who were informed of how many miles they had already earned were willing to pay a higher price when at the beginning and a lower price when halfway and near the end.

Across three experiments, we show that motivation to reach a goal is often higher when either far from the goal or close to the goal, and lower when halfway toward reaching the goal. We argue that this tendency to get *stuck in the middle* is due to the lower value an additional unit of progress is perceived to have when halfway toward reaching the goal.

“The “Small Area” Effect: How Progress Monitoring Influences Participation in a Reward Program”

Minjung Koo, Sungkyunkwan University, Korea

Ayelet Fishbach, University of Chicago, USA

A large part of consumer behavior aims to achieve goals. Especially, in the context of reward programs, consumers invest a stream of efforts to earn future rewards. Previous literature has shown that their motivation to participate in and invest efforts to a reward program is largely driven by the perception of progress towards the goal (e.g., Carver and Scheier 1990; Kivetz, Urminsky and Zheng 2006; Nunes and Dreze 2006; Soman and Shi 2003).

This research introduces the “small area” effect, which demonstrates the role of proportional valuation of progress that each

action would achieve towards goal attainment. By “area”, we are referring to the size of goal progress that one can attend in terms of either accumulated progress to date or remaining progress to go (Koo and Fishbach 2008). For example, consumers can monitor their progress by counting the number of stamps collected so far versus stamps to be collected on a frequent-buyer card. We propose that the focus on the “small area” is more motivating than the focus on the “large area,” because an additional action is seen as yielding greater progress when people compare it to a small (vs. large) number of actions. Specifically, we predict when the level of progress is low (less than 50%), the focus on accumulated progress to date would be more motivating than remaining progress to go. For example, for a consumer who has progressed up to 20% of goal attainment, focusing on 20% of progress that is already made (small area) would be more motivating more than focusing on 80% of progress more to go (large area). Conversely, when the level of progress is high (more than 50%), the focus on progress to go would be more motivating than progress to date. For example, for a consumer who has progressed up to 80% of goal attainment, focusing on 20% of progress more to go (small area) would be more motivating than focusing on 80% of progress that is already made (large area).

Three studies tested these predictions. Study 1 was a large-scale field experiment, in which we monitored over 1000 consumer purchases at a sushi restaurant. Customers were offered to enroll for free in a reward program of the restaurant, in which they had to make ten sushi meal purchases in order to earn a reward of free meal. To allow tracking of their purchases, members were required to carry a frequent sushi card. We manipulated the focus on accumulated progress to date versus remaining progress to go, by providing customers with a card on which a sushi-shaped stamp is added for each purchase (i.e., the visual focus is on the number of completed slots) versus a card on which a sushi-shaped stamp is removed for each purchase (i.e., the visual focus is on the number of remaining slots). We tracked 1) the number of purchases on their first visit (i.e., their level of goal progress); 2) whether they return during the promotion period (3 months); and 3) the number of purchases on their second visit. As expected, we found that as members made higher progress on their card on their first visit, the card that emphasized remaining (vs. accumulated) purchases was more motivating—that is, they were more likely to come back and made more purchases on their second visit. That is, emphasizing a small area was more motivating than a large area.

To further investigate the underlying process of the effect, study 2 extended the results to the context of a coffee reward program, in which we experimentally manipulated both the level of progress (30% vs. 70%) and the focus on accumulated vs. remaining purchases. As expected, we found that when the level of progress was low (vs. high), those with a coffee card that emphasized completed (vs. remaining) slots indicated higher willingness to participate in the program and greater anticipated progress by their next purchase, and vice versa. Important, we further found that the increase in anticipated progress mediated the effect of emphasizing the small area on willingness to participate in the program.

In our last study, we show that the focus on small area is more motivating than the focus on the large area only when people have a high desire to approach the goal end-state. That is, we predict that when people have a low desire to complete the goal (e.g., gift card), the small area effect would not hold because people do not draw higher proportional value from making progress toward the end-state. In study 3, we manipulated participants’ desire to reach the end-state by employing two different reward programs at a bagel store—a regular “buy 10 get 1 free” reward card (high desire to reach the end-state) and a gift card that participants get discount for

10 purchases (low desire to reach the end-state). As predicted, we replicated previous effects in the reward card condition, whereas the effects were reversed in the gift card condition.

Taken together, these studies provide convergent evidence for the impact of importance of subjective evaluations of anticipated progress in goal pursuit. We believe that our findings have important theoretical and practical implications for motivation and goal behavior and for reward programs and marketing promotions.

“Almost There? The Role of Absolute vs. Relative Error in Perceived Progress Towards an Accuracy Goal”

Oleg Urminsky, University of Chicago, USA

Recent research on goal progress has investigated the impact of people’s perceptions of distance from a goal (e.g. Kivetz, Urminsky and Zheng 2006, Koo and Fishbach 2008). In this paper, we use the context of prediction accuracy to explore how people perceive differing degrees of progress to a goal. How do people determine when a prediction is closer to the accuracy goal (e.g. more or less accurate relative to the actual value)?

When people make a series of such assessments, the perceived discrepancy from the accuracy goal is primarily driven by attempting to assess and incorporate two salient pieces of information: the absolute and the proportional (percentage) error. Specifically, participants judgments exhibited what we term *quasi-proportionality*: the same absolute error will be evaluated as worse when the actual value is relatively small, while the same relative error will be evaluated as worse when the actual value is large. Furthermore, the relative weight on absolute vs. proportional distance in forming a distance judgment is systematically affected by the magnitude of the actual value. In particular, more weight is put on absolute error for large true values and more weight is put on proportional error for small true values.

In an initial study (N=40), which of a pair of election predictions is seen as more accurate is significantly affected by framing the outcomes in terms of the winning candidate’s share (large true numbers) or the losing candidate’s share (small true numbers), impacting how proportional errors are perceived.

In the second study, 111 participants evaluated a series of (16) pairs of predictions of different students’ test scores, choosing the one they saw as more accurate. Participants’ assessments exhibited quasi-proportionality, incorporating both absolute and proportional error, and the weights placed on each type of error in turn depended on the scale of the numbers (e.g. the average of the two actual values). The effects are shown not to be explainable by heterogeneity, not to vary based on beliefs about the distributions of scores and not to be affected by the participants’ own mathematical ability.

The third study (N=116) extends the findings to three additional contexts: election outcomes, weather predictions and salesperson’s outcomes. In particular, in assessing predictions of how many cars a salesperson will sell in a given time period, expressing the same rate expressed with small numbers over a shorter interval (one month) or with larger numbers over a longer interval (10 months) affects whether absolute errors or relative errors have more of an effect. When the same monthly rates for the sales predictions and outcomes are expressed as 10 month totals, participants place more emphasis in their judgments on absolute discrepancies relative (rather than proportional discrepancies).

The fourth study presented participants with a series of judgments designed specifically to distinguish between competing accounts of accuracy judgments. For example, in one task, 68% of participants evaluated a prediction of 20 vs. 24 actual as better than a prediction of 60 vs. 72 actual. In a separate task, only 36% of the participants evaluated a prediction of 68 vs. 72 actual as bet-

ter than a prediction of 204 vs. 216 actual, a significant difference ($p=.04$). Note that in both tasks, the proportional errors are equal for both predictions (20% in the first task and 6% in the second task) while the absolute errors are the same in the first option for both tasks (12) and in the second option for both tasks (4). Thus, neither proportional nor absolute distance can explain the pattern of choices. In contrast, quasi-proportionality (specifically the shifting-weights account of incorporating absolute and proportional discrepancies) was consistent with the findings. Furthermore, the patterns of choices could not be explained by the established view of the psychophysics of difference judgments (e.g. Marks and Cain 1972) or by a simple averaging model (Wright 2000).

The implications of the proposed account of accuracy judgment for choices among available agents are discussed. The implications of quasi-proportionality, beyond the specific context of accuracy goals, are discussed. In particular, perceptions of general goal progress are proposed to be governed by quasi-proportionality, such that the perception of distance to the goal is determined by both absolute and relative distance remaining, with relative emphasis on absolute vs. relative determined by the scale of the numbers under consideration. The implications for motivation are discussed.

"Can You" or "Will You": How Progress-Based Inferences Impact Motivation in Consumer Goal Pursuit

Ying Zhang, University of Texas at Austin, USA

Szu-Chi Huang, University of Texas at Austin, USA

A classical proposal in the study of goal pursuit is that people's motivational strength increases as they accumulate progress and approaches goal attainment (Hull 1932; Kivetz et al. 2006). Although it is well established that progress can have an impact on people's subsequent motivation, it is less clear whether the source of the progress would change its impact, and whether such influences would vary depending on one's relative positions in a pursuit. In the present research, we explore two different sources of motivation and propose that because people move from seeking information on goal attainability to information on goal value in the establishment of goal commitment as they progress toward achieving the goal, endowed and earned progress will have different impacts on individuals' motivation, depending on the stage of goal pursuit.

Specifically, low progress on attaining a certain goal raises the question of whether the goal is attainable. The amount of existing progress toward attaining the goal and the effort that people have expended on making that progress, in turn, indicate the difficulty of goal attainment. Compared with those who made progress without expending effort, people who have invested effort in achieving the same low level of progress would infer that the attainment would be more difficult, and thus be less motivated in further pursuit.

When the level of progress on achieving a goal is relatively high, however, people feel that the goal attainment is secured and would shift to focus on the value of the attainable goal. In these times, progress that is acquired through personal effort should be more motivating because it signals one's conscious commitment to pursuing the goal. In contrast, endowed progress carries little diagnostic information in terms of signaling goal value. Accordingly, we expect that when the progress on attaining a goal is high, progress that individuals have earned by expending effort (vs. endowed progress) should elicit greater motivation in further pursuit.

We test these hypotheses in four studies. In Study 1, we tested our hypothesis in two consumer loyalty program scenarios. We manipulated the type of progress by describing it either as made through personal effort, or as endowed without effort. We then manipulated the level of progress by describing it as either a large or small portion of what was needed for the final reward. We found

that when the progress level was low, participants whose progress was endowed (vs. earned) were more motivated to keep pursuing the goal despite inconveniences in accumulating points, but when the progress level on the program was high, those who made progress through personal effort (vs. endowed) expressed higher motivation.

In Study 2, participants completed a word-completion task and encountered a difficult question either at the beginning or toward the end of the task and progress that they accumulated before encountering the difficult question was either earned through their personal effort or was awarded by the computer. We found that among the participants with low progress, those who had made progress without expending effort persisted longer than did those who had invested effort to make the same amount of progress. Conversely, among the participants with high progress, those who had made the progress without expending effort persisted less than did those who had invested effort.

Study 3 tested our proposed mechanism and investigated whether it is indeed people's inferences at different stages of goal pursuit that influence their subsequent motivation. Participants in this study completed a word recognition task on computers and were made to listen to annoying noise when waiting for a question, either toward the beginning or approaching the end of the task. We further manipulated the progress type by convincing participants that the progress they had accumulated was either the result of their effort investment, or was given to them for free by the program. We then measured participants' persistence on waiting for the question under noise as well as the inference they made during the goal pursuit. We found that when the progress was low, participants with earned progress (vs. endowed progress) inferred lower attainability of the goal, and this inferred attainability decreased their persistence in waiting. When the progress on the task was high, however, participants with earned progress (vs. endowed progress) inferred greater value of the goal, and the higher inferred value further increased their persistence.

Finally, Study 4 used a field experiment to test our hypothesis in a real consumption context. In this study real customers at a local sandwich shop were given a loyalty card that required either a small or large number of additional purchases for a free meal, and they were led to believe that they received the initial progress on the card either because they had made past purchases at the shop (earned progress) or because the shop was running a general promotion (endowed progress). We found that although highlighting customers' efforts in making progress increased their subsequent purchase frequency when they were close to redemption, doing so at early stages of the program actually decreased their purchase frequency.

Lalin Anik, Harvard Business School, USA

EXTENDED ABSTRACTS

“Micro-financing Decisions”

Jeff Galak, Carnegie Mellon University, USA

Deborah Small, University of Pennsylvania, USA

Andrew Stephen, INSEAD, France

A recently-hyped effort to alleviate world poverty has emerged in the form of micro-financing, or small loans made to small businesses and entrepreneurs in developing countries. These types of loans have provided \$25 billion in small collateral-free loans to the poorest of the poor. Given limited lending capital, a system of direct-to-borrower financing has been established to allow individuals to make uncollateralized loans to individuals and small businesses in need. This contemporary form of helping the poor has won favor because it appeals to economically-minded individuals who believe that supporting entrepreneurial endeavors will spur growth and thus do more good than traditional charitable giving (Yunus, 1999).

If micro-finance is indeed a more sensible solution to poverty, an important question is whether people who lend money are, in fact, behaving sensibly by making decisions that maximize social welfare. Recent research emphasizes the distorting impact of emotions on rational decision making. Much of this research focuses on choices for which the outcomes primarily affect the chooser's welfare. However, emotions can also bias decisions where the outcomes affect social welfare. For instance, when people donate to charity, emotional responses to victims and situations do not map onto to the gravest needs. Specifically, all else being equal, people are more likely to donate to a single individual than to a group of individuals (Kogut & Ritov, 2005a; Kogut & Ritov, 2005b). A single individual in need is more vivid and emotionally-compelling than multiple or statistical victims (Small & Loewenstein 2003; Small, Loewenstein, & Slovic, 2007). This is often sub-optimal because more people can benefit when resources are shared rather than concentrated on a single person.

Similarly, micro-finance loans to groups should be more beneficial than loans to individuals. However, our evidence suggests that lenders do the opposite. We analyzed micro-finance lending data from Kiva.org, a non-profit organization that links individual lenders and needy borrowers, who can be either individuals or groups. Lenders have full information about each loan request including information about the borrower(s) and the number of people in the borrower group. Lenders evaluate borrowers' requests and decide to whom and how much to lend (starting at \$25). We analyzed 371,521 loans made to 23,024 borrowers (individuals or groups; size $M=1.37$, $SD=1.17$, $\text{min.}=1$, $\text{max.}=20$) between November 27, 2007 (the first day Kiva allowed group borrowers), and June 18, 2008.

We find two independent conclusions to support the contention that lenders are biased towards individual borrowers. First, we observe that it takes less time to fill a loan if it is requested by an individual. Second, we observe that as group size increases, the amount loaned (calculated as a proportion of the remaining loan available to fund) decreases non-linearly. As the size of the borrower group increased, loan sizes decreased exponentially. Hence, individual borrowers were more likely fund their loans faster and to receive larger loans than groups of borrowers acting as a consortium.

A second analysis on a similar data set revealed that lenders are more likely to lend to borrowers whose social distance is mini-

mized (Flippen et al., 1996; Hewstone et al., 2002). After coders (on Amazon's mTurks system) parsed the names, gender, and occupation of 163,736 unique lenders, we were able to analyze the similarity between lenders and borrowers on these three dimensions (lender information was provided by Kiva.org). We observed a similarity effect for all three. Specifically, lenders were more likely to lend to borrowers who share their gender, occupation, and even, strikingly, the same first initial (Pelham et al., 2002). Though not specifically a bias, these results suggest that when lenders make decisions regarding whom to lend to, their decisions are influenced by factors other than optimal helping.

Because of the large volumes of money being distributed, as well as the gravity the problem of world poverty that micro-finance is purported to help solve, it is important to understand lending behaviors. Our evidence suggests a strong preference for (and perhaps bias toward) individual borrowers. This preference is apparent despite the logical argument that helping groups of individuals should be better both in terms of the number of people benefiting from the loan and the likelihood of successful loan repayment. Additionally, our evidence suggests that lender have a preference to lend borrowers who are similar to themselves, suggesting that loan distributions may be sub-optimal.

“Social Preferences and Charitable Giving: How Pay-What-You-Want Pricing can Optimize Social Welfare”

Ayelet Gneezy, University of California, San Diego, USA

Uri Gneezy, University of California, San Diego, USA

Leif D. Nelson, University of California, Berkeley, USA

In 2007, *Radiohead*, an enormously popular British rock band, released its most recent album through their website and allowed their fans to download the album for any price they chose to pay (including \$0). This pay-what-you-want (PWYW) pricing set of a cascade of media coverage, but relatively few certain answers to the most obvious questions: was the mechanism profitable and was it *more* profitable than a traditional release? If you let your customers pay as little as they want is there any reason that they would pay enough to make it a good decision?

We first considered these questions by seeking data from other companies who tried PWYW pricing. We received 15 months of download data from an independent artist who, like *Radiohead*, had released its album at PWYW (Study 1). Results indicated that the sale had an enormous influence on demand as over 600,000 people downloaded the album and generated nearly \$1 million in revenue. Both figures dwarfed previous releases by the same artist. A second set of field data (Study 2), this time from a video game developer, told a similar story: in just two weeks the company saw more than 80,000 downloads, and nearly \$200,000 in profits. Both were considerably more than a typical two week period for the company.

These data provided a sense that PWYW may be a profitable business strategy, but they did not necessarily provide evidence that it was a *better* business strategy than a more traditional alternative. By any traditional logic, PWYW would surely be considerably less profitable. We conducted a field experiment to try to answer this question (Study 3). A tour boat company photographed customers as they boarded the boat, printed the photos while the customers were at sea, and then posted them for sale at the point of disembarkation. The company traditionally sold the photos for \$15, but during the

experiment some boats were randomly assigned to either a control condition (\$15), a low-price condition (\$5), or a PWYW condition. These three radically different prices were nearly identically profitable (with PWYW being slightly ahead of the other two). Even when given the opportunity to pay nothing for a novelty photo, people chose to pay enough to make it quite profitable for the firm. Most interestingly however, was the discovery that customers were *less* likely to purchase the photo at PWYW than they were at \$5. We reasoned that this occurred because the social pressures of PWYW (e.g., “I don’t want to look like a cheapskate.”) drive people either to pay more or to not buy at all. Could the same social pressures be manipulated to drive prices even higher?

If people are concerned about looking fair in a traditional exchange, certainly they must feel doubly so when dealing with a charitable organization. We conducted a field study at a large amusement park (Study 4) in which participants ($n=116,834$) rode a rollercoaster-like attraction, were photographed during the ride, and later chose whether to purchase a print of the photo. A 2x2 between participants design crossed the photograph price (either the regular \$12.95 price or PWYW) with a charitable giving promotion (either no charity or half of the revenue went to charity). Purchase rate was low and similar in the two fixed \$12.95 treatments. PWYW increased purchase rates by an order of magnitude in PWYW with charity, and was twice as high again in PWYW without charity. However, people paid significantly more per photo when half of the revenues went to charity than with no charity ($t(3535)=43.24$, $p<.001$). PWYW, when combined with a charitable partner, was the most profitable condition for the company (by more than \$50,000 a year) and it led to a substantial charitable surplus (nearly \$1 million per year).

Pay-what-you-want pricing is certainly not for all firms, but as witnessed in these four studies, under the right circumstances it can lead to sustainable profitability and charitable giving.

“The Counterintuitive Effects of Thank-you Gifts on Charitable Giving”

George E. Newman, Yale University, USA
Y. Jeremy Shen, Yale University, USA

Donations are one of the largest sources of revenue for most nonprofits and charities and, as a result, a great deal of research in psychology, economics, and marketing has explored what factors encourage charitable giving. In this paper we focus on the effectiveness of offering small ‘thank-you’ gifts, such as a pen, coffee mug, or tote bag, as means of soliciting charitable donations. Given the ubiquity of these kinds of requests (e.g., National Public Radio fund-drives) and the real-world consequences of their effectiveness (or ineffectiveness), it is critically important to directly investigate this issue. Yet, despite decades of research on the relationship between external incentives and altruistic behavior, whether such offers do in fact increase charitable donations is unclear.

As an initial test of people’s lay beliefs, we asked adults to predict whether a thank-you gift (a pen bearing a PBS logo) would encourage people to donate more, less, or the same amount to public broadcasting compared to a donation request that did not offer a thank-you gift. The majority of participants (68%) predicted that thank-you gifts would *increase* donation amounts. Analogously, participants predicted that the group who was offered a thank-you gift would donate significantly more money than the group who was not.

In Study 2, a new group of adult participants were presented with the same materials as in Study 1. However, the presence or absence of a thank-you gift was manipulated between-subjects. In stark contrast to Study 1, participants who were simply asked

for a donation (without any offer of a thank-you gift) were willing to donate significantly more than participants who were offered a thank-you gift. Moreover, the total amount of money donated was also higher in the no-gift condition than in the gift condition. Thus, despite people’s predictions, the offer of a thank-you gift actually decreased donations both in terms of the average amount per individual as well as the total amount donated. Moreover, such counterintuitive patterns were not due to changes in beliefs about the importance of the charitable cause or to explicit beliefs about the influence of thank-you gifts.

Study 3 replicated this effect using actual donations, rather than hypothetical ones. In this experiment, participants were asked to donate a percentage of their winning from a lottery to the Save-the-Children foundation. Replicating the previous experiment, participants who were offered a thank-you gift, donated significantly less compared to participants who were simply asked for a donation.

One explanation this effect may be that participants inferred that the gift was undesirable because it was free (Kamins et al., 2009; Simonson et al., 1994). To test this possibility, Study 4 had three conditions: a desirable gift (a box of chocolate), an undesirable gift (an ugly tie), as well as a no-gift control. As expected, participants rated the chocolates as significantly more desirable than the tie. However, despite this difference in gift desirability, participants in the no-gift condition were willing to donate significantly more than participants in both the desirable-gift condition or the undesirable-gift condition. Donation amounts in the two gift conditions were not statistically different. Thus, the negative effect of thank-you gifts does not appear to be due to the undesirability of the gift offered.

An alternative explanation is that in assessing the value of the gift participants may have generated a relatively low value that anchored the subsequent amount participants were willing to donate. We tested this explanation by offering participants either an expensive gift (nice pen), an inexpensive gift (cheap pen), or a no-gift control. Despite the difference in gift value, however, participants in the no-gift condition were willing to donate significantly more than participants in either the expensive-gift or cheap-gift conditions. The two gift conditions were not statistically different. Thus, direct manipulation of the gift value within the same experiment did not alter donation amounts and in fact, we observed slightly higher donation amounts in exchange for a *less* (rather than more) expensive gift.

Study 6 examined the possibility that thank-you gifts reduce donation amounts because the external incentive undermines or “crowds out” participants’ altruistic motivations (e.g., Deci, 1975; Lepper & Greene, 1980). To test this explanation the same gift (a cloth shopping bag, bearing the organization’s logo) was framed as either something that could be used in a personally beneficial way (for shopping) or in a manner that benefited others (to increase awareness of the cause). As in previous studies, participants in the no-gift condition were willing to donate significantly more than participants in the benefit-to-self condition. However, consistent with the crowding out hypothesis, participants in the benefit-to-others condition also donated significantly more than participants in the benefit-to-self condition. Donation amounts in the no-gift condition and the benefit-to-others conditions were not statistically different. Thus, merely reframing the gift as consistent with altruistic goals attenuated the negative effect of thank-you gifts on donation amounts.

In sum, although people have the strong prediction that the offer of thank-you gifts should increase donations, such offers actually reduce charitable donations both in terms of the average amount donated per individual as well as the total amount donated. This effect is observed across a wide variety of charities and gifts types,

regardless of whether the donations are hypothetical or real, the gift is desirable or undesirable, the charity is familiar or unfamiliar, or the gift is more or less valuable. Moreover, such patterns cannot solely be explained in terms of inferences about the charity's quality (e.g., either their efficacy or current wealth), the undesirability of the gift itself, or simple anchoring effects. Instead, results were consistent with the hypothesis that the offer of external incentives undermines or "crowds out" altruistic motivations.

"The Prosocial Workplace: Prosocial Spending Improves Employee Satisfaction and Job Performance"

Lalin Anik, Harvard Business School, USA

Michael I. Norton, Harvard Business School, USA

Lara B. Aknin, University of British Columbia, Canada

Jordi Quoidbach, University of Liège, Belgium

Elizabeth W. Dunn, University of British Columbia, Canada

Recent surveys indicate that employee job satisfaction is at a twenty-year low in the United States (Conference Board, 2010)—perhaps because over the same time frame, Americans spend more and more of their time at work at the expense of devoting time to pursuits known to be linked to well-being, from forming social connections to engaging in prosocial acts such as volunteering (Schor, 1991). These findings, while seemingly aligned, also raise a puzzle: For many people, the line between work and social life is blurred, from spending time outside of the office with their friends from the office, to engaging fellow employees in prosocial behavior such as selling their daughter's Girl Scout cookies. We suggest that rather than forcing employees to make a losing tradeoff between social life and work life, employers can co-opt this tradeoff and focus instead on creating what we term a "prosocial workplace" by encouraging their employees to engage in prosocial behavior while at work. In two studies, we show that employers and employees alike can benefit by allowing employees to engage in prosocial spending—spending money on others instead of themselves—by providing them with money to spend on charities and on each other.

We base our interventions on recent research which demonstrates that individuals who spend money on others such as buying gifts for friends and donating money to charity—engaging in *prosocial spending*—are happier than those who spend on themselves (Dunn, Aknin, & Norton, 2008). We explore whether these individual benefits extend beyond the individual, conducting two field studies investigating whether prosocial spending lead to greater well-being, job satisfaction, and job performance. Indeed, previous research suggests that both happiness and prosocial behaviors are key predictors of success in the workplace. First, a large body of research demonstrates a link between people's overall well-being and their outcomes in many domains of life, including success at work (Boehm & Lyubomirsky, 2008; Lyubomirsky, King, & Diener, 2005). Second, several investigations have demonstrated that employees who chose to give money to an employee support program or engaged in helping behaviors in the workplace became more committed to their organization and performed better in their jobs (Bacharach, Bamberger, & Sonnenstuhl, 2001; Grant, 2008; Grant, Dutton, and Rosso (2008). We suggest that engaging employees in prosocial spending—encouraging them to spend money on others rather than on themselves—will therefore increase their individual well-being, their satisfaction with their jobs, and their actual performance at those jobs.

In Study 1, employees at an Australian company ($N=179$, 58% female) were randomly assigned to receive a \$50 voucher or a \$100 voucher that they could redeem online to donate to a charity of their choice; a control group of participants did not receive a voucher. We measured employees' overall well-being, as well as

their satisfaction with their jobs, both prior to receiving the voucher and after redeeming it, approximately two weeks later. Compared to employees who did not receive a voucher, those who received a \$100 voucher were significantly happier and reported higher job satisfaction.

But does this increase well-being and job satisfaction lead to better performance? In Study 2, we explored the impact of prosocial spending on the performance of two very different kinds of teams: Members of an intramural dodgeball league in Canada, and members of pharmaceutical sales teams in Belgium. For the dodgeball league, members of some teams were given \$20 to spend on themselves (*personal spending*), while members of other teams were given \$20 to spend on a teammate (*prosocial spending*). Similarly with the sales teams, members of some teams were given 15% to spend on themselves, while members of other teams were given 15% to spend on other members of their team. As we predicted, teams that had engaged in prosocial spending performed better than those that engaged in prosocial spending, across both samples. For the dodgeball league, prosocial spending teams showed an increase of the percentage of games won over the course of the season (moving from 50% to 81%) while those who engage in personal spending showed no improvement (50% to 43%). Similarly for sales teams, prosocial spending teams showed a significant increase in total sales after the intervention (going from an average of 3335? in sales to 3524?), while again personal spending teams did not improve (3928? to 3938?).

In sum, these studies demonstrate the positive impact of prosocial spending for organizations. We show that when employers build prosocial elements into the workplace by offering employees the opportunity to spend money on others—both their co-workers and those in need—both the employees and the company benefit, with increased job satisfaction, team performance, and revenues. Given that satisfaction with one's work is an essential component of people's overall well-being (Blustein 2008; Lucas, Clark, Georgellis, & Diener, 2004) and the previously mentioned decline in overall employee satisfaction, interventions that can improve both overall well-being and satisfaction may be timelier than ever.

Will I Change My Emotion, Or Will It Change Me? Emotion Regulation and Emotional Processing in Consumer Behavior

Nicole M. Verrochi, University of Pennsylvania, USA

EXTENDED ABSTRACTS

“Will I Always Choose Champagne?: How Emotion Norms Shape Consumption Choices”

Eugenia Wu, Gavan Fitzsimons, Mary Frances Luce, Duke University, USA

Patti Williams, University of Pennsylvania, USA

Though emotion norms regarding when we should feel specific emotions and which emotions are appropriate to what situations provide a constant backdrop to everyday life, little research has examined how they might influence our consumption behavior. In this research, we begin to bridge that gap by exploring how emotion norms might encourage individuals to make nonintuitive consumption choices in an attempt to achieve or avoid specific emotional states. We focus specifically on how the emotion norm associated with feeling ashamed can lead individuals to make choices that are inconsistent with mood regulation and the hedonic principle. In particular, we propose that because shame is typically characterized by feelings of worthlessness and undeservingness (Tangney and Dearing, 2002), shame comes with an emotion norm that one does not deserve to feel positively. Furthermore, we suggest that this anti-positivity emotion norm, in combination with our basic desire to make hedonic choices and alleviate negativity (Gilbert, Wilson and Centerbar, 2003), leads ashamed individuals to prefer consumption products that elicit neither positive nor negative emotion but psychologically uncomfortable and aversive mixed emotions instead.

Study 1 validates that the emotion norm in shame is positivity avoidance. Participants were asked to rate how appropriate it would be for an individual who had done something he was ashamed about or sad about to engage in a series of positive and negative activities. Results revealed that individuals in the sad condition rated it as more appropriate for him to engage in mood-repair type activities relative to individuals in the shame condition. Thus, we find some confirmation that the emotion norm associated with shame is an avoidance of positivity.

In study 2, we examine how emotion norms might affect individuals' consumption choices. Participants were primed to feel shame or in a control condition and asked to allocate 100 points among a positive, a negative and a mixed emotion-eliciting novel. Results revealed that relative to the control condition, participants in the shame condition allocated fewer points to the positive novel option and more points to the mixed emotion option. Of note, the behavior of the shame condition individuals is in direct opposition to the classic mood repair findings and occurs despite the fact that mixed emotions are psychologically uncomfortable and aversive.

In study 3, we set out to provide further support for the existence of an emotion norm in shame and to rule out an alternative explanation for our effects. Participants were first asked to read a short paragraph that encouraged, discouraged or said nothing about relying on their sense of appropriateness to make decisions. Then, participants completed either a shame or neutral prime before allocating points across four novel options (positive, negative, neutral and mixed) and completing a measure of shame-proneness. Results revealed that shame condition consumers continued to divert their points from the positive to the mixed option, despite the presence of the neutral option. This result rules out the possibility

that ashamed participants chose the mixed emotion option because they expected the positive and negative components of the mix to cancel out and result in emotional neutrality. Furthermore, shame condition participants who were encouraged to rely on their sense of appropriateness allocated the most points to the mixed emotion option, suggesting that it is indeed emotional appropriateness that is driving our effects. Finally, these effects were moderated by individual differences in shame-proneness such that effects were exacerbated for individuals high in shame-proneness.

In study 4, we explore how the anti-positivity emotion norm in shame might lead individuals to prefer products that elicit specific combinations of mixed emotions over others. If emotion norms deter ashamed individuals from feeling purely positive emotions because they are undeserving, then we expect ashamed consumers would prefer mixed emotions where the positive component of the mix is other-focused rather than self-focused. Participants completed a shame or neutral prime and then allocated 100 points among novel options. In this study, the emotions characterizing the mixed emotion book were manipulated so that the focus of the positive and negative emotion components varied across conditions. The results of the study revealed that consistent with previous studies, shame condition participants allocated more points to the mixed option relative to control condition participants. Importantly, shame condition participants were especially likely to allocate points to the mixed option when the positive emotion component was other-focused rather than ego-focused. This result is consistent with the idea that positive other-focused emotions are more in line with the shame-related emotion norm than positive self-focused emotions.

Taken together, this work builds on and extends the existing research on motivated emotion, mixed emotion and emotion norms in 1) suggesting a novel reason for why individuals might seek out one emotional state or another 2) providing an explanation for why mixed emotion-eliciting products might succeed in the marketplace 3) demonstrating that not all negative emotions lead to hedonically driven behavior and 4) examining how this fundamental social structure influences consumption behavior.

“Emotions and Motivated Reasoning: How Anger Increases and Shame Decreases Defensive Processing”

Adam Duhachek, Indiana University, USA

Da Hee Han, Indiana University, USA

Nidhi Agrawal, Northwestern University, USA

Consumer research in recent years has explored how emotional experiences impact consumer attitudes and behaviors. While most early research focused on the role of valenced affective states (i.e., positive or negative mood), recent research has begun to look at the role of specific discrete emotional states in information processing and persuasion. This literature on information processing has assumed that emotion driven consumers are either motivated to form accurate attitudes (e.g., Teidens and Linton 2001) or are driven to regulate their mood (e.g., Agrawal and Duhachek forthcoming).

In this paper, we examine how emotions impact the processing of consumers driven by defense motivation. In the persuasion literature, consumers have been shown to process messages in a defense motivated manner when they have a preference or an attitude towards a product and are exposed to preference consistent versus inconsistent information. Consumers tend to be receptive toward

preference consistent information but tend to discount or ignore preference inconsistent information (e.g., Jain and Maheswaran 2000). The present research examines how emotions will impact the processing of such information.

Bringing together the literature on emotional appraisals with the work on defensive processing in the Heuristic Systematic Model, we draw novel predictions about how emotions will influence information processing. We contrast the two emotions of anger and shame and show that their appraisals determine their influence on the processing of preference inconsistent information. Both anger and shame arise from negative outcomes/situations, but diverge in who is held responsible for the negative outcome. Anger holds other people in a negative role where as shame casts the self in a negative light. In other words, anger say “I am right” where as shame could prompt “I am wrong.” We suggest that these appraisals could serve as information when dealing with preference inconsistent information such that anger appraisals would prompt greater defensiveness against preference-inconsistent information where as shame would prompt an acceptance of ones’ existing attitude being incorrect and hence an openness towards preference inconsistent information. We further show that, for high involvement products, individuals are able to ‘correct’ for the effects of these incidental emotions on their judgments.

Three studies examined how incidental anger and shame influence the processing of preference consistent versus inconsistent information. In all three studies, participants were first primed with either anger or shame. Then they were exposed to information about a brand that convinced them that the brand was better than another competing brand. After a filler task, they saw follow-up information about the brands that either reinforced their initial favorable opinion of the brand (i.e., preference consistent information) or conflicted with their existing favorable opinion (i.e., preference inconsistent information). While emotions had no effect on the processing of preference consistent information, they systematically affected the response to preference inconsistent information. Consistent with our predictions, anger increased resistance to preference inconsistent information where as shame led to an eagerness to accept preference inconsistent information. These effects manifested in attitude change (study 1) as well as cognitive responses (study 2) and only manifested under low involvement conditions (study 3).

Our findings contribute to research on emotion appraisal by showing that appraisals of self versus other blame can heighten or counteract defense motivation. We also extend the existing literature by identifying conditions emotional appraisals influence information processing (e.g., exposure to preference inconsistent information), when emotions have no effect on processing (e.g., exposure to preference consistent information), and when the effect of emotions on processing is corrected (e.g., high involvement conditions). Our finding that shame counteracts defensive processing by encouraging people to adopt preference inconsistent views makes a unique contribution to the literature on motivated reasoning and persuasion. While most past research has suggested that consumers tend indulge in motivated reasoning that helps them to maintain their preferred attitudes or helps them improve/maintain their existing emotion, we show that under some circumstances, emotions might work through appraisals to counteract or bolster the effects of such motivated reasoning. The implications of our findings for the literature on emotions, motivated reasoning, and persuasion will be discussed, as will the managerial implications for the placement of preference-inconsistent information.

“Feeling Like My Self: Emotion Profiles and Identity”

Nicole M. Verrochi, University of Pennsylvania, USA

Patti Williams, University of Pennsylvania, USA

When do people want to change their emotional experience? Known as *emotion regulation*, individuals can self-manage their emotions by intervening in the ongoing emotional experience to adjust when, what, and how intensely they feel particular emotions (Gross 1998). Generally, people try to change their emotions when they feel bad, as when a person eats a chocolate bar after reading a sad story (Labroo and Mukhopadhyay 2009). However, there may be other reasons to experience emotions aside from simply “feeling good.” Emotions do have hedonic components (Higgins 1997), but emotions are more than just valence—the appraisal dimensions and action readiness tendencies may be leveraged in assistance of other goals. Perhaps individuals will regulate their emotions in order to achieve goal-related benefits—even at the expense of feeling good (Cohen and Andrade 2004). The current work posits that there are associations between discrete emotions and specific social identities, and that individuals will choose to regulate emotion in order to maintain consistency between the active identity and the emotion experience. In this framework, emotions are integral to manifesting a given social identity, and thus can be used to achieve an identity-consistent experience.

Over the course of one pretest and four studies, this paper shows that there are associations between specific social identities and discrete emotions: giving rise to an *emotion profile* of each social identity. The pretest isolated two emotion profiles: athletes are associated with anger, but volunteers with sadness. In all studies, participants were first primed with either an athlete, volunteer or control identity. After activating the target identity, participants then experienced an emotion. In study 1, individuals exerted more effort when their emotion was consistent with their active identity, while in study 2 participants reported more positive attitudes and higher behavioral intentions for ads in which the emotion matched their identity.

While studies 1 and 2 established that individuals benefit from emotions which match the emotion profile of their active identity, Study 3 sought to evaluate whether individuals will actively manage their emotions in order to match their active emotion profile. Following the identity prime, participants engaged in an attention task which assessed emotion regulation. This task asked participants to quickly and accurately categorize the letter T, which was shown either right-side up or upside-down. Importantly, sad and happy pictures were interspersed within this perceptual task. As sadness is inconsistent with the athlete’s emotion profile, participants with an active athlete identity should *divert* their attention away from sad pictures in order to avoid experiencing the inconsistent emotion of sadness. Volunteers, on the other hand, should *focus* their attention on the sad pictures, as they want to experience the identity-consistent emotion of sadness. This pattern of attention shifts was demonstrated: athletes were significantly slower and less accurate than volunteers when responding after sad pictures. No differences were found between athletes and volunteers following happy pictures. These results demonstrate individuals actively regulating their emotions to maintain consistency with the active emotion profile.

The final study presented participants with a product positioned as regulating their emotions: either enhancing or reducing emotional intensity. Again, participants were primed with an identity, and then emotions were induced via a film clip. Following the film, participants tried a beverage which was positioned as enhancing or reducing their emotional experience. As predicted, participants consumed (in grams) more of the beverage that aligned their emotions with the identity’s emotion profile. For instance, athletes drank

significantly more of the emotion *reducing* beverage when they were sad (inconsistent emotion), but more of the emotion *enhancing* beverage when they were angry (consistent emotion). This study both replicates the results of study 3 with consumption, and demonstrates that individuals will choose to experience an unpleasant emotion when it is valued by the active identity.

This research introduces emotion profiles, which constrain the emotions that are valid for each identity. This represents a new area of research, as well as suggests a new way in which the emotion regulation process may be initiated. Building on findings that demonstrate individuals approach products and enact behaviors which are identity-consistent, while avoiding those which are identity-inconsistent (White and Dahl 2007), this paper shows that individuals are motivated to regulate their emotions in identity-consistent ways. Specifically, people enhanced their experience of identity-consistent emotions, and reduced their experience of emotion profile-inconsistent emotions. This paper not only addresses a gap in the marketing literature by enriching our understanding of the concepts contained within an identity, but also provides an essential pre-condition to emotion regulation, furthering conceptualizations of the emotion management process. Beyond establishing that emotions are included within social identity structures, the current research suggests that identity-marketing appeals can be positioned as identity consistent without ever mentioning the salient identity, but rather by simply leveraging an emotion profile-consistent frame.

“Getting to Know Is Getting to Like: Implicit Cognitive Progress Can Awaken Liking”

Aparna A. Labroo, University of Chicago, USA

Ying Zhang, University of Texas—Austin, USA

Ayelet Fishbach, University of Chicago, USA

The facial expressions of a loved one, the first tune of a favorite night comedy, or the immediate associations of a much-frequented restaurant are all examples of things that are readily accessible in memory and surface in the mind most easily. These familiar objects are also among the things that people instantly consider among the most pleasant and hold dearest in their hearts. On the other hand, the liking of certain other things, such as subtle jokes or novel music, might follow a different pattern of evaluation. Novel objects often appear odd at first, but given sufficient consideration, they become interesting and well liked, and a person’s experience of increasing familiarity may account for one’s positive evaluation.

Understanding factors that underlie evaluative judgment is a central concern of attitude research (Ajzen & Fishbein, 1980; Petty & Cacioppo, 1986), and several experiments now show that the ease of processing the target of evaluation is an important factor that affects evaluation (Reber, Schwarz, & Winkielman, 2004; Schwarz, 2004). It has been consistently demonstrated that people prefer targets that feel immediately familiar because their perceptual characteristics or their meaning is easy to process (Lee & Labroo, 2004; Lee 2002; Whittlesea, 1993; Zajonc, 1968). The focus of existing literature is on immediate response to a target stimulus and evaluation appears to capture a pleasantness-based affective response resulting from high immediate accessibility (Winkielman & Cacioppo, 2001).

We propose that there is a second, unexplored aspect of accessibility—a change in accessibility—which may affect evaluation of a target in later stages of processing. This is because in the processing of a target stimulus, recently changed accessibility is likely to be associated with feelings of cognitive progress, implicit learning, and interest (rather than pleasantness). Interest in a target builds or diminishes over time; it is high when change in accessibility is positive, but it is reduced when change in accessibility is constant. Changed accessibility is inconsequential when evaluation is immediate, and if that is the case, evaluation is based on an immediate, absolute accessibility (and pleasantness). In contrast, high accessibility is inconsequential in later stages of processing of a target which is instead more sensitive to changes in accessibility that mark cognitive progress.

This proposition is compatible with experiments that show that perceptual fluency might follow an inverted U-shaped pattern; specifically, moderately frequent prior exposure to a stimulus results in maximum liking, and overexposure leads to habituation and reduced interest with the stimulus (Bornstein, Kale, & Cornell, 1990; Lee 2001). But this proposition is also distinct from these past findings which presume that pleasantness and interest are on a continuum; we argue that fluency comprises of two distinct sources: immediate accessibility and pleasantness and a sense of implicit cognitive progress over time which reflects in interest. Immediate

evaluation follows pleasantness; evaluation after a delay follows cognitive progress.

Two experiments tested these predictions that a change in accessibility influences the interest in a stimulus and changes in its positive evaluation after a delay. Experiment 1 (and a pilot experiment) demonstrated that the evaluation of target words that follow a typical prime decreases with delay because accessibility is constant over time and the evaluation of target words that follow an atypical prime increases with delay because accessibility increases. Experiment 2 demonstrated that the decrease (vs. the increase) in the evaluation of target words that follow a typical (vs. an atypical) prime corresponds to changes in interestingness rather than the pleasantness of the evaluated stimuli over time.

By focusing on changes in evaluation over time, this research shows that people’s immediate response is different from their response to the same stimulus only a few seconds later. This research provides insight into how evaluation evolves over short periods of time and highlights its mercurial nature. Attitudes toward the same target are different depending on when response toward the target is evoked; attitudes build over a short delay and change substantially as more processing is added. (*Manuscript in preparation*)

“Decision Quicksand: When Trivial Sucks Us In”

Aner Sela, University of Florida, USA

Jonah Berger, University of Pennsylvania, USA

Common wisdom suggests that people should spend more time and effort deliberating on important decisions (e.g., what 401k plan to use) than unimportant ones (e.g., what toothbrush to buy). However, we often find ourselves mired in trivial, everyday decisions, such as ordering at restaurants or buying flight tickets, and end up feeling that we spent similar or even larger amounts of time and effort than on decisions far more consequential. In such instances, choosing often becomes more difficult when we try to resolve it through deliberation (Dijksterhuis and Nordgren 2006; Wilson and Schooler 1991), as if sinking in quicksand. But while such experiences are quite common, our understanding of their underlying causes is limited.

We propose that metacognitive inference contributes to what we describe as “decision quicksand”. Conflict of some degree is a defining property of choice, whether of important or trivial consequences. Our central premise is that people use the ease or difficulty experienced while making a decision as a cue to guide how much further time and effort to spend. We hypothesize that people hold naïve theories according to which more important decisions should be more difficult. Consequently, experiencing difficulty in choice may lead people to perceive the decision as more important which, in turn, increases the amount of time and cognitive effort they are motivated to expend on the decision (Alter et al 2007; Chaiken and Maheswaran 1994). We propose that this may lead to a vicious cycle whereby expending more effort further increases perceived importance and thus experienced difficulty.

Importantly, however, the influence of metacognitive experiences tends to be stronger the more the experience deviates from people’s expectations (Schwarz 2004). Consequently, we predict that the tendency to spend more time and effort on difficult deci-

sions would be more pronounced when the decision is perceived as unimportant, than when it is important. Because important decisions are expected to be difficult (Kivetz, Netzer, and Schrift 2009), the real-time experience of difficulty does not provide additional information. In contrast, decision difficulty should be more informative as a cue for decision importance when it is unexpected (cf. Maheswaran and Chaiken 1991).

We test these propositions in three experiments. In experiment 1, people chose between two flight options described using regular (fluent) or degraded (disfluent) font. In addition, the decision was described as either important (related to a business meeting) or relatively unimportant (visiting distant relatives). We measured how much time people spent before deciding and whether or not they would like to consider more options. Consistent with our prediction, when the decision was unimportant, people spent more time deliberating and were more likely to seek more options when the stimuli were disfluent (versus fluent). However, fluency did not have an effect in the important framing condition.

Experiment 2 manipulated decision difficulty through the number of difficult tradeoffs. People chose between two flight options, containing either few or many tradeoffs, and the task was again framed as either important or unimportant. In addition, we tested whether the effect of difficulty in the unimportant condition disappeared when difficulty could be attributed to a cause other than importance (by telling half the participants that people often find the task difficult). As predicted, increased decision difficulty led people to spend more time deliberating, but only in the unimportant framing condition and, ironically, more so in absolute terms than in the important framing conditions. Moreover, when people could attribute the difficulty to an unrelated cause, this effect disappeared, consistent with the notion that the effect of difficulty on deliberation resulted from misattribution.

Experiment 3 examines the progressive nature of “decision quicksand”. After viewing the initial choice-set, as in experiment 2, participants were offered the opportunity to view more features for each option before making a selection. Compared to people who considered only the initial set, those who viewed the enhanced set spent increasingly more time considering the additional features, and this effect was more pronounced under unimportant than under important decision framing.

While prior research has shown that decision difficulty can lead people to defer choice (Dhar and Simonson 2003; Tversky and Shafir 1992), we show that choice difficulty can influence people’s perceptions of the decision itself, through its role as a metacognitive cue. Especially in seemingly trivial decisions, this can have painful consequences for consumer decision making. (*Manuscript in preparation*)

**“Understanding Why People Sometimes
Form Judgments and Decisions Too Hastily
(Or How to Market a Political Candidate)”**

Adam L. Alter, New York University, USA

Daniel M. Oppenheimer, Princeton University, USA

Jeffrey C. Zemla, Rice University, USA

People are frequently faced with the difficult task of deciding how much information to gather before settling on a decision or forming a judgment. Information gathering is a balancing act, because although people are motivated to form accurate conclusions about the world, they are also cognitive misers who prefer to think as little as possible about their decisions and judgments (Fiske & Taylor, 1991). Decades of research suggests that this introspective process is systematically flawed, and people frequently overestimate their understanding of focal events. To date, researchers have found

this so-called *illusion of explanatory depth* (IOED; Rozenblit & Keil, 2002) when people assess their understanding of mechanical and natural processes (e.g., how bicycles and solar systems work). In this paper, we argue that people are prone to similar errors in many other domains—including political and consumer judgment and decision-making.

In four experiments, we sought to explain why this miscalibration in judgment occurs, and to show that this general mechanism explains why IOEDs occur in novel domains that researchers have not yet considered. Drawing on Construal Level Theory (Trope & Liberman, 2003), we argue that people consult inappropriate metacognitive cues (their sound understanding of the target’s abstract properties—e.g., why a bicycle exists—rather than their poorer understanding of its concrete properties—e.g., how the bicycle’s parts enable it to move). We also explain how these results inform marketing practices and enhance our understanding of consumer decision-making.

In Experiment 1, participants were primed to adopt either an abstract mindset or a concrete mindset. Participants in the concrete condition explained *how* three mundane processes occur, whereas participants in the abstract condition explained *why* the same three processes occur. As expected, participants in the abstract condition were significantly more likely than participants in the concrete condition to overestimate their understanding of processes like how a zipper works and how a bicycle lock works. We also administered a questionnaire that assessed how concretely or abstractly participants construed 13 everyday activities. A mediation analysis suggested that participants in the concrete construal condition showed a diminished IOED because they adopted a more concrete construal style.

The results in Experiment 1 were encouraging, but we were concerned that the construal prime was too similar to later questions that asked participants to assess their knowledge about the target process. Specifically, by asking them *how* certain processes worked, we had primed them to answer a subsequent question about *how* deeply they understood a mechanical process with greater accuracy. Accordingly, in Experiment 2, we used a second construal manipulation that was not at all related to the second phase of the experiment. Participants completed a construal manipulation questionnaire. The questionnaire listed 10 objects, and participants were asked to identify either a superordinate category to which the object belonged (inducing higher-level, abstract construal; e.g., a whale is a mammal or an animal) or a specific example of each object (inducing lower-level, concrete construal; e.g., an example of a whale is an orca or a baleen; adopted from e.g., Fujita & Han, 2009). Again, participants more profoundly overestimated their understanding of how the target processes worked in the abstract construal condition, when they were primed to attend to their knowledge of inappropriately abstract information.

Finally, in Experiments 3 and 4, we showed that the effect occurred in a novel domain: self-assessments of how well participants understood their favored 2008 Presidential Primary candidate’s policies. Whereas participants who were induced to adopt an abstract construal style showed a strong IOED, participants who adopted a concrete mindset showed a significantly diminished IOED. Experiments 3 and 4 therefore demonstrated the IOED in a novel domain, suggesting that construal style is a domain-general mechanism that underpins the effect.

We conclude by considering how this construal-based mechanism might illuminate a range of social and judgment-based biases, and how marketers might promote fledgling political candidates and new products most effectively. (*Paper under review*)

“Building Attitude Certainty to Promote Attitude Change”Joshua J. Clarkson, *University of Florida, USA*Zakary L. Tormala, *Stanford University, USA*Derek D. Rucker, *Northwestern University, USA*

Imagine two individuals who hold equally favorable attitudes toward an object. Although these individuals have similar attitudes, they differ in attitude certainty. For example, perhaps because one individual has greater familiarity with the object, he or she feels more certain than the other. Intuitively, it is reasonable to expect that individuals who are certain of their attitudes will be more resistant to change than individuals who are uncertain of their attitudes. Similarly, an aspiring persuader generally would be advised to target the less certain individual, or to strategically undermine the more certain individual's certainty prior to delivering a message. Indeed, the conventional view of attitude certainty is that it is a metacognitive property of attitudes that makes them harder to change (see Tormala and Rucker 2007; Gross et al. 1995).

The current research asks whether this same metacognitive property might sometimes act as a *catalyst* rather than obstacle to change. That is, we posit that under some conditions, being certain of an attitude can actually make people more open to attitude change. We present a new perspective on attitude certainty—the *amplification hypothesis*—which suggests that rather than invariably strengthening attitudes, certainty amplifies the dominant tendency of a particular attitude in a particular situation. If a given attitude tends to be open to change in a given context, for instance, we propose that increasing attitude certainty will promote rather than obstruct this openness. If, however, an attitude tends to be resistant to change in some setting, increasing attitude certainty will increase this resistance, as in past research.

An extensive literature now highlights the conditions under which attitudes tend to be open rather than resistant to change. For example, all else equal, ambivalent attitudes tend to be more open to change than univalent attitudes (e.g., Visser and Mirabile 2004). Even among univalent attitudes, however, openness sometimes prevails. For instance, research on message position effects suggests that attitudes tend to be open to pro-attitudinal messages but resistant to counter-attitudinal messages (e.g., Lord et al. 1979; Petty and Cacioppo 1979). Yet even in the face of counter-attitudinal messages, attitudes are sometimes open. As an example, attitudes often show substantial change in the direction of counter-attitudinal attacks that match their cognitive or affective basis (e.g., Fabrigar and Petty 1999), whereas they tend to resist change toward messages that mismatch their basis. The present research explores whether increased attitude certainty might amplify rather than attenuate many of these classic effects.

In experiment 1, we orthogonally manipulated ambivalence and attitude certainty by presenting participants with evaluatively congruent or incongruent reviews of a new department store from a high or low credibility source. Following this information, we presented a persuasive message about the store and assessed attitude change in response to this message. Results indicated an interaction between congruence (univalence/ambivalence) and source credibility (high/low attitude certainty) on attitude change. When participants had univalent initial attitudes, they showed greater attitude change when the credibility manipulation induced low rather than high attitude certainty. When participants had ambivalent attitudes, however, they showed greater change when the credibility manipulation induced high rather than low certainty. Thus, certainty increased ambivalent attitudes' openness to change.

In experiment 2, we used a similar department store paradigm. In this study, however, we manipulated initial attitudes to be unambiguously positive or negative toward the store, manipulated

attitude certainty using a priming procedure, and finally presented a persuasive message that was either pro- or counter-attitudinal. Results indicated an interaction. Participants who received a counter-attitudinal message changed more toward it when they were induced to have low rather than high certainty. In contrast, participants who received a pro-attitudinal message changed more toward it when they were induced to have high rather than low certainty. Thus, certainty increased univalent attitudes' openness to pro-attitudinal messages.

In experiment 3, we explored the effects of messages that matched or mismatched the basis of the target attitude. All participants were given initial positive affect-based attitudes toward a fictitious animal and were induced to hold this attitude with high or low certainty. Subsequently, participants received a negative message about the animal that was either cognitive or affective in tone. As predicted, we found an interaction between attitude certainty and the affective/cognitive tone of the message. Participants who received the mismatched (cognitive) message evinced greater attitude change under low compared to high certainty, whereas those who received the matched (affective) message showed greater change under high compared to low certainty. Thus, certainty increased affective attitudes' openness to matched (i.e., affective) counter-attitudinal messages.

Discussion. In summary, conventional wisdom and past research suggest that if a persuader seeks to change someone's attitude, he or she would benefit from first decreasing the target's attitude certainty. In contrast, the present research suggests that *increasing* attitude certainty can sometimes promote change. These findings are consistent with the amplification hypothesis, suggesting that under conditions in which attitudes tend to be open to change, increased certainty can augment this openness. Implications for our understanding of metacognitive factors in attitudes and persuasion are discussed. (*Completed manuscript*)

Losing Control When We Least Expect It (and Surprising Ways to Get It Back!)

EXTENDED ABSTRACTS

“Clouds on a Sunny Day: The Downside of Positive Mood for Goal Pursuit”

Jordan Etkin, University of Maryland, USA

Francine Espinoza, ESMT, Germany

Anastasiya Pocheptsova, University of Maryland, USA

A consistent finding in the literature is that positive mood is beneficial for goal pursuit and self-control. For example, happy mood signals a person to adopt an accessible goal and, consequently, one performs better on self-control tasks (Fishbach and Labroo 2007). However, previous research on the beneficial effects of positive mood primarily focuses on the pursuit of a single focal goal. Yet, consumers frequently pursue multiple goals simultaneously: An individual may wish to enjoy nice restaurants, lose ten pounds, spend time with family and exercise regularly. Multiple goal-pursuit often creates a self-control dilemma when pursuing one goal is seen to be in conflict with pursuing another goal (Fishbach and Dhar 2005). In these situations, individuals must exert self-control and distribute their efforts across the pursuit of many goals that are important to them. In this research we explore the role of positive affect in the pursuit of multiple goals.

We propose that in contrast to a beneficial effect of positive mood on the pursuit of a single goal, positive mood will have a detrimental impact on self-control when multiple goals compete for an individual's resources. We predict this happens because positive mood affects how individuals construe the relationships among their goals; by increasing perceived inter-goal conflict. Previous research has found that positive affect results in recognition of more, and more different, aspects or features of items (Isen et al. 1985; Isen, Daubman, and Nowicki 1987). When in positive mood, individuals are open to a larger diversity of information, giving rise to a greater recognition of differences and increasing the complexity and richness of a set (Kahn and Isen 1993). Applying these findings to the context of multiple-goal pursuit, we propose that positive mood will increase perception of the differences between goals and hence result in greater perceived inter-goal conflict. Increased goal conflict leads people to be less likely to engage in goal-consistent behaviors (Emmons and King 1988; Riediger and Freund 2004). Therefore, we propose that being in a positive mood while pursuing multiple goals will lead people to perceive greater differences among their goals, and the resulting increase in perceptions of inter-goal conflict will have detrimental effects for goal pursuit and self-control.

Across several studies, we find support for this proposition. In a pilot study, following a mood manipulation using a sad versus a happy video clip, participants were primed with three goals that had been pretested to be important for this population. We find that participants in a positive mood perceived significantly greater conflict among their goals than participants in a negative mood ($M_{happy}=3.86$ vs. $M_{sad}=2.84$). In study 1, following the same mood manipulation, participants were asked to list the three most important goals they were pursuing. We found that participants in a positive mood were less motivated (willing to devote less energy and work less intensely in pursuing their three most important goals) than participants in a negative mood ($M_{happy}=4.28$ vs. $M_{sad}=4.75$). Further, the effect of mood on self-control was mediated by perceived inter-goal conflict.

Goal conflict can be reduced by choice of multifinal means, which allows consumers to jointly pursue their conflicting multiple

goals (Chun and Kruglanski 2005; Kopetz, Fishbach and Kruglanski 2010). However, in order for a multifinal mean to reduce inter-goal conflict, consumers must be able to recognize that the mean facilitates the attainment of more than one of their goals. If being in a positive mood highlights the differences between goals, we predict that happy consumers should be less likely to perceive any one mean as simultaneously serving the pursuit of more than one goal, thus making the means appear less multifinal (Zhang, Fishbach, and Kruglanski 2007). To test this, in study 2, after completing the mood and goal listing task as in Study 1, participants were asked to list means to achieve their goals and rate the extent to which the listed means served multiple goals. Consistent with our theorizing, participants in a positive mood perceived the means they listed as less multifinal than participants in a negative mood, who perceived their listed means as more likely to help them achieve more than one goal ($M_{happy}=4.80$ vs. $M_{sad}=5.94$). Importantly, mood did not influence the number of means generated.

To further explore the relationship between positive mood and means multifinality, in study 3 we examined whether explicitly providing participants with a multifinal mean would help reduce conflict for participants in a positive mood, thereby attenuating the detrimental effect of positive mood on motivation in multiple goal pursuit. After watching the sad versus happy videos, participants were primed with one or three goals as in the pilot study, and then were presented with an anagram task that was described as either unifinal (helping to achieve the first primed goal) or multifinal (helping to achieve all three primed goals). Motivation to pursue the primed goals was measured via the time participants persisted in the anagram task. We find that in the multiple goals condition participants in a positive (vs. negative) mood persisted less in the task when it was presented as being unifinal ($M_{happy}=146.5$ vs. $M_{sad}=186.9$), but they persisted more than participants in a negative mood when the task was described as multifinal ($M_{happy}=221.4$ vs. $M_{sad}=162.1$), supporting our prediction. Further, we found that participants in a positive (vs. negative) mood spent more time on the task when only one goal was primed, replicating the beneficial effect of positive mood for pursuit of one focal goal demonstrated in previous research ($M_{happy}=197.1$ vs. $M_{sad}=159.6$).

Taken together, our findings support the idea that positive mood leads to greater perceptions of inter-goal conflict, which, in turn, decreases consumers' motivation when pursuing multiple important goals. Though previous research suggests that positive mood improves self-control performance, we find that positive mood may have a detrimental impact on self-control when individuals pursue multiple goals. We also show that the choice of multifinal means attenuates this effect. Our findings contribute to the literatures on mood and self-regulation by expanding our understanding of the interplay between emotions and self-control in the context of multiple goals.

“When Guilt Guides Us to the Lap of Luxury”

Kelly Goldsmith, Northwestern University, USA

Margaret Gorlin, Yale University, USA

Ravi Dhar, Yale University, USA

Consider a consumer who is choosing between two expensive pairs of shoes. Further imagine that prior to choosing a pair, she starts experiencing guilt. How would this consumer's guilt affect her choice? While it is now well established that guilt can serve a self-

regulatory function, increasing self-control and inhibiting preference for more hedonic options (Amodio, Devine and Harmon-Jones 2007; Zemack-Rugar, Bettman and Fitzsimmons 2007) relatively little is known about how the activation of guilt will affect choices among indulgent options. For example, would this person be more or less likely to choose the more expensive pair of shoes in comparison to a person who was not feeling guilty?

This paper explores how a choice between two indulgent or luxury options is impacted when guilt is incidentally activated prior to the choice. Prior work has shown that unrelated emotions (i.e., guilt) may be carried over and affect behavior outside of awareness (Lerner and Keltner 2000; Lerner et al. 2004). We draw from research on guilt and behavioral decision theory to propose that when guilt is primed, consumers will experience an increased need to justify their decision (Dhar and Wertenbroch 2000; Kivetz and Simonson 2002; Okada 2005; Strahilevitz and Myers 1997). Because options providing maximum luxury may be easier to justify when they offer the consumer a special or unique peak experience (Dhar and Simonson 1999; Goldsmith and Dhar 2010; Kapner 2009) we argue that consumers primed with guilt will be *more* likely to choose the option in the set that offers maximum luxury (e.g., a more expensive special treat) than consumers for whom guilt is not activated. Thus we predict a counter-intuitive effect of guilt on choice: priming guilt can *increase* choice of more expensive, luxury options.

We test our predictions in four studies. Study 1 tests for our proposed effect. Using non-conscious guilt priming (sentence scrambles; Goldsmith, Kim and Dhar 2010), we manipulate if guilt is activated prior to a choice between two luxury goods (two entrée courses at a high priced restaurant), one being a more expensive and indulgent than the other (a higher priced entrée special). Supporting our central claim, we observed that priming guilt increased choice of the more expensive option ($P_{\text{guilt}} = 72\%$, $P_{\text{control}} = 53\%$, $p < .05$). Study 2 demonstrates an important boundary condition for this effect. By manipulating both guilt (versus control) and the product category (a choice between two indulgent chocolate bars versus a choice between two utilitarian highlighter sets), we show that guilt increases choice of the option offering maximum luxury only when the product category is associated with indulgence. In line with our predictions, we find choice of the more expensive chocolate bar increases with guilt ($P_{\text{guilt}} = 26\%$, $P_{\text{control}} = 9\%$, $p = .02$); however, guilt has no effect on choice of the more expensive highlighter set ($P_{\text{guilt}} = 6\%$, $P_{\text{control}} = 13\%$, $p = \text{n.s.d.}$; guilt * product category interaction: $p = .04$). These results help to rule out an alternate account for the pattern of results in Study 1 by demonstrating that guilt does not facilitate a mindset that reduces barriers to spending regardless of the product category (Huber, Khan and Dhar 2007), the effect is specific to product categories associated with indulgence, where the justification process is more likely to operate.

Testing for the mechanism behind this effect, Study 3 manipulates the salience of the justification for the more expensive good (e.g., quality ratings are provided and made focal to participants), and assesses how guilt and the salience of this justification affect consumers' interest in maximum luxuries. The results again demonstrate that guilt increases interest in maximum luxuries (dependent measure: a choice between two luxury hotel stays; $P_{\text{guilt}} = 71\%$, $P_{\text{control}} = 42\%$, $p = .02$). Additionally, we observe that when the justification for the maximum luxury is made salient to those in the control condition, there is an analogous effect on choice (choice of the maximum luxury increases significantly; $P_{\text{control}} = 62\%$, $p < .05$). As the effect of guilt and justification salience is non-additive, this suggests that those primed with guilt were already focused on the relevant justification for the maximum luxury, in line with our proposed theoretical account. Finally, Study 4 confirms that

these effects of guilt are counter-intuitive: when asked, consumers overwhelmingly predict that they would be *less* likely to choose the maximum luxury when guilt was activated ($p < .01$).

As the need for justification can affect consumer decisions and shift preference towards options that are supported by the best reasons, this research has clear implications for marketers seeking to maximize their understanding of consumer decision processes at the point of choice. Further, it extends what is currently known about the effect of guilt on consumer behavior, showing that guilt is not always associated with increased self-regulatory function: in the domain of luxury goods when the most salient justification may be maximum indulgence, guilt increases choice of maximum luxuries. We have two ongoing studies that are presently being run to further explore the process underlying this phenomenon. Specially, we seek to demonstrate: (1) that an increased desire to justify one's choice mediates the observed effects and (2) that the same guilt prime can lead to more (less) indulgent choices depending on the nature of the choice set (e.g., a choice between luxuries versus a choice between a luxury option and a utilitarian option). We hope that the current research will prompt future inquiry into this area.

“Distance Makes the Will Grow Weaker: When Distance Hinders Self-Control”

Lawrence Williams, University of Colorado—Boulder, USA
An Tran, University of Colorado—Boulder, USA
John Bargh, Yale University, USA

Within the literature on judgment and choice, psychological distance and abstract thinking are often treated as interchangeable concepts. Construal level theory (CLT; Trope and Liberman 2003) provides a broad and powerful framework for accounting for the effects of temporal, social, and spatial distance on judgments, such that people in a psychologically distant (close) mindset think more abstractly (concretely), focus more on the desirability (feasibility) of action (Liberman and Trope 1998), and have an easier time deciding between options with nonalignable attributes (Malkoc, Zauberman and Ulu 2005). The success of CLT has resulted in an unintended consequence of limited exploration of the effects of psychological distance that are outside of the purview of the theory. The research described herein was designed to address that gap in knowledge.

It has been previously found that when people think abstractly, they become more committed to their self-control goals (Fujita, Trope, Liberman and Levin-Sagi 2006). For example, participants encouraged to think of why they pursue goals (priming high-level, abstract construal) persisted longer on a physical endurance task than participants who were encouraged to think about how they pursue goals (priming low-level, concrete construal). Also, people primed to think abstractly viewed potential temptations (that could interfere with self-control goals) more negatively, compared to people primed to think concretely.

Given the manner in which psychological distance and abstraction are intimately linked in the literature (e.g., Labroo and Patrick 2009), it would be tempting at this point to expect that psychological distance would produce the same effects on self-control as abstraction does, namely that psychological distance would help people accomplish their self-control goals. However, in addition to altering the level at which features of a decision context are construed, psychological distance should also influence the affective intensity of those features. There is an important, often-overlooked association between psychological distance and affective states. People in a distant mindset show reduced emotional intensity in their responses to emotionally evocative stimuli (Williams and Bargh 2008), and people who have emotionally intense experiences feel psychologically closer to those experiences (Van Boven, Kane, McGraw and

Dale forthcoming). In what follows, we experimentally examine the role distance plays in supporting people's capacity for self-control independent of changes in construal level, by examining their judgments of tempting foods (calorie estimates), and their choices.

In Study 1, participants were primed with physical distance or physical closeness by plotting points on a Cartesian plane. Participants in the physical distance condition plotted a set of points that were relatively far from each other on the Cartesian plane, whereas participants in the physical closeness condition plotted points that were relatively close to each other on the plane. This method was chosen to activate psychological distance versus closeness concepts without any contaminating co-activation of social concerns that might separately influence self-regulatory efforts. Furthermore, a separate study demonstrated that due to the absence of a self-referent in the priming task, using this method to activate distance (closeness) concepts does not produce corresponding changes in construal. Next, participants were asked to estimate the number of calories in five relatively unhealthy foods (chocolate bar, cheeseburger) and in five relatively healthy foods (apple, brown rice). We found that participants primed with distance viewed junk food as having fewer calories, compared to participants primed with closeness. In contrast to previous work demonstrating that abstract thinking promotes devaluation of tempting stimuli, these results suggest that psychological distance may attenuate the feeling that tempting foods are dangerous, perhaps making these unhealthy options seem more appropriate for consumption.

In Study 2, we hypothesized that if psychological distance attenuates the emotional features of the self-control decision context, then people in a distant mindset should be more committed to self-control when they are primarily experiencing feelings of pleasure associated with temptation, but should be less committed to self-control when they are primarily experiencing feelings of guilt associated with temptation. In this study, participants were first asked to recall either a time in which they felt particularly guilty when succumbing to temptation, or a time in which they felt particularly pleased when succumbing to temptation (between-subjects). Afterwards, participants were primed with either physical distance or physical closeness (using the same methodology used in Study 1). Finally, as thanks for participating in the study, participants were asked to choose between a chocolate cupcake and a (relatively healthier) granola bar. As predicted, we find that distance (vs. closeness) priming attenuated guilty feelings, undermining self-control and lead participants to choose the unhealthy cupcake more frequently. However, we also find that distance priming attenuated pleasurable feelings as well, thus bolstering self-control and leading participants in this condition to choose the healthier item more frequently.

This pattern of findings is informative for understanding how contextual factors help or hurt people's ability to exercise self-control. Furthermore, these investigations go a long way toward specifying when psychological distance and abstract thinking will produce similar versus dissociated effects on judgment and choice.

“Defeating Depletion: How Self-control Can Increase Self-regulatory Resources

Uzma Khan, Stanford University, USA

Amar Cheema, University of Virginia, USA

Self-control is often viewed as an exhaustible resource. Consistent with this notion, past research on ego-depletion has shown that exerting self-control impairs the ability to control one's self later. Whereas a significant amount of research has examined the sources of ego-depletion, relatively little is known about how self-control resource can be replenished (Baumeister, Schmeichel & Vohs

2007). The current article fills this void by examining when exerting self-control may augment, rather than deplete, the self-regulation resources.

We propose that experiencing a self-regulation task that gets easier over time can replenish self-control resources rather than deplete them and can thus increase self-control on subsequent unrelated tasks. We posit that experienced ease in exerting self-control, such as when the difficulty of a task decreases over time, induces a sense of subjective vitality. Subjective vitality is the feeling of having energy available to the self (Ryan & Frederick 1997). The experience of vitality refers to energy that is perceived to emanate from the self and has an internal perceived locus of causality (Deci & Ryan 1985). Thus to the extent that people perceive themselves as getting better on an effortful self-regulation task—as suggested by decreasing experienced difficulty—it can increase the subjective experience of vitality. Experiencing subjective vitality can then counter the depleting effects of initial self-regulation and can increase, rather than decrease, self-control subsequently (Muraven et al. 2008).

Three studies provide support for our proposition. In Study 1, as a potentially depleting task participants solved 5 anagrams—either in an increasing or in a decreasing order of difficulty. Next, participants proceeded to an *e*-crossing task where they crossed as many *es* in a passage of text as they could. To the extent that facing increasing difficulty requires great amount of self-control, participants who face anagrams in decreasing order of difficulty should be less depleted than those who solve the same anagrams in increasing order of difficulty. Thus, the former should persist longer in the subsequent task. Accordingly, participants who solved the anagrams in decreasing order of difficulty persisted longer on the *e*-crossing task ($M=536$ vs. $M=407$ seconds), $F(1, 39)=4.42, p<.05$).

Study 2 tests whether exerting effort in a decreasing order of difficulty can increase self-control and whether this replenishing effect is greater than allowing people to rest after initial self-regulation. As a choice requiring self-control participants chose between a cookie and a plain yogurt (Khan & Dhar 2007). Prior to choosing between the snacks participants solved anagrams that served to deplete them. Participants were randomly assigned to four conditions. In the first condition participants solved three hard anagrams. In the second condition participants solved the same three hard anagrams and then solved four easy anagrams. In the third condition, after the hard anagrams participants were given a three minute break. Finally, in a control condition participants did not solve any anagrams but proceeded straight to the choice. Results showed that exertion of self-control (reflected by the choice share of yogurt) was significantly lower when participants only solved hard anagrams (32%) as compared to in the control condition (65%; $\chi^2=3.95; p<.05$) suggesting that hard anagrams are indeed depleting. Moreover, the proportion exerting self-control was significantly higher when participants solved easy anagrams after solving the hard ones (86%) as compared to when they only solved the hard anagrams (32%; $\chi^2=12.18, p<.001$). In other words, while people solved fewer anagrams in the former condition they were more depleted as compared to those who solved the same anagrams plus some easy ones. Furthermore, the replenishing effect of a break after solving the hard anagrams was not significant, with 53% of participants exerting self-control in this condition vs. 32% for participants who only solved hard anagrams; $\chi^2=1.68; p=.19$. This rules out an account that easy anagrams serve as a break after the hard ones.

Purpose of Study 3 is threefold. 1) Replicate the effect in a clearly aversive domain. 2) Provide evidence of the subjective vitality based process 3) Test if the effect can be explained by positive affect or self-esteem changes that might ensue as self-regulation

becomes easier over time. Study participants listened to 2 aversive sound clips-either in increasing or decreasing order of difficulty. Next, they completed a survey with measures of SV, mood, and self-esteem. Finally, participants completed an *e*-crossing. Results showed that compared to a control condition (where participants did not listen to any aversive sound), persistence on the *e*-crossing task significantly decreased after participants heard increasingly aversive sounds ($M=492$ vs. $M=375$ seconds; $t(60)=2.68$; $p=.01$). However, persistence on the *e*-crossing task significantly increased after participants heard decreasingly aversive sounds ($M=492$ vs. $M=591$, $t(62)=-1.97$; $p=.05$). These effects were mediated by the level of subjective vitality but neither positive mood nor self-esteem mediated the effect of initial task on subsequent persistence.

The findings contribute to the self-control and depletion literatures by showing how initial effortful self-regulation can increase, rather than deplete, subsequent self-control. Our studies suggest the importance of appreciating temporal patterns of self-regulation and examining *how* self-control is exercised and not just whether it is exerted or not. The results also have implications for the ordering of self-control targets that consumers set for themselves (e.g., weight-loss goals) or of tasks that are set for others (e.g., academic performance and sales targets), suggesting that in some contexts it may be useful to stack harder tasks up front relative to later in the sequence.

Diffusion, Word of Mouth, and Social Epidemics: From Individual Psychology to Collective Outcomes

Jonah Berger, University of Pennsylvania, USA

Andrew Stephen, INSEAD, France

EXTENDED ABSTRACTS

“You Snooze You Loose: Comparing the Roles of High Activity and Connectivity in Information Dissemination over Online Social Networks”

Andrew Stephen, INSEAD, France

Yaniv Dover, Hebrew University, Israel

Jacob Goldenberg, Hebrew University, Israel

A rapidly growing trend among users of social media websites and online networks is to use these platforms not solely for the purposes of connecting with friends, but rather as tools for sharing information and digital content (e.g., links to videos on YouTube or news articles). What determines how widely a piece of information introduced into one of these networks will spread? Although there are a large number of potential drivers, we focus on factors related to the individuals who introduce or “transmit” the content in the first place, and individual psychology that could result in certain transmitter characteristics making information receivers more or less likely to retransmit, or pass on, information shared in online networks. Retransmission is a critical ingredient for information diffusing widely in this context.

Past literature has focused on so-called “hubs” or people in social networks with exceptionally high numbers of connections. E.g., when hubs adopt products diffusion processes tend to speed up. But are there other easily observable and measurable transmitter characteristics that could also play a role? An overlooked transmitter characteristic is simply how frequently they post content in a network. Psychologically, people who transmit more often may be perceived as being able to provide “fresher” content and, as such, their information may be more likely to be retransmitted since it is perceived as being more novel. A similar prediction is not possible for hubs; while they expose many people to information, this does not imply that their audience will be more likely to pass it on. This distinction suggests that, in the context of information sharing in online social networks, a transmitter’s activity should at least play a role in driving information diffusion, perhaps more than their network connectivity.

We compare transmitter activity and connectivity to test this claim in three studies: an experiment, an agent-based simulation, and empirical analysis of a large link-sharing dataset from Twitter. Generally, we find that despite recent findings suggesting that hubs drive diffusion processes, we find that a transmitter’s posting activity is at least as informative, if not more. First, in a laboratory study we tested whether people exposed to information in a Twitter- or Facebook-like online network were more or less likely to retransmit that information depending on the connectivity and activity of the transmitter who exposed them to the information. We found a positive main effect of activity (i.e., transmitters who post more frequently are more likely to have their information retransmitted) but no effect of connectivity (and no interaction). Mediation analysis showed that the activity effect on retransmission was mediated by a perception that the information transmitted by the more active transmitters was “fresher” and “newer.” Second, in an agent-based simulation we built a formal model of information sharing and tested it in large, realistic simulated social networks. We varied where a given piece of information started spreading

(the seed node) and that node’s connectivity and activity. We found that activity, not connectivity, was the critical driver of how widely information diffused. Third, we analyzed data from a random sample of approximately 2,500 Twitter users who we observed over 44 days. These users posted 114,711 tweets in this period, of which 21,430 (18.7%) contained URLs linking to outside-Twitter content. The diffusion of the content pointed to by these links was tracked and we examined how the extent of diffusion was affected by transmitters’ connectivity (number of Twitter followers) and activity (average daily tweet posting rate). Consistent with the previous studies, we again found a strong positive effect of transmitter activity on extent of diffusion, but no effect of connectivity.

Taken together, these studies—employing three very different but complementary methodologies—show that transmitter content-posting activity is an important predictor of information diffusion in online social networks, and likely more important than how well connected these people are in the networks.

“Early Adopters: Opinion Leaders or Opinion Keepers?”

Sarit Moldovan, Technion, Israel

Early adopters are believed to be essential to new product success as they ignite the diffusion process (Rogers, 1995). An important yet unresolved question is whether early adopters are opinion leaders. On the one hand, some studies show that early adopters are socially integrated and connected, show leadership, and are willing to volunteer information about products (e.g., Rogers 1995). On the other hand, the chasm theory claims that there is a break in communication between early adopters and the main market (Goldenberg, Libai, and Muller 2002; Moore 1999). If early adopters are opinion leaders then they should promote new products and accelerate the diffusion process. Why, in that case, is there a chasm?

This research uses a meta-analysis to propose a solution to this contradiction between the chasm theory and the studies that show that early adopters are opinion leaders. It shows that early adopters believe that they are opinion leaders, but although they are indeed communicative, they are not always influential. When the innovation is too radical and perceived as too risky, consumers may be reluctant to adopt it despite early adopters’ w-o-m.

First, a meta-analysis on early adopters was employed to explore the correlation between early adoption and opinion leadership. The results confirmed a correlation between the two traits: $r=.28$ ($p<.01$). However, this correlation ranges between $r=-.39$ and $r=.82$, which indicates that there may be a moderator that affects this relationship.

Next, two meta-analyses on the characteristics of early adopters and opinion leaders were used to compare the similarities and differences between the two groups. Results indicate that there are many similarities between early adopters and opinion leaders. Both groups tend to be more confident, creative, risk-seeking and younger than the rest of the population. In addition, both groups show higher product knowledge, involvement and usage. Interestingly, both groups are also more communicative and influential than other consumers. This, once again, raises the question of why there is a chasm. The meta-analysis also showed some differences between early adopters and opinion leaders, confirming that these are two separate groups.

The next step was to search for possible moderators that can explain when early adopters act as opinion leaders and when they do not. Opinion leaders are reluctant to adopt radical innovations since they fear losing their leadership (Rogers 1995). It is therefore possible that early adopters of radical innovations lose their ability to influence others. These early adopters may think that they are opinion leaders because they spread w-o-m, but others may not be influenced. In that case early adopters will still be communicative but not as influential.

When early adopters are primed with radical innovations, or asked to recall their actual behavior after real product adoption, they may acknowledge that they are not as influential as they believed. We therefore explore whether early adopters' self-reported level of opinion leadership (communicativeness and influence) is moderated by (a) the type of scale that was used to measure early adoption (actual adoption of an innovation vs. a fictitious scenario), and (b) the product that was used as a stimulus in the study (high-risk/low-risk innovation).

The correlation between level of early adoption and level of influence was much higher in studies where early adopters were recognized using a self-reported early adoption scale, compared to studies where early adopters were recognized by stating that they have adopted a specific product ($r_{scale} = .45$; $r_{actual} = .15$, $F = 43.1$, $p < .01$). This suggests that early adopters report themselves as highly influential when they have not adopted the target innovation, but acknowledge that their influence is much lower when they are asked about a specific product that they have adopted. The level of communicativeness was the same regardless of the early adoption scale used in the studies, suggesting that early adopters spread the word but not everyone follows. A similar effect was found when comparing the type of product used as a stimulus in the study. When early adopters were primed with a low-risk innovation they reported being more influential than when primed with a high-risk innovation ($r_{low-risk} = .36$, $r_{high-risk} = .25$; $F = 6.2$, $p < .02$), while the level of their communicativeness remained the same.

The results were replicated in a lab experiment. Participants were primed using anagrams of words related to radical innovations (such as creative, pioneering, and unique) or to fruits. Early adopters reported that they are also opinion leaders when primed with fruit but not with innovation-related words ($r_{fruit} = .57$; $r_{innovations} = .03$, interaction term $b = .34$, $p = .01$).

“Tie Strength and Need for Uniqueness Influences on Positive Word of Mouth”

Amar Cheema, University of Virginia, USA

Andrew M. Kaikati, University of Georgia, USA

An important factor driving word-of-mouth (WOM) information flows is social tie strength, which is represented by frequency of social contact and type of relationship (e.g. close friend, acquaintance). Prior research has identified contextual factors, including referral rewards (Ryu and Feick 2007) and information value (i.e., opportunity cost to an endorser; Frenzen and Nakamoto 1993), that impact positive WOM to weak vs. strong ties.

We aim to build upon this literature on WOM and tie strength. Across three studies, we investigate how an individual characteristic of the potential endorser (need for uniqueness, NFU) influences positive WOM for discretionary products to varying social ties. Consistent with Cheema and Kaikati (2010), we find that high-uniqueness individuals are less likely to generate positive WOM than low-uniqueness individuals. Prior research suggests that the disutility from decreased uniqueness (Snyder 1992) dissuades high-uniqueness individuals from recommending others to buy the product. However, the present research demonstrates that need for

uniqueness attenuates positive WOM *only* to strong ties and not to weak ties.

We propose that because consumers evaluate themselves more against close peers than socially distant individuals, adoption of unique products by close others may threaten their identity (Berger and Heath 2007), decreasing high-uniqueness endorser's motivation to engage in WOM to close others. In contrast, product adoption by acquaintances and strangers is less likely to threaten one's identity, and in this case we expect that uniqueness will not affect WOM.

Consistent with this expectation, we find that among high-uniqueness individuals, positive WOM is more likely across weak ties than across strong ties. We find this moderation in within-subject surveys (study 1), a between-subjects experiment (study 2) and in analyses of real-world reports of WOM activity for two products (study 3).

Study 1 compares the within-subject likelihood of communicating positive WOM across strong (i.e. best friends), intermediate (i.e. classmate), and weak ties (i.e. another student), and measures chronic level of NFU. Participants imagine themselves in a scenario where they acquire a recently-launched cell phone (the Motorola KRZR), and rate their likelihood of telling another person positive things about it (1=not at all likely, 9=very likely). Results confirm a significant NFU x tie strength interaction. Univariate analyses reveal that high- (vs. low-) NFU respondents are less likely to engage in WOM to strong and intermediate ties, but not weak ties.

Study 2 replicates the study 1 effects using a between-subject design and a multi-item WOM measure. Participants imagine they own an Apple iPhone (study was conducted at time of the iPhone launch), and decide what to tell either a strong tie (best friend) or weaker tie (casual acquaintance) about it. The uniqueness x tie strength interaction supports our prediction—higher need for uniqueness significantly decreases positive WOM across strong ties but not across weak ties. Also, among high-uniqueness participants, WOM was greater to weak versus strong ties.

Study 3 examines real-world WOM data from BzzAgent. We compare WOM activity of agents across strong ties (e.g., best friends) and weaker ties (e.g., acquaintances, coworkers) for publicly- and privately-consumed products. The significant pattern of results in studies 1 and 2 is replicated for the public but not the private product, consistent with Cheema and Kaikati (2010).

The observation of increased WOM across weak versus strong ties is in contrast to prior research which finds that as a potential endorser's opportunity costs increase, “information is more likely to flow over strong than weak ties” (Frenzen and Nakamoto 1993, 372). This finding is also ironic, given the “strength of weak ties” in diffusing information (Granovetter 1973). In talking to weaker ties, consumers may contribute to macro-level information dissemination and to making possessions mainstream more quickly than if they restricted WOM only to strong ties.

“What Do People Talk About and Why? How Product Characteristics and Promotional Giveaways Shape Word-of-Mouth”

Jonah Berger, University of Pennsylvania, USA

Eric Schwartz, University of Pennsylvania, USA

Why are certain products talked about more than others? Some movies get a great deal of buzz and some restaurants are the talk of the town, but what characteristics of products lead them to be talked about more? Further, word-of-mouth marketing companies often send consumers free products or gifts to encourage them to talk about the brand. But which types of giveaways actually increase buzz?

We examine psychological drivers of word of mouth, investigating how product characteristics and campaign giveaways shape what

people talk about. While prior WOM research has focused on the impact of “special people” (i.e., influentials) or network structures, we focus on how the items themselves drive collective outcomes. One psychological factor that might influence whether people talk about a product is the amount of interest it evokes. But while it seems intuitive that people would talk more about interesting products than boring ones, this may not actually be true. Self-presentation (people want to see themselves as interesting) and memory biases (interesting topics are easier to remember) may lead people to *think* they talk more about interesting things, even if this is not actually the case. Further, given that interest fades, it is unclear whether more interesting products get more WOM overall (i.e., over time). Finally, to the degree that most conversations resemble idle chatter, what people talk about may be driven by what happens to come to mind than what is the most interesting. This points to the importance of conceptually-related cues in shaping WOM. Products that are cued more by the surrounding environment should be more accessible, leading them to be talked about more.

We investigate our questions in two ways: a model of an observational dataset and a large-scale field experiment. First, we analyze real WOM data from over 200,000 consumers in 330 buzz marketing campaigns (from BzzAgent). The data indicate how many times each person in each campaign talked about that particular product over an approximately ten week period. We examine WOM as a function of product characteristics and promotional giveaways. Groups of independent raters were given a description of each product and asked to rate them on either how interesting they were or how frequently they were cued by the environment. We also recorded the promotional giveaways sent to the agents (i.e., whether they received a free product, sample, coupon, or general gift as well as how many of each of these items). We use a hierarchical level model to control for unobserved individual differences and unobserved differences across product-campaign to test the relationships of interest.

Results indicate that while products that are cued more often were discussed more frequently, more interesting products did not get more WOM overall. Similar measures to interest (e.g., novelty, surprise, originality) yield the same results. Interest did predict WOM intentions in a separate sample, however, suggesting that people may think they will talk about more interesting things even if they do not actually do so. In addition, consistent our perspective, interest is related to WOM right after participants receive the product, but that this relationship fades over time. The relationship between WOM and cues, on the other hand, strengthens over time. Results also indicate which promotional giveaways are linked to WOM.

Second, building on the results of this statistical analysis, we conducted a large field experiment with random assignment across various US cities involving over 1,500 consumers. By directly manipulating the main psychological driver identified in the model (cues), we test its causal impact on word-of-mouth. We manipulated cues by manipulating the messaging different participants received during a BzzAgent campaign for the restaurant chain Boston Market. Half the agents received a message linking the product to a particular cue (dinner), while the other half received a control message. We also measured participants’ prior associations between the brand and the cue to directly test whether cueing is driving any observed effects.

The results underscore the findings of the cross-campaign analysis; increasing the cues for a product, in this case, linking it to a usage situation that some participants did not already associate it with, increased WOM. Among participants who did not already associate Boston Market with dinner, linking the product to that cue led them to talk more about the brand.

Taken together, our findings sheds light on the psychological processes behind word-of-mouth, and provides insight into how companies can design more effective buzz marketing campaigns.

The Dynamic Pursuit of Consumers' Social Identity Goals

Carlos J. Torelli, University of Minnesota, USA

EXTENDED ABSTRACTS

“American=Men? Gender and Cultural Dynamics in the Marketing of Male-Symbolic Brands to Women”

Carlos J. Torelli, University of Minnesota, USA

Chi-yue Chiu, Nanyang Technological University, Singapore

Hean Tat Keh, Peking University, China

Nelson Amaral, University of Minnesota, USA

Marketers are sensitive to gender differences in consumer preferences, as reflected by the development of brands that target a specific gender (e.g., Victoria's Secret for women). Some of these brands resonate strongly within the gender group they set out to target and become symbols of the group (or gender-symbolic brands) (Keller 1993). Yet, increasingly we find brands that try to leverage their equity by broadening their appeal to consumers of the opposite gender (e.g., Jockey women's underwear). Surprisingly, consumer research has little to say about the factors that contribute to a brand's success in bridging the gender divide. If any, recent research suggests unfavorable consumer responses to product-brand mismatch along the gender dimension of brand personality (Grohmann 2009), a finding that seems to recommend against marketing across the gender line.

The present research distinguishes between knowledge of consensual assumptions regarding the cultural symbolism of brands and personal agreement with these assumptions. Specifically, we propose that in the U.S., both men and women have high agreement on which brands can represent the two genders. More intriguingly, we argue that due to some socio-historical biases against women in the U.S., both men and women perceive a widespread consensus in American society that only male-symbolic brands are symbols of American culture. Analogous to previous research on “American=White” (Devos and Banaji 2005), we term this collective perception the “American=men” fallacy. We propose that how people act on and react to the “American=men” fallacy depends on their gender and extent of identification with their gender. Men, regardless of how much they identify with their own gender, would accept this perception as valid, and personally believe that only male-symbolic brands are symbols of American culture. Women, particularly those who identify strongly with their gender, personally disagree with the consensual perception and feel that female-symbolic brands should also be accepted as symbols of American culture.

We further suggest that women may like a male-symbolic brand via its association with the American identity. When this common in-group identity is salient, female consumers would tend to like male-symbolic brands that are symbols of America. However, when female consumers are made to feel “less American,” they would tend to dislike male-symbolic brands that symbolize American culture. Because of the weak cultural associations of female-symbolic brands with the common American identity, cultural identification would have minimal effects on male consumers' liking for female-symbolic brands.

Study 1 tested the collectively perceived “American=men” fallacy. To test this hypothesis, we asked three different samples of participants from the two genders to rate the extent to which a large and varied group of brands (from pretests) symbolize American culture, men, and women (using the cultural symbolism scale, or CS, Torelli, Keh, and Chiu 2010). We found that brands that were rated more highly on male symbolism were also rated more highly

on American culture symbolism (r across all brands = .58, $p < .001$). In contrast, the correlation between American culture symbolism and female symbolism was significantly lower ($z = 3.22$, $p < .005$) and not significantly different from zero, $r = -.13$, $p > .1$.

Study 2 investigated gender differences in consumers' personal agreement with the perceived consensus regarding the cultural symbolism of gender-symbolic brands. Participants from both genders rated three brands (male-symbolic, female-symbolic, or gender-neutral) on the extent to which they symbolized American culture from the perspective of an average American (perceived consensus), as well as from their own personal perspective (after a filler task). They also indicated their gender identification. Results showed that both men and women perceive a consensus in American society that only male-symbolic brands are symbols of American culture. However, men agreed with the consensual view regardless of their level of gender identification. In contrast, women with relatively low identification with their gender personally agreed with the cultural consensus that only male-symbolic brands are symbols of American culture, whereas women with relatively strong identification with their gender (although aware of the cultural consensus) personally felt that female-symbolic brands are also symbols of American culture.

In Study 3, we recruited two samples to investigate female consumers' evaluation of male-symbolic brands as a function of whether the “women=American” identity link is salient. We manipulated the “women=American” link in two ways. First, in sample 1, we increased the salience of a positive American identity to enhance women's identification with the common in-group identity. Next, in sample 2, we directly manipulated the salience of the link by highlighting women's contributions to American society versus the history of gender discrimination in the U.S. We measured brand evaluation and willingness to promote the brand. Results indicated that women evaluated a male-symbolic brand more favorably either when a positive American identity was salient or when women's contributions to America were highlighted. In contrast, they evaluated a male-symbolic brand less favorably when they were reminded of the exclusion of women from the common American identity.

“Brand Preferences During Identity Transitions”

Shirley Y. Y. Cheng, Hong Kong Baptist University, China

Sharon Ng, Nanyang Technological University, Singapore

Iris W. Hung, National University of Singapore, Singapore

Brands are intimately related to self-identity—consumers like brands that match their active self-concepts (Aaker 1999) and use brands to tell others who they are (Escalas and Bettman 2005). Prior research has extensively studied brand preference when consumers have *stable* identities. However, how do *identity transitions* influence brand preference? This question remains largely unexplored despite its theoretical and practical relevance.

In face of an identity transition, consumers anticipate both the end of a current identity and the start of a future identity. Consumers may feel happy finishing an important life stage (e.g., finishing school). At the same time, they may feel upset about starting an uncertain future identity (e.g., starting work) and thus experience mixed emotions. This research seeks to understand brand preference in response to mixed emotions emerging from identity transitions.

We propose that some consumers are more likely than others to use brands for managing identity transitions. Those who consider

their identity in their brand choice (i.e., *enactors*) would have an instrumental view of brand and identity construction. To them, identity-symbolizing brands can help in constructing their identity. So we hypothesize that when they feel mixed emotions about a transition, they would show a tendency to “move on”—their liking for brands that symbolize the expiring identity decreases but liking for brands that symbolize the new identity increases. However, for those who don't tend to consider identity issues when making brand choices (i.e., *non-enactors*), mixed emotions about identity transitions would have negligible effects on brand preferences. We tested this hypothesis and its underlying mechanism with undergraduate students, using graduation as the focal identity transition. In all four studies, we measured how much participants normally consider their student identity when they choose brands (i.e., levels of enactment) and use the rating as a continuous variable in the analyses.

In study 1, undergraduates first wrote an essay about how graduation makes them feel and rated the extent of mixed emotion they feel about graduation. Then, in an ostensibly unrelated study, the participants rated their liking for a student-brand (i.e., a brand that symbolizes student identity). As predicted, enactors' level of mixed emotion about graduation negatively correlated with liking of the student-brand. Whereas for non-enactors, mixed emotion did not correlate with their liking of the student-brand.

Study 2 provided evidence on the causal effects of feeling mixed emotions on enactors' tendency to “move on” in their brand preference. We manipulated participants' feeling toward graduation using a print ad on a photo-taking service for graduating students. The ad either portrayed graduation as a joyful or sentimental event; results confirmed that the sentimental ad elicited higher level of mixed emotion. Then, participants rated their reactions toward the student-brand relative to a work-brand (i.e., a brand that symbolizes work identity). As predicted, the mixed emotion manipulation decreased enactors' purchase intention, liking, and self-brand connection of the student-brand relative to the work-brand. The emotion manipulation did not affect responses of non-enactors.

We argued that enactors and non-enactors differ because enactors often use brand choice for constructing their identities. Thus, when dealing with the transition, enactors would find student-brands (vs. work-brands) less (vs. more) appealing. Inducing enactors to focus on preserving the expiring identity during identity transition (rather than constructing a new identity) should attenuate the effects of mixed emotion on brand preferences. We tested this hypothesis in study 3. Specifically, we manipulated the focus of identity management in two between-subject conditions. In the identity-preserving condition, participants read a description of a social networking platform that could help immigrants connect to people in their home country (“*Find your old friends from your home country! Savoring the old you!*”). In the control condition, participants read that the social networking platform could help immigrants connect to people in the new country (“*Make new friends in your new home! Creating the new you!*”). All participants were asked to imagine being an immigrant when reading the message. Then, in two ostensibly separate studies, participants rated mixed emotions about graduation and responses to the work-brand. Results in the control condition replicated the effects found in previous studies: Enactors who felt higher (vs. lower) level of mixed emotions preferred the work brand more (vs. less). More importantly, results in the identity-preserving condition supported our hypothesis. Priming the participants to focus on preserving an old identity attenuated enactors' tendency to “move on” in their brand preference—feeling mixed emotions did not increase their preference for the work-brand. This finding provides evidence on the proposed mechanism of enactors' “moving on” effect.

Lastly, we conducted a field study to examine whether enactors were indeed more likely to “move on” in their brand preference when they faced the real transition. We surveyed graduating seniors after they completed all their examinations. Results showed that for non-enactors and enactors who had not found a job, the more (vs. less) they miss being a student, the more (vs. less) they like a student-brand. However, for enactors who have already found a job, how much they miss student life no longer predicted liking for the student-brand. We reasoned that having a job at the time of the survey marked the actual transition from student identity to work identity. For enactors, having a job means that they have a new identity to enact, thus they moved on and their brand preferences dissociated from their feelings about student life.

“I am Too Much of a Man to Be Artistic: Signaling Incompetence to Reduce the Threat of Being Associated with a Dissociative Group”

Mohammed El Hazzouri, University of Manitoba, Canada

Sergio W. Carvalho, University of Manitoba, Canada

Kelley Main, University of Manitoba, Canada

It is widely accepted that consumers often make consumption decisions in ways to protect their self-views. Previous research has shown that consumers are reluctant to use products that send negative cues (Banister and Hogg 2004) and avoid selecting products that are associated with dissociative reference groups, especially when the product is more symbolic in nature (White and Dahl 2006). Such actions are presumably driven by a desire to avoid the negative associations of the dissociative referent. However, in many real-life situations, people may not easily stay away from these negative associations. For instance, if a guy is just asked to wrap a gift for a co-worker, would he worry that doing so very neatly might be perceived by others as possessing the ‘artistic’ trait often associated with women? This research argues that, under certain conditions, such situations can be self-threatening and heighten the need to distance the self from undesirable associations, even by making oneself appear as incompetent.

Research on stereotype threat (e.g., Steele, Spencer, and Aronson 2002) suggests that people can feel a threat to the self when they become aware that their poor performance on a task can confirm the negative reputation associated with the groups they belong to. The presence of such threat seems to impair performance by introducing an additional pressure in order to disconfirm the negative stereotype (e.g., Aronson et al. 1999). We turn this relationship upside-down by extending the effects to the stereotype threat from the positive reputation associated with a dissociative reference group. We predict that when people's performance on a task can associate them with a dissociative reference group, they will also feel a threat to the self that leads to poorer performance. However, in this case, performing poorly is not driven by added pressure to *disconfirm* a negative stereotype, but instead by the desire to *confirm* that one does not fit the positive stereotype. Poor performance would signal that one does not possess the characteristic associated with the dissociative referent, and hence help dissociating from it.

Study 1 tested this prediction using a 2 (stereotype threat: present vs. absent) x 2 (gender: male vs. female) between subjects design. Participants were first primed with a positive stereotype of women: they are more artistic than men. In a subsequent, unrelated task, stereotype threat was manipulated by informing half of the participants that a gift-wrapping task they were about to do was designed to test the wrapping materials (stereotype threat absent) or to test their artistic ability (stereotype threat present). As expected, results demonstrated that stereotype threat significantly reduced performance for male but not for female participants. Further, results

revealed a reduction in perceived competence, and performance satisfaction for men and not for women. No gender differences emerged when the stereotype threat was absent.

Study 2 was conducted to rule out the alternative interpretation that men's poorer performance may be driven by self-handicapping strategies (e.g., Steele and Aronson 1995) and not by the heightened dissociative needs argued here. Stone (2002) showed that when Caucasian athletes were threatened by the stereotype that Caucasians are incompetent in sports, they self-handicapped by practicing less before a sports-related task. Study 2 was similar to study 1, but the wrapping exercise was presented as a practice phase in which participants would have up to 8 minutes to practice before performing the main and more complicated gift-wrapping task (which did not occur). Results showed that male participants in the threat present condition took significantly more time to practice than those in the threat absent condition, presumably because doing so would signal their incompetence in terms of gift-wrapping (i.e., lack of artistic abilities). No effect of threat was found among female participants.

Study 3 was designed to more directly assess the notion that a desire to signal a lack of artistic abilities underlies men's poorer performance in the gift-wrapping task. We reasoned that men cued with their 'inartistic' nature should not exhibit these heightened needs, which in turn should mute the effects. We tested this proposition in a field study using a 2 (stereotype threat: present vs. absent) x 2 (inartistic cue: present vs. absent) between subjects design. Male participants were primed with the stereotype that females are more artistic than males, and were then told that gift-wrapping is either indicative or not of artistic ability. Men's inartistic nature was cued by having the experimenter replace a ribbon with an already made bow stating that males are not artistic enough to use a ribbon/no explanation was provided (present vs. absent). Study 1's results were replicated in the inartistic cue absent condition. In contrast, when cueing with men's inartistic nature, the stereotype threat present condition positively impacted participants' performance, perceptions of competence, and performance satisfaction. Interestingly, when inability was signaled, performance, perceived competence, and performance satisfaction reached the same level as when the stereotype threat was absent.

Our findings show that the prospect of being perceived as possessing the traits of a dissociative referent can be self-threatening, which in turn can trigger subsequent behavior aimed at confirming that one does not fit the stereotype of the undesirable group. To the extent that the barriers that separate gender and ethnic-based products become blurred (i.e., cross-marketing), the self-threat effects described here are likely to be more common. Our findings provide a framework to understand how consumers cope with such threats and adjust their behaviors to dissociate from undesirable social identities.

"Substituting Brands with Social Behavior to Satisfy Identity Needs"

Robert Kreuzbauer, Nanyang Technological University, Singapore
Chi-yue Chiu, Nanyang Technological University, Singapore

People use brands to communicate important aspects of self-definition (Escalas and Bettman 2005). For example, a marketing professor might choose to wear for class a suit from a fashion label in order to signal distinctiveness from his students. Similarly, a college student might wear a T-shirt with the college's logo to signal connectedness with her institution. In both examples, brand usage provides the means to satisfy identity needs (e.g., distinctiveness and connectedness respectively). This research departs from prior work that explains how consumers use brands to achieve an optimal connectedness-distinctiveness balance (Berger & Heath 2007) and

demonstrates that the mere act of being handed a brand can satisfy a salient distinctiveness (connectedness) need, and results in a reduced likelihood of expressing this need in a subsequent social task. This shows that consumers flexibly use brands and social behavior to satisfy social identity needs.

According to optimal distinctiveness theory (ODT, Brewer, 1991), individuals desire to attain an optimal balance of connectedness (belongingness) and distinctiveness *within* and *between* social groups and situations. These basic social needs can be flexibly satisfied through alternative means of attainment (e.g., by buying a product or by engaging in social activities, Kruglanski et al. 2002). Distinctiveness and connectedness needs are in constant opposition with each other. In most experimental conditions (cf. Brewer, 2003), situations that tilt self-categorization processes in one identity direction arouse the opposing need until the optimal point is reached again. This research uncovers an alternative mechanism for achieving optimal distinctiveness. We show that the balance between these two needs can also be achieved by satisfying the need for distinctiveness (or connectedness) through a brief encounter with a branded product, which consequently brings both needs back to an optimal level. We further show the flexible manner by which consumers can satisfy distinctiveness (or connectedness) needs. The mere act of being handed a low-involvement product (e.g., a branded tea-bag) associated with distinctiveness (connectedness) made people less interested to work alone (in a group). In other words, consumers can interchangeably use consumption and other social behaviors in order to restore the balance between distinctiveness and connectedness. Four experimental studies demonstrate the hypothesized effects.

The first two studies were set up to test these basic predictions. In study 1, participants were shown an advertisement about a tea-bag brand. The advertisement conveyed the notion that using the tea-bag brand would make a person feel distinctive. After seeing the advertisement, half of the participants were handed the same tea-bag shown in the advertisement (distinctiveness condition), whereas the other half were handed a different tea bag (control condition). We reasoned that receiving the "distinctive" tea-bag would help participants in the 'distinctiveness' condition to satisfy their need for distinctiveness more than those in the control condition. To assess this, after receiving the tea-bag, participants were presented with an ostensibly unrelated writing task in which they rated their willingness to work alone or in groups. Results showed that participants in the 'distinctiveness' condition were less willing to work alone than participants in the control condition were. Study 2 replicated the findings for a tea-bag brand associated with connectedness (instead of distinctiveness). In this case, participants who satisfied their need for connectedness when handed the tea-bag brand were less inclined to work in groups in the subsequent writing task.

The last 2 studies were designed to rule out an alternative interpretation of the findings based on possible 'disappointment' on the part of control participants handed a different (or 'wrong' bag), and to prime the target social need in a more controlled manner. Study 3 followed a procedure similar to that used in study 1. However, we first primed all participants with distinctiveness by presenting them with a set of related words and images. We also added two conditions in which participants read a neutral advertisement about the tea-bag brand. The design was then a 2 distinctiveness of tea-bag message (distinctiveness or neutral) X 2 tea-bag received (same in the ad or different). As expected, only participants handed the 'distinctive' (and same) tea-bag showed a decreased willingness to work alone compared to their counterparts handed a different bag, and also compared to those in the two 'neutral message' conditions

that were handed the same or a different tea-bag. Study 4 replicated the findings with the same design, but using this time a tea-bag associated with connectedness. That is, participants who received the “connected” tea-bag brand were less willing to work in a group than participants in the other three conditions. Results from these two studies persisted after controlling for gender, mood and individual differences in the need for distinctiveness and belongingness.

In summary, our findings suggest that consumers' pursuit of identity goals is a dynamic process continuously shaped by their interactions with products. We show that people's interaction with a low-involvement product, such as a tea-bag, can trigger social identity needs that affect their subsequent social behaviors.

EXTENDED ABSTRACT

“Interiority in Consumer Culture”

Jeppe Trolle Linnet, University of Southern Denmark, Denmark

This presentation considers an issue that lies close to sense of place (Sherry 2000), but has a more abstract dimension that manifests itself across physical spaces, social circles and symbolic structures: the relation between inside and outside, or interiority and exteriority.

Interiority is strongly exemplified by the experience of homeyness (McCracken 1989). It will be illustrated here by the Danish concept of *hygge*, on which I have done ethnographic research among families in Copenhagen. *Hygge* is a form of atmosphere (Pennartz 1999), which to most Danes denotes the essence of having a pleasurable, good time with other people in an informal spirit (Hansen 1980). In ways that resemble the anti-market normativity around home and family life, the families I have researched appreciate the experience of ‘warm’ sociality in contrast to the ‘harder’ and ‘colder’ interaction forms that characterize their professional life, the market economy, and public urban life. Yet this atmosphere is not limited to home or family life. The feeling of being in a well known, secluded space or even shelter, where intrusion from the outside world is experienced as a disturbance, also arises in commercial settings (Lugosi 2009) such as retailers and cafés. These ‘3rd places’ are experienced as homey and authentic, often through the presence of close social ties among neighborhood, guests and staff.

Considering this phenomenon on a higher level of abstraction, symbolic and/or virtual structures without any material enclosure or social company to envelop the consumer can deliver this experience too. This is where the concept of interiority is worth exploring, as it concerns the experience of “inner space” as a form of identification and placement rather than a relation to spatial form (McCarthy 2005). Interiority is constructed through repetition, e.g. acts of routine behavior, cyclical changes in the environment, or the way humans create a sense of differentiation through symbolic or material structures. Branding is mentioned by McCarthy as one such practice, which through the repetition of stories, designs and other symbolic elements creates a sense of something well known, a bounded space that consumers step into through everyday acts of consumption. Technologies also interact with the human faculties of memory and imagination to create new forms of interiority, e.g. when the mobile phone “transport(s) its user to the memory of an interior” (McCarthy 2005: 122), effecting the form of public, semi-private behavior that has become a ubiquitous phenomenon in much of the world. If seen as a case of interiority, this might be a form of coziness on the go.

The concept of interiority is worth exploring because it suggests an analytical level where certain phenomena that otherwise seem separate become comparable. This might create a more holistic understanding of consumer culture. What can be learned about symbolic domains such as brands by thinking about their similarities to physical homes or a circle of friends, and vice versa? New product categories and brands offer forms of symbolic, material and social enclosure that are qualitatively new forms of community.

In terms of charting the historical development of consumer culture, interiority can alert us to the emergence and disappearance of spaces such as the gendered social spaces where either men or

women would encounter only their own gender in equality-oriented Scandinavia (Frykman and Löfgren 1987). The concept of interiority can inspire one to consider whether the emergence of one form of space (or interior) is related to the disappearance of another.

In terms of consumers’ desire to try something new, e.g. to become part of a brand community, the concept of interiority is one way of considering the beckoning force of mystery that many closed structures possess, the seductive “desire to enter (as distinct from the actuality of entering) a ‘space one might occupy’”. Can a brand be managed on the basis of recognizing that humans are drawn to inner spaces, but also that they can only feel themselves located in an interior by speculating or fantasizing about the outer world? When seen through the lens of interiority, a boundary is a two-way membrane for the imagining of the exterior from the interior, and vice-versa—and thus for the presence of each in the other.

“Networked Styles and Normalizing Taste Narratives”

Zeynep Arsel, Concordia University, Canada

Jonathan Bean, University of California-Berkeley, USA

Taste, the ability to identify and choose the legitimate, has been a fundamental modus of establishing and signifying social class distinctions (Bourdieu 1984). Yet, contemporary social theorists suggest that tastemaking no longer serves to maintain a social hierarchy that differentiates highbrow from lowbrow. Rather, tastes are fragmented (Featherstone 1991) subculturally bounded (Thornton 1996), or established through contextualized negotiation of meanings (Holt 1997). As a result, the power of traditional highbrow authorities has diminished (Johnston and Baumann 2007). Furthermore, individuals with higher cultural capital resources tend to break conventions and normative combinations of conventional styles and utilize a pastiche of high and low (Holt 1998). Within the concept of place, how do the material manifestations of taste such as styles referred to as “modern” or “traditional” as well as their sub-genres and hybrids (i.e. “shabby chic”) emerge and become crystallized?

Our research demonstrates a process through which styles are normatively constructed through social networks. We argue that consumers are not nomadic postmodern mix-and-match artists who layer and imitate styles, but rather that they contribute to and help create coherent taste narratives that circulate in popular culture and serve as a distributed form of cultural authority. These narratives help consumers establish a sense of place by serving as a normative model for the right way of ordering objects in space, legitimizing preferences for particular arrangements and types, and, most significantly, by inviting, even requiring, consumers to create visual and textual representations of place in order to perpetuate the taste narrative.

Our empirical site, the popular home design blog Apartment Therapy [AT], started in 2004 and quickly grew to establish itself first as a web phenomenon and then as a serious competitor to now-defunct magazines such as Martha Stewart’s *Blueprint* and Condé Nast’s *Domino* (Green 2004). The effect of AT is like that of shelter or lifestyle magazines: it establishes a regime of visual and material order (Hand and Shove 2004). But unlike magazines, readers of the website participate in the creation of a taste narrative that prescribes a distinct way of creating place through organizing material objects and configuring practices within the home.

To show how consumers use the taste narrative for creating a sense of place in the home, we utilize longitudinal multi-method analysis. First, we analyze the blog content with special emphasis on normative discussions, advice seeking and contests. Second, we also include the spinoff book *Apartment Therapy: The Eight-Step Home Cure* (Gillingham-Ryan 2006) in this narrative analysis. We use the book to engage in an auto-ethnographic process of following the “cure” and transforming our homes. Third, we conduct interviews with participant-creators of the blog and individuals whose homes are featured in exemplary tours and competitions. We also incorporate participant observation in the production of the blog¹.

Our first finding highlights how tastemaking works in an increasingly fluid social hierarchy transformed by the adoption of new social technologies. We demonstrate that the participatory nature of new media enables a dialogical and collective process of tastemaking that sharply contrasts with the traditional models of cultural authority. While magazines have long used write-in features or visits to “actual homes” to relate ideas to readers (Keeble 2007), their core content is under direct editorial control and relies on the editors’ position of authority. In contrast, the content of many of AT’s popular post types —contests, “good questions,” and house tours— comes from what would typically be thought of as the audience. We argue that these normative dialogues crystallize the boundaries of styles and instill a sense of normalcy in the participants while appearing ostensibly democratic. Our findings also show how the agency of cultural authority shifts between the collective and individual. Apartment Therapy engages with a corporate identity of “we,” creating a master narrative which functions as a principle actor itself, again blurring the line between author and audience. Readers of the blog become a part of this “we” identity, commenting on posts, sending questions and content, and adapting similar narrative strategies to those employed by the “official” (i.e., paid) contributors. This “we” identity shifts the agency and authority to determine what is legitimate to the taste narrative instead of a specific individual or group. In this process we highlight the normative and exclusionary action of creating the AT archive (Derrida 1996). We argue that this taste narrative takes on jussive force (Bowker 2008).

With our presentation, we aim to highlight the changing dynamics of taste making in an increasingly participatory culture and show how homes are made through a collaborative process. Our contributions are twofold. First, we illustrate a relatively new mode of taste formation through participatory media. Second, we show how closely bound the relationship between individual action and collective meaning can be, recapitulating the classic debate on structure and agency.

“Materializing and Valorizing Cultural Capital: An Investigation of the “Cafe-scape” of a Gentrifying Neighbourhood”

Yesim Ozalp, York University, Canada

Cultural Capital of the artists is rubbed off the walls of neighborhood and is appropriated by the middle classes who are eager to accumulate both cultural and also economical capital. (Ley 2009)

Gentrification, investigated as a residential phenomenon for almost four decades, can also provide a social “lab” to study the “distinction” game played by retailers (Zukin and Kosta 2004). By investigating this distinction game, this study provides not only a context to provide a more dynamic account of cultural capital, one that goes beyond categorizing consumers into two levels (Low

Cultural Capital and High Cultural Capital, e.g. Holt 1998; Henry 2005); but also a more comprehensive method of accounting for consumption spaces that goes beyond narrative- or semiotics-based accounts of studying consumption spaces (cf. Sherry Jr. 1998).

Cultural capital, coupled with other forms of capital, is central to the position a subject occupies in a society (Bourdieu [1979] 1984). Its role in consciously or unconsciously shaping consumer preferences and processes has been investigated in Consumer Culture Theory (Holt 1998; Henry 2005). These studies, however, treat cultural capital as a “characteristic” or “trait” held by an individual. Even though this approach towards cultural capital clearly reproduces Bourdieu’s lengthy analysis in *Distinction*, partially; it ignores the reconversion strategies mentioned in the same work. Bourdieu ([1979] 1984: 131-132) identifies two reconversion strategies in social space: vertical (movements within the same field) and transverse (a shift to another field). While vertical movements do not alter the composition of the assets (different capitals), transverse movements, such as those from the field of economic capital to the field of cultural capital, involve a transformation in the composition of assets. Although Bourdieu was more interested in the role of education and educational capital as well as structural transformations, the concept of transverse movements is critical in understanding consumption as a process of reconversion. In the microcosm of retail gentrification, retailers, through their use of space, provide knowledge of “authentic” tastes, “cool” places and “trendy” places to be, in exchange for the economic capital of their patrons. In constructing these ideals of authentic, cool, hip or trendy, retailers not only use their own sources of cultural capital (as identified by Bourdieu himself in the transformation of retail sector, [1978] 1984: 141) but also resources from the neighborhood’s identity (Zukin and Kosta 2004). Naturally, this cycle of conversion also aims to produce more economic capital for the retailers themselves. Retail spaces mediate the transverse reconversion process between economic and cultural capital, providing a rich context that demonstrates how cultural capital is materialized and valorized.

In order to investigate how the transverse transformation is played out in the retail distinction game, it is essential to reframe the understanding of the concept of space in the CCT field. According to Lefebvre (1974/1991), social space is represented by a triad composed of the enactment of visions of planners and the businesses, the appropriation and representation of users, and the spatial practices through which the prior two are negotiated. In much CCT work, it is the social as well as the symbolic facets of consumption spaces that have attracted scholars’ attention, and these concerns are frequently addressed separately (cf. Sherry Jr. 1998; Kozinets et al. 2004). These studies prioritize the agency and stories of consumers over those of producers and retailers, and specifically of a subset of consumers over the “mainstream” consumer. Nor has much attention been given to material objects and the space itself. However, as Lefebvre argues, space can be reduced neither to the symbolic and material work of any of the actors, nor to discourses or to institutions. Similarly, from an Actor-Network Theory perspective, space is constructed within a network of relationships between actants (Latour 2005). The social — e.g. interactions among residents of a neighbourhood — cannot create or define space — e.g. the neighbourhood — unless it is stabilized and woven with material such as houses, the retailscape, urban furniture, etc. (Murdoch 1998). Therefore, the complexity of how consumption spaces are constituted, embodied, enacted and represented can only be understood by looking beyond a group of consumers’ representations or acts, to the space, the objects, the producers’ symbolic strategies, and to other groups’ representations and strategies.

¹From 2007-2008, one of the authors of this paper (Bean) was a paid contributor to *Re-nest*, a website focused on green design which is affiliated with *Apartment Therapy*.

Employing ethnographic research techniques supported by visual and textual archival material, I investigated the “cafe-scape” of a gentrifying neighbourhood in Toronto. Looking at the aesthetics of space, objects, arrangements of objects, spoken and unspoken strategies and also consumers’ interpretations, I will provide the details of four distinctive types of spaces, which I label *hybrid*, *retro*, *simple*, and *traditional*. For example, while the hybrid cafe-scape houses spatial practices of other retailers (e.g., displays with an appearance akin to those of jewelry stores), the *retro* cafe-scape stages objects which appeal to and to contribute to “bohemian” taste, characterizing the neighbourhood according to the promotional materials of condo developers. While some products (such as desserts) are sold as designed objects (artistic creations of a chef), other products enjoy being the object of a taste quest for “simple, not fancy”, such as the case in the *simple* cafe-scape. Customers also play an important role in embodying the taste narratives of these consumption spaces. While knowing how to order a personalized coffee in a Starbucks may be valuable cultural capital for some, in many of the other cafes such capital is made inaccessible by restrictively limiting the menu to “pre-chosen” or “curated” ingredients, such as the case in *simple* or *traditional* cafe-scapes. While unpacking the network of relationships that construct these spaces, I will also show how these spaces utilize, produce, embody and categorize different sources of capital (e.g., cosmopolitan vs. local) and embody different movements of transverse reconversion (e.g., economic>cultural>economic vs. economic>cultural + social>economic).

“Shangri-La, a Journey From an Imaginary Place to a Non-place”

Rosa Llamas, University of León, Spain

Russell Belk, York University, Canada

James Hilton’s (1933) *Lost Horizon* is set in Shangri-La, a fictional paradise on Earth somewhere in the Himalayas. The myth of Shangri-La, a multi-ethnic community living a perfect life in an unblemished and wondrous natural enclave, enjoying harmony, longevity and supernatural powers, grew with the *Lost Horizon* screen version by Frank Capra (1937). Since then this imaginary paradise has been the object of Westerners’ desires, sparking countless expeditions in the hope of finding it. Such a demand for utopian enclaves has yielded a number of pseudo-Shangri-Las blooming in the Himalayas. These Shangri-Las suffer from placelessness, the “casual eradication of distinctive places and the making of standardized landscapes that results from an insensitivity to the significance of place” (Relph 1976, ii) and are fostered by McDonaldized forms of tourism (Ritzer, 1998). In a bid to gain differentiation from this serial production of synthetic Shangri-Las, the PRC State Council announced a contest to assign Shangri-La’s brand name to the “real” one. So, after decades of being a fantasy imaginaryscape, Shangri-La finally got some coordinates on Google Earth, which coincide with Zhongdian, a humble town in Diqing Tibetan Autonomous Prefecture, Yunnan Province (China).

The Shangri-La appellation allowed the town to ascend the status ladder, leaving behind its “life” as a modest village to become a paradisaical tourist destination with world renown. Appearance was a key aspect in this transformation. The exotic, ethnic and sacred traits of Shangri-La (Kolås, 2004) were re-created in order to build a place to be consumed. These features combine material, spiritual and social place-making, an interwoven set of aspects that according to Sherry (2000) should be a focus of consumer researchers. Drawing on our observations and interviews with insiders (local and non-local players), we explore how paradise builders have

enhanced or created these material, spiritual and social aspects in the making of Shangri-La as a placeless paradise.

The material issues in the still-under-construction Shangri-La include an international airport, museums, a temple with the biggest prayer wheel in the world, a renovated monastery, a reconstructed Old Town, and paved roads leading to natural attractions which are integral to marketing this tourist paradise. Fancy shops (offering a wide range of souvenirs ranging from fake yak skulls to local and imported crafts), restaurants (with hybridized menus offering yak burgers, Tibetan momos and pizza), soulless mega-hotels (like the Hotel Paradise), homestays at villagers’ places, stupas and some stylized “local” constructions in the Old Town merge together in a superficially seductive appeal to exotic otherness. This combination, resembling a theme park or a “museumized” place, has led to one journalist to describe Shangri-La as a “Tibetan toy town” (MacGregor, 2002: quoted in Kolås, 2008).

During the Chinese Cultural Revolution (1966-1976) the Government erased every religious sign, but nowadays efforts are addressed to restoring and promoting Buddhist symbols whether in sacred or profane buildings. Buddhist iconography is present in the airport décor (Tibetan thangkhas, bass prayer wheels and stupas) as well as in the mega-hotels (Tibetan Wheels of Life, thangkhas and mandalas). Indeed, the main investments in Shangri-La are the new temple and the renovated Monastery, cardinal touristic attractions and integral to the town’s Buddhist aestheticization. Captivated by the exotic allure of these photogenic symbols, tourists take pictures and spin the prayer wheels. Whether their function is sacred or aesthetic, Buddhist signs are a key contribution to the Disneyfication of Shangri-La.

The Shangri-La brand name has changed the ethnic distribution of the place. Indigenous people in their traditional clothing mix with laid-back Caucasians who have settled down in Shangri-La looking for a hip atmosphere, ambitious Han Chinese who have increased their numbers in town, and busloads of tourists armed with cameras. Tibetans are the main ethnic group but the region is very rich in terms of ethnic diversity. In this vein, the quaint ethnic villagers are part of the exotic rapture of Shangri-La, offering a more plural and colorful experience to suit Western Orientalist demands (Yan and Santos, 2009) by amusing the tourists and emphasizing fabled harmony.

Ancient craft techniques, shepherding and mushroom harvesting coexist with Internet cafes, shopping centers and tour groups. Old Buddhist rituals such as circumambulation of temples while whispering holy mantras mesh up with modern ones like following the touristic guide umbrella and dancing to recorded folk music in the town square each evening — a metaphor of harmony and solidarity. According to Relph (1976:141) “place is a fusion of human and natural order and any significant spatial center of a person or group’s lived experience.” Experiencing Shangri-La as an insider or outsider shapes different identities and meanings for different individuals and groups (Relph, 1976). We find a plurality of Shangri-Las: it is still Zhongdian for the natives, the “Lost Horizon” for Western travelers, “El Dorado” for Han Chinese businessmen, “just another touristic spot” for Chinese tourists and “Shangri-La” for Westerners living there.

Material, social and spiritual aspects guide Shangri-La’s journey from a fictional place in the collective imagination to a placeless paradise in Yunnan Province. One of the manifestations of placelessness embodied by Shangri-La is “other-directedness”, i.e., “places made up of a surrealistic combination of history, myth, reality and fantasy that have little relationship with a particular geographical setting” (Relph, 1976: 95). Shangri-La also suffers from “lack of human scale” or “gigantism” since it hosts the biggest prayer wheel

in the world ("Fortunate Victory Prayer Wheel"), the largest white terrace in China (Baishui Terrace), the largest Tibetan monastery in Yunnan (Ganden Sumtseing Monastery) and the deepest gorge in the world (Tiger Leaping Gorge). Uniformity and standardization are also being adopted in Shangri-La with the construction of new roads, concrete squares and shopping centers and the cable cars and escalators that will likely dominate the future of the once pristine Paradise Lost.

Consumers Behaving Badly

Maferima Touré-Tillery, University of Chicago, USA

Ayelet Fishbach, University of Chicago, USA

EXTENDED ABSTRACTS

“Recycling—A License to Waste?”

Chen-Bo Zhong, University of Toronto, Canada

Nina Mazar, University of Toronto, Canada

Brendan Strejcek, (Unaffiliated)

In the past few decades, conservation and environment protection have taken increasing significance in shaping public policy, corporate and marketing strategy, and individual consumer behavior. With more consumers expressing their environmental concerns through product choice (Laroche, Bergeron, & Barbaro-Forleo, 2001), companies are incentivized to integrate environmental and social issues into the production, packaging, and marketing of their products.

Of special interest is the recycling sector that involves manufacturing and marketing products using reusable content such as fiber, glass, and metal, preserving limited raw materials and reducing landfill wastes. The recycling industry has witnessed an impressive growth and has become a significant force of the economy: utilizing data from 1997 to 1999, the *U.S. Recycling Economic Information Study* reported that the recycling and reuse industry consists of approximately 56,000 establishments that employ over 1.1 million people, generate an annual payroll of nearly \$37 billion, and gross over \$236 billion in annual revenues. More and more products are advertised and marketed with the universal recycling symbol, highlighting their ecological friendliness.

In this paper, however, we propose a counterintuitive prediction that recycling products may actually *increase* the net use of raw materials. We argue that consumers feel licensed to use more of a product when they know that the product is made, in part or totally, of recycled materials. In addition, consumers do not typically engage in rational calculations on the percentage of recycled material to set limits on how much more of the recycled product they could consume compared to a comparable conventional product that will not result in a net increase of the use of raw materials. For example, if a brand of paper is made of 50% recycled material and 50% raw material, consuming 2 sheets of the recycled paper will result in the same amount of raw materials used as consuming 1 sheet of paper that is made of conventional (i.e. raw) material. If knowing that the paper is made of recycled materials licensed people to consume 3 sheets when they could have just used 1, this will result in a 50% increase of the use of raw materials. This is consistent with research in other domains showing that sampling healthy food (as opposed to tasty food) makes people hungrier afterwards and actually consumes more food later (Finkelstein & Fishbach, in press). We test this prediction in a controlled experiment.

Eighty-four undergraduate students were randomly assigned to one of three conditions: recycled paper vs. conventional paper with packaging vs. conventional paper without packaging. Participants were told that they were going to engage in an origami contest. They saw step-by-step instructions of a somewhat complex origami on the computer screen and were told that their goal was to successfully complete the origami as quickly as possible. Participants had 5 minutes to practice before the actual contest. They were told to grab as many sheets of paper from a nearby desk as they want for the practice. In the recycling paper condition, the stack of paper was wrapped in a paper package with the universal recycling symbol as

well as a label indicating that the paper is made of 30% recycled content; in the conventional paper with packaging condition, the stack of paper was wrapped in a paper package without the symbol and any mentioning of recycled material; finally, in the conventional paper without packaging, the stack of paper was not wrapped in any packaging. In actuality, the same paper (conventional) was used in all 3 conditions. The sheets of papers used by participants in the practice session were recorded and used as dependent variable.

The result supported our prediction; participants in the recycled paper condition used about 22% more raw materials than those in the control conditions. This finding highlights the importance of a fuller understanding of consumer psychology in purchasing and consuming products made of recycled materials. Although people may prefer to buy recycled products, they may feel licensed to use more than needed, resulting in more waste than if they buy and consume conventional products.

“When Psychological Closeness Creates Distance from One’s Moral Compass”

Francesca Gino, University of North Carolina at Chapel Hill,

USA

Adam D. Galinsky, Northwestern University, USA

Does feeling psychologically close to another person who acts unethically make one behave more or less dishonestly? Suppose you find out that a peer who shares your birth date is inflating her expense report or cheating on her taxes. How would you react to these dishonest behaviors? You might suppose that you would view them critically, judge the behaviors as harshly as an objective observer, and distance yourself from the individual with tainted morality. In this paper, we make the opposite prediction: We propose that if a person is psychologically connected to someone who engages in selfish or dishonest behavior, she may become vicariously motivated to justify that person’s actions and thus more likely to behave unethically herself. We propose that even the subtlest of psychological connections, such as sharing the same birthday, can influence the likelihood that an individual will cross ethical boundaries.

Research has shown that people feel connected to others not only when they share a common group membership, but also when they share much subtler similarities. For example, people experience a sense of psychological closeness to another person when they share common attributes, such as a similar name or the same birthday.

As people grow closer, even when this closeness is just psychological, the line between self and other becomes blurred, leading to increased self–other overlap. This clouding of self and other is very common in close relationships and friendships, and can result from people’s cognitive orientation or mindsets. For instance, people who construe the self as interdependent define themselves in terms of their groups’ attributes (Brewer & Gardner, 1996). Similarly, individuals who dispositionally tend to take the perspective of others, or who are asked to do so, psychologically take on the characteristics of others (Galinsky, Ku, & Wang, 2008).

Even when subtle, these psychological connections create numerous vicarious possibilities. When people feel connected to others, they notice and experience others’ emotions (Hatfield et al., 1994), including joy, embarrassment, and pain. More recently, Gunia, Sivanathan, and Galinsky (2009) found that a psychological connection between two decision makers leads the second decision maker

to escalate commitment by investing further in a failing program orchestrated by the initial decision maker, even in the face of direct financial costs to the second decision maker. These findings suggest that psychological closeness blurs self-others boundaries, and thus can lead individuals to experience and behave more consistently with others' internal states.

In this paper, we examine the effects of feelings of psychological closeness on one's own ethical behavior. We suggest that a psychological connection to another individual who engages in selfish or dishonest behavior, however subtle, creates distance from one's own moral compass. We argue that, because of the psychological connection, one becomes vicariously motivated to justify the other person's selfish or unethical actions and to judge these actions as less morally problematic. We predict this should lead individuals who have formed a psychological connection with a wrongdoer to behave selfishly themselves—for example, by keeping more money for themselves when asked to share a fixed amount with others—or even dishonestly.

We observed a consistent pattern of results across five studies in which we measured people's intentions to behave selfishly or dishonestly, as well as their real behavior. Our results show that taking the perspective of a psychologically close person who behaved selfishly led people to report being more likely to behave selfishly themselves (Experiments 1 and 4), and that feelings of embarrassments mediated this effect (Experiment 4). Psychological closeness also led to higher levels of dishonesty in Experiment 2, in which we considered real, unethical behavior. We found that when participants shared attributes with a confederate who cheated, they were more likely to behave dishonestly by inflating their task performance and thus earned undeserved money. The same findings were replicated in a follow-up study in which we manipulated psychological closeness by activating an interdependent mindset through priming (Experiment 3). The results of Experiment 3 also show that people with an interdependent mindset view the selfish behavior of others as less unethical or wrong. Taken together, these studies provide convincing evidence that even subtle forms of psychological closeness lead individuals to vicariously justify the actions of the person they feel connected to and thus to be more likely to behave less ethically themselves.

Experiment 5 introduces the presence of out-group observers as an important moderator of the impact of psychological closeness. The results show that individuals respond differently to the selfish actions of a person to whom they feel psychologically close, depending on whether out-group observers are present or absent. When only in-group observers are present, feeling psychologically close to the wrongdoer increases one's own likelihood of acting selfishly. But when out-group observers are present, the opposite pattern occurs.

“Taking Advantage of Future Forgiveness?—Licensing vs. Consistency Effects in the Context of Ethical Decision Making”

Shahar Ayal, Duke University, USA

Francesca Gino, University of North Carolina, USA

Nina Mazar, University of Toronto, USA

Dan Ariely, Duke University, USA

To many, the concept of confession is inextricably tied to the notion of forgiveness, which has recently become a topic of study for psychologists. This increased interest stems from the recognition that forgiveness represents an important response to a fundamental human challenge: how to maintain relations with others after harming them or being harmed by them (Fincham, Jackson, & Beach, 2005). Similarly, confession allows individuals to restore their

relationship with God in the case of the Catholic Church and open a new leaf in their moral account.

While prior work provides useful insights into the determinants and consequences of forgiving, it remains silent on the influence that expectations of forgiveness might have on individual behavior before and after making a confession. In this paper, we focus on a specific type of behavior: dishonesty, and test whether and how expected and received forgiveness through confession influences the likelihood to engage in dishonest behavior. Furthermore, we compare people's predictions to their real behaviors and explore the accuracy of their intuitions.

Prior research suggests that moral behaviors are figured into an implicit calculation of self-perception such that ethical behaviors boost one's moral self-image and transgressions dampen it (Jordan, Mullen, & Murnighan, 2009). Given that people typically care about morality and want to maintain a positive self-image but behaving morally often comes at a cost, people tend to be strongly motivated to engage in ethical behaviors if their moral self is threatened by a recent transgression; they are least likely to scrutinize the moral implications of their behaviors and to regulate their behaviors right after they experienced a boost from a good deed. For example, Carlsmith and Gross (1969) found individuals more likely to comply to help-requests after they violated moral rules.

Along similar lines, as individuals face ethical dilemmas, they can fall prey to the temptation to behave dishonestly, perhaps especially when they know their behavior will be forgiven and their moral violations “erased.” That is, an expected future confession with its element of forgiveness might act as a moral offset that individuals can put into their current mental moral tap, and thus allows them to transgress even before the confession takes place without hurting their moral self-concept. This implies that an expected future forgiveness can license preceding unethical behaviors. Furthermore, dishonest behavior might be higher before than after an expected confession.

On the other hand, research on the consistency effect has found that drawing consumers' attention to moral standards could reduce dishonest behavior. For example, in studies conducted by Mazar, Amir & Ariely (2008) signing an honor code or recalling the Ten Commandments increased the saliency of one's own standards for honesty such that it subsequently increased honest behavior consistent with these standards. In line with this research, consumers will avoid dishonest behavior after receiving forgiveness and after the mentioning of a future confession. That is, the expectation of a confession might increase attention to morality and therefore result in behavior consistent with one's moral standards (i.e. decrease unethical behavior before and after the confession).

The predictions of the licensing and consistency effects were juxtaposed across three studies. In the first two studies we examined individuals' intuitive beliefs about the effects of both expected and received forgiveness on other people's likelihood to cheat. Study 1 showed that participants' adopted a cynical view of others, expecting strategic moral calculation. That is, participants predicted others to be more likely to cheat before rather than after an expected future confession. Study 2 extended the findings to test the influence of temporal distance. Similarly to the results of Study 1, participants predicted the likelihood of others to cheat to increase the closer a future confession, to drop right after the confession, and to increase again the further in the past the confession would be. Thus, participants predicted licensing before confession and consistency after confession with diminishing effectiveness of the latter over time.

Finally, Study 3 tested the effect of an expected confession on one's own dishonest behavior in a task in which participants had opportunities to cheat in order to earn more money. Interestingly,

while we did find participants' dishonest behavior to decrease after (vs. before) an expected confession and to slowly increase again with distance from the confession (similar to the prediction results from Study 1 and 2), participants' dishonest behavior *before* the expected confession was lower than in a control condition where participants' did not know about the future confession.

Taken together, our findings suggest that individuals are much more concerned about their moral self-image and less strategic as their cynical view of humanity might suggest. We found that an expected confession does not license unethical behavior in the period leading to it, but rather produce beneficial effects on *honest* behavior. Thus, expecting forgiveness seems to act as a reminder of one's ethical standards leading consumers to act in consistency with these standards.

“Slacking in the Middle: Relaxing Personal Standards in the Course of Goal Pursuit”

Maferima Touré-Tillery, University of Chicago, USA

Ayelet Fishbach, University of Chicago, USA

Goals often require the completion of a sequence of actions, such as students finishing a series of assignments to pass a class, or consumers with frequent buyer cards that require the purchase of a number of items to get a reward (e.g. free coffee). In the course of pursuing such goals, people decide how closely to follow their personal standards for each action, based on whether the benefits of relaxing these standards outweigh the costs. One such cost is the negative impact on self-image, as relaxing standards can signal to oneself that one has low standards. Indeed, people learn about themselves from their actions (Brehm and Festinger 1957; Koo and Fishbach 2008). Therefore, even when external costs are low, self-image concerns get in the way of relaxing standards. In the context of unethical behavior, Mazar et al (2008) showed that one way people resolve this internal conflict is by cheating “just a little bit”: enough to benefit, but not enough to incur the costs to self-image. These findings are evidence that people behave in ways that allow them to present themselves *to themselves* in a positive light, and that actions serve as signals to the self.

We suggest that actions in the course of goal pursuit have differing signaling values for the self, and that relaxing standards on actions with low signaling value would minimize negative consequences on self-image. Previous research demonstrated significant order effects in sequences of information and events, with beginning and end being particularly important (Anderson 1965). Within this perspective, we propose that actions at the beginning and end of goal pursuit are stronger signals to the self of the true nature of the self than actions in the middle. Therefore, people protect their self-image by giving themselves a good first and last impression of themselves. Accordingly, we predict that people will be more likely to relax their standards in the middle of a sequence of goal-related actions than at the beginning/end.

Six studies confirmed our hypothesis in the contexts of ethical, performance and religious standards. In study 1, participants completed a word recognition task privately, and had the opportunity to cheat at the beginning/middle/end of the task, by claiming to know the meaning of a fake word. We found that a greater number of participants claimed to know a fake word (dishonest answer) when it appeared in the middle (vs. beginning/end) of the sequence. In study 2, we replicated this pattern using a less ambiguous form of dishonesty. In private, participants flipped a coin 10 times to assign themselves randomly to a series of 10 long vs. short proofreading tasks. We found that they were more likely to (falsely) report the favorable outcome of the coin flip (assigning themselves to the short passage) for tasks in the middle than for those at beginning/end. In

study 3, we replicated our findings in a more social context, where participants interacted with the experimenter throughout the task. They had the opportunity to take advantage of the experimenter's “forgetfulness” and get undeserved credit for a task that they did not do. We found that more participants accepted the undeserved credit for a task in the middle (vs. beginning/end) of the 7-task sequence. In study 4, we extended our findings to performance standards. Participants completed a shape-cutting task at their own pace. We found that out of the six shapes in the task, they cut the first/last shapes better than the middle ones. Study 5 was designed to examine underlying mechanisms by testing the idea that first/last (vs. middle) actions are stronger signals to the self. In the context of unethical behavior, we found that participants judged another person more harshly for cheating at the beginning/end (vs. middle) of goal pursuit. Because the mechanisms for judging the self mirror those for judging others, these findings suggest that people would think of themselves as more dishonest for cheating at the beginning/end (vs. middle) of pursuing a goal. Finally, with respect to meeting religious standards, study 6 found that participants were more likely to engage in the Hanukkah ritual of lighting menorah candles on the first/last (vs. middle) nights of the 8-night Jewish holiday.

Taken together, these studies provide convergent evidence that people are more likely to relax their standards in the middle (vs. beginning/end) of a sequence of goal-related actions, because actions at the beginning/end (vs. middle) are stronger signals to the self of one's standards.

Small Influences with BIG Consequences: Consumer Decisions in the Wild

Cynthia Cryder, Washington University in St. Louis, USA

EXTENDED ABSTRACTS

“Racial Preferences in Charitable Behavior Vary by Age of Recipient”*Deborah Small, University of Pennsylvania, USA**Devin Pope, University of Pennsylvania, USA**Mike Norton, Harvard University, USA*

Decades of experimental research provide evidence about factors that influence charitable giving. Recent research in consumer behavior emphasizes characteristics of the description of the charity (Kogut & Ritov, 2005; Small & Verrochi, 2009) and characteristics of donation request strategies (Lui and Aaker, 2008; Shang & Croson, 2009) as crucial for understanding when charitable appeals succeed. Although this research is useful for isolating cause and effect relationships and for pinpointing psychological mechanisms, researchers and practitioners remain skeptical about the extent to which such effects persist in real charity markets, where the precise control of the laboratory is lacking. Thus examining factors that influence charitable donations in natural settings is an essential step for understanding the psychology of giving.

The present research utilizes data from an online charity that allows individuals to connect directly with classrooms in need. The charity’s mission is to improve public education by empowering teachers to make changes and to enable citizens to be philanthropists. Public school teachers submit short proposals for needs for their classroom (e.g., microscope slides for biology class, violins for a school recital). Individuals browse proposals online and choose to give any amount. Once a project reaches its funding goal, the charity delivers the materials to the school.

Teachers can also include a picture that appears alongside their proposal—some 33% choose to do so. Given that vivid images tend to have a larger effect on judgment, memory, and behavior than pallid statistical information (Nisbett & Ross, 1980), posting a picture seems to be a wise strategy for a teacher requesting funds. Indeed, we find that proposals including a picture are 5% more likely to be funded than otherwise identical proposals. However, specific attributes of the pictures likely matter as well. For instance, Small and Verrochi (2009) found that when victim expressed sadness in a picture on a charity advertisement, people donated more than when the victim expressed happiness or neutral emotion. We expected that many other aspects of a picture may predict charitable giving choices.

Two features of a classroom in need that become particularly salient in the presence of a picture are the age of the students and their race. Given past research on stereotype activation (Devine, 1989), in-group preference in helping, and infrahumanization of African-Americans (Cuddy, Rock, & Norton, 2007), we expected that *for older children*, proposals containing pictures of Caucasian children would be more likely to be funded than those containing pictures of African-American children. However, we expected this common pattern to disappear or even reverse when the children are young because young African Americans will not be saddled by the same negative stereotypical associations as older children (e.g., Nosek et al., 2007).

We coded the race of the students in the pictures and used information provided in the proposal summary to ascertain the grade level of the students (either pre-K through 5th grade, or 6th through 12th grade). Our final sample includes 539 and 250 proposals that include a picture of African-American students in pre-K-5 and grades

6-12, respectively, and 894 and 332 proposals that include a picture of Caucasian students in preK-5 and grades 6-12, respectively.

We employ multivariate regression analysis to control for all other aspects of a proposal (amount of money being requested, type of project, poverty level, etc.) to isolate the causal effect of race and age and the interaction between race and age on the probability of a proposal being funded.

Overall, proposals with pictures of African-American students are funded 3.7% *more often* ($p=.06$) than otherwise similar Caucasian proposals. This general preference for African American classrooms—which runs counter to findings in much of the discrimination literature—could simply reflect the selective makeup of donors that participate in this particular online charity or the donors’ assumptions regarding which classrooms benefit the most from their donation.

However, the simple comparison between donation rates by race masks an important underlying interaction of age and race. For young classrooms (pre-K-5), African-American proposals are funded at an even higher rate relative to Caucasian proposals: 6.7% higher. For older classrooms (grades 6-12), on the other hand, African-American proposals are funded 2.5% *less often* than otherwise similar Caucasian classrooms. Along with being economically large, this interaction effect is also statistically significant ($p=.03$).

In sum, we utilize donation data from a real charity to examine the subtle effects of the race and age of charity recipients on charitable donations. Future research will attempt to parse out different potential psychological mechanisms for the pattern of effects.

“The Sunny Side of Giving”*Cynthia Cryder, Washington University in St. Louis, USA**Roberto Weber, Carnegie Mellon, USA*

In 2008, charitable giving in the United States totaled over \$300 billion dollars (Giving USA 2009). This is over 2% of Gross Domestic Product—a significant share. Despite the fact that charitable giving constitutes such a large portion of economic activity, the basic reasons why people give to others still are not firmly understood (e.g., Batson et al. 1981). Here, we test how an everyday environmental influence, sunshine, influences generosity.

Sunshine is associated with stock market trading (Hirschleifer and Shumway 2003), tipping (Cunningham 1979), and decisions about where to attend college (Simonsohn 2010). Sunshine’s effect on behavior typically is attributed to mood; people consistently report being happier and more satisfied with their lives on sunny days as opposed to rainy days (Schwarz and Clore 1983).

Mood commonly is linked to generosity. Both positive and negative moods increase generosity compared to neutral moods. People who experience a mood-lifting event are more likely to help others than are people in a neutral state (Isen and Levin 1972). Similarly, people who are asked to recall a sad event are more likely to volunteer to help others than are people in a neutral state (Manuncia, Baumann and Cialdini 1984). Therefore, the prediction for how sunshine might influence giving is not clear. Prior works suggest that donations may increase with sunnier weather because sunny weather improves mood, while other prior works suggest that donations may decrease with sunnier weather because cloudy weather dampens mood. A curvilinear relationship in which both extremely sunny and extremely cloudy weather increase donations compared to average weather is also possible.

Here, we investigate two questions. First, does sunshine have a meaningful impact on charitable giving (and how large is that impact)? Second, if sunshine influences charitable giving, what type of influence does it have?

The dataset includes information for each U.S. contact made by a university phone fundraising team during 63 days in October-December of 2007 (N=5,224). Student fundraisers used standard university fundraising scripts throughout; they asked potential donors to update their contact information, thanked them for past support, told them about campus news, and finally requested a donation. Fifty-one percent of those answering donated nothing; forty-nine percent donated \$1-\$5,023 (of donations, Mean donation=\$178.30, SD=\$355.46, Median=\$75). Dataset variables include call date, amount donated, contact's zip code, graduation year, and gender.

Based on zip code, we collected weather data for the contact's location on the call date and date before the call from Weather Underground (www.wunderground.com). Variables of interest included visibility distance and hourly cloud cover.

Linear regression models predicting amount donated based on clearness and visibility demonstrate robust effects. Controlling for gender, years since graduation (an age proxy), seasonal time trend (a "day" variable assigning each date a number, 1-63, corresponding with the day of data collection), and previous day clearness, we see that (completely) clear days as opposed to (completely) cloudy days are associated with an average \$44.58 increase in donations per call ($b=44.58, t(3,990)=3.79, p<0.0005$). Similarly, a regression using the visibility variable and analogous controls, reveals that a one mile increase in visibility is associated with an average \$9.53 increase in donations per call ($b=9.53, t(3,982)=4.75, p<0.0005$). Including a variable controlling for weather at callers' location did not significantly alter results, nor did including the first three digits of each contact's zip code as a fixed-effects location control. Squared terms for clearness and visibility were not statistically significant ($p's>0.25$), suggesting no curvilinear influence of sunshine on giving. Coefficients for previous day sunshine are negative suggesting that sunshine contrast is important. Holding today's weather constant, it is easier to raise donation dollars today if yesterday was cloudy.

Logistic regressions in which the dependent variable indicated whether the potential donor donated or not showed no significant effects of clearness nor visibility. Thus, the effect seems to be that sunnier weather encourages people already giving to give more, not that sunnier weather encourages people who would give nothing to give something.

In sum, we see a robust and substantial positive effect of sunshine on charitable giving. The finding has important implications for fundraisers and donors, but also underscores the powerful influence of everyday environmental factors like weather on consequential decisions like in this case, decisions about giving resources to others.

"The Effect of Providing Peer Information on Retirement Savings Decisions"

John Beshears, Harvard University, USA

James J. Choi, Yale University, USA

David Laibson, Harvard University, USA

Brigitte C. Madrian, Harvard University, USA

Katherine L. Milkman, University of Pennsylvania, USA

We report a field experiment evaluating a social norms marketing approach to influencing retirement savings decisions. Social norms marketing campaigns aim to encourage a behavior by informing individuals that the behavior is prevalent among their peers. We find some evidence that social norms marketing can increase savings rates, but our overall results suggest that social norms marketing may have limited power and can even produce boomerang effects.

Theoretical work suggests that an individual may mimic peers' actions because those actions signal information that is unavailable to the individual yet relevant to her payoffs. Empirical work shows that peer effects have a large impact in a range of settings (Goldstein, et al. 2005; Schultz, et al. 2007; Cialdini, et al. 1990; Kallgren, et al. 2000; Cialdini, 2003). Our paper joins the line of work that asks whether peer effects can be used to encourage desirable behaviors.

Our experiment was conducted at a large manufacturing company and included all U.S. employees ages 20-69 who were eligible for, but not participating in, the company 401(k) plan ("non-participants"), or who were participating in the plan at a before-tax contribution rate less than both their employer match threshold and 6% ("low savers").¹ These employees received letters encouraging them to enroll in or increase their contribution rate in the 401(k) plan. By checking a box on the letter and returning it to the company, employees could begin contributing 6% of their pay to the plan.

We randomly assigned employees to receive one of three types of letters: (1) a letter containing no peer information; (2) a letter offering information about the aggregate savings decisions of coworkers in the recipient's five-year age category (e.g., ages 25-29); or (3) a letter offering information about coworkers in the relevant ten-year age category (e.g., ages 20-29). For non-participating recipients in the peer information conditions, the letter stated the fraction of coworkers in the five-year or ten-year age category who were already enrolled in the plan. For low-saving recipients, the letter stated the fraction of plan participants in the five-year or ten-year age category who were already contributing at least 6% of pay. These peer information numbers were all greater than 70%.

We tracked contribution changes over two months following our mailing. We measured the effect of *presence* of peer information by comparing the extent to which employees in the peer information groups increased their contribution rates relative to the control group. We estimated the effect of *magnitude* of the peer information number that employees saw by exploiting: 1) variation generated by random assignment to different peer information as a result of differences in the 5-year and 10-year age categories and 2) age group boundary discontinuities.

Employees in our study naturally fell into four subpopulations: (1) unionized non-participants, (2) non-unionized non-participants, (3) unionized plan participants with low contribution rates, and (4) non-unionized plan participants with low contribution rates. We evaluate unionized employees separately from non-unionized employees because the latter were previously automatically enrolled in the retirement savings plan at a 6% contribution rate unless they opted out, while unionized employees were not subject to automatic enrollment. Prior research has found that automatic enrollment has a large impact on 401(k) enrollment, contribution rates, and asset allocations because employees often passively accept the default options (e.g., Madrian and Shea, 2001). Non-unionized employees who passively accepted the 6% contribution rate default did not receive letters. Therefore, among the four subpopulations who received a mailing, only unionized non-participants had never made an active 401(k) savings decision.

The effect of peer information in our experiment was mixed. Among non-unionized non-participants, exposure to peer information increased the likelihood of enrolling in the plan from 0.7% to

¹The match threshold, which is the minimum employee contribution rate at which an employee receives all available employer matching contributions, varied from employee to employee. For many employees (including all non-unionized employees), it was equal to 6%.

3.4% ($p < 0.10$). Among those non-unionized non-participants who received peer information, a one percent increase in the reported fraction of peer coworkers enrolled in the plan increased enrollment by 0.9 percent ($p < 0.10$). However, the impact of peer information was reversed among unionized non-participants: the presence of peer information decreased the enrollment rate from 10.4% to 6.5% ($p < 0.05$), and a one percent increase in the peer information number reduced enrollment by 1.8% ($p < 0.05$). We find no statistically significant effects among either unionized or non-unionized participants with low contribution rates.

The negative response of unionized non-participants to peer information is somewhat surprising. This reaction is probably not due to learning that coworkers had a lower plan participation rate than expected, since the enrollment rate and contribution rate changes of unionized non-participants were also decreasing in the size of the peer information value they received.

“Spurious! Implicit Egotism in Marriage and Moving Decisions: Lessons for Consumer Research”

Uri Simonsohn, University of Pennsylvania, USA

Multiple papers demonstrate the notion of *implicit egotism*: people like things more if these remind them of themselves. People like their initials, the numbers of their birthday, brands that resemble their names, etc... (see e.g., Anseel and Duyck 2008; Brendl, Chattopadhyay, Pelham and Carvallo 2005; Chandler, Griffin and Sorensen 2008; Nelson and Simmons 2007; Nuttin 1985; Pelham, Carvallo and Jones, 2005).

Several papers have taken this notion of implicit egotism and assessed whether it matters for big decisions.² Pelham, Mirenberg and Jones (2002) find that people are more likely than expected by chance to live in and move to streets, towns, and states that resemble their name, and to a town that contains a number from their birthday in their name (e.g., people born on February 2nd are disproportionately likely to live in “Two Oaks”). Jones, Pelham, Carvallo and Mirenberg (2004) find that people are disproportionately likely to marry others who share the initial of their last name, that share the exact same last name, and that have similar first names.

The current paper challenges the validity of all of the findings listed above. It does so by reanalyzing the same data sources used in the published articles and also looking at larger and cleaner sets. For every demonstration considered the name letter effect not only becomes statistically insignificant, it becomes very very close to zero. For example, for the first-name/marriage effect the original paper considers 12 names, 10 of which show a statistically significant effect. In my analyses, with a sample of 102,000 observations, none of the 12 names shows the effect and the average effect drops from 30%*** to 4% *ns*.

Here is a subset of the confounds documented in the paper:

- 1) Living in a city similar to one’s last name: towns with names resembling last names (e.g. Smithville) are often founded by people with those last names. Smiths don’t move to Smithville, they name the town where they already live Smithville. I conducted the analyses on the 10 largest cities in the US, where such reverse causality is implausible, and found a very precise 0 effect for name letter (e.g., people named York are not more likely to live in New York City).
- 2) Marrying someone with a similar last name: A small share of brides change their last names to their soon-to-be husbands’

names *before* marriage. Using public records I document a large number of people marrying each other, then divorcing, then marrying each other again. In the second marriage the bride has the groom’s last name. Consistent with a measurement error explanation, I show that while exact last name matching are much more likely than would be expected by chance, very similar last names matching are not. E.g., a Gonzalez groom is twice as likely as would be expected by chance to marry a Gonzalez bride, but just as likely as expected by chance to marry a Gonzales bride.

- 3) Marrying someone with a similar first-name: Factors that influence the popularity of baby names (e.g., location, religion, fashionability of a given name over time, etc...) influence male and female versions of the name simultaneously. For example, the variation over time of the number of babies named Andrew and Andrea is $r = .99$. These factors influencing name popularity also influence who one marries (e.g., people marry others born around the same birth year). I show that if one uses as control names other people who have similar distribution of spouse choices the effect drops to 0 (intuitively, if one compares Andrews to other male names that were popular at the same time Andrew was, the effect goes to 0).

ACR this year is focusing on big picture issues. This paper raises big picture issues with respect to conducting psychological research outside the lab. Consumer research in the field is often apologetic about the non-experimental nature of the research but it falls short of employing state of the art techniques to analyze the data properly. The present paper exemplifies the shortcomings of such an approach. Economists routinely obtain convincing results from field data; should we not demand the same from our consumer researchers?

The paper also exemplifies the folly of arguing that if a paper contains multiple studies which a single explanation can account for, then we should not worry about the multiple alternative explanations for each of the studies, as the former is more parsimonious. Among other problems, this argument ignores the degree of freedom the authors possess in choosing which studies to run and which results to publish. The convincingness of evidence should be assessed on a study by study basis. Implicit egotism is the only explanation simultaneously consistent with all the studies reviewed above, and yet it cannot convincingly explain a single one of them.

²Two papers studying implicit egotism in real life decisions for small stakes are not affected by the confounds I discuss in the present paper, see (Chandler et al. 2008; Nelson and Simmons 2007).

SPECIAL SESSION

Layers of Feeling: Exploring The Complexity of Emotions

Iris W. Hung, National University of Singapore, Singapore

Anirban Mukhopadhyay, Hong Kong University of Science and Technology, China

EXTENDED ABSTRACTS

“Differentiating Between Simple and Complex Emotions: It’s A Matter of Abstractness”

Loraine Lau-Gesk, *University of California, Irvine, USA*

Joan Meyers-Levy, *University of Minnesota, USA*

Jesse R. Catlin, *University of California, Irvine, USA*

Three studies demonstrate that emotions can vary in their construal level, ranging from fairly high-level abstract emotions to low-level concrete ones, and uncover process insights. Relational- (vs. item-specific) processing appears to underlie abstract (vs. concrete) emotions and their association with higher (vs. lower) construal levels. These findings are discussed in light of recent work on complex emotions.

The present research explores the possibility that emotions vary in their construal level, ranging from fairly high level abstract emotions to low level concrete ones. Drawing on construal level theory, we propose that higher level abstract (lower level concrete) emotions may entail mentally engaging in farther (closer) psychological distances (Liberman, Trope, and Stephan 2007). That is, emotions arising from appraisals that involve comparisons vis a vis a distant alternative are likely to be more abstract than those that involve comparisons with a proximal alternative. We suggest that certain complex emotions (Johnson-Laird and Oatley 1989; Ortony and Turner 1990), such as hope, pride, and awe, are likely to be fairly abstract because experiencing them requires that people compare their own situation to ones that are physically, socially, temporally, or hypothetically distant. For example, experiencing hope or pride involves a comparison with a distal expectation, ideal, or norm (Frijda, Kulpers and ter Schure 1990; MacInnis and de Mello 2005). By contrast, more concrete emotions include happiness, sadness, and fear since these arise from responses to more immediate situations and stimuli (i.e., close psychological distances; Liberman et al. 2007). Perhaps not surprisingly, these lower level, concrete emotions tend to be viewed as basic—feelings that are experienced universally from birth and in response to immediate needs (Ekman 1993; Plutchik 1981).

Study 1 explored whether emotions may indeed vary in their abstractness. We reasoned that people who experience more abstract versus concrete emotions should engage in a higher construal level and thereby should be more responsive to requests expressed at a higher versus lower construal level. Participants first wrote about an experience where they felt either proud or happy (i.e., abstract or concrete emotion). Subsequently they learned about a charity and were asked their willingness to make a donation—a request expressed at a high construal level, and to specify the precise amount they would donate—a request expressed at a low construal level. Participants also completed a BIF task, which directly assesses construal level (Vallacher and Wegner 1989). As expected, after participants had invoked the abstract emotion of pride versus the more concrete emotion of happiness, they were more willing to donate to the charity (a high level request) yet they committed a smaller dollar sum (a low level request). BIF results also showed after invoking pride versus happiness, participants construed data at a higher level.

Study 2 tests our theorizing more directly. Participants were randomly assigned to one of four conditions, where they experienced awe (abstract emotion) or happiness (concrete emotion)

through a writing task, or engaged in a laddering exercise that prompted lower or higher level construal. Participants then read a blog reviewing a new brand of chocolate chips. One blog reader’s comments posted below the review described a recent experience at the target brand’s store where a clerk who prepared a customized box of chocolate shortchanged the consumer. The box was either severely or slightly underweight. If abstract (vs. concrete) emotions correspond with higher (vs. lower) construal levels, then participants in these conditions should be sensitive to the degree of unethical behavior displayed by the clerk. Indeed, Eyal, Liberman and Trope (2008) found that a higher (vs. lower) construal level led people to respond more favorably to moral virtues and less favorably to moral transgressions. Thus, we expected participants who had experienced awe (vs. happiness) or whose laddering task induced a higher (vs. lower) level construal would be harsher in their judgments of the chocolate company. Supporting our theorizing, in both conditions where construal level was expected to be high (but not where it was low), evaluations were less favorable when unethical behavior was more versus less severe.

Study 3 explored yet another abstract emotion and examined its influence on creativity. Prior evidence indicates that the use of relational (but not item-specific) processing can elevate creativity (Friedman and Forster 2001). Particularly pertinent, however, theorists also suggest that relational processing may partially underlie abstract thought because relational thinking facilitates identification of commonalities, which fosters the production of higher level abstractions (Hunt and Einstein 1981). Based on this logic, we expected that among individuals who experience either the abstract emotion, hopefulness, versus a concrete emotion, happiness, performance on a creativity task is likely to vary depending on whether individuals also receive a priming task that incites either no particular processing type (i.e., control condition), item-specific processing, or relational processing. Assuming that relational processing truly contributes to abstract thinking, several hypotheses follow. First, under control conditions, creativity should be higher among participants who experience hopefulness versus happiness. In addition, creativity among those who experience the abstract emotion of hopefulness should be higher if they receive a control prime versus an item-specific prime, but their creativity should be higher still if they receive a relational prime. On the other hand, people who experience the concrete emotion of happiness should exhibit equal and relatively low levels of creativity regardless of receiving a control or item-specific prime, but their creativity should be enhanced if they receive a relational prime. Study 3, which was designed to test these hypotheses, offered some support for each of these predictions. Implications of our findings are discussed in light of recent work in construal level theory and complex emotions.

“Benign Violations: Humor as a Mixed Emotional Experience”

A. Peter McGraw, *University of Colorado, Boulder, USA*

Caleb Warren, *University of Colorado, Boulder, USA*

Humor is frequently pursued by consumers and marketers but is not well understood by consumer researchers. We hypothesize that humor can be a mixed emotional experience. In five studies, we show that humor is aroused by benign violations and benign moral violations can elicit negative emotion as well as amusement.

Understanding humor is important for consumer research. Consumers seek humor in television, movies, and web content, while marketers attempt to deliver humor in feature entertainment (Martin 2007) and commercial interludes (Eppers, Mukherjee, and Hoyer 2004). Humor offers consumers hedonic benefits (Martin 2007) and helps attract attention and improve memory for marketing communications (Eisend 2009; Krishnan and Chakravarti 2003).

Although humor is typically considered a positive emotional experience (Gervais and Wilson 2005; Martin 2007), several theories suggest that humor requires some sort of violation, such as a threat, a norm breach, or taboo content (Freud 1928; Gruner 1997; Veatch 1998). Building on ideas proposed by humor theorists (Koestler 1964; Rothbart 1973; Veatch 1998), we hypothesize that humor is aroused by violations that simultaneously seem benign. Because a violation is a necessary condition to elicit humor, we suspect that successful humor attempts may be accompanied by negative emotion. Indeed, situations that encourage multiple interpretations often elicit mixed emotions (Larsen, McGraw, and Cacioppo 2001; Larsen et al. 2004; Andrade and Cohen 2007). Using marketing and consumer behaviors considered wrong, we test whether benign violations similarly elicit mixed emotions. Because moral violations typically cause disgust (Chapman et al. 2009) benign moral violations may cause amusement and disgust.

Study 1 investigates consumers' reactions to twelve morally questionable behaviors. For each scenario we constructed a control condition, describing a normal behavior, and a violation condition, describing a similar but potentially benign taboo behavior. In one scenario, for example, *Jimmy Dean* hires either a farmer (control) or a rabbi (violation) as a spokesperson for its pork products. Participants were more likely to respond to the violations with amusement (47% vs. 17%), disgust (58% vs. 10%), and mixed amusement and disgust (24% vs. 2%).

In Study 2 we observed behavioral responses rather than relying on self-report measures. An experimenter blind to condition was more likely to observe mixed emotional responses in participants' exposed to a violation, a man snorting his dead father's remains, than in participants exposed to a similar control behavior, a man burying his dead father's ashes (19% vs. 3%).

The remaining studies examine ways a behavior can be appraised as both a violation and benign. Benign violations may occur when one norm suggests the behavior is wrong but another salient norm suggests it is acceptable. Consequently, behaviors that are wrong according to one moral norm but acceptable according to another should elicit mixed emotions. Conversely, behaviors forbidden by both norms should elicit only negative emotions. In study 3, participants read an adapted scenario about a man rubbing his genitals against his pet kitten (Schnall et al. 2008). The behavior violates a norm against bestiality. We manipulated whether the behavior also was acceptable according to another norm based on harm. In the harmless condition, the kitten "purrs and seems to enjoy the contact." In the harmful condition, the kitten "whines and does not seem to enjoy the contact." Participants were equally disgusted by the two behaviors (94% vs. 94%). However, participants reported more amusement (61% vs. 28%) and mixed amusement and disgust (56% vs. 22%) in response to the harmless (vs. harmful) bestiality.

Consumers who are less committed to a moral norm have less at stake when that norm is violated. They may see the violation as benign and be both amused and disgusted. Conversely, consumers more committed to a moral norm should only be disgusted when that norm is violated. To test this hypothesis in Study 4, participants either read about a church (violation) or a credit union (control) that gives away a Hummer SUV as part of a promotion. Most consumers recognize that churches are sacred and should not be

governed by the same market-pricing norms as credit unions, which are secular (McGraw, Schwartz, and Tetlock 2010). However, only churchgoers are likely to be committed to this norm. As predicted, most non-churchgoers were both amused and disgusted by a church giving away a Hummer (69%). Churchgoers were also disgusted, but less likely to be amused (35%). There were no differences in the control condition.

Psychological distance may reduce the threat posed by a violation thereby making the violation seem benign and thus amusing. Study 5 tests this hypothesis by priming either far or near distance before exposure to a violation or a control scenario. After plotting points far from or near one another on a Cartesian plane (Williams and Bargh 2008), participants read a scenario adapted from Haidt and colleagues (1993) in which a man either *has sexual intercourse with* (violation) or *marinates* (control) a chicken before eating it. Compared to participants who plotted points close together, participants who plotted points far apart were significantly more likely to respond to the violation with amusement (73% vs. 39%) and with mixed emotions of amusement and disgust (64% vs. 28%). No differences were present in the control condition.

"Choosing with Crying Smiles and Laughing Tears: The Dual Effects of Mixed Emotions on Variety Seeking"

Jiewen Hong, Hong Kong University of Science and Technology, China

Angela Y. Lee, Northwestern University, USA

This research examines the dual effects of mixed emotions on consumer variety seeking. Three experiments provide evidence that when people engage in affect regulation to reduce the conflicted feeling from mixed emotions, they seek less variety; however, people seek more variety when their focus is on the informational value of mixed emotions instead.

This research examines the influence of mixed emotions on decision making, and specifically, variety seeking. Following prior research (Ratner and Kahn 2002), variety seeking is conceptualized as the amount of variety chosen when selecting multiple items from a choice set on a single occasion. Building on the literature of affect regulation (e.g., Zillman 1988) and affect-as-information (e.g., Schwarz and Clore 1996), we argue that people's motivation to regulate their affect may prompt those who experience mixed emotions to narrow their scope of consideration when they attempt to reduce the feeling of conflictedness, which would in turn steer them toward committing to fewer options and seeking less variety. However, mixed emotions may also signal to people that they have multiple goals, which would in turn broaden their scope of consideration and lead to their seeking more variety.

Experiment 1 tested the dual effects of mixed emotions on variety seeking by manipulating the extent to which people feel conflicted from mixed emotions. The rationale is that if people experience conflictedness from mixed emotions, they are more likely to engage in affect regulation, which would in turn lead to less variety seeking. However, when people do not feel conflicted from mixed emotions, they are more likely to rely on mixed emotions as informational input, leading to more variety seeking. To vary whether people feel conflicted from mixed emotions, we manipulated participants' construal level: how abstractly or concretely they mentally represent information (Trope and Liberman 2003). We reason that mixed emotions would lead to less discomfort for those with high-level construals because they process information more inclusively and thus are better able to accommodate conflicts. Participants first completed a construal level manipulation in which they were asked to generate categories to which some objects belong (high-level construal induction), or exemplars of these ob-

jects (low-level construal induction; Fujita et al. 2006). Then they were asked to recall a mixed emotions life event (mixed emotions induction) or list activities from the past week (neutral induction). Finally, participants were asked to choose five M&M's from nine different colors of M&M's in any combination. Variety seeking was measured as the number of different colors of M&M's participants chose. As predicted, mixed emotions led to a feeling of conflictedness for participants primed with low-level construal, which in turn led to less variety seeking relative to the neutral control condition. The reverse occurred for those primed with high-level construals.

Experiment 2 tested the robustness of these findings by using a different method to operationalize affect regulation vs. affect-as-information. Participants first watched a video clip that either elicits mixed emotions or neutral affect. Then they were asked to perform a word fragment completion task to prime either a thinking or a feeling mindset. We reason that people are more motivated to reduce the conflicted feeling from mixed emotions when they focus on their feelings; but they should be more likely to draw inferences from their emotional state and incorporate it into their decision making when they focus on thinking. Finally, a similar measure of variety seeking as in Experiment 1 using candy bars was used. As hypothesized, we found that mixed emotions led to less variety seeking for participants primed to focus on feeling than the control, whereas the opposite occurred for those primed to focus on thinking.

The objectives of Experiment 3 were to provide convergent evidence by measuring participants' chronic inclination to regulate their affect, and to provide evidence for the mechanisms underlying the observed effects. Participants first completed a modified version of the Negative Mood Regulation Scale (Catanzaro and Mearns 1990) to measure their affect regulation tendency. The same emotion induction as in Experiment 2 was used. Participants were then asked to indicate how conflicted they felt and the extent to which they have multiple goals. To measure variety seeking, participants engaged in an actual choice task—they were asked to take 5 candy bars from 9 different bowls of candy bars. As predicted, results showed that mixed emotions led to less variety seeking among high affect-regulators compared to those in the control condition. Mediation analysis showed that this effect was driven by participants' feeling of conflictedness, providing evidence for the affect regulation mechanism. Conversely, mixed emotions led to more variety seeking among the low affect-regulators relative to the control, and this effect was mediated by participants' cognition of having multiple goals.

The current research adds to the mixed emotions literature by examining the influence of mixed emotions on consumer decision making via affect regulation and affect-as-information. It also adds to the literature on affect and decision making by demonstrating the unique affect regulation consequences and the informational property of mixed emotions, and identifying the conditions under which affect regulation vs. affect-as-information would occur.

“Effects of Perspective-Taking on the Experience and Influence of Multiple Mixed Emotions”

*Iris W. Hung, National University of Singapore, Singapore
Anirban Mukhopadhyay, Hong Kong University of Science and Technology, China*

Mixed emotions may differ not only in valence, but also the extent to which they are hedonic vs. self-conscious. Four experiments examined the role of visual perspectives in the relative intensities of these mixed emotions, and their impact on effectiveness of emotion appeals of unrelated products that are subsequently encountered.

Consumers often experience mixed emotions when thinking about their decision or processing advertised situations about

various real-life dilemmas. Would the use of different perspectives influence the way consumers interpret information described in these dilemmas, thereby affecting the relative intensity of mixed emotions and the effectiveness of emotional appeals? The present research examines two factors that might influence their responses in such situations. These are (1) the nature of the emotions (hedonic or self-conscious) that the advertisement elicits, and (2) the visual perspectives (whether they see themselves as actors or observers) that individuals use in appraising the advertisement.

Research in mixed emotions has focused on the simultaneous experience of mixtures of specific emotions (Larsen, McGraw, and Cacioppo 2001; Lau-Gesk 2005). In an impulse-buying situation, for example, one often feels both happy and guilty when deciding to buy (vs. not buy), and proud but sad when choosing not to buy (Mukhopadhyay and Johar 2007). These emotions not only differ in valence, but also in the extent to which they are hedonic (vs. self-conscious) in nature. Hedonic emotions such as happiness and sadness correspond to more immediate reactions toward an event, whereas self-conscious emotions such as pride and guilt correspond to more elaborate reactions toward that event (Giner-Sorolla 2001). Not much is known about the conditions that determine the relative intensities of hedonic vs. self-conscious emotions. We examine these issues in the context of self-control dilemmas. Specifically, we propose that the visual perspectives people employ in appraising a given self-control related situation can influence the relative intensities of the hedonic vs. self-conscious emotions they experience.

Jones and Nisbett (1972) suggest that the salience of information about the internal states of actors and observers differ in that actors tend to focus on circumstances involved in a given situation, whereas observers tend to focus on the actor in the situation. We propose that this difference in salience of information can lead to differences in emotional appraisals of the same event as perceived by actors and observers. We conjecture that when making a choice of a vice over a virtue, actors might experience a stronger feeling of more immediate emotions such as happiness than observers whereas observers who see themselves choosing a vice over a virtue might experience relatively stronger self-conscious emotions such as guilt. Further, based on an ease of processing account (Schwarz 2004), we suggest that these hedonic and self-conscious emotions could facilitate/undermine the processing of emotional appeals in advertising.

Four experiments support these propositions. Participants took either an actor's or an observer's perspective to process a choice that led to mixed hedonic and self-conscious emotions, and reported the emotions they felt (experiments 1-2). Regardless of the choice, actors [observers] indicated more intense hedonic [self-conscious] emotions than observers [actors].

Experiments 2 to 4 demonstrated that (1) the use of visual perspectives could influence the impact of emotions in advertising, and (2) this effect was mediated by the ease of processing of the emotional appeals. Participants viewed appeals that described a choice in a self-control dilemma (either choosing a virtue over a vice or a vice over a virtue) and an emotion that one could experience about this choice. The emotion described was positive self-conscious (pride), negative self-conscious (guilt), positive hedonic (happiness), or negative hedonic (sadness). Participants took either an actor or an observer perspective to process the appeal. Across experiments, we operationalized visual perspectives and emotion appeals in different ways to rule out alternative explanations. Specifically, participants recalled a previous self-control situation using an actor vs. observer perspective and then saw an ad for an unrelated product (experiment 2), had their visual perspective induced and then saw an ad that cued a related product (experiment 3), or had

their visual perspective and emotion manipulated simultaneously by the same ad execution (experiment 4). Results consistently showed that the advertised product and the ad were evaluated more favorably when participants took an *actor* [*observer*] perspective than when they took an observer [*actor*] perspective to view a *hedonic* [*self-conscious*] emotion appeal. This effect was mediated by the ease of processing the emotional appeals, and was observed when the visual perspective was induced incidentally as well as integrally by the advertisement, and whether the advertisement was viewed subsequently or simultaneously.

Overall, results from these experiments shed new light on the role of situational factors (the nature of mixed emotions, and the use of visual perspectives to process events) in the experience and impact of mixed emotions on effectiveness of emotions appeals. Theoretical and practical implications will be discussed in the session.

Priming Susceptibility: The Role of the Self in Moderating Nonconscious Priming Effects

Heather Johnson, University of Maryland, USA

Amna Kirmani, University of Maryland, USA

EXTENDED ABSTRACTS

“The Role of the Self-Concept in Susceptibility to Priming Influences on Behavior”

Dirk Smeesters, Erasmus University, The Netherlands

Considerable research has demonstrated that behavior is influenced by construct accessibility, and there is rapidly growing evidence suggesting that susceptibility of the self-concept to influence can determine the susceptibility of individuals to primed constructs. In this presentation, we present several studies showing effects self-related processes can have in determining whether primed constructs will affect behavior.

A first factor that determines susceptibility to priming influences is the accessibility of the chronic self-concept. In the context of economic decision-making, two experiments tested whether participants with more accessible self-concept representations would be less likely to be influenced by primed constructs, but more likely to act in line with their chronic self-characteristics (Smeesters et al. 2009). Results of the first experiment showed that those who had highly accessible social value orientations acted in line with those self-representations and not with the primed constructs. Those who had less accessible social value orientations did *not* act in line with those self-representations, but rather acted consistently with the primed concepts. In a second experiment, the accessibility of the self-concept was manipulated. The primes affected participants whose self-concept was not made accessible by self-related words. However, when the accessibility of self-concept was increased, participants were no longer susceptible to the primed constructs.

A second factor that can determine susceptibility to priming influences is private self-consciousness. Past research on this dimension has found opposite effects: some demonstrated that private self-consciousness increased priming effects (Hull et al. 2002), whereas other showed that it decreased priming effects (Dijksterhuis and van Knippenberg 2000). Self-consciousness is a multifaceted construct containing two important dimensions: internal state awareness and self-reflectiveness (Wheeler, Morrison, DeMarree, and Petty 2008). Participants who score high on the internal state awareness factor of the private self-consciousness scale should be less susceptible to priming influences. Self-reflectiveness, on the other hand, might increase susceptibility to priming influences, as those who engage in self-reflection tend to process external feedback in terms of its implications for the self, thereby leading it to have greater effects on self-views and behavior (Wheeler et al. 2008). These predictions were tested in a study in which participants' scores on both internal state awareness and self-reflectiveness were measured (Wheeler et al. 2008). Results revealed independent interactions between primes and both internal state awareness and self-reflectiveness.

A third factor that can determine susceptibility to priming effects concerns the extent to which the context facilitates confusion of the primed content with one's actual self-views. When the context signals that a prime is “not me”, it can diminish the prime's effect on behavior. In one experiment (Wheeler, Sleeth-Keppler, and Morrison 2010), non-Asian participants were subliminally primed with intelligence or not via a lexical decision task. Results indicated that the intelligence primes had an effect only when not preceded by Chinese characters, presumably because the Chinese characters signaled to non-Asian participants that the intelligence primes did not apply to them. In a follow-up study, participants

who identified or disidentified with math were subliminally primed with the elderly stereotype (or not). Either math symbols or a row of XXX served as forward and back masks to the priming stimuli. These results are consistent with the idea that the math symbols served as a signal as to whether the prime was self-relevant or not.

These studies contribute to a growing body of research showing the important role that the self-concept can play in prime-to-behavior effects and emphasize the importance of the self-concept in driving behavior.

“Priming Susceptibility: The Moderating Role of Self-Brand Connection on Nonconscious Priming Effects”

Heather M. Johnson, University of Maryland, USA

Amna Kirmani, University of Maryland, USA

This paper proposes that self-brand connection serves an important moderator of priming effects. Self-brand connection reflects the extent to which a brand fits with one's self-concept (Escalas and Bettman 2005). Counter to prior research demonstrating main effects of nonconscious cue exposure, we predict an inverted U-shaped effect: consumers with a moderate level of self-brand connection to a target brand are more susceptible to a nonconscious prime's influence on their subsequent purchase intentions toward the target brand. For these individuals, a nonconscious prime renders related constructs accessible and this fluency effect will increase purchase intentions toward the product, consistent with main effects findings in the nonconscious priming literature (Berger and Fitzsimons 2008). However, consumers' high and low self-brand connection to a target brand shields them from influence of nonconscious cues.

In addition, we predict that consumers' self-brand connection to a competing brand also influences behavioral intentions toward a prime-congruent (target) brand after encountering a nonconscious prime related to that target brand. For example, if John has high self-brand connection to Nike he may be resistant to the influence of a Puma-related incidental cue on his propensity to purchase Puma. We show that this prediction holds, and interestingly that a nonconscious prime may even prompt individuals high in self-brand connection to a competing brand to express *decreased* purchase intentions toward the target brand.

Two experiments demonstrate the moderating effect. In the first study, we measured self-brand connection for both target (Puma) and competing brands prior to participants' encounter with a dog prime, and show that individuals with low or high self-brand connection are less susceptible to the prime. Study 2 employs a novel priming paradigm to provide generalizability to a different product domain, laptop computers. Participants again provided self-brand connection ratings for target (Apple) and competing brands in the category (e.g., Dell) and were exposed to an incidental cue related to the target brand (the flavor orange). We again show that by increasing the accessibility of the target brand for consumers moderate in self-brand connection, the prime can lead to increased purchase intentions, while consumers low or high in self-brand connection for the target or competing brands in the category do not express increased purchase intentions for the target brand. Interestingly—and importantly for marketing practitioners—we find that individuals with high self-brand connection for Dell express decreased purchase intentions for Apple laptops upon encounters with the Apple-related prime. These empirical findings extend recent main effect studies demonstrating a nonconscious prime's influence

on purchase intentions by showing that consumers' susceptibility to these influences is based on self-brand connection.

"The Effect of Action and Inaction Goal Primes on Consumers' Information Processing"

Juliano Laran, University of Miami, USA

Action and inaction primes have been shown to influence motor output, such as doodling on a piece of paper and eating, and cognitive output, such as recall and problem solving (Albarracín et al. 2008). These primes can influence decision satisfaction, choice satisfaction, and ultimately the likelihood that consumers will be willing to perform behavior congruent with a marketer's intent (i.e., buy a given product). In other words, action and inaction primes make consumers more susceptible to performing *any* behavior intended by a marketer if the goal can be satisfied. I predict that priming of an action goal will make consumers willing to evaluate an increased amount of product information and be highly satisfied with the decision process when choice sets offer a lot of attribute information. Alternatively, priming of an inaction goal will make consumers willing to evaluate fewer pieces of product information and be highly satisfied with the decision process when choice sets offer only few pieces of attribute information. Satisfaction with the decision process may influence choice satisfaction and the likelihood to buy the chosen brand.

All studies were composed of three phases. In phase 1, participants were told that they would participate in a sentence recall test. Participants were exposed to ten sentences, which could be action-oriented (e.g., "you can do it"), inaction-oriented (e.g., "you deserve to relax"), or neutral, depending on the goal priming condition. In phase 2, an ostensibly unrelated study, participants were asked to make choice between two brands of digital cameras. In the low load condition, I presented information about 4 attributes, whereas in the high load condition, I presented information about 9 product attributes. In phase 3, participants were asked a series of questions, including satisfaction with the process of deciding which brand to choose and satisfaction with the chosen option. In study 1, participants in the action goal prime condition showed higher decision satisfaction when making a choice from a choice set offering high information load than when making a choice from a choice set offering low information load. Participants in the inaction goal prime condition showed higher decision satisfaction when making a choice from a choice set offering low information load than when making a choice from a choice set offering high information load. There was no influence of information load in the neutral prime condition. Choice satisfaction was found to be fully mediated by decision satisfaction. In a similar study, decision satisfaction also led to an increased likelihood that people would actually purchase the brand.

Study 2 examined whether these results would extend to actual behavior. Participants primed with an action goal were willing to donate more money to their favorite charity when a lot of information was presented. Participants primed with an inaction goal were willing to donate more money to their favorite charity when little information was presented. These results suggest that allowing people to process an amount of information congruent with a primed action or inaction processing goal makes them more susceptible to an external agent's influence outside of their awareness.

Study 3 manipulated goal achievement by having participants perform an action (i.e., solve GRE problems) vs. an inaction (i.e., close eyes and relax) task after being exposed to the goal primes. In the action (inaction) goal prime condition, after having performed an action (inaction) task, participants were more satisfied with the

decision process and showed higher likelihood of purchasing the chosen brand when the choice set offered low (high) information load.

"Individual Susceptibility to Priming Effects"

Stacy Wood, University of South Carolina, USA

Cait Poyner, University of Pittsburgh, USA

Tanya Chartrand, Duke University, USA

The purpose of this research is to test the susceptibility concept and identify the characteristics that would contribute to individual differences in susceptibility to priming (STP). While priming researchers would benefit from the creation of an STP scale because it would serve as a useful covariate, consumer behaviorists are likely to be interested in the concept of STP because of its implications for advertising efficacy. We posit that, counter to intuition, people who are both attentive to their environment and have a tendency to strong associational processing are those who are *most* susceptible to priming. Indeed, the mechanisms by which priming work suggest that primes require 1) physical (but not necessarily aware) exposure and 2) associative processing, suggesting two paths to priming susceptibility. We build on this conceptual development to generate a simple 6-item reflective STP measure. Three studies demonstrate that our STP index does predict the magnitude of an individual's response to a prime.

Study 1 demonstrates that priming individuals with concepts of the elderly (akin to the "walking to the elevator" study by Bargh, Chen, and Burrows [1996]) can influence susceptible consumers to "move slowly" in consumer domain, specifically in adversely affecting their attitude toward the speed of high tech product innovations. In study 1, we expose participants to a modified version of an "elderly prime and test the impact of this prime on responses to a survey about attitudes toward the speed of technological change; specifically, we predict that an elderly prime will serve to decrease reported attitudes toward speedy innovation. We anticipate that the STP index will moderate the effect of this prime, such that priming effects are strongest for those with higher STP.

Participants engaged in two ostensibly unrelated tasks that were, together, the focal task. In the first part of this task, participants filled out a survey that asked them to look at a list of brand names for products (e.g., Dasani water, Kleenex tissues) and to identify which brands they thought were American brands and which brands were Canadian brands. In the elderly prime condition, six fictional brand names were words associated with the elderly (e.g., Bingo cookies, Slow-Pour syrup). In the neutral condition, these words were replaced with unrelated words (e.g., Bell cookies, Sweet-Pour syrup). Participants then moved on to another separate survey about their attitudes about high tech products intended to tap into participants' attitude toward the pace of technological change.

We first created an STP index for each participant by averaging across the 6 STP items ($r=0.76$, $M=5.57$, $SD=.74$). We then analyzed the data using the STP index and the prime condition of the participant as predictors of attitudes towards technological change. The main effect of the prime ($F(1, 151)=.14$, $p=.71$) was not significant. However, there was a significant overall interaction of priming condition and STP scale score ($F(1, 151)=4.08$, $p=.04$). We then probed the nature of this interaction using spotlight analysis as suggested by Aiken and West (1991). This analysis indicates that the prime was ineffective for low and moderate STP individuals, who did not rate technology differently than did their unprimed counterparts (moderate: $M_{\text{prime}}=4.92$, $M_{\text{no prime}}=4.85$, $F(1,151)=.14$, $p=.71$; low: $M_{\text{prime}}=4.77$, $M_{\text{no prime}}=5.09$, $F(1,151)=1.41$, $p=.49$). However, among high STP individuals, the prime did have an effect. Higher STP individuals exposed to the elderly prime were significantly more likely to describe the pace of technological

change as too fast ($M=5.08$) than those not exposed to the prime ($M=4.61$, $F(1,151)=3.46$, $p=.05$).

Studies 2 and 3 further support our hypotheses. Study 2 demonstrates that a subtle work-oriented prime can alter prime-susceptible college students to report increased intentions to study. Study 3 demonstrates that priming the concept of promotion versus prevention (Aaker and Lee 2006) within an advertisement can increase susceptible consumers' valuation of a promotion-congruent product attribute. These studies provide insight both into susceptibility to primes and to the nature of the prime itself: In some cases, the use of the index provides more nuanced interpretation of an apparently robust prime, showing that its overall effect is actually localized to only a subset of the population. In other cases, the use of the index allows a weak or marginally-significant aggregate effect of a prime to be understood as quite strong if only among a section of the sample.

When Do Goals Succeed Versus Fail? Effects of Consumer Beliefs on Self-Regulation

Claudia Townsend, University of Miami, USA

EXTENDED ABSTRACTS

“Choice as Magic: Using Current Consumption to Control Uncertain Future Outcomes”

Soraya Lambotte, University of Chicago, USA

Aparna A. Labroo, University of Chicago, USA

Ravi Dhar, Yale University, USA

We propose that people attempt to control the fate of uncertain future outcomes by being virtuous in their current consumption choices. When hoping for a positive outcome for which they feel responsible, or fearing a bad outcome due to chance, they reason, “If I am good, then good things will happen to me,” and thus make virtuous current choices in an attempt to improve their potential position.

“If the conductor arrives before I count to seven, he (my fiancé) is alive.”

~ Audrey Tatou as Mathilde, *A Very Long Engagement* (2004)

In waiting for important news over which you have no control, such as the review of a submitted paper, or a job offer, you may hope for the best, and fear the worse. That is, you may hope for a positive review, or an offer, and yet fear getting neither. In such a situation in which the end product is out of your hands, how might you respond? Would you decide to indulge yourself by going shopping, or eating unhealthy foods, or would you decide to be virtuous and exert restraint, and go exercise or do nothing of major consequence until all the results are in? And why should you modify your current consumption in any way, after all, the uncertain future outcome has nothing to do with the current consumption choices you are considering.

In the present research, we explore how people use their current consumption choices in an attempt to exert control over uncertain future outcomes. We look at why one may decide to engage in a virtuous choice over an indulgent one when making a current choice depending on one’s perceived level responsibility for an uncertain future outcome and whether one is focused on hoping for the best or fearing the worst for the very same outcome. In particular, we find that people who generally have an indulgence goal, will show restraint and be virtuous by making healthy food choices in two cases: when they hope for a positive outcome for which they feel responsible, and when they fear a negative outcome for which they do not feel responsible. Specifically, in a 2 (responsibility: self vs. external) x 2 (outcome focus: hope vs. fear) x 2 (goal: indulgence vs. health) between-subjects design, participants were asked to recall a time during which they felt responsible for an outcome (vs. attributed to chance) that could go either way, as they hoped for the best or feared the worst. After this task, in an unrelated choice task, participants were asked to make a series of snack food choices, picking between healthy and unhealthy options. Those participants who felt responsible for the event described and hoped for the best, self-regulated, and made indulgence-goal inconsistent choices in an attempt to regulate fate. Conversely, participants who attributed the event to chance, indulged when they hoped for a good outcome, but showed restraint and were virtuous when they feared a bad outcome. This pattern of effects was only found among indulgent people, who by not indulging, could maintain their good fortune (in the case in which they felt responsible for a good outcome),

or improve their standing (in the case in which they feared a bad outcome due to chance). “If I am being good,” the reasoning goes, “then good things will happen to me, and I will not tempt fate,” and so in each of these cases, participants tried to improve their potential outcomes by being virtuous. Those with a health goal did not show a similar pattern of results, they generally made healthy choices in line with their overarching goal. To complement this finding, in a follow-up study, we further tested people’s belief in magic, which leads them to be virtuous in their current choices when they want to improve or maintain their expected outcome. That is, when they feel responsible for a good outcome, or when they do not feel responsible for a bad outcome, they make virtuous current choices, so as not to tempt fate, and potentially demean or worsen their position in the future, as past research has shown that people hold the intuition that actions which tempt fate increase the likelihood of negative outcomes.

This research thus provides first evidence of how people use current choice to exert control over uncertain future outcomes. People who are generally indulgent use self-regulation as magic in order to try and improve the odds of a future outcome when hoping for the best and feeling responsible for the outcome, and when fearing the worst for an outcome one is not responsible for. Moreover, such behavior is mediated by feelings and perceptions of luck, such that people will engage increasingly in this self-regulatory behavior, the more they believe in luck and fear tempting fate.

“Lay Theories of Obesity”

Brent McFerran, University of British Columbia, Canada

Anirban Mukhopadhyay, Hong Kong University of Science and Technology, China

Four experiments demonstrate that people mainly hold one of two different lay theories about what causes obesity: poor diet and lack of exercise. These lay theories influence food quantity decisions, and influencing their accessibility changes portion sizes chosen. Non-dieters are more likely to change behavior due to such interventions.

Consumers make over 200 food choices per day, and obesity has become a severe public health concern in many countries. Diet and exercise guides advocate numerous approaches to weight loss, variously implicating genetics, consumption, and exercise in explaining our expanding waistlines. While some authors point to sedentary lifestyles (Blair and Brodney 1999) or genetics (Comuzzi and Allison 1998), the strongest evidence implicates a marked increase in consumption of food and drink as the main driver of obesity (Young and Nestle 2002). Consumer researchers have investigated several factors that help explain this increase in eating. These include social influence (McFerran et al. 2010), regulatory focus (Sengupta and Zhou 2007), and recollections of prior instances of indulgence or restraint (Mukhopadhyay, Sengupta, and Ramanathan 2008). Of interest, recent research has demonstrated that consumers’ food choices may be influenced by their lay theories, or naïve beliefs, such as those pertaining to self-control (Mukhopadhyay and Johar 2005) or emotions (Labroo and Mukhopadhyay 2009).

In this research, we take a more direct approach and examine the prevalence and consequences of lay theories about the causes of obesity itself, and demonstrate how they can profoundly influence consumers’ food quantity decisions. Dar Nimrod and Heine (2010) report that people who believe that obesity is caused by

genetic factors tend to eat more than those who believe it is caused by social reasons (Christakis and Fowler (2007). We extend this work by proposing that consumers have other, more prevalent lay theories of obesity: specifically, consumers largely believe that obesity is caused either by poor diet or by lack of exercise. Further, we predict that all else equal, those who believe that not exercising causes obesity eat more than those who believe that it is caused by a poor diet.

We tested our basic proposition in a survey of 100 Amazon.com users ($N=100$, 47% male, mean age 34). Respondents indicated what they thought was the primary cause of obesity: eating too much, not exercising enough, or genetics, and allocated 100 points among the options. Results indicated equal numbers of respondents sharing the diet and exercise lay theories (44 vs. 48); which was reflected in the points allocation ($M_s=44.06$ vs. 38.97). The genetics lay theory was far less prevalent (8 respondents, $M=17.05$). This is initial evidence supporting the prevalence of our lay theories of interest.

Study 2 tested whether lay theories about the relative importance of diet and exercise can actually affect consumption quantities. Participants were given a cup of chocolates while they filled out some unrelated questionnaires, including a measure assessing the relative weights of their lay theories of obesity. We found that those who believed that a lack of exercise was relatively more likely to cause obesity ate more chocolates from their given cups.

Study 3 aimed to establish the causal effects of these lay theories. Following Labroo and Mukhopadhyay (2009), participants read a paragraph, purportedly real research, which either stated that obesity is caused by diet or by exercise. As a second factor, they recalled a previous instance when they had resisted a tempting food or had succumbed to it (Mukhopadhyay et al. 2008). The order of the lay theory induction and the recall task was counterbalanced. Finally, they were presented with a hypothetical task involving making selections at an ice-cream parlor (McFerran et al. 2010). Results provided strong support for the role of lay theories as accessible cognitions in influencing eating quantity decisions. When the recall task came first, implying that lay theories were more accessible, those who had been primed with the exercise (versus diet) lay theory chose significantly more ice cream. When the recall task came second, those who read about the exercise theory chose smaller quantities, but only if they had recalled resisting.

Study 4 tested if certain types of individuals are more susceptible to lay theory inductions. Chronic dieters have a highly accessible goal of consumption restraint (Scott et al. 2008), and thus may be less likely to accept alternative lay theories. Unrestrained eaters have no such chronic preoccupation, and thus may be more likely to use other accessible cognitions (i.e., lay theories) to guide their behavior. Procedures followed the Study 3 lay theory first/succumb condition, except real consumption was measured (as in Study 2). Results revealed that dieters consumed the same amount regardless of whether the article claimed diet or exercise as the cause of obesity, but unrestrained eaters ate more if they had read the exercise article than the diet one.

Across four studies, we provide the first evidence that (a) people have mainly two different lay theories about what causes obesity (diet vs. exercise), (b) these lay theories guide actual food choices, (c) the accessibility of these lay theories can be influenced to change portion sizes, and (d) non-dieters are more likely to change behavior as a result of alternative lay theories. These results help answer the big picture question of what causes obesity, by explaining a large part of consumers' portion sizes.

“Is making plans good for you? The Differential Impact of Planning on Behavior”

Claudia Townsend, University of Miami, USA

Wendy Liu, UC San Diego, USA

In four field studies we find that planning does not benefit everyone equally. Although making plans improves subsequent behavior when individuals consider their position positive in the relevant area, ironically making plans has a deleterious effect on actual behavior when decision-makers feel in poor standing in the relevant domain.

Both academic research and lay beliefs suggest that planning is advantageous for goal attainment and self-regulation (see for example Gollwitzer 1996, Schifter and Ajzen 1985). Yet, little is known about the emotional response to planning and how this may influence subsequent behavior. We consider that planning for self-regulation may produce emotional responses similar to those of positive self-statements and positive feedback which are not always constructive. While positive thinking and positive feedback are generally thought to improve mood and affect, there are instances when a boomerang effect can occur leading to worsened mood (Eisenstadt and Leippe 1994, Wood, Perunovic, and Lee 2009). The explanation is that when people feel that the feedback or positive statement is too positive and does not fit their self-conceptions, the discrepancy between their believed actual self and the idealized self as described by the feedback or statements becomes particularly salient. Like positive statements and feedback, by creating a plan one is, in essence, describing the acts of a possible future superior version of the self. If this possible future self as described in the plan is too different from one's perceived actual self then the plan may be outside the “latitudes of acceptance” and lead to psychological reactance (Sherif and Hovland 1961). We predict this will result in negative emotions such as stress which, in turn, likely might cause someone's actions to boomerang—and go in opposition to the proposed plan. Thus, while planning may be helpful for some, it may be harmful for those whose perceived self is dramatically different from the future self as described in the plan. The difference in these two selves promotes negative feelings such as stress leading to less goal-consistent behavior. Specifically, our hypothesis is that those who perceive themselves to be in good standing with respect to the relevant goal will be helped by planning with planning causing more goal-consistent behavior. Those who perceive themselves not to be in good standing are actually less likely to behave goal-consistently after planning than in the absence of planning. We examine this in four field studies.

In study 1 we consider the impact of planning on eating—whether planning one's diet has a positive or negative effect on subsequent snack choice. We find that those who perceive themselves as not overweight are aided by planning; planning decreases likelihood of selecting the unhealthy snack. However, those who perceive themselves as overweight are hindered by planning with planning increasing their likelihood of selecting the unhealthy snack. We also isolate the effect to planning in the relevant context, thus ruling out an explanation based on ego depletion (Baumeister, Bratslavsky, Muraven, and Tice 1998). Additionally, we examine the content of the plans and find that more and less confident people do not differ in the plans they make revealing that any differences in behavior are not due to plan content.

In study 2 we investigate the mechanism through which this occurs—how planning interacts with one's sense of security in the relevant area. We examine how planning makes people feel and whether one's emotional response to planning differs depending on perceived standing in the relevant area (overweight or not for our diet context). We find that for respondents who are not in good

standing in the relevant domain planning calls attention to their deficit in the domain and accentuates how much demanding work they must accomplish in order to improve. Planning is, therefore, a stressful and upsetting task for them. In contrast, respondents in good standing do not find planning to be stressful or upsetting.

In the third study we use the same context of the impact of planning on eating, but also examine whether manipulation of perceived standing in the relevant area impacts behavior. A shortcoming of studies 1 and 2 is that self-perception is measured rather than manipulated and there may be a spurious correlation. In study 3 we manipulate whether someone feels in good or poor standing in the relevant area *after* the plans are made and, indeed, find this to affect the impact of planning as predicted.

In the fourth and final study, we consider the impact of planning in a different context—saving. We analyze consumers' use of the 2008 Economic Stimulus Tax Rebate and whether planning one's use of the money has a positive or negative effect on how it is spent. Study 4 replicates our original findings in another context and in several ways offers a more stringent test of our theory.

The findings presented in this research are relevant to numerous areas including work on goals, habits, self-regulation, and behavioral change. Implications on when and how planning should or should not be advocated are also discussed.

“The Effects of Goal Breadth on Consumer Preferences”

Eunice Kim, Yale University, USA

Ravi Dhar, Yale University, USA

Broadly versus narrowly defining a goal affects choice. A series of studies demonstrates that individuals with a broader focal goal are more likely to choose a high price, high quality option over a low price, low quality option because broader goals decrease the consideration of the other relevant goals that shoppers have, such as the goal to be frugal.

While most of the goals research examines how a single goal affects choices and subsequent evaluations, in reality, individuals simultaneously maintain multiple goals that can interact to affect choices (Fishbach and Dhar 2005). Shah and Kruglanski (2002) state that for any given goal—a focal goal—individuals can also have other goals in that context, referred to as alternative or background goals, which can affect the pursuit of that focal goal. A question that arises is how focal and background goals interact to affect choice.

The current research examines how the breadth of the focal goal, whether it is broad (e.g. goal to buy clothes) or narrow (e.g. goal to buy jeans), influences the extent to which these other alternative or background goals are considered (e.g. goal to be frugal), and therefore leads to very different choice outcomes. To examine why and how the breadth of a focal goal might affect consumer choice, we rely on recent advances in a theory of goal systems by Kruglanski and his colleagues (2002). According to this framework, goals are described as an inter-related network of nodes. We propose that the setting of a broad focal goal leads to a spreading of activation to a greater number of related sub-goals and means. The activation of more sub-goals and means requires the consumption of more cognitive resources. This means that fewer resources remain for the consideration of other relevant background goals in any given context. The setting of a narrow focal goal, however, activates fewer related sub-goals and means, which leads to the consumption of fewer cognitive resources, and therefore leaves more resources for the consideration of other background goals. Thus, we propose that individuals who are assigned to a broad focal goal are less likely to consider other goals that are relevant to a shopping context, such as the goal to be frugal, than are individuals assigned to a narrow focal goal. As a consequence, those individuals assigned

to a broad focal goal are more likely to choose the option that is best on the focal goal.

A series of studies test these hypotheses. These studies are generally composed of two parts. The first part is goal activation where participants are randomly assigned to either a broad or a narrow focal goal by imagining a broad focal goal (e.g. buy clothes) or a narrow focal goal (e.g. buy jeans) and writing about it. The second part is the choice task. Studies 1 and 2 find that individuals with a broad focal goal are more likely to choose a more expensive, higher-quality option compared to individuals with a narrow focal goal. In addition, these studies rule out two potential alternative accounts. The first account is that a broad goal might activate a more abstract mindset that focuses people on aspects of desirability (Liberman and Trope 1998). We address this by demonstrating that the effect of goal breadth on choice, unlike the effect of mindsets, does not carry over to all subsequent tasks but only applies to choices between goal-related options. A second alternative account is that a broad goal might call upon a larger mental budget that makes it easier to spend (Morewedge, Holtzman, and Epley 2007). We find, however, that even when participants are given a fixed budget, those with the broad focal goal are more likely to choose the high quality expensive option compared to those with the narrow focal goal.

The next set of studies examines the underlying mechanism. Study 3 shows that when participants with a narrow focal goal are subjected to a cognitive load task, which consumes cognitive resources, the competing background goal to be frugal becomes less accessible, and the difference in the preference for the higher priced option across goal breadth is attenuated. Studies 4a and 4b employ various methods, including a lexical decision task, to demonstrate that a broad focal goal increases the accessibility of various sub-goals and means, but decreases the accessibility of the goal to be frugal. Study 5 demonstrates that this effect may be bounded by the chronic activation of a frugality goal. Study 6 extends the effect of goal breadth beyond the domain of shopping to the domain of health and consumption. Lastly, Study 7 examines the intuitions held by people regarding the effect of goal breadth on consumer preferences.

We demonstrate that the breadth of a focal goal plays an important role in how multiple goals interact by influencing the extent to which background goals are considered in choice. Furthermore, these findings have implications for how consumers can set broad or narrow goals to aid in self-control.

The Excluded Consumer: Impacts of Social Exclusion on Consumer Behavior

Yuwei Jiang, Hong Kong Polytechnic University, China

EXTENDED ABSTRACTS

“Lonely are the Brave: Effects of Social Exclusion on Consumer Risk-Taking”

Echo Wen Wan, University of Hong Kong, China

Yuwei Jiang, Hong Kong Polytechnic University, China

Rod Duclos, Hong Kong University of Science and Technology, China

Social exclusion, i.e., feeling ignored or rejected, is common in life (Baumeister et al. 2005; Williams 2007). Receiving a cold treatment from coworkers, being “dumped” by a significant other, getting evicted from a social organization are just a few examples of such unfortunate fate. The current research examines the impact of social exclusion on consumers’ risk-taking in financial decision-making.

Previous research finds that experiencing social exclusion leads to feeling hurt, pain, and loneliness (Sommer et al. 2001). In turn, these feelings increase one’s motivation to forge new social bonds (Maner et al. 2007). But how can one rebuild social connections after being rejected? According to Zhou, Vohs, and Baumeister (2009), ostracized individuals can use *money* to regain access to their social world and derive benefits from it once again. Building on this work, we predicted that consumers would respond to social exclusion by engaging in riskier but more lucrative investment opportunities.

To test this proposition, we invited participants in study 1 to play Cyberball (Williams et al. 2000), an online ball-tossing game intended to manipulate one’s state of social inclusion versus exclusion. Next, in a seemingly unrelated study, subjects indicated their preference between two hypothetical gambles of equal expected utility (i.e., 20% chance of winning \$800 vs. 80% chance of winning \$200). As predicted, socially-excluded participants favored the riskier option more strongly than their included counterparts.

Though encouraging, study 1 leaves several questions unanswered. For instance, what is the directional impact of social exclusion on financial decision-making? I.e., does exclusion lead to riskier behavior (as theorized earlier), or does inclusion lead to preferring safer options? Furthermore, could affect (rather than social exclusion itself) be the real driving force behind our effect? After all, it is conceivable indeed that interpersonal rejection also leads to negative mood.

To answer these questions, we invited participants in study 2 to elaborate on one of four personal experiences. Per our theorizing, subjects in the first two conditions recalled a social experience where they felt either included or excluded (Pickett et al. 2004). To assess the directional impact of social exclusion, we added a control condition where participants recalled everything they ate and drank in the last 48 hours. Lastly, to rule out affect as an alternative explanation for our effect, we added a negative-mood condition where subjects recalled an instance during which they experienced physical pain (e.g., migraine, tooth ache). Next, in a seemingly unrelated gambling study, participants indicated their preference between two options of *unequal* expected utility (i.e., a 20% chance of winning \$200 vs. a sure gain of \$30). To make our task consequential, we bound participants in this study to their choice and paid them accordingly. As predicted, socially-excluded subjects exhibited stronger preferences for the riskier but more lucrative option than their counterparts in both the control and negative-mood conditions. Interestingly, socially-included

participants also differed from the latter two conditions, but in the *opposite* direction. I.e., included subjects exhibited strong risk aversion and preferred a sure gain of \$30 over a more lucrative but uncertain gamble. These results replicate and extend those of study 1 in two ways: first, by contrasting the directional impact of social exclusion (vs. inclusion) on financial decision-making; second, by ruling out affect as an alternative mechanism for our effect. Indeed, while we readily concur that social exclusion is likely to be accompanied by negative mood, the latter (by itself) failed to replicate the effect documented across experiments.

From a theoretical perspective, our studies contribute to the literature by documenting and nuancing a new effect, that of social exclusion (vs. inclusion) on financial decision-making. Furthermore, by disentangling negative mood from social exclusion, these findings also shed light on the consequences proper to interpersonal rejection per se. Lastly, from a societal perspective, our results illustrate the significant impact that common experiences such as feeling rejected versus accepted can have on consumers’ daily lives.

“Does A Broken Heart Lead to an Empty Wallet? Exclusion Increases Willingness to Pay for Unappealing and Illegal Products”

Nicole L. Mead, Tilburg University, The Netherlands

Roy F. Baumeister, Florida State University, USA

Kathleen D. Vohs, University of Minnesota, USA

Tyler F. Stillman, Florida State University, USA

Catherine D. Rawn, University of British Columbia, Canada

Humans are a hyper-social species and have a fundamental need for positive social relationships. Consequently, people experience social exclusion as deeply aversive. How does social exclusion influence personal spending? Prior research suggests several possibilities, such as mimicking others’ choices, impulse spending, and buying lovely gifts to relieve the sting of rejection and self-soothe. However, accumulating research suggests that the need to belong conforms to a specific pattern: when it is thwarted, people become motivated to affiliate with others. We therefore hypothesized that socially excluded people would use personal spending as a way to build social bonds. Specifically, in two experiments we tested whether social exclusion would increase willingness to consume products that were (1) expressly unappealing and (2) illegal and potentially harmful to the self when doing so could help commence or cement a social relationship.

In experiment 1, we tested whether social exclusion would increase participants’ willingness to spend on an unfamiliar and visually unappetizing food item: chicken feet. To manipulate social exclusion, participants completed a personality test and received false feedback concerning how their personality would impact future social connections. Participants assigned to the exclusion condition were led to believe they could anticipate a life devoid of social connections whereas participant assigned to the acceptance condition were led to believe they could anticipate a life full of strong social connections.

After the manipulation, participants ostensibly shared information with their partner about their food preferences in preparation for the food-tasting task. In reality, participants received a sheet filled out by a same-sex confederate, which indicated that his or her favorite food was chicken feet. After viewing this information, participants were shown a slide show of four different foods from

around the world (chicken feet, borscht, black pudding, and herring). They were asked to indicate their willingness to pay for each item, ostensibly because it would be used to determine which food item they would sample at the conclusion of the experiment.

However, before indicating willingness to pay, we varied whether preferences would be visible to the partner and whether participants had an opportunity to affiliate with the partner. This was done to ensure that increased willingness to spend on the chicken feet was a function of desire to affiliate rather than passive mimicry or conformity. In the public/interaction condition, participants were led to believe their spending intentions would be public and that they would sample the food item with their partner. In the private/interaction condition, spending intentions were not public but the joint tasting would take place. In the public/no interaction condition, spending intentions were visible but no joint tasting would take place. As predicted, exclusion only increased willingness to spend on the chicken feet when both spending intentions were made public and they had the opportunity to meet their partner, indicating that socially excluded people were not simply mimicking or conforming to their partner's preferences.

In experiment 2, we sought to extend the finding of experiment 1 to willingness to consume an illicit substance. First, participants were randomly assigned to recall a time in which they felt socially accepted, socially excluded, or when they were ill (negative non-social control). After the social exclusion manipulation, participants received one of two scenarios. Participants in the private condition imagined that one night, when they were home alone, they found some cocaine that had been left behind by a new friend. Participants in the public condition were asked to imagine that a new friend asked them to do cocaine with him or her when they were out at a party. All participants were asked to indicate how willing they were to try the drug. Results showed that, as compared to socially accepted and negative non-social control participants, socially excluded participants reported a higher willingness to use the cocaine, but only in the public condition. In the private condition, there was no difference in willingness or desire to use the cocaine as a function of the social exclusion condition. Additional analyses indicated that mood did not mediate the effect of social exclusion on increased desire to try the cocaine.

In sum, results from two experiments provide support for our hypothesis that socially excluded people use spending as a way to build new social bonds. The present studies suggest that the social motivation of affiliation has direct implications for consumption that are both theoretically and practically meaningful.

“If I Ignore You, You Spend; If I Reject You, You Help: Different Types of Social Exclusion Threaten Different Needs and Produce Different Outcomes”

Jaehoon Lee, University of Texas at San Antonio, USA

L. J. Shrum, University of Texas at San Antonio, USA

Previous research suggests that social exclusion can produce two seemingly contradictory responses: antisocial responses such as aggression and prosocial responses such as conformity. One possible explanation for these contradictory outcomes is that different types of exclusion threaten different social needs. Exclusion can threaten social needs such as belonging, self-esteem, control, and meaningful existence, and reactions to restore threatened needs may drive either prosocial or antisocial responses. Individuals with relational needs (belonging and self-esteem) may behave prosocially because relational needs motivate them to be adaptive, whereas individuals with efficacy needs (control and meaningful existence) may behave antisocially because efficacy needs motivate them to increase visibility (Williams 2007). Research also suggests a distinction

between being rejected (explicit) and being ignored (implicit). Being rejected increases threats to relational needs such as self-esteem, whereas being ignored increases threats to efficacy needs such as meaningful existence (Molden et al. 2009). Taken together, the consequences of being rejected may be prosocial to be affiliative, but the consequences of being ignored may be antisocial to achieve immediate recognition. Moreover, some indirect antisocial behaviors may include the symbolic superiority over others (Baumeister et al. 1996), which may be achieved through consumption. Conspicuous consumption is a showy behavior intended to gain attention, and may provide the easiest and surest way of gaining immediate recognition, thereby satisfying efficacy needs. Thus, being ignored should increase conspicuous consumption (but not helping behavior). In contrast, being rejected should pose threats to relational needs, which should motivate individuals to engage in prosocial behaviors such as helping (but not conspicuous consumption).

Four experiments tested these propositions. Participants either wrote about (exp. 1-3) or imagined (exp. 4) an instance of either being rejected or being ignored or going grocery shopping, and then indicated their preferences for products with conspicuous vs. non-conspicuous brand logos and their helping intentions (operationalizations were varied). As expected, ignored conditions increased conspicuous consumption preferences but not helping intentions, whereas rejected conditions increased helping intentions but not conspicuous consumption preferences (exp. 1-4). Moreover, both sets of effects were greater for high than for low materialists (exp. 2). Materialistic values may be driven by *both* the needs to bolster self-esteem and bolster meaningful existence (Richins and Dawson 1992). Thus, materialism is a useful trait measure to serve as a proxy for need to bolster two different needs. However, when the underlying needs that are differentially threatened by being ignored versus being rejected were boosted prior to providing consumption and helping judgments, both social exclusion effects were eliminated. Specifically, under no-boost conditions, the effects of being ignored and being rejected were replicated. However, a self-esteem boost (exp. 3, 4) eliminated the effects of being rejected on helping intentions, but a power or meaningful existence boost did not, whereas a power (exp. 3) or meaningful existence (exp. 4) boost eliminated the effects of being ignored on conspicuous consumption preferences, but a self-esteem boost did not.

These studies provide evidence of social exclusion effects on consumption behavior, a topic that is relatively new to consumer behavior. In addition, the results provide a tentative explanation of inconsistent findings on the effects of social exclusion on pro- and anti-social behavior. Finally, the results provide important information regarding the motivations underlying both conspicuous consumption and helping behavior such as volunteering and charitable contributions.

“The Effect of Social Exclusion on Consumers’ Sensitivity to Construal Levels”

Jing (Alice) Wang, University of Iowa, USA

Meng Zhang, Chinese University of Hong Kong, China

Being excluded has been shown to have adverse effects on people's psychological and physical well-being, such as anxiety and depression, aggressive behavior, feeling cold and painful (e.g., Baumeister and Tice 1990). However, little research has examined whether social exclusion can impact people's sensitivity to differential mental representations, which in turn, may influence their decisions in subsequently encountered, seemingly unrelated tasks. The current research examines such a possibility. We hypothesize that relatively speaking, socially excluded people will be more sensitive to low-level construals (concrete, superordinate repre-

sentations) and adopt a concrete, how-oriented thinking, whereas socially included people will be more sensitive to high-level construals (abstract, subordinate representations) and adopt an abstract, why-oriented thinking.

We draw our predictions on some interesting parallels observed between social exclusion and construal level. Specifically, prior research finds that people will focus more on proximal (distal) temporal distance when a low- (high-level) construal is induced or social exclusion (inclusion) is made salient; people's ability to exert self-control will be impaired (enhanced) when a low- (high-level) construal or a social exclusion (inclusion) is manipulated. Based on these lines of research, we propose an association between exclusion and a low-level construal, and inclusion and a high level construal. We tested our predictions in four experiments.

Experiment 1 used a product classification task. We propose that those who construe information at a high level would be more inclusive and use fewer categories to classify products than those who construe information at a low level. We first manipulated social exclusion using a method developed by Twenge et al. (2001). Specifically, participants were asked to fill out a personality questionnaire, and they received one of the three versions of bogus feedback concerning their future: they will be alone (exclusion), socially accepted (inclusion) or prone to accident (negative control). Then they were asked to perform two classification tasks. In each task, they placed a number of products into groups by writing down the items that belong together. As expected, the results showed that participants in future alone condition used more categories to classify both tasks than those in future belonging and accident prone conditions. The differences between the latter two conditions, however, were small and insignificant, indicating that negativity could not be an alternative explanation of the results.

Experiment 2 tested our prediction on consumers' evaluations of ads. It had a 2 (social: inclusion vs. exclusion) x 2 (product version: positive values associated with high-level construals, but negative associated with low level construals vs. positive values associated with low-level construals, but negative associated with high level construals) between subject design. We used a different method to manipulate social exclusion (Twenge et al. 2001). Specifically, participants were asked to form groups and were either be accepted or rejected by the confederate. Then in an unrelated task that followed, participants were asked to evaluate two ads of new products—a lotion and a drama—adopted from Kim et al. (2008). Significant interactions were found on both ads. As expected, socially rejected participants, as compared to socially included participants, reported a lower evaluation of the product which had positive high-level features, but a higher evaluation of the product which had positive low-level features.

Experiment 3 further tested our prediction on participants' chronic tendencies. We measured participants' chronic tendency to social exclusion (Russell 1996) and their chronic tendency to high/low construals (Vallacher and Wegner 1989). The results provide additional support for our hypothesis, showing that those who were lonelier tended to construe events at a lower level.

Finally, in the on-going experiment 4, we induced social exclusion by a brand scenario. Participants were asked to apply for a membership in a brand community club, and were informed later that their application was either accepted or rejected. The preliminary results showed that participants, who were excluded by the brand club, adopted a more single-minded thinking strategy in a later task. They were more successful in identifying details missing within a coherent visual whole than their counterparts who were included in the brand club. Collectively, these experiments provided converging evidence to our predictions in different

decision domains, using different methods to operationalize social exclusion and construal levels.

The Neglected Dimension of Affective States: New Findings on the Effects of Stress, Relaxation, Anxiety, and Arousal, on Consumer Behavior

Michel Tuan Pham, Columbia University, USA

EXTENDED ABSTRACT

“Decisions Under Distress: Stress Profiles Influence Anchoring and Adjustments”

Karim Kassam, Carnegie Mellon University, USA

Understanding how stress affects decision making is complicated by the fact that not all stress responses are created equal. Challenge states, for example, are characterized by efficient cardiovascular profiles, higher resource relative to demand appraisals, and are associated with approach motivation. Threat states, in contrast, involve less efficient cardiovascular profiles, higher demand relative to resource appraisals, and are associated with withdrawal motivation. We randomly assigned participants to social feedback conditions designed to engender challenge and threat states, as well as a control condition. Participants then completed an anchoring and adjustment questionnaire.

Anchoring and adjustment is a common mode of interaction of conscious and unconscious processing, we frequently make conscious adjustments to our beliefs, estimates and opinions based on information and social context. Following the stress manipulation, participants completed a number of trivia questions involving adjustment from self-generated anchors (e.g. What is the freezing point of vodka?). Adjustment from anchors on such questions has been shown to require conscious processing—participants generate intuitive answers they know to be incorrect but close to the right answer (e.g. 32 degF), and then serially adjust in the direction of the correct answer (Epley & Gilovich, 2001).

In order to engender challenge and threat stress responses, we used a modified version of the Trier Social Stress Task (Kirschbaum, Pirke, & Hellhammer, 1993)—a mock job interview consisting of speech and question-and-answer tasks. After application of physiological sensors, participants sat quietly for a 5-minute baseline period. Participants were then asked to imagine they were interviewing for a desirable job. They were given five minutes to prepare a speech describing their strengths and weaknesses, which they then delivered to two interviewers.

Previous research suggests that this stressor can engender challenge or threat states depending on the nonverbal feedback given by interviewers (Akinola & Mendes, 2008). Approximately thirty seconds into the speech, interviewers in the challenge condition began to express positive nonverbal feedback by nodding, smiling, and leaning forward. In the threat condition, interviewers expressed negative nonverbal feedback by shaking their heads, frowning their brows, and crossing their arms. In the control condition, participants completed the same tasks but were alone in the experiment room. They were instructed that we were interested in physiological changes associated with delivering a speech, but we would not be watching them during the task. Immediately after the interview, all participants were given two minutes to provide their best guesses in response to nine anchoring and adjustment questions labeled “Trivia”.

We found that type of stress, and not just the amount of stress, can have a significant impact on people’s abilities to engage in cognitive tasks. Participants placed in a stressful situation with positive feedback cognitively adjusted more than those who experienced negative feedback, an effect that was mediated by cardiovascular (CV) reactivity. Those who exhibited CV responses consistent with

challenge (increased cardiac output and decreased total peripheral resistance) showed greater cognitive adjustment than those who exhibited CV responses consistent with threat (decreased cardiac output and increased total peripheral resistance).

These findings have important implications for recent research showing incidental emotions can influence decision making. For example, anger has been shown to increase optimism and risk-taking relative to fear (Lerner & Keltner, 2000), and sadness affects people’s willingness to buy and sell consumer goods (Lerner, Small, & Lowenstein, 2004). As work in this area continues to develop, it will be interesting to see if—like challenge and threat—the effects of emotion on decision-making can be indexed with *under the skin* responses.

“Relaxation Increases Monetary Valuations”

Michel Tuan Pham, Columbia University, USA

Iris W. Hung, National University of Singapore, Singapore

Gerald J. Gorn, Hong Kong University of Science and Technology, China

Whether buying a house or considering whether to invest in the stock market, common wisdom holds that people should be relaxed and at ease. Relaxation is among the most important environmental states marketers try to create, whether in spas, hotel rooms, or restaurants. Yet, there is little consumer research on relaxation and the research that has been done has tended to focus on how states of relaxation affect reactions to print ads (c.f. Gorn et al. 1997; Bosmans & Baumgartner, 2005).

Our research documents an intriguing phenomenon. We find across six experiments that states of relaxation increase consumers’ monetary valuations of products, compared to equally pleasant but less relaxed states. We interpret these findings as follows. Based on research suggesting that relaxation encourages broader thinking (Fredrickson & Branigan 2005), we propose that relaxed consumers have more global and abstract representations when assessing the monetary value of products than non-relaxed consumers. Research has also found (Lieberman & Trope (1998) that individuals who have more abstract representations (higher-level construals) of goal-directed activities (e.g., going on a vacation in Mexico) focus more on the overall desirability of these activities (e.g., how appealing Mexico is), whereas individuals who have more concrete representations (lower-level construals) focus more on the feasibility of these activities (e.g., its cost). Linking these two streams of research together, we suggest that relaxation encourages a more abstract representation of the value of products, and this shifts the consumers’ focus towards the general desirability of products and away from their more concrete characteristics. Because most consumer products (e.g., vacations, cameras) are inherently desirable, such a shift in representation results in products being valued more by more-relaxed consumers than by less-relaxed consumers. For example, in assessing the monetary value of a digital camera, a relaxed consumer would focus more on the overall desirability of owning the camera like the memories they can collect with it, and less on the concrete features of the camera itself like its size and weight. This shift in representation should result in relaxed consumers perceiving the camera to be more valuable than less-relaxed consumers.

Across six studies (total N=560), participants were induced into either a state of relaxation, or into an equally pleasant (but less relaxed) affective state using pre-tested videos. Next, as part of a supposedly unrelated study, they were asked to assess the monetary value of products. The results consistently showed that more-relaxed participants assigned greater monetary value to products than less-relaxed participants. This held true for the perceived prices they assigned to various products supposedly from a product catalogue (Studies 1 and 2), and for the maximum amount of money participants were willing to bid for a camera they were asked to imagine they were interested in and bidding on eBay for, and for their estimates of how much it was really worth (Studies 3 to 6).

Our reasoning was confirmed in Studies 4 to 6. For example, in Study 5 direct support for the proposed explanation was obtained through a priming manipulation of participants' levels of representation. If the effect of relaxation on monetary valuation is due to higher levels of representation, then the priming of an abstract level of thinking should amplify this effect by reinforcing relaxed individuals' tendency to represent the value of products at a higher level. Conversely, the priming of a lower level of construal should attenuate this effect. The results were supportive and further suggested that relaxed individuals inflate the monetary value of products. Using process measures of concrete versus abstract thinking, Study 6 further shows that relaxed consumers indeed have more abstract and less concrete representations of the products' value than less relaxed consumers.

Interestingly, across experiments 3-6, it was found that the bids of less-relaxed participants in the bidding experiments were generally close to the market value for the product. More-relaxed participants' estimates were however substantially higher than the market value, unless high-level construals were discouraged by the manipulations. Even though it is typically not in people's material interest to have inflated perceptions of the monetary value of products they might buy, our evidence suggests that they do nonetheless have them.

“Focused on a Feeling or the Cause? The Regulation of Anxiety”

*Aparna A. Labroo, University of Chicago, USA
Derek D. Rucker, Northwestern University, USA*

Imagine that you are in the process of planning your annual vacation when your doctor calls. The results of a recent cholesterol test show deterioration and you feel anxious. How might you regulate your anxiety? Could simply browsing a brochure that makes you consider why your vacation will be calming help? Would completing an arm flexion exercise help? Given that neither the brochure nor the exercise addresses the problem that caused your anxiety, why should they have any effect on your current state? Would it matter whether your focus was on your anxious feelings or what caused the feelings: the test results?

Negative feelings typically result because of a problem and foster efforts to resolve the problem (Schwarz and Clore 1983). Thus, anxiety arising from a problematic test result could only be addressed by resolving the cause of those feelings. However, recent evidence suggests that anxiety is associated with a general avoidance orientation (Raghunathan and Pham 1999). According to this perspective, therefore, any outcome that fits with avoidance should be preferred, even though the outcome may not directly address what caused the anxiety. Thus, merely considering a calming vacation—an outcome associated with an avoidance orientation—or engaging in arm flexion exercises, which also simulate avoidance (vs. approach), might be beneficial. How might these two views be reconciled?

We propose that once negative feelings become activated, people can focus either on the problem that caused the feelings or on the negative feelings themselves. Focusing on the feelings activates a motivation to avoid threat or to approach reward, because all feelings are intrinsically tied to motivation. As a result, any positive outcome that fits with the general motivational state can mark symbolic progress and facilitate the regulation of the negative emotion. Only when individuals focus on the cause of their emotion, will actions that address the particular problem reduce their negative emotion.

Across five experiments, we first establish that when participants focus on feelings, both anxiety and calmness, considered by us in this research, correspond with an avoid-threat orientation whereas happiness, also considered by us, corresponds with an approach-reward orientation (Exp. 1). We then demonstrate that avoidance motivation intensifies over time when participants experiencing unresolved anxiety focused on feelings, but decays when they focused on the cognitive appraisals of the causal event, replaced by specific thoughts regarding the problem that evoked anxiety (Exp. 2). We next show that among anxious participants who focus on their general anxious feelings, avoidance motivation is reduced when they complete a short exercise in the interim that employs a motivational orientation that fits with that of the negative emotion (i.e., flex arm outward as if pushing a bad thing away vs. flex arm inward as if pulling a good thing; Exp. 3). Similar emotional benefit is not observed if participants focused on the causal event. Experiment 4 shows that participants who focused on feelings of anxiety rather than causal events, get emotional benefit from merely evaluating an outcome that fits with avoidance (calming vs. happy vacation ad), and perform better on a subsequent task known to benefit from positive feelings (e.g., the Remote Associates Test). A final experiment (Exp. 5) provides a dynamic measure of affect regulation. Anxious or non-anxious participants report their mood, they then read a happy or calming ad, and again report their mood. The data again suggest that a fit in avoidance orientation between the preexisting anxiety and the positive (calming) outcome is a basis for affect regulation, but only when people are focused on their feelings.

In summary, our results demonstrate that when consumers focus on their feelings (vs. causes), higher order motivational states are activated and merely considering any positive outcome compatible with the general motivational state can provide symbolic emotional benefit.

“Arousal and Subjective Probabilities: An Alternative Interpretation of Wishful Thinking”

Joachim Vosgerau, Carnegie Mellon University, USA

Desirability bias denotes the tendency to judge desirable outcomes as more likely than undesirable outcomes. For example, in the classic study by Crandall, Solomon, and Kellaway (1955), participants were asked to predict random independent draws from decks of ten cards. Even though they knew that each deck contained 7 winning cards, they predicted drawing a winning card 89% of the time.

While such findings are typically interpreted as people suffering from a desirability bias, they actually don't show desirability bias at all. Knowing that the objective probability of a winning card is 70%, a rational decision maker would predict a winning card in 100% of the draws (thereby maximizing accuracy of prediction). So, compared to a rational decision maker, participants in the above experiment appear to be pessimistic or at least not accuracy-maximizing. Whatever is the case, they are certainly not overoptimistic.

Rather than always being too optimistic, I propose that the likelihood of an event may be judged by how aroused the stakeholder is. The greater the stake in the outcome, the more aroused will the stakeholder be, and the higher s/he will judge the likelihood of the outcome occurring or not occurring.

Study 1 employed a 2 (arousal vs. no arousal) x 2 (probability of occurrence vs. non-occurrence) between-subjects design. Half of the participants were asked questions such as "How likely do you think the Yankees will win the World Series?"; the other half was asked for the complementary probabilities. Arousal was manipulated by printing questionnaires on either pink or grey paper. As hypothesized, participants judged both outcomes (the Yankees winning and the Yankees not winning) as more likely in the arousal condition (pink paper).

In study 2, half of the participants were first asked to rate their arousal level, and subsequently to judge the likelihood of outcome occurrence or non-occurrence (outcome: participants won \$5 when they got at least one 3 within four die-rolls, $p=51.77\%$). The other half was first asked the likelihood question and then the arousal question. Misattribution of arousal to likelihoods was found as participants rated likelihoods higher before than after the arousal measures.

Study 3 employed a 2 (probability of outcome occurrence vs. non-occurrence) x 3 (stake in outcome: win a shot-glass vs. neutral vs. lose a shot-glass) between-subjects design. Half of the participants was asked how likely a computer, when rolling a die four times, would roll a 6 twice ($p=11.57\%$). The other half was asked how likely the computer would not roll a 6 twice. As hypothesized, participants judged the probability of getting a 6 twice higher when they could win ($M=19.77\%$) or lose a shot-glass ($M=38.91\%$) than in the neutral condition ($M=13.44\%$). Likewise, they judged the probability of not getting a 6 twice also higher in the win ($M=72.32\%$) and the lose condition ($M=61.79\%$) than the neutral condition ($M=55.83\%$).

In study 4 German soccer fans imagined watching an upcoming match either live (more aroused) or taped (less aroused; Vosgerau et al. 2006, JCR). Fans were asked to indicate how likely their team (Stuttgart) was to win. When having the prospect of watching the match taped, Stuttgart was judged as equally likely to win/tie ($M=52.40\%$) as to lose ($M=51.36\%$). In contrast, for the live broadcast conditions, Stuttgart was rated as more likely to win/draw ($M=58.48\%$) and also as more likely to lose ($M=67.92\%$). Taken together, the four studies demonstrate that arousal (from having a stake in the outcome) can make consumers more optimistic and more pessimistic. Such optimism and pessimism call into question the ubiquity of wishful thinking.

Embodied Consumption: Understanding Avatared Consumers

Haiyang Yáng, INSEAD, Singapore
Amitava Chattopadhyay, INSEAD, Singapore

EXTENDED ABSTRACTS**“Marketing to Avatars: The Impact of Virtual Embodiment on Consumer Self-Concept and Behavior”**

Haiyang Yáng, *INSEAD, Singapore*
Amitava Chattopadhyay, *INSEAD, Singapore*

Hundreds of millions of people have entered three dimensional virtual worlds, interacting with each other and living out their digital second lives as avatars. Two streams of research shed light on the mechanism through which avatar embodiment may influence consumer self-concept. First, Aaker (1999) showed that self-concept is not a static and stable structure, but a malleable one. The content of the working self-concept depends on what has been invoked by the individual as a result of an experience, event, or situation at the given time (Markus and Kunda 1986). Second, people may make inferences about their own attitudes and values from observing their own behaviors, in a way similar to an outside observer (Bem 1972). These findings suggest that avatar embodiment experience may lead consumers to activate or form a working self-concept that is consistent with their avatar.

Consumer research provides ample evidence of the behavioral implications of the malleable-self. Mick and Buhl (1992) found that individuals under different self-concepts interpret advertisements differently. Aaker (1999) showed that situational cues can activate different personality traits, which, in turn, influence attitudes toward brands with different personality associations. These suggest that, if avatar embodiment results in changes in working self-concept, consumers may exhibit behavior consistent with the shifted working self-concept.

Furthermore, the research on close relationships (Aron et al. 1991) shows that individuals in close relationships tend to have highly overlapping mental representations of one another, and may confuse cognitions about a close other with cognitions about the self. The research on perspective-taking (Galinsky and Moskowitz 2000) demonstrates that perspective-taking may cause subjects to include mental representations of the target or target’s group in their evaluations of themselves, leading subjects to evaluate themselves more in line with the perceived attributes of the target or target’s group. Given that being embodied in an avatar may establish a close relationship between consumers and the avatar and enable them to take the perspective of the avatar, consumers, to the extent that they relate to the avatar, may view themselves as more in line with the avatar. That is, the shift in self-concept and change in behavior are moderated by the extent to which consumers identify with the avatar.

Finally, prior research has shown that people often are unaware of their mental processes and fail to realize external influences on their behaviors (Bargh 2002). In the context of avatar embodiment, consumers may not be consciously aware that they are identifying themselves with the avatar and incorporating the avatar’s attributes into themselves. When, however, their identification with the avatar is made salient, consumers are likely to become aware of the influence of avatar embodiment and correct for it in their decision making.

To test our hypotheses, we developed two avatars that were identical in all aspects except the clothing. The first avatar (hereafter BizPerson) was dressed in business attire, whereas the second (hereafter Surfer) was dressed in surfer style. A pretest established

that the avatars were perceived to be equally likable but significantly different on the images they projected.

In Experiment 1, participants were randomly assigned according to a 2 (avatar type: BizPerson vs. Surfer) x 2 (identification level: high vs. low) between-subject factorial design. Those in the high-identification condition (1) customized their avatar using a collection of business (surfer) style clothing items and (2) saw how the avatar looked using virtual mirrors. Through a yoked design, participants in the low-identification condition received avatars customized by those in the high condition. Embodied in their avatar, participants explored a virtual photo gallery, and then reported their self-concept and rated four photographs that were pretested to be congruent with the image of the Surfer. We found that, under the high-identification condition, participants’ working self-concept shifted towards the projected image of the avatar they were embodied in; moreover, in comparison with those embodied in the BizPerson avatar, participants using the Surfer gave significantly higher ratings for the target photographs. When identification is low, however, we neither observed any significant differences in self-concept between the two avatar conditions, nor see any significant differences in the ratings of the target photographs.

In Experiment 2, we used a 2 (avatar type: BizPerson vs. Surfer) x 2 (identification awareness: before vs. after completing the dependent measures) between-subject factorial design. Those in the “before” awareness condition answered, prior to the dependent measures, a set of questions regarding the extent to which they identified with the avatar. The opposite was true for those in the “after” condition. The experimental procedure was identical to that of Experiment 1 except that (1) all participants customized their avatar, (2) we unobtrusively recorded participants’ behavior in the virtual world and coded the amount of time they spent on the photographs, and (3) participants were also asked to experience a virtual vehicle that was modeled after a stereotypical surfer van. We found that those embodied in the Surfer avatar spent significantly more time looking at the target photos, and, when not made aware of their identification, rated the virtual van and its brand significantly higher.

Overall, the results of our experiments provided support for our hypotheses: when participants identified with their avatar, they formed self-conceptions consistent with the image of their avatar and had higher evaluations of the product congruent with the avatar. Moreover, the embodiment experience influenced behavior through a predominantly unconscious process. We are currently running additional experiments, aiming to show that the effects of avatar embodiment persist across worlds and can impact consumer decision making in the real world.

“The Role of Context and Content on Recognition Accuracy in Virtual Worlds”

Francesco Massara, *IULM University, Italy*
Thomas Novak, *University of California, USA*

Virtual worlds such as Second Life, There.com and Blue Mars are three-dimensional, visually compelling, interactive environments inhabited by avatar representations of real world consumers. Such virtual worlds are beginning to be leveraged as platforms for consumer and marketing research (Novak 2010). An important

question is the degree to which behavior occurring within virtual worlds is unique and different from behavior occurring outside the context of virtual worlds. For example, Bell, Castronova and Wagner (2009) have argued that research studies fielded within the context of a virtual world, rather than in an external context such as Web-based survey, prevent a break in immersion that might interfere with accurate recall of the virtual world environment. In general, however, there has been no formal consideration of how context (virtual world vs. Web survey) may interact with the form of information content (visual vs. text), and how the relationship of context and content may vary for different user tasks.

We consider distinctive aspects of virtual worlds for recognition tasks, for visual vs. text stimuli. As highly visual environments, virtual worlds are more likely to induce imagery processing, while Web browsers are more likely to induce discursive processing. When considering target stimuli that are either visual or text-based, this raises the question of whether a match or mismatch of context and content (i.e. assimilation or contrast effects) would be expected in recognition tasks.

We address this question in a series of three studies. Our first study, together with an extensive set of pretests, has been completed and uses a signal detection task (SDT) designed as a low elaboration recognition manipulation involving the shallow encoding of information. Hypotheses for our first study, with brief rationales, are as follows. H1. Recognition accuracy for visual stimuli will be greater than for text stimuli (the often demonstrated “picture superiority effect”). H2. Greater signal strength leads to greater recognition accuracy (at short exposure times there is not sufficient time to encode the information properly). H3. There will be an interaction of content and context. Response accuracy on stimulus recognition is higher for a text (visual) stimulus in a virtual world (web based) environment, and is lower for a text (visual) stimulus in a web based (virtual world) environment. (In virtual worlds the imagery processing system is used to process the context, so the alternative discursive system has greater resources for encoding the stimuli, leading to superior results for text. The reverse is true in Web based environments.) H4a: The interaction of content and context in H3 will be significant at high levels of signal strength (greater time is available for encoding). H4b: The interaction of content and context in H3 will be nonsignificant at low levels of signal strength (insufficient time is available for encoding).

In a 2x2x2 design we 1) administered an SDT either within the context of a virtual world (Second Life) or a Web browser, where we 2) presented a slideshow of either 40 visual or 40 text-based stimuli, where 3) signal strength was manipulated by presenting stimuli at relatively short (500ms, the shortest presentation time feasible in Second Life) or long (1500ms) exposure durations. After the slideshow, a second series of 40 stimuli was shown (20 that were presented before and 20 new) and respondents were asked to indicate if they recognized the stimuli from the first slideshow. Our primary dependent measure from this SDT was *b*, decisional criterion or bias, which is sensitive to content/context manipulations and which can be interpreted as the likelihood of good memories with respect to false memories. An additional dependent measure was *d'*, which indicates the sensitivity of the respondent in recognizing previous information.

A total of 256 respondents completed Study 1. H1 was supported for sensitivity *d'* ($p < .001$) but not bias *b*, so that subjects were more sensitive towards pictures but not more accurate in recognizing them. H2 was supported for both sensitivity *d'* ($p < .01$) and bias *b* ($p < .01$) so that higher signal strength lead to greater recognition accuracy. For H3 we found supporting significant two-way interac-

tions between context and content on both sensitivity *d'* ($p < .01$) and bias *b* ($p < .05$). As predicted, means for *b* were higher in the virtual world context for text ($M = 1.75$) than for pictures ($M = 1.45$), while means were higher in the Web condition for pictures ($M = 1.61$) than for text ($M = 1.20$). H4a and H4b are supported in that the three way interaction was significant for bias *b* ($p < .05$). Further, at high (low) levels of signal strength the simple interaction effect of context and content was significant (not significant).

Thus, Study 1 demonstrates a contrast effect whereby text stimuli are recognized more accurately in virtual worlds, but visual stimuli are recognized more accurately in Web browsers. Mismatch between context and content improves recognition accuracy. Our second study will employ a manipulation requiring a deeper encoding of the stimuli, and hypothesizes an opposite interaction whereby an assimilation effect (i.e. match) improves recognition accuracy. Our third study will show pairs of matched pictures and text (semantic coherence) or mismatched pictures and text (semantic incoherence) to test the hypothesis that a contrast effect will be observed in the mismatched condition, but not in the matched condition. Together, this set of studies has important implications for response accuracy in contexts that vary in imagery vs. discursive processing, as well as the recall of marketing communications in virtual world vs. Web contexts.

“Trust among the Avatars: Playing Trust Games in a Virtual World, with and without Textual and Visual Cues”

Stephen Atlas, Columbia University, USA

Louis Putterman, Brown University, USA

As experimentalists explore the potential of virtual worlds to provide a low-cost medium to study a diverse pool of subjects, exploration of established behavioral phenomena “in-world” provides value by both validating theory and establishing consistency of social norms across platforms. This investigation replicated the original Trust Game (Berg, Dickhaut and McCabe, 1995) paradigm (hereinafter BDM) in the virtual world, Second Life, with compensation comparable to “in-world” wages that are far below those of physical labs. The results reveal that baseline trust and reciprocity in the virtual lab is comparable to that of physical labs, suggesting that pro-social motivations extend to anonymous interactions while embodied in an avatar. We further found that pro-social behaviors in virtual worlds are heavily influenced but not eliminated by verbal and visual contextual cues and, in apparent contradiction with economists’ expectations trust increases with age, employment and income among avatars.

Data was collected from 300 subjects from 39 countries. Among the first wave of in-world trust games, our lab is (to our knowledge) the first instance of a persistent economic experiment in a virtual world that eliminates interaction with the experimenter by automating recruitment, instruction, measurement and compensation. Further, this experiment appears to be unique in using payoffs commensurate with earnings from in-world jobs. As in-world wages are approximately one twentieth of the self-reported wage from real-world employment (55% of our subjects report holding a job in Second Life with hourly wages averaging L\$170 per hour, corresponding with USD\$0.65 per hour), we paid subjects a tenth of the amount paid by Fiedler et al. (in press) and by Chesney et al. (2009) without threatening incentive compatibility. Though subjects earned an average of L\$177 (66 cents) for twenty minutes of involvement, 88% of respondents stated that the prospect of earning Lindens was “very important” or “moderately important” for their participation in the study.

The baseline treatment replicated the BDM trust game design. Subjects were endowed with L\$100 (38 cents) and randomly as-

signed to be a first-mover or second-mover. The first decision maker chose to send an amount from their endowment; that amount was tripled and given to the second mover. This amount was in addition to their initial endowment, which is anonymously given to rule out a first-mover fairness motivation; (see Cox, 2004, for a review of this confound). The second mover could then anonymously send an amount to the first mover up to the tripled amount received. Equilibrium play assuming common knowledge of rationality and self-interested preferences is for the second mover to send nothing and, expecting this, the first mover sends nothing. In contrast, BDM and many replications reveal that a majority of first-movers and second-movers receiving money send positive amounts, a result widely interpreted as evidence of efficiency-enhancing social preferences wherein the first-movers trust and the second-movers exhibit reciprocity.

Evolutionary psychologists hold that social preferences are determined by innate predispositions that respond to environmental triggers (see Buss, 2008, for a review). One example is provided by Bateson, Nettle and Roberts (2006), who found that honor system payments were three times higher when the price list contained an image of human eyes than when it contained flowers. In this vein, we explored how virtual environmental stimuli influence trust and reciprocity through the inclusion of visual and verbal treatments. The visual treatments added optimistic and cautionary images to the baseline lab environment, while the textual treatments respectively added a cooperative and a competitive line to the instructions. To explore whether the visual and textual cues were mutually reinforcing, we also included treatments including the optimistic with cooperative cues and cautionary with competitive cues.

The baseline results reveal that first-movers sent on average 51.8% of their endowment, a finding remarkably similar to BDM (51.6%) and other replications in virtual and real labs. The smaller stakes, a more diverse subject pool and virtual environment in this case did not appear to impact average first-mover sending behavior. Mann-Whitney tests reveal that the differences within verbal treatments and visual treatments are each economically meaningful (close to a quarter of the total endowment size) and statistically significant ($p < 0.05$). The combined treatments were not significantly different from the separated treatment effects. The second movers in the baseline treatment returned roughly half (50.7%) of the tripled amount received. This is considerably higher than the 33.3% necessary to make first-movers break even, higher than the 29.8% in BDM. Raw second-mover sending was predicted by treatment, but these effects disappeared after controlling for first-mover sending, indicating that the treatments did not influence reciprocity beyond its influence on trust.

The social preferences revealed by second-mover decisions resulted in a 42% return on trusting for the first-movers and in our virtual lab, trust facilitated a Pareto-superior allocation to the endowment. Our results highlight the potential advantages of experimentation in virtual worlds, including the potential to motivate subjects with lower incentives and to test the robustness of theories in an unconventional domain. Our experiment affirmed results from a brick-and-mortar laboratory setting and strongly support the notion that, social behaviors in virtual worlds, like the real world, are responsive to environmental cues.

When is Disfluency Desirable? The Effects of Metacognitive Effort on Product Evaluations and Forecasting Behavior

Elise Chandon Ince, Virginia Tech, USA

Debora V. Thompson, Georgetown University, USA

EXTENDED ABSTRACT

“If it’s Hard to Read, It’s Worth It: When Metacognitive Effort Enhances Product Value”

Debora V. Thompson, Georgetown University, USA

Elise Chandon Ince, Virginia Tech, USA

Extensive research demonstrates that people’s attitude toward a product becomes less favorable when product information is hard to process. Song and Schwarz (2008) showed that people misread the difficulty of reading a description of a target behavior as indicative of the difficulty of executing it. For instance, lowering the processing fluency of a description of an exercise routine or a cooking recipe significantly increased perceptions of required effort and skill and decreased one’s willingness to engage in these tasks. Recent research (Pocheptsova, Labroo, and Dhar 2010) shows that in the context of special-occasion products, disfluency increases product attractiveness by making it appear unique or uncommon. Building on this research, we propose that disfluency has a positive effect on consumers’ evaluative judgments in domains in which skill is an important driver of value. Consumers frequently hire professional agents or contract services because of their specialized skills and expertise. In such contexts, will product valuations increase when processing is less (rather than more) fluent? We examine this hypothesis in two studies.

In study 1, fifty-eight students were randomly assigned to either a low or high fluency condition. All participants were presented with a description of a service that helps students apply to graduate programs. After reading the information, participants provided their evaluations of the target service. Processing fluency was manipulated via background contrast (light blue font vs. black font). As expected, participants in the low fluency condition rated the service description as more difficult to read than participants in the high fluency condition. More interestingly, those in the low fluency condition reported higher willingness to pay (\$191.2 vs. \$76.4) for a one-subscription ($F(1, 56)=3.7, p=.058$), and perceived greater value in the target service (5.0 vs. 4.1) than those in the high fluency condition ($F(1, 56)=6.9, p<.05$). Lowering processing fluency increased participants’ perceptions of how much expertise the target service provided. Notably, expertise ratings were a significant predictor of perceived service value ($\beta=.47, p<.01$).

Recent research indicates that disfluent stimuli are perceived as riskier because they are viewed as more novel/less familiar than fluent stimuli (Song and Schwarz, 2009). Thus, in study 2, we predicted that when an avoidance goal is made salient, disfluency will reduce consumers’ valuations, despite its positive effect on skill inferences. One hundred and nine undergraduate students were randomly assigned to a 2 (goal: approach vs. avoidance) x 2 fluency (high vs. low) between subjects design. Participants were asked to imagine that they had relatives coming to visit and that they were searching for a restaurant for dinner on a Saturday evening. In the approach goal condition, participants read that they could be adventurous in their restaurant choice, as their relatives like trying new things. In contrast, in the avoidance goal condition, participants read that they should be conservative in their restaurant choice, as their relatives avoid trying new things. All participants then read a description of a local restaurant. The manipulation

of processing fluency was the same as in study 1. As expected, there was a significant goal by fluency interaction on participants’ likelihood to select the restaurant ($F(1, 104)=8.3, p<.01$). While in the approach goal condition disfluency enhanced evaluations of the restaurant; this effect was reversed in the avoidance condition. Moreover, those in the low fluency condition expected the restaurant’s chef to be more skilled ($F(1, 104)=3.9, p=.05$), and the restaurant to be more novel/less conventional than those in the high fluency condition ($F(1, 104)=5.6, p<.05$). In the approach condition, ratings of the chef’s skills were a significant positive predictor of restaurant evaluations ($\beta=.41, p<.01$). In contrast, when avoidance goals were made salient, perceived novelty was a negative predictor of restaurant evaluations ($\beta=-.27, p<.07$), while the effect of perceived skill became nonsignificant ($\beta=.41, p<.01$).

A third study will test whether the positive effect of disfluency extends to domains in which convenience, rather than skill, is the primary benefit sought by consumers (e.g., home cleaning, laundry services, etc). We expect consumers’ willingness to pay for such products or services to increase when they are described in a less fluent manner because of consumers’ naïve theories about the amount of effort that is required to perform them. Overall, our findings point out to a different consumption domain in which experiences of disfluency can enhance consumers’ evaluative responses.

“Is What You Feel What They See?”

Ted Matherly, University of Maryland, USA

Anastasiya Pocheptsova, University of Maryland, USA

People frequently use products to express their identity and infer the identities of others. In this paper, building on the body of research on subjective experiences, we propose that people will use feelings of ease or difficulty of information processing when evaluating products that signal in-group or out-group identities.

A body of research on subjective experiences shows that these experiences can serve as information for decision-making, and that the interpretation of such experiences is context dependent. Ease of processing (fluency) is often interpreted to mean that a product is familiar, more common, and this perception leads to increased liking (Schwarz 2004). Recent research also illustrates that less fluent products are seen as less common and more unique. This leads to a preference for these products in consumption domains where uniqueness adds to the perceived value, such as special occasion goods (Pocheptsova, Labroo and Dhar 2010). Applying these findings to the context of identity signaling, we propose that less fluent products will be seen as better signals of identity compared to more fluent ones. People often use products to communicate about themselves to others. To ensure that these exchanges are effective, signaling products must effectively associate users with other people who have the same identity, as well as differentiate them from outsiders (Berger and Heath 2007). We propose that less fluent products will be more effective signals when one tries to differentiate an in-group from other groups, as low fluency would indicate that the product is less common and more unique.

In our first study, we tested the effect of fluency on the perception of signaling quality of a product. Participants imagined they were buying a t-shirt that was described as being very popular on their campus. Participants were presented with either a low or

high fluency t-shirt, and rated its signaling quality of either a low or high fluency t-shirt. In addition, half of the participants read a short article describing their university's success in a sporting event against a rival school. This was designed to get participants to focus on associating with their university community rather than differentiating themselves from others. Consistent with our predictions, we find that the low fluency t-shirt was viewed as a better signal of one's identity compared to the high fluency t-shirt. However, when participants were motivated to identify with their university, they focused on the common usage of the product among group members, and fluency did not affect the perceptions of the signaling quality of the product.

The second study addresses the extent to which the desire to differentiate the self from others demonstrated in the first study affects the perception of processing ease or difficulty of signaling products. In this study, participants were shown an advertisement for a coffee mug that was described as popular among an in-group (their campus), an out-group (a rival school), or was generally popular (control). Consistent with the results of study 1, participants viewed the in-group mug advertisement as less fluent compared to the out-group and control conditions. This suggests that the perception of self-relevant identities as being more unique can carry over to affect perceptions of signaling products. Moreover, no significant difference in perceived fluency between the out-group and control conditions implies that the results were not driven by a desire to denigrate a disliked out-group, but instead were influenced by the participants' views of signals of their own identity.

By showing the role that fluency can play in identity communication, this research is the first to our knowledge to connect these two lines of research. Our results suggest that low fluency products are perceived as better identity signals because they are more unique and thus more effective in differentiating members from non-members. Further, peoples' beliefs about their uniqueness may carry over to affect their perceptions of the fluency of products that signal their identity.

"Choice Difficulty Moderates Inferences about Preference Generalizability"

Mary Steffel, University of Florida, USA

Chris Janiszewski, University of Florida, USA

Daniel M. Oppenheimer, Princeton University, USA

Consumers may often draw upon choices as a source of information for gauging their preferences. Self-perception theory posits that people learn about their preferences by observing their own behavior (Bem, 1972). More recently, Bodner and Prelec (2003) have argued that people's choices signal something about their traits and dispositions to themselves and others.

Although the impact of choices on self inferences is well-documented, relatively little is known about the impact of the metacognitive experiences that accompany those choices. The present research explores how the metacognitive experience of choice difficulty impacts the inferences people make about the generalizability of their preferences. Holding all else constant, people who easily prefer one option to another are likely to have a stronger underlying preference for the features of the chosen option and are more likely to make similar choices in the future than people who struggle with the decision. Decision-makers who are asked to predict the likelihood that they will make similar choices in the future are likely to focus on extracting what information choice difficulty provides about their underlying preferences. They are likely to infer that the easier a choice feels, the stronger their underlying preferences, and the more likely they are to choose similar options in the future.

When choices feel difficult, decision-makers may infer that their underlying preference is weaker and that they are less likely to make similar choices in the future. The metacognitive experience when choices are difficult is likely to include competing emotions, preferences, motives, and values. Making salient a person's multiple motives and values may cast doubt on any one unified set of decision rules, set competing expectations for future behavior, and lead decision-makers to discount the diagnosticity of a particular choice for predicting their future choices. This may lead decision-makers to make less extreme predictions about their future behavior.

The inferences that people draw from choice difficulty are likely to be bounded by the perceived relevance of the current choice to choices in other domains, situations, or contexts. Thus, the inferences people draw may often be domain-specific. Additionally, the inferences people draw from choice difficulty may be limited to self versus social inferences. Observers do not have direct access to a decision-maker's feelings of choice difficulty and cannot be sure whether their own feelings of choice difficulty are representative of the individual whose preferences they are assessing. Observers, therefore, may place less diagnostic weight on choice difficulty as a cue for assessing a decision-maker's underlying preferences and predicting that person's behavior.

Study 1 examined the extent to which people would generalize their risk preferences from easy or difficult choices between low- and high-risk lotteries. Participants made a series of choices between lotteries that were constructed so that the low-risk options were always chosen. Choice difficulty was manipulated via relative attractiveness (i.e. the difference in relative value between the lotteries). Generalization was measured by asking participants to rate the likelihood that they would engage in risky behaviors in gambling, investment, and health/safety domains using the domain-specific risk attitude scale (Weber, Blais, & Betz, 2002). Participants rated themselves less likely to gamble at a casino, in a poker game, at a horse race, or at a sporting event when choices were easy than when they were difficult. Generalization was domain specific—choice difficulty did not impact the inferences participants made about their risk preferences in the investment or health/safety domains. This finding suggests that the inferences drawn from choices have to do with the specific content of those choices and the perceived relevance of that content to other domains, situations, or contexts. To explore whether preference generalization was limited to self versus social judgments, observers were instructed to review a previous participant's choices and predict the likelihood that the person would engage in risky behaviors in each of the three domains. Observers drew weaker inferences than did the decision-makers themselves. Furthermore, observers did not draw different inferences from easy choices versus difficult choices.

Study 2 utilized a fluency manipulation to vary choice difficulty while holding constant the actual relative value of the choice options. Fluency was manipulated by presenting choice options in an easy-to-read or difficult-to-read font. As in Study 1, decision-makers drew stronger inferences about their gambling risk preferences from easy choices than hard choices. These inferences were domain-specific and did not extend to social judgments.

Together, these studies show that people make less extreme generalizations about their preferences when choices feel difficult versus easy. Although easy choices engender confidence that similar options will be chosen in the future, this confidence may often be undiagnostic of actual choice behavior. Implications for accurately assessing preferences and predicting behavior will be discussed.

“Debiasing Effect of Fluency on Linear Trend Prediction”

Julie Huang, Yale University, USA

Hyunjin Song, Yale University, USA

John Bargh, Yale University, USA

The assessment of future potential—that is, whether a certain event or characteristic will develop, continue, or stop over time—is a fundamental part of everyday judgments. For instance, people predict whether economic growth rates will continue or crash before they invest in the stock market, and employers predict whether a promising job candidate’s career will continue to rise or eventually cease. Previous research has shown that people from Western cultures tend to predict that linear trends will continue into the future rather than change direction (Ji, Nisbett, & Su, 2001). The present research suggests processing disfluency can attenuate this heuristic by disturbing the feeling of momentum.

Processing fluency is the metacognitive experience of ease or difficulty associated with processing information and can be affected by incidental variables such as exposure duration, high or low figure-ground contrast, and easy or difficult-to-read fonts. Recent research identifies *simulation* as a mechanism underlying fluency effects. When people process information, they oftentimes mentally simulate the content; the nature of this simulation influences their subsequent judgments. For instance, people predict a task will require more time when the instructions are printed in difficult-to-read font than in easy-to-read font, presumably because simulation requires more time for the former (Song & Schwarz, 2008). Moreover, fluency increases liking for repeatedly presented stimuli (Zajonc, 1980); but blocking simulation of the presented oral stimuli (words) by chewing gum actually attenuates this traditional fluency effect (Topolinski & Strack, 2009).

These results suggest that judgments regarding a trend can be influenced by fluency. When people process information about a trend, fluency may lead to faster simulation of the trajectory, feeding the sensation of momentum, whereas disfluency may disrupt simulation and contribute to feelings of discontinuation. Therefore, we predicted that fluent processing of a trend will increase judgments that the trend will continue into the future. Specifically, we hypothesized that people who read descriptions of increasing or decreasing trends in easy-to-read font would be more likely to predict that the trend would continue into the future, compared to people exposed to difficult-to-read font.

In study 1, one-hundred thirty participants read a passage about a psychology professor’s career trajectory from graduate student to assistant professor, including funding information. In each stage of his career he received one more grant. This vignette was presented in either an easy-to-read font (Arial) or a difficult-to-read font (Mistral). Afterwards, participants answered a question regarding career trend continuation, specifically, whether the professor would receive more grants in his next career stage (1=Not at all likely; 8=Very likely). An independent samples t-test revealed that participants who read the passage in an easy-to-read font predicted that the professor was more likely to continue getting more grants in his next career phase ($M=7.08$, $SD=1.56$), compared to participants who read the passage in a difficult-to-read font ($M=6.14$, $SD=1.82$), $t(126)=3.12$, $p\text{ rep}=.98$, $d=.56$.

Study 1 suggests that processing fluency increases people’s predictions that a trend will continue into the future. It could be argued, however, that processing fluency elicits positive affect (Zajonc, 1980), which results in a general positive: in this case, perceptions of a better career. To rule out this alternative hypothesis, Study 2 featured a decreasing career trajectory. Since decreasing career trends are negative in nature, if fluency increases judgments that negative career trends are more likely to continue, this will

demonstrate that the effect is not merely driven by mood. In Study 2, one-hundred thirty-two participants read about a professor’s career in either easy-to-read font (Arial) or difficult-to-read font (Mistral). In this version, however, the professor first received six grants and in each successive career stage, he received one fewer grant. Participants rated the likelihood that the professor would continue to receive fewer grants (using the same response scale from Study 1). Replicating the results from Study 1, we found that participants who read the passage in an easy-to-read font predicted that the professor would receive fewer grants in the future ($M=5.14$, $SD=1.65$) compared to participants who read a difficult-to-read font ($M=4.55$, $SD=1.58$), $t(126)=2.07$, $p\text{ rep}=.89$, $d=.37$.

Two studies suggest that processing fluency influences people’s perceptions of whether a trend will continue into the future. Every day, people derive predictions about the future across many domains including sports statistics, medical reports, weather patterns, and market performance. Varying the presentation of these materials through print clarity, background noise, or repeated exposure to news reports may influence public opinion regarding the future direction of a trend. Additional research may address these possibilities.

Expensive or Cheap? Reference Prices and Consumer Perception of Value

Aaron Brough, Northwestern University, USA

EXTENDED ABSTRACTS**“When Does Expensive Food Taste Better? Top-Down and Bottom-Up Processing in Price-Quality Inferences”***Manoj Thomas, Cornell University, USA**Vicki G. Morwitz, New York University, USA**Leonard Lodish, University of Pennsylvania, USA**Jin Seok Pyone, Cornell University, USA*

It is widely accepted that price influences consumers' responses to marketplace offerings in two distinct ways. Price not only serves as a measure of economic sacrifice, but also influences consumers' inferences about the quality of the product. However, research has shown that the relationship between price and perceived quality is inconsistent; consumers sometimes consider a higher price as a signal of better quality, and sometimes do not. Several influential papers have presented different perspectives on when and why consumers use price as a signal of quality. The present research extends this body of work by suggesting that whether consumers use price as a signal of quality is contingent on the type of cognitive process they rely on to make inferences. We show that consumers tend to rely on two distinct types of cognitive processes to make inferences about quality: a top-down process based on prototype resemblance or a bottom-up process based on their belief about the correlation between price and quality. Under conditions of top-down processing, consumers begin with the representation of a prototypical high quality product in their mind, and make spontaneous inferences by comparing the new product to this mental prototype. Usually, a prototypical high quality product has a conjunction of positive attributes (i.e., attributes that are associated with high quality). Therefore, when the new product has a conjunction of positive attributes and thus resembles the prototype, they infer that the new product will have the same quality as the prototype and this spontaneous inference makes them more likely to consider a higher price as an indicator of better quality. Conversely, when the new product has one or more negative attributes and thus does not resemble the prototype, they do not consider a higher price as an indicator of better quality. Even when the new product has a higher price, they infer that since the new product does not resemble the prototype it will not have the same quality as the prototype. We refer to the tendency to inconsistently interpret price based on top-down processing as the prototype resemblance effect in price-quality inferences. Interestingly, this prototype resemblance effect does not manifest when inferences are based on bottom-up processing (i.e., based on their belief about the correlation between price and quality.)

As an illustrative example, consider the example of a consumer who is trying to infer the quality of food at two new restaurants in her city. Both restaurants have unimpressive decor. However, they differ on price. A typical meal at one of the restaurants costs \$25 while at the other restaurant it costs \$12. Will she consider the higher priced restaurant to have better quality food than the lower priced one, given that both restaurants have unimpressive decor? This consumers' inference will be contingent on the type of cognitive process she relies on to make the inference. If she relies on top-down processing, she will infer that the expensive restaurant will not have better quality food because it has unimpressive decor and thus does not resemble a prototypical high quality restaurant. In contrast, if she relies on bottom-up processing, she will infer

that the expensive restaurant will have better food because price is positively correlated with quality.

Three experiments and a field study were conducted to examine the role of top-down and bottom-up processing in quality inferences. The studies presented in this article characterize how the activation of prototypes influences price-quality inferences. Although there is a rich literature on the role of prototype-based processing in consumer behavior (see Loken, Barsalou and Joiner 2007 for a recent review), and some researchers have examined the role of knowledge and beliefs in quality inferences (Baumgartner 1995; Kardes et al. 2004; Rao and Monroe 1988), we are not aware of any research that specifically examined the effects of prototype activation on price-quality inferences. The present research aims to remedy this omission. We address three specific questions in this research: (i) What is the structure of mental prototypes used in quality inferences (Study 1)? (ii) How do these prototypes influence consumers' interpretation of price (Study 2)? (iii) How do top-down prototype based inferences differ from inferences that are based on beliefs about the correlation between price and quality (Study 3)? We use response time data to examine whether consumers actually rely on their price-quality beliefs to make quality inferences. We show that participants' response times are influenced by prototype resemblance, but not by their price-quality beliefs. To the best of our knowledge, none of the previous studies have examined the patterns in response times and its implications for the theories of price-quality inferences. Further, we use data collected outside laboratory settings to empirically test which of the two modes of inferences is more pervasive in everyday quality inferences—the top-down process based on prototype resemblance or the bottom-up process based on beliefs about the correlation between price and quality. We analyze consumers' food quality ratings of 1,620 restaurants, and find that the dominant propensity is to rely on prototype resemblance. Finally, this study also contributes to the small but growing body of literature which suggests that a high price can play the role of a placebo and unconsciously influence consumers' actual product experiences (see Rao 2005; Shiv, Carmon, and Ariely 2005). The results from our field study, together with findings from placebo effect research (Shiv, Carmon, and Ariely 2005), suggest that when a restaurant with good décor charges a higher menu price, a consumer might actually experience the food to be of better quality. But when similar food at the same price is offered by a restaurant with mediocre décor, the consumer's experience might not be so favorable.

"When Payless Meets Prada: Subtractive Judgments in Evaluating Product Bundles"

Aaron R. Brough, *Northwestern University, USA*

Alexander Chernev, *Northwestern University, USA*

Consumers often encounter combinations that include products from different price tiers. For example, retailers and manufacturers commonly bundle high- and low-priced products together, such as a computer with a printer or a sofa with an ottoman. Additionally, some combinations are formed coincidentally, such as when consumers place items from different price tiers into a shopping basket or purchase them in the same shopping episode. Despite its importance, the notion of how consumers determine their willingness to pay (WTP) for combinations is not well-understood.

Logically, estimating a bundle's overall value should involve adding the subjective value of each individual item. Some research assumes that bundle valuation is perfectly additive, such that WTP for a bundle is equal to the sum of WTP for its individual components (Bitran and Ferrer 2007). Empirical evidence shows that, in fact, WTP is often subadditive, such that the value of two items is discounted when they are evaluated together rather than separately (Cooke & Pecheux; Heeler et al. 2007). Regardless of the magnitude of this discount, conventional wisdom would suggest that the value of the bundle should be higher than the value of any individual item in the combination.

In contrast to prior literature documenting bundle valuation that is perfectly additive or subadditive, we identify conditions in which it is instead subtractive. That is, we show cases in which WTP for a combination is less than WTP for a single item in the combination, despite the fact that when evaluated individually, each item in the combination has positive utility for consumers. In addition, we propose a novel explanation for this subtraction effect and show that it cannot be explained by consumer expectations for quantity discounts or inferences that one of the bundle components is low-quality.

We argue that adding an inexpensive item to an expensive item decreases rather than increases WTP for the offering because of categorization. In particular, we argue that when items classified into opposite categories (e.g., expensive vs. inexpensive) are combined, the combination is perceived to be less extreme than its components (e.g., moderately expensive). Relying on this overall impression of the combination, individuals assign a lower numeric value to the combination than to the expensive item when articulating WTP. As a result, WTP for the combination is lower than WTP for the expensive item alone, despite the combination's objectively greater value.

We conducted four experiments to document the subtraction effect and examine its antecedents and consequences. Study 1 tests the proposition that individuals are less willing to pay for an expensive item when it is combined with an inexpensive item rather than evaluated alone. Across six product categories, online participants evaluated either an expensive item alone, an inexpensive item alone, or a combination that included the same expensive and inexpensive items presented to participants in the first two conditions. Results demonstrate the subtraction effect by showing that WTP for the

combination was lower than WTP for the expensive option alone in each of the six categories, as well as overall across categories.

Study 2 examines the role of impression formation in the subtraction effect by comparing WTP for a combination when items are presented side-by-side but evaluated either individually or as a combination. In particular, it shows that neither quality inferences nor expectations for quantity discounts can fully account for the subtraction effect. We predict that the subtraction effect is more likely to be observed when consumers evaluate the combination as a whole rather than evaluating each component of the combination in piecemeal fashion. As expected, mean WTP across categories was lower for the combination (when the offering was evaluated holistically) than for the expensive option alone (when the offering was evaluated in piecemeal fashion).

Study 3 provides further evidence that categorization causes the subtraction effect by documenting that this effect is attenuated when people focus on other attributes, such as functionality, rather than price. This study was similar to study 1, but in order to prompt categorization on a dimension other than price, half of the participants answered a question about the functionality of each product prior to articulating WTP. For example, when evaluating luggage, some participants were asked to indicate the expected size of the luggage relative to an average brand. As predicted, the subtraction effect was attenuated when participants focused on functionality rather than price.

Finally, Study 4 documents the role of categorization by showing that the subtraction effect is weaker when options are classified into the same category rather than opposite categories. We reason that introducing an extremely high reference price prior to evaluation should reduce the likelihood that expensive and inexpensive items are classified into opposite categories, since both items are likely to be perceived as inexpensive relative to the high reference price. Thus, participants estimated the likely price of a reference item prior to evaluating the target item(s) for each category. Reference items were selected such that participants would perceive the price to be relatively similar or extremely high compared to the prices of the target item(s). Consistent with our prediction, exposure to an extremely high reference price prior to evaluating the target option attenuated the subtraction effect.

Data from four studies offer converging support for the notion that adding an inexpensive item to an expensive one can decrease rather than increase the perceived value of an offering. This research has important managerial and theoretical implications. In particular, it suggests that bundling products from different price tiers may result in decreased revenue. Furthermore, it illuminates the role of categorization in value judgments, showing that changes in the qualitative classification of item(s) can impact numeric evaluation.

“The Effect of Shipping Fee Structure on Consumer Evaluations of Online Offers”

Nevena T. Koukova, *Lehigh University, USA*
 Joydeep Srivastava, *University of Maryland, USA*
 Martina Steul-Fischer, *University of Erlangen-Nuremberg, Germany*

Long Abstract. According to Forrester Research, online spending in the U. S. in 2008 was about \$141 billion and should reach \$156 billion in 2009. The growth in e-commerce as well as direct to consumer retailing has highlighted the importance of shipping fees. A critical decision is how to present these fees to consumers particularly when 30% of online shopping carts are abandoned due to shipping and handling surcharges (Jupiter Research 2006). Despite its importance to online and other direct retailers, only a few studies have examined the effects of shipping fees (cf. Lewis 2006; Lewis, Singh and Fay 2006; Schindler, Morrin and Bechwati 2005).

We investigate the effects of two common shipping fee structures—flat rate shipping and threshold based free shipping—on consumer evaluations of online offers. Drawing on the price partitioning literature (e.g., Hamilton and Srivastava 2008; Morwitz, Greenleaf and Johnson 1998), the basic premise is that separating the shipping fee from the product price makes the shipping fee more salient. Given that most evaluations are based on some standard of comparison (Kahneman and Tversky 1979), we propose that consumers use different referents to evaluate the shipping fees. Specifically, while the referent used to evaluate flat rate shipping is likely to be based on prior experience and/or knowledge and is somewhat imprecise, the natural referent used to evaluate threshold based free shipping is the possibility of free shipping that is more precise. A memory based referent requires more effort to access in the case of flat rate shipping whereas the stimulus based referent of free shipping in the case of threshold based free shipping is vivid and easily accessible. As such, given threshold based free shipping, order values below the threshold are coded as a loss whereas order values above the threshold are coded as a bonus or a quantity discount relative to the natural referent of free shipping. Our main prediction is that online offers will be evaluated less (more) favorably when the shipping structure is threshold based free shipping than flat rate shipping for order values below (above) the threshold for free shipping.

We report the results of five between-participants experiments which demonstrate that evaluations systematically vary as a function of shipping fee structure. Study 1a shows that compared with flat rate shipping, consumer evaluations are more favorable when an online offer has threshold based free shipping for order values above the threshold. The reverse is true for order values below the threshold for free shipping as the offer is evaluated less favorably with threshold based free shipping than with flat rate shipping. In addition, perceptions of shipping fee fairness mediate the effect of shipping fee structure and order value on offer evaluations. Study 1b demonstrates that the results are robust to the difference between order value and the threshold for free shipping. Specifically, consumer evaluations do not differ when the order value is just below the threshold (e.g., order value of \$19.99 relative to a \$25 threshold for free shipping) or significantly below the threshold (e.g., order value of \$19.99 relative to a \$75 threshold for free shipping).

Study 2 sheds more light on the underlying mechanism by examining the effect of shipping fee structure on consumer evaluations when an alternative referent is made salient. Our conceptualization suggests that making an alternative referent salient is likely to shift attention away from the shipping fee and reduce the reliance on the shipping fee referents, thus attenuating the effect of shipping fee structure on consumer evaluations. For example, an offer that

is presented as a 20% discount off the regular price is likely to alter the focus of attention from shipping fee to the price discount. Consistent with the proposed mechanism, study 2 demonstrates that the effects of shipping fee structure are similar to those in study 1 in the absence of an alternative referent. However, there is no difference in consumer evaluations across the threshold based free shipping and flat rate shipping structures in the presence of an alternative salient referent, regardless of order value. These results highlight the shift in attention from the shipping fee and the associated referents in each of the two shipping fee structures to the price discount when it is made salient. Importantly, we rule out positive affect as an alternative explanation for the results.

Another question that this research investigates is whether the shipping fee structure affects consumer perceptions of the extent to which retailers use shipping fees to generate profits. Study 3 demonstrates that while participants are more likely to believe that the retailer is making profit in the threshold based free shipping condition than in the flat rate shipping condition for order values below the threshold, the reverse is true for order values above the threshold. With a flat rate shipping structure, since all consumers have to pay for shipping regardless of order value, the shipping fee is more likely to be viewed as the actual cost that the retailer incurs for delivery. With a threshold based free shipping structure, in the presence of the referent of free shipping, consumers are likely to believe that the retailer is using the shipping fee to generate profits.

Study 4 examines whether providing a justification for shipping fee structure and linking the shipping fee to the actual cost of delivery moderates the effect on evaluations of online offers as well as perceptions of shipping fees as generating profits. The results suggest that consumer evaluations as well as perceptions of shipping fees as generating profits do not differ across the flat rate and threshold based free shipping structures for all order values when a justification for the shipping fee is provided. The justification for the shipping fee and linking it to actual cost of delivery encourages consumers to view the shipping fee as the cost of doing business rather than as a loss or that the retailer is trying to making money on the shipping fee.

“More than Just a Constraint: Budget Constraints Shape Preference”

Jeffrey Larson, *Brigham Young University, USA*
 Ryan Hamilton, *Emory University, USA*

No matter their income or net worth, consumer purchases are all constrained by finite resources. Few consumer decisions are not affected by budget constraints. Despite its omnipresence in consumer decision making, research on the role of budget constraints on consumer decisions has been surprisingly limited. Heath and Soll (1996) and Ulkumen, Thomas, and Morwitz (2008) both focus on the mechanics of consumer budget setting and budget estimation, but devote less attention to how budgets impact consumer decision making. Hauser and Urban (1986) examine budget planning and show how budget constraints influence consumers' desire to maximize “bang for the buck.”

While economists' notion of the hyper-rational agent has been sufficiently lambasted over the years, it is still universally accepted that consumers try to get the most for their money. While this effort is bound to be error-prone, consumers nevertheless attempt to assess the value of products relative to their price, and purchase the product that offers the most utility relative to the utility of the money exchanged. Extant theory posits that budget constraints should not play a role in the evaluation of a product's utility, but only in the evaluations of the relative price comparisons.

In contrast, we demonstrate that consumers' budget constraints affect even their evaluations of a product's desirability in two different ways. First, consumers tend to devalue products that are outside of their budget. Rather than recognizing that expensive products are superior to less expensive products (although perhaps not be worth the extra expense), consumers who are unable to afford a product convince themselves that expensive products are actually inferior. Second, consumers become sensitized to quality differences within the range of prices they are accustomed to shopping. For example, a woman accustomed to buying handbags in the price range of \$50 to \$100 would more readily notice the difference in quality between a \$75 and a \$95 handbag than between a \$150 and \$300 handbag.

To test our first proposition, we recruited 78 members of an online panel to participate in a study on product preferences. We told all participants to consider that they were planning to purchase an iPod nano™ to exercise with. Participants were told that they had budgeted \$170 for the purchase and had narrowed the decision down to one of two options—one with 8 GB storage for \$133.99 or one with 16 GB storage for \$159.95. They evaluated the desirability of each iPod nano on a 0 to 100 sliding scale and made a selection. In their evaluations of the products (in this and the following evaluations), they were asked to ignore price and only evaluate the product's desirability. After making this decision, participants were then told that they also wanted to purchase an armband to hold their iPod during exercise. Of course, their remaining budget for this decision depended on their previous iPod selection. Those who had selected the 8 GB nano had \$36.01 remaining in their budget, while those who had selected the 16 GB nano had only \$10.05 of their original budget remaining. The two armbands offered cost either \$17.95 or \$6.80. Thus, participants either had enough money in their budget for both or only for one of them. We hypothesized that those with only \$10.05 would devalue the more expensive armband. Consistent with our prediction, the group with enough money remaining for either armband gave the cheaper armband an average rating of 58.8 and the more expensive armband a 64.9. The limited budget group, on the other hand, rated the cheaper armband a 67.6 and the more expensive armband a 57.5. The average difference in the two ratings was significantly different ($p=.04$, one-tailed).

To test our second hypothesis, that consumers become sensitized to quality differences within their budget range, we recruited 131 participants from an online panel for a study on product evaluations. To begin the survey, we asked each participant to report the most they had ever spent on a product from each of 10 product categories. Participants were then asked to rate five products, labeled with their actual online retail price, from several of these categories. Participants were also asked to rate the quality of each product in the set on a 0 to 100 sliding scale. Each person made these ratings for five products from four different product categories. All participants rated surround sound systems, sunglasses, and watches (the sunglasses and watches shown were gender-matched). Men further rated golf clubs, while women rated a set of handbags.

We hypothesized that participants' quality ratings would be sensitized to their budget range. We determined each participant's budget range from the most they had spent on the product category. If \$100 was the most they had spent on a golf club, then their budget range must extend below and above \$100. This reference value was matched to two products from the five products each participant rated. For example, we showed male participants golf clubs (all drivers) priced at \$45, \$87, \$129, \$171, and \$213. A person who has spent at most \$100 on a golf club should be sensitized to the difference between the \$87 and \$129 golf club such that the difference in quality between these two golf clubs is higher than between other clubs. Therefore, we modeled difference in quality ratings between each product and the product just above it. As expected, participants were more sensitive to quality differences in their budget range than between other products. The average difference in quality rating was significantly higher between the two product near the budget reference than between other products ($p=.006$).

If consumers desire to get the most for their money, they need to be able to reliably evaluate products. Based on findings from this research, product evaluations seem to be at least partially determined by consumer budgets; a factor which could prevent some consumers from maximizing utility.

Strategic and Impulsive Allocation of Attention: Behavioral and Emotional Consequences

Suresh Ramanathan, University of Chicago, USA

EXTENDED ABSTRACTS**“Accentuate the Positive, Eliminate the Negative: Attention and Emotion Regulation”***Nicole M. Verrochi, University of Pennsylvania, USA**Patti Williams, University of Pennsylvania, USA*

Individuals frequently manage their emotions, such as during a sad television commercial, looking at a soothing picture in a waiting room, or avoiding a plate of cookies at a party. In marketing, there is growing interest in understanding these emotion regulation processes and which strategies consumers use in various situations. Research (e.g., Gross 1998) has proposed five classes of emotion regulation strategies: situation selection, situation modification, attention deployment, cognitive change, and response modulation. To date, the bulk of research has focused on cognitive change and response modulation (Gross and Levenson 1993), while newer work has explored situation selection (e.g., Andrade and Cohen 2007). While each of these papers contributes to a deeper understanding of emotion regulation and its psychological components, certain strategies remain under-investigated.

This paper investigates attention deployment, whereby individuals strategically shift their attention toward or away from emotional stimuli to manage emotional experiences. Two studies demonstrate that people use attention shifts when presented with emotional stimuli, and a third shows that these changes in attention influence the intensity of experienced emotion, supporting an attention-based emotion regulation strategy.

Two studies tested whether individuals use attention shifts to regulate emotions when they encounter emotional stimuli. To examine these strategic attention shifts, a novel paradigm was created combining attention measures with emotional experiences. Attention was indexed by participants' accuracy as they identified rapidly presented targets. These measures captured whether the individual was focusing closely on the target or diverting attention away from it. Thus, participants were asked across many iterations to indicate whether a letter “T” was presented either upside-down or right-side-up as quickly as possible (the “T task”). Intermixed with the “Ts”, participants were also exposed to a series of pictures. These pictures were from the International Affective Picture System (IAPS; Lang, Bradley and Cuthbert 2005), and reliably elicit emotional responses. The pictures appeared in the target location periodically throughout the study. Thus, if participants shift attention toward and away from emotional triggers, accuracy should change for the “Ts” which follow each emotional picture.

In the first study, participants were exposed to pictures that were positive (e.g., puppies) and negative (e.g., car crashes). Results showed that participants performed worse (lower accuracy) on the T task following negatively valenced emotional stimuli ($p < .001$). This suggests that individuals are diverting their attention away from the target when they encounter a negative stimulus, versus focusing their attention on the target when it was positive.

To test the influence of specific emotions on the efficacy of attention shifts, the second study involved a two-group design. The negative pictures were all either fearful (e.g., attacks) or sad (e.g., crying children) pictures. Research has shown differences between emotions of the same valence, such as fear and sadness; both are negative but fear is characterized by uncertainty and heuristic processing, while sadness is certain and engenders systematic

processing (Tiedens and Linton 2001). In the fear condition, attention was unchanged across emotional stimuli ($p > .25$), but in the sad condition, performance worsened after a negative (sad) versus positive picture—as in study 1 ($p < .01$). This would suggest that in the sad condition, participants are strategically shifting their attention away from negative stimuli. However, for fearful stimuli, attention seems to remain focused on the target, reducing the likelihood that an individual could shift attention away from fearful stimuli. The results from studies one and two suggest that individuals naturally use attention shifts when encountering emotional stimuli, however certain negative emotions (fear) may be resistant to an attention-based emotion regulation strategy.

These two studies support attention as a key moderator of emotional experience, but do not connect these shifts to emotional experience. The third study captured this effect. Participants watched an emotional video clip (sad, fearful) under attention instructions. Participants were told to either focus on the faces of the actors (directing attention toward emotional cues) or on set design (diverting attention away from emotional cues). By manipulating participants' attention, the study assessed whether diverting attention away from emotional cues (versus directing attention toward) would reduce the intensity of emotion. Results show that within the sad condition, participants who directed their attention toward emotional cues (faces) experienced higher levels of sadness ($M = 5.04$) than those who diverted attention away from emotional cues (scenes: $M = 3.69$, $p < .05$). This pattern supports the hypothesized function of attention: when attention is directed onto emotional cues the intensity of emotion increases, but when attention is diverted away from these cues intensity decreases. For ratings of fear, however, the attention manipulation was non-significant ($p > .20$).

These studies demonstrate that individuals shift their attention in response to emotional stimuli, and that changes in attention influence the experience of emotion. Additionally, these results identify specific emotions which are more or less susceptible to regulation via attention deployment—an important boundary condition. Taken together, these studies certify that attention can be used to effectively manage emotional experiences, suggesting new directions for emotion regulation and consumer research.

“Can We Help Consumers Make Healthier Food Choices? The Role of Product Associations”*Juliano Laran, University of Miami, USA**Marcus Cunha, University of Washington, USA*

It is lunch time and Mary heads to the fast food restaurant near her office. She was about to order the usual Combo # 1, featuring a chicken sandwich and fries, when she notices that the restaurant introduced a second option, Combo # 2. This option features the same chicken sandwich available in Combo # 1 and mixed greens salad. Mary likes fries and salad to the same extent, so what will determine whether she chooses Combo # 1 or Combo # 2? The choice might be explained by whether consumers feel they have made enough progress on a healthy eating goal recently (Fishbach & Dhar, 2005), by the amount of self-control resources available to consumers at the time of choice (Baumeister, Bratslavsky, Muraven, & Tice, 1998; Vohs & Faber, 2007), and by the most activated goal (i.e., healthy eating or indulgence) at the time of choice (Chartrand, Huber, Shiv, & Tanner, 2008)

Our research adds to the growing interest in understanding the role of presentation format on consumers' evaluations and choices of healthy vs. unhealthy food pairings (e.g., Fishbach & Zhang, 2008; Wilcox, Vallen, Block, & Fitzsimons, 2009). We propose that a mechanism of protection of associations can change the salience of each option in the scenario described above (Cunha, Janiszewski, & Laran, 2008; Kruschke, Kappenman, & Hetrick, 2005). We will show how this protection mechanism can contribute to understanding the process via which resources depletion and goal priming may operate as drivers of self control.

The Association Protection Mechanism. Consumers develop a large number of associations throughout their lifetime. For example, through repetition and co-occurrence, consumers learn that bacon and eggs, hamburger and Coke, tuna and mayonnaise go well together. Protecting these learned associations from interfering associations decreases cognitive costs and helps consumers more rapidly learn and adapt to their environment. The idea of protection of associations is grounded on attentional learning theory (Cunha et al., 2008; Cunha & Laran, 2009; Kruschke, 2001) and is predicted to occur when the cognitive system directs attention to information that can solve this potential conflict in the knowledge structure. Attention is then steered toward information that is useful in acquiring novel knowledge while still protecting prior knowledge.

For instance, when Mary first learned about Combo #1, featuring chicken sandwich and fries, there was no previous association between the food items and "Combo #1". Therefore, it is likely that both food items became associated with Combo # 1. When Mary became aware of Combo # 2, featuring chicken sandwich and salad, a conflict occurred (chicken sandwich partially defines Combo #1). Combo # 2 features a new food item (salad) that can facilitate the acquisition of new knowledge while preserving prior knowledge. Because reassessing and updating prior associations of Combo # 1 could be cognitively taxing, Mary can solve the conflict by simply shifting attention away from "chicken sandwich" and toward "salad" when presented with Combo # 2. As a result, "chicken sandwich" should become more strongly associated with Combo # 1 than with Combo # 2, whereas "salad" should become more strongly associated with Combo # 2 than "fries" are associated with Combo # 1. If Mary finds the chicken sandwich to be more desirable than the distinct items, she will judge Combo #1 to be more desirable overall. If she finds the distinct items to be more desirable than the chicken sandwich, she will judge Combo #2 to be more desirable overall.

The experiments involved the sequential presentation of food pairings followed by judgments of likelihood to consume each pairing. The sequential presentation was used to influence the strength of associations between food-items and their respective pairings. Study 1 shows that these associations may determine whether food choices are healthy or unhealthy. Study 2 shows that depleting consumers of their self-control resources affects their attentional capacity. As a consequence, we observe and amplification of the basic effect reported in Study 1. Study 3 and 4 show that the effect can be replicated using actual restaurant menus with a single exposure to the menus.

An important question stemming from our research is how policy makers and marketers can use our results? Policy makers can raise consumers' awareness of their tendency to protect associations so that they can more efficiently allocate attention when making choices with implications for consumer welfare. Legislators can also enforce that marketers design product displays, in a way that directs attention to specific options first, which will drive subsequent attention and choice.

"A Decision-Path Model of Attention and Consideration at the Point of Purchase"

Wesley Hutchinson, University of Pennsylvania, USA

Eric Bradlow, University of Pennsylvania, USA

Pierre Chandon, INSEAD, France

Consumer behavior at the point of purchase is influenced by out-of-store memory-based factors (e.g., brand awareness and brand image) and by in-store attention-based factors (e.g., position and number of facings). In today's cluttered retail environments, creating memory-based consumer pull is not enough; marketers must also create "visual lift" for their brands—that is, incremental consideration caused by in-store visual attention. The problem is that it is currently impossible to precisely measure visual lift. Surveys can easily be conducted to compare pre-store intentions and post-store choices but they do not measure attention. They cannot therefore tell whether ineffective in-store marketing was due to a poor attention-getting ability—"unseen and hence unsold"—or to a poor visual lift—"seen yet still unsold". Eye-tracking studies have shown that eye-movements to brands displayed on a supermarket shelf are valid measures of visual attention, are correlated with brand consideration, and are influenced by POP marketing (Chandon et al. 2009; Russo and Leclerc 1994; Van der Lans, Pieters, and Wedel 2008). However, they have not provided a method for separating the effects of attention and memory on consumer decisions. They have also not shown that attention to a brand causes consideration, rather than memory for a brand to be considered causing visual search for that brand.

In this study, we show how eye-tracking data can be used to separate the effects of visual factors from memory-based factors as a determinant of brand consideration and hence to decompose a brand's consideration into its baseline and its visual lift. To achieve this goal, we develop a parsimonious decision-path model of visual attention and brand consideration.

The model is designed for simple eye-tracking data consisting of joint observations of the number of eye fixations provided by the study (zero, one, two, three, or at least four) and the consideration decision (yes or no) for each brand and consumer. We model the P-O-P decision making process as a sequence of events that alternate between sub-decisions to consider the brand and sub-decisions to make an eye fixation on the brand (see Figure 1). The first decision is a memory-based, pre-store consideration that is made before the brand is noticed. Next, consumers decide whether or not to look at the brand. If the brand is not fixated, no new information is acquired, and the consideration decision remains unchanged. If the brand is fixated, the new eye fixation provides a new opportunity to consider the brand. We assume that consideration is irreversible; that is, having considered a brand, consumers might choose to look at it again but they do not "un-consider" it. Of course, consumers may still decide not to buy the brand even though it is included in the consideration set. The model allows us to examine, first theoretically and then empirically, the effects of looks on consideration and the effects of POP activity on each of the attention and consideration decisions. First, the model shows that the conditional probability of consideration given fixation increases with the number of fixations, regardless of any marketing effects. Second, the model predicts that there are diminishing returns in the gain from each additional look. Third, we examine various models with asymmetries in attention and consideration probabilities, which allow us to examine whether people look more at brands already considered or whether facings change the "quality" of each look.

We applied this model to eye-movements and brand consideration data collected in collaboration with a leading eye-tracking company. We created a fractional factorial design which allowed

us to test the effects of the number (4, 8, or 12) and location (which of four horizontal shelves and four vertical blocks) of shelf facings independently of any brand-specific effects using only 12 planograms. We recruited 384 adult shoppers and asked them to look at two categories (soap bars or pain relievers) and to make either consideration decisions while their eyes were being tracked. Each planogram includes the 11 top brands of the category and one brand unfamiliar to the participants. We obtained a total of 8,304 observations.

Our key findings for the soap category are that, out of an average consideration probability of 25%, 18% comes from pre-store consideration and 7% from in-store visual lift. For pain relievers, the average consideration was 24%, the average pre-store consideration was 11%, and the average visual lift was 13%. The higher visual lift for pain reliever was partly because, in this category, people are more likely to look at unconsidered brands (76%) than at already-considered brands (66%)—hence looks are more useful. In contrast, consumers were even slightly more likely to look at soap brands that they had already considered (79%) than at brands that they had not considered (76%). We also found that facings were particularly effective at attracting attention to unconsidered brands and that this effect was robust across the two categories. Finally, we found that facings slightly improved the quality of looks. Rather than simply providing another chance to toss the coin, looks caused by facings made the coin toss more likely to lead to consideration. This was particularly true for the first looks. Facings did not change the quality of looks after the fourth one. Further analyses looked at the effect of past purchase behavior. They found that visual lift is higher for regular users than for occasional users or for non users. On the other hand, the effects of facings were strongest for occasional users.

“Sticky Desires or Tricky Self-Control? Dynamic Processes in Attentional Bias Towards Temptations”

Suresh Ramanathan, University of Chicago, USA

Jun Lu, University of Chicago, USA

A rich body of literature has looked at impulsive or indulgent behaviors through the lens of self-control, suggesting that such behaviors arise due to weakness of will or failures in self-control (Baumeister 2002). We propose an alternative view, suggesting a larger role for desires than previously thought. Specifically, we suggest that indulge tendency arises due to a strong attentional bias towards temptations that manifests in greater and more recurrent desires, particularly among impulsive individuals.

Previous literature has identified two types of attentional bias: *orientation bias* that results in spontaneous attraction towards stimulus and *engagement bias* that results in continued engagement with the stimulus. In three studies, we show that engagement bias better predicts people’s yield to temptation and stems from people’s tendency to approach temptations rather than a diminution in their ability to avoid. Furthermore, training impulsive individual to focus on stimulus inconsistent with their chronic goal can worsen the situation as their desire for temptation surges upon subsequent encounter.

Experiment 1 seeks to determine the nature of attentional biases towards temptations among impulsive vs. prudent people and whether indulgent behavior results from attentional bias. Participants first completed a scrambled sentence task that was either neutral or designed to activate the need for something sweet. They then engaged in a visual probe task (Bradley et al. 2002), in which participants were required to respond as quickly as possible to a small dot probe which was presented immediately after the display of a pair of pictures consisting one of dessert and one of healthy option. Picture pairs were presented for either 100 ms or 1250 ms

on the screen after a fixation cross that appeared for 500, 750 or 1250 ms at random. These were followed by a dot probe that appeared in one of the two positions and remained on screen till the respondent’s response. Attentional bias scores were computed for each participant where positive values indicate greater vigilance for temptations. Positive values at the 100 ms exposure level indicate automatic visual orientation towards temptations, while those at the 1250 ms level indicate continued attention towards desserts even when the probe appeared in the position of the fruit. After the dot probe task, participants were given the opportunity to take cookies from a filled tray as an unrelated study. Finally, impulsivity was measured via the Consumer Impulsiveness Scale (Puri 1996) two weeks after the study. Results showed that impulsive individuals exhibited an orientation bias towards temptations. In addition, impulsive individuals who were primed with hedonic goal showed greater engagement with pictures of temptations. More importantly, those who exhibited the engagement bias took more cookies than those who exhibited orientation bias or no attentional bias, implying that engagement bias towards temptations leads to subsequent indulgent behaviors.

Experiment 2 examines the psychological processes underlying such attentional biases. In particular, we were interested in the dynamics of desire and avoidance towards the temptation in an attempt to determine whether indulgence is caused by strengthened desire or weakened avoidance. We changed the design of the dot probe task such that the dot probe would appear more frequently (90% of the trials) either at the location of the dessert picture or the fruit picture, thus manipulating attention in one direction. Subsequently, we measured desire-avoidance reactions towards a tempting chocolate snack on a 2-D grid by moving a mouse cursor continuously for 60 seconds. Participants indicated whether they felt little or a lot of desire and avoidance towards the snack right at the moment on two orthogonal dimensions. Using a new technique from dynamical psychology called Recurrence Analysis, we examined the trajectories followed by the time series for desires and avoidance, specifically looking for the extent to which the trajectories visited the same region in state space over time. Results confirmed that impulsive individuals who were manipulated to attend to desserts showed higher recurrence of desires and remained longer in a state of desire but not non-impulsive individuals, suggesting only impulsive individuals kept revisiting the same hedonic goal and were trapped in that goal state for a longer period of time. This phenomenon of trapped states is described in dynamical system theory as a “fixed point attractor” wherein individuals keep returning to a given state or goal despite occasional fluctuation (Carver 2004, Vallacher and Nowak 1999).

In experiment 3, we further explore how training attention engagement towards either towards temptation or healthy options can impact subsequent behavior when reward-seeking systems are activated at different time points. We followed the same procedure as in experiment 2 except that participants were additionally asked to sample a small piece of chocolate before or after the dot probe task. Sampling even a small bite of chocolate can cause activation of the reward-seeking system (Wadhwa et al. 2008). Results showed that impulsive individuals experienced higher recurrence of desire towards temptation when manipulated to attend to desserts if sampling before. More interestingly, impulsives experienced even higher recurrence of desire when they attended to healthy options first and then sampled a temptation. This data pattern suggests that reactance against goals inconsistent with their chronic goals may arise as a consequence of forced attention engagement on healthy options among impulsive individuals, hence training to focus on virtue can be a bad strategy to reinforce healthy behavior.

In summary, our research demonstrates that indulgent behavior exhibited by impulsive individuals is an immediate consequence of an engagement bias towards temptation that results in greater desires rather than weaker self-control. However, strengthened desire is not only limited to an elevated level of desire, but also extends to a more frequent recurrence of desire state and a longer trap time in that state. Forcing attention away from the temptation may backfire, resulting in higher recurrence of desire and consequently greater indulgence in impulsive individuals.

Beyond Informational and Normative Influence: Conformity in Consumer Decision Making

Young Eun Huh, Carnegie Mellon University, USA

Joachim Vosgerau, Carnegie Mellon University, USA

EXTENDED ABSTRACTS**“Social Influence on Choice under Uncertainty”***Young Eun Huh, Carnegie Mellon University, USA**Joachim Vosgerau, Carnegie Mellon University, USA**Carey Morewedge, Carnegie Mellon University, USA*

Choices are often made under uncertainty. While traveling abroad, for example, consumers often must choose among alternatives with information provided in a foreign unfamiliar language. Under such circumstances, one cue that decision-makers use is the choice of another decision-maker (e.g. a stranger at another table). In this research, we show that this cue is disproportionately weighted under conditions of uncertainty and investigate the underlying mechanisms of choice mimicry under uncertainty.

Social influence has been shown to play an important role in the decision making process (Childers and Rao 1992; Bearden and Etzel 1982; Campbell and Fairley 1989). The major paradigms in the social influence literature to explain social conformity have been normative influence and informational influence (Deutsch and Gerard 1955). Normative influence denotes the tendency to conform to the expectation of others. Informational influence denotes the tendency to accept information obtained from others (e.g., observation of others' behavior) as evidence about reality. We demonstrate that neither normative nor informational influence can explain choice mimicry under uncertainty. Alternatively, we propose the 'choice default' account. Under uncertainty, consumers trade off the effort of making a choice with the importance of making a correct decision. When the decision is of low importance, consumers simply follow others, but when it is of high importance, they expend the effort required to make a choice.

In Study 1, we tested whether participants would follow another decision-makers choice under uncertainty but not under certainty. The study consists of a 2 (prior choice: prior choice vs. no prior choice, a between-subjects factor) X 2 (product type: uncertain products vs. certain products, a within-subject factor) mixed design. All participants chose one tea from a set of two Korean teas (uncertain products, as our participants could not read Korean) and one tea from a set of two English breakfast teas (certain products) as remuneration for participating in the study. In the prior choice condition, participants followed a Caucasian confederate to the next room where the confederate first chose one of the two teas (Korean tea set and English tea set) and left the room. The participant was then left alone for making her choices. In the no prior choice condition, the participant went to the next room alone and made her choices. As hypothesized, more participants (79%) chose the Korean tea that was also chosen by the confederate compared to 56% who chose this tea in the no prior choice condition ($(1)=4.66, p<.05$). No such choice-mimicry was observed when participants chose among English teas (58% versus 51% in the control condition, $(1)=.35, ns$). Participants did not appear to mimic the confederate's choice under uncertainty because they believed that she was more knowledgeable—participants did not think that they would enjoy the Korean tea that they chose more than the Korean tea that they did not choose. However, participants thought they would enjoy the English tea that they chose more than the English tea that they did not choose. Thus, the observed choice-mimicry under uncertainty is not due to informational influence whereby participants believe

that the confederate's choice conveys information about the chosen options' utility.

In Study 2, we tested whether choice-mimicry under uncertainty is caused by normative influence. Participants choose one tea out of two Korean teas. In the absent-after-choice condition, the confederate chose a tea and left the room before participants chose a tea. In the present-after-choice condition, the confederate chose a tea and remained in the room while the participant chose a tea. In the control condition, participants chose a tea without observing the confederate's choice. Consistent with study 1, more participants chose the Korean tea that was also chosen by the confederate when the confederate left the room before participants made their choice (80% versus 48% in the control condition, $(1)=3.86, p<.05$). This choice mimicry, however, was reversed when the confederate remained in the room, as more participants chose the Korean tea that was not chosen by the confederate than in the control condition (only 17% followed the confederate's choice, $(1)=4.18, p<.05$). The results rule out the normative influence account of choice mimicry, which would predict more mimicry when the chooser makes the decision in the presence of others than in private.

In Study 3, we tested the choice default account in a 2 (choice stake: high stake vs. low stake) X 2 (prior choice: prior choice vs. no prior choice) between-subjects design. All participants were asked to choose among two different brands of Korean crackers. Participants in the low stake condition were told that they could take home their choice of cracker as remuneration for participating in the study. Participants in the high stake condition were told that they had to eat the crackers while in the lab. According to the choice-default account, choice-mimicry was expected in the low-stake but not the high-stake conditions. Consistent with the previous studies, in the low-stake conditions most participants chose the crackers that the confederate had chosen (78% versus 45% in the control condition, $(1)=6.36, p=.01$). This choice mimicry, however, was eliminated in the high stake conditions, as participants were no more likely to follow the confederate's choice compared to the control (41% vs. 48%, $(1)=.58, ns$).

Previous literature has demonstrated choice-mimicry under uncertainty due to either informational or normative influence. The current research demonstrates that choice-mimicry can also occur because consumers treat others' choices as defaults when they are not willing (or able) to exert mental effort to make their choice.

“Seeing Ourselves in Others: Consumer Compliance with Recommendations Made by Ambiguous Agents”*Rebecca Walker Naylor, Ohio State University, USA**Cait Poyner, University of Pittsburgh, USA**David A. Norton, University of South Carolina, USA*

Consumers often seek the influence of others when making product decisions. In these cases, social influence is explained by the information provider's expert status or the consumer's past experience (Gershoff and Johar 2006; Gershoff, Broniarczyk, and West 2001). However, many companies now present online reviews authored by individuals with whom a target consumer has no prior relationship, and which are often posted with no identifying information other than a user name. How does social influence operate when “influencers” are poorly identified, as opposed to known to be similar or dissimilar to the self?

We propose that in the absence of other information, consumers project their own characteristics onto an ambiguous individual. We argue that such “egocentric anchoring” occurs because the self constitutes the most psychologically proximate, accessible information source (Trope, Liberman, and Wakslak 2007, Mussweiler 2003). Thus, consumers infer that an ambiguous other will be similar to themselves. As a result, these unidentified others exert relatively strong influence on preference and choice. However, since the self is an anchor, we also show that it can be adjusted. First, self-anchor effects can be moderated by making non-self-related cognitions more accessible. Second, directly disconfirming the hypothesis of similarity can also weaken the self-anchor and lower compliance with an ambiguous reviewer.

Four studies support the egocentric anchoring account and subsequent adjustment mechanisms. In study 1, participants read either a moderately positive or moderately negative restaurant review ostensibly written by another consumer. Participants saw either (1) no information about the reviewer (ambiguous reviewer condition), (2) information about a reviewer who was similar to the average student at their university (similar reviewer condition), or (3) information about a reviewer who was different from the average student at their university (dissimilar reviewer condition). Anticipated compliance was equivalent for ambiguous and similar reviewers. However, compliance with the recommendation was significantly lower for the dissimilar reviewer compared to the other conditions. Importantly, we show that these differences in compliance are mediated by participants’ inferences of similarity to the reviewers. This pattern of effects held whether the review was moderately positive or moderately negative. Study 2 replicates this effect using a multi-product, multi-reviewer context.

Study 3 demonstrates that the egocentric anchor can be adjusted in this way, specifically, by making other-related cognitions more accessible. In this study, participants first described themselves (self prime) or the other people in the room with them (others prime). Next, participants read a restaurant review provided by one of the three types of reviewers (identical to the stimuli used in study 1). When self-related thoughts had been externally activated, there was again no difference in compliance with the recommendation between the similar and ambiguous reviewer conditions. However, when other-related thoughts had been made more acceptable, the self anchor was no longer adopted. Participants no longer assumed similarity with the ambiguous source, and, thus, were less likely to try the restaurant in the ambiguous versus similar reviewer condition.

A second way to prompt adjustment from an anchor is to directly disconfirm that the anchor provides an appropriate ground for inference-making. Study 4 shows that direct disconfirmation of the similarity hypothesis can also reduce reliance on the self-anchor. In this study, participants read reviews of an album on an online music review website, written by a similar, ambiguous, or dissimilar reviewer. Potential hypothesis-disconfirming information was given in the name of the website: www.CollegeMusic.com or www.AllMusic.com. The first website name was pretested to allow participants to believe the reviewer population was relatively homogeneous. In the homogeneous cue case, participants inferred similarity to and complied with the ambiguous reviewer at an equivalent level to the reviewer identified as similar, and more than the reviewer identified as dissimilar, suggesting reliance on the self-anchor as in prior studies. However, when participants saw the heterogeneous website name, this effect was attenuated, such that compliance was significantly higher for the identified similar reviewer than for the ambiguous and dissimilar reviewers.

In addition to providing theoretical insights regarding social influence and ambiguity, this work provides actionable advice for

managers who allow consumers to post user-generated review content. Although managers of such sites may tend to err on the side of “more is better” in terms of reviewer identification, our research suggests that posting reviewer-identifying information along with a review may not be the best strategy in all cases. Rather, by constraining the amount of information a reviewer can provide, managers may be able to gain the benefits of similarity without raising the dangers associated with dissimilarity.

“Social Treatment and Its Impact on Consumer Behavior”

Monica Popa, University of Alberta, Canada

Jennifer Argo, University of Alberta, Canada

Small-talk, ridicule, compliments, or insults are all type of social treatments that consumers commonly experience. In the present research we demonstrate that receiving a social treatment from one individual has implications for how the recipient of the treatment reacts toward other people in subsequent interactions. Furthermore, we find that the outcomes of social treatment are often counterintuitive. For example, we show that ‘pay-it-forward’ (the notion that a person who is treated well by someone should be nice toward others and conversely, a person who is treated badly may treat other people badly in turn) does not always occur; in fact, consumers often behave in the opposite manner. We offer a general theoretical framework that integrates previously fragmented investigations of social treatment (e.g., flattery, Campbell and Kirmani 2000; threat, Heatherton and Vohs 2000; teasing, Keltner et al. 2001) and reformulate context-specific explanations in terms of underlying dimensions.

Two dimensions of social treatment (affiliation: friendliness vs. hostility; and relevance for self-assessment: high vs. low) are predicted to interact in influencing consumers’ behavior, and in particular consumers’ socially-elevating behavior (i.e. behavior that requires a personal sacrifice and enhances the welfare of another person by providing material or psychological benefit). Receiving friendly versus hostile treatment is hypothesized to increase, through positive affect, consumers’ likelihood to engage in socially-elevating behavior, but only when the treatment has low relevance for self-assessments. When relevance is high, social treatment’s friendliness influences both affect and perceived self-efficacy in society. Affect and social efficacy act as opposing forces, because self-efficacy in society is predicted to have a negative effect, decreasing socially-elevating behavior. Furthermore, this research argues that the role of social efficacy becomes more prominent when the salience of the need for social connectedness is increased. The proposed relationships are tested in three studies.

Study 1 used a scenario-based methodology to examine the impact of receiving a social treatment from one shopper on a consumer’s likelihood of helping another consumer pick up bags of scattered groceries. The social treatment was either compliment (friendly/high-relevance), small-talk (friendly/low-relevance), threat (hostile/high-relevance) or grumble (hostile/low-relevance). As predicted, in the case of low relevance the friendly treatment generated a higher likelihood to help than the hostile treatment. However, when social treatment was highly relevant, friendliness did not motivate consumers to be more helpful and in fact the opposite tendency was observed. Two follow-up experiments provided process evidence for affect and perceived social efficacy.

Study 2 used a field experiment to study how many people would pick up the tab for another shopper after receiving a social treatment. In the study each participant was given money to buy and consume products at a mall together with another participant (in actuality a confederate). During the purchase, the real participant received a social treatment from a customer standing behind them in the line-

up. A significantly higher percentage of participants picked up the tab for the confederate after being treated with small-talk versus grumble. However, a significantly lower percentage of participants picked up the tab after being complimented versus threatened.

In study 3, also conducted at a mall, participants first received a task which primed either the need for social connectedness or the need for independence. They then made an individual purchase and were either complimented or threatened by a customer. When receiving cash back from the vendor, participants were overpaid by \$1. The dependent variable was participants' reaction to the seller. As expected, consumers primed with social connectedness were significantly more willing to return the dollar after receiving the hostile (versus friendly) treatment. However, this effect was eliminated when the need for independence was primed.

Overall, this research extends the literature regarding social influences on consumer behavior. We show that social treatment (i.e. how the influencer treats the influenced person) is important and can have far-reaching behavioral consequences.

“Feature Similarity, Popularity, and Cultural Success”

Jonah Berger, University of Pennsylvania, USA

Eric Bradlow, University of Pennsylvania, USA

Alex Braunstein, Google, USA

Some songs become hits while others languish and some products achieve blockbuster status while others are ignored. Why do certain things become more popular than others and how might the similarity between cultural items shape their success?

Some research has considered how item characteristics affect diffusion (i.e., innovations that are easier to try are adopted faster, Rogers 1995), but these perspectives tend to treat items as independent. While they recognize that “better” items (whether functionally superior or otherwise) tend to win out, they tend to ignore how the similarity between items might shape popularity. Take the example of first names. Might the popularity of other similar names help determine how popular a given name becomes? Might the future popularity “Karen,” for example, be influenced not only by its current popularity, but also be the popularity of other names that start with a hard “K” sound, such as Carl, Katherine, and Katy?

Similar items may act as substitutes or complements. One possibility is that items with common features compete. If collective tastes are fixed (i.e., 25% of people like indie rock), then similar options being more popular should shrink the remaining audience and hurt the ability of another indie song to succeed. Alternatively, similarity to other items may help success. Exposure to a stimulus, or others choosing it, can increase liking or choice of that stimulus (i.e., same item effects, Zajonc 1968), but this increased favorability may also generalize to stimulus components (Gordon and Holyoak 1983; Monahan, Murphy, and Zajonc 2000). If that is the case, then people might prefer cultural items which share features with what they have been exposed to previously (i.e., cross item effects).

We examine cross item effects in the popularity of first names. We focus on first names for a number of reasons. First, there is relatively little influence of commercial effort (i.e., advertising) or technological advantage (names are essentially value neutral tokens). The absence of these other factors makes it easier to examine the relationship between phonetic similarity and cultural success. Second, given that people can choose whatever name they like, choice is unconstrained by producers who may have an incentive to make options similar over time (i.e., this years' televisions tend to look like last years).

To examine our research question, we analyze 100 years of data on the popularity of every first name in the US. We break each name up into its phonetic parts (Karen=K EH R AH N), and then

look at the evolution of popularity of each of the 44 phonemes over time, based on their popularity both the past year and cumulatively the over 10 years prior. We do this for the phonemes at beginning and end of names as well as internal phonemes. Importantly, our analysis parcels out direct exposure effects. Thus we look at how the number of Karen's born one year relate to the popularity of the “K” sound the following year, outside of number of Karen's born that next year. We then aggregate these effects across all phonemes to look at the overall pattern.

Our results (1) suggest that social influence has cross item effects and (2) demonstrates the importance of such relationships for cultural success. Across all phoneme positions the more a phoneme is used in names one year, the more popular it will be in *other* names the following year. This relationship also holds for cumulative popularity over the ten years prior. Not surprisingly we also find that the more popular a name is one year the more popular it will be the next, but the cross-item effects persist even when controlling for such same item effects. These cross-item effects are strongest for phonemes that begin the name, consistent with the notion that this position should receive more stress. In addition, the coefficient on the quadratic terms of past popularity are negative, suggesting that too much popularity can lead to reduce future adoption.

These findings suggest a novel way in which social influence shapes popularity. Exposure to others choices not only affects whether people adopt that thing, but may also affect whether they adopt other things with common features. This has important implications for the way culture evolves. Things not only become popular based on their own characteristics, or whether they are better or worse than competing items, but may also be shaped by whether they share common features with what is currently popular.

Conspicuous Consumption in a Recession: Trends, Motivators, and Perceptions

Nailya Ordabayeva, Erasmus University, The Netherlands

Keith Wilcox, Babson College, USA

EXTENDED ABSTRACTS

“Conspicuous Consumption in a Recession: Toning it Down or Turning it Up?”

Joseph C. Nunes, University of Southern California, USA

Xavier Drèze, University of California, Los Angeles, USA

Young J. Han, University of Southern California, USA

Luxury goods that prominently display their brands are out. The recession has led wealthy consumers to adopt more subdued designs that reflect taste rather than signal status. At least that is what the pundits in the press would have you believe. The financial crisis has aimed a “death ray” at the ethos of conspicuous consumption according to the *New York Times*. “The muted, logo-free look is gaining traction as the standard-bearer for a new kind of luxury: subtle, long-lasting and recession proof,” claims a report on the recession’s impact on luxury by ad agency JWT.

Have consumers really toned it down? Reports about how conspicuous consumption is out of vogue are based on interviews with consumers and presumed experts; no data or scientific studies are cited. Ideally, researchers would track consumer behavior longitudinally documenting purchases and the use of luxury goods used to signal status both before and during a recession. This research takes a more practical albeit less direct approach.

We focus on luxury handbags, considered by the Chicago Tribune the “21st Century American woman’s most public and pricey consumer craving.” We examine data on product offerings collected from luxury handbag superpowers Louis Vuitton (LV) and Gucci, the world’s top two luxury brands (Interbrand 2009), before and in the midst of the recession. We contrast what occurs with these two brands with what occurred at Hermès, a boutique brand concentrating on subtlety prior to the recession. If consumers are indeed demanding less conspicuous products, it would be reflected in these manufacturers’ product lines and we should observe LV and Gucci offering more understated designs. Or, if firms do not tone down their products, we should observe a marked decrease in profitability as they fail to meet customer demand. This is not what we find.

Our research finds evidence that Louis Vuitton and Gucci have changed their product lines during the financial crisis to offer significantly more conspicuously branded products. These brands are far more prominently displayed on new product introductions when compared to those products withdrawn. Further, both brands simultaneously increased prices significantly. Louis Vuitton’s new designer handbag line was priced an average of 31% higher than its product line one-and-one-half years earlier, while Gucci raised prices on 50% of those products the manufacturer did not remove, by 1% to 5%.

These tactics have not resulted in financial ruin. Profits for LVMH’s fashion and leather goods rose from \$814 million in June 2007 to \$815 million in June 2008 and on to \$919 million in June 2009. The percentage of LVMH’s revenues coming from the U.S. did not change between 2008 and 2009, remaining at 28%. The luxury goods division of PPR SA—the parent company of Gucci Group—recorded an increase in EBITDA from \$363 million in June 2008 to \$377 million in June 2009. Retail sales by Gucci, the division’s flagship brand, were up 2.4%, led by an “extremely robust showing from leather goods.”

In contrast, Hermès, which concentrated on understated designs before the recession, did not introduce more conspicuous products. This implies that desires amongst those consumers who sought understated designs prior to the recession did not change and many of those who do not exit the luxury goods market during a recession are still interested in logo-laden products, and perhaps even more so.

We posit a segmentation explanation based on consumers’ need for status. Consumers low in their need-for-status don’t use luxury goods to dissociate themselves from less well-to-do consumers (Han, Nunes and Drèze 2010). They bought quiet goods before the recession began, and they can reduce or postpone consumption without feeling their status is threatened. Hence Hermès, which caters exclusively to this customer segment, did not change its product line because doing so would be futile.

Conversely, high need-for-status consumers, who are also wealthy, use luxury as a mechanism to dissociate themselves from the have-nots. They feel a need to do this even in recessionary times, perhaps even more reinforcing that they are not impacted as much by the recession. This would shift demand for luxury goods toward loud products favored by this segment and encourage managers to alter the product lines accordingly. Hence, Louis Vuitton and Gucci steered their product introductions towards this segment and away from those that favor quieter displays.

Thus our data support the notion that those who are still in the market for luxury goods still like the loud products and are willing to pay a hefty sum for them. As with most platitudes, 2008-9 is not the first time that observers have predicted the downfall of conspicuous consumption and a rise in “conservative consumption.” A general sentiment oft described is that consumers will economize out of necessity, but as incomes rise and frugality gives way to profligacy, consumers will eschew their wasteful ways of the past. Our findings suggest consumer researchers need to be certain conspicuous consumption has declined before saying it will never reclaim its previous place in consumer decision-making.

“The Ironic Effects of Credit Card Balances and Credit Limits on Conspicuous Consumption”

Keith Wilcox, Babson College, USA

Lauren Block, Baruch College, USA

During the current economic crisis, consumers are facing sobering amounts of debt. In 2008, the average outstanding credit card balance per household was \$10,679 (Nilson Report 2009) and approximately 13.9% of consumers’ disposable income went to service credit card debt (U.S. Congress’ Joint Economic Committee 2009). Additionally, the rising job losses are leading even those with good credit histories to incur unbearable amounts of credit card debt (Andrews 2009). Despite the staggering numbers virtually no research has examined how credit card debt affects consumer spending.

Previous research has documented a tendency by individuals to abandon a goal after failure (Cochran and Tesser 1996), particularly when goal failure represents a behavior that a person is trying to avoid. Because consumers try to avoid card debt, we suggest that carrying a balance makes consumers less focused on incurring credit card debt and subsequently increases spending. Moreover, we suggest this effect is strongest for people with high self-control. Because credit cards increase spending, and those with high self-

control strategically avoid using payment mechanisms that increase spending (Raghubir and Srivastava 2009), prior to a balance being incurred, consumers with high self-control should be more focused on avoiding credit card debt. However, once a balance has been incurred, it signals goal failure, which increases their spending and shifts their preference towards high-priced luxury brands.

However, research suggests that the more resources individuals have available for consumption, the weaker the proportional impact of any one unit of consumption on one's overall resources (Morewedge et al. 2007). This suggests that the perceived magnitude of the failure from incurring a credit card balance may depend less on the actual value of the balance than on the proportional impact of the balance to the resources that are available on the credit card (i.e., the available credit). This also suggests another ironic effect: that the influence of an outstanding balance can be attenuated by increasing the available credit on the credit card, while holding the value of the balance constant. Thus, once a balance has been incurred, we propose that increasing the available credit should reduce the perceived magnitude of the failure and actually lower consumers' preference for luxury brands.

Four studies were conducted to test our predictions. In study 1, half of the respondents were told to imagine that they had \$1,000 in their bank account and a credit card with a \$1,000 credit limit and no outstanding balance. The remaining participants were instructed that they had a credit card with \$1,500 credit limit and a \$500 outstanding balance. Participants were asked to choose between two pairs of gender neutral sunglasses: a pair of Louis Vuitton sunglasses and a pair of Ray-Ban sunglasses. As expected, those with high self-control were more likely to purchase the Louis Vuitton sunglasses when they carried a balance compared to when they had no balance. No difference was observed for those with low self-control.

Study 2a replicated the basic findings of study 1 and provided evidence that the magnitude of the failure moderates the effect of a credit card balance on preference for luxury brands. Specifically, it shows that increasing the available credit reduces the magnitude of the failure and lowers conspicuous consumption for high self-control individuals. Study 2b, provides process level support for the effects found in Study 2a; specifically, we demonstrate that increasing the available credit reduces consumers' spending by making them more focused on debt avoidance.

Study 3 replicates the findings of previous studies while ruling out different inferences about wealth as an alternative explanation. Specifically, we provided respondents with two credit cards (a high available credit card and a low available credit card), but kept the total available credit and the outstanding balance between the two cards the same; we only manipulated which card carried the balance. We find that consumer spending depends on available credit on the credit card that carried the balance. Specifically, when the balance is carried on a card with low available credit, it increases the likelihood of purchasing a luxury product compared to when it was carried on the card with high available credit.

In this era of economic crisis and pending credit card regulation changes, it is important to better understand the factors that influence consumer spending and conspicuous consumption. Findings from the body of literature in this domain are often integrated into policy guidelines to aid and educate consumers to help them spend wisely and avoid debt. Future research that informs industry or regulatory guidance is encouraged.

“Effects of Perceived Income Distribution, Equality, and Economy on Preferences for Conspicuous Consumption”

Nailya Ordabayeva, Erasmus University, The Netherlands

Pierre Chandon, INSEAD, France

Daniel Goldstein, London Business School, UK

It is widely believed that increasing income equality should reduce conspicuous consumption (Bagwell and Bernheim 1996). It is also believed that conspicuous consumption should drop in a recession, due to falling incomes and rising income equality (Moses 2008). Yet recent findings reported that boosting equality may backfire and increase conspicuous consumption among relatively poor consumers, as it allows those who consume to “leapfrog over” a larger portion of the population stacked in middle tiers (Ordabayeva and Chandon 2010). These arguments assume that consumers have an accurate perception of the income distribution and how it is changing. To correctly interpret them and to recommend effective strategies to reduce conspicuous consumption in a recession, it is important to test the role of perceptions. In this research, we examine the effects of perceived and actual income distributions on people's preferences for conspicuous consumption and test the roles of beliefs about equality and economy.

Specifically, we test whether conspicuous consumption is motivated by the perceived or the actual income distribution, income level or income rank, and examine how it changes depending on consumer beliefs about equality and economy. We predict that, due to its implications for social position, conspicuous consumption is predicted by income rank (i.e., position in the income distribution) rather than income level. Specifically, it is driven by rank in the local, rather than country-level, income distribution, consistent with social comparison theory (Festinger 1954). Further, because it is difficult to know the shape of the actual distribution, the effect of local rank should be moderated by perceived rather than actual distribution equality. Consistent with the “leapfrogging” hypothesis (Ordabayeva and Chandon 2010), high perceived equality should reduce conspicuous consumption among relatively rich consumers, but it should ironically boost conspicuous consumption among relatively poor consumers. We believe this ironic effect of equality could reverse when anticipating a recession.

In the first study, participants from a representative sample of US households used the Distribution Builder tool online (Goldstein, Johnson, and Sharpe 2008) to build the distribution of income that they believed was prevalent in the US. Afterwards they made three choices between inconspicuous and conspicuous consumption (renting an economy car vs. a premium car for a high school reunion, spending on necessities vs. luxuries if anticipating a salary bonus, saving on home decoration vs. home maintenance if anticipating an increase in expenses). We computed each participant's percentile in the perceived, country-level, state-level, and local area (core based statistical area)-level income distributions and GINI indices of the perceived and corresponding state- and local area-level income distributions. As predicted, percentile in the local income distribution predicted consumption decisions better than income level or percentile in the perceived, state- or country-level income distributions. The effect of local income rank was moderated by the GINI index of the perceived distribution. High perceived equality led to weaker preferences for conspicuous consumption among the top 50% of local earners, but it led to *stronger* preferences for conspicuous consumption among the bottom 50% of earners. Hence boosting perceived equality may indeed backfire for relatively poor consumers.

In the second study, we tested whether this ironic effect of equality would be similar in an economic expansion and a recession. This study was conducted in the lab, it focused on relatively

poor consumers (who are at a higher risk of overspending) and actually provided the local distribution of a status product. The participants read that they were going on a beach vacation with their classmates and that they brought old unbranded sunglasses with them. At the beach, old sunglasses put them at the bottom (tier 5) of the distribution of sunglasses in their group, which led them to consider spending €90 on higher-status tier 3 sunglasses instead. The distribution of sunglasses was equal (with 15%, 25%, 15%, 40%, 5% of people in tiers 5-1) or unequal (with 15%, 15%, 15%, 40%, 15% in tiers 5-1), and the vacation was taking place in the time of an economic expansion or a recession (we provided basic facts about an expansion or a recession). The participants chose between spending €90 on tier 3 sunglasses and saving the money. As expected, when anticipating an expansion bottom-tier people were more likely to spend the money in the equal (vs. unequal) distribution. But anticipating a recession decreased their overall likelihood to spend, even more so in the equal distribution. A pilot study showed that this could be due to people's desire to fit in and to strengthen bonds with others in recessionary times. This showed that a recession may reduce the conspicuous consumption of relatively poor consumers, especially when equality increases at the same time.

Overall these findings improve our understanding of the macro-level and individual-level factors that drive conspicuous consumption. They show that merely changing people's beliefs about equality may be sufficient to shift their preferences for conspicuous consumption, which could be especially useful for increasing savings in this recessionary period.

“Judging a Book by Its Cover: How Consumers Perceive Conspicuous Consumption by Others”

Maura L. Scott, University of Kentucky, USA

Martin Mende, University of Kentucky, USA

Lisa E. Bolton, Penn State University, USA

During tough economic times, consumers experience a heightened sensitivity to the level and type of conspicuousness of a seller (Williams 2008) and the source of affluence supporting the conspicuousness (Christopher et al. 2005). However, evaluation of others is highly context sensitive (Gawronski and Bodenhausen 2006) and differs depending on social settings (Gawronski, LeBel, and Peters 2007) and social roles enacted by targets (Barden et al. 2004). Consequently, we study how consumers—during the recession—perceive conspicuous consumption in commercial contexts. This research investigates how conspicuous consumption affects consumers' person perception of sellers, proposing that consumers infer personal characteristics from conspicuous consumption that, in turn, affect attitudes and behaviors toward the focal seller. Furthermore, we show how inferences consumers make about sellers' conspicuous consumption are moderated by the presence of a relationship and the nature of the commercial relationship.

Five studies—all conducted during the economic crisis—examine consumers' attitudes about sellers who engage in conspicuous versus modest consumption (e.g., level of caring, competence) and consumers' subsequent behavioral intentions. We demonstrate that in a communal (exchange) relationship, consumers perceive that sellers who engage in conspicuous versus modest consumption are less caring (more competent), which in turn drives less (more) favorable behavioral intentions. As a result, conspicuous consumption by sellers (such as service providers) affects consumer response (such as WOM and purchase intentions) in systematic ways—suggesting that firms may wish to use consumption cues to signal qualities in ways that improve their relationship building efforts with their customers.

Five studies provide support for the underlying psychological process while at the same time establishing boundary conditions on the phenomenon of interest. Studies 1 and 2 were a 2 (relational norm: communal/exchange) x 2 (conspicuous consumption: yes/no) between-subjects experiments. In study 1 scenarios, we manipulated relational norms based on relational norm definitions. In study 2, we manipulated relational norms by varying the profession of the seller (communal as medical doctor, exchange as financial advisor). We manipulated conspicuousness based on the seller's possessions (such as the watch, clothing, and car). We found that behavioral intentions decline when communal service providers engage in conspicuous consumption, while behavioral intentions increase under the exchange norm and the seller engages in conspicuous consumption.

Study 3 was a 2 (relational norm: communal/exchange) x 2 (conspicuous consumption: yes/ no) x 2 (customer relationship/ none). A three-way interaction in this study finds that the effects of conspicuous consumption on service provider attitudes depend critically on the existence of a provider relationship. The customer relationship makes salient relational norms, which translates to the attitude effects consistent with studies 1 and 2; in the absence of a buyer-seller relationship, the effects are not observed.

Study 4 examines the moderating role of the target's consumption focus (i.e., work-related or personal conspicuousness). Study 4 was a 2 (relational norm: communal/exchange) x 2 (conspicuous consumption: yes/no) x 2 (target's consumption: work-related/ personal) between-subjects experiment. The target's consumption factor examined whether the conspicuousness was reflected in business trappings (e.g., designer furniture, expensive equipment, etc.) or personal consumption (e.g., designer clothing, expensive car and watch). When conspicuous consumption is personal, the behavioral intentions are highly similar to prior studies; however, the behavioral intention effects were not significant for work-related conspicuous consumption—establishing a boundary condition on the impact of conspicuous consumption cues.

Study 5 was a 2 (relationship norm: communal/exchange) x 2 (source of affluence: luck/ earned) between-subjects experiment. The seller engaged in conspicuous consumption in all conditions. In the earned conditions, behavioral intentions are higher under exchange versus communal norms—consistent with the notion that earned income facilitates consumer inferences about competence (Christopher et al. 2005). In the luck conditions, behavioral intentions are higher under communal than exchange norms—which we argue occurs because the affect driven connection in a communal relationship creates a “luck may rub off” effect. More generally, the source of wealth is shown to be a boundary condition on consumers' responses to conspicuousness.

Our findings contribute to the literature by i) examining conspicuous consumption as perceived by others (rather than how and why consumers engage in such consumption), and ii) extending research on the importance of social and relational norms on consumer behavior in commercial contexts.

Consumer Acculturation in an Age of Globalization: Critiques, Revisions and Advances

Dannie Kjeldgaard, University of Southern Denmark, Denmark

Marius K. Luedicke, University of Innsbruck, Austria

EXTENDED ABSTRACTS

“Metacculturation’: Cultural Identity Politics in Greenlandic Food Discourses”

Søren Askegaard, University of Southern Denmark, Denmark
Dannie Kjeldgaard, University of Southern Denmark, Denmark
Eric J. Arnould, University of Wyoming, USA

The majority of previous consumer research on ethnicity focuses on consumer acculturation by consumers who come from one (presumably homogeneous) consumer cultural context and acculturate to another (presumably homogenous) cultural context (Peñaloza 1994). The present article problematizes the relatively clear-cut dichotomy of home and host culture by exploring food consumption discourses from cooking literature and consumers’ narrative in the context of Greenlandic consumers (Askegaard, Arnould & Kjeldgaard 2005; Kjeldgaard & Askegaard 2006). We argue that the articulation of ethnic identity through food consumption becomes a master trope of the definition of “Greenlandic”, and that this articulation unfolds in and through a context of historically established (marketplace) mythologies of Danish and Greenlandic culture. Consequently, home as well as host cultures emerge as outcomes of the acculturation processes rather than antecedents thereof. We emphasize that this approach stands in marked contrast to standard assumptions in the acculturation literature, in which home and host are generally seen as antecedents to and not outcomes of the process. We argue that cultural reflexivity that is both a cause and a consequence of this discursive process represents a kind of cultural ‘awakening.’ This awakening is produced through the boundary drawing between food cultures; a reflexivity which represents an acculturation to being a carrier of a particular cultural identity. Since this is a second-order acculturation or, we have chosen the neologism ‘metacculturation’ as its denominator. In order to explore the dynamics of metacculturation among Greenlanders, we focus on food cultural consumption as it pertains to the establishment of identity among twenty Greenlandic migrants to Denmark and a sample from two high school classes totalling 12 young consumers in Greenland.

The socially informed perception of space and time appear as two fundamental and interrelated dimensions differentiating consumer experiences in the different cultural contexts. In the Greenlandic perspective, the spatial and temporal differences in social organization between Greenland and the Western world (represented by Denmark) are expressed in terms of a dichotomous distinction between nature and culture, Greenland representing the natural (space and time). These dimensions of nature and culture are reflected in a set of master tropes of a discursive definition and distinction of Greenlandic food culture that we elicit from our primary and secondary data. The close connection between the formulation of a Greenlandic identity and Greenlandic food culture is thus reflected in the data. Furthermore, the role of the cultural tropes ascribed to the colonial power (Denmark), in terms of food as well as more generally, are central for the formulation of a Greenlandic identity, both as a negative mirror image but also as a source for the cultural reflexivity generating the interest in the identity project in the first place. Consequently, the dynamic nature of food discourse shows us that the concept of authenticity can only exist as a perceptual construct on the basis of how a culture views its “self” and Others. In other words, we are witnessing an

editing of ‘authentic’ food culture through processes of remembering and forgetting certain elements of the historical constitution of contemporary Greenlandic foodways.

Wilk (1996; 1999) discusses similar processes in his attempts to account for “cultural constructionism” in Belize and the grid of “global structures of common difference” that is containing this construction. But in Wilk’s work, the acculturation processes into the notion of culture are more implicit, since he is focusing on various specific domains of the global structures of common difference, the beauty pageant (Wilk 1996) or the food cultural the creation of “real Belizean food” (Wilk 1999). Wilk, however, stops short of nominating the notion of culture itself a part of the overarching grid of global structures of common difference. Cultural boundaries are expressed, and therefore defined through the global structures, but culture and glocal cultural changes remain the boundary that contains these global structures and their manifest expressions

Summarizing, the concept of acculturation as it has been used in previous consumer research (Peñaloza 1994, Askegaard, Arnould & Kjeldgaard 2005, Holt and Üstüner 2007) as the negotiation of the tension experienced by having two (or more) cultural contexts of identification, becomes problematized when the notion of culture itself becomes a reflexive process (Askegaard, Kjeldgaard & Arnould 2009). Acculturation in this perspective is not just a matter of negotiating the tensions between host, home or ‘third’ cultures but it is also a matter of acculturation into the notion of culture itself. The notions of host and home cultures hence emerge as discursive outcomes of this culture of cultures rather than as building blocks of the acculturation process. We call this acculturation process into cultural reflexivity ‘metacculturation’.

“Consumer Acculturation and Competing, Countervailing Taste Structures”

Özlem Sandıkcı, Bilkent University, Turkey
Berna Tari, TOBB University of Economics and Technology, Turkey

Olga Kravets, Bilkent University, Turkey
Sahver Omeraki, Bilkent University, Turkey

Over the years conceptualizations of consumer acculturation process have moved from the “melting pot” model to a “postassimilationist” perspective Postassimilationist research (Askegaard, Arnould and Kjeldgaard 2005; Oswald 1999; Penaloza 1994) challenged the linear acculturation model and conceptualized consumer acculturation as a dialogical process characterized by ongoing cultural negotiation and “culture swapping” (Oswald 1999). These studies revealed how consumers mix and match resources from the minority and dominant cultures and pursue hybrid identity projects as they integrate into their new environment. Recently, postassimilationist research has come under criticism for its bias toward studying contexts that are characterized by postmodern consumer culture which allows consumers to pursue hybrid identity projects (Ustuner and Holt 2007). Instead, Ustuner and Holt 2007 introduced “dominated consumer acculturation” model to account for the acculturation experiences of consumers in less developed countries. The authors argue that different sociocultural structures produce different patterns of consumer acculturation. In the case of less developed countries, immigrant consumers tend to have little economic, social and cultural capital; host consumer culture tends toward “an orthodox modern form” where tastes are rigidly

defined by the upper social classes; and immigrants' culture tends to be in conflict with the ideologies of host culture (Ustuner and Holt 2007, 44). As a result, rather than individuated, hybrid modes of acculturation, immigrants collectively construct their identities as consumers either by reterritorializing the minority culture or pursuing the dominant culture as a myth through ritualized consumption. Some, however, may fail to do either and experience "a shattered identity project" (ibid).

Our goal in this research is to contribute to this line of inquiry and further question some of the underlying assumptions in the theories of consumer acculturation. Specifically, we seek to draw attention to the following issue. Existing scholarship conceptualizes the dominant culture that consumers seek to (or fail to) acculturate as singular. Whether the focus is Haitians immigrated to the US, Greenlandic immigrants in Denmark, or peasants moved into urban Turkey, the host culture is characterized by a singular dominant consumer ideology and taste structure. This dominating culture is always in the shape of Western consumer ideology, be it in a localized version. Hence, little is known about how acculturation process unfolds when the host culture is characterized by multiple, co-existing, equally powerful, and competing taste structures and consumption ideologies (e.g., Sandıkcı and Ger 2010). We investigate this question through a qualitative study of Turkish rural to urban migrant women living in squatter dwellings in Istanbul and Ankara.

Similar to other developing countries, rural to urban immigration has been a key feature of Turkish history. Since 1950s, limited availability of non-agricultural work, increasing mechanization of farming, political turmoil, and difficulties in accessing to health and education pushed rural people to the cities. Given the insufficiency of public housing and high levels of unemployment, rural migrants typically settle in squatter houses located at the periphery of the big cities. For the Western urbanites or what Ustuner and Holt (2007) refer to as "*Batici*," squatter neighborhoods represent stigmatized ghettos and their residents the inferior and even threatening Other. The immigrants' multi-faceted alterity menaces *Batici*'s Western lifestyle that expresses a localized version of the global consumerist sensibilities coupled with a secular orientation. Western consumer goods and consumption practices, which have penetrated into Turkey after the adoption of neoliberal economic policies in the 1980s, constitute a key aspect of the urban modern middle-class ethos. However, since the 1980s, another global ideology has been increasingly influential in Turkey: Islamism. An important outcome of the Islamist movement has been the emergence of a new Islamist middle class (Sandıkcı and Ger 2010). According to the authors, "this new class owes its existence to the upward mobility and urbanization of the formerly rural, peripheral elites" and "now forms a parallel structure that competes with urban secular elites". Consumption practices of the Islamist middle class entails a new sense of hybrid aesthetics which is informed by Islamic as well as modern sensitivities.

Our analysis shows that the Islamist habitus provides a new set of resources for rural immigrants to draw from while pursuing their identity projects. Their accounts of migration-consumption experiences and practices suggest that Western secular consumer culture is not the only and dominating ideology that migrants have no choice but acculturate to. While our informants, similar to those of Ustuner and Holt, lack economic, social and cultural capital resources necessary to participate into the "*Batici*" lifestyle, they draw from resources provided by the Islamist habitus and acculturate into an Islamist yet modern urban lifestyle. Their consumption practices reflect pursuit of a hybrid identity project and empowerment through acquisition of new resources provided by the Islamist structure. Overall, our study indicates that host culture may not always be

defined by a singular dominant culture and that different forms of hybridity may characterize acculturation processes and consumer identity accomplishments in less developed countries.

"Acculturating Masculinity: Second Generation Turks Becoming Men"

Nil Özçaglar-Toulouse, Université de Lille 2, France

Lisa N. Peñaloza, EDHEC Business School, France

Previous work on consumer acculturation in the CCT tradition has emphasized the importance of situating consumption phenomena within contextual layers of history, colonial relations, and socio-economic difference between (Askegaard, Arnould, and Kjeldgaard 2005; Oswald 1999; Peñaloza 1994) and within nations (Kjeldgaard and Askegaard 2006; Üstüner and Holt 2007). Recent work addressing dimensions of gender has focused on women (Chytкова and Özçaglar-Toulouse 2009). Our work takes as its focus masculinity among second generation (Portes 1996) Turkish men in France. This topic is of particular relevance in the era of globalization. First, unlike the subordinated relations between Mexico (Peñaloza 1994a) and Haiti (Oswald 1999) with the U.S., and for Greenland in relation to Denmark (Askegaard, Arnould, and Kjeldgaard 2005), Turkey has never been colonized, and counts within its history the dominant status of the Ottoman Empire. Further, due to alliances with European nations in WWII, the widespread anti-colonial, anti-Western rhetoric characterizing the Middle East has not been as dominant here. And yet, like other minority groups studied, Turks are a minority in France, forming the largest immigrant group there and in several other nations within the European Union.

The theoretical framework brings together this previous work on consumer acculturation with that on gender and masculinity. Particularly useful is Butler's (1990) work emphasizing gender performance, as persons enact, reproduce, and challenge gender conventions in ways that transcend binary understandings of gender. Also useful is Connell's (1995) attention to economic institutions in legitimizing masculine ideals and practices. While drawing from this work, we emphasize the negotiations of gender in consumption as accommodated and reproduced in market cultural institutions (Holt and Thompson 2004).

The research entails on-going ethnographic study of 18 young men between the ages of 18 and 30. Interviews and observations were carried out in areas frequented by the young Turks in the suburbs of Lille and Paris. These suburbs are characterized by a high concentration of Turkish and Northern African minorities, under and unemployment, deindustrialisation and dense population similar to that documented by (Wacquant 2007). Among our research objectives are: 1) documenting ideals, norms, and practices of masculinity; 2) analyzing how the various cultural contexts—at home with their fathers and mothers, with friends and significant others in cafés, at work, dealings with France and Turkey, and various national and transnational media forms and institutions associated with each of these groups—come together in consumption ideals and practices associated with masculinity; and 3) addressing whether such contexts are converging in fashioning consumption ideals and practices favoring the homogenization of masculinity.

Our results derive four themes: becoming a father, not loitering in the street, protecting your honor, and conquering adversity. In articulating these themes, we emphasize a number of creative contradictions in the ways these young men navigate what it is to be a man in drawing upon idealized French fatherhood, relations with their girlfriends and mothers, Turkish history, and rural traditions in differentiating themselves from other minorities and their fathers. This research contributes to postassimilationist understandings of globalization by detailing the ways these young men forge distinc-

tions from other minorities, it adds to understandings of consumer acculturation by documenting the processes and practices of second generation immigrants moving from a nation lacking a colonial past into a more subordinated, minority status; and finally this work contributes multicultural understandings of gender in elaborating how young Turkish men draw from multiple cultural domains in producing masculine ideals, norms and practices.

“Broadening the Scope of Consumer Acculturation Theory”

Marius K. Luedicke, University of Innsbruck, Austria

The existing body of consumer acculturation literature can broadly be divided into two parallel streams of research. The first stream, beginning around 1980, was predominantly concerned with assessing differences in immigrant/ethnic consumption behavior vis-à-vis the commercial mainstream (Desphande et al. 1986; Donthu and Cherian 1992; O’Guinn et al. 1986; Reilly and Wallendorf 1984; Saegert et al. 1985; Wallendorf and Reilly 1983). This insightful work produced significant knowledge on cultural consumption patterns, and illuminating preferences in emerging ethnic market segments that were, at the time, foreign to most marketers. The second stream, pioneered by Peñaloza in 1989, moved away from (literally) counting eggs to exploring immigrant consumers’ identity projects and personal acculturation experiences. This body of work produced—and continues to produce—many important insights into the cultural complexities of consumer acculturation, including the troubling pushes and pulls from two socio-cultural systems, the wealth of despised and appreciated discourses and practices that migrants cope with, and the range of more or less integrative (and beneficial) outcomes of this process (Askegaard et al. 2005; Mehta and Belk 1991; Oswald 1999; Peñaloza 1989, 1994, 2007; Peñaloza and Gilly 1999).

The triple purpose of this presentation is (1) to revisit prior studies with respect to the conceptual and methodical paths that they have taken, (2) to show where these paths have begun to limit the scope of consumer acculturation research under globalizing cultural conditions, and (3) to propose an alternative model that highlights facets of consumer acculturation phenomena which have thus far receive little scholarly attention.

In particular, the author addresses three points of critique: an idea of consumer identity construction as a largely autarkic process of mixing and matching available cultural resources; a conceptualization of cultural resources as robust and largely independent of migrants’ consumption practices; and a predominance of single-perspective (i.e. migrant-centric) ethnographic accounts as predominant sources of empirical insight. Based on this critique and on two influential and path-breaking studies of Thompson and Tambyah (1999) and Üstüner and Holt (2007), the author puts an alternative model of consumer acculturation forward for discussion that attenuates these critiques by conceptualizing consumer acculturation as a multi-directional, perpetuate process of cultural adaptation that focuses more on the discourses, practices, and resources that migrants and locals use for negotiating their intercultural relations (cf. Chrikov 2009; Chung and Fischer 1999).

Such an alternative lens may inspire consumer acculturation researchers to explore acculturation as mutual cultural adaptation embedded in an active and agentic network of observation, evaluation, and adaptation through consumption. In such a network, local and migrant consumers potentially observe the visible consumption practices of the respective others, evaluate these observations based on specific inter-cultural discourses and more general attitudes towards multiculturalism, religious diversity, or sharing of market resources (cf. Nagel 1994), and adjust their own consumption choices dependently.

In summary, a thus broadened field consumer acculturation theory may benefit from also taking intra- and inter-cultural discourses into (empirical) account that define local, national, and transnational (stereotypical) views about certain cultures, illuminate how consumers translate these meanings into practices of sharing or competing, and, potentially, reveal which discourses and consumption practices (i.e. cuisine, arts) may evoke integrative spirits where segregation prevails.

The Construction of Celebrity in Contemporary Consumer Culture

EXTENDED ABSTRACTS

“The Construction of Ordinary Celebrity”

John Deighton, Harvard University, USA

Leora Kornfeld, Harvard University, USA

We compare four forms of “ordinary” celebrity, building on a comparison of Susan Boyle of Britain’s Got Talent, Dave Carroll of United Breaks Guitars, Jill and Kevin of JK Wedding Dance, and the Balloon Boy hoax. In 1961, Boorstin characterized a celebrity as a person who is “famous for being famous,” which Gabler (2006) termed an epitaph for any serious consideration of celebrity. But Boorstin’s comments were more generative when he described celebrity as a “human pseudo-event,” “manufactured for us” but lacking in substantiality, a “manifestation of our own hollowness.” This perspective locates celebrity in the deficiencies of consumers, not the talents of the celebrated. Our paper uses celebrity as Boorstin does but offers a more complex view of the interplay between celebrity as manufactured for us and as manufactured by us.

In contrast to celebrity grounded in achievement, the ordinary celebrity’s claim to fame rests on intrinsic ordinariness (Turner 2000). It is vested in performative claims to be an essential self plucked from obscurity by chance or fortune, rather than a cultivated, tutored or trained self transformed deliberately and calculatedly for motives invisible and therefore not entirely to be trusted. Ordinary celebrity is an element of success in several areas of market economies such as politics (Sarah Palin), religion (Joel Osteen) and sport (Dennis Rodman) and informs the narratives of entrepreneurs linked to brands like Orville Redenbacher popcorn and Wendy’s hamburgers.

Ordinary celebrity has become more ubiquitous with the rise of video sharing sites like YouTube. We distinguish celebrity built on television from celebrity built on video sharing sites. We also draw distinctions among the generative processes based on two attributes: (1) whether the claim to celebrity is managed by an economic insurgent or an economic incumbent, and (2) whether the consumer initiates or responds to the claim of ordinary celebrity.

Traditionally media like television were considered carriers of power located in the State or commercial interests rather than as motivating ideological or economic forces in and of themselves (Turner 2006). The media were so-called because they mediated between the locations of power and their subjects. Turner contends that through the commercial success of reality television, media have become authors, not mere mediators, of cultural identity. In particular, reality TV produces an identity that celebrates the lack of exceptional talent or training, as long as people perform their ordinariness with some specificity or individuality. As media become economic actors with interests once the prerogative of the State and large corporations, the celebration of the ordinary becomes a profitable business strategy as much as an ideology.

We extend Turner’s analysis by contending that in important respects YouTube, the dominant carrier of populist video content, benefits from the myth that media is an element of the center of the social (Couldry 2003). We argue that it (along with its parent, Google) shares the incentive to achieve cultural effects for economic interests. As has often been noted, however, YouTube differs from television in that it publishes user-generated content that is voted up or down by a massive, virtually global, democratic process. YouTube is, therefore, a house divided against itself. On one hand

it operates an ideological system with power to serve incumbent economic and social interests. On the other hand it operates a system that empowers insurgent interests.

The first distinction in our typography of ordinary celebrity is between the interests of economic incumbents like large corporations and media groups (United Airlines and Sony Recorded Music in the cases we investigated,) and economic or social insurgents, the formerly powerless individuals now empowered as creators of content in pursuit of either economic power or social identity, such as wedding dancers Jill and Kevin or the parents of Balloon Boy. The second distinction has to do with whether consumers initiate or respond to the announcement of celebrity and therefore to the claim of ordinariness. Media like YouTube allow the passive emergence of celebrity by a process of implicit voting or preferential attachment (Barabasi and Albert 1999). Thus it allows for what we have termed celebrity manufactured by us. In our work we place Jill and Kevin in this category. We contrast this with ordinary celebrity that is made for us, as in the case of Susan Boyle. We also highlight that the distinctions among the processes of construction of ordinary celebrity are not simply played out by responsive consumers. Our paper illustrates that consumers rely on but also defy broadcast media as each tries to control the production of ordinary celebrity.

“Personal Blogging, Performance and the Quest for Fame”

Zeynep Arsel, Concordia University, Canada

Xin Zhao, University of Hawaii-Manoa, USA

The democratization in mass communication brought about by the participatory media (Jenkins 2006) opens new avenues to celebrity. Consider for example Julie Powell’s crossover from a commoner to celebrity through her blog interlacing introspections on cooking Julia Child’s recipes with glimpses of her marriage. Her chronicle formed the basis of the blockbuster movie *Julie & Julia* (Scott 2009). Estimates suggest there are 133 million blogs worldwide, with the number increasing by 1.4 new blogs per second (Technorati 2009). While stressing that not all bloggers want fame, our paper discusses how ordinary people seek to gain a discursive power and “a voice above others” (Marshall 1997) in the clutter of cyberspace by blogging (in most cases) about subject matters as mundane or trivial as cooking dinner. We frame blogging practice as an interactive performance through which the authors perform their lives in the eyes of the others and provide a dramaturgical analysis (Goffman 1959) of this practice.

Indisputably, the Internet produces new means for public self-presentation (Schau and Gilly 2003), and new avenues for research (e.g. Zhao and Belk’s (2007) examination of blogs as channels for conspicuous consumption and Kozinets et al’s (2010) study of narrative styles of word of mouth communicators in blogging networks). As yet, however, there is a theoretical void concerning performance in the production of blog content. This omission begs redress given that the social web features ever more specialized and dramatized blogs, a few of which garner fame and following by producing narratives on seemingly everyday consumption practices such as parenting (<http://www.dooce.com/>), cooking (<http://smittenkitchen.com/>), traveling (<http://camelsandchocolate.com/>), fashion (<http://www.bryanboy.com/>), gardening (<http://www.yougrowgirl.com/>), or running (<http://runningat30.blogspot.com/>). These blogs are not individualistic introspections, but are joint leisure activities that are shared among the blogger, his or her friends, and –if successful–

the stranger blog audiences. With our work, we aim to explore this under-theorized territory.

Our methodology incorporates both in-depth interviews and narrative analysis of blogs. We utilize a netnographic (Kozinets 2001, 2010) method to collect blog data. The blog entries are treated as consumers' retrospective and introspective narratives, through which they impose meanings on their daily activities and selectively underline particular aspects of consumption experiences (Thompson 1997). We juxtapose these narratives (the front stage) with the interview data to probe them about particular instances and stories and the underlying motives of representation (back stage). We also inquire about how bloggers imagine and construct their audiences through the comments left on their blogs or other monitoring processes. Our inquiry into the imagined audience further enables us to anchor the dramaturgical aspect of blogging processes and underscore the ways blog performances are shaped. As a supplemental data source, we also have collected interviews with famous bloggers from various media sources.

Our findings demonstrate how bloggers stylize the mundane and stage their lives to appeal to their audience in a dramatic fashion formalized by Goffman (1959). First, bloggers often seek to idealize (Goffman 1959) their mundane daily lives through weaving actual consumption experiences with readily available literary narratives, scripts and ideals. Blogging allows people to enact consumption fantasies encoded in popular culture rather than merely witnessing them. Second, bloggers continuously try to mystify their audiences to keep their audience involved and intrigued. Details about their lives are shared selectively, and contacts to the audience are regulated to maintain a social distance. By idealizing and mystifying consumption experiences, bloggers can conceal daily challenges thus enabling followers some escape from their own lived realities when they read and fantasize about bloggers' lives. By manipulating back stage and front stage selves, bloggers can instill different cultural meanings into their online persona.

Participatory media dilute the institutional structures through which fame is traditionally made. Our analysis of bloggers shows how consumers strive to gain a discursive voice and power (Marshall 1997) and manufacture a persona that could gain them celebrity status within relatively limited social networks or the greater cultural sphere. Whereas celebrities deploy scripted and readily available dramatic roles to fashion cultural meanings (McCracken 2005), bloggers create their own dramas and embellish their mundane activities through drawing upon a wide variety of cultural resources. We discuss the implications of our findings for theories of celebrity and self-representation and conclude our paper with further questions about the consumption of these blogs by their audiences and audience engagement with the celebrity blogger.

“The Role of Brand Communities in the Construction of Celebrity”

Marie-Agnès Parmentier, HEC Montréal, Canada
Eileen Fischer, York University, Canada

Celebrities abound in our culture, as do writings on celebrity in the social sciences (e.g., Gamson 1994, Turner 2004). And while we know that consumers feel attachment to people who have acquired considerable celebrity we do not know why consumers make investments of attention and begin to feel attachments with those who as yet possess little or no fame. Given our cultural fascination with celebrity and its alleged democratization (e.g., Andrejevic 2002), it is timely to address this question. We focus in particular on an online brand community's attention and attachments to reality TV contestants.

Following others who examine celebrities in consumer research and cultural studies (e.g., Schickel 1985; Thomson 2006) we draw on relationship-focused theories to inform our understanding. However, our examination differs in two important ways. First, our focus is on relationships that develop between communities and individuals versus those between an individual consumer and a celebrity. Second, we focus on the formation of relationships between communities and those who possess little celebrity versus the evolution of relationships between fans and those who already possess a considerable level of fame (e.g., Tyra Banks).

As our goal is theory development, we use qualitative methods well suited to the purpose. Data was gathered through a 20 month netnography (Kozinets 2002) in the online brand community comprised of fans of America's Next Top Model (ANTM). In order to narrow down the dataset the material generated on one popular site (Television Without Pity), for contestants in one season (“Cycle” 9, Fall 2007) was collated. Out of the thirteen contestants who competed for the ANTM title that season, eight became the focus of our analysis: the four who generated the most attention in the community (e.g., posts and file size) and the four who generated the least from the moment threads for each contestant were created (August 26th 2007) to roughly three months after the season finale, and as the next cycle began (February 29th 2008). The analysis for this study follows the principles of grounded theory (Strauss and Corbin 1998). We engaged in open coding, axial coding, and constant comparison using Atlas ti software.

Our data analysis suggests that the formation of relationships with individuals under scrutiny by a community cannot be disentangled from the formation/maintenance of relationships between members of the community. That is, consumers forge relationships with some—but not all—contestants in the process of interacting with others who share an interest in this set of people who are vying for attention. To some extent, the visibility a contestant achieves and the meanings invested in that person are a by-product of the process of community practices such as communing, socializing, spoiling, and gossiping that have been identified in prior consumer and fan research (e.g., Baym 1999; Holt 1995; Jenkins 2006). Our analysis also reveals that the process of meaning creation for contestants is influenced both by what consumers perceive the focal individual to be or do and by what others with whom they are being compared are perceived as being or doing. That is, the pervasive practice of comparison with other contestants in current and prior cycles impacts visibility and meanings that a community attaches to a given individual. Another finding concerns the dimensions along which a community's relationship with a contestant varies. One dimension is the extent to which the relationship features coaching: for some contestants, the community collectively provides advice about what she is doing wrong and right and about how she might further enhance her human potential. Another dimension is the extent to which the relationship features play: that is, some contestants garner considerable attention and differentiated meanings because the relationship between them and the community is a playful one that involves games such as coming up with the best metaphor to describe the individual's hairstyle, or competitive lampooning of the individual's character or demeanor. A third dimension is the extent to which the relationship features empathy: some contestants garner much greater sympathetic identification than do others. Our analysis links these relational dimensions to differences in the extent to which contestants achieve less measures of celebrity, within the community and beyond.

“Above Celebrity: Maintaining Consumers’ Experiences of Heritage-Based Fame”

Cele Otnes, U. of Illinois at Urbana-Champaign, USA

Elizabeth Crosby, U. of Illinois at Urbana-Champaign, USA

Pauline Maclaran, Royal Holloway University of London, UK

Consumers often seek connections to people possessing fame based on heredity, rather than on deeds. One example is the British Royal Family Brand (BRFB). Images and narratives pertaining to the BRFB are perpetuated through goods, services and experiences in myriad industries, and especially in tourism, media, and commemorative/souvenirs. Balmer (2007) asserts the BRFB is “a global brand” (31). Its appeal extends from the Victorian Era, when one-fourth of the world’s population and total land mass were under British rule (Aronson). BRFB images are highly mediated, and therefore often intermingle in discussions of glamour, manners and lifestyles. While it might be assumed that hereditary Royals are “only celebrities,” they also resonate in ways achievement-based celebrities do not. As Balmer (2007) observes, monarchies as (human) brands possess an irresistible combination of five differentiating aspects: royal, regal, relevant, responsive, and respected.

In this paper, we explore two research questions: How do those responsible for orchestrating consumers’ experiences with the BRFB perceive the Royals, vis-a-vis the notion of “celebrity?” How do these perceptions shape the ways stakeholders create and manage BRFB consumption experiences? Interviews were conducted with eight service providers England from April-August, 2005. (Follow-up interviews, for the purpose of member checks and updating providers’ perspectives, are planned for summer 2010). Informants include three retailers, three journalists (including the founding editor of a global magazine devoted to royalty) and two senior employees of royal palace museums. The text from the 2005 interviews yielded over 280 typed pages of single-spaced text.

Our analysis reveals that with regard to the first question, no provider believes “celebrity” describes the BRFB. Rather, because the brand represents the heritage and history of others, providers believe most members deserve more respect and tolerance than “regular” celebrities (even as they acknowledge the human failings of individual Royals). Indeed, many providers evoke monikers such as “Saint,” “Savior” and “Hero/Heroine,” supporting these terms with narratives from past history or current events. Yet most also distinguish between this elevated stature of BRFB members and the more celebrity-like stance of Princess Diana. One informant flatly states that BRFB members “are not celebrities. They are way above that...all this celebrity bit comes from Diana...the Queen is hardly glamorous...if you see the queen as a celebrity [it] really cheapens everything...in the back of their [consumers’] minds, they know the history behind it all [the BRFB].” Another believes the moral duties of the BRFB distinguish them from celebrities: “...more is expected of the Royal Family...somebody said the Queen should have commented on such and such a crisis...So there is this expectation that the Royal Family be involved.” However, our media informants also recognize (and acknowledge their role in perpetuating) an overlap in celebrity-like status of the BRFB, as media outlets are more invasive and the public is provided more access.

With regard to the second research question, we note providers use several strategies to help distance the BRFB from other celebrity-based human brands. First, they try to Connect the brand directly to consumers—e.g., by reminding them of the salience of the BRFB in their own lives. For example, one museum featured a “memory wall” where consumers left written remembrances of the memorable ways their lives had intersected with the BRFB. Providers also Enable consumers, by perpetuating aspects of the BRFB through narratives that support a distance from mere celebrities.

Providers also Sacralize the brand—supporting and offering narratives and displays that deify or differentiate the BRFB from other famous people. BRFB providers may also Teach, or reinforce the importance of the brand through history lessons, pageantry or narratives, to attract new BRFB admirers. Finally, unlike marketers of celebrities, providers Protect the brand by orchestrating consumers’ experiences to focus more on positive aspects, and downplaying potentially tarnishing events or people. For example, although cheap porcelain exists that commemorates the BRFB, one informant only displays the finer variants. While he stocks lesser-quality goods, he hides them in a cabinet until a consumer requests those items. Interestingly (and perhaps counter-intuitively), journalists also use Protect in their daily or weekly coverage of the BRFB. Finally, providers also Aestheticize, by perpetuating the BRFB experience through sensory-laden activities (e.g., exhibitions and displays). Furthermore, they often actively discourage consumers from engaging in the lower-quality BRFB consumption (e.g., buying souvenirs from street vendors, or printing negative reviews of BRFB television programs). We explore these and other themes more fully in the paper.

Psychological Aspects of Charitable Giving: Surprising New Insights About Benefactors, Beneficiaries, and the Giving Context

Eesha Sharma, New York University, USA

EXTENDED ABSTRACTS

“Cheaped Altruism: Discounting Prosocial Behavior by Friends of Victims”

Fern Lin, University of Pennsylvania, USA

Deborah A. Small, University of Pennsylvania, USA

Abundant research has investigated the factors and motivations causing charitable giving, but researchers have not explored folk psychological beliefs about its causes. This paper provides a first look at how people perceive charitable donors. The term charitable credit will refer to perceptions that a donor is a benevolent, charitable person whose prosocial behavior is driven by underlying altruistic qualities.

When are charitable donors given more or less credit for their donations? We believe that donors with a personal connection to the target cause, such as a relationship with a victim, are given less credit than donors without a personal connection because the personal connection cheapens the prosocial act. We theorize that even in the absence of potential material gain, these “friends of victims” are perceived as selfishly motivated and are thus given less credit for their donations. In other words, the perception of selfish motivation mediates the effect of a relationship with a victim on charitable credit. It follows that changing the perception of selfish motivation changes charitable credit and thus can moderate the effect of a relationship with a victim on charitable credit. That is, if friends of victims can undo the perceptions of selfish motivation, they can restore credit.

We propose two such moderators of the effect of relationship with a victim on charitable credit. First, giving to other unrelated charities makes the donation to the target cause indistinct, which should inhibit people from attributing the donation to selfish motivation. Second, stating an other-oriented reason for giving should also offset perceptions of selfish motivation.

Three studies support our theory. In all three, participants saw a profile of a donor to a leukemia charity who either lost a friend to the disease or who does not know any victims of the disease. Participants then rated the donor on four charitable traits and made three likelihood judgments about future charitable behaviors. These seven measures were averaged to form a composite charitable credit score.

In the first study, we confirm the basic hypothesis that when friends of victims donate to a charity that serves the cause that claimed their friend’s life, they are given less credit for the donation compared to donors who do not know any victims.

The next study investigates if this effect is moderated by whether the donor also supports other unrelated charities. We predicted that donating to other charities reduces the diagnosticity of friendship with a victim on the donor’s inherent charitable qualities because the donation to the same-misfortune charity is no longer distinctive; the relationship with a victim cannot account for the other charitable behavior. Additionally, we included a control condition in which participants received no information about the donor’s relationship with a victim, allowing us to investigate whether the lower credit granted to friends of victims results from a credit loss to friends of victims (attributional discounting), a credit boost to donors who do not know any victims (attributional augmenting), or both. Among donors who donated only to the leukemia

charity, friends of victims were given the least credit, and donors who do not know any victims were given the most. In the control condition, charitable credit fell between the other two conditions. Among donors who gave to multiple charities, however, there was no credit difference between friends of victims, donors who do not know any victims, and the control condition. This pattern supports our prediction that distinctiveness moderates charitable credit and demonstrates that both attributional discounting and augmenting contribute to friends of victims being given less credit than donors who do not know any victims.

The third study examines a different moderator based on the donor’s words, not actions. We expect that friends of victims who express an other-oriented motivation for donating restore the credit loss that results from their relationship with a victim. We also examine the mediating role of perceived selfish motivation. As in the previous studies, when donors did not provide a reason for donating, friends of victims were given less credit than donors who do not know any victims. When donors expressed an other-oriented reason for donating, however, this difference disappeared. In other words, expressing an other-oriented reason for donating moderates the effect of relationship with a victim on charitable credit. Measures of perceived selfish motivation followed the same pattern. A bootstrap confidence interval test confirmed that the moderating effect of an other-oriented reason on charitable credit acts indirectly through perceived selfish motivation.

To conclude, this research demonstrates that not all charitable actors are viewed as charitable, even when the donation presents no potential material gain. In particular, donors with a personal connection to a cause are given less charitable credit for their donations, for they are perceived as selfishly motivated. These donors can restore credit, however, by demonstrating other-oriented behavior and motivations.

“I Give Therefore I Have: Charitable Donations and Subjective Wealth”

Zoë Chance, Harvard University, USA

Michael I. Norton, Harvard University, USA

Prosocial behavior is associated with a host of personal benefits. Helpers enjoy greater happiness (Dunn, Aknin and Norton 2008; Lyubomirsky, Tkach and Sheldon 2004); reduced mortality rates (Musick et al. 1999); less depression (Musick and Wilson 2003); better immune function (Post and Neimark 2007); and elevated dopamine levels (Bachner-Melman et al. 2005). Indeed, a longitudinal study of older adults (Brown et al. 2003), found that givers benefitted more than receivers. We suggest another important benefit of charitable behavior: Feelings of subjective wealth. How wealthy one feels is a function of objective and subjective inputs: current wealth level, income and expectations, gains and losses compared to a reference point, one’s position in a wealth distribution, and psychological traits and states. As such, subjective wealth is malleable and may not always move in the same direction as objective wealth; our studies show that charitable donations—which decrease objective wealth—can increase feelings of subjective wealth.

We propose that philanthropy may have an unintentional self-signaling effect—when we observe ourselves making charitable donations, we infer we must be prosperous. Indeed, in a pilot study, we explored a romantic domain and found that men and

women who spent more money on their Valentine reported feeling wealthier the next day, even holding monthly income and relationship satisfaction constant.

In Study 1, we tested the general relationship between giving and subjective wealth using a large national dataset. Some participants predicted how they would spend a hypothetical windfall, and others reported how they had actually spent real windfalls that year. For those who imagined receiving money, giving intentions were positively associated with subjective wealth. This association held up for those who had actually received extra money—feeling wealthy was associated with charitable giving, at all levels of wealth, and predicted donation behavior over and above the effects of income. These correlational data suggest that the feeling of subjective wealth may induce generosity, though the more intriguing interpretation, which we explore in our next studies, is whether causality also works in the reverse direction. In Study 2, we tested the impact of charitable giving on subjective wealth. Respondents were randomly assigned to one of five conditions; a control group (no donation) or one of four groups in a 2 (Real vs. Hypothetical) X 2 (Mandatory Donation vs. Self-Selection) between subjects design, in which some respondents donated \$1 to a national or local charity. We found that all donors felt wealthier than the control group, whether donation was real or hypothetical, and whether they chose to donate or were required to. These findings are consistent with recent fMRI experiments showing that the reward centers of the brain are activated by donating money to charity in a similar way as receiving money for personal use (Moll et al. 2006), even when giving is mandatory (Harbaugh et al. 2007).

Study 3 explores the mechanism behind this giving/wealth relationship. According to Luks (1988), volunteers report experiencing a “helper’s high” or physical sensation of calmness and warmth, associated with giving, with 43% of his sample reporting increased strength and energy. If, as we suggest, giving sends signals of resource abundance to the self, it follows that the boost in subjective wealth may be associated with strength or power. We measured feelings of power using the Sense of Power scale (Anderson and Galinsky 2006). Participants either received \$1 to donate, \$1 to spend on batteries, or no additional money. Givers reported feeling wealthier than spenders, and both felt wealthier than the control group. The group differences were fully mediated by feeling a sense of power, which affected the givers but not the spenders.

In sum, our current research shows that while decreasing objective wealth, giving money away can increase subjective wealth. We have gathered evidence in support of our self-signaling hypothesis, that we interpret charitable donations as signals of wealth and power, even when the donations are our own.

“One vs. Many: The Effect of Efficacy and Entitativity on Charitable Giving”

Eesha Sharma, New York University, USA

Vicki G. Morwitz, New York University, USA

Given the ongoing economic crisis, donating money is increasingly difficult. The popular press notes that donors are (a) demanding more transparency from charities, (b) voicing growing interest in increasing their “philanthropic returns,” and (c) seeking more efficient giving opportunities. An important factor for donors is their perceptions of whether they can help (Bendapudi, Singh, and Bendapudi 1996). Sometimes, making a small impact—helping “one” beneficiary—assures donors that they will make any impact at all. Because of this, people frequently donate to singular, identifiable victims vs. numerous statistical victims, and tactics employed by organizations such as Kiva (i.e., sponsor one specific microloan

and Heifer International (i.e., buy one heifer, one trio of rabbits, one flock of chicks) are effective.

Clearly, in terms of providing large-scale aid, mass donations to “one” are not as effective as mass donations to “many,” and fundraising for one particular need is a less efficient use of advertising dollars than fundraising for large-scale needs. Still, a robust finding in the charity literature is that people prefer helping one vs. many beneficiaries, often because “one” is more tangible, concrete, and sympathy-provoking, whereas “many” blunt sympathy and caring (Jenni and Loewenstein 1997; Kogut and Ritov 2005a,b; Small and Loewenstein 2003). Still, just as numerous factors influence giving aside from purely altruistic ones, numerous factors also influence giving to one vs. many beneficiaries, aside from purely emotional ones (for a review, see Bendapudi et al., 1996). While specificity, tangibility, and the singularity of identified victims have received a significant amount of attention, with emotion as the underlying mechanism, we examine an alternative mechanism: efficacy.

Efficacy has been defined as the conviction that a person can successfully execute a behavior to produce a desired outcome (Bandura 1983). We propose that, over and above emotion, efficacy can significantly impact charitable giving. There are different forms of efficacy (e.g., self efficacy: “I can make a difference;” cause efficacy: “UNICEF can make a difference,” program efficacy: “this initiative can make a difference,” beneficiary efficacy: “the beneficiary can be helped”) and thus there are various ways to increase perceptions of efficacy. Our studies focus specifically on self- and cause-efficacy. Through four studies, we examine the role of efficacy to understand (a) how one can increase giving to many and (b) situations in which it may hurt vs. help to focus on one vs. many. We then examine the role of entitativity (i.e., beneficiary cohesiveness, Campbell 1958) to demonstrate (a) how perceiving a collection of targets as an entity may or may not be beneficial and (b) that this relationship hinges on perceived efficacy.

Study 1a and b test whether people donate more to one vs. many, regardless of whether “one” refers to a singular beneficiary (i.e., one child) or a singular collection of beneficiaries (i.e., one village of many). As predicted, participants in study 1a donated more to one child vs. many children; we replicated this effect in study 1b for one village vs. many villages. We suggest that perceived efficacy generally tends to be low in giving contexts. By focusing on one manageable segment, benefactors have a stronger perceived ability to help. These perceptions in turn influence willingness to donate, over and above the influence of emotion. Thus, we replicated previous findings that people tend to donate more to one vs. many (Kogut and Ritov 2005a,b; Small and Loewenstein 2003; Burson et al., under review), and extend them by (a) demonstrating the robustness of the effect for a singular collection of beneficiaries and (b) suggesting efficacy as the underlying mechanism.

Study 2 tests whether increasing perceived efficacy boosts charitable giving to many relative to one. We hypothesized that providing feasibility, or “how to,” information in a charitable appeal would influence the achievability of “making a difference,” and would thereby increase giving to many vs. when no feasibility information was provided. Indeed, we observed a significant interaction between number of beneficiaries (one vs. many) and appeal focus (control vs. feasibility information) such that participants who did vs. did not receive feasibility information donated more toward many beneficiaries. Emotions measures were also collected but did not have a systematic influence on donations.

Study 3 uses a 3 x 2 between-subjects design which crosses a beneficiary scope (one vs. many vs. one of many) manipulation with an efficacy (higher vs. lower) manipulation. Including three beneficiary scope conditions allowed us to test efficacy as the mechanism

underlying giving behavior to both a singular beneficiary (i.e., one child) and also a singular collection of beneficiaries (i.e., one village of many). As predicted, donation intentions toward one vs. many beneficiaries depended on whether efficacy was perceived as being higher vs. lower. Specifically, when efficacy was lower vs. higher, people preferred to donate to one (i.e., one child and one village of many children) vs. many. However, when efficacy was higher, participants donated more to many vs. one. We collected several other intentions measures (e.g., volunteering, joining a Facebook group, starting a club) and replicated the same patterns.

In study 4 (in progress), we manipulate beneficiary entitativity (i.e., cohesiveness) to examine how it impacts donations to one vs. many beneficiaries. Our preliminary results indicate that people give systematically more to a homogenous group of individuals, and that the mechanism underlying this result is perceived efficacy.

In summary, this work identifies ways of boosting giving to many, primarily by increasing perceived efficacy. We propose that: (a) generally, focusing on “one” (i.e., a singular beneficiary or a singular collection of beneficiaries) is an effective strategy to boost charitable giving, but (b) this is only effective when perceived efficacy is low; (c) when perceived efficacy is high, it is more effective to focus on many. Finally, since the effect of entitativity on giving is mediated by perceived efficacy, there may be instances in which perceiving many as a singular collection might hurt vs. help. In addition to its theoretical contributions, this work provides several practical implications, as there are numerous circumstances in which it is neither appropriate nor feasible to focus on “one.”

“Giving Against the Odds: When Highlighting Tempting Alternatives Increases Willingness to Donate”

Kelly Goldsmith, Northwestern University, USA

Jennifer S. Danilowitz, Yale University, USA

Ravi Dhar, Yale University, USA

Charitable giving is a large and important industry. Nearly 70% of all Americans gave to charity in 2006, creating a total of over a trillion dollars in revenue received by non-profits (Grabstads 2010). Despite the pro-social and personal benefits of charitable giving (Anik et al. 2009), the current economic crisis has caused many to reconsider making such donations. Thus the question of how to motivate charitable giving may be more relevant now than ever before. Prior research has identified certain factors that increase consumers’ willingness to donate, such as one’s information processing style (Liu and Aaker 2008; Reed, Aquino and Levy 2007) or mood (Hibbert et al. 2007; Small and Verrochi 2009). However, much of this work has focused on examining how such manipulations affect giving by influencing consumers’ perceived relationship to the cause. In contrast, we propose that highlighting alternative ways to spend one’s money can ironically increase consumers’ willingness to donate by enhancing the self-signal the donation provides (Dhar and Werternbroch 2010).

For example, imagine a consumer who is asked to make a small donation to the UNICEF. Prior to his decision, he sees a note which calls his attention to other ways his money could be used (e.g., purchasing a new hit song off of iTunes). How will his exposure to this alternative affect his likelihood of making the donation, in comparison to someone who did not see the note? As stated, we argue that making certain opportunities salient may be one way to increase charitable donations. While Frederick and colleagues (2009) have documented countless examples how salient opportunity costs generally reduce consumers’ overall likelihood of purchase, other research suggests that bringing to mind certain opportunities may increase the self-signaling utility associated with an available option (here, the option to donate). Specifically, research

by Dhar and Werternbroch (2010) demonstrates that the self-signal one derives from any given choice is context dependent and can be affected by the non-chosen options available in the choice set. For example, these authors find that the over-all utility associated with a virtuous choice (e.g., a healthy apple) increases when that option is presented in a choice set where vices (e.g., tasty chocolates) are also available. Based on these findings we argue that simply making a hedonic opportunity salient in the context of a donation choice can increase the over-all utility consumers associate with the act of donating, specifically because the act of donating will send a more positive self-signal thereby increasing the utility from donating.

These hypotheses are tested in a series of lab and field experiments. In the two lab experiments, participants read a charity appeal asking them to make a donation (Experiment 1a: \$50 to UNICEF; Experiment 1b: \$75 to Hurricane Katrina Victims). Before reporting their willingness to donate to the charity, respondents in the hedonic opportunity salient conditions were reminded that for the same amount of money, they could indulge themselves with a hedonic reward (Experiment 1a: a silver Tiffany bookmark; Experiment 1b: a massage at a spa). Finally, all participants indicated their interest in making the donation (scale: 1–not at all interested to 9–very interested). The results supported our prediction. In both experiments, participants were more interested in donating when the hedonic opportunity was made salient as compared to the control condition (Experiment 1a: $M_{\text{salient}}=7.0, M_{\text{control}}=5.9, p=.04$; Experiment 1b: $M_{\text{salient}}=6.9, M_{\text{control}}=3.6, p=.001$).

The next two experiments test for these effects in actual choice scenarios where consumers were able to donate real money. Further, Experiment 2 was designed to rule out an alternate account for the observed results by showing that the pattern is specific to hedonic alternatives (as opposed to all alternatives). The self-signaling account implies an increase in utility only when indulgent options are rejected, since the positive self-signal results from denying oneself the hedonic (but not utilitarian) alternate opportunity. In Experiment 2 we manipulate if a hedonic versus a utilitarian alternative is made salient and compare their effects on donation to a control condition. Supporting our prediction, we observe the presence of a hedonic alternate substantially increased actual donation rates over the control condition ($P_{\text{hedonic salient}}=88\%, P_{\text{control}}=47\%, p=.01$). Further, as predicted, the utilitarian opportunity reduced donation rates as compared to the hedonic opportunity ($P_{\text{utilitarian salient}}=57\%, p=.03$) and approximated that of the control condition ($p>.5$). The final field experiment tests for convergent support for this phenomenon by investigating if the observed effect on monetary donations replicates when consumers are asked to donate their time. Participants received a charity appeal via email asking them to consider donating two hours of their time to help their local UNICEF chapter. The dependent measure was participants’ choice to donate their time. For half of the participants, prior to the donation question, a hedonic opportunity was made salient (“Remember, it takes two hours of your time to watch the Season Finale of MTV’s The Jersey Shore”). The results supported our prediction and the findings thus far. When the hedonic opportunity was made salient a significantly greater percentage of participants agreed to donate their time ($P_{\text{salient}}=32.1\%, P_{\text{control}}=11.8\%, p=.023$).

This research achieves several goals: we identify a subtle and practical means to increase charitable donation rates. Further, we extend what is currently known about opportunity costs and demonstrate when making such opportunities salient can actually increase spending. Our ongoing experiments are presently testing for self-signaling as the mechanism underlying these effects.

SPECIAL SESSION

Evolution, Consumer Behavior, and Decision-Making

“The Evolutionary Roots of Decision Biases: Erasing and Exacerbating Loss Aversion”

Yexin Jessica Li, Arizona State University, USA

Doug Kenrick, Arizona State University, USA

Vladas Griskevicius, University of Minnesota, USA

Steven Neuberg, Arizona State University, USA

From an evolutionary perspective, recurring biases such as loss aversion may reflect adaptive human heuristics. For example, because our ancestors lived in environments where it was difficult to obtain sufficient calories for survival, resource losses that could result in starvation matter more than gains. Consistent with this reasoning, loss aversion is a well-documented and robust finding in humans and other species.

Although a tendency toward loss aversion may initially appear to be a human universal, an evolutionary perspective suggests that organisms generally do not evolve domain-general biases. Instead, organisms manifest different biases in different evolutionary recurring domains (e.g., survival, reproduction, etc.) (Kenrick et al. 2009). We suggest that whereas loss-aversion is adaptive in the evolutionary critical domain of survival, loss aversion is unlikely to be adaptive in the domain of mating. Thus, whereas loss aversion should be exacerbated when survival-related motives are active, loss aversion may be erased when mating motives are activated.

Further consideration of human mating suggests that men are especially unlikely to be loss averse when motivated to pursue a mate. From an evolutionary perspective, men should tend to value an opportunity to mate more than women. Consistent with this reasoning, recent research shows that men's cognitions and behaviors are more attuned than women's to potential mating opportunities, leading men to downplay potential fiscal losses when mating opportunities are salient (Griskevicius et al. 2007). Thus, we predict that men should perceive gains and losses differently when thinking about mating. In particular, mating motives should spur men to underestimate the costs of losses and overestimate the benefits of gains.

In Study 1, we experimentally activated mating or control motives by having men and women read pre-tested stories (Griskevicius et al. 2007). Then, participants indicated how much money they would spend to gain or to avoid a drop in status. As predicted, men became significantly less loss averse in the mating condition compared to control, whereby men no longer showed loss aversion. For women, mating motives did not influence loss aversion.

In study 2, we examined how mating motives influenced loss aversion using a different methodology. After activating mating or control motives, participants indicated how happy or unhappy they would be if they lost or gained particular amount of money (Harinck, Van Dijk, Beest, and Mersmann 2007). For example, participants in the 'gain' condition were asked how happy or unhappy they would be if they found \$50, \$100, \$200 and \$400. As in the first study, mating motives erased loss aversion for men, meaning that men no longer showed this bias in the mating condition. Mating motives again did not influence loss aversion for women.

We earlier noted that loss aversion is likely to be an adaptation for solving survival challenges. Thus, we should observe the highest levels of loss aversion when individuals are motivated to protect themselves from danger. In Study 3, we activated either

a self-protection motive or a control motive. Then, as in study 2, participants indicated how happy or unhappy they would be if they lost or gained particular amounts of money. Consistent with predictions, self-protection motives exacerbated loss aversion, leading both men and women to care significantly more about losses and care less about gains. This means that the bias toward loss aversion was strongest specifically when survival-related motives were salient.

Overall, these studies suggest that loss aversion is not a general universal human bias. Instead, this bias is highly sensitive to evolutionary critical contexts of survival and mating. Across studies, two evolutionary motives resulted in vastly different patterns in the relative valuation of gains versus losses. Specifically, because loss aversion likely evolved as an adaptation to survival challenges, we find that this decision bias is exacerbated when survival-related motives are salient (Study 3). However, loss aversion appears to be erased for men when the mating motives are salient (Study 1 and Study 2). More broadly, these findings suggest that evolutionary motives can alter decisional biases in ways that make functional sense in light of more general theories of evolution and cognition.

“Ovulation, Female Competition, and Product Choice: Hormonal Influences on Consumer Behavior”

Kristina Durante, University of Minnesota, USA

Vladas Griskevicius, University of Minnesota, USA

Normal Li, Singapore Management University, USA

Sarah Hill, Texas Christian University, USA

Carin Perilloux, University of Texas Austin, USA

Much research has examined women's consumer behavior. For example, early research found that women have a high level of interest in shopping for fashion-related items. Women desire to stay up-to-date on fashion trends and purchase new items even when they are not dissatisfied with the products they already own. Women also tend to use clothing to enhance their mood and social self-esteem, and they are significantly more likely to go shopping to pass time, browse around, or just as an escape. However, research thus far has not examined whether women's consumption might be influenced by hormonal factors.

Emerging research in evolutionary biology shows that various aspects of women's psychology shift during the brief window within each monthly cycle when conception is possible. For instance, near ovulation, women prefer men who show classic biological indicators of male genetic fitness (e.g., facial symmetry, social dominance), are more motivated to cheat on their current romantic partners, have more favorable attitudes toward attending social gatherings,

and desire to look sexier (e.g., Durante, Li and Haselton 2008; Gangestad and Thornhill 2008).

Drawing on this emerging theory and research, the current research tested the prediction that women's product choices shift toward products that enhance physical appearance at high fertility. We also examined whether ovulating women buy such products to appear sexier in an attempt to impress men or if ovulating women buy such products primarily in an attempt to outdo other attractive women.

Study 1 tested whether women at high fertility are more likely to choose sexier and more revealing clothing and accessories. In this study, women shopped for products using a simulated, online shopping website. Results showed that women's product choices shifted toward sexier and more revealing fashion items near ovulation. For example, ovulating women selected tops, skirts, and pants that were pre-rated to be more revealing and sexier. This shift occurred even though the women were not aware that they were currently ovulating.

The second study examined conditions that should exacerbate or suppress this ovulation effect. In Study 2, ovulating and non-ovulating women completed the same shopping task as in Study 1. However, prior to the shopping task, women were primed to think about one type of person: (1) attractive local women, (2) unattractive local women, (3) attractive local men, or (4) unattractive local men. Results showed that although women chose sexier and more revealing outfits when primed with attractive men, it did not make a difference whether the women were or were not ovulating. This finding suggests that the effects of ovulation on product choice are not predicated on mating motives directly. Instead, when women were primed with attractive female rivals, ovulation produced the largest effects on choice, leading ovulating women to choose much more sexy outfits and accessories. Findings support the notion that the ovulatory product-choice effect is predicated on same-sex competition with attractive rivals.

An additional study addressed the alternative possibility that simply priming attractive women, regardless of whether the women are viewed as potential rivals, would produce the ovulatory effect. Participants viewed photos of the same attractive women used in Study 2. However, whereas in Study 2 participants were told that the attractive women were local to the area (i.e., potential rivals), participants in the current study were told the women were not local. Results showed that ovulation had no effect on the percentage of sexy items that were chosen. Thus, women's ovulation-regulated desire for sexy items appears to be tied to the attractiveness of local, but not distant, same-sex others.

This theoretically driven and rigorous study of how hormones influence product choice marks the potential beginning of a new frontier in consumer research. The study of how biological factors such as hormones influence consumption has not only vast implications for linking consumer behavior with other disciplines (e.g., biology, animal behavior, anthropology, evolutionary psychology), it also presents a fruitful avenue for future research.

"Peacocks, Porsches and Thorstein Veblen: Conspicuous Consumption as a Mating Signaling System"

Jill Sundie, University of Houston, USA

Kathleen Vohs, University of Minnesota, USA

Vladas Griskevicius, University of Minnesota, USA

Each year consumers spend hundreds of millions of dollars for conspicuous consumption products, often paying significant mark-ups to purchase premium brands (Han, Nunes and Drèze 2010). Previous work examining conspicuous consumption from an evolutionary perspective found that conspicuous product displays are linked to mating motives for men (Griskevicius et al. 2007). Men were motivated to conspicuously consume to impress women, while women were inclined to use other means (such as public displays of helping) to impress men. This research demonstrated one motive for purchasing luxury products (among men), but also raised additional theoretical questions about the links between men, mating, and conspicuous spending.

Conspicuous consumption is a risky spending pattern—for all but the wealthiest people, it involves trading off future financial security for frivolous indulgences today. As such, conspicuous spending may indicate financial irresponsibility and narcissism, characteristics generally not sought by women in a committed partner. Conspicuous spending is, however, one means for men to display risk-seeking and social dominance. Under what circumstances would women favor social dominance and risk-seeking in a mate (as conspicuous spending indicates) over financial security and cues to a man's willingness to share and invest his resources wisely within a committed partnership? An evolutionary perspective suggests that short-term (uncommitted) mating contexts may be one such set of circumstances.

Study 1 examined how mating motives influenced conspicuous consumption. Participants either read about attractive members of the opposite sex seeking dates (mating stimuli) or about possible housing options (control). Conspicuous consumption was measured via how a windfall gain was spent on various goods and services pre-rated for conspicuousness. Findings showed that men chronically seeking short-term partnerships were significantly more motivated to conspicuously consume in the mating versus the control condition, but more commitment-oriented men were not. Women, regardless of their interest in short-term vs. long-term partnerships, did not engage in more conspicuous consumption in the mating condition.

Study 2 examined how different active mating opportunities (long-term committed vs. short-term uncommitted) would influence men's desire to engage in conspicuous spending. After receiving either a short-term, long-term, or neutral prime, participants indicated how much they would spend on eight conspicuous products. Men with an interest in short-term partnerships spent more on conspicuous products (relative to the control condition) when uncommitted mating opportunities were salient, but not when committed partnership opportunities were salient. Neither commitment-oriented men, nor women, indicated they would spend more conspicuously in either mating condition.

Study 3 investigated whether conspicuous consumption would make a man more desirable to women as (a) a committed partner, and (b) as a short-term partner. Participants evaluated an opposite-sex target whose biography indicated he/she had just purchased either an expensive conspicuous car or a modest inconspicuous car. Men were rated significantly more desirable as a date if he had purchased a conspicuous car, but *not* more desirable for marriage. Female desirability did not vary with the type of car purchased for either relationship type. Further, the male target was perceived as significantly more likely to be seeking short-term, uncommitted partnerships if he purchased the conspicuous car.

Overall, we investigated conspicuous consumption signals by examining (1) which individuals send them, (2) which contexts trigger them, and (3) how observers interpret them. Two experiments demonstrated that conspicuous consumption is driven by men who are following a lower-investment (versus higher-investment) mating strategy, and is triggered specifically by short-term (versus long-term) mating motives. A third experiment showed that observers interpret such signals accurately, with women perceiving men who conspicuously consume as interested in short-term mating. Furthermore, conspicuous purchasing enhanced men's desirability as a short-term (but not as a long-term) mate. Overall, the current pattern of data suggests that flaunting status-linked goods to potential mates is not simply about displaying economic resources. Instead, conspicuous consumption appears to be part of a more precise signaling system focused on short-term mating.

"Evolutionary Goal Scaffolding: Building Social Motives on a Physical Foundation"

Julie Huang, Yale University, USA

Joshua Ackerman, MIT Sloan School of Management, USA

John Bargh, Yale University, USA

The current research begins with age-old question: Are superheroes lonely? More specifically, does having a power like invulnerability (in mere mortal terms, feeling safe from physical harm) heal the wounds of social exclusion? An evolutionary perspective suggests that this prospect may be more than pulp fiction. Modern models of hierarchical motivation suggest basic physical needs and goals, including hunger, warmth and safety, are evolutionarily more ancient than social needs and goals. Because evolution typically works through derived adaptation—building off of (and maintaining links to) pre-existing structures—it is possible that physical goal mechanisms acted as a mental scaffold for the development of social goal mechanisms. Indeed, evidence indicates that physical and social threat processing involve common neural and hormonal substrates. Both also produce states of mental withdrawal, lead people to devalue risky options, and trigger goals to restore feelings of safety through social connection (e.g., Epley et al. 2008; Griskevicius et al., 2009).

The evolved overlap between social and physical safety processing suggests a novel framework for studying consumer goal-pursuit. We propose that cues to physical safety may substitute for social safety cues, thereby completing active social goals. For example, social rejection elicits compensatory goals such as a desire to reconnect with friends or, failing that, a desire for indulgences like Ben & Jerry's. However, feelings of physical safety may satisfy these desires, restoring cognitive resources and de-biasing decisions. This cue substitutability would provide a means of connecting what are seemingly qualitatively different forms of goal-pursuit.

The current experiments provide some of the first research on how evolutionary goal scaffolding affects decision-making. We present three studies showing that responses to social rejection can be alleviated through simulations of physical safety.

Study 1 tested whether a physical safety manipulation interfered with responses from a prior rejection experience. Participants in two conditions recalled in detail a past experience with social exclusion. One group then received a guided visualization task in which they imagined having a superpower—being completely invincible from physical harm. The other group received no such instructions. A third comparison condition first received the superpower manipulation and then completed the exclusion recall task. All participants then responded to several indicators of negative affect. Participants who received the superpower prime after rejection reported less negative feelings than the other groups, suggesting that physical safety cues "turn off" rejection responses in goal-consistent fashion.

In Study 2, participants recalled either a past rejection experience or details about their last meal. Next, half of participants received the invincibility visualization, and the other half imagined having a different, but non-safety related, superpower—the ability to fly. All participants then completed established measures of social reconnection, the desire for which has been shown to strengthen after exclusion. "Flying" participants showed the expected greater desire to interact with friends, whereas "invincible" participants did not. Safety completely attenuated the rejection-control difference, again supporting a goal scaffolding framework.

Study 3 extended these findings to the realm of consumer product decisions. Participants recalled a rejection experience and then received either the flying or invincible superpower manipulation. They then reported their desire for both high status/image-related (e.g., fancy dinner, cosmetics) and low status/non-image-related (e.g., minivan, sofa) consumer products. Invincible participants desired image-related products more and non-image-related products less than participants who could fly. Thus, consumers may feel more freedom to acquire high status, flashy products when unconstrained by self-presentational, social reconnection concerns.

In summary, three studies show that responses to social rejection can be interrupted by processing cues to physical safety, consistent with an evolutionary goal scaffolding framework. This social-physical substitutability has important implications for researchers and marketers, the most significant being that consumer behavior applications need not focus purely on social goal modification, but may also benefit from changing perceptions of related physical needs.

From Evaluation to Compliance: Anthropomorphism and the Role of Loneliness, Trust, Uncertainty and Guilt

Hee-Kyung Ahn, University of Toronto, Canada

EXTENDED ABSTRACTS

“Once Bitten, Twice Shy: Differences in Social Efficacy Affect the Perceived Efficacy of Anthropomorphizable Products”

Bart Claus, Catholic University Leuven, Belgium

Luk Warlop, Catholic University Leuven, Belgium

Anthropomorphism as a practitioners' technique of imbuing brands with human-like qualities has longtime been used, and has proven to be efficient in the development of brand personality and brand relationships. Recent work by Aggarwal and McGill (2007) signals a shift in attention from brands towards anthropomorphic products. Additionally, anthropomorphization recently has been studied from a more phenomenological stance, with an interest in dispositional and situational drivers of anthropomorphization. Epley and colleagues (2007) found sociality motives to be one of the driving factors of anthropomorphization. Lonely people seek human company, which increases their susceptibility to anthropomorphize. The latter might lead to the inference that lonely consumers seek and prefer anthropomorphic products.

Loneliness can indeed be a motivator to reconnect to other people, and by extension to anthropomorphs. Loneliness then reflects a limited *quantity* of social interaction. However, loneliness is also often considered as the result of poor *quality* social interactions, i.e. negative social experiences. This kind of loneliness is caused by negative social experiences, not by the lack of social experiences. Although people may want to reconnect to others, social anxiety might influence their attitude towards new social contacts (Maner, DeWall, Baumeister, & Schaller, 2007).

In our research, we study whether attitudes that were originally directed towards humans, can spill over to non-human targets that are subject to anthropomorphization. With regard to anthropomorphization of products, we expect that lowered social efficacy will translate into lower *a priori* expectations towards the anthropomorph at hand. On the other hand, an unexpectedly successful interaction with an anthropomorph might bring relief to people's feelings of low social efficacy. We tested these inferences in several studies.

In Study 1, we found that people with a higher tendency to feel lonely indeed favor anthropomorphic products over nonanthropomorphic ones. However, people that were first submitted to an ostracism manipulation (Williams, Cheung, & Choi, 2000) showed the opposite effect, especially when they had a higher chronic tendency to feel lonely.

In Study 2, we this negative attitude. We again manipulated social efficacy between subjects, using the ostracism task. The product that had to be evaluated was an automatic vacuum cleaner, and we asked participants about their expectations about the efficacy of the product. We manipulated anthropomorphism by describing the product either in terms of its technical characteristics and product code “Samsung VC-RS60H”, or in terms of more human traits and the friendlier name “Roomba”. Results show that people's estimates of the product's efficacy were hampered by lower social efficacy—but only for anthropomorphs.

In study 3, we built on Leary et al.'s Sociometer Theory (Leary, Tambor, & Terdal, 1995), in assessing people's chronic efficacy in social interactions. We had participants evaluate the expected number of times they would ‘guess’ the same number as a number

generator, depicted either as an ordinary personal computer, or an anthropomorphic computer (manipulated similarly to earlier studies). Afterwards, a trait measure of self-esteem (Rosenberg, 1965) was administered. Results show that in the anthropomorphization condition, trait self-esteem is positively related to people's estimation of future outcomes the product will deliver—more than in the control condition. This indicates that what is affected is people's belief in their own efficacy to interact with anthropomorphs.

Study 4 used a similar design as study 2, but with a digital picture frame as product stimulus. Control participants were told that this prototype contained sensors that adjusted the picture on display according to the atmosphere in its vicinity. Participants in the experimental condition were told that the frame was ‘smart’ and ‘able to sense’ the atmosphere. Participants then estimated the efficacy of the frame as part of a product evaluation survey. As in earlier studies, participants that had been ostracized stated lower beliefs in the efficacy of the frame, but only for the anthropomorphic description of the product. Subsequently the frame ‘selected’ one of the pictures. Using initial evaluations as a covariate, we found previously ostracized participants in the anthropomorphic condition to be most satisfied with the frame's selection performance.

In four studies, we used different operationalizations of anthropomorphism and different products. Using chronic gauges as well as momentary manipulations, we show that differences in social efficacy affect *a priori* evaluations of products more when these products are more readily susceptible to anthropomorphization. We also show that product sampling can overcome this effect. Our contribution is in demonstrating that social attitudes can bridge the gap towards non-human entities when anthropomorphization takes place.

“Who or What to Believe: Trust and the Differential Persuasiveness of Anthropomorphized and Human Agents”

Maferima Touré-Tillery, University of Chicago, USA

Ann L. McGill, University of Chicago, USA

Current research on anthropomorphism suggests that people interact with anthropomorphized agents according to their generalized beliefs about people. Indeed, Epley et al. (2007) describe anthropomorphism as a specialized process of inductive inference in which knowledge about humans is used to make inferences about nonhuman agents. Aggarwal and McGill (2007) showed that consumers evaluate an anthropomorphized product more positively when it possesses characteristics congruent with the proposed human schema, if this schema is linked to positive affect.

In the present research, we investigate this question in the persuasion context by comparing messages from human sources to those from anthropomorphized entities. In persuasion, individual differences in interpersonal trust are particularly relevant: people low (vs. high) in interpersonal trust are harder to persuade because they generally believe that social agents are neither reliable nor credible (Rotter 1967). Based on the assumption that individuals use their knowledge about people when interacting with humanized objects, we should expect messages from anthropomorphized agents and human sources to elicit similar responses, such that individuals low in trust would be equally skeptical of both messages. We propose, however, that people who hold negative views about human nature (e.g. “people are not trustworthy”), might be motivated to perceive

anthropomorphized agents in a more positive light (e.g. more trustworthy) than humans.

Epley et al (2008) found that dispositionally lonely people were more likely to anthropomorphize pets to satisfy their need for social connection. To us, these findings suggest that lonely people might be motivated to perceive humanized agents as more capable of providing social connectedness than real persons. Within this perspective, we propose that people low in interpersonal trust will perceive an anthropomorphized agent as more trustworthy than a human under similar circumstances. In the communication context, we predict that a message delivered by an anthropomorphized agent will be more persuasive to low trust individuals than one from a human source. As a result, behavioral intentions of people low in trust should align more closely with messages from anthropomorphized (vs. human) sources. However, people high in trust should respond similarly to anthropomorphized and human sources because they do not hold negative views about the trustworthiness of social agents.

In all studies, we measured trust using Rotter's (1967) interpersonal trust scale. In study 1, we tested our hypothesis in a health communication context. Participants read a message about a disease, including prevention information. The message was delivered by University authorities (human source), or by the disease itself (anthropomorphized source). We found that low trust participants were more fearful of the disease and more likely to comply with health recommendations when the source of the message was the anthropomorphized disease than when the source was human, suggesting greater perceived credibility for the "talking" disease. In the next two studies, we sought to replicate these findings for positive attitude objects to rule out the alternative explanation that low trust individuals transferred their fear of people onto the anthropomorphized agent. In study 2, participant saw a message delivered by a car advertiser (human source), or by the car itself (anthropomorphized source). The contents of the messages were identical, but low trust participants who read the message from the anthropomorphized (vs. human) source responded more positively to the car, and were more likely to buy it. Study 3 replicated these results: low trust participants preferred a fictitious brand of floss and were more likely to buy it when they read a message from the anthropomorphized (vs. human) source. Finally, study 4 demonstrated that for low trust individuals, the credibility of an anthropomorphized source is enhanced, not only for information pertaining to the source itself, but also for other pieces of information in the message. Participants read a message delivered by a fictitious dental floss advertiser or by the floss itself (Max Floss). The message from the advertiser objectified Max Floss and presented it as the best weapon against gingivitis. In the anthropomorphized source message, Max Floss presented itself as the reader's best ally against gingivitis. Participants low in trust felt more threatened by gingivitis when the message came from the anthropomorphized source (Max Floss) than when the source of the message was human. As expected, across all four studies, high trust participants responded similarly to messages from anthropomorphized and human sources.

Taken together, these studies provide convergent evidence that people low in interpersonal trust perceive anthropomorphized agents as more trustworthy than real persons in a similar context, and as a result are more persuaded by messages delivered by anthropomorphized (vs. human) agents.

"Seeing Smiles: Consumers' Adoption of Anthropomorphized New Product"

Lan Jiang, University of British Columbia, Canada

JoAndrea Hoegg, University of British Columbia, Canada

Darren W. Dahl, University of British Columbia, Canada

It has become a common practice for marketers to design an anthropomorphized representation of a product or a brand. This strategy has also been widely used in the verbal descriptions of a product, i.e. using the personal pronouns instead of "it". Wetmore (1998) studied the phenomena of people befriending their cars and suggested that anthropomorphism helps individuals counteract the feelings of fear, threat or confusion with technology. Epley, Waytz and Caciopp (2007) further examined the motives underlying peoples' tendency to imbue nonhuman agents with humanlike characteristics, and one of them is the need to avoid uncertainty.

In this research, we seek to investigate whether consumers would be more likely to adopt humanlike new products. Launching new products is a risky task, since consumers are faced with high levels of uncertainty in understanding and applying new products in their lives. If the need to avoid uncertainty indeed drives an individual's tendency to desire anthropomorphized products, we should expect the strategy of anthropomorphizing products to be more effective for new products that entail higher uncertainty. Three lab experiments have been conducted to test this hypothesis.

In the first study, we pre-tested four products, two rated more uncertain than the others, and introduced them to the participants in either human or object terms. The two high-uncertainty products were a green printer and a concept phone, and the two low-uncertainty products were a nightlight and a scuba mask. The human version of the verbal descriptions included the phrases like "this little guy" and "eats your coffee dregs", while in the object condition these words were replaced by "this little machine" and "takes your coffee dregs". The study adopted a 2 (presentation: human vs. object) x 2 (uncertainty: high vs. low) mixed design. Analysis revealed an interaction effect of uncertainty and anthropomorphism. Participants rated the high-uncertainty products more favorably when they were presented in human versus object terms, but for low-uncertainty products there was no difference between two presentation formats. Participants also indicated a higher intention to adopt the high-uncertainty products when introduced in human rather than object terms, but no differences for low-uncertainty products.

Study 2 followed up the same design and further tested the hypothesis. A major difference of this study was that we manipulated the anthropomorphism visually, so in the anthropomorphism condition the images were professionally-morphed to possess more human features, such as smiley eyes or mouth. We kept the green printer and the nightlight, but for the ease of visual manipulation we replaced the concept phone with a bluetooth headset and used a pair of speakers to replace the scuba mask. Results from Study 2 further supported our hypothesis that anthropomorphism exerts stronger influences when people evaluate or plan to adopt new products that are high in uncertainty. Participants formed more favorable attitudes towards the green printer and the bluetooth when they were morphed to be humanlike, and indicated a higher intention to adopt. However, for low-uncertainty products, the ratings were equally favorable, regardless whether the images were original or morphed.

The main purpose of Study 3 was to test whether it is the feeling of familiarity generated by anthropomorphism that helps to alleviate the uncertainty and facilitate the comprehension, thus increasing the liking and adoption. We selected the green printer as our focal product and varied the uncertainty by either labeling it as "product #124-green printer" or "product #124". Visual morphing

was used to manipulate the anthropomorphism. Consistent with the previous studies, a main effect of anthropomorphism emerged, where participants reported more favorable attitudes and behavioral intentions towards the green printer when the image featured a smiling face. More interestingly, we found an interaction between anthropomorphism and uncertainty. Participants indicated a preference for the anthropomorphized green printer, and this preference was stronger when the printer was labeled without a name. We further examined the familiarity measure, and the results followed the same pattern. Sobel test (Sobel 1982) confirmed the mediating role of familiarity in driving the effects of anthropomorphism.

In sum, we examined the effects of anthropomorphism, using both verbal and visual manipulations, on people's attitudes and adoption intentions towards the products and how uncertainty moderates the effects. The findings are consistent with our premise that people have a motive to avoid uncertainty and seek comprehension, and in consumption contexts anthropomorphism provides a solution when consumers are presented with new uncertain products. The human terms used to describe the products or the humanlike appearances increase the familiarity, and thus facilitate people's liking and adoption of them.

“Guilt Driven Compliance by Anthropomorphized Social Causes”

Hee-Kyung Ahn, University of Toronto, Canada

Hae Joo Kim, University of Toronto, Canada

Pankaj Aggarwal, University of Toronto, Canada

Finding a cost-efficient and effective tool to enhance public welfare is important given that the U.S. state governments annually spend over 85 billion dollars on environmental and health issues (U.S. Census 2007). In the present research, we argue that adding anthropomorphic features to public policy campaigns can more effectively persuade consumers to comply with a social cause.

Particularly, we hypothesize that individuals will show more favorable behavioral intentions to comply with a public policy campaign when it depicts social causes with humanlike features than when these features are absent. To explain the underlying mechanism, we draw on literature in the interpersonal domain that associates helping behavior with feelings of guilt (e.g., Carlsmith and Gross 1969). Helping is an act of communion, and guilt is based on a threat to communion regardless of whether the relationship at stake concerns a close other or stranger (Baumeister, Stillwell, and Heatherton 1994). Applying this social principle to anthropomorphism, we predict that when individuals are faced with humanlike (vs. non-humanlike) agents, feelings of guilt will arise when contemplating the consequences of not complying, which consequently leads to increased compliance. Furthermore, we hypothesize that framing matters, such that information that intensifies (e.g., monetary penalty) or alleviates (i.e., monetary substitution) guilt will moderate the effect of anthropomorphism. Three studies were conducted to test these predictions.

In study 1, we examine the effect of anthropomorphism on compliance to an energy conservation campaign. Participants were assigned to either a control condition or an anthropomorphism condition. In the former (latter), participants were exposed to a campaign poster depicting a picture of a light bulb (with humanlike physical features) and a slogan written in a third-person (first-person) perspective. As predicted, behavioral intentions to comply with the energy conservation campaign were higher in the anthropomorphism condition than in the control condition.

In study 2, we replicate this effect in the context of a food waste recycling campaign. Participants were similarly exposed to a campaign poster with a waste bin depicted as a human in the

anthropomorphism condition. Their control counterparts were exposed to the same poster in non-humanlike terms. In addition to measuring behavioral intentions of complying with the recycling campaign, we assessed participants' feelings of perceived guilt if they did not comply with the campaign. Once again, behavioral intentions to comply with the campaign were higher in the anthropomorphism condition than in the control condition. More importantly, we find that increased feelings of guilt partially mediated the effect.

In study 3 (in progress), we examine whether the framing of monetary information can moderate the effect of anthropomorphism on compliance. Participants are exposed to a food waste recycling campaign similar to study 2. In addition to an anthropomorphism manipulation, we manipulate the frame of monetary information included in the campaign poster such that it intensifies or alleviates feelings of guilt from not complying with the campaign. In the high guilt frame, the poster contains a warning for a financial penalty/fine if the participants do not recycle, “If you do not recycle, you have to pay \$5.” In the low guilt frame, the sentence is modified such that participants can avoid recycling by paying a small fee (i.e., “If you pay \$5, you do not have to recycle.”). When guilt is intensified by a monetary penalty we expect the compliance to be significantly greater than when the guilt is reduced by monetary substitution, showing the moderating effect of framing on feelings of guilt elicited by anthropomorphism.

To summarize, we find that campaign ads where social causes are anthropomorphized are more effective in heightening behavioral intentions to comply with the campaign compared to when the social causes contain no humanlike features. This effect was partially mediated by increased feelings of guilt upon considering the consequences of not complying with the public policy campaign. Moreover, information that can amplify or dampen feelings of guilt from not doing a prosocial act moderates the effect of anthropomorphism on compliance. Our findings contribute to the research on anthropomorphism by testing its effects in the domain of public policy and by identifying an underlying process of guilt. These findings have practical important implications for public policy makers who are concerned with improving the effectiveness of their prosocial messages. Additionally, they have practical implications for public policy makers whose concern is designing effective communication tools to increase prosocial behavior.

Having More: New Insights on the Impact of Numerosity on Consumer Decision Making

Haiyang Yang, INSEAD, Singapore

EXTENDED ABSTRACTS

“Decisions Based on External versus Internal Cues: The Dual Effect of Attribute Quantity on Choice”

Aner Sela, Stanford University, USA

Jonah Berger, University of Pennsylvania, USA

People almost always consider some amount of attribute information when making decisions. They compare nutrition information when grocery shopping, examine compositions when choosing 401k plans, and contrast product features when selecting household goods.

But could the mere number of product attributes presented influence what type of option people choose? Some car-rental websites, for example, highlight only a few key features of each vehicle (e.g., make and model) whereas others list dozens of features under each option (e.g., cargo room, gas mileage, and various safety features). Product displays in stores may include just the basic facts (e.g., a smart-phone’s weight and type of networks covered) or more detailed descriptions (e.g., applications, multimedia capabilities, and whether it has a camera). Might more exhaustive attribute lists lead people to favor efficient sedans over beefy roadsters, for example, or productivity- over fun-oriented smart-phones?

In a series of experiments, conducted in the field and the laboratory, we demonstrate that attribute quantity influences choice regardless of its content. We propose that, as the overall number of attributes increases, the focus of evaluation shifts from internal (i.e., experiential or memory-based cues) to external (i.e., stimulus-based) cues. Importantly, these different foci have different implications for choice under deliberate versus heuristic processing, such as with regard to the ubiquitous choice between hedonic and utilitarian options (e.g., Dhar and Wertenbroch 2000).

Under effortful deliberation, few attributes promote mental imagery (MacInnis and Price 1987), which tends to favor hedonics (Shiv and Huber 2000), whereas multiple attributes promote a more cognitive and analytical mode of thought (Peters and Slovic 2000) which highlights the appeal of utilitarian options (Rottenstreich et al. 2007). Under heuristic processing, however, fewer attributes promote reliance on accessible heuristics from memory, which often favor utilitarian options (Kivetz and Keinan 2006), whereas the presence of multiple attributes can be used as an external heuristic cue for practicality (Thompson et al. 2005) which tends to benefit hedonic more than utilitarian options (Nowlis and Simonson 1996).

Four experiments examine the dual role of attribute quantity in choice and explore underlying mechanisms. In experiment 1, four smart-phones (two described as “made for fun” and two as “made for work”) were displayed on tables and passers-by were invited to select their preferred option. The options were described using either two or ten attributes. Next, participants completed the need for cognition scale. Consistent with our conceptualization, people higher in NFC were more likely to select a work phone in the ten-attribute condition and a fun phone in the two-attribute condition, but the opposite pattern emerged among people low in NFC.

Experiments 2 and 3, manipulated, rather than measured, participants’ ability and motivation to deliberate. In addition, they used either all-hedonic (experiment 2) or all-utilitarian (experiment 3) attributes to demonstrate that the effects occur independently of attribute content. Consistent with experiment 1, participants who were encouraged to deliberate carefully selected more utilitarian options (work laptops and printers) as attribute quantity increased

continuously from 1 to 3 to 8 attributes. In contrast, participants under time pressure selected more hedonic options (gaming laptops and mp3 players) as attribute quantity increased. In addition, experiment 3 directly tested the underlying process behind these effects under both high and low deliberation. Specifically, the effect of attribute quantity under effortful deliberation was mediated by the extent of analytical thinking, whereas the effect under heuristic processing was mediated by the extent to which hedonic (but not utilitarian) options were perceived as practical.

Experiment 4 used thought-protocols to directly test the mediating role of shifting from memory- to stimulus-based evaluation. Participants were shown two utilitarian orthopedic backrests and two hedonic foot massagers, described using either 1 or 8 attributes. They were asked to write down their thoughts as they were considering which option to choose. Consistent with the hypothesized process, content analysis suggested that the effect of attribute quantity on option choice was mediated by the ratio of thoughts related to concrete, stimulus-based attributes relative to thoughts relating to people’s internal experiences and memories.

In addition to shedding light on how attribute quantity affects what type of options consumers choose, this research makes two further theoretical contributions. First, dual process theories generally assume that under heuristic processing, increasing the number of attributes (or arguments) should increase option favorability, regardless of the type of option being evaluated. In contrast, we demonstrate that more attributes can have a differential effect on heuristic evaluation of hedonic versus utilitarian options. Specifically, we show that hedonic options benefit from attribute numerosity more than utilitarian ones. Second, dual process theories have assumed that heuristic cues, such as mere attribute quantity, influence evaluation under heuristic, but not under deliberative processing (e.g., Petty and Cacioppo 1984). In contrast, the present research suggests that seemingly irrelevant peripheral cues may in fact have a dual role in decision making, influencing evaluation under heuristic as well as deliberative processing, albeit in different ways.

“The Effects of Emotional versus Cognitive Processing on Short-Term versus Long-Term Preference Consistency”

Leonard Lee, Columbia University, USA

Song-Oh Yoon, Korea University, Korea

Dan Ariely, Duke University, USA

A substantial body of research has established the benefits of conceptualizing the complex human mind as a dual-system model—the emotional system versus the cognitive system—in explaining a wide variety of human behavior (e.g., Loewenstein and O’Donoghue 2004). On the one hand, preferences based on deliberative processing and elaboration of relevant information has been shown to result in strong attitudes that are persistent over time and resistant to contextual changes (Krosnick and Petty 1994; Levin and Gaeth 1998). On the other hand, recent research suggests that too much cognitive processing can generate cognitive noise and degrade preferences stability across time (Lee, Amir, and Ariely 2009; Nordgren and Dijksterhuis 2009).

In this research, we seek to reconcile these two seemingly divergent sets of findings. Specifically, we propose that one moderating condition is the time frame over which decisions are made. Within a short time frame, people’s emotional states remain relatively stable, and the holistic nature of emotional processing facilitates the making of consistent summary assessments of target stimulus, hence

promoting preference stability; conversely, the analytical nature of cognitive processing can lead to more variations in stimulus assessments across time (e.g. changes in the specific attributes on which people focus) and generate greater preference inconsistency. When this time frame is extended, an opposite pattern may emerge: individuals might experience more fluctuations in their emotional states, which can impose a larger negative impact on preference stability than the cognitive noise inherent in deliberative processing.

In experiment 1, we adopted a 3 (processing-mode: emotion vs. cognition vs. control) x 2 (time-frame: short-term vs. long-term) between-subjects design. Participants were asked to rate the attractiveness of 10 electronic gadgets (each presented in the form of a picture and a brief description) in two different sessions (T1 and T2); these two sessions were separated by a 1-hour (1-week) gap in the short-term (long-term) condition. We manipulated participants' processing mode using a procedure adapted from Nordgren and Dijksterhuis (2009): participants in the *emotional* condition were instructed to evaluate the products based on their first impressions of and immediate emotional reactions toward them, whereas participants in the *cognitive* condition, on their cognitive deliberation and analysis of the products' pros and cons; participants in the *control* condition did not receive any specific processing-mode instructions. To minimize the possibility that participants evaluated the products at T2 simply based on their recalled evaluations at T1, we introduced two procedural-design elements. First, of the 10 products presented at each session, only 5 (target products) appeared in both sessions; the others were fillers. Second, different rating scales were used across the two sessions: a 0-100 scale at T1, versus a 13-point Likert scale (1: very unattractive, 13: very attractive) at T2.

The difference in participants' standardized ratings between the two sessions (to account for the different scales) was compared across conditions. A 2x3 ANOVA revealed a main effect of time frame, indicating that preference consistency was lower in the long-term than in the short-term condition. While there was no main effect of processing type on consistency, there was a significant time-frame X processing-mode crossover interaction. In the short-term condition, participants who evaluated the products based on their emotions were *more* consistent in their preferences compared to participants in both the cognitive and control conditions; consistency between the latter two conditions did not differ significantly. Conversely, in the long-term condition, participants in the emotion condition were *less* consistent in their preferences than those in the other two conditions (which, again, did not differ significantly.)

We replicated these results conceptually in experiment 2 using a more subtle approach to invoke different processing modes and to measure preference consistency over a more extended time frame in the long-term condition. This experiment was conducted online. Each participant was randomly assigned to one of four conditions in a 2 (product-representation: pictures vs. names) X 2 (time-frame: short-term vs. long-term) between-subjects design. Participants were first asked to study a set of ten electronic gadgets similar to the ones in experiment 1. Subsequently, they were shown all binary combinations of these products (45 pairs total) and asked to choose the one they preferred in each pair. Half the participants (short-term condition) had to make all their 45 choices in one sitting. In contrast, the other participants (long-term condition) made their choices over an extended period of time: after choosing from the first pair of products, they had to wait for a day before they received an email which directed them to a website to view and choose from the next pair of products; consequently, these participants made all their 45 product choices over more than 45 days. To manipulate processing mode, half the participants saw the products presented in the form of pictures during the product-choice stage, whereas the other half

saw the products in terms of their names. This manipulation was based on the notion that pictures tend to elicit greater emotional processing than names (Hsee and Rottenstreich 2004). To examine the degree of consistency in participants' choices, we compared the number of transitivity violations that participants made across conditions (Kendall and Babington Smith 1940). That is, given a set of any three products *A*, *B*, and *C*, a transitivity violation occurs when participants choose *A* over *B*, *B* over *C*, but *C* over *A*, hence leading to a (intransitive) preference cycle. The more violations participants made, the more inconsistent were their preferences.

A 2x2 ANOVA of the number of transitivity violations participants made revealed a similar pattern to that in experiment 1: there was a marginally significant main effect of time-frame, a significant interaction between time-frame and product-representation, but no main effect of product-representation. Again, whereas short-term participants who saw the products in terms of pictures made *fewer* transitivity violations than those who saw the products in terms of names, long-term participants who saw the products in terms of pictures made *more* transitivity violations.

Together, these results suggest that emotional processing and cognitive processing can have opposite effects on preference consistency depending on the amount of time between decisions.

“When and Why Having More can Feel Worse than Having Less”

Haiyang Yang, INSEAD, Singapore

Ziv Carmon, INSEAD, France

It is commonly believed that having more physical possessions (e.g., houses, furniture, cars) or engaging in more experiential consumptions (e.g., vacations, shows, dates) can bring more satisfaction. This belief is one reason consumers whose basic needs are satisfied, strive to and indeed consume more. In this research we propose that having more can dampen rather boost satisfaction, and offer an explanation for this phenomenon.

Whether an option is considered singularly or along with other options can significantly affect choices. For example, choosing between comparable options, rather than whether or not to choose one, can induce conflict and reduce choice probability of either option (Tversky and Shafir 1992). Building on such findings we propose that over the same duration, having multiple goods in the consumption set can be less satisfying if each good shares with other goods one or more features on which it is less attractive.

The notion that people often spontaneously contrast comparable objects at an early stage of cognitive processing and with minimal cognitive resources (see e.g., Wedell 1994) suggests that when consuming comparable goods, consumers may spontaneously contrast the consumption experiences. Consider, for example, a consumption set of two goods *X* and *Y*, each with two attributes α and β , and each yielding a similar level of overall satisfaction when consumed singularly over the same duration. When α_x is equal to α_y and β_x to β_y , comparing *X* with *Y* is unlikely to lead to dissatisfaction; thus consuming both *X* and *Y* will produce higher satisfaction than just one of the goods. When α_x is larger than α_y and β_x than β_y , the comparison, due to the shift in the reference point, may increase satisfaction derived from consuming *X* and decrease it for *Y*; but the total satisfaction derived will be higher than consuming only one of the goods. However, when α_x is greater than α_y , but β_x smaller than β_y , comparing *X* and *Y* can result in dissatisfaction, as both goods appear deficient on the respective dimensions. When the dissatisfaction is sufficiently large, consuming both goods can thus be less satisfying than consuming just one. Furthermore, given that consumers with a maximizing tendency regularly seek the best option (Schwartz et al. 2002) and that contrasting attributes makes

the imperfections of both goods salient, maximizers more than satisficers, are likely to experience negative impact of having more.

We tested these predictions in two studies. In the first experiment, participants were randomly assigned to one of three consumption set conditions (good1, good2, or both). Building on Hsee and Leclerc (1998), we asked participants in the both-goods condition to imagine consuming two goods jointly (for possessions such as framed photographs) or sequentially (for experiential goods such as movies), and those in the single-good conditions to imagine consuming the one good; participants then indicated how satisfied they were overall with the consumption. As predicted, consuming both good1 and good2 jointly was less satisfying than consuming either one singularly. In experiment 2, we extend and replicate the prior experiments by assessing the consumption experiences with measures of pleasure equivalence (cf. Carmon and Ariely 2000; e.g., “How many M&M chocolate candies do you need to consume to achieve the same amount of pleasure”), and utilizing the Maximization Scale (Schwartz et al. 2002). As expected, we found a significant interaction effect—participants’ maximization tendency significantly moderated the negative impact of having more. A field study examining consequences of having more possessions (e.g., houses, furniture, cars) or more experiences (e.g., vacations, shows, spouses, dates) in the ‘real-world’ is in progress.

To explore a boundary condition, we predicted that when participants elaborate on the difference between owning one versus both goods and thus assess the consumption more holistically, they will be less dissatisfied with having more. We tested this prediction in experiment 4. We asked a group of participants in the both-goods condition to rate how dissatisfied they would be if they didn’t own one of the goods, before completing other dependent measures. As predicted, these participants reported a higher level of satisfaction than those did not receive the manipulation question.

Overall, the results of the four studies shed light on an explanation for the negative impact of having more, and establish a boundary condition on the link between consumption and satisfaction.

“Set and Option Attractiveness as Moderators of the ‘Too Much Choice’ Phenomenon”

Leilei Gao, Chinese, University of Hong Kong, China
Itamar Simonson, Stanford University, USA

The “too much choice” phenomenon has received a great deal of attention in the past two decades. Large assortments were found to associate with greater decision difficulty, weaker preference, and greater likelihood of choice deferral (e.g. Iyengar and Lepper 2000; Schwartz 2004; Chernev 2003). In this research, we propose that the presence or absence of the “too much choice” phenomenon depends on the interplay between assortment size and the order in which consumers make the “whether to buy” and “which option to buy” decisions.

Large assortments generally represent situations where the choice set is attractive in general, but making a selection among options is rather difficult. Hence, if consumers are initially asked to select an option from the set, decision difficulty tends to reduce preference clarity and result in higher likelihood of choice deferral. However, in real-world purchase situations, consumers not only choose an option from a given assortment, they also consider whether or not to buy from the assortment (store). A typical purchase decision is twofold: “whether to buy” and “which option to buy”. Although both decisions may be made simultaneously, sometimes the consumer first identifies an attractive option and then considers whether he or she actually needs it (a process that can be classified as a “select-buy” decision); in other situations, the consumer may

first make a tentative decision to buy and then focus on making a selection from the available options (a “buy-select” decision).

We propose that the degree of the initial emphasis placed on either the buy/no-buy or option selection decision is important, because these decisions tend to be driven by different criteria. When the option selection decision is considered first, the attractiveness of the option selected relative to the available alternatives is the main driver of the decision to buy. If the selection can be easily made (such as when the assortment size is small), then the consumer is more likely to purchase the option selected. Conversely, when the decision about whether to buy from a given set of options is emphasized initially, the consumer is likely to first “eyeball” the set to determine whether an attractive option is likely to be found within it. When a shopper engages in a more holistic processing of the set, it is the overall attractiveness of the option set, rather than the differences among the options within it, that is likely to loom large, with the identification of a specific choice left until later. Accordingly, any cues suggesting that the option set is generally attractive and contains options that may be worthy of selection (e.g. large assortment) are expected to increase the likelihood that the consumer will make a tentative or even irreversible commitment to purchase.

Study 1 was designed to test this basic proposition. Study participants were randomly presented with a large or small set (10 vs. 50 options) of jelly beans. In the select-buy sequence group, participants first selected a jelly bean flavor and then indicated whether they would prefer to receive one pack of jelly beans or \$1 as a reward. Those in the buy-select sequence group were asked the same questions, but in reverse order. Our findings demonstrate that, the negative correlation between the number of options and choice likelihood is only observed when consumers focus initially on the option selection decision. Conversely, the probability of making a purchase is significantly enhanced as the number of options in the set increases when consumers focus initially on the decision whether to purchase.

Study 2 extended this investigation into a different product domain (i.e. chocolates) and employed a 2 x 2 between-subject manipulation of overall asset attractiveness and relative option attractiveness. In particular, beyond the large and small assortments presented to our participants, we created a third condition where products in the large assortment were grouped into meaningful categories to reduce selection difficulty; we also created a fourth condition where we blurred product information in the small assortment to increase selection difficulty. The results suggest that purchase likelihood is primarily determined by the overall attractiveness of a choice set when the “whether” question is emphasized early in the decision process, and by the relative attractiveness of the individual options within it when the “which” question is privileged. The greatest likelihood of a purchase occurs when both the overall set is attractive and making a selection is relatively easy.

Studies 3 and 4 extended our investigation to another important choice domain- the asymmetric dominance effect. Consistent with our general proposition and the earlier studies, the findings of studies 3 and 4 show that an initial focus on the decision whether to buy greatly reduces or eliminates the effect of asymmetric dominance in the choice set. Thus, the decision context and choice set context interact and are mutually dependent.

Finally, in a study to examine participants’ thought protocols, we show that when asked to make an option selection decision, participants elaborated more on the relative attractiveness of individual options in the set. Conversely, following a “whether to buy” decision, participants’ thoughts focused on more the overall attractiveness of the option set and their needs/wants for the product

category. In addition, the decision “whether to buy” or “which one to buy” only affects the type of thoughts rather than the number of thoughts provoked by the purchase situation, hence providing further support to our hypotheses.

The Self-Concept from Near and Far: Psychological Distance and the Consumer Self

Liad Weiss, Columbia University, USA

EXTENDED ABSTRACTS

“Understanding the “Self” in Self-Control: The Effects of Connectedness to Future Self on Far-Sightedness”

Daniel M. Bartels, University of Chicago, USA

Kerry F. Milch, Columbia University, USA

Oleg Urminsky, University of Chicago, USA

The exercise of self-control involves setting priorities and adhering to plans, even in the face of immediate temptations. Many decisions requiring self-control involve trading off consumption or happiness in the present or immediate future with consumption or happiness in the distant future. We posit that a crucial variable in such decisions is how a person views her distant future self (i.e., as a different person from her current self or as fundamentally the same person). In three studies, we show that how people view their future selves influences intertemporal preferences.

A decision maker is more closely linked to the person she will be tomorrow than to the person she'll be in 10 years, in terms of self-defining psychological properties, such as beliefs, values, and ideals. For this reason, she may prefer to allocate benefits to her more connected, sooner self at the expense of her less connected, later self. We propose that when people feel less psychologically connected to their future selves (e.g., because they foresee significant changes to the self), they will be less motivated to forego immediate benefits to provide long-term benefits for that future self, and we find that make “short-sighted” decisions over periods of time in which they anticipate the greatest changes in their identity. People who feel disconnected from the future self are more likely to choose so-called “vices” (options for which the short-run utility exceeds the long-run utility) over so-called “virtues” (options for which the long-term utility exceeds the short-run utility), and they engage in less responsible financial planning. They also tend to dehumanize that future self and indicate less willingness to take on burdens in the present to mitigate health risks in the distant future.

In Study 1, undergraduate participants read either that identity radically changes in early adulthood (especially during the college years), inducing a low degree of connectedness to their future self, or they read that the core features of one's identity are fixed in early childhood (and stable during college), inducing high connectedness to their future self. Participants were more likely to choose a lottery for a bookstore over bakery gift-certificate (e.g. virtue over relative vice) in the high-connectedness condition (after reading about the stability of their identity) than in the low-connectedness condition (after reading about how they would change).

In Study 2, we asked college seniors, who were about to graduate, how difficult it would be to generate either 2 or 10 reasons why their identity would not change as a result of college graduation. Participants in the 2-reasons condition, who found the task easier, inferred that their identity would be stable over time, yielding a greater sense of connectedness to their future self than for participants in the 10-reasons condition. The more highly connected participants in the 2-reasons condition then indicated that they would allocate more of their resources to those budgetary categories that they themselves separately judged to be the most responsible uses of money, suggesting a higher motivation to provide for the future self.

Study 3 was designed to learn more about how people view their future selves and how this relates to their willingness to engage in preventive health measures. We investigated how connectedness to a future self relates to the kinds of traits people ascribe to their

future selves, and how this in turn impacts people's motivation to incur immediate costs for the sake of improved odds of long-term health. We found participants who felt disconnected from their future selves tended to “dehumanize” the future self. Using Haslam & Bain's (2007) measures of “human nature” traits, we found that people who felt disconnected from their future selves tended to characterize the future self as rigid, inert, and lacking in emotional warmth and depth. High connectedness between present and future selves and low dehumanization of the future self each predicted people's willingness to endure pain in the present (e.g., from a diagnostic procedure) in order to reduce the likelihood of negative health states (e.g., joint pain) experienced in old age.

Across these studies, we demonstrate that how we think of our future selves plays a fundamental role in how people approach the kind of tradeoff represented by self-control dilemmas—the tradeoff between immediate temptations and long-term benefits. We will also discuss how the effect of connectedness on self-control behaviors relates to other factors implicated in such choices, including salience of future outcomes, guilt and justification.

“In-self’ and ‘Out-self’ Products: Assimilation and Contrast with Consumers’ Traits”

Liad Weiss, Columbia University, USA

Gita V. Johar, Columbia University, USA

Marketers and researchers commonly ask consumers to evaluate branded products on different scales. To encourage truthful responses, product evaluators are often promised the product they evaluate as part of their compensation. Can the notion of keeping the evaluated product, in other words mere ownership, have a systematic effect on the assessment of specific brand traits such as creativity or sincerity?

The current research examines this question from a categorization perspective. We suggest and find that consumers sometimes act as if products they own are extensions of themselves. Consequently, when consumers get to keep a product, their view of it is directly affected by their perceptions of their own traits. However, these very same perceptions inversely affect the view of non-owned products. For example, consumers who perceive themselves as more (less) creative, evaluate products they keep as more (less) creative, but products that they don't keep as less (more) creative.

This effect is proposed to be an outcome of a categorization process. Previous research suggests that people classify others as in-group or out-group members. In-group members are considered to be an extended form of consumers' self-concept (e.g., Brewer 1991). Consumers are suggested to classify objects into two equivalent categories, in-self or out-self objects, as determined by object ownership. Owned objects become members of the in-self category, yet another extended form of the individual's self-concept (Belk 1988).

The self-concept can be a salient prime. Therefore, categorizing people or objects as members of one's self-concept (i.e., as in-group members or in-self objects) may affect the way they are evaluated. Categorization of a prime and a target together, commonly yields assimilation, namely a direct effect of the prime on target evaluation. However, exclusion of the prime from the target's category, may lead to its comparison with the target. This commonly yields contrast, namely, an inverse effect of the prime on target evaluation. In line with previous research on the effect of self concept on the evaluation of in and out group members, we predicted that

self-view will directly (inversely) affect the evaluation of in-self (out-self) products.

This prediction was supported in two studies. In Study 1, participants first rated their own creativity. Then, after a filler task, they were asked to evaluate a pen. Half of the participants were promised the evaluated pen to keep. The rest were promised a luxurious mechanical pencil instead. All participants then received the same information about the pen, which was pretested to be perceived as moderately creative. Then, after trying the pen, participants rated how creative it was. As predicted, the interaction between ownership (keep/no-keep) and self-creativity ratings on pen creativity ratings was significant. The pen was rated as more creative by more creative individuals in the keep condition, and by less creative individuals in the no-keep condition.

In Study 2, differently from study 1, participants' perceptions of their own creativity were manipulated. This was achieved through an ease of retrieval manipulation. The rest of the procedure followed that of study 1. The dependent variable measured how likely it was that they would recommend the pen to "John" who was described as having different occupations that varied in their perceived creativeness (e.g., clerk as low and copywriter as high creativity occupations). As predicted, among participants in the keep condition, those in the high creativeness condition were more likely to recommend the pen to John if he was in a creative occupation. Conversely, among participants in the no-keep condition, those in the low creativeness condition were more likely to recommend the pen to John if he was in a creative occupation. There were no differences in recommendation to John if he was in a less creative occupation. To support our proposition that this effect was driven by the usage of the self-concept as a prime, we measured level of self-consciousness. As expected, we find that the aforementioned interaction was stronger for individuals that are high (vs. low) on self-consciousness.

“Opposing Selves: How American and Moral Identity Interact with the Psychology of International War to Undermine Charitable Giving to Foreign Civilians”

Stephanie Finnel, University of Pennsylvania, USA

Americus Reed II, University of Pennsylvania, USA

Karl Aquino, University of British Columbia, Canada

At the 2009 Nobel Prize ceremony, President Obama tried to promote his Afghanistan policy, using a strategy psychologists know to be effective: he encouraged people to morally disengage from (justify or excuse) the casualties of war (Aquino, Reed, Thau, and Freeman 2007). However, Obama has another goal: during his campaign, he said he wanted to double foreign aid. But if U.S. consumers are disengaged from the casualties of war, as Obama's speech encouraged, are they still likely to support charitable efforts that assist foreign civilians?

We propose that morally disengaging from the casualties of war often relates negatively to support for charitable efforts benefiting foreign civilians. By disengaging during war, consumers likely come to see themselves as more distant from foreign civilians, and hence they may be less helpful to foreign civilians in a subsequent, unrelated context (see Bushman and Anderson 2009).

However, if our effect really is driven by psychological distance between the self and foreign civilians, then it should become stronger when consumers are focused on an aspect of the self that amplifies this distance (e.g., American identity) but should become weaker when they are focused on an aspect of the self that attenuates this distance (e.g., moral identity). When American identity is activated, U.S. consumers likely perceive greater distance between themselves and foreign civilians. American identity may thus

reinforce disengagement: both are expected to decrease helpfulness toward foreign civilians. By contrast, moral identity, that is, consumers' views of themselves along traits commonly ascribed to moral exemplars (e.g., kindness), encourages concern for distant others (Aquino et al. 2007) like foreign civilians. Thus when moral identity is activated, U.S. consumers likely perceive less distance between themselves and foreign civilians. Moral identity may thus undermine disengagement: whereas disengagement is expected to decrease helpfulness toward foreign civilians, moral identity is expected to increase it. Therefore, we propose that disengagement during war is negatively related to support for charitable efforts benefiting foreign civilians, particularly when American (moral) identity is more (less) rather than less (more) central to the self and when American rather than moral identity is primed.

Study 1 tested this hypothesis with real donations. Participants first completed moral and American identity centrality scales (Aquino et al. 2007). Next they watched a slide show containing images from the Abu Ghraib prison scandal and completed a moral disengagement scale, which contains statements that justify harming others (e.g., "It is alright to fight to protect your friends.") (Aquino et al. 2007). Although this scale does not mention war, we expected participants to interpret it in the context of war, since it came just after the Abu Ghraib images.

Participants then received \$4 and donated them as they pleased across three charities: (1) the United Services Organization, which aids American soldiers, (2) the Global Fund, which aids primarily foreign civilians, and (3) Amnesty International, which aids not only civilians but also soldiers and prisoners. We were interested in consumers' charitableness to foreign civilians so we focused on the Global Fund. Consistent with our hypothesis, more disengaged participants donated less to the Global Fund, particularly when their American (moral) identity was more (less) rather than less (more) central.

However, one could argue that the results emerged only because consumers explicitly traded off aiding foreign civilians against aiding Americans. Study 2 therefore presented the opportunity to aid foreign civilians separately, without reference to Americans. It also manipulated rather than measured identity activation.

Study 2 was a two-group (American versus moral identity prime) between-subjects design. Participants first completed a moral disengagement scale specific to war (e.g., "Military force is justified when a nation's economic security is threatened.") (McAlister, Bandura, and Owen 2006). Next they watched a slide show that primed either American or moral identity. Then, they sampled a bottled water whose manufacturer was purportedly donating a portion of its proceeds to the Global Fund. Finally, they rated the water's taste and their liking for the company's partnership with the Global Fund. Consistent with our hypothesis, we found that more disengaged participants liked the taste and the partnership less, but only when their American rather than moral identity was primed.

Therefore, reactions to war, along with aspects of the self salient during war, predict not only support for war (Aquino et al. 2007) but also support for seemingly unrelated charities benefiting foreign civilians. We believe this occurs because different aspects of the self can increase or decrease U.S. consumers' psychological distance to foreign civilians. Our findings illustrate how different aspects of the self can have opposing effects on charitable giving, and suggest that it may be hard to mobilize public support for both war and foreign aid, as Obama would like to do.

“He or I Determines What or How: Effects of Visual Perspective on Perceived Self Change and Choice”

Camille S. Johnson, *Stanford University, USA*

Dirk Smeesters, *Erasmus University Rotterdam, The Netherlands*

S. Christian Wheeler, *Stanford University, USA*

Advertisements frequently prompt consumers to reflect on how they have changed over time. For example, the “Wild Thing” Viagra ad asks men to “remember that guy who used to be called ‘Wild Thing,’” thereby prompting them to reflect on how their sexual behaviors have changed over time. How do people assess how much they have changed over time? How does this affect their choices?

The current studies test whether the visual perspective one adopts when assessing self-change over time (e.g. the first person actor’s perspective versus the third person observer’s perspective) can affect the extent of perceived change. We advance beyond prior research by providing evidence for a new mechanism by which visual perspective affects perceived self-change (i.e., reliance on retrieval content vs. ease) and by showing its implications for resulting self-views and choices.

We show that when visualizing their past selves from the third-person perspective, people use the content of their recollections in assessing self-change. We also show that when visualizing their past selves from the first-person perspective, people use their experiences of retrieval ease. Hence, visual perspective and aspects of the retrieval task interact to determine perceptions of self-change. We further demonstrate that perceptions of change affect behavior differently depending on whether people perceive they have changed positively or negatively over time. When people perceive positive change, they choose products that are consistent with that change, but when people perceive negative change, they choose products that are inconsistent with that change, presumably to repair their self-views.

In the first experiment, college participants wrote about how their intellectual abilities had either changed or remained stable from either the first-person or third-person perspective. They then indicated how much their intellectual abilities had changed, their current intellectual abilities, and their preference for intellectual vs. non-intellectual products. Results indicated that those who wrote about change (stability) from the third-person perspective perceived more change (stability), perceived themselves as more (less) intellectual, and were more (less) likely to choose intellectual products than those who estimated change from the first-person perspective.

Participants in this first study were instructed to generate as many instances as possible, thereby leading participants to generate extensive content with high perceived difficulty. To provide better evidence that the effects of perspective were driven by reliance on content vs. metacognition, we manipulated the difficulty of the task (via required number of examples). The task was similar to that in experiment one, except that participants were instructed to generate either two or eight examples of stability or change from the first- or third-person perspective. They then completed an open-ended measure of their self-views, estimated their self-change, and chose between intellectual and non-intellectual products. In the difficult (i.e., eight examples) condition, results replicated experiment one. Those who estimated eight examples of change (stability) from the third-person perspective perceived more (less) change, perceived themselves as more (less) intellectual, and were more (less) likely to choose intellectual products than those who estimated change (stability) from the first-person perspective, suggesting that the third-person perspective increased reliance on retrieval content. These results were reversed in the easy (i.e., two examples) condition. Those who estimated two examples of change (stability) from the third-person perspective perceived less (more) change, perceived

themselves as less (more) intellectual, and were less (more) likely to choose intellectual products than those who estimated change (stability) from the first-person perspective, suggesting that the first-person perspective increased reliance on retrieval ease.

In our third experiment, we used an advertisement as our manipulation and tested our effects in a domain (i.e., healthy eating) in which our population expected negative change over time. College participants viewed an advertisement from the perspective of an eater or eater observer. The copy asked how the ad recipient was eating and said, “Think of two [eight] ways in which your eating habits have changed.” Participants then estimated how their eating habits had changed over time and, at the experiment’s conclusion, chose between an apple and candy bar. Results for perceived change conceptually replicated those from experiment two, except that perceived change was negative (i.e., participants who perceived change believed they ate worse than they used to). Choice results, however, were the opposite; people chose products inconsistent with perceived change. Those who perceived the greatest change (i.e., those who retrieved eight examples of change from the third-person perspective or two examples from the first-person perspective) choose healthier snacks, suggesting that snack choice was an attempt to repair self-perceptions of being an unhealthy eater.

Doing Well and Doing Good: New Frontiers in Firm/Brand Perceptions and Perceptions of Social Good

Amit Bhattacharjee, University of Pennsylvania, USA

EXTENDED ABSTRACTS

“Is Profit Evil? Incentive Neglect and the Association of Profit with Social Harm”

Amit Bhattacharjee, University of Pennsylvania, USA

Jason Dana, University of Pennsylvania, USA

Jonathan Baron, University of Pennsylvania, USA

As sentiments arising from the current financial crisis illustrate, people often behave as if profit-seeking and social good are necessarily at odds. Narrative themes involving evil capitalists have been prevalent in literature and films from Shakespeare to the modern day (Ribstein 2009). However, economists have long noted that this association is carried too far, such that profit-seeking is seen as fundamentally in conflict with social welfare: an “ineradicable prejudice that every action intended to serve the profit interest must be anti-social by this fact alone (Schumpeter 1954 p. 234).”

We build on Caplan’s (2007) notion of antimarket bias, which proposes that the benefits of the market mechanism in creating and rewarding value for society are systematically underestimated (Caplan and Cowen 2004). In other words, market transactions are regarded as mere transfers of wealth from the pockets of consumers to firms (Caplan 2007). Thus, profits may be perceived to indicate value being taken from consumers rather than provided to consumers—the opposite of what one might expect in a functioning market. Consistent with this theorizing, we show in three studies that consumers neglect the incentive properties of profit in rewarding value, and instead focus on the perceived intentions of organizations.

In study 1, participants either estimated or viewed actual profit figures for 32 US firms sampled from the Fortune 500 list and rated them on a number of dimensions of social good. Across firms, estimated profits were systematically far higher than actual profits, consistent with past findings of profit overestimation (e.g. Bolton Warlop and Alba 2003). More importantly, higher estimated profits were positively correlated with perceptions of social harm, unfair business practices, and a lack of value to society, but also with effectiveness in achieving organizational goals. Thus, even though higher profits are thought to indicate effectiveness in achieving firm objectives, those objectives are presumably seen as socially harmful and out of step with the objectives of society. This pattern also held for *actual* gross profits, suggesting that participants’ perceptions were reasonably accurate, and actual revenues, suggesting that size and prominence may serve as a proxy for perceived profitability.

In order to eliminate pre-existing associations with particular firms and test these notions in a more tightly controlled setting, study 2 provided participants with descriptions of the business practices of hypothetical organizations across four different industries, varying only whether the organization was described as a for-profit corporation or a non-profit organization. After reading each scenario, participants rated the organization described on perceived social value and effectiveness. Consistent with study 1, even identically-described hypothetical organizations were seen as less valuable to society, yet more effective, when they were described as for-profit corporations (vs. nonprofit organizations). Thus, independent of actual profitability, merely being motivated by profits was enough to produce seemingly contradictory, simultaneous judgments of greater effectiveness and diminished value.

Study 3 sought to further explore perceptions of different types of businesses and consumers’ focus on intentions. Participants rated types of firms across 42 industries on perceived profits, deservingness of these profits, value to society, source of these profits (i.e. whether they came at the expense of others), and the motives of those running the firms. Across industries, perceived profits were almost perfectly negatively correlated with the perceived social value the industry creates. Furthermore, higher perceived profits were associated with lesser perceived deservingness, less perceived value to society, and greater belief that these profits came at the expense of others. The only significant moderator of this correlation across individuals was the perceived motives of firms. Participants who did not exhibit this negative association of profits with social value tended to believe that businesses are motivated primarily by a desire to serve society or consumers. In other words, our participants believed that firms provide social value only when they intend to do so, not because profit-seeking encourages the creation of social value.

Together, our results suggest that consumers have little faith in the power of markets to create and reward value. Though even “base,” self-interested profit-seeking should motivate firms to promote the common good (Caplan 2007), consumers neglect the incentive properties of profit and the workings of the market mechanism. Instead, they focus on the intentions of firms, associating a profit motive with social harm.

“Non-Profits Are Seen as Warm and For-Profits as Competent: Firm Stereotypes Matter”

Jennifer Aaker, Stanford University, USA

Kathleen Vohs, University of Minnesota, USA

Cassie Mogilner, University of Pennsylvania, USA

In 2002, recent college graduate Charles Best started a philanthropic organization in the basement of his parents’ home (Alter 2007). It consists of a Web site (DonorsChoose.org) that allows teachers to easily post requests for donations to fill specific pedagogical needs. Through donorschoose.org, requesters are not required to write in a heavy, formal grant-writing form (which is the norm when submitting aid requests); they can simply use plain language. For instance, a teacher in a high poverty district of New York City wrote to ask for “\$1266 to purchase five laptop computers to help build the students’ math and literacy skills.”

Initially, outsiders were skeptical that the idea would work. In fact, MBA graduates from a prominent business school investigated the organization and declared that DonorsChoose.org was unlikely to stay in business. They even went so far as to withdraw a large gift tagged for the organization because they believed the non-profit’s business plan was shabby. Seven years on, the organization is still afloat. DonorsChoose.org is, in fact, hugely successful, having won multiple awards and much acclaim.

We argue that the underlying story of donorschoose.org is a common one. The organization was perceived as caring and targeting a worthy cause, but as not possessing a high level of competency. This led to our inquiry into how people view non-profit and for-profit organizations. We proposed that people possess stereotypes of organizations merely based on the knowledge that a firm is a for-profit or not-for-profit.

People’s judgments of other people often fall along two primary dimensions, namely how much they exude warmth and competence

(Judd James-Hawkins Yzerbyt and Kasima 2005). These two dimensions emerge in contexts as varied as split-second evaluations (Ybarra Chan and Park 2001), liked and disliked groups (Cuddy Fiske, and Glick 2007), employee hiring decisions (Casciaro and Lobo 2008), leadership qualifications (Chemers 2001), and romantic partner choices (Sinclair and Fehr 2005). The robustness of these two dimensions has led them to be deemed “fundamental” (Fiske Cuddy and Glick 2007). We examined whether warmth and competence color the way consumers view companies—in particular, non-profits and for-profits—and whether those judgments influence marketplace decisions. We then tested whether consumers’ stereotypes can be altered to enhance perceptions of non-profits (since they lagged behind their for-profit counterparts on key metrics of marketplace appeal).

Across three experiments, we found that stereotypes do in fact exist for non-profit and for-profit organizations and that they predict crucial marketplace behaviors, such as likelihood to visit a website and willingness to buy a product from the organization. In experiment 1, participants viewed a description of a product made by a company whose URL ended with either dot-com (www.Mozilla.com) or dot-org (www.Mozilla.org). Results showed that consumers perceived the non-profit as being warmer than the for-profit, but as less competent. Relatedly, consumers perceived the non-profit as more needy, and the for-profit as more greedy.

In experiment 2, we used the same manipulation but with a different product and a different company (www.worldofgood.com vs. www.worldofgood.org), and in addition to measuring consumers’ perceptions of the firm’s characteristics, we measured consumers’ intent to purchase a product from that firm. The results showed that although the non-profit was perceived to be more warm, consumers were more willing to buy a product offered by the for-profit because of perceptions of the company as more competent. Consequently, when perceived competence of the non-profit was boosted by an endorsement from a highly credible source (the *WSJ*, rather than *The Detroit Free Press*), we found that consumers were equally willing to buy from the non-profit as the for-profit. Furthermore, reconnecting with the participants one month after the initial study allowed us to see that the effect persists and impacts actual behavior (likelihood to have visited the firm’s website since learning of it in the initial study).

In experiment 3, we showed that an even more subtle manipulation which boosts perceived competence (i.e., the implicit activation of money) can serve to increase consumers’ willingness to buy from a non-profit. In identifying these stereotypes, our findings underscore the importance of framing firms as non-profits or for-profits (e.g., through the use of dot-org vs. dot-com internet domain names). To our knowledge, this research is the first to investigate whether stereotypes are used to evaluate non-profit and for-profit organizations, whether these stereotypes have downstream consequences on consumer behavior, and whether such stereotypes can be dispelled through marketing actions.

“Can Luxury Brands Do Poorly by Doing Good? Brand Concepts and Responses to Socially Responsible Actions”

Carlos Torelli, University of Minnesota, USA

Alokpama (Sonia) Monga, University of South Carolina, USA

Andrew Kaikati, University of Georgia, USA

Though brands across a wide spectrum of industries actively communicate CSR messages, surprisingly little is known about how these efforts might interact with brand concepts and influence consumer outcomes. The current four studies fill this gap in the literature by: (1) identifying brand concepts that are spontaneously more compatible or incompatible with a CSR image, (2) document-

ing the unintended negative consequences from communicating the CSR actions of a brand with a CSR-incompatible concept, (3) uncovering the psychological processes underlying these unintended effects, and (4) devising branding strategies to offset them.

Brand concepts are brand-unique abstract images arising from particular combinations of attributes, benefits, and marketing efforts that translate these benefits into higher-order meanings (Park Milberg and Lawson 1991). Carefully crafted to distinctively appeal to target customers, brands concepts vary as much as people’s self-relevant concerns and personalities (Aaker 1997). Communicating a brand’s CSR actions can help marketers build a brand concept associated with a prosocial image (Brown and Dacin 1997). We argue that the results of such efforts depend on the compatibility of a brand’s existing image with a prosocial one.

Prior research suggests that people’s self-relevant concerns follow a circular structure in which some concerns are consistent, opposed to each other, or orthogonal (Schwartz 1992). Pursuing concerns linked to a high-order value dimension (e.g., status concerns linked to self-enhancement values) inhibits the pursuit of concerns linked to an opposing value dimension (e.g., prosocial concerns linked to self-transcendence values), but does not affect the pursuit of orthogonal value dimensions (e.g., openness or conservation; Maio et al. 2009). Because consumers use brands to fulfill their identity goals (Aaker 1999), this motivational structure should be reflected in spontaneous perceptions of incompatibility (compatibility) between prosocial and status (conservation or openness) images. In particular, information about CSR actions of a status brand should create confusion, diluting the brand image and decreasing brand evaluations. In contrast, no such effects are anticipated for conservation or openness brands.

We tested this proposition in experiment 1 using a fictitious brand in a 3 (brand concept: conservation/openness/status) X 2 (CSR information: present/absent) between-subjects design. Participants were given information consistent with the corresponding brand concept followed by CSR (vs. neutral) information. When exposed to CSR information, participants exhibited less favorable evaluations and brand image clarity for a status versus conservation or openness brand concept. In contrast, when the CSR information was absent, brand evaluations and perceptions of brand image clarity were similar across brand concepts. For the status brand concept, evaluations and clarity were less favorable when CSR information was present versus absent.

Experiment 2 extended these findings to a real luxury brand and investigated the role of people’s preferences for status products (as an expression of their value orientation) on the evaluation of luxury brands engaged in CSR. We anticipated that people with status concerns, for whom the status affordances of a luxury brand are more self-relevant, should be more likely to exhibit the dilution effects found in experiment 1. We used a 2 (status concerns: low, high) x 2 (new brand information: CSR, control, openness) between subjects design. When exposed to CSR information, participants evaluated the luxury brand less favorably and perceived it less clearly in terms of a status image than those in a control condition, whose evaluations were based on their prior knowledge of the luxury brand. This was not the case for participants exposed to product information describing the brand in terms of stimulation values. In addition, these effects were stronger among individuals for whom status products are particularly self-relevant.

The last two experiments examined the process underlying the effect and explored ways to offset it through branding and communication practices. In experiment 3, we either encouraged participants to elaborate (or not) upon the congruity between prosocial and status images (e.g., by presenting examples of high-status persons who

behave in prosocial ways). We replicated the previously documented effects in the no elaboration condition, in which participants relied on spontaneous perceptions of CSR-status incompatibility. However, when participants elaborated on the congruity between status and CSR, the effects dissipated.

Experiment 4 further investigated the reflexive nature of the effect and identified a sub-branding strategy as a viable option for offsetting it. Communicating the CSR actions of a luxury brand under a sub-brand strategy was more effective than doing so under a direct brand strategy. However, the favorable effect of the sub-branding strategy only emerged when participants had the resources available to reconcile the CSR and luxury images by sub-typing the information. When cognitive resources were insufficient, the sub-brand strategy failed to provide any benefit.

“Are Inconsistent CSR Associations Always Detrimental? The Influence of Dialectic Thinking on Brand Perceptions”

Aloparna (Sonia) Monga, University of South Carolina, USA

Zeynep Gürhan-Canli, Koç University, Turkey

Vanitha Swaminathan, University of Pittsburgh, USA

The recent upsurge in CSR efforts reflects the belief that CSR is not only the “*right thing to do*,” but also leads to *doing better* through its positive effects on customers and other stakeholders” (Bhattacharya and Sen 2004). In reality however, brands are finding it difficult to maintain a consistent image on CSR. For example, Starbucks is known for having good CSR record, yet it was involved in exploiting Ethiopian coffee growers (Wagner Lutz and Weitz 2009). Similarly, McDonald’s has committed to reducing unhealthy trans-fats in its menu but the extent of such fats in its food varies from country to country (Wagner et al. 2009). BP, the oil company that positions itself as being environmentally friendly, started oil exploration in the Alaskan sands, attracting criticism from environmental groups (Macalister 2007). Furthermore, many brands that are now engaging in CSR were previously associated with a negative CSR record (e.g., oil companies; Yoon Gürhan-Canli and Schwarz 2006). Thus, many brands appear to be communicating inconsistent CSR associations to their consumers.

Prior research suggests that inconsistent brand associations can lead to negative consequences for the brand (Keller 2007; Loken and John 1993; Monga and John 2008). In this paper, we draw upon the literature on dialectic thinking to suggest that not all consumers are likely to be negatively affected by the inconsistent CSR information. Recent research suggests that dialectic thinkers appear to accept contradiction more easily than non-dialectic thinkers (Peng and Nisbett 1999). For example, dialectic thinkers appear to be more receptive to dialectical proverbs like, “sorrow is born of excessive joy.” On the other hand, non-dialectic thinkers appear to like non-dialectical proverbs like “half a loaf is better than none.” Dialectic thinkers are also more likely to resolve a social contradiction (e.g., a conflict between a mother and daughter) by accepting that both parties are correct (mother and daughter). In contrast, non-dialectic thinkers are more likely to choose one of the two parties as correct (e.g., mother or daughter). Thus, dialectic thinkers appear to be more favorably disposed to seeking out the middle ground and being more accepting of contradictory ideas (Peng & Nisbett, 1999).

By drawing upon this research, we predict that dialectic thinkers, who are more open to contradiction, are more likely to evaluate an inconsistent CSR brand more favorably than non-dialectic thinkers. Study 1 exposed participants (from an online consumer panel) to a news article about an oil company that was bad in CSR in the past and is now engaging in positive CSR activities (adapted from Yoon et al., 2006). A median split was used to identify dialectic and

non-dialectic thinkers. Consistent with our expectations, dialectic thinkers, compared to non-dialectic thinkers, evaluated the brand more favorably and had higher behavioral intentions.

Prior research shows that dialectic thinking emerges when individuals fear being negatively evaluated by others. Consequently, those individuals conceal their views when they believe that they are in the minority. Thus, we expected that the nature of the decision context would affect responses to inconsistent CSR brands. In a public decision context, dialectic thinkers would respond more favorably to an inconsistent CSR brand than non-dialectic thinkers. However, in a private decision context, the difference would disappear. Study 2 employed a 2 (dialectic vs. non-dialectic) x 2 (public, private) between subjects design. The stimuli consisted of a car brand with positive CSR record partnering with a brand with a negative CSR record. As expected, we found that when the decision context was public, dialectic thinkers provided more favorable brand evaluations and behavioral intentions than non-dialectic thinkers. However, in a private decision context, the difference between dialectic and non-dialectic thinkers dissipated.

Prior research has distinguished between proactive and reactive CSR strategies (Wagner et al. 2009). Proactive strategies are those that consist of a positive CSR statement followed by a negative CSR behavior by the company. A reactive strategy consists of a negative CSR behavior by the company followed by a positive CSR statement. In study 3, we used a 2 (dialectic vs. non-dialectic) x 2 (proactive, reactive) between subjects design and found that purchase intention toward an inconsistent CSR brand was more favorable among non-dialectic thinkers than among dialectic thinkers when the strategy was proactive. However, no differences emerged in the reactive strategy. Taken together, our findings make important contributions to the areas of CSR, brand strategy, and consumer behavior.

On the Psychology of Affective Forecasting: Inconsistency, Antecedents, and Consequences

EXTENDED ABSTRACTS

“The Effects of Duration Knowledge on Forecasting Versus Actual Affective Experiences”

Min Zhao, University of Toronto, Canada

Claire Tsai, University of Toronto, Canada

Lay people predict that knowing the duration of an aversive episode would improve their experience, whereas knowing the duration of a pleasant episode would weaken their experience. The present research examines this intuition. We hypothesize that the lay prediction of the effect of duration knowledge is inconsistent with its actual effect. That is, rather than weakening the experiences, duration knowledge actually intensifies affective episodes experienced over time.

To understand how duration knowledge influences people's affective experiences, we need to consider how subjective experiences change over time. We draw on anticipated utility (AU) theory to develop our hypothesis. AU theory suggests that people derive enjoyment/pain from future events (savoring good things and dreading bad things) and the savoring/dreading intensifies as the events draw near (Elster & Loewenstein 1992). When an aversive episode is about to end, people savor the relief more. The positive feelings arising from anticipating the relief contrast with and worsen the on-going negative experience. Similarly, when a pleasant episode is about to end, people dislike the ending more. The negative feelings arising from anticipating the ending contrast with and enhance the on-going positive experience. As a result, duration knowledge decreases the evaluation of aversive episodes and increases the evaluation of pleasant episodes, thereby decelerating hedonic adaptation.

We tested this hypothesis in study 1 with a 2 (experiencer vs. predictor) x 2 (duration knowledge) x 2 (valence) between-subjects factorial design. Experiencers were asked to listen to a short song bite. Half of them were informed about the duration of the song (30 seconds), whereas the other half did not know the exact duration. The song was either recorded by the original singer (positive condition) or by an experimenter with a terrible voice (negative condition). Experiencers evaluated their pain/enjoyment both online and retrospectively. The results showed that the actual effect of duration knowledge was indeed the opposite of the lay predictions. Specifically, predictors indicated that duration knowledge would weaken their experience, rendering a positive event less enjoyable and a negative event more irritating. However, experiencers with duration knowledge actually rated the good song more positively and the bad song more negatively than those without duration knowledge. As expected, real-time rating of enjoyment showed that consistent with prior research on hedonic adaptation, when duration was unknown, the enjoyment leveled off quickly. In contrast, when duration was known, enjoyment became more intense towards the end of the song.

Similar evidence was obtained in study 2 (field study) where we further generalized our findings to relatively long experiences (45 minutes instead of 30 seconds). Study 2 fully replicated study 1.

Study 3 further tested the underlying mechanism and identified one boundary condition. The results showed that the duration knowledge effect was eliminated when a pleasant episode was followed by another pleasant episode. Presumably, matching the

valence of the target event with the valence of the end of the event reduced the contrast between the on-going experience and the feelings arising from anticipating the end. However, if the duration information was unavailable, the presence of the second episode played a negligible role.

Our work contributes to research on affective forecasting and hedonic adaptation by identifying a circumstance in which the actual effect of duration knowledge contradicts people's intuition. Duration knowledge interrupts hedonic adaptation by intensifying affective experiences toward the end but people are in general unaware of this effect.

“Belittling Can Be Flattering”

Luxi Shen, University of Chicago, USA

Christopher K. Hsee, University of Chicago, USA

Jiao Zhang, University of Miami, USA

Xianchi Dai, Chinese University of Hong Kong, China

Suppose that a person receives a guess at her monthly income. Imagine two alternative scenarios: In one scenario, the guess is higher than her actual monthly income (i.e., a flattering guess). In another scenario, the guess is lower than her actual monthly income (i.e., a belittling guess). Which guess will make her happier, the flattering guess or the belittling guess?

Both conventional wisdom and previous research on self-enhancement suggest that people feel happier about flattering guesses than belittling guesses. We, however, found that in certain situations belittling guesses can make people happier, which we call the belittling-is-pleasing effect here.

In one study, for example, we interviewed employees from various companies in China about their monthly salary. Most of these respondents earned about ¥5,000 per month. The interviewer guessed either that they made ¥7,500 per month (a flattering guess) or that they made only ¥2,500 a month (a belittling guess). Respondents receiving the belittling guess were significantly happier.

We propose a dual-route model of affective reactions to explain this belittling-is-pleasing effect. The central premise of our model is that a guess influences the listener's feelings through two routes, direct and indirect. Through the direct route, the guess indicates the truth. More positive guesses reflect better beliefs from others. Therefore, the better the guess, the happier the listener. Through the indirect route, the guess serves as a reference point by which the listener evaluates the actual value of what she possesses. Here, the better the guess, the less happy the listener is. For example, suppose that you make ¥5000 a month, but a friend guesses that you make ¥7,500 a month. You may treat ¥7,500 as a reference point, and in comparison, your actual income—¥5000—is relatively low and you feel annoyed and unhappy.

According to the dual-route model, the belittling-is-pleasing effect occurs when the indirect route is more prominent than the direct route. We identify two factors that influence the prominence of the indirect route: whether or not the listener knows the actual value being guessed at and whether she cares more about the consequences associated with the actual value or about others' impression. We propose that the belittling-is-pleasing effect is more likely to occur when the receiver knows the actual value being guessed at and cares more about the actual value than others' impressions.

The proposition was tested in a study in which we examined participants' affective reactions to a flattering guess versus a belit-

ting guess at the bonuses they received. We manipulated both the knowledge of truth, whether the guess was received before or after the participants found out how much bonus they would receive, and the objective of seeking a high bonus, whether they needed the bonuses to make ends meet or they needed the bonuses to leave their friends an impression that their boss treated them well. In support of our proposition, we found that participants favored the belittling guess over the flattering guess only when they knew their actual bonuses and sought a high bonus for its own benefit.

In sum, our research shows a counterintuitive belittling-is-pleasing effect and specifies when it occurs. Our theory enriches existing literature on self-enhancement and impression formation, and yields practical implications for marketer-consumer relationships.

“Motivated Underpinnings of the Impact Bias in Affective Forecasts”

Eva Buechel, University of Miami, USA

Carey Morewedge, Carnegie Mellon University, USA

Joachim Vosgerau, Carnegie Mellon University, USA

Affective forecasters exhibit an impact bias, whereby they overestimate the emotional reaction to future events. The impact bias has been shown to occur unintentionally, resulting from biases in attention and memory a failure to correctly anticipate hedonic adaptation, and erroneous lay theories about which features of events matter most. It is a robust bias. People not only overestimate the hedonic impact of events repeated once, they overestimate the hedonic impact of events they have experienced frequently.

Given its resistance to feedback, it seems worth examining whether the impact bias might persevere because it confers some benefit to forecasters. As anticipated and experienced emotions are potent sources of motivation, affective forecasters may exaggerate their forecasts to motivate themselves to produce desired outcomes.

This hypothesis makes three predictions, which were tested in four experiments. First, the impact bias should be greater for events of greater personal importance. In line with the first prediction, Study 1 found that the more hockey fans considered a hockey game to be personally important, the more likely they were to overestimate how happy they would be if their team won. (Previous research has shown that sports fans believe that they can personally control the outcome of sporting events).

Second, the hypothesis predicts that the extremity of affective forecasts should influence the effort expended to produce desirable outcomes. In Studies 2 and 3, low and high standards of comparison were used to induce contrast effects that experimentally manipulated the extremity of affective forecasts for desirable outcomes. Subsequent mental (Study 2) and physical effort (Study 3) expended to produce those outcomes were recorded. As predicted, participants first exposed to a lower standard made more extreme forecasts than did participants exposed to a higher standard, and consequently expended more effort to produce the desirable outcomes. As the extremity of forecasts mediated the effect of the contrast manipulation on mental and physical effort expended, Studies 2 and 3 suggest that extreme affective forecasts motivate forecasters to produce desired outcomes.

Third, forecasters should make more extreme forecasts when they believe they can influence an outcome than when they believe they cannot. This was tested in Study 4. Participants forecasted how happy they would feel if they won \$5 in a die-roll before rolling the die, or after rolling the die (while the outcome of the roll was unknown). A separate condition experienced winning/not winning \$5 after rolling a die. Participants who made forecasts before rolling the die predicted they would feel happier if they won than did participants who made forecasts after rolling the die. Participants

who experienced winning \$5 also made less extreme forecasts, similar to participant who made the forecasts after rolling the die. Thus, participants made more extreme forecasts when they were able to influence an outcome that had yet to be determined than when it was determined but unknown or when it was experienced.

Errors in affective forecasting are often costly. They may lead patients to make medical decisions based on erroneous predictions of the impact that declines in their health will bring, partisanship among voters who overestimate the ineptitude of opposing parties, and so on. It is questionable, however, whether people would exercise, mend broken relationships, or spend late nights in the office if they accurately forecasted how easily they would adapt to sickness, solitude, and a larger income. This research is the first to suggest that errors in affective forecasting may confer some benefit—they may provide the motivation necessary to achieve the outcomes one desires.

“Can Consumers Make Smarter Investment Decisions By Improving Their Affective Forecasting?”

Karthik Easwar, Ohio State University, USA

Patricia West, Ohio State University, USA

This research seeks to better understand how consumers' investment decisions can be improved by reducing the “affective forecasting error” (Kermer, Driver-Linn, Wilson and Gilbert, 2006; Gilbert & Wilson, 2000). Gilbert has shown that humans tend to misforecast their affective reactions to both good and bad events. For example, people predict that winning the lottery would significantly increase happiness and that losing a limb would permanently impair quality of life. However, these predictions have been shown to be wrong. Lottery winners are no happier than non-winners and amputees' reported quality of life rebounds more quickly than forecasted.

Psychological research examining the impact of goals on performance has demonstrated an interesting and relevant paradox. According to Garland (1984) people who set higher goals tend to perform better than those who set lower goals or no goal, yet feel worse about their performance.

Heath et al (1999) offer an explanation for this paradox. Like Gilbert's experiments, Heath's subjects read hypothetical vignettes about two individuals who were facing the same task (e.g., taking a test) but starting with different goals (e.g., hopes to get a score of 90 versus hopes to “do her best”). In the scenario, both individuals experienced the same outcome, sometimes exceeding the individual's goal and other times falling short of the goal. Subjects' forecasts of these individuals' affective states showed that goals serve as reference points dividing successes from failures, and that loss aversion and diminishing sensitivity also exist.

We strive to reduce loss aversion and thus improve the affective forecasting ability of individuals by giving them the opportunity to learn from their own or others past actions. We ask whether people can learn to correct for the affective forecasting error by experiencing it for themselves or receiving feedback on the discrepancies between their forecasts and actual feelings and if this frees them to be more risk-seeking.

Participants made a series of investment decisions and were paid based on the performance of the funds they select. Participants were randomly assigned to one of two conditions (see Fig. 1). Individuals in the *no experience* condition made a series of 24 investment decisions, using detailed information on nine actual mutual funds that varied in their level of risk. After each selection, participants were given their investment's performance (a range of predetermined outcomes in a random order) and asked to report their affective reaction.

Individuals in the *first-hand experience* condition predicted their affective response to 12 hypothetical outcomes. These differ from actual decisions in that the subjects are merely told the outcome for a given period and asked to respond to it, rather than go through the fund selection process. Following this, they made a series of 12 investment decisions as described above. After reporting their affective state, they received feedback on the discrepancy between their actual feelings and their forecasts from the hypothetical phase.

All participants engaged in a second phase of hypothetical outcome forecasting that was 10 periods long. Following this task, individuals made eight actual investment decisions. Again, the actual outcomes came from a pre-determined set. After each outcome, participants reported their affective state. These last responses were compared to the affective predictions reported to measure the size of participants' affective forecasting error. Contrary to previous literature, simple experience was enough to show significant improvement in affective forecasting. Over and above this, explicit feedback had a marginal effect of improving forecasting. The impact of improved forecasting on fund selection and risk-seeking is discussed. This suggests that practice makes perfect, and that even simulated practice could be beneficial to investment decisions.

It's Not Only in the Mind: Physical Actions Steer Our Thoughts

Jiska Eelen, K.U. Leuven, Belgium

Aparna Labroo, University of Chicago, USA

EXTENDED ABSTRACT**“Sitting Position and Self-control”***Joan Meyers-Levy, University of Minnesota, USA**Rui (Juliet) Zhu, University of British Columbia, Canada**Ravi Mehta, University of British Columbia, Canada*

Research on embodied cognition suggests that cognitive representations are fundamentally grounded in their physical context. A central tenet of this theory is that human cognition, including high-level conceptual processes (e.g., inferences and categorizations), relies not only on the brain's modal systems (e.g., vision) but also on actions (e.g., body movement; Barsalou 2008). One mechanism through which embodiment can influence cognition is through situated action (Barsalou et al. 2003). Specifically, repeated situations can become entrenched in memory as situated concepts. These situated concepts usually include sensory or motor states experienced in those situations. Thus, “victory” as a situated concept might include such embodiments as hand waving and hugging. On one hand, the activation of a situated concept can make salient its constituent sensory-motor states. On the other hand, the experience of such embodiments can trigger the situated conceptualization. In other words, sensory-motor states or embodiments are associated with situated conceptualization, such that priming one can trigger the other (Niedenthal et al., 2005).

Building on the above theorizing concerning embodied cognition, we examine whether certain body postures, specifically sitting positions, can affect individuals' inclination to exert self control. Prior research has found that when sitting in an upright versus a slumped manner, individuals experienced fewer feelings of helplessness when confronted with a frustrating task (Riskind and Cotay 1982), greater confidence about their thoughts (Brinol, Petty, and Wagner 2009), and greater feelings of pride upon succeeding in an achievement task (Stepper and Strack 1993). Based on observations like these, we hypothesize that individuals who maintain an upright versus slouched sitting position should exhibit greater self-control. The logic is that an upright body posture is usually associated with situations where people engage in activities that are virtuous and right. Thus, sitting in an upright position may prime individuals to do the right thing by engaging self-control, being modest, and choosing virtue versus vice. In contrast, a slouched position is often associated with situations where individuals feel relaxed and carefree. As such, maintaining a slouched position can trigger individuals to relax their rules, enjoy life, and thereby indulge more. A series of experiments were conducted to test our hypothesis.

Sitting position was manipulated in the same manner across our studies. Those in the upright condition were asked to “sit in an upright position... put your legs and feet together, lift up the upper part of your body so that your spine is very straight. Lift your shoulders and bring them back slightly, and do not lean against the back of the chair.” In contrast, those in the slouched position were told to “sit in a relaxed position... put your legs and feet apart, about shoulder width. Drop your rib cage and curl your shoulders forward.”

The first two studies tested our main hypothesis using different tasks. In study 1, participants were asked to complete a number of unrelated tasks. As they did so, they were offered a snack (i.e., some grapes). Self-control was assessed by the number of grapes individuals ate during the study session. As predicted, those in the

upright sitting position ate fewer grapes compared to those in the slouched position. Study 2 conceptually replicated the main effect by demonstrating that when sitting upright, participants exhibited greater self-control by choosing less risky options.

In study 3, we extended our theorizing by proposing that different sitting positions might affect people's valuation of various types of products. Specifically, we anticipated that utilitarian products were likely to be valued more by those in the upright versus slouched sitting position, whereas the opposite should occur for hedonic products. Thus, this study employed a 2 (sitting position) X 2 (type of products) factorial design. Participants were asked to indicate highest price they would be willing to pay for a number of utilitarian and hedonic products. Results supported our theorizing, such that those in the upright (versus slouched) position were willing to pay significantly more for utilitarian products, yet the reverse was true for hedonic products. Study 4 offered evidence that the observed effects of sitting positions were sensation-based, and thus should be more salient among those who are more in tune with their bodily sensations.

To this point our findings have demonstrated that physical postures can affect behavior and product judgments. But could they also affect cognitive processes? That is, can sitting positions also affect people's thinking style? The last study sought to explore this idea. We posited that an upright sitting position might activate thoughts about self-control; in turn, this might prompt individuals to also think in a “controlled” manner. Consequently, these individuals should be less likely to think outside-of-the-box, and thereby exhibit lower creativity. A typical creativity task was employed in this study, and as predicted, individuals in the slouched versus upright position exhibited greater creativity.

“Spreading Activation Model Reconsidered: Motor Action Can Result in Habit Spirals”*Aparna A. Labroo, University of Chicago, USA**Jesper Nielsen, University of Arizona, USA*

In consumer psychology, the spreading activation model has been fundamental to understanding memory processes. The basic idea is that knowledge is represented in memory as a network of nodes and associative pathways between the nodes. When a part of the memory network is activated, activation spreads through the associative pathways to related concepts or nodes. The activation of any node can result from direct priming, or how frequently and recently that target concept was activated, or can result from indirect (associative) priming, or how frequently and recently associated concepts were activated, and the strength of association between the related and target concept. An important core assumption of the spreading activation model is that the spread of associations resides purely in the mind. In a departure from this basic assumption, in the current research we argue that cognition is for action, therefore (a) habits, good or bad, are stored in memory as cognitive structures, as things to be approached or avoided, as a whole, and (b) our own physical sensations or motor activities when merely exposed to a tempting bad habit can predispose us favorably toward that bad habit, but (c) most importantly, those positive associations evoked by one's motor actions can spread to other bad habits that reside within the habit structure, thus strengthening the tendency for an individual to not only adopt one bad habit but to essentially start on a downward spiral of becoming predisposed to multiple bad habits.

Recent research supports the idea that cognition is for action, and as a consequence, cognition is not an activity of just the mind alone, but is instead distributed across the entire interacting situation, especially one's body (e.g. Beer, 1995, pp. 182-183; Greeno & Moore, p. 49; Thelen & Smith, 1994, p. 17; Wertsch, 1998). In particular, motor actions that usually result from or accompany thought also facilitate accessibility to those very thoughts, and in this manner our bodies exert a powerful effect on our minds. For instance, standing upright results from and results in feeling powerful, holding a heavy weight can lead to "heavy" thinking, and writing with a dominant hand rather than the non dominant one can help validate ones thoughts. Similarly, approach actions can result in more favorable evaluations of a neutral target whereas avoidance actions can result in less favorable evaluations of a neutral target that one is exposed to at the time one is engaged in motor approach or avoidance. Building on these findings, in the current research we investigate whether given a particular exposure to a prime, can accompanying motor actions impact the strength of activation of the prime and of associated concepts, with a particular focus on the adoption and spread of bad habits.

Across three experiments we provide support for our propositions. We show that merely sitting on a chair that is leaning slightly forward (versus backward) when viewing acts of physical aggression predisposes a person to subsequently engage in greater financial risks (experiment 1), that moving ones head forward (versus backward) while examining a party CD can increase the amount a person binges on junk food (experiment 2), and that drawing marbles out of a box (versus dropping them into the box) while viewing sexy pictures of persons of the opposite sex can increase the consumption of sexy foods (dark chocolate) but reduce consumption of homey foods (grandmas cookies; experiment 3). Taken together, the data suggest that, a) habits are stored as cognitive structures in people's minds, and b) our bodies can control the activation and spread of associations to linked habits in those memory structures. Motor actions that simulate physical approach toward one bad habit not only can result in yearning for that bad habit but the positive associations towards that particular bad habit then spread to associated bad habits in memory, resulting in spirals of bad habits being adopted. Thus, the feeling that one is giving in to one bad habit can result in a person giving in to all kinds of other bad habits, and it is one's own unintended motor actions when considering a bad habit that contribute to the adoption or inhibition of other bad habits.

"Embodied Preferences: How the Easiness of Grasping Objects Affects Their Liking"

Jiska Eelen, K.U.Leuven, Belgium

Siegfried Dewitte, K.U.Leuven, Belgium

Luk Warlop, K.U.Leuven, Belgium

When consumers shop in a store, they have no verbal lists of product features available for making choices, but they do observe physical products. That is why we investigate whether product presentations influence product preferences. Merely seeing a product activates an action tendency to grasp the product (Chao & Martin, 2000; Tucker & Ellis, 1998). Processing information about products that one can easily interact with is less effortful (Helbig, Graf, & Kiefer, 2006). In addition, it has been shown that fluent information processing of a stimulus increases its attractiveness (Reber, Winkielman, & Schwarz, 1998; Winkielman & Cacioppo, 2001). Hence, it could be hypothesized that products consumers can easily interact with will be liked more than products that are more difficult to interact with. Ping, Dhillon and Beilock (2009) have found preliminary evidence for this motor fluency effect. In three experiments we manipulate ease of interaction by the fit between the

hand participants use for grasping products (right or left hand) and the orientation of products' handles (towards the right or left hand).

In a first experiment, we demonstrate that it is more difficult to interact with products oriented away from the hand used for grasping and that products oriented to the left suggest interacting with the left hand. Right-handed participants (N=18, 72% male) were shown one tool at the time on a table and were asked to move it with their dominant right hand to a shopping basket at their right side. For each participant, we created a percentage score that expressed how often products were grasped by their handle. We found that the tools were mainly grasped by their handle (M=93.72%), rather than by another part. If the handles were oriented towards the left hand and thus more difficult to grasp, the tools were grasped by their handle (M=89%) significantly less often than if the handles were oriented towards the right hand (M=98%, $t(17)=-4.18$, $p<.001$). We also found out that tools which were oriented towards the left were sometimes (mistakenly %) grasped with the left hand, whereas this never happened for tools with their handle towards the right (S=22.5, $p<.01$).

In a second experiment, participants had to select which of two tools, on a table in front of them, they would prefer to use. Right-handed participants (N=40, 40% male) indicated their preference by picking up the tool with their dominant hand and moving it to a box at their right side. Tool pairs were different products from the same product category (e.g. two different pizza cutters). One tool was easy to grasp, whereas the other tool was difficult to grasp. Overall, the easy-to-grasp-tools were chosen more often than the difficult-to-grasp tools (56%, $Z=2.16$, $p<.05$). However there were large individual differences in the extent to which this motor fluency effect occurred.

In a third experiment, pictures of one easy and one difficult-to-grasp product were shown on a computer screen, simulating an online shopping environment. Participants indicated their preferred product by tapping on "D" (for the left product) or "K" (for the right product) on the keyboard. Half of all right-handed participants used their right hand to indicate their preference, whereas the other half used their left hand. After the choice experiment we measured participants' degree of right-handedness by means of a handedness scale. We predicted that if right-handers are flexible enough to capture environmental cues, using the left hand would lead to a preference for products oriented with its handle towards the left. For each participant (N=62, 23% male) we created a percentage score that expressed how often products oriented with its handle towards the right were chosen. The main effect for hand used was not significant (right hand: M=52%; left hand: M=46%), nor was the effect of right-handedness. However degree of right-handedness moderated the effect of the hand used ($F(1, 58)=15.51$, $p<.001$). The interaction motor effect occurred for soft right-handers (M-1SD), but not for hard right-handers (M+1SD). Soft right-handers who used their right hand picked more products oriented towards the right than random (M=61%, $p<.001$) and soft right-handers who used their left hand picked more products oriented towards the left (M=39%, $p<.05$). Hard right-handers (M+1SD) showed no preference for particular product orientations, using their left (M=52%, $p=ns$) or right hand (M=43%, $p=ns$). Hence, our data suggest that the motor fluency effect only occurs for people who are not bounded by dexterity and construct their preference on-line on the basis of constraints by both their body (using left or right hand) and the environment (i.e. product presentation).

The present work about product preferences differs from prior consumer research by showing that consumers' physical interactions with products have an impact on decision making processes. Our findings indicate that information processing is flexible and

situated. This implies that the fit between body characteristics and product presentations affect consumers' choices.

“On the One Hand, on the Other Hand’: Motor Movements Activate the ‘Balance’ Goal”

Spike W. S. Lee, University of Michigan, USA

Norbert Schwarz, University of Michigan, USA

Life is a series of trade-offs and we often face situations that require a balancing of competing goals. The expression “on the one hand, on the other hand” is used to describe the weighing of pros and cons, strengths and weaknesses, or benefits and costs. It is often accompanied by a specific gesture: holding both hands palm-up and moving them alternately up and down, as though the two palms were balance pans on a scale. Pluses and minuses are thus compared by weighing what is “on the one hand” against what is “on the other hand.”

While this may seem merely a convenient figure of speech, recent advances in cognitive science suggest otherwise. A growing body of work shows that human cognition is grounded in sensorimotor processes (Barsalou, 1999, 2008) and guided by metaphors that link abstract domains to more concrete ones (Lakoff & Johnson, 1980, 1999). For example, the abstract sense of comprehension of ideas is grounded in the more concrete sense of control and manipulation of objects (e.g., “I can finally grasp the idea”). The conceptual metaphor “Understanding Is Grasping” (Lakoff & Johnson, 1999, p. 54) explains why the same hand movement has no particular meaning when we hold the hands palm-down: An object can be grasped by the palm side, but not the back side of the hand. When an object sits atop the palm, it can also be weighed. The abstract sense of importance is embodied in the concrete sense of weight (Jostmann et al., 2009). Just as a balance weighs an object on one pan against another object on the other pan, the decision maker holds one idea (e.g., an attribute, an option) “on the one hand” and weighs its relative value against another idea “on the other hand.” A sense of balance is conferred by the alternate up-and-down movements of both hands.

This analysis suggests that both hand movement and palm orientation are necessary to activate a sense of balance, resulting in three specific predictions. (1) The gesture of holding both hands palm-up and moving them alternately up and down should activate the goal to balance things out. (2) Holding the hands in the same position without moving them should not activate the goal. (3) Moving the hands, but with palms facing down, should also not activate the goal. Three experiments tested these predictions and showed that hand movements affect what people value (Experiment 1) and how they spend their time (Experiment 2) and money (Experiment 3).

Experiment 1. As part of an ostensible motor control task, participants (N=88) were induced to move their hands palm-up, or palm-down, or simply hold their hands stationary palm-up. While maintaining the gesture for 15 seconds, participants read a list of 10 values (balance in life, creativity, wealth, etc.) on a clipboard held by the experimenter, allegedly to save time. Afterwards, they ranked the values in order of personal importance (1=most important, 10=least important). As predicted, participants who had moved their hands palm-up ranked “balance in life” significantly higher (rank-out-of-10 $M=2.94$, $SD=1.84$) than those who had moved their hands palm-down ($M=4.15$, $SD=2.71$; planned contrast $t(85)=2.06$, $p=.04$; Cohen’s $d=0.52$) or those who had rested their hands ($M=4.18$, $SD=2.26$; $t(85)=2.15$, $p=.04$, $d=0.60$). Ranks in the last two conditions were not significantly different, $t(85)=.04$, $p=.97$.

Experiment 2. While moving their hands palm-up or palm-down for 20 seconds, participants (N=80) thought about how to allocate their available time during a typical weekday to various

activities (e.g., studying, hanging out with friends). Afterwards, they wrote down their allocations. Participants who moved their hands palm-up allocated time more evenly to work and leisure ($M=50\%$ for work-related activities, $SD=22\%$) than those who moved their hands palm-down ($M=40\%$ for work-related activities, $SD=23\%$), $t(78)=2.18$, $p=.03$, $d=0.49$.

Experiment 3. Preliminary data from Experiment 3 extended these findings from work-life balance to the emergence of compromise effects in consumer choice (Drolet, Luce, & Simonson, 2009). While moving their hands palm-up, or palm-down, or holding their hands stationary, participants (N=43) were asked to choose three products, each from three available options. Two were extreme options (e.g., speakers with high power and price, low power and price), one was a compromise option (medium power and price). Participants who moved their hands palm-up were more likely to choose compromise options than those who moved their hands palm-down or those who held their hands stationary ($\tau-c=.34$, $SE=.14$, $t=2.40$, $p=.02$, for balancing vs. the other two gestures, which were not significantly different).

Hand movement and palm orientation together create a “balancing” gesture that has cognitive and motivational consequences: it activates the goal to balance things out, as reflected in differential value reports, time allocation intentions, and product choices. These findings combine insights from the embodiment and conceptual metaphor perspectives, lending support to the notion that abstract concepts and goals can be activated by motor movements. They highlight the importance of taking motion and orientation (e.g., Linkenauger et al., 2009) into account simultaneously. Lacking either component eliminates the balancing effect on values and choices. Implications for consumer decision making will be discussed.

Beauty Beyond Affect: Positive and Negative Effects of Visual Attractiveness on Consumers' Judgments and Behaviors

It has long been recognized that beauty can exert a strong motivational influence on people. In a consumption context, aesthetically appealing products have been linked to favorable attitudes and higher purchase intentions as well as willingness to pay price premiums of up to fifty percent of a product's value. Yet after becoming the proud owner of a beautiful product—which often gets conspicuously displayed to the world—consumers sometimes become reluctant to actually use it for fear they might damage its pleasing visual appearance. What exactly could be driving these behaviors? Why do beautiful products motivate such responses in consumers?

A potential explanation suggested in the literature refers to the pleasure and positive mood elicited by beautiful objects, which may in turn explain the positive attitudes and behaviors triggered by attractive products. Yet mood alone may fail to account for why consumers place such a high value on aesthetics and why visual appeal sometimes has a downright anomalous impact on choice and usage behaviors. Currently there is an emerging view that consumers' responses to aesthetics differ from the low-level affective reactions typically associated with hedonic product attributes, yet we do not know exactly how. We propose that a mechanism more complex than mood may represent that powerful and unique driving force behind beautiful products. This mechanism—which we call A.I.R. (Aesthetics-Induced Responses)—implies that appealing products engage us on three dimensions: affective, cognitive, and conative.

On an affective dimension, appealing products touch our hearts. One look at a beautiful object, and, similarly to looking at an attractive person, we can experience something akin to love-at-first-sight. We call this hot, emotion-laden response "spontaneous affect". On a cognitive dimension, beautiful products hold the promise of making us more attractive and socially desirable through possession. This effect—which is comparable to the social premium bestowed on us by having a good-looking partner—will be called "self-enhancement". Finally, on a conative (motivational) level, beautiful products elicit an immediate and powerful approach desire that manifests itself in a craving for sensory proximity. Not surprisingly, museums try to address this issue by asking viewers not to touch the displayed art. We call this motivational response "instantaneous approach". Together, these three dimensions of A.I.R. are believed to explain the effects of aesthetics on consumers' behaviors better than mood can.

We tested this assumption in an experiment in which we presented participants with the image and brief description of a highly attractive desktop computer. Participants then rated their mood, the A.I.R. measure, their behavioral intentions towards the computer, and their aesthetic impressions of the computer. The A.I.R. measure consisted of a 10-item scale which included the dimensions of spontaneous affect, instantaneous approach, and self-enhancement. Mood was measured using a validated scale that included both positively- and negatively-valenced items. We measured two types of behavioral intentions: those pertaining to simple consumption behaviors (such as buying a product) and those

pertaining to more complex and difficult-to-enact behaviors (such as delaying a purchase until the desired product becomes available).

A structural equation analysis indicated that the proposed model—with aesthetic impressions as independent variable, behavioral intentions as dependent variable, and the three-dimensional A.I.R. concept as mediator—provided a very good fit to the data, both for simple and for complex behaviors. In both cases, the direct path from aesthetics to behavioral intentions was not significant, indicating full mediation through A.I.R. However, when mood was used as a mediator instead of A.I.R., this path remained significant in each case, suggesting only a partial mediation through mood. This indicates that A.I.R. can explain the relationship between aesthetics and several types of consumer behaviors better than mood can, and thus represents a superior mediator. Aesthetics create decidedly more than just a mood effect, and thus go beyond the simple pleasure response typically associated with "hedonic" product attributes.

Additionally, we collected measures of the computer's perceived functionality, novelty/interestingness and status-signaling qualities and showed that, when these measures were entered into a model simultaneously with aesthetics and A.I.R., the path from aesthetics to A.I.R. remained significant, but none of the paths from the other measures to A.I.R. were significant. This indicates that the A.I.R. measure is directly driven by aesthetic impressions and is not a consequence of the functionality, novelty or status-signaling attributes of the attractive product.

Taken together, the present findings shed light on the powerful motivational force behind product aesthetics and allow us to better understand the unique processing mechanism through which aesthetics impact various consumer behaviors.

"The Beauty Penalty: Too Sexy for the Job?"

Meng Zhu, Carnegie Mellon University, USA

Joachim Vosgerau, Carnegie Mellon University, USA

Uri Simonsohn, University of Pennsylvania, USA

Existing research has shown that physically attractive people benefit from various types of positive discrimination, from higher salaries, beneficial treatment in game shows, to more favorable offers in lab experiments. Explanations for this effect—called beauty premium—fall into two classes: taste-based explanations and statistical-based explanations. Taste-based explanations argue that beauty itself is valued by others but unrelated to productivity. Statistical-based explanations, in contrast, argue that beauty serves as a reliable indicator for productivity. For example, evolutionary accounts argue that both intelligence/fitness and beauty are inheritable characteristics. Since intelligent/fit men are more likely to mate with beautiful women, a positive correlation between beauty and productivity results. Recently, a third, belief-based explanation has been suggested, namely that beautiful people appear more confident, and since confident people are erroneously believed to be more productive, they are paid more.

We propose a slightly different belief-based explanation to account for the discrimination towards attractive people. Social psychology literature has shown that attractive people are not only perceived as more confident, they are also perceived as more sociable, dominant, and better adjusted than unattractive people. Given this validated positive link between beauty and perceived social skills, we conjecture that a beauty premium occurs for professions in

which social skills are important, because people believe that beauty pays off in social interactions. In contrast, a beauty penalty occurs for professions that require analytical skills and extensive solitary training. This penalty effect is due to people believing that less attractive individuals incur higher costs in social interactions than attractive individuals, and are thus more likely than their attractive peers to engage in analytical activities and extensive training that do not require or may even inhibit social interactions. We test our explanation in three studies.

For Study 1 we selected 12 photos (3 of attractive and 3 of unattractive individuals of each gender) from a large set of working professionals. Respondents rated each photo along the dimensions of attractiveness, social and analytical skills. Consistent with our hypothesis, social and analytical skills were negatively correlated. Furthermore, individuals rated as more attractive were perceived to have better social skills but worse analytical skills.

Study 2 examined whether physical attractiveness would influence people's preference for service providers. In a separate pretest, we found that for lawyers (doctors), people judge social (analytical) skills to be relatively more important for career success. Thus, we expected participants to prefer attractive lawyers to plain-looking lawyers, but to prefer plain-looking doctors to attractive doctors. Further, we manipulated skill importance. We expected that preferences for attractive lawyers and plain-looking doctors would be attenuated when social and analytical skills are not important. Participants were asked to imagine that they either had a medical condition or needed to go to court to appeal a property tax estimate. They were then provided with the CVs and headshots of two equally qualified doctors/lawyers (one was attractive and the other was plain-looking) and asked to indicate which professional they would choose. Additionally, we manipulated the importance of analytical and social skills to be either high (kidney surgery or an \$8,000 tax appeal) or low (getting a drug prescription or a \$500 tax appeal). In support of our hypothesis, choice proportions did not differ when social/analytical skills were not important, but differed significantly when social/analytical skills were important. We found a beauty premium for social skills, as a majority of subjects selected the more attractive professionals in the legal case, and found a beauty penalty for analytical skills as a minority selected the more attractive professionals in the medical case.

In Study 3, we manipulated the requirement of social versus analytical skills within the lawyer profession. The procedures were similar to what we used for the lawyer condition in study 2, except for having 9 photo pairs within each professional's gender. Participants were told that they needed to hire a lawyer for a property tax reduction in the range of \$6,000-9,000. Half of the participants were told that the lawyer needed to file a written appeal with the Board of Review (analytical skills condition), the other half was told that the lawyer needed to present their case in front of a jury (social skill condition). As hypothesized, we found a beauty premium for social tasks, as a majority of subjects in the jury-trial condition selected more attractive lawyers, but a beauty penalty for analytical tasks, as a minority did so for the paper-petition.

In conclusion, we demonstrate a beauty penalty effect, that is a negative discrimination against attractive service providers. Our results suggest that the beauty penalty might be as common as the beauty premium depending on whether social or analytical skills are required for the job. Further, our findings suggest that the beauty penalty versus premium cannot be explained by taste-based discrimination, as the same attractive persons are discriminated in favor of or against on tasks requiring different skills. Our results provide support for belief-based discrimination: People believe beauty pays off in social interactions, but hinders engagement and

training in analytical tasks. Whether people's beliefs that attractive people possess better social but worse analytical skills are indeed valid is an open question for future research.

“The Good, the Bad, and the Ugly: Aesthetic Effects in Product Feature Judgments”

JoAndrea Hoegg, University of British Columbia, Canada

Joseph W. Alba, University of Florida, USA

Darren W. Dahl, University of British Columbia, Canada

Prior research examining the influence of product design on evaluation has demonstrated a powerful effect of aesthetics on overall liking and judgments in the absence of other information, but the question of whether aesthetics can influence judgments of objective feature information is unresolved. We address whether and how aesthetics might alter performance evaluations of specific product features. Specifically, we examine how consumers make functionality judgments when aesthetic information conflicts with feature performance information. In taking this approach, we also address what appears to be an implicit assumption in research and practice: that being attractive is always better than being unattractive. If consumers generally expect more attractive designs to perform better, when faced with conflicting functional and aesthetic cues, how does this violation of expectation impact judgment? We examine how consumers judge relative feature performance of two competing brands when both options possess conflicting cues (i.e., one is superior to the other on a performance attribute but inferior in attractiveness).

Three outcomes are possible. Given that the task is evaluation of relative performance of a functional feature, the normative outcome would be no effect of aesthetics. A second possibility is that feature judgments will be biased in the direction of the inferior but more attractive product due to a positive halo. A final possibility is that feature judgments will be biased in the direction of the less attractive product, reflecting a negative aesthetic effect. Assuming consumers recognize the inconsistency between their expectations and the observed pattern, they will attempt to resolve it, and in so doing may elaborate on the conflicting feature. Elaboration can render beliefs about an object more evaluatively consistent and lead to a polarized assessment. We test these possibilities in four studies.

Study 1. Participants were presented with fictitious *Consumer Reports* reviews for two brands, which were written so that one target feature was clearly superior to the other. We then manipulated whether these reviews were accompanied by pictures of the product designs. Half the participants saw only the two reviews; the other half saw the reviews accompanied by pictures of the product designs (presented side-by-side). One design was more attractive than the other. The more attractive design was paired with the review of the inferior feature, and the less attractive design was paired with the review of the superior feature. In addition we manipulated cognitive load by having participants memorize either a 2-digit or 11-digit number. The study conformed to a 2 (visual information: present vs. absent) x 2 (cognitive load: high vs. low) x 2 (product replicate: cookware vs. speakers) design. The key dependent measure was participants' judgment of which brand's target feature was superior. A rating of zero would indicate they thought the two brands were equal on the target feature. A positive rating would indicate they perceived the brand with the objectively superior feature (the unattractive design) to indeed be superior on the target feature. A negative rating would indicate they perceived the brand with the objectively inferior feature (the more attractive design) to be superior.

Analysis of relative judgments of the superiority of the target feature revealed a significant visual information X cognitive load

interaction. Consistent with the negative aesthetic effect, we found that in the absence of cognitive constraints, participants seeing the pictures perceived the unattractive brand as *even better* on the target feature than did participants not exposed to pictures. This effect occurred only when participants had the cognitive capacity to consider the information. For participants who saw reviews and pictures, the addition of cognitive constraints moved the relative feature judgments in the direction of the more attractive design (inferior feature).

Study 2. In study 2 we manipulated the pairing of the visual and written information so that half the participants were presented with incongruent visual and written information as in the previous study, and half were presented with congruent visual and written information (i.e., attractive design paired with superior target feature, and less attractive design paired with inferior target feature). We also manipulated cognitive load. If consumers believe that attractive products perform better, evaluating a product where design and functionality conform to expectations (i.e., are congruent) should make processing easier, so people in the congruent conditions should not be affected by cognitive load. The procedure followed that of study 1.

Results indicated that when the picture and target feature were congruent, participants strongly favored the superior feature, regardless of cognitive load. However, when the picture and target feature were incongruent, participants favored the functionally superior (but aesthetically inferior) brand only when under low cognitive load. Moreover, when under low load, participants took more time to make their judgments when faced with incongruent rather than congruent information, supporting the inconsistency reconciliation explanation.

Study 3. In study 3 we investigated order as a potential boundary condition. Using the same incongruent pairings of design and reviews, we manipulated whether participants saw the visual and verbal information simultaneously or saw the pictures prior to reading the reviews. We found that when participants saw the designs of the competing brands prior to reading the reviews about them, the advantage for the unattractive product disappeared.

“Blinding Beauty: How Unexpected Product Attractiveness Can Overpower Negative Information”

Hanna Kim, *Chungnam National University, China*

Andreas Eisingerich, *Imperial College, UK*

Gratiana Pol, *University of Southern California, USA*

Visual attractiveness can distort quality perceptions by making products appear significantly higher in quality than they actually are. What happens, however, if an attractive product is accompanied by less-than-stellar functionality information? Can beauty overpower such information, and if yes, when and through what psychological mechanism? The present study aims to answer these questions.

Building upon order effects theory, one can expect that, when an attractive product is paired with negative performance information—a violation of consumers' expectations—attractiveness may attenuate the negative impact of this information depending on whether the product's appearance is encountered before or after the functional information.

Recent research has indeed shown that, when the attractive product *picture* is presented *first*, it elicits an affect-based impression that can positively bias the subsequent processing of verbal information. This results in higher product quality evaluations than if the picture and functionality information were presented side-by-side. In real life, however, consumers sometimes receive information in the opposite order, meaning that they hear or read negative performance information about a product before actually

experiencing its attractive design. When one is then exposed to the appealing product, contrast theory predicts that the discrepancy between the low expectations induced by the negative information and the pleasantly surprising sight of the attractive design can magnify the positive impact of attractiveness on product evaluations. Thus, one can also expect consumers to form enhanced product quality evaluations when encountering the product *picture last* rather than simultaneously with functionality information. This order effect has not yet been examined.

To test whether product attractiveness will have a stronger positive impact when encountered *first* or *last*, we conducted a 2 (order: picture-first versus picture-last) x 2 (product performance: superior versus inferior) between-subjects study. Participants were presented with the picture of an attractive computer and fictitious consumer reviews depicting the computer as either superior (4.8 out of 5 stars) or inferior (2 stars) in performance. Half of the participants saw the computer image before the reviews, while the remaining participants saw the two in the opposite order. To ensure that the information was processed in the required order and to prevent recency effects, we asked participants to elaborate in writing on the first piece of information.

The results revealed an interaction between performance and order, such that, when the picture was presented first, product quality evaluations differed significantly between the superior- and inferior-performance conditions. However, when the picture was presented last, despite the rather large objective difference in product performance between the two conditions, consumers perceived the product to be just as high in quality in the inferior-performance condition as in the superior-performance condition. This suggests that, as predicted by contrast theory, when an attractive product is presented last, attractiveness can override negative performance information by positively distorting product quality evaluations. We call this the “blinding beauty” effect. In Study 2 we confirmed that this effect happens only for attractive and not unattractive products.

Study 3 aimed to confirm that the effect is indeed motivated by surprise and to elucidate the mechanism through which the effect occurs. Since consumers make quality judgments by combining both verbal and visual product information, their higher quality evaluations in the picture-last condition could have been formed through one of two possible processing mechanisms. First, given that the pleasantly surprising sight of an attractive product elicits positive affect, consumers could have distorted or even discounted the functional information encountered beforehand, which represents an affect-confirmation process. Alternatively, consistent with the inference-based view that people use visual design cues to form beliefs about unobservable product attributes, consumers could have drawn on the image to generate positive inferences about the product's quality, which often happens in the case of attractive products. This process should be intensified by attractiveness coming as a surprise, given that surprise-inducing stimuli enhance attention and elaboration. One would therefore expect an attractive product to trigger particularly favorable appearance-based quality inferences in the picture-last condition. By contrast, in the picture-first condition, the reduced surprise effect of attractiveness paired with the subsequent encounter of negative information may attenuate these positive inferences, resulting in lower picture-based product quality evaluations.

To verify the exact cause as well as the mechanism behind the blinding beauty effect, Study 3 employed a design similar to Study 1, and included several process measures. The results showed that the surprise induced by the attractive product image was indeed higher for picture-last than for picture-first participants. Visual recall measures further corroborated these findings by revealing

that picture-last participants paid significantly more attention to the image than did picture-first participants, even though attractiveness perceptions—an alternative attention-enhancing variable—were identical between conditions.

When it comes to the processing mechanism associated with the surprise response, the product quality evaluations derived from the reviews as well as the reviews' credibility did not differ between the picture-first and picture-last condition, which argues against a mood-consistent distortion or discounting of the negative verbal information. In contrast, the quality perceptions inferred from the picture showed the same pattern as the surprise ratings, meaning that picture-last participants perceived the image as conveying higher product quality than did picture-first participants. Notably, since attractiveness ratings did not differ between conditions, a "beautiful-is-good" effect can be ruled out. Additionally, the quality inferred from the product image fully mediated the relationship between presentation order and overall quality evaluations, while verbal information-based quality perceptions did not.

Together, these findings suggest that when an attractive product is paired with inferior functionality information, showing the product picture last creates a strong surprise response that draws attention to the product appearance and can override the damaging impact of the functionality information. This "blinding beauty" effect can be best explained by consumers deriving superior product quality inferences from the attractive product design when encountering its picture last.

Context Effects Revisited: New Antecedents, Moderators and Extensions

Selin A. Malkoc, Washington University in St. Louis, USA

EXTENDED ABSTRACTS

“The Middle Option Bias: Is the Compromise Effect Driven by a Response Order Effect”*Daniel Mochon, Yale University, USA**Shane Frederick, Yale University, USA*

In the Compromise Effect an option gains choice share when an alternative is added to the choice set that makes this previously available option the middle one in the attribute space, and consequently the ‘Compromise’. For example, in one study an average priced/average quality television was chosen more often relative to an expensive/high quality one when a cheap and low quality option was added to the choice set (Simonson 1989). This effect is generally attributed to the increased ease of justifying the compromise option (Simonson 1989), an aversion to extreme options (Simonson and Tversky 1992) and to inferences about the attributes themselves (Wernerfelt 1995).

One problem with many demonstrations of this effect is that they confound the position of the options in attribute space, with their position in physical space, since options are generally ordered by their attributes. For instance, in the above example, the televisions were ordered by price, and thus adding the cheap/low quality alternative made the ‘Compromise’ option the middle one in the response order as well.

Many studies have demonstrated that the order in which options are presented affects which one is ultimately selected (Krosnick 1999). For example, participants often show a primacy effect, where they are more likely to pick options presented earlier than those that appear later (Carp 1974). In this research we propose a new response order bias, which we label the ‘Middle Option Bias’ whereby participants are more likely to choose the second option presented when there are three rather than two options, independent of what the options might be. Consequently, we suggest that part of the Compromise Effect may be driven by the mere change in the ‘Compromise’ option’s position on the survey, rather than its position in attribute space. In the first study we demonstrate the existence of this Middle Options Bias in a context where the options have no clear attributes, and therefore we would not expect any other context effects. In the second study we show how this bias can account for the Compromise Effect.

In the first study we tested the existence of the Middle Option Bias in a general context where the options don’t have any attributes that can be ranked. This allows us to demonstrate this response order bias in a setting where other context effects should be absent. In this study, participants were told to imagine that they were in a contest where a ball would be drawn from an urn, and if they guessed the correct color, they won \$10. They were told that the urn contained either 30 balls of each of 2 colors, or 30 balls of each of three colors, and were then asked to select the color they would guess. Participants were assigned to one of twelve conditions, based on a full factorial 2 Number of Options Presented (2 vs. 3) X 6 Order of the Options design. Thus each option appeared once in each position for both the two and three options conditions. We then examined how the order in which the options were presented affected their choice. In line with the Middle Option Bias, participants chose the second option presented more often when there were three options (42.1%) than when there were only two (34.0%). The increase in

the choice probability of the middle option relative to the first one was statistically significant ($p < .05$).

In the second study we tested whether the order in which the options are presented affects the magnitude of the Compromise Effect. In this study participants were asked to make choices in four domains, each domain appearing on a separate page in a random order. The number of options (2 vs. 3) and the order of these were manipulated between subjects. When focusing only on the two conditions with the order typically used in Compromise Effect studies (with the compromise option appearing second), the probability of choosing the ‘Compromise’ option was higher when there were three options than when there were two [54.5% vs. 39.1%; $p < .01$]. This effect however seems to be mainly driven by the fact that the ‘Compromise’ option is the middle response, rather than the fact that it is the middle one in attribute space. When we compare how often people choose the ‘Compromise’ option (the middle one in attribute space) independently of order—when averaging across the order manipulation—we find no Compromise Effect [45.0% vs. 44.6%, $p = .9$].

In these studies we suggested a new explanation for the Compromise Effect, where we argued that the effect might be driven by the order in which the options are presented, and not their position in attribute space. While we do not suggest that all of the Compromise Effect is driven by a response order effect, our findings do suggest that the effect may be much smaller than previously thought.

“Between a Rock and a Hard Place: Desirability Based Attenuation of Attraction Effect”*Selin A. Malkoc, Washington University in St. Louis, USA**William Hedgcock, University of Iowa, USA**Steve Hoeffler, Vanderbilt University, USA*

Many important decisions people face involve choosing between options that are undesirable — the proverbial “lesser of two evils.” Consumers face budget or geographical constraints that lead to mostly undesirable consideration sets, yet a choice is necessary. We examine the role of desirability in the context of the attraction effect (Huber, Payne and Puto 1982). Based on negative information processing research, we argue that choosing from less desirable options will activate a more vigilant system, thus attenuating or eliminating the attraction effect. Conversely, when evaluating desirable options, heuristic processing is used, leading to attraction effect. Five studies found consistent support for our proposition.

In Experiment 1, we manipulated option desirability by employing an attribute space that varied from -10 to $+10$ for the rating of the product features (where a score of zero was considered average). The ratings on the desirable (undesirable) domain took positive (negative) values. Participants chose a fitness club. Three choice sets were tested: (1) set {A, B}, where there was no decoy, (2) set {A', A, B}, where A asymmetrically dominated and (3) set {A, B, B'}, where B asymmetrically dominated. The analyses showed the attraction effect in the desirable domain, where choice of A was highest when A' (83%) was present, moderate when there was no decoy (64%) and lowest when B' was present (40%). As predicted however, presence or location of decoy had no effect in the undesirable domain (77%, 74%, 64%).

To test the robustness and increase the generalizability of the effect, remaining studies manipulated desirability in unique, yet normatively familiar ways, without the use of negative signs. In Experiment 2, we used high and low attribute values to manipulate

desirability. Participants chose a hotel from one of the two sets: {A', A, B} or {A, B, B'}. Results replicated study. When the options were desirable, we observed higher choice of A, when A' was present (73%) than when B' was present (36%). When they were undesirable however, there were no differences across conditions (54% vs, 47%).

In Experiment 3 manipulated desirability by setting a reference point for the attribute levels (industry average) and using geographical constraints to justify having a consideration set that falls above/below this point. Participants chose a frequent flyer program, where half of them saw options that were above industry average, whereas the other half saw options below the industry average. We found that the attraction effect persisted in the desirable domain (32% vs, 6%), but not in the undesirable domain (37% vs 30%).

In Experiment 4, we kept attribute values constant but varied participants' reference points (which served to make the exact same stimuli more or less desirable, depending on the prior reference point). Participants chose between two cell phone plans. These two plans were identical in desirable and undesirable domains. Instead the specifications of their current cell phone plan was manipulated to make these options appear more or less desirable. We found that when options were perceived to be more desirable, the attraction effect surfaced (76% vs, 39%), but was eliminated when the options were perceived as less desirable (63% vs 53%).

In addition, Experiment 3 and 4 examined whether simply evaluating desirable versus less desirable options changed the post-choice regulatory focus and whether such changes could account for the asymmetry in the attraction effect. These studies ruled out regulatory focus as the process.

Experiment 5 used a positive and negative framing manipulation to change the perceptions of desirability. We kept the attribute values and the reference points constant, only altering how the attribute values were framed. Participants chose a humidifier, where the attributes were either framed positively (95% effective, returns permitted within 30 days), or negatively (5% ineffective, returns denied after 30 days). Once again, we found that attraction effect persisted in the desirable domain (73% vs, 38%), but not in the undesirable domain (64% vs. 54%). In this study, we also recorded participants' response latencies to test whether a processing shift can explain the desirability-based attenuation of the attraction effect. The mediation analysis indicate that the effect of (un)desirability on the attraction effect works through an increased processing while making the choice.

Lastly, we examined whether other context effects would also be susceptible to changes in the desirability of the set. To provide an initial test, a new study used the positive/negative attribute space manipulation from Study 1 and created two sets {A, B, C}, {B, C, D}. We find that share of B is higher when it is the compromise option (44%) than when it is the extreme (12%). However, this was not the case in the undesirable domain (8% vs. 14%). These results indicate that desirability of the choice set might be relevant for other context effects as well.

We provide evidence for the attenuation of the well-established attraction effect when choice involves less desirable alternatives, which is more commonplace with the current economic conditions. We suggest that the attraction effect (and other context effects) might be more malleable than previously thought of.

“Preferences, Interrupted”

Wendy Liu, UC San Diego, USA

Jonathan Levav, Columbia University, USA

In everyday life, decisions are often made in multiple stages due to interruptions or suspensions. For example, a consumer may

be considering a purchase, but may be sidetracked for a while by other interests. In this paper we ask, what is the effect of such interruptions on preferences? Recent research (Liu 2008) shows that interrupting or postponing a decision can have a significant effect on decision outcome by changing the way people think about the decision. In particular, when thinking about a choice after a brief period of separation from initial exposure to the problem, thinking becomes more high-level and top-down, resulting in greater focus on high-level construal and less attention to low-level detail. Thus, people choose items that rate high on desirability (a high-level trait; Trope and Liberman 2000) rather than feasibility (a low-level trait). For instance, when choosing between a hiking trail that has beautiful scenery but is far away, and another that is plain but easily accessible, after an interruption people are more likely to choose the former option, compared to when the decision is not interrupted.

The current research builds on the growing interest in the dynamic course of decision making, and examines the effect of interruption on the degree of context-dependence in decisions. We find that interrupting decision-makers as they consider the option set attenuates the attraction effect, but increases the compromise effect. We propose that this occurs because interruption leads to a greater reliance on one's inherent, chronic preferences, rather than a construction of preferences based on contextual cues. Furthermore, this process shares similarities to the effect of thinking about the distant future, whereby the person focuses on the high-level construal of the problem.

In our studies we contrast two classic context effects: the compromise effect (Simonson 1989) and the attraction effect (asymmetric dominance; Huber, Payne and Puto 1982). Behavioral decision theory posits that choices are determined by two types of information concerning the options: preferences that exist in people's memory and responses to current contextual stimuli (Tversky and Simonson 1992). We propose that the two types of information correspond to different levels of “preference construal.” Inherent preferences concern people's pre-stored attitudes toward objects. However, because memory is a limited resource, preferences for many objects is constructed rather than retrieved (Bettman, Luce and Payne 1998). We suggest that, as a result, retrieved preferences concern high-level dimensions of objects, such as the product's identity (e.g., its brand) or the identities of its main attribute dimensions. We associate these types of retrieved preferences with a “high level” of preference construal. In contrast, contextual information refers to specific relationships among the values contained in the decision situation, such as the attribute levels themselves. Since people typically do not have pre-sorted preferences regarding aspects such as attribute levels, they make decisions based on the relation between different attribute levels (e.g., dominance). We associate preferences that are based on this type of reasoning as reliant on a “low level” of preference construal. For example, in choosing between two computers, a high-level construal involves the identity of the attributes (e.g., the attributes of memory); a lower-level construal involves the values on these attributes (e.g., 2 GB for memory). We hypothesize that because the person processes at a higher level construal after a period of interruption in a decision, he/she will pay more attention to attribute identity, rather than relationships in attribute value after an interruption.

This hypothesis implies a different prediction for the attraction and compromise effects. The attraction effect relies on a perception of a peculiarity in attribute levels, namely, a dominance between values of one option. However, the attention to such a dominance relationship may be attenuated if a person's focus is on higher-level constructs such as the identity of the attribute dimensions, rather than attribute values. Consequently, we expect an interruption in

decision making will reduce the attraction effect. This effect is confirmed in S1, where an interruption reduced the attraction effect in all categories.

On the other hand, the compromise effect is a result of feeling of conflict between two attribute dimensions. That is, if two attribute dimensions are both important to a decision (and both have reasonable attribute values), people may feel great conflict giving up value on either dimension, and as a result choose a middle ground where each value is at a middle level. We propose that when people pay greater attention to the higher level construal of attribute identity after an interruption, they are likely to feel even greater conflict between the attributes, and therefore be more likely to choose the compromise option. This prediction is borne out in S2 in 4 out of 4 categories.

A third experiment studies the mechanism underlying the interruption effect. Specifically, we find that temporal distance has a similar effect as decision interruption, attenuating the attraction effect, while increasing the compromise effect.

“Choice Context from Distal Similarity Signals”

Uzma Khan, Stanford University, USA

Ab Litt, Stanford University, USA

Itamar Simonson, Stanford University, USA

When and how are we influenced by others' preferences and product recommendations? Trust, liking, closeness, and credibility of recommenders are likely important considerations. Another critical factor is how *similar* people feel they are to the recommender, e.g., in preferences, personality or beliefs (Simons et al., 1970). While similarity in choice-relevant preferences is a reasonable factor to consider in decision-making, we propose that people over-generalize similarity on one dimension to infer similarity in domains unrelated to the focal decision. For instance, a common taste in obscure art-house movies might be over-generalized to infer similarity in cell-phone preferences. Such distal *similarity signals* can exert important contextual influence in decision-making, influencing both choice and recommendation efficacy.

The “signal-value” of similarity cues and relative strength of associated context effects can depend on various factors, e.g., whether the signaled similarity is on a dimension important to one's self-identity, intensity or idiosyncrasy of the preference or characteristic, etc. For example, for a liberal individual, a review of a right-wing conservative book might have *high* signal-value, whereas that of kitchen utensils would have relatively *low* signal value. We examine whether distal similarity can serve as an influential contextual factor in decision-making by exploring similarity-induced asymmetric dominance (Huber et al., 1982). We show that varying the choice context established by different similarity signal permutations (high/positive vs. high/negative vs. low) can reverse and shift the asymmetric dominance effect.

Study 1: Participants chose a preferred digital camera from several options. Each option was recommended by another consumer, for whom participants were provided a sample product review in an unrelated domain. In the Control condition, they chose between two cameras, A and B, reciprocally dominating each other in mega-pixels and price, respectively. In two other conditions they chose between three cameras: A, B, and C. Option C here had the *same* objective specifications as B. A and B were recommended by consumers whose other reviews were of a calculator and kitchen utensil, respectively (low signal-value). In contrast, C was recommended by a consumer who previously reviewed a right-wing/conservative book (high signal-value), either positively (Pro-Conservative condition) or negatively (Anti-Conservative condition). For political liberals (who predominated in our sample),

the review in the Anti-Conservative condition was hypothesized to send a *positive* similarity signal, versus a *negative* (or dissimilarity) signal in Pro-Conservative condition.

Despite B and C having identical objective attributes, we hypothesized this similarity signal difference would influence relative preferences between these options. Consistent with this view, in Pro-Conservative condition the choice-share of B increased among the options {A,B,C} compared to the control choice-set {A,B}. The choice-share of A declined substantially compared to the control, whereas C was chosen by only one participant. Thus, camera-B asymmetrically dominated camera-C.

As evidence that this effect was due specifically to the unrelated preceding product review, in the Anti-Conservative condition we observed a reversal. Here, B's choice-share *decreased* and was below that of C, and A's choice-share also fell. This preference reversal between B and C combined with decline in A's share is consistent with C asymmetrically dominating B in this condition. As expected based on the nature of this similarity context, results were moderated by political liberalism

Study 2: An alternative account for Study 1 is that, instead of signaling similarly/dissimilarity, pro/anti-conservative reviews simply influenced how much participants *liked* that reviewer, which affected how participants evaluated that person's camera recommendation. Study 2 disentangled these factors by using a product review that induced liking of the reviewer but simultaneously signaled *dissimilarity*. We did so with a product review of a book on charitable giving, as part of which the reviewer revealed an extremely charitable lifestyle (e.g., dedication of 50% of annual income to charity). While such a person may be liked, their extreme nature (82% of participants reported donating 5% or less of annual income to charity) was hypothesized to cause dissimilarity to be inferred. The procedure was identical to Study 1's, though with only one {A,B,C} condition in which camera-C was recommended by the aforementioned extreme-charitable reviewer. Consistent with expectations, participants rated this reviewer as both more liked but more dissimilar to themselves than those who recommended camera-A and camera-B (for whom provided product reviews were of a calculator and kitchen utensil as in Study 1).

Supporting a similarity-based context effect (and opposite to a liking-based account) results were analogous to the Pro-Conservative condition in Study 1, i.e., a *dissimilarity* signal for C caused B to asymmetrically dominate it. Specifically, compared to the control choice-set {A,B}, the choice-share of B increased, that of A declined and C was chosen least frequently in the {A,B,C} choice-set condition. Moreover, individuals who chose B from the {A,B,C} choice-set reported lower perceived similarity between themselves and the charitable person than did those choosing A or C.

Conclusions. Results support an important role of distal similarity signals in establishing choice contexts, as observed here in inducing and reversing asymmetric dominance effects. When similarity between oneself and another is inferred, even in domains or dimensions unrelated to a focal decision, recommendations by that other person are more influential and likely to be heeded. These findings illustrate a novel way of influencing choices through contextual cues, and reveal an important moderator of the efficacy of product recommendations and potentially other forms of interpersonal influence.

In (or out of) Control: The Effect of Perceived Influence on Consumer Behavior, Decisions, and Satisfaction

“Power and Spending on Oneself versus Others: From Psychological to Economic Value”

David Dubois, Northwestern University, USA

Derek D. Rucker, Northwestern University, USA

Adam D. Galinsky, Northwestern University, USA

Power—defined as asymmetric perceived control over resources or people—has been a central force in the study of organizational behavior. However, only recently has power been brought into marketing to understand consumer behavior. For instance, recent work suggested that states of powerlessness increase consumers’ desire for products associated with status. This effect is argued to occur out of a desire to compensate for a lack of power via the demonstration of status to others.

The present work proposes that power, even for non-status products, can have a considerable effect depending on who a product is being bought for. Specifically, we hypothesize that psychological states of power and powerlessness can also provide information with respect to the *value* of one’s self versus others.

Why would this occur? Based on work suggesting that increased power leads to greater value associated with one’s own thoughts and goals, we hypothesize that a state of powerlessness accentuates one’s feeling of dependence on others, making others more valued to an individual, consistent with work suggesting the powerless are better at taking the perspective of others and more sensitive to their immediate environment than the powerful. In contrast, a state of powerfulness signals that one is important and thus is of greater value.

If our hypothesis concerning differential value is correct, we propose that power should asymmetrically affect how much consumers are willing to spend on purchases for themselves versus others. When purchasing an item for another individual (e.g., gift certificates, chocolates), low-power individuals should spend more on the item than high-power individuals. However, when purchasing an item for themselves, this spending propensity should reverse: high-power individuals should spend more on the item than individuals in a state of low power. These ideas are tested across three experiments, using multiple power manipulations and dependent measures. In addition, we focus on relatively mundane objects, in order to avoid any status-seeking motive by low power participants.

In the first experiment, participants were randomly assigned to imagine themselves in a role of high power (i.e., a boss) or low power (i.e., an employee). Subsequently, as part of an ostensibly unrelated task, they indicated the amount they would spend on gifts (i.e., certificates for the movies, a casual restaurant) for themselves or another person. When purchasing items for themselves, high-power individuals were willing to spend more than low-power individuals. In contrast, when purchasing items for another person, low-power individuals were willing to spend more than high power individuals. Thus, the findings of experiment 1 support our differential value hypothesis.

In our second experiment we tested the hypothesis that the effects were dependent on people explicitly considering who would receive the gift. We hypothesized that when the recipient (self, other) was not made salient any effects of power would be attenuated.

Participants were assigned to low or high power via an episodic recall task. Subsequently, participants took part in a bidding study. Participants were told they would have an opportunity to bid on several objects (i.e., a mug, a t-shirt) and that they would be able to purchase the object if they bid more than an undisclosed reserve price. We randomly assigned participants to (a) bid on the object for themselves, (b) bid on the object for another person, or (c) no instructions on the target of the bidding. Replicating Experiment 1, when bidding on the object for themselves, high-power individuals bid higher than low-power individuals. In contrast, when bidding for another person, low-power individuals bid higher than high-power individuals. Finally, when the recipient of the object was not made salient, there were no differences in bidding behavior among low and high power participants.

The final experiment sought to provide evidence for the notion that it was the enhanced psychological value of others or one’s self that led to the differential spending of high and low power individuals. Power was manipulated through a real hierarchical role whereby participants were assigned to take the role of an employee or boss in an upcoming task. It was made clear that in the upcoming interaction the boss (employee) had complete control (no control) over the employee (boss) in terms of how the task would be conducted. However, prior to this task, participants took part in a study on purchasing behavior. In this study, participants were randomly assigned to a task that allowed them to purchase a number of chocolates for themselves or another person. When participants were purchasing for themselves, individuals purchased significantly more chocolates when assigned to the high as opposed to low power condition. In contrast, when participants were purchasing for another person, individuals purchased more chocolates when assigned to the low as opposed to high power condition. In addition, meditation analyses revealed that high power increased self-importance and self-importance uniquely mediated the effects of power on spending on self. In contrast, low power increased dependence on others, and dependence on others uniquely mediated the effect of power on spending on others.

Overall, these studies support our proposition that perceived control, through power shifts the psychological value placed on oneself and others and consequently affect how much people are willing to spend on themselves or others.

“Mere Influence Effect: When Motivation to Influence Drives Decision”

Xianchi Dai, Leilei Gao, Chinese University of Hong Kong, China

Baba Shiv, Stanford University, USA

People want to make sure that they live a meaningful life and they have control over the environment around them. One way to realize these dreams is to show that their actions can have some impact on others, the environment, and the world. We propose that this motivation to influence, independent of hedonic considerations of the choice options, can systematically affect decision making.

To demonstrate the *mere influence effect*, imagine a person is voting for one of two presidential candidates. In a close election, voting for the leading candidate (i.e., the slightly favored candidate as revealed by the poll) will most likely help to maintain the trend

and increase the leading candidate's winning margin. If the person votes for the challenger (i.e. the slightly disfavored candidate), however, her vote could potentially be the "critical vote" that reverse the result. Voting for the challenger thus has a higher likelihood of making an influence. On the other hand, in a large-margin or one-sided election, it is highly unlikely to change the election result with one more vote for the challenger. Comparatively, voting for the leading candidate is an influence-maximizing action because the voter can at least entertain herself that she is on the winning side.

Based on the above reasoning, we predict that in a close competition, those who care more about influence are more likely than those who care less to vote for the challenger, whereas in a large-margin or one-sided election, the reverse would be true. More generally, we propose that the motivation to make an influence can systematically affect decision making independent of hedonic considerations of the choice options. We demonstrate the mere influence effect on decision making in four studies.

In the first two studies we showed that in a close competition higher motivation to influence leads to greater preference for slightly less favored option (by others). In study 1, participants were asked to vote for two traffic control programs varying in cost and effectiveness. We manipulated the influence potential of the voting results. We found that if the voting result was the sole determinant of which of the two traffic improvement programs to implement, participants were more likely to favor the slightly less supported program; whereas when the voting result was said to be an unimportant piece of information for the policy makers, participants were equally likely to support both programs. Study 2 adopted the same context but manipulating influence by priming participants' need to influence. Those who were primed with high need to influence were more likely to favor the slightly less supported program than those low in this need.

Study 3 and 4 further demonstrated that the margins of the competition moderate the effect of need for influence on consumer preference. In study 3, participants were informed that \$100 (real money) would be donated to a foundation to save endangered animal species and they were asked to vote for an animal species (from two candidates) as the beneficiary. Participants were further informed of the "voting statistics" based on previous participants' votes. Half of the participants were told that the supporting rates were 49% versus 51% for the two animals (a close competition), the other half were told 31% versus 69%. Our proposition was supported. In the small margin conditions (counterbalanced options), those who had stronger motivation to influence were more likely to vote for the less favored animal and the reverse was true in the large margin condition. In the final study we asked more than 2000 randomly selected senior citizens to recall their actual voting behavior in the past 4 US presidential elections. We also measured their individual levels of motivation for influence and other individual characteristics. Consistent with our theorizing, in the 1996 (Clinton vs. Dole) and 2008 (Obama vs. McCain) presidential elections, which we pretested (and were predicted by national polls) to be easy wins, those who had stronger motivation to influence were more likely to vote for the leading candidates; whereas in the 2000 (Bush vs. Gore) and 2004 (Bush vs. Kerry) presidential elections, which were predicted to be close games, those who had stronger motivation to influence were more likely to vote for the challenging candidates.

Overall, these studies support our proposition of the mere influence effect. The fact that people are motivated to influence others and the environment is consistent with a general psychological tendency of seeking control to cope in an uncertain world.

"Control Deprivation and Compensatory Shopping"

Charlene Y. Chen, Columbia University, USA

Leonard Lee, Columbia University, USA

Andy J. Yap, Columbia University, USA

Control motivation is a dynamic and ubiquitous force that potentially reacts to everyday events. Violation of the basic need for control can provoke distress that initiates efforts to reassert control. Considering the abundance of opportunities people encounter in contemporary society to acquire goods and services, could consumer spending be an avenue via which control-deprived individuals attempt to recover their sense of control? This research examines whether control deprivation results in compensatory shopping behavior. In contrast with self-control that has been the focus of recent literature, "control" here refers to a more general notion involving control over external circumstances. We propose that people shop and spend more when they experience a weakened sense of control. This hypothesis runs counter to the view that control deprivation would engender passivity and withdrawal that could lead to reduced spending.

Experiment 1 was designed to establish the effect of control deprivation on compensatory shopping in a field setting—a local supermarket. Regular shoppers ($N=192$) were recruited as they entered the store to participate in a short study in exchange for a \$2-coupon. Before they commenced shopping, participants were randomly assigned to one of three conditions: they were asked to write about (1) an incident in which they had experienced a loss of control (LC condition), (2) one in which they had experienced a sense of control (HC condition), or (3) a typical day during the past month (baseline condition). After shopping, they handed their receipts to a research assistant to redeem the coupon.

Consistent with our hypothesis, LC participants spent significantly more than participants in both the HC and baseline conditions. Importantly, expenditure was not significantly different between the latter two conditions, thus indicating that control deprivation increased spending. Further analysis revealed that LC participants bought more items, particularly utilitarian products, than both the HC and baseline participants. However, the number of hedonic products purchased did not differ across conditions. To rule out the alternative explanation that differential spending across conditions was due to different emotions induced by the control manipulation, participants' writings were content analyzed by two independent raters for ten different affective states (i.e., anxious, fearful, sad, ashamed, frustrated, angry, disgusted, contented, happy, and excited). After controlling for these emotions (separately or in clusters through factor analysis), the control manipulation exerted the same effect on spending. Together, these results suggest that increased spending (particularly in potentially order-restoring utilitarian products) can serve as a strategy for individuals to regain a sense of control.

Experiment 2 was designed to conceptually replicate this effect within a controlled lab environment, while testing the underlying mechanism by relying on an individual-difference factor: need for cognitive closure (NFCC). Prior research has shown that, compared to low-NFCC individuals, high-NFCC individuals are more motivated to reach firm conclusions swiftly, and more averse toward ambiguity and unpredictability. Therefore, we expect high-NFCC individuals to be more sensitive toward control deprivation and to exhibit a higher tendency to compensate through spending when their sense of control is reduced.

In experiment 2, after completing the NFCC-Scale and a filler task, participants ($N=60$) were manipulated to experience either a momentary sense of control or not using the same recall task in experiment 1. As a token of our appreciation for their participation, they were then invited to shop at a store in the lab purportedly un-

related to the experiment. A variety of eight items comprising both hedonic and utilitarian products with prices ranging from \$0.50-\$5 (e.g., chocolates and school supplies) were offered for sale; participants were told that these products were experimental stimuli from previous studies sold at discounted prices. While each participant shopped, a research assistant (blind to the assigned conditions) recorded the number of items examined by the participant and rated the participant's involvement on a five-point scale.

As hypothesized, LC participants spent more than HC participants. LC participants also bought more utilitarian products than HC participants. In addition, LC participants examined more items in the store, and were more involved in the shopping process. Furthermore, there was a significant interaction effect between control and participants' NFCC scores. In particular, among high-NFCC participants, those in the LC group spent significantly more than those in the HC group. However, among low-NFCC participants, there was no significant difference in spending between both LC and HC participants. The interaction between control and NFCC also significantly predicted the number of utilitarian products purchased, with the pattern of interaction similar to that found for expenditure.

In sum, our findings demonstrate a compensatory mechanism that operates in response to control deprivation. In particular, shopping seems to serve as a strategy that individuals adopt when their sense of control is undermined. What remains uncertain however is which aspect(s) of the complex shopping process (e.g., browsing, selecting, spending, and consuming) help consumers regain their sense of control. Additionally, future research should also appraise the efficacy of consumer spending as a compensatory strategy. Specifically, personal control could be measured after spending to evaluate whether control is restored to initial levels before control deprivation.

“Power and Choice: A Compensatory Theory of Control”

Simona Botti, London Business School, UK

M. Ena Inesi, London Business School, UK

Research has shown that the provision and exercise of choice is an important means through which consumers experience control and its corresponding benefits, such as increased motivation, better mood, and greater satisfaction. More recent findings have demonstrated that choice is not always beneficial: Participants who chose one option from among undifferentiated alternatives were only as satisfied as those who were randomly assigned the same option, and participants who chose from among differentiated but undesirable alternatives were even more dissatisfied. While *prima facie*, these results seem to undermine the relation between choice and control, they actually provide additional evidence that the effects of choice on consumer well-being depend on the associated perceived control. When choosing among undifferentiated alternatives, participants felt less in control of the eventual quality of the outcome, which mitigated their satisfaction; when choosing among differentiated but undesirable alternatives they felt in control of an aversive outcome, blamed themselves for it, and experienced greater dissatisfaction.

Choice is not, however, the only way in which individuals can attain perceived control. The literature has suggested a theoretical link between control and power in that power has been defined as the capacity to control other people. Indeed, recent research has empirically proved that powerlessness leads to perceived loss of control and power to the experience of control.

Although choice and power both seem to provide a sense of control, their interactive effect on people's welfare has not been studied in prior research. What if people could achieve a sense of control both through the exercise of choice and the provision of power? We hypothesize a compensatory hypothesis for this interac-

tive effect of power and choice according to which power and choice compensate for each other in satisfying people's need for control.

We tested this hypothesis in two studies. Study 1 investigated whether the absence of choice affects high-power participants less negatively than neutral-power participants. We used a recall task to either provide participants with a sense of power or leave them in a neutral state. Participants then engaged in an alleged second study, in which they imagined having dinner at a restaurant where they could choose their menu or where the chef had chosen a fixed menu. Participants indicated how much they liked the choice process they had experienced and how satisfied they thought they would be with the meal. Results support our compensatory hypothesis. High-power participants liked choosing their own meal as much as having the chef choosing it for them, whereas neutral-power participants liked choosing their own meal more than having the chef choose it for them. High-power participants also thought they would be as satisfied with the self-chosen meal as with the chef-chosen meal, whereas neutral-power participants thought they would be more satisfied with a self-chosen than with a chef-chosen meal. Providing further support to the idea that those in power were less affected by the loss of choice, high-power participants reported greater liking for the choice process and greater expected satisfaction than neutral-power participants in the chef-choice condition, but not in the self-choice condition.

Study 2 provided direct evidence of control as the mechanism for this compensatory effect. Following prior research, after manipulating power and choice we provided participants the opportunity to regain perceived control with an anagram task. We predicted that, relative to higher-power participants, lower-power participants would attempt to regain perceived control by persisting more on the anagram task when deprived of choice. Participants were first randomly assigned to a high- or low-power condition by telling them that they would simulate either the role of “Boss” or “employee” in an organization. Next, they participated in a taste-test for the snack options in their fictional organization's cafeteria. Participants in the choice condition chose which snack to eat, whereas those in the no-choice condition tasted a randomly selected snack. The last task was described as simulating a challenging situation at work consisting of unscrambling twenty anagrams which varied in difficulty (length). We measured persistence by recording how long participants spent on the last three anagrams, since persistence is most evident with fatigue. Consistent with prior literature, participants persisted longer on the final anagrams when they were randomly assigned a snack compared to when they had choice. The effect of choice was, however, weaker for high-power than for low-power participants: whereas the choice method significantly affected persistence in the low-power condition, it did not affect persistence in the high-power condition. Consistent with our theory, this interaction was stronger for the more difficult, 7-letter anagram, than for the easier, 3-letter anagram.

In summary, two studies support the hypothesis that choice and power compensate for each other in providing consumers with a sense of control. Lower-power participants were more sensitive toward a loss of choice than higher-power participants and, consistently, tried harder to regain control when deprived of choice.

Adaptation Can Enhance Consumption Experiences

Young Eun Huh, Carnegie Mellon University, USA

Joachim Vosgerau, Carnegie Mellon University, USA

EXTENDED ABSTRACTS

“Thought for Food: Top-down Processes Moderate Sensory-Specific Satiation”*Young Eun Huh, Carnegie Mellon University, USA**Carey Morewedge, Carnegie Mellon University, USA**Joachim Vosgerau, Carnegie Mellon University, USA*

Hedonic adaptation (Fredrickson and Loewenstein 1999) denotes the typically observed decline in pleasure when positive consumption experiences are repeated. In food consumption, it has been shown that consumption of a specific food leads to a decrease in liking of the food, without diminishing liking of foods not consumed. Such food specific adaptation is called sensory-specific satiation (Rolls, Rowe, and Roll 1982; Rolls, Rolls, Rowe, and Sweeney 1981). People typically react to sensory-specific satiation by switching to alternatives or consuming less (Herrnstein and Prelec 1991; McAlister 1982).

Whereas extant research on satiation has focused on the impact of initial consumption on the pleasure from subsequent consumption, this research focuses on the effect of imagined consumption on subsequent actual consumption. Mental imagery has been found to produce similar physiological responses (e.g., Brandt and Stark 1997; Huber and Krist, 2004), neurological processes (Kosslyn, Ganis, and Thompson 2001), and behavioral responses (e.g., Garcia, Weaver, Moskowitz, and Darley 2002; Woldmann, Healy, and Bourne 2007) as the actual consumption experience. If imagined consumption can act as a substitute for the sensory experience of consuming a food, imagining consuming a food should, like actual consumption of the food, lead to a decrease in its subsequent actual consumption. We investigated this possibility in five studies.

In study 1, participants were assigned to one of three conditions. In the control condition, participants imagined inserting 33 quarters into a laundry machine, one at a time. Participants in the small virtual consumption condition imagined inserting 30 quarters into a laundry machine and then imagined eating 3 M&M's. Participants in the large virtual consumption condition imagined inserting 3 quarters into a laundry machine and then imagined eating 30 M&M's (so in all conditions participants imagined 33 repetitive actions). After their imagination task, participants were given a bowl containing 40g of M&M's and ate as many M&M's as they would like to. Participants who imagined eating 30 M&M's ate significantly fewer M&M's than did participant who imagined eating 3 M&M's or no M&M's. Moreover, the amount of M&M's eaten in participants who imagined eating 3 M&M's or no M&M's did not significantly differ between conditions. These results suggest that imagined consumption of a food leads to virtual satiation rather than a wetting effect.

In study 2, we orthogonally manipulated imagined consumption experience (eating M&M's vs. inserting quarters into a laundry machine) and the amount of imagined consumption (3 M&M's/quarters vs. 30 M&M's/quarters) between-subjects. Participants who imagined eating thirty M&M's subsequently consumed fewer M&M's than participants who imagined eating three M&M's. No difference was found for respondents who imagined inserting thirty or three quarters into a laundry machine.

Study 3 employed a 2 (imagined consumption experience: eating M&M's vs. putting M&M's into a bowl) x 2 (amount of imagined consumption: 3 M&M's vs. 30 M&M's) between-subjects

design. As in the previous studies, participants who imagined eating thirty M&M's consumed significantly fewer M&M's than did participants who imagined eating three M&M's. The amount of M&M's eaten by participants who imagined putting 3 M&M's or 30 M&M's into a bowl did not differ. This finding demonstrates that virtual satiation is indeed caused by the imagined experience (consumption vs. putting M&M's into bowl) rather than the imagined stimuli (which were constant across experimental conditions).

An alternative explanation for the above results might be that participants who imagined eating many M&M's might have been primed to feel “full” and thus subsequently ate fewer M&M's. Study 4 ruled this out by employing a 2 (imagined consumption experience: eating M&M's vs. eating Gummi Bears) x 2 (amount of imagined consumption: 3 M&M's/Gummi Bears vs. 30 M&M's/Gummi Bears) between-subject design. Participants who imagined eating 30 M&M's ate fewer M&M's than participants who imagined eating three M&M's. Contrarily, participants who imagined eating 30 Gummi Bears ate more M&M's than those who imagined eating 3 Gummi Bears. These results demonstrate that imagined consumption induces sensory-specific satiation (as does actual food consumption) and not simply a feeling of being full.

Study 5 extended the findings to another food. Half of participants imagined eating 3 M&M's or 30 M&M's and the other half imagined eating 3 Cheese Cubes or 30 Cheese Cubes. Unlike the previous experiments, participants in Study 5 ate Cheese Cubes after their imagined consumption. Participants who imagined eating 30 Cheese Cubes ate less Cheese Cubes than those who imagined eating 3 Cheese Cubes. The amount of Cheese Cubes eaten by participants who imagined eating 3 M&M's or 30 M&M's did not differ.

The present research demonstrates that satiation can be induced without external stimuli through virtual consumption; thus, satiation is not only a consequence of physiological processes (a bottom-up process) but also involves cognitive “top-down” processes. We believe the foregoing research may help develop effective behavioral interventions to combat obesity. Thought suppression, a popular self-control method that many dieters use, has been shown to increase craving for the to be avoided food (Johnston, Bulik, & Anstiss 1999). Our research proposal examines whether the exact opposite may be most effective. Because people can habituate to a food by merely imagining eating it, willful and controlled imaginary consumption of foods that a dieter tries to avoid could be an effective way to decrease the appeal of, craving for, and intake of the food.

“Motivated Taste Change for Diet Coke”*Jason Riis, Harvard Business School, USA**Samuel McClure, Stanford University, USA*

While a number of studies have shown that changes in preference can occur with changes in consumption and exposure (Rozin, 1999), the question of whether taste change can be facilitated by motivation is more controversial (Loewenstein & Angner, 2003). Evidence for motivated taste change comes mostly from studies of dissonance, whereby people are thought to reduce negative feelings of disappointment by shifting their preferences to objects that happen to be in their possession (Brehm, 1956). In the present work, we investigate taste change that is motivated by concerns about health, and find that such concerns can influence awareness of taste change, and that this awareness has implications for future choice intentions.

The particular source of motivation that we investigate is the widespread concern about the health effects of sugared soda consumption. Obesity is considered by some public health experts to be the second leading cause of preventable death in America, and at least a third of American adults are attempting to lose weight (Kruger et al., 2004). Sugared sodas are thought to be one of the major contributors to the obesity epidemic, and diet sodas are rapidly gaining market share from sugared sodas.

Interestingly, many people claim that not only do they prefer diet soda because it is healthier, but that they also prefer the taste. In a pilot study with participants drawn from a paid, nationally representative panel, we found that 85% of the 120 frequent Diet Coke drinkers in the sample said that Diet Coke tasted better than regular Coke. More impressively, however, 70% of those who preferred the taste of Diet Coke said they used to prefer the taste of regular Coke. They also cited concerns about health and fitness, and not taste, as their original reason for switching to Diet Coke. These data are consistent with the possibility that concerns about health (i.e., motivation) led to an actual change in the liking of a product. Along these same lines, a recent Diet Coke ad even claims that, "It's the no calories that make it taste so good"

In the present studies we sought to test this possibility. In Study 1 we examined whether or not motivation is related to expectation of taste change. We hypothesized that it would be. People tend to be optimistic in their estimates of the likelihood of good outcomes (Weinstein, 1980). Since health-motivated people would be more likely to consider a taste improvement for a healthy product to be a good outcome, they should thus be more likely to expect this outcome to occur. This is indeed what we found. We asked 58 regular Coke drinkers to imagine that they were to drink Diet Coke daily for two weeks. The health-motivated participants predicted that their liking of Diet Coke would improve during such a trial, while the unmotivated participants predicted that they would come to like Diet Coke even less.

In Study 2 we actually examine taste change by exposing both motivated and unmotivated Coke drinkers to Diet Coke for two weeks. Based on previous mere exposure studies (e.g., Bertino et al., 1982, 1986), we expected blind taste tests to reveal increased liking of Diet Coke in both groups. In branded tests, however, we expected the groups to differ, with the motivated participants being more likely to report increased liking.

Participants were selected based on a pre-screening survey for heavy consumption of Coca Cola (mean of 3.8 cans per week) and for their level of concern about the effects of sugared soda on their health. Half of the participants were highly concerned (i.e., "motivated") and half were minimally concerned (i.e., "unmotivated"). The two groups did not differ in their soda consumption habits. Both groups were given a two week supply of Diet Coke, with the instruction to drink one can each day, and to refrain from drinking sugared soda. (Compliance, reported anonymously, was very high.) Participants were not asked about their expectations of taste change for fear that this would influence their subsequent reporting. Two kinds of taste tests were given, both at the beginning and end of the two week consumption period. In blind tests, participants drank several colas in clear, unlabelled plastic cups, and then rated the taste of each one on a 9 point scale (anchored at "dislike very much" and "like very much"). In "branded" taste tests, participants opened a can of Diet Coke, poured approximately one ounce into a clear plastic cup, tasted it, and then rated the taste using the same 9 point scale.

Both high-concern and low-concern participants revealed a large (4/5ths of a standard deviation) increase in liking of Diet Coke following the two-week consumption period. However, with

the branded test, only the high concern participants revealed an increase in liking. Furthermore, the high concern subjects reported a greater increase in intention to purchase Diet Coke in the future. These results suggest that motivation for taste change may be independent of its actual occurrence, but that it may be required for awareness of its occurrence, and, importantly, for the intent to act on that taste change. The results do not isolate expectation as the mechanism of the motivational effect, although the results of Study 1 are consistent with this possibility.

"Processing Fluency and Satiation"

Jeff Galak, Carnegie Mellon University, USA

Joseph Redden, University of Minnesota, USA

Consumers frequently consume products and experiences to the point where they no longer enjoy them, a process commonly referred to as "satiation" (Coombs and Avrunin 1977). This happens for a variety of stimuli ranging from the primarily physiological like food (Rolls, van Duijvenvoorde, and Rolls 1984) and sex (O'Donohue and Geer 1985), to the primarily non-physiological like music (Ratner, Kahn, and Kahneman 1999), television programs (Nelson, Meyvis, and Galak in press), art (Berlyne 1971), homes (Hsee et al. In Press), and cars (Frank 1999). In fact, satiation is often cited as a primary barrier to enduring happiness since, regardless of how satisfying a stimulus might be initially, that satisfaction tends to fade with repetition (Brickman and Campbell 1971).

One way to reduce unwanted satiation is to change the consumption experience. Prior work has shown that people satiate less when they consume slower (Galak, Kruger, and Loewenstein 2009), can more easily perceive the variety of an assortment being consumed (Kahn and Wansink 2004), or can subcategorize the consumption episodes (Raghunathan and Irwin 2000; Redden 2008). These approaches all act as preventive measures that slow satiation. In the present work, we instead explore remedies that can be used *after* satiation has occurred. If people can recover quickly and easily from a satiated state, then satiation poses a smaller problem for consumer enjoyment and happiness. In other words, people can fight satiation by either limiting it in the first place, or reversing it after the fact. We focus on the latter.

Past research has demonstrated that one antecedent to satiation is the degree to which an individual recalls past consumption experiences (Higgs 2002, 2008). We propose that while memory for past experiences is central in informing satiation, the subjective feeling of how much one has consumed is as, if not more, important. Specifically, we propose that when a person finds it particularly difficult to recall past consumption experiences, he or she will feel less satiated, as compared with someone who does not find the recall task difficult. For example, when a person attempts to recall many past consumption episodes, that recall task is subjectively difficult and he or she will feel like he or she has not consumed much—regardless of the fact that he or she may have recalled quite a number of past consumption episodes and thus should feel quite satiated. In contrast, a person who's task is to recall only a few past consumption episodes, will find the task relatively easy and thus infer that he or she has consumed a lot, leading to a heightened degree of satiation.

In Studies 1 and 2 we adapt the classic processing fluency paradigm from Schwartz et al. 1991. Participants recalled either the last 3 or 10 most recent television programs that they had seen (Study 1), or the last 2 or 6 times they consumed their favorite food (Study 2). We found that, presumably because it was subjectively more difficult to recall 10 television programs and 6 eating occasions, participants in the former conditions reported feeling less satiated even though they, in fact, recalled more instances.

In Study 3, satiation was induced in participants by exposing them to a photograph 20 times in a row (without explicit knowledge of how many times they were exposed to the photograph). Following this exposure and a short filler task, participants were asked to recall how many times they had seen the photograph with two different sets of response options created by adapting the paradigm from Schwartz et al. 1985. Participants in the *saw many* (*saw few*) condition answered the question with response options that ranged from “1-3 times” (“1-30 times”) to “more than 15 times” (“more than 150 times”). Consistent with the first two studies, participants who were made to feel like they had seen the photo many times (*saw many*), felt more satiated than those who were made to feel like they had seen it few times (*saw few*). In summary, the subjective sense of how much one has consumed was a strong antecedent of satiation.

Across these three studies we demonstrate that feelings of satiation are malleable even after the consumption experience has ended and that they are informed based on the subjective sense of how much one has previously consumed.

“The Role of Expectations in Unfolding Experiences”

Jongmin Kim, Yale University, USA

Ravi Dhar, Yale University, USA

Nathan Novemsky, Yale University, USA

Suppose you bought a present for your friend, and the store offered an option of gift wrapping at additional cost, or suppose your waiter in a restaurant suggested a glass of a special champagne before your meal. Would accepting these offers enhance the enjoyment of the gift or the meal, respectively? People generally believe that adding positive aspects to an experience will make the experience better. Therefore, we wrap gifts attractively to raise enjoyment of the gifts, and sometimes have a glass of champagne before a meal to make the experience better. Of course, adding positive features to the beginning of an experience can increase enjoyment of the experience, but it can also trigger unexpected effects. Positive moments early in an experience can establish high expectations against which the subsequent moments are compared, leading to a worse overall experience.

A large body of research has demonstrated that hedonic experiences can be contrasted with a prior expectation when there is a discrepancy between the expectation and the actual experience. Drawing from research on this expectation-disconfirmation model, we propose that adding positive moments early in an experience may result in lower satisfaction if subsequent moments in the experience do not meet the high expectations set by the early moments. For example, gift wrapping can decrease the liking of the gift, and great tasting champagne can detract from the rest of the dinner by establishing high expectations that are not met.

Study 1a examines people’s lay beliefs about the effects of wrapping on evaluations of gifts. The results show that people believe gift wrapping increases liking of a gift regardless of the attractiveness of the gift (e.g. attractive DVD: the Lord of the Rings or unattractive DVD: Microcosmos documentary). Study 1b compares the enjoyment of wrapped and unwrapped presents to test the accuracy of the beliefs documented in study 1a. In study 1b, participants evaluated a hypothetical gift from a friend in a 2(wrapped vs. unwrapped) X 2(attractive vs. unattractive gift) between subjects design. Participants in the wrapped condition were told that their friend gave them a birthday present and were shown a picture of an appealing wrapped gift box. On the next page, participants imagined that they found a DVD set when they opened the wrapping. People in the unwrapped condition simply imagined that their friend gave them a DVD set as a present. Half of the participants in each condition were told the DVD set was the Lord

of the Rings (attractive condition) or Microcosmos documentary (unattractive condition). The results showed that for the attractive gift, participants showed a non-significant trend toward liking the gift more when it was wrapped compared to unwrapped. However, for the unattractive gift, participants liked the gift significantly *less* in the wrapped condition than the unwrapped condition. This result partially contradicts the lay beliefs in study 1a that gift wrapping raises evaluations of both attractive and unattractive gifts.

The result of Study 1b supports our proposition that appealing gift wrapping sets high expectation for the gift and can decrease the evaluation of unattractive gifts. In Study 2, we manipulate the level of expectations established by using both appealing and unappealing gift wrapping to test whether setting low expectations compared to high expectations can raise evaluations of unattractive gifts. Participants in Study 2 imagined that they received a birthday present and were shown a picture of either an appealingly or unappealingly wrapped gift box. Participants then imagined that they found the Microcosmos (unattractive) DVD inside the wrapping and evaluated the gift. The results showed that participants liked the gift *more* in the unappealing wrapped condition than the appealing wrapped condition. This result is consistent with our prediction that unappealing gift wrapping sets low expectations leaving recipients less likely to be disappointed with the unattractive gift.

Study 1a suggests that when people predict the impact of gift wrapping they do not incorporate the idea that gift wrapping establishes expectations against which the gift is compared. In Study 3, we examine whether erroneous prediction for gift wrapping documented in Study 1a can be corrected by providing a cue to think about expectations. Participants predicted the impact of gift wrapping in a 2 (cue vs no-cue) X 2(attractive vs. unattractive gift) between subjects design. All the participants were asked to consider receiving both an appealingly wrapped and an unwrapped present from a friend. Participants in the cue condition answered a question about when they would set a higher expectation for the gift between the two situations: receiving a wrapped vs. unwrapped gift. Participants in the no-cue condition were not asked such a question. Next, participants imagined that they found either the Lord of the Rings (attractive) or Microcosmos (unattractive) DVD when they opened the wrapping. The results demonstrated that for the attractive gift, participants in both the cue and no-cue conditions believed that appealing gift wrapping would raise liking of the gift. For the unattractive DVD, however, providing a cue significantly changed participants’ prediction. Participants in the cue condition were less likely to predict that gift wrapping will increase liking of the gift than those in the no-cue condition. This result suggests that people do not spontaneously consider expectation in prediction, but when their attention was drawn to expectations, they make more accurate predictions.

In summary, we find that appealing gift wrapping can decrease evaluations of a gift by setting high expectations. Using less appealing gift wrapping can actually set lower expectations and thereby enhance evaluations of a gift. However, people often fail to accurately predict this trend because they do not think about expectations spontaneously. Once reminded to consider expectations, however, people incorporate expectations into their predictions.

SPECIAL SESSION

Partners in Sustainability:

Consumer Culture Theory Approaches to Personal and Social Transformation

Melea Press, University of Wyoming, USA

Robert V. Kozinets, York University, Canada

EXTENDED ABSTRACTS

“Social Media for Social Change: Sustainability-based Community in a Sustainable World”

Robert V. Kozinets, York University, Canada

Frank-Martin, Belz, Technische Universität München, Germany

As of 2010, the important role of social media in fostering and facilitating consumer engagement in political and marketing campaigns, and in facilitating other forms of activism are indelibly established. This presentation seeks to consolidate, broaden, and develop the view that social media and online communities can be useful sites of social betterment that consumer researchers should include in their studies.

We place our presentation in the context of sustainability concerns, and contribute to this literature by charting the intersections between social media and sustainable consumption. Overridingly, our concern is a practical one. How might online communities and their constituents help foster a more sustainable consumption style and a more sustainable consumer culture? This is a large question; in this session we aim to start the discussion by recognizing and connecting research streams, offering initial findings, and suggesting particular paths.

The presentation has three main sections. First, there is an overview of extant research on social media with a focus on the alleviation of social problems and the promotion of consumer behaviors that lead to self- or social betterment. Research in the area increasingly suggests that online communities act as locations for the personal and collective enactment of social betterment. Our necessarily broad and brief overview looks at three broad categories of social media-social connection: (1) altering institutional relationships, (2) offering emotional benefits, and (3) encouraging social involvement. We provide numerous references and pragmatic examples about these institutional, emotional, and social effects, across a variety of cases.

Next we consider the relationship of online communities—and online/offline community combinations—to issues of ecological orientation or sustainability. We explore how the role of local, involved, engaged communities has been increasingly invoked as the key to the transition to a more ecologically sustainable society. We are concerned with the specific and more generalizable role of intentional communities, which are widely viewed and held up publicly as a hotbed of political innovation and organized political influence.

We then offer initial observations and findings from netnographic and blended ethnographic/netnographic fieldwork on several of these communities in Europe and North America. Our initial findings regarding sustainability-oriented social media tell us four things. First, social media help consumers focus their awareness and attention together on particular options. Second, social media carry conservative values, in that they seek to foster more traditional forms of community. Third, online and offline media and community work together in new, important, and evolving ways. Finally, a “customizing” and “segmenting” of communal types of participation was evident in the diverse space of the Internet. As we continue to collect data and analyze it (the next stage of data

collection is from June-September 2010), we expect these initial findings to deepen and broaden.

“Transformative Outcomes of Identification Formation and Narrative Transparency”

Melea Press, University of Wyoming, USA

Eric J. Arnould, University of Wyoming, USA

Moving toward greater sustainability at any level of society (individual, community, institutional) involves transformations on an individual and collective level. Transformations have been discussed in literature on consumption communities, in policy literature, and in managerial literature. Furthermore, some have shown that the relationships built between constituents and organizations can be evocative and transformational (McAlexander, Schouten and Koenig 2002), yet the process of how these connections form has not been explored.

This presentation will look at both sides of identification formation, and how identification can lead individuals down the road towards meaningful connections with organizations, and ultimately to personal transformation, in this case towards more sustainable consumption patterns. From the constituent side, we will examine what drives these relationships to form and the value and behavior change that ensue. Then, from the organizational side, we look at what drives constituents toward the organization. We show that narrative (as opposed to measured) transparency and connection to long-standing cultural values provide a route for constituents to form meaningful relationships with organizations.

First, with data from constituents in two different contexts, we present a model of identification formation. The first data set contains 18 longitudinal interviews with members of a Community Supported Agriculture program, and the second data set contains 41 cross-sectional interviews with employees of an advertising agency. Using this new theoretical framework that brings together the concepts of identification formation and participation, we show three different modes of identification formation: Epiphany, Assimilation, and Exploration. We also show two conduits for participation, that is, through formal and informal means, and we reveal the role of productive consumption in personal transformation. We then demonstrate that when individuals identify with an organization, they take on the values of the organization as illustrated by individual behavior change.

Next, we use a third data set compiled from 50 Community Supported Agriculture websites to illustrate the importance of narrative transparency in expressing the values of the organizations to constituents. Transparency information is typically communicated through reporting of facts and figures. On CSA websites, we find that transparency is communicated through personal narrative, that is, through detailed and personal stories of activities on the farm. This data set also reveals the inadvertent way organizations connect to deeply held cultural values to build meaningful relationships with constituents, as well as legitimacy for the market form.

This research shows processes on both the constituent and the organization side of identification formation. It also shows how individuals transform their values and behaviors through closer relationships with model organizations.

Partners, Masters, Friends, and Flings: Exploring the Multiple Roles of Brand Relationships

Vanitha Swaminathan, University of Pittsburgh, USA

Susan Fournier, Boston University, USA

EXTENDED ABSTRACTS**“Partners and Servants: Adopting Traits of Anthropomorphized Brands”***Pankaj Aggarwal, University of Toronto, Canada**Ann L. McGill, University of Chicago, USA*

Research in social psychology has shown that automatic or non-conscious behavior may result from the activation of a social category. For example, Bargh, Chen, and Burroughs (1996) found that priming the construct of the ‘elderly’ led to participants walking more slowly since the elderly are strongly associated with the trait of being slow. Recent research by Fitzsimons, Chartrand, and Fitzsimons (2008) found that participants exposed to the Apple brand behaved more creatively, and those exposed to the Disney brand responded more honestly to questions compared to controls. These results are interesting in that they show that effects previously observed for social constructs replicate in the domain of brands.

In this research, we argue that one reason for this effect may be that the iconic brands studied by Fitzsimons et al. (2008) were perceived much like people, that is, respondents may have anthropomorphized those brands. If this argument is correct, it implies that by anthropomorphizing brands, consumers open the door to “quasi social influences” in which brands elicit effects previously seen for responses to people. We examine this possibility by considering differences in the adoption of traits for brands that have been anthropomorphized or not. We assume that “trait adoption,” a shorthand term for behaving in ways consistent with the characteristic of the brand, follows a motivational process such that the behavior adopted in response to brand exposure is goal-directed. To inform our theory, we rely on work by Cesario, Plaks, and Higgins (2006) who demonstrate that priming a social group triggers goals corresponding to people’s desire for a successful social interaction. People adopt or reject a trait to the extent that the corresponding behavior achieves these interaction goals. Thus, priming ‘elderly’ led participants who like the category to walk more slowly, but if they disliked the category they walked faster presumably to get away (Cesario et al. 2006).

To test this framework, we propose two moderators of trait adoption for anthropomorphized (but not objectified) brands which determine the best route to achieve the goal of a successful social interaction. These moderators are liking for the brand, and perceived role for the brand—as a partner or as a servant. Consumers may adopt traits of anthropomorphized brands perceived as partners if they like them because in this case, trait adoption—acting the same way as the brand—promotes getting along with and helping the partner. By contrast, consumers reject traits of anthropomorphized partner brands if they dislike them because rejecting the trait pushes them away. Further, consumers reject traits of servant brands they like because successful interaction involves letting the servant “take care of the work.” For example, consumers who see an anthropomorphized Volvo as a servant devoted to their safety may actually behave in riskier ways than those who see Volvo as a partner in safety. On the other hand, brands that are not anthropomorphized would not be affected by liking or role because the goals of successful social interaction are not triggered for objects, making the relevance and impact of these social factors inconsequential.

We test our proposed framework in three studies. In study 1, we consider two partner brands, Kellogg’s and Krispy Kreme, near opposites on the healthy-unhealthy spectrum. Using an unrelated dependent variable that taps into people’s healthy (taking the stairs) or unhealthy (waiting for the elevator) behavior, we find consumers to be more likely to adopt the trait when they like the anthropomorphized brand, and reject the trait when they dislike it. In study 2, we consider two servant brands: Volvo (associated with safety) and Discovery Channel (associated with knowledge). We find consumers to be less likely to adopt the trait when they liked the anthropomorphized brand, and more likely to adopt the associated trait when they disliked it as evidenced by differences in unrelated tasks such as certainty equivalence for a risky gamble (Volvo) and responses to a set of SAT questions (Discovery Channel). In study 3, we manipulated perceived role of the brand, Volvo, under the pretext of testing two alternative advertising slogans that portrayed it either as a partner (works with you) or a servant (works for you). Results replicate the main effect in a more controlled environment.

This research is significant in its examination of an important yet an under-studied phenomenon in marketing—brand anthropomorphism. To our knowledge this is the first research that looks at the moderating effect of brand role on consumer’s goals and subsequent behavior. Thus, this research contributes to an emerging literature that highlights the value of understanding how inanimate objects may extend into our social realm.

“Bridging the Divide: Identity Expression with Brands Following a Self-Threat”*Sara Loughran, University of Pittsburgh, USA**Vanitha Swaminathan, University of Pittsburgh, USA*

Since Belk (1988) introduced the concept of possessions “extending the self,” a vast amount of research has confirmed that because consumers identify with objects, they use possessions to create and narrate their identities (Kleine, Kleine, and Allen 1995). In this research, we show that when individuals experience anxiety in their interpersonal relationships, they use objects and brands that assert their in-group identities as a way of coping, which leads to increases in the valuations of these objects and brands. Relationship anxiety is a function of an individual’s view of self (Bartholomew and Horowitz 1991). Individuals with high relationship anxiety desire close relationships but yet are unsure about whether they can depend on others. They are characterized by a fear of rejection and abandonment and describe their most important interpersonal relationships in terms of jealousy, longing for reciprocation, and emotional highs and lows.

One way of coping with this anxiety is to gravitate towards objects and brands that help restore confidence in the social self (Gao, Wheeler, and Shiv 2009; Swaminathan, Stillee and Ahluwalia 2009). In study 1, undergraduate student participants (N=149) began by writing either about an anxious relationship they had experienced (relationship anxiety group) or their average day (control group). Following this manipulation, respondents participated in a typical endowment effect experiment (Kahneman, Knetsch, and Thaler 1990), assuming the role of buyers and sellers of one of three ball point pens: one from their university (in-group good), one from a rival university (out-group good), or one that was non-descript (neutral good).

Comparing the selling prices for the in-group object, we find that those in the relationship anxiety condition had significantly greater selling prices than those in the control condition. In the out-group condition, a different pattern emerges. In the no relationship anxiety condition, the standard endowment effect occurs with participants reporting greater selling prices than buying. In the high anxiety condition, for the outgroup good, sellers and buyers did not report different prices from one another. It appears that relationship anxiety decreased selling prices for an out-group object. For the neutral good condition, we observed the classic endowment effect in both the control condition and the relationship anxiety condition. Relationship anxiety had no effect on either selling prices or buying prices of the neutral good.

In study 2, participants ($N=261$) in a nationally representative panel completed the same anxiety manipulation and then responded to a variety of questions regarding attitudes toward one of two given brands: DKNY (feminine) or Levi's (masculine). In this study, therefore, in-group/out-group was manipulated using the gender of respondents and the personality (masculinity/femininity dimension) of the brands. We first tested an ANOVA using social self-concept connection to the brands as our dependent variable. The interaction of anxiety and in-group was significant ($F(1, 253)=11.94, p<.001$). In the in-group brand condition, high anxiety led to greater social self-concept connection compared to low anxiety. In the out-group brand condition, however, high anxiety led to lower self-concept connection compared to low anxiety. We ran a similar ANOVA using willingness to pay for the brands as the dependent variable. Once again, only the interaction of in-group brand and anxiety was significant ($F(1, 250)=8.61, p<.01$). High anxiety led to greater willingness-to-pay for the in-group brand compared to low anxiety, and a lower willingness-to-pay for an out-group brand compared to low anxiety. Further analysis revealed that social self-concept connection mediated the effect of the interaction of in-group brand and anxiety on willingness-to-pay (Sobel's Z -score=1.97, $p<.05$). Implications of the findings for brand relationship theory will be discussed.

"Brand Flings and the Transitional Self"

Susan Fournier, Boston University, USA
Claudio Alvarez, Boston University, USA

This study advances the brand relationship agenda by providing a phenomenological illumination of one unexplored relationship: brand flings (cf. Fournier 1998). As an analytic device, the research also contributes to brand relationship theory validation efforts by exploring the differences and similarities between brand and person-to-person flings.

Sixteen phenomenological interviews provide data for this investigation. Informants in half of the interviews discussed flings with brands; eight discussed flings with other people. Informants were men and women between the ages of 18-35. Gender was equally distributed to capture potential differences in how men and women experience flings. Informants were pre-recruited via telephone to ascertain their resonance with, and ability to discuss, the subject of human (brand) flings. A homework assignment instructed informants to select and bring to the interview "5-6 images that express your thoughts and feelings about having a fling with a (person/brand)." These images provided a structure around which the interviews unfolded. Interviews lasted from 2-3 hours, and were conducted by a mixed gender, 3-person team.

Our analysis suggests four emerging themes qualifying brand flings. Most characteristic is the emotionality of the fling experience. A deep sense of satisfaction and tremendous amount of excitement, passion, and enjoyment characterizes the playful brand

encounters that launch and sustain the fling. Secondly, some degree of obsession is embedded in the fling relationship, with significant investments of time, energy and attention dedicated to the brand. A third theme concerns a lack of rationality and sense of being out-of-control. Finally, a brand fling is temporary and time-bounded (though brand flings can recur). People experiencing brand flings are excited and obsessed but only for a while, after which time feelings and meanings taper almost unnoticeably as the person simply moves on. Our analysis highlights significant contrasts between brand flings and person-to-person flings. Person-to-person flings are most characteristically associated with freedom from commitment, and are surrounded by an aura of secrecy that derives from a sense of cultural taboo.

Collectively, thematic results support a role for brand flings that is analogous to the role played by transitional objects in psychoanalytic theories of child and adult development (Winnicott 1971). Brand flings open up a creative space in consumers' daily lives where people establish object relations that allow them to experiment playfully with different senses of self. Importantly, flings allow engagement with the concept of "not me;" a pivotal idea in object attachment theory. Consumers have flings with brands they typically don't buy; brands not recognized as reflecting a known self. This separation from "the me" emerges as a fundamental goal of having a brand fling: to be taken out of ordinary life and away from the established self, if only for a brief moment or phase. Brand flings deliver squarely against Winnicott's (1971) idea of the "potential space" existing between the "me" and the "not-me" that forms as an individual develops and grows.

The transitional self activated via transitional brand flings is fundamentally different from other self conceptualizations explored in brand relationship research: ideal selves (Sirgy 1982), feared selves (Fournier 1998), and possible selves (Schouten 1991). Flings are simply not that consequential: the motivation to engage in flings comes less from one particular self image that is desired/feared/speculated than from the opportunity to leave the current self behind. "I am looking for a new excitement in something", as one informant explains. To a certain extent, what this "something" is doesn't matter much as long as it is new and different. Flings serve as transitional object relations that help consumers create and play with transitional selves.

This study supports brand flings as a relevant mechanism for consumer-brand engagement and provides a solid conceptual foundation for future research. The "potential space" filled by brand flings is a vital area in the mental life of the developing person. This finding is significant as prior research supports brands as replacements for under-realized interpersonal relationships, not valued relational objects in and of themselves. Research can explore the value of flings over partnerships in delivering brand attraction, willingness to pay, emotional commitment, and favorable brand experiences. The qualities of addiction and dependence evoked by transitional objects (Winnicott 1971) also suggest relationship maintenance in the face of stresses and strains. Transitional objects also serve as a defense against anxiety, and operate as soothing, comfort mechanisms in times of loneliness, deprivation or depressive moods, thus suggesting a role for brand flings as coping mechanisms when the anxious self is primed. Since transitional object relations occur at predictable developmental moments (e.g., the child becoming a separate individual, the teen becoming a young adult, the young adult becoming a parent), research can also investigate whether there exist productive, targetable periods for brand fling experiences along similar developmental lines.

“Brand Are Like Friends: Goals and Interpersonal Motives Influence Attitudes Toward Preferred Brands”

Christopher R. Long, *Ouachita Baptist University, USA*

Philip A. Gable, *Texas A&M University, USA*

Christina Albee, *Ouachita Baptist University, USA*

Courtney Boerstler, *University of Oregon, USA*

The present series of studies suggest similarities between consumers' interpersonal relationships and brand relationships. Specifically, these studies demonstrate ways in which consumers draw closer to brands that facilitate specific goal pursuits, in the same way that consumers draw closer to acquaintances who facilitate such pursuits. Previous research has shown that when particular goals are activated, people feel closer to acquaintances who help them meet those goals (but not to other acquaintances; Fitzsimons and Shah 2008). In addition, research suggests that people tend to anthropomorphize products when those products symbolically address particular social deficit states (e.g., human-like products seem more human when people feel lonely; Epley et al. 2008). Building on this work, the present studies indicate how consumers evaluate preferred brands more positively when brand-relevant goals are activated and how this tendency is accentuated among consumers who have particular relational orientations (e.g., heightened belongingness needs or avoidant interpersonal attachment styles).

We performed three studies with college student participants. In Study 1, participants ($N=101$) completed the Need to Belong (NTB) scale, for which higher scores indicate increased investment in social acceptance (sample item: “I do not like being alone”). In addition, participants completed attitude measures targeting several popular shoe brands, including the brands they self-nominated in an earlier task as most helpful toward their goal of being healthy.

In Study 2, participants ($N=31$) completed an initial version of a subtle goal-priming task adapted from Fitzsimons and Shah (2008). This task required participants to unscramble sentences containing words related to healthiness (e.g., “active,” “well”) or, for control purposes, neutral words. Participants then completed attitude measures targeting several shoe brands, including the one that most facilitated their goal of being healthy. Shoe brands were self-nominated in an ostensibly unrelated earlier task.

In Study 3, participants ($N=49$) nominated a website which helped them achieve the goal of social connectedness and completed the Experiences in Close Relationships scale, comprising two subscales on which higher scores indicate greater attachment anxiety and attachment avoidance, respectively. Sample items include “I worry about being abandoned” (anxiety) and “I get uncomfortable when a romantic partner wants to be very close” (avoidance). One week later, in an ostensibly unrelated session, participants completed a goal priming task (similar to the task in Study 2) in which they were assigned to exposure to words implicating social connectedness (e.g., “associate,” “community”) or healthiness. Then, participants completed attitude measures targeting several brands and websites, including the websites they nominated one week earlier.

In Study 1, we found that NTB was positively related to feeling close to one's most helpful shoe brand ($r, .86, p=.02$) and negatively related to liking one's least helpful shoe brand, $r(24)=-.38, p=.05$. In Study 2, we found that participants primed with health-related words subsequently rated their self-nominated goal-relevant shoe brands as a better value than did participants who were primed with neutral words, means=6.75 vs. 5.94 on a 7-pt scale; $t(27)=2.54, p=.02$. In Study 3, we found that participants in the social connectedness prime condition felt closer to websites that helped them achieve social connectedness than did participants in the healthiness condition, means=5.84 vs. 4.58 on a 7-pt scale; $F(1, 47)=5.54, p=.01$. Likewise, attachment avoidance ($b^*=-.29,$

$p=.04$) was predicted feelings of closeness, even while controlling for the priming effect ($b^*=-.28, p=.05$).

Studies 2 and 3 suggest similarities between processes governing consumers' relationships with goal-relevant people and with goal-relevant brands. In addition, Studies 1 and 3 indicate that individual differences in consumers' relational orientations can predict differences in consumers' brand attitudes. Our findings highlight the essential social character of consumers' brand representations in ways not documented by previous research. For researchers and practitioners, we see value in identifying similarities between motivational and dispositional forces regulating interpersonal relationships and those regulating brand relationships.

EXTENDED ABSTRACTS

“Ask and You Shall (Not) Receive: Choosing Between a Gift Registry Gift and Free Choice”

Morgan K. Ward, University of Texas, Austin, USA

Susan Broniarczyk, University of Texas, Austin, USA

Gift exchanges are complex transactions with relational and psychological implications for both giver and recipient. Givers strive to meet the needs and desires of the recipient with a gift that is both appealing and meaningful. When choosing a gift, the giver has three distinct goals: the item must 1) satisfy the recipient, and 2) reflect the relational intimacy between giver and recipient. The giver's task is complicated by the asymmetry of preference information between giver and recipient. Retailers have partnered to resolve this asymmetry in the form of gift registries, which provide perfect information about a recipient's preferences and preferred gifts to gift givers. However, while a registry reconciles the asymmetry, it may also constrain the giver from choosing a gift that signals relational intimacy.

We look at the circumstances in which givers are willing (vs. resistant) to choose from a registry. Our main hypothesis is that when choosing for a close (vs. distant) friend, the giver will discount the recipient's explicit preferences in favor of a gift that signals the giver's identity or the relationship between them. Further, we suggest that givers are more likely to make a free (vs. registry) choice for a close (vs. distant) friend, resulting in an increased likelihood of choosing a less desirable gift.

In Study 1, university staff members chose a gift for someone they knew in a professional setting and had rated on social closeness. Participants were presented with three lamps which had been pre-tested by a group similar to themselves. The pretest revealed that two lamps were equally liked and the third was significantly less liked than the others. Participants were told that the recipient had rated each of the three lamps either “good” or “excellent”: the lamp liked the *least* in pretest was rated “excellent” by the recipient and the other two lamps (pre-tested as ‘more liked’) were rated “good” by the recipient. Thus, the recipient preferred one lamp and the givers preferred the other two. Givers chose a lamp to give to the recipient.

As predicted, givers indicating a closer relationship with the recipient were more likely to opt for one of their own preferred lamps (rated ‘good’ rather than ‘excellent’ by the recipient). Thus, we see evidence that givers are more likely to select a freely chosen gift and risk choosing something less liked when buying for a close friend.

In Study 2, we examine givers' specific strategies when choosing a gift for a close (vs. distant) friend. We primed givers with altruism (vs. no prime) as our presumption is that givers choosing for a close friend are motivated to choose something that will maximize the recipient's happiness. In order to manipulate social closeness between giver and recipient, close givers were told personal information (e.g. the recipient has “classic tastes”) and distant givers were given no taste information about the recipient. The giver was then faced with three choices of lamps representing different aesthetic styles: classic, modern and plain. Pretests confirm that the modern lamp was the most preferred by givers, however, the plain lamp is designated by the recipient to be on the registry.

Thus, in this study setup, participants' preferences and recipients' expressed desires conflict, as givers know the recipient's registry choice but personally prefer the modern lamp. An added layer of complexity exists in close-friend conditions: the recipient has indicated the control lamp on the registry but the giver is aware that the recipient's tastes match the classic lamp. Thus, close givers perceive the wish list to be misaligned with the recipient's tastes while distant friends are unaware of his/her tastes.

The data reveal that distant givers display no effect of the altruistic prime. In both prime and no-prime conditions these givers' dominant strategy is to choose the registry lamp and secondarily, the modern lamp, which matches their own preferences. In close-friend conditions, the results are strikingly different. Givers in the no-prime condition again dominantly choose the registry gift. However, in the altruistic-prime condition, givers are equally likely to choose the registry lamp as the classic lamp.

It appears that when givers are focused on the goal of meeting recipients' needs (in altruistic conditions), they are more likely to achieve it when choosing for distant (vs. close) friends. Further, when choosing altruistically for close friends, givers appear to use their knowledge of the recipient to guide the choice rather than the recipient's explicit preferences.

In Study 3, we use a procedure similar to Study 2, to investigate givers' objectives in making a free-choice gift. In a 2 (Relationship Signaling: Signaling vs. Non Signaling) x 3 (Motivation Embodied by Gift: Explicit Recipient Preferences, Giver's Preferences, Relationship Intimacy) design, participants are told to imagine that they were exchanging gifts with friends who live far away using a “Secret Santa” paradigm. Importantly, participants are informed that after the gifts are given, their identity will be revealed (vs. not revealed) to the recipient, to remind the giver that s/he will (vs. not) receive attribution from the recipient for having chosen a well-liked gift. All participants are also told that the recipient has “classic tastes” and are faced with the same gift choices of lamps as described in Study 2.

The data reveal that givers make different choices when they receive (vs. do not receive) attribution from the recipient for the gift chosen: in the Relationship Signaling condition, givers were equally likely to choose from the registry as to choose the classic lamp, while in the Non-Relationship-Signaling condition, the registry choice was dominant. These results confirm that givers diverge from the registry to signal relational closeness rather than to match the recipient's inferred preferences.

These studies provide some insight into the paradox of gift-giving that well-intentioned givers are more likely to choose inappropriately for the people who matter to them most (i.e. close friends), as their needs to express themselves and the relationship supersede their goals of pleasing the recipient.

“For You or For Me? How the Intended Recipient Influences the Customization Experience and Valuations of Customized Products”

Leff Bonney, Florida State, USA

Kelly B. Herd, University of Colorado, USA

C. Page Moreau, University of Colorado, USA

While recent interest in customization is growing among academics (e.g., Franke, Keinz, and Steger 2009; Moreau and Herd

2010), researchers have focused exclusively on consumers who are designing products for themselves. Many customization firms, however, are successfully positioning themselves as sources for unique gifts, enabling consumers to create custom products for others.

In two studies, we examine how the intended product recipient (self versus other) interacts with the level of design support provided (Study 1) and brand (Study 2) to influence customer's product reactions to customized products. Using participants drawn from the relevant target market, both studies involve real customization tasks undertaken on live web sites. Customized tote bags were selected as the product category for both studies and in both studies, participants were able to make a several design decisions including size, fabric for three different sections of the bag (from a collection of 37 patterns and colors), and embroidered personalization.

In the first study, two factors were manipulated between participants: (1) the intended recipient (self vs. other) and (2) design support (present vs. absent). Design support was manipulated both in the instruction packet and on the website itself. Participants' self-assessed design skill was measured.

Following Irwin and McClelland (2003), design skill was treated as a continuous measure, and regression was used to test the effects of the independent variables on participants' expectations of their bags at the time of design. The results revealed a significant interaction between the two manipulated factors ($\beta=1.09$, $t=2.84$, $p<.01$) as well as a three-way interaction among all of the independent variables ($\beta=-.16$, $t=-2.67$, $p<.01$). An ANOVA was used to interpret the two-way interaction. When the tote bag was intended as a gift, the presence of design support significantly increased participants' expectations ($M_{\text{Other, Support Present}}=8.2$ vs. $M_{\text{Other, Support Absent}}=7.7$, contrast: $F(1, 41)=4.06$, $p<.05$). However, when the bag was intended for the participant herself, design support had little influence on expectations ($M_{\text{Self, Support Present}}=7.5$ vs. $M_{\text{Self, Support Absent}}=7.5$, contrast n/s). We also find that when the tote bag was intended as a gift, design support significantly reduced participants' anxiety-related negative emotions ($M_{\text{Other, Support Present}}=2.7$ vs. $M_{\text{Other, Support Absent}}=3.7$, contrast: $F(1, 41)=4.69$, $p<.05$). However, when the bag was intended for the participant herself, design support had little influence on these feelings ($M_{\text{Self, Support Present}}=3.6$ vs. $M_{\text{Self, Support Absent}}=4.0$, contrast n/s).

Approximately six weeks later, the bags arrived and willingness to pay measures (WTP) were taken. Interestingly, participants were willing to pay more for a bag designed for someone else rather than for themselves ($M_{\text{Other}}=\$28.11$ vs. $M_{\text{Self}}=\$25.52$). This main effect was qualified by the interaction. The presence of design support had a significant, positive influence on participants' WTP when the bag was for themselves ($M_{\text{Self, Support Present}}=\27.03 vs. $M_{\text{Self, Support Absent}}=\23.00) yet a negative influence when it was for someone else ($M_{\text{Other, Support Present}}=\26.13 vs. $M_{\text{Other, Support Absent}}=\30.58).

To determine whether participants differentially valued the effort they put into designing the bags, the correlation between self-reported effort and willingness to pay were assessed separately for those in the self and other conditions. There was a positive, significant correlation between effort and willingness to pay for those designing the product as a gift ($r=.41$, $p<.05$). For those designing the bag for themselves, the correlation was negative and non-significant ($r=-.13$, $p>.10$).

In Study 2, no one received design support, participants did not expect to actually receive the bag they had designed, and the entire study was completed online. Both the intended recipient (self vs. other) and brand (present vs. absent) were manipulated between-participants in this 2x2 study. As a known brand (Vera Bradley) was used in the study, participants' attitude towards that brand was used as a covariate (see Moreau and Herd 2010) along with participants' self-reported design skill.

The results revealed a significant interaction between brand and the intended recipient ($F(1, 75)=4.33$, $p<.05$) on willingness to pay. The presence of the brand had a significant, positive effect on willingness to pay when the product was intended for the self ($M_{\text{Self, No Brand}}=\30.05 vs. $M_{\text{Self, Brand}}=\$38.84$, $F(1, 36)=3.75$, $p=.05$). However, when the product was intended as a gift, brand actually had a negative, but non-significant influence ($M_{\text{Other, No Brand}}=\40.11 vs. $M_{\text{Other, Brand}}=\35.41 , $F(1, 38)=1.46$, n/s).

A similar ANOVA was used to test product expectations. The results reveal an interaction between brand and the intended recipient that was marginally significant ($F(1, 75)=3.23$, $p=.07$). Following the pattern observed for willingness to pay, brand had a significant, positive effect on expectations when the product was for the self ($M_{\text{Self, No Brand}}=6.7$ vs. $M_{\text{Self, Brand}}=7.7$, $F(1, 36)=4.67$, $p<.05$). However, when the product was intended as a gift, brand actually had a negative, but non-significant influence ($M_{\text{Other, No Brand}}=7.7$ vs. $M_{\text{Other, Brand}}=7.3$, $F(1, 38)=.61$, n/s).

We also find that when the tote was intended for the self, there was no significant correlation between time spent and willingness to pay ($r=.02$, n/s). However, when the tote was intended as a gift, this correlation was both positive and significant ($r=.34$, $p<.05$).

“Give Them What They Want: The Benefits of Explicitness in Gift Exchange”

Francesca Gino, University of North Carolina, USA

Francis J. Flynn, Stanford University, USA

Gifts account for more than four percent of the typical household budget (Davis 1972; Garner & Wagner 1991), which suggests that gift-giving is a routine activity for most people. Nevertheless, research consistently shows that many individuals are poor gift-givers, often purchasing gifts that others would not choose to buy themselves (Waldfogel 1993) or focusing on the wrong criterion in attempting to select a meaningful gift (Flynn & Adams 2009). Thus, despite the fact that people spend a significant amount of time and money on gift-giving, their purchases often are less appreciated than they hope.

One means by which individuals attempt to facilitate gift exchange is by telling others explicitly what gifts they would like. To this end, people frequently organize registries for various occasions (e.g., baby showers, weddings) that list for potential gift-givers the items they should purchase. Is such transparency effective, or are gift-givers wary that gifts directly requested by the gift-recipient will not be appreciated as much? In anthropological studies, gift-giving is often described as a social exchange process, rife with symbolic meaning and interpersonal subtleties (e.g., Boas, 1895; Mauss, 1925). Accepting suggestions for gift purchases from the intended recipient could be interpreted as a sign that the giver does not know the recipient well enough to identify a meaningful gift, or does not wish to spend the time and effort needed to figure out what such a gift might look like.

Failures in gift-giving may reflect a problem in perspective-taking that afflicts many social exchanges. When predicting how others will evaluate their actions, people tend to focus too heavily on their own perspective (Epley, Savitsky, & Gilovich, 2002), and overestimate the extent to which others will share their point of view (Keysar, 1994; Van Boven, Dunning, & Loewenstein, 2000). Given this egocentric bias, gift-givers may fail to pay close attention to what a gift-recipient directly requests. Instead, they may believe that purchasing an unrequested item will signal a sincere concern for the recipient because they have gone out of their way to identify the gift. Yet, gift-recipients may be frustrated that the giver did not take note of the recipient's explicit suggestions. Indeed, gift recipients will likely report that gifts they requested are more

thoughtful and considerate of their needs than those not requested because the former indicate that the giver is attentive and responsive.

In the present research we investigate the role of explicitness in gift-giving. In Study 1, we examine personal gift registries and ask people to consider how much they would appreciate an item purchased off the registry versus a highly similar item that was not listed. In Study 2, we consider registry and non-registry gift purchases and examine whether gift-recipients appreciate the gifts they request more than the gifts they do not, and whether gift-givers can account for this important difference. In Study 3, we attempt to highlight the underlying psychological mechanism for this failure in perspective taking: whereas gift-givers believe that requested gifts will appear less thoughtful and considerate than non-requested gifts, gift-recipients maintain the opposite belief. Finally, in Study 4, we consider a boundary condition for this effect—the number of gifts requested.

The results of our four studies demonstrate that gift-recipients are more appreciative of gifts chosen from a set of desired items than they are of alternative gift choices (Studies 1-3), but that gift-givers believe both types of gifts will be equally appreciated (Studies 2-3). We also show that when the recipient explicitly highlights his or her preferred gift, givers are receptive to such suggestions (Studies 4). Thus, while gift-givers often attempt to be more thoughtful by choosing a gift not included on a given list, they do not realize that sticking to the list will elicit stronger feelings of appreciation.

Our findings contribute to the literature on egocentric biases and perspective taking in social judgments. Prior work has found that people often fail to take others' perspectives into account and struggle to read their minds (Epley et al., 2004). We go beyond this point to investigate the impact of explicitness in one pervasive perspective-taking context: gift exchange. We find that even when gift-recipients provide a list of what they would like, givers fail to heed this clear-cut advice. Instead, gift-givers think it would be better to ignore the gift-recipient's explicit requests. It remains unclear whether gift-givers eventually learn to respond to gift-recipient's explicit cues, and thereby become better at eliciting appreciation. Gift-recipients are reluctant to reveal their true feelings of disappointment with the gifts they receive (Mauss, 1925). As a result, gift-givers may be left in the dark about their failed attempts to elicit appreciation and many may believe that their gift purchases are more effective in eliciting appreciation than is actually the case.

According to Webley, Lea, and Portalska (1983), "Gift-giving clearly fulfills an important social function and it is the act of giving...which is of prime importance, not the actual gift itself" (p. 237). Our results offer a different point of view—that whether the act of gift-giving counts may depend largely on whether or not the giver is attentive and responsive to the recipient's explicit suggestions when they are made available. Gift-givers would be wise to pay attention to gift registries, wish lists, and explicit requests from friends or significant others. Nevertheless, they often ignore such solicitations and underestimate the costs of doing so. Conversely, gift-recipients can help facilitate the gift-giving process by not only being more direct in making suggestions for gifts, but being more specific as well. Rather than put together one big "wish list," they should instead list one big wish.

"Paying it Forward: Greed and Generosity in Upstream Reciprocity"

Kurt Gray, Harvard University, USA

Adrian F. Ward, Harvard University, USA

Michael I. Norton, Harvard University, USA

Paying it forward is a heart-warming notion, one that has long captured the attention of luminaries such as Ralph Waldo Emerson

(1841) and Benjamin Franklin (1784) as well as laypeople (Hyde 2000). The concept is simple: A is kind to B, and B—rather than pay that kindness back to A—pays it forward to C. C then pays that kindness forward to D, and so on, creating a chain of goodwill. On any given day, however, people are the recipients of both generous and selfish acts from others. If people pay forward these negative behaviors as well, then selfish acts may similarly create chains of ill will. In this paper, we examine whether people are more likely to pay forward generosity or greed, and how being the victim of greed or the beneficiary of generosity drives subsequent behavior.

In our first experiment, we examined paying it forward in the domain of money. In one of four conditions, participants completed a dictator game, splitting \$6 between themselves and an anonymous future receiver (give-only condition). In the three pay it forward conditions, participants were told that a previous dictator had completed the same game, with the participant as the receiver. They first learned how much money the previous dictator had given them—a greedy (\$0/\$6), equitable (\$3/\$6), or generous (\$6/\$6) split—and then acted as the dictator in another game, splitting an additional \$6 between themselves and a different future receiver. As expected, participants in the greedy condition gave the least ($M = \$1.36$), followed by those in the give-only condition ($M = \$2.40$), followed by those in the equal ($M = \$3.38$) and generous conditions ($M = \$3.71$).

Paying it forward in the real world, of course, often involves more informal exchanges than the disbursement of cash; in any workplace, for example, there are both enjoyable and onerous tasks, and co-workers may divide this labor more or less equitably. Experiment 2 investigates if those who receive greedy (vs. generous) divisions of labor are more likely to pay forward their treatment, as well as the roles of affect and perceptions of fairness in mediating the extent to which participants paid behavior forward.

This experiment was similar to Experiment 1, except that instead of receiving and giving money, participants completed enjoyable and irritating tasks. The enjoyable task involved making free associations to words, while the irritating task involved circling vowels in passages of Italian prose. All participants were given a set of eight tasks—four good and four bad—and were told to complete any four of them and pass on the remaining four to a future participant. Participants could leave any combination of good versus bad tasks for future participants. One group of participants (give-only condition) simply completed four tasks and passed on the remainder. In the three pay it forward conditions, participants first learned that a previous participant had been asked to split these eight tasks, and had left them either a generous (completing all four bad tasks themselves and leaving the four good tasks for the participant), greedy (completing all four good and leaving all four bad tasks), or equitable split (completing two of each kind and leaving two of each kind). In these conditions, participants completed the four tasks that the previous participant had ostensibly left for them, then divided eight additional tasks (four good and four bad) between themselves and an unknown future participant. After completing the four tasks that the previous participant had left for them, participants indicated the extent to which they were feeling a variety of positive (e.g., happy) and negative (e.g., upset) affective states.

Replicating Experiment 1, participants in the greedy condition ($M = 1.04$) gave significantly fewer good tasks than participants in all other conditions. The give-only gave the next least ($M = 1.67$), though not significantly less than the equitable ($M = 1.95$) or generous conditions ($M = 1.91$). The equitable and generous conditions again did not differ from each other. The four conditions also differed significantly on negative affect, such that participants in the greed condition experienced significantly more negative affect

than those in the other conditions. As we predicted, this incidental negative affect mediated the link between good tasks received and good tasks paid forward.

These results have both heartening and disheartening implications. We find that people do pass on some degree of kindness to others, but not to the same extent that they received it themselves. Thus the person who awakes to find his long driveway mysteriously cleared of snow and as a result holds the door for three seconds for a co-worker may feel he has "paid forward" a generous act, but the discount rate is sufficiently high that the perpetuation of this chain of good will likely ends there. On the other hand, the person who awakes to find his driveway blocked with snow from his neighbor's efforts to clear her own driveway may continue to pay forward bad deeds, creating a significantly longer chain of ill will.

On The Psychology of Construal mindsets: Determinants & Consequences Of Concrete Thinking

Manoj Thomas, Cornell University, USA
Claire I. Tsai, University of Toronto, Canada

EXTENDED ABSTRACTS

“The Scale Effect: How Larger Measurement Units Shrink Perceived Size and Expand Mental Horizon”

Sam Maglio, *New York University*
Yaacov Trope, *New York University*

Maglio and Trope. When do people look at the world in fine-grained detail instead of in broad brushstrokes? And what are the consequences—both for visual perception and cognitive processing—of this small- versus large-scale distinction? We propose that a critical factor is the person’s proximity to the target of judgment, that is, how psychologically close the object is to the person. A series of five studies suggest that smaller scale increases size estimates while also prompting more proximal timing estimates as well as a pattern of concrete thinking that generalizes to new targets.

How could perception fall prey to something as incidental as scale? Research on the clutter effect (Sadalla & Staplin, 1980) suggests that the presence of more distinct items (e.g., intersections crossed in a walk) increases perceived distance. We propose that smaller unit of measurement produces the same effect.

Are certain objects more likely to be measured in small scale? Construal level theory (Lieberman & Trope, 2008; Trope & Liberman, 2003) points to one possibility: a person’s psychological distance from a target. Those that are near (in time, space, or likelihood) are mentally construed according to their concrete, contextual features; more distal targets are construed in terms of their abstract, universal features. Of importance, distal (versus proximal) targets tend to be categorized into fewer categories (i.e., broader units) and described using more abstract language (Fujita, Henderson, Eng, Trope, & Liberman, 2006; Henderson, Fujita, Trope, & Liberman, 2006).

Study 1 tested two important predictions. First, a distal target should be measured using larger units relative to a proximal target. Second, this difference in unit size should give rise to differential clutter, producing different estimates of size. Thus, we presented participants with a piece of paper containing a straight diagonal line meant to represent a path to a grocery store that was either physically proximal or distal. Participants first created a single unit of measurement with which to subsequently measure the path. We found that those in the proximal condition estimated the line to look larger; this effect of condition was mediated by differences in scale size.

Our next studies directly manipulated scale to investigate its consequences for size perception as well as mental construal. Studies 2A and 2B provided participants with either a curved or straight line, respectively, and had them measure it using either millimeters, centimeters, or decimeters. The results indicated a linear increase in size perception with finer scale. In Study 3, participants who measured a curved line (meant to represent a road trip) using smaller scale not only indicated that it looked bigger but also that they expected it to happen sooner in the future (i.e., temporally proximal). Finally, Study 4 asked participants to measure a hallway in either feet or yards. Those measuring in feet estimated larger size and described a set of actions more concretely (versus abstractly) than those measuring in yards.

In sum, larger unit of measurement consistently elicited not only smaller visual estimates of size but also more abstract mental construal, characterized by judgments of temporal distance and

high-level action identification. These effects were found both for the original target of measurement as well as for new, unrelated targets—evidence that large scale leads to big picture thinking.

“Carry-Over Effects of Self-Control on Decision-Making: A Construal Level Perspective”

Echo Wen Wan, *University of Hong Kong, China*
Nidhi Agrawal, *Northwestern University, USA*

Wan and Agrawal. Past research has examined the effect of exerting self-control on subsequent decision-making from the resource perspective. Regulatory depletion theory (Vohs, Baumeister, and Tice 2008a) posits that exerting self-control leads to a temporary deficit in self-regulation resources and consequently harms subsequent self-control behavior such as the decision about unplanned purchase (Vohs and Faber 2007). The current research proposes a construal level driven complementary process through which regulatory depletion affects subsequent decisions.

Prior studies on regulatory depletion have shown that performing self-control leads to a heightened feeling of fatigue (e.g., Baumeister et al. 1998) that can increase the salience of current lack of resources (Agrawal and Wan 2009). Resources constitute the means of carrying out the action. Construal level theory (Trope and Liberman 2003) posits that individuals tend to adopt lower (vs. higher) levels of construal when considering the means of performing the action. Therefore, we propose that exerting self-control heightens a focus on resources that leads consumers to construe subsequent situations at lower levels, which will systematically prompt preferences for options with attractive lower-level construal features in their decision-making.

Five studies tested our propositions. Study 1 manipulated self-control with a letter-detecting task (Baumeister et al. 1998) and measured participants’ construal levels (BIF, Vallacher and Wagner 1989). We found that participants with prior self-control scored lower than those without prior self-control, supporting our proposition that exerting self-control lowers construal levels. Studies 2–5 tested the effect of exerting self-control on subsequent judgments or choices that involved decision options varying in higher and lower construal level features: primary versus secondary features, temporal proximity versus distance, feasibility versus desirability.

In study 2, participants completed a continuous-choice task that manipulated self-control (Vohs et al. 2008b), and then indicated their intention of patronizing a restaurant described as either having attractive primary feature and non-attractive secondary feature (great food, mediocre view) or having attractive secondary feature and non-attractive primary feature (great view, mediocre food). Participants with prior self-control had greater dining intention than those without prior self-control when the restaurant offered an attractive secondary feature, supporting our proposition. Study 3 had participants first exert self-control or not in an emotion-control task (Muraven et al. 1998) and then actually choose between two calendars as the reward for their participation, one organized by week (temporal proximity) and another by month (temporal distance). A larger proportion of participants chose the weekly calendar (temporal proximity) when they exerted prior self-control than when they didn’t. In study 4, participants completed a thought-listing task that manipulated self-control (Vohs and Faber 2007) and then

chose between two hiking spots that varied in desirability (scene) and feasibility (transportation). As expected, a larger proportion of participants chose the park with high feasibility when they exerted prior self-control than when they didn't. Moreover, this effect was mediated by a focus on resources. Study 5 followed the same procedure as used in study 4 with one change: Half the participants were primed to adopt the higher-level construals ("why" mindset, Freitas, Gollwitzer, and Trope 2004) whereas the other half didn't (control). Results of study 4 were replicated in the control condition but were eliminated in the why mindset condition, suggesting that the effect of exerting self-control on subsequent choice was driven by the downward shift in construal levels.

This research contributes to the construal level literature by identifying self-control and regulatory depletion as an important trigger of construal level variation. It also extends the understanding of self-control and consumer decision by uncovering a new mechanism that complements the resource depletion theory in explaining the psychology of how self-control and depletion affect decision-making.

"When Does Anticipating Regret Help Consumer Decision Making and When Does it Hurt?"

Rebecca W. Hamilton, University of Maryland, USA

Debora V. Thompson, Georgetown University, USA

Hamilton and Thompson. Avoiding regret is an important motivator in consumer decision making (Zeelenberg and Pieters 2007). For example, asking consumers to anticipate the regret they would experience if they made the wrong decision increases their willingness to pay more for a higher-priced brand of video player (Simonson 1992). It is not clear, though, whether considering anticipated regret helps consumers make more satisfactory purchase decisions because anticipated regret is often not a very accurate predictor of experienced regret.

In this paper, we focus on differences in the regret emotions that are anticipated and experienced. Research has shown that consumption experiences themselves can change the way consumers think about products because consumption experiences induce a more concrete mental construal than indirect experiences such as reading product descriptions (Hamilton and Thompson 2007). One key difference between anticipated regret and experienced regret is that anticipated regret is considered in prospect, while experienced regret is considered during or shortly after an experience. Construal level theory (Trope and Liberman 2000) proposes that the greater an individual's psychological distance from target events, the more abstractly these events will be represented. Thus, anticipated regret, which is considered in prospect, should feel more psychologically distant, evoking more abstract thought than experienced regret, which should evoke more concrete thought.

Notably, previous research has distinguished between two different kinds of regret: "hot" regret and "cold" or "wistful" regret (Gilovich, Medvec and Kahneman 1998; Kahneman 1995). Kahneman (1995) proposed that hot regret is a more short-term form of regret, which focuses on direct reactions to the outcome. In contrast, wistful regret is a more long-term form of regret, which focuses on counterfactual alternatives to the outcome. Using construal theory to link these two streams of research together, we propose that anticipated regret is more similar to cold regret, while experienced regret is more similar to hot regret.

In our research, we focus on this construal-based explanation for the gap between anticipated and experienced regret, and we conducted a series of three studies to examine the size of this gap and its effect on consumer decision making. In our first study, participants evaluated two different digital video players, an easy-to-use basic

model (high feasibility) and an advanced model with three times the number of features (high desirability). After choosing one of them, they answered several items designed to measure anticipated regret. Next, participants used their chosen product and answered items designed to measure experienced regret. Based on earlier research indicating that consumers tend to focus on the desirability of products prior to use but on the feasibility of products during consumption (Thompson, Hamilton and Rust 2005), we expected that participants would anticipate more regret when they chose the basic model, but actually experience more regret when they chose the advanced model.

As we had predicted, those who chose the basic model were more likely to anticipate regretting their choices than those who chose the advanced model. However, those who chose the advanced model were significantly more likely to regret their choices after using the product than those who chose the basic model. Notably, anticipated regret and experienced regret were not even significantly correlated ($r=.09$, $p>.27$).

In our second study, we replicated this misprediction of experienced regret in a new domain by having participants choose either a large or small set of art posters from which they would select their favorite poster for a raffle. We also measured emotions specific to hot regret and cold regret as well as anticipated and experienced regret.

In our third study, our goal was to see whether we could help participants make better choices by instructing participants to consider either hot regret or cold regret before choosing a product. We expected that those who considered hot regret emotions such as irritation and frustration before making their choice would be more likely to choose the basic product, experiencing more satisfaction and less regret after using the product. In contrast, those who considered cold regret emotions such as disappointment and longing for missed opportunities before choice were expected to be more likely to choose the advanced product.

As predicted, those who considered hot regret emotions prior to choice were more likely to prefer the basic player than those who considered cold regret emotions prior to choice. Notably, after using their chosen products, those in the hot regret condition evaluated them more favorably, indicated that they would be more likely to recommend it to others, and were marginally more satisfied with their choices than those in the cold regret condition. Considering hot regret before choosing between a basic and an advanced product seems to attenuate the "feature fatigue" effect (Thompson et al. 2005) demonstrated in previous research.

Taken together, these studies suggest that anticipated and experienced great differ not only quantitatively but also qualitatively. Because direct experiences with products shift consumers' construal levels from abstract to concrete, anticipating "hot" regret emotions can increase consumption satisfaction relative to anticipating "cold" regret emotions.

"When Does Metacognitive Experience Influence Preference? The Moderating Role of Construal Mindset"

Claire I. Tsai, University of Toronto

Manoj Thomas, Cornell University

This paper explores how level of construal interacts with metacognitive experience to influence evaluative judgments. A large body of research has shown that consumers' judgments are not only based on the information content, but also on the ease or difficulty of processing the information content (Schwarz 2004; Alter and Oppenheimer 2009). In this paper, we suggest that the ease-of-processing effect is contingent on construal level. We hypothesize and find that people in a concrete-construal mindset

are more likely to use ease of processing as an input for judgment. An abstract-construal mindset prompts them to ignore contextual details that are not central to the judgment. Consequently, they are less likely to consider the subjective experiences of ease or difficulty under conditions of abstract-construal mindset.

The notion that abstract-construal mindset reduces consumers' tendency to use metacognitive experience as a cue is consistent with the process of abstraction as postulated by construal level theory (Trope and Liberman 2003). According to this theory, the concrete-construal mindset elicits lower-level construals that are concrete and contextualized representations which include subordinate and incidental features of events. In contrast, higher-level construals are schematic and decontextualized representations that extract the gist from the available information and omit contextual features. Since metacognitive experience is likely to be considered a contextual cue, consumers under abstract-construal mindset are likely to disregard their metacognitive experience while making judgments.

Study 1 showed that abstract-construal mindset mitigated the ease-of-processing effect demonstrated in extant literature. Participants first completed a task that evoked a concrete- or abstract-construal mindset. They then proceeded to the ostensibly unrelated main task and evaluated a fictitious brand of chocolate truffles based on either a clear (easy to process) or blurry (difficult to process) print advertisement. Participants assigned to the concrete-construal mindset liked chocolate less when the ad was blurry and difficult to process. In contrast, ease of processing did not affect liking for chocolate for participants assigned to abstract-construal mindset, confirming our hypothesis.

Since our primary interest in Study 1 was to test the moderating role of construal mindset, the information content was kept invariant across the conditions. However, a change in metacognitive experience might be accompanied by a change in the informativeness, a key determinant of judgment. How might construal mindset influence judgments in such situations? We investigated this issue in Study 2 and manipulated metacognitive experience by asking participants to generate either two or eight reasons for donating to a charitable cause (conserving polar bears). The results showed that abstract-construal mindset not only weakened the effect of metacognitive experience but also augmented the effect of information content, thereby reversing the effect of retrieval fluency. Study 2 expanded the findings by using a behavioral measure (donation) in a non-hedonic context and ruled out entitlement to consume as an alternative explanation. Although the consumption of hedonic products is often justified by effort (e.g., "If I exerted effort, I deserve to indulge"), it is unlikely that effort can be a justification for increased donation because donating to a charitable cause is not indulgent consumption. Study 3 further generalized the findings by replicating Study 2 (single-alternative) in a choice task (choosing between two paintings) and ruled out processing motivation as an alternative explanation.

Construal level theory posits the reason why ease of processing does not influence judgments in higher level construal is that subjective experiences are considered contextual and peripheral. If subjective experiences are deemed to be central to the task, then ease-of-processing effect will manifest even in higher level construal. We test this hypothesis in Study 4. Specifically, Study 4 showed that when feelings was described as a key determinant for judgment, ease of processing increased liking for chocolate for participants with abstract-construal mindset. These findings provide a clearer picture of when and why metacognitive experience affects evaluative judgments.

“One Without the Other: The Effects of Priming Individual and Collective Mindset on Consumer Choice and Valuation”

James A. Mourey, University of Michigan, USA

Carolyn Yoon, University of Michigan, USA

Daphna Oyserman, University of Michigan, USA

What is peanut butter without jelly or bacon and lettuce without tomato? What would Ken be without Barbie? Is a shirt just a shirt or is it part of an outfit, completed with just the right tie, belt, and shoes? In some way, once a relationship is created among items, each alone feels incomplete and less desirable. If Ken without Barbie feels like a belt without a buckle, consumers should not want one without the other.

Priming individual- and collective-mindsets has been shown to influence cognitive processing style but, in the domain of marketing, the focus has been primarily on the influence of self-construal on interpersonal relationships. Mindsets are cognitive schemas that include content, procedures, and goals relevant to separating and decontextualizing, or connecting and contextualizing. Societies are likely to differ in whether a collective or an individual mindset is chronically accessible, but both mindsets are available to be used in every modern society so that the effects of mindsets can also be studied by priming a mindset or making it temporarily salient (Oyserman et al. 2009). When cued, mindsets influence the propensity to view objects in the world as either part of larger, related, and connected units (collective mindset), or as separate and discrete items (individual mindset). The current studies extend cultural mindset theory to predict the consequences of primed mindset for consumption of inter-product relationships, especially when consumption involves multiple sequential choices.

Although previous research has demonstrated the impact of salient mindsets on basic cognitive procedures (e.g., memory, visual and auditory processing) and on acceptance of brand extensions (Monga and John 2007), little is known about the consequences of salient mindsets on perceptions about products and services. We move beyond prior theorizing and research to predict that salient mindset will influence the extent that products and services are perceived as either related parts of a larger item unit or as separate units, and that these perceptions have consequences for willingness to consume partial sets and willingness to pay to complete such sets.

In three experiments we show that mindset priming influences both the relationships consumers perceive among products and their responsiveness to these relationships. Consumers primed with collective-mindsets see more relationships among products than those primed with individual-mindsets, which leads to differences in initial product selection in a consumption context. Having made initial product selections, consumers primed with collective-mindsets are reluctant to break apart related items by consuming a partial set, whereas those primed with individual-mindsets do not exhibit such tendency. These differences influence the willingness to pay to complete sets, implying that the differences between the primed mindset groups are likely due to different valuations of relationships among items.

In our first study, we explore the proposed influence of mindset in the domain of snacks and beverages. As predicted, consumers primed with individual mindset primes exhibit a greater tendency

to select obvious pairs of related beverage/snack combinations (e.g., milk and cookies, fitness water and a health bar) compared to collective mindset prime consumers who select beyond the obvious relationships and elaborate on the possibilities of relatedness among items (e.g., fitness water and cookies given their compensatory healthy/unhealthy relationships).

In our second study, we focus specifically on the differences between prime groups in their tendency to break up items perceived as being related, in this case cute puppy siblings. After making an initial puppy pair selection, participants are told they are only to have one puppy and must make one selection from all the puppies presented initially. As predicted, collective mindset prime consumers shift their selection to avoid breaking up sibling puppies while individual mindset prime consumers do not.

Our third study was conducted in the context of an online shopping experience, specifically that of Amazon.com. In addition to replicating the first two studies, the final study investigated whether the explicitness of the product presentation made a difference. We found that presenting products explicitly attenuates differences in the initial selection behavior between the prime groups. Additionally, a difference in the willingness-to-pay to restore partial sets emerged for collective mindset prime consumers who had selected to consume a partial set of products, suggesting that valuation of relationships drives the observed differences.

This work makes theoretical contributions with respect to the better understanding of the notion of situated cognition via individual- and collective-mindset priming, extensions beyond self-construal and processing, and differences in product relationship perceptions among consumers. Practical contributions with respect to product bundling, up-selling, cross-selling, and advertising or point-of-purchase displays are also discussed.

“Playing misMatchmaker: The Impact of Matching versus Mismatching Brand Personalities in Incidental Brand Exposure”

Keisha M. Cutright, Duke University, USA

Linyun Yang, Duke University, USA

Gavan Fitzsimons, Duke University, USA

Tanya Chartrand, Duke University, USA

How often do you watch television where just one commercial is shown during the commercial breaks? When was the last time the commercial break on your favorite radio station was filled with the ad of just one brand? It is safe to say that such experiences are pretty rare; brands are generally surrounded by the messages of many other brands.

This research seeks to understand how exposure to more than one brand in a given context affects attitudes toward the focal brand. More specifically, we focus on whether being exposed to brands with ‘matching’ or ‘mismatching’ personality traits impacts attitudes toward the focal brand. Moreover, in light of consumers’ inability to process all of the messages they encounter and their unwillingness to do so (as suggested by the rise of DVRs), we seek to understand how the impact of the brand environment differs based on whether people are attentive to the brands or are incidentally exposed to them.

Our hypothesis is that when consumers are incidentally exposed to brands, they prefer a focal brand more when it is paired with a brand with a mismatching personality than one with a matching

personality. We argue that this is because being paired with a brand with a mismatching personality makes the focal brand appear more distinct and unique. We base this hypothesis on prior research demonstrating that (moderately) incongruent information often enhances individuals' attention and evaluations (e.g., Alden, Mukherjee, and Hoyer 2000; Lee and Mason 1999; Meyers-Levy and Tybout 1989). However, we do not expect this pattern to exist when people pay attention to the brand pairs and can therefore analyze the specific attributes of each brand more carefully.

In study 1, we tested the hypothesis that incidental exposure to mismatching brands leads to more favorable attitudes toward a focal brand than exposure to matching brands. Our focal brand was Dove chocolate, which we paired with a soft drink. After pre-testing several soft drinks, we found that Canada Dry is very similar in personality to Dove, while Mt. Dew is very different. In study 1, participants were asked to study faces in 20 photographs of individuals engaging in a variety of tasks. Unobtrusively embedded in four pictures were two brands. In one condition, participants were exposed to the two brands with matching personalities (Dove and Canada Dry). In the second condition, participants were exposed to the brands with mismatching personalities (Dove and Mt. Dew). Participants were then given a real choice between Dove and Ghirardelli chocolate. Analyses revealed that participants were more likely to choose Dove when it was paired with Mt. Dew than when it was paired with Canada Dry.

In study 2, we replicate study 1 while using a focal brand with traits different than those of the focal brand in study 1. We also wanted to demonstrate that our results hold for incidental exposure to brands, but not regular exposure. After watching the first two minutes of a clip from Discovery Channel's *Planet Earth* series, participants were shown two commercials (pre-tested to be similar in general, but very similar or very different in terms of the brands' personalities.) Specifically, one condition saw a Mt. Dew and a Hummer commercial (match), while the other condition saw the same Mt. Dew commercial paired with a Honda Pilot commercial (mismatch). Importantly, half of the participants watched the commercials at normal speed. The other half watched the commercials at 10x normal speed (i.e., the incidental exposure condition, similar to fast-forward speeds on DVR). As expected, when participants were exposed to the commercials incidentally, those who saw Mt. Dew paired with Honda (mismatch) were more willing to purchase Mt. Dew than those who saw Mt. Dew paired with Hummer (match). This pattern did not exist when participants viewed the commercials at regular speed. Moreover, preferences for other soft drinks were unaffected.

In study 3, our goal was to demonstrate that consumers also prefer a focal brand more when it is paired with a mismatching brand than when it is shown alone and to show this pattern is mediated by consumers' perceptions of the distinctiveness of the focal brand. The design of study 3 was similar to that of study 2; the only difference being that the condition in which participants watched the 'Mt. Dew and Hummer' commercials in study 2 was replaced with a 'Mt. Dew only' condition. As expected, participants in the incidental exposure condition rated Mt. Dew higher when it was paired with Honda Pilot than when it was seen alone. But, this was not true in the regular exposure condition, nor was it true for the other soft drink brands. Further, we found that the effect in the incidental exposure condition was mediated by participants' enhanced perceptions of the uniqueness of the Mt. Dew brand when it was shown with the Honda Pilot commercial.

Overall, these studies demonstrate that being paired with a brand with an opposite personality can enhance attitudes toward the focal brand, particularly under incidental exposure conditions.

This research allows us to take a broader perspective of how non-conscious exposure to brands impacts behavior by looking beyond the effects of an individual brand to exploring the environment in which it is situated. It also broadens our perspective of the impact of brand personalities. Not only do such dimensions affect individuals' evaluations of a focal brand itself, but they also impact attitudes toward other brands that the focal brand is associated with for just a short moment. Finally, this work suggests that marketers should consider responding to the increasing threat of DVRs by working strategically with media agencies to expose their brands with appropriately 'mismatching' brands.

"Penny Wise Lb Foolish: From Ambition to Intemperance"

Aparna A. Labroo, University of Chicago, USA

Sara Kim, University of Chicago, USA

In 2008, with per capita income of over \$47,000, the USA comprised of some of the wealthiest and possibly the most ambitious people in the world. With over 74% of her population classified as obese, she was also one of the fattest, suggesting that she also comprised of some of the most intemperate people in the world. Much research is now establishing that ambition results in chasing material wealth but troublingly, material wealth does not make people happy; rather, it is investing in oneself that is the source of subjective well being. So why is it that ambitious people overinvest their efforts in the pursuit of material goods and under invest their efforts in the development of the self, the result being that they end up living increasingly intemperate but not happier lives?

In our research, we argue that one reason for this miscalibration is that mere reminders of ambition activate general reward seeking goals. This goal activation results in people who have been reminded of ambition: (a) investing additional effort to secure goal relevant indulgent or immediately rewarding outcomes, and more importantly (b) inferring from their own sense of effort while engaged in the pursuit of such indulgent and immediately rewarding outcomes that such outcomes must be more valuable than they actually are. Put simply, people reminded of ambition not only put effort to secure indulgent outcomes, but from their own sense of effort when engaged in securing such outcomes, they assign added value to such outcomes, leading to upward spirals of hedonism.

Thus, it is not just a general quest for rewards that is activated by ambition; rather, once this quest has been activated the subjective effort associated with a quest for rewards further enhances their perceived value. This latter prediction is in line with recent reports showing that because people associate effort with the pursuit of their most important goals, when engaged in the pursuit of any goal, they also see outcomes that are a means to goal attainment as more valuable when such outcomes are associated with a subjective sense of effort. In particular, building on self-perception theory which suggested that people infer their attitudes from their actions, Labroo and Kim (2009) demonstrated that people who were engaged in the pursuit of important goals (e.g., be a kind person) tended to infer that an outcome (donation to a particular charity, Kids-in-Danger) was more important to them when it was associated with subjective effort (its appeal employed slightly blurry versus clear font). By similar argument, if reminders of ambition might make people value decadent foods and actively channel their efforts into attaining such foods, then these individuals might also end up valuing decadent foods more when those foods are associated with a token effort, even subjective effort that in no way reflects a positive value of the outcome. Abstinence, and token reminders of abstinence, on the other hand, can result in upward spirals of wellbeing. Not only do such people start to reallocate their efforts towards the pursuit of activities that strengthen their inner core selves, but

importantly, from their very own sense of effort while engaged in the pursuit of self-strengthening outcomes, they infer added value of such outcomes. Ambition therefore feeds into and feeds out of immoderate living—that is, upward spirals result from reallocating effort to chase indulgence over self-strengthening and additionally, inferring an enhanced value of such outcomes from a subjective sense of effort associated with the pursuit of such outcomes. And abstinence feeds into and is derived from one's subjective sense of effort to improve oneself.

Across three studies we provide evidence that (a) the ambition primed are more willing than non-ambition primed participants to exert real effort to attain indulgent outcomes, (b) that ironically, associating subjective effort (versus ease) to an indulgent outcome increases the valuation of that outcome among ambition-primed individuals but reduces the valuation of those outcomes among forsake ambition primed individuals, and (c) associating subjective effort (versus ease) to self-strengthening outcomes (e.g., yoga) reduces the valuation of that outcome among ambition-primed individuals but increases the valuation of those outcomes among forsake ambition primed individuals.

“You’re Cramping My Style: When Employee Appearance Leads to “Bad” Consumer Choices”

Andrea Morales, Arizona State University, USA

Gavan Fitzsimons, Duke University, USA

Nancy Sirianni, Arizona State University, USA

Iana Castro-Nelson, Arizona State University, USA

In an attempt to make purchase decisions they will be happy with, consumers rely on cues in retail and service environments, such as the appearance of employees, to help guide them to the right choices. This research examines the strong influence that employee appearance can exert on consumer choices, and while such a result has important practical implications, it is to be anticipated from a theoretical perspective given the growing number of papers demonstrating the powerful influence of activating or priming a context on consumer choices (e.g., Chartrand et al. 2008; Ferraro, Bettman and Chartrand 2009). What is perhaps most interesting and novel in our current work is the examination of the downstream consequences of this phenomenon. The focus of this research is on understanding how consumers subsequently feel if the appearance of an employee led them to choose a product that they might not otherwise have chosen.

For example, imagine walking into a retail store with the goal of purchasing a new business suit. As you explore the available options, a sales associate offers his assistance. You notice that he is formally dressed in black dress pants and shoes, a white long-sleeve oxford shirt and a navy blue tie. Based on his clothing, you infer that he is conservative, serious and perhaps a little old-fashioned. You tell him what you are looking for and he provides you with an assortment of business suits. Will his traditional appearance have an effect on the type of suit that you eventually choose? Perhaps you were considering buying a less conventional, modern-style business suit. Does this idea now seem wrong to you? What type of suit do you buy and will you be happy once you’ve brought it home?

Following theory in impression formation and stereotype activation (Fiske, Lin and Neuberg 1999, Quinn, Macrae and Bodenhausen 2003), we propose that consumers who interact with an employee in a retail or service setting will categorize the employee based on observable cues derived from his or her overall physical appearance. Consumers will use this information to draw inferences about the employee’s personality traits, goals and behaviors, and these inferences will have an impact on the choices consumers make in the presence of the employee. In order to make the right choice in

the situation, all consumers will experience (either consciously or nonconsciously) pressure to choose in accordance to the presumptions they have made about the employee. Some consumers will then make a decision they believe the employee would make (behavioral assimilation), while others will choose to make a decision that does not conform (behavioral contrast) to the employee.

To understand how employee appearance can act as a contextual prime that influences both consumer choice and post-choice judgments, we conducted a series of experiments in which we manipulated the appearance of a confederate, who posed as an employee, to portray either formal or casual personal style during interactions with study participants. Our findings show that when a consumer perceives that he and an employee share similar traits, goals and behaviors, he makes his purchase decisions freely and is later satisfied with those choices. However, when a consumer perceives that he and the employee do not share similar traits, goals and behaviors, the consumer feels pressure to alter his behavior to conform to that of the employee. After the choice has been made, we find that consumers in the latter group experience lower levels of satisfaction (study 1) and higher decision regret (study 2) than those consumers who do not give in to the inferred pressure caused by the employee’s appearance.

These results suggest that even though consumers conform out of a desire to meet informational, normative and self-concept goals (Cialdini and Goldstein 2004), making decisions in opposition to their natural choice tendencies leads to substantial negative downstream consequences. The tension between consumers’ social interaction goals and their choice tendencies causes feelings of unrest. Therefore, consumers who disregard their own desires to make seemingly right choices based on employees’ inferred traits, goals and behaviors later realize that they have made the wrong choices, which results in them experiencing negative consequences. While our results show that employee appearance can prime participants to make choices that they would not normally make, the novel contribution of our research is in providing an understanding of how consumers feel about those choices once they have been made. These findings contribute to our understanding of employee-consumer interactions as well as to the growing literature on contextual priming and consumption.

EXTENDED ABSTRACTS

“An Induction-Deduction Model of Consumer Inference: Implications for Selecting Optimal CSR Strategy”

Haiyang Yáng, INSEAD, Singapore
Amitava Chattopadhyay, INSEAD, Singapore

People often act as “intuitive psychologists” in understanding the behaviors of others and use the observed behaviors to make inferences about general or abstract characteristics of the observed other (Heider 1958); these inferences are called inductions (Beike and Sherman 1994). Extant research has provided ample evidence that consumers frequently make inductive inferences based on firms’ behaviors and form generalizations about firms (cf. Kardes et al. 2004). Furthermore, recent research indicates that these inferences are often formed spontaneously, requiring limited cognitive resources and without attention or awareness (cf. Uleman et al. 2008). For example, when consumers are exposed to the information that a firm donated millions of dollars to protect wildlife, they may spontaneously induce that the firm is environmentally responsible.

In addition to inductive inferences, consumers also engage in the opposite type of inference—deducing and predicting specific firm behaviors based on the generalizations they hold about the firm (Beike and Sherman 1994). Unlike inductive inferences that are often generated spontaneously, deductions require more deliberative reasoning and are less likely to be formed spontaneously (Rotello and Heit 2009). For instance, deliberative reasoning is likely required to deduce from the generalization that the firm is environmentally responsible, to that the food products manufactured by the firm are of superior quality.

Research on knowledge representation suggests that concepts are organized as conceptual webs, in which concepts are represented by nodes and relations among the concepts are represented by the link structure of the network (e.g., Goldstone 1996). Building on this literature, we define distance between two concepts as a function of the number of nodes that need be traversed to link the two concepts and the strength of the relations between these nodes (see Rada et al. 1989 for a similar definition). For example, the conceptual distance between MONKEY and BANANA is shorter than that between DEER and BANANA, because the concept of MONKEY can be directly linked to BANANA via a “eat” relation, whereas it requires intermediate nodes to link DEER to BANANA. Moreover, given that people assess how plausible a focal scenario is, using the principle of concept coherence—how well the scenario corresponds with their conceptual knowledge (e.g., Connell and Keane 2004), conceptual events that are closely related tend to be considered more plausible than ones that are far apart. For example, people are likely to judge events associated with MONKEY affecting BANANA as more plausible than events associated with DEER affecting BANANA. Thus, we posit that although different CSR actions can lead to similar inductive generalizations (e.g., the firm cares about wildlife; it’s a good firm), actions that are perceived to be conceptually closer (e.g., protecting a species of monkey rather than deer) to the firm’s product (e.g., banana) have a stronger impact on the deductive inferences about the product (e.g., taste, quality).

To test this hypothesis, we designed several pairs of CSR actions; each pair was pretested to ensure that (1) the CSR actions

differ significantly in conceptual distance to a target product and (2) each CSR action leads to similar inductive generalizations about how likable and socially/environmentally responsible the firm is. Participants were shown the scenarios, each describing two firms pursuing either conceptually close or distant CSR actions, and were asked to decide which firm’s product is superior on certain attributes and which they would purchase. As expected, significantly more participants favored the firm whose action is conceptually closer to the target product; for example, over 73% participants believed that the manufacturer aiding victims of tsunamis (vs. earthquakes) produces safer boats, the firm using wind-turbine generated (vs. solar) energy to reduce CO₂ emission manufactures aerodynamically superior planes, and the firm protecting the natural habit of a species of monkey (vs. deer) produces more tasty bananas.

Cognitions vary in their temporal stability; whereas factual details are forgotten most rapidly, generalizations are the most stable cognitions over time (Chattopadhyay and Alba 1988). The differences in accessibility between the specific details of CSR actions and inductive generalizations formed based on the actions are likely to impact consumer inference (Kardes et al. 2004). In memory-based tasks, consumers tend to rely on the more memorable, higher-order cognitions—generalizations (e.g., the firm cares about the environment; it’s a good firm)—to make deductive inferences about the product. However, in stimulus-based tasks, consumer inference is influenced by not only the generalizations but also the specific details (conceptual distance). Thus, we predict that consumers can make significantly different deductive inferences about the product in stimulus- vs. memory-based tasks.

This hypothesis was tested in Experiment 2 using a 2 (conceptual distance: close vs. distant) x 2 (task type: stimulus- vs. memory-based) between-subject design. Participants were randomly assigned to evaluate one of two magazine ads about a consumer electronics firm’s CSR initiative. The ads were identical in all aspects except the descriptions about what the firm’s environmental action entailed—conceptually distant vs. close. Participants in the stimulus-based condition, were asked, with the ad present, to rate how much they liked the firm, the extent to which the firm is environmentally responsible, the extent to which the firm’s products are energy efficient, and how likely they would purchase this firm’s products. Those in the memory-based condition completed the same set of measures after a 24-hour delay. As expected, the generalizations, attitude, and perceived environmental friendliness, did not differ across the conditions. Nonetheless, a significant interaction effect was found for the inferences about the firm’s product; without delay, those in the conceptually-close condition reported significantly higher energy efficiency and purchase likelihood ratings than those in the distant condition; with a delay, however, no difference was found.

Overall, the results of the experiments provided support for the theoretical model we proposed. We found that the conceptual distance between a firm’s CSR action and its product can significantly impact consumers’ inferences about the product, and that this inference can differ significantly in stimulus- vs. memory-based tasks. We are currently running two more experiments examining the moderating role of cognitive resources; these studies will provide additional support for our model by showing that those with high need-for-

cognition (experiment 3) or more cognitive resources (experiment 4) are significantly more influenced by conceptual distance.

“Self and Social Signaling Explanations for Consumption of CSR-Products”

Aronte Bennett, Villanova University, USA

Amitav Chakravarti, New York University, USA

Consumers frequently encounter, and buy products that have a CSR association (e.g., cell phones giving a portion of proceeds to cancer research). It is well documented that products with a CSR-association are extremely popular among consumers and consumers may even be willing to pay a premium for these products. However, what are some key motivations that underlie a consumer's decision to purchase these products? In our research, we find that consumers like CSR-associated products for two distinct reasons.

First, we find that consumers like the fact that these products send out highly visible, social signals regarding their benevolence. We find that a consumer's likelihood of adopting a CSR-associated product varies positively with the product's social signaling potential, even when that signaling potential is very subtly cued. Specifically, in three studies we manipulated the social signaling potential of the target product by (a) varying the suggested location of the product, as either for use in a private (i.e., bedroom) or a public (i.e., living room) living space, (b) describing the target product as being especially helpful either for social (i.e., entertaining friends) or for personal (i.e., indulging oneself) occasions, or (c) varying, literally, the visibility of the CSR-association of the target product (i.e., whether the CSR-association's trademark LIVESTRONG™ yellow color was easily, partly, or not visible). Across these three studies, our results indicate that when the products did not have a CSR association they were evaluated equally regardless of their social signaling potentials. However, when the products had a CSR-association, the products were evaluated more favorably in the high social signaling potential conditions than in the low social signaling potential conditions. In fact, low social signaling potential actually lead to lower evaluations than the ones in the control (no CSR association) conditions, thus indicating that consumers tended to devalue a CSR-associated product when it had a poor social signaling potential.

Consistent with this reasoning, in a fourth study we find that owners of a CSR-associated product tend to use it in ways that maximize its social signaling potential. The study showed that consumers prefer to use a CSR-associated product in a highly socially visible location (e.g., living room) rather than in a less socially visible one (e.g., bed room), a preference that did not occur for the equivalent, control products that did not have a CSR-association. Ironically, however, these attempts to send out social signals of their benevolence appear to be wasted since in a fifth study we find that consumers are not sensitive to these social signals. In other words, observers appear to be blind to consumers' attempts to consume CSR-associated products that have high social visibility.

Finally, we also find that consumers like the more private, self-signaling potential associated with the purchase of these products, even when a strong social signal is absent. Perhaps reassuring from a normative perspective, the ability to send social signals mattered less to consumers when they were explicitly reminded about the high self-signaling potential of CSR-associated products. These studies, using disparate manipulations and dependent measures, provide convergent findings. In sum, we find that the valuation of a CSR-associated product is jointly determined by its social and self-signaling potential.

“Competing Through Corporate Social Initiatives: The Roles of Initiative Participation and Brand Trust”

Shuili Du, Simmons College, USA

C.B. Bhattacharya, ESMT, Germany

Sankar Sen, CUNY, USA

Defined broadly as “a commitment to improve [societal] well-being through discretionary business practices and contributions of corporate resources” (adapted from Kotler and Lee 2005), corporate social responsibility (CSR) occupies a prominent place on the global corporate agenda in today's socially conscious market environment. An increasing body of research has shown that there are multi-faceted business benefits companies can reap from engaging in CSR activities, such as more favorable product evaluation (Sen and Bhattacharya 2001), greater consumer loyalty and advocacy (Du, Bhattacharya and Sen 2007). According to a survey reported in McKinsey Quarterly (2009), companies are using CSR initiatives to build and strengthen their competitive position in the market. However, to the best of our knowledge, prior research on CSR has focused overwhelmingly on single brand contexts and therefore has excluded any potential effects of competition on the business returns to CSR.

Using the context of a challenger-leader competition, this research examines the efficacy of CSR initiatives as a challenger's competitive weapon against a market leader. We did a series of focus groups on participants and non-participants of a real-world corporate social initiative aimed at improving oral health among disadvantaged Hispanic communities. The initiative was undertaken by an oral care brand whose market share in the U.S. Hispanic segment was lagging behind its major competitor and hence was in a challenger position. Interviews with brand managers indicated that one of the business objectives in launching this social initiative was to gain market share in the Hispanic segment. The focus group study highlighted two factors that might affect consumers' reactions to the initiative, their participation (or not) in the challenger's initiative and their extant trust in the leader. More specifically, we find that consumers who had participated in the initiative described the challenger as more trustworthy (e.g., caring, trustworthy, angelical, and Latino-it is one of us) regardless of their trust in the leader. In contrast, the reactions of consumers who were merely aware of the initiative varied dramatically depending on their level of trust in the leader. Specifically, aware consumers who had high trust in the leader tended to question the sincerity of the challenger's CSR motives (e.g., “*they help the community to make a name for themselves and to gain popularity.*”), or argue that the leader provided similar benefits to the community. On the other hand, aware consumers who were not emotionally attached to the leader embraced the challenger's social initiative (e.g., “*this means they care about our welfare and want us to get ahead.*”) and displayed favorable reactions to the challenger's initiative similar to those of the participant consumers.

Based on the exploratory focus group study and prior research on relationship marketing, trust, and attributions, we developed a series of hypotheses which were then tested in a follow-up field survey in the same empirical context. Results from our survey provided support for our hypotheses regarding (1) the interactive effects of initiative participation (vs. awareness) and brand trust in the leader on consumer reactions to the challenger's initiative, (2) the mediating role of brand trust in cultivating consumer loyalty, and (3) the mediating role of CSR attributions in building brand trust.

Our research contributes to the literatures of CSR, trust, and competition. By looking at the real-world scenario involving a challenger brand trying to make inroads into the incumbent brand's turf, we are able to paint a more nuanced, realistic picture of the

business returns to CSR compared to previous CSR research. As well, in light of extant thinking that a late entrant's superior marketing mix is often ineffective in the face of an incumbent brand's advantage (Bowman and Gatignon 1996; Shankar, Carpenter, and Krishnamurthi 1998), our research shows, for the first time, the late entrant's ability to leverage its CSR to overcome the incumbent advantage among not only participant consumers but also non-participant consumers who are aware of the CSR and whose trust in the incumbent is relatively low. Also importantly, our research points to the pivotal role of consumers' affective trust in the dynamics of challenger-leader competition. While the unique advantage of CSR in helping a challenger compete stems from the ability of such actions to engender trust amongst its desired consumers in a relatively short period of time, turning them into not just customers but champions, consumers' trust in the market leader represents the essential competitive barrier the challenger must overcome in order to win them over.

"Can Corporate Social Responsibility Hurt New Brands?"

Stefanie Rosen, University of South Carolina, USA

Stacy Wood, University of South Carolina, USA

Corporate social responsibility (CSR) can be used as an effective marketing technique and in 2007 companies spent \$4.4 billion on CSR (Lawrence and Mukai 2008). While many brands, new and established, engage in CSR activities, new brands are increasingly positioned as socially responsible options. For instance, a new brand on the market, Method, is positioned as an environmentally-friendly line of household cleaners. CSR, defined as a "company's status and activities with respect to its perceived societal obligations" (Brown and Dacin 1997, 68), can increase customer satisfaction with the company (Marin and Ruiz 2007) and enhance brand evaluations (Brown and Dacin 1997). However, recent research suggests that consumers perceive more ethical brands to be less effective (Luchs et al. 2008). Here, we investigate this "moral discount" and find that activities can potentially hurt new brands and that the type of "ethical element" (what we refer to as the CSR attribute) strongly influences this effect.

Attributes of a product can either be centrally tied to the product's use, i.e., intrinsic attributes, or peripherally related to the product, i.e., extrinsic attributes (Richardson, Dick, and Jain 1994). Consumers use both extrinsic and intrinsic attributes when making evaluations of a brand (Jacoby, Olson, and Haddock 1973). In regards to a CSR attribute, an example of an intrinsic attribute is earth-friendly ingredients and an example of an extrinsic CSR attribute is when the company donates money to a charity.

When a brand engages in a CSR campaign, the CSR attribute becomes an important piece of accessible information for consumers to use when evaluating a new brand. According to the accessibility-diagnosticity model, accessible information will be used as input into judgment if the information is perceived to be more diagnostic than other accessible inputs (Feldman and Lynch 1988). When accessible and diagnostic, consumers use memory-based information (Menon, Raghuram, and Schwarz 1995); however, this is only possible for established/familiar brands. Context-based information, information given during the time of the decision, is used when memory-based information is not accessible. With a new/unfamiliar brand, consumers cannot rely on previous associations of the brand and therefore, the context-based information of the CSR attribute becomes diagnostic. We predict that when context-based information is related to a typical extrinsic CSR attribute, e.g., donating money to a charity, consumers will fall prey to Luchs et al. (2008) 'ethical equals less effective' lay theory. Thus, we hypothesize that

compared to a non-CSR attribute, an extrinsic CSR attribute will decrease perceived brand effectiveness for an unfamiliar/new brand.

Since the physical makeup of a product does not change with an extrinsic CSR attribute, this type of attribute is generally easy to implement. However, many new brands are also focused around intrinsic CSR attributes (e.g., Method Cleaner). Thus, do consumers' perceptions of a new brand change when the CSR attribute is intrinsic versus extrinsic? We hypothesize that an intrinsic CSR attribute actually helps a new brand because the attribute becomes part of the contextual cues used to define the product. However, extrinsic CSR attributes do not provide the same depth of contextual information and therefore are not strong indicators of the product.

In study 1, we test our hypotheses and include a familiar/established brand as our control condition. The study was conducted among undergraduate students. Participants saw a picture of an acne medicine in one of six conditions in a 2 (brand: familiar vs. new) X 3 (attribute: extrinsic CSR attribute, intrinsic CSR attribute, no CSR attribute) between-subjects design. The first factor manipulated the brand of acne medicine (familiar brand, i.e., Clearasil, versus a new brand, i.e., Dermisa). The second factor manipulated the product's attribute (extrinsic CSR attribute, intrinsic CSR attribute, no CSR attribute). In the extrinsic CSR condition, the slogan stated "20% of All Profits Donated to Environmental Charities." In the intrinsic CSR attribute condition, the slogan stated "Made with All-Organic Ingredients." In the no CSR attribute condition, no CSR information was provided. Participants then responded to questions regarding the expected efficacy of the product. We conducted a 2 X 3 ANOVA with perceived effectiveness as the dependent variable. The results support our predictions; there is a significant Attribute X Brand interaction ($F(1, 136) = 3.13, p < .05$). Follow-up analyses in the new brand condition show the product that donates profits to charities is perceived to be significantly less effective than the product made with all-organic ingredients ($F(1, 44) = 8.74, p < .01$) and the product with no CSR information ($F(1, 38) = 4.61, p < .05$). However, for the familiar (control) conditions, there are no differences among the products, regardless of the attribute type (all p 's $> .14$).

To examine our results across different segments of the population, study 2 was conducted among adults ($M_{age} = 40$). Participants saw a household cleaner in one of six conditions in a 2 (brand: familiar vs. new) X 3 (attribute: extrinsic CSR attribute, intrinsic CSR attribute, no CSR attribute) between-subjects design. The first factor manipulated the brand of the cleaner (familiar brand, i.e., Lysol, versus a new brand, i.e., Dettol) and the second factor manipulated the product's attribute. As in study 1, the extrinsic CSR condition referred to making a donation, the intrinsic CSR condition referred to being made with all-organic ingredients, and the non-CSR condition did not contain any CSR information. Participants were then asked questions regarding the expected efficacy of the cleaner. We conducted a 2 X 3 ANOVA with perceived effectiveness as the dependent variable. There is a significant Attribute X Brand interaction ($F(1, 88) = 3.21, p < .05$). For the new brand, the product that donates profits to charities is perceived to be significantly less effective than the product made with all-organic ingredients ($F(1, 28) = 10.87, p < .01$) and the product with no CSR information ($F(1, 29) = 7.89, p < .01$).

We conducted two more studies as product category replications, using candy bars and laundry detergent, respectively. The results of these two studies support the findings described above. Overall, this research demonstrates that, in promoting new socially responsible brands, managers should consider the type of CSR activity in which they engage.

“Effects of the Consumer Review Process on Attitude Formation and Communication”

Stephen He, Georgia Institute of Technology, USA

Samuel Bond, Georgia Institute of Technology, USA

The past decade has observed a dramatic increase in the use of consumer-generated content (CGC). Modern consumers are involved in creating, sharing, and reading content, and these behaviors have received increased attention from marketing practitioners and scholars. In particular, there has been a growing interest in the effects of product reviews on consumers' purchase behavior (Chevalier and Mayzlin 2006; Weiss, Lurie, and MacInnis 2008). However, very little research has focused on the effects of review writing on the writers themselves (c.f. Moore et al 2009). In order to address this need, the current paper considers a number of questions related to review writing and attitudes; in particular, we explore how the format of the review task affects the process of review writing and readers' comprehension of the review.

We start by assuming that a consumer has recently engaged in a consumption experience and holds some attitude toward the experience, however weakly formed. We consider two different scenarios, in which consumers write a text review either before or after reporting their attitude regarding the consumption experience. Our central argument is that these two scenarios generate fundamentally different motivations, which in turn dictate the reviewing process and downstream consequences. When the review task precedes any rating, reviewers are motivated to address the different views of unknown readers. This motivation leads to a more open-ended, unstructured review task that allows the reviewer to elaborate extensively on different aspects of the experience and his or her reactions towards them (Tetlock, 1989; Schlosser, 2005). Such an 'explorative unfolding' of information allows the consumer to bring to mind a wide variety of attitude-relevant information, resulting in attitude change.

A stark contrast exists when the reviewing task follows evaluation. In this case, reviewers who have already reported their attitude will feel committed to their rating and utilize their review to engage in "defensive bolstering" (Tetlock, 1989). However, individuals are generally poor at recognizing the reasons underlying their preferences (Nisbett and Wilson 1977), and this inability should lead reviewers to encounter difficulty generating sufficient support for their stated evaluations. In keeping with the principle of metacognitive inference (Schwarz, 2004), we suggest that this perceived difficulty may result in attitude moderation. Moreover, due to their one-sided, purposeful nature, text reviews written after a rating may not be very effective at conveying the authors' attitude to readers.

In a series of lab experiments, we examined hypotheses related to the two different cases above. A pretest utilizing various short animated movie clips revealed consistent attitude differences between participants who wrote a text review of a clip and participants who simply evaluated the movie. These pretest results provided initial evidence that the mere act of writing a text review changes reviewers' attitudes.

Study 1 explored the effect of task order on attitude change and actual review content. In the experiment, undergraduate participants (N=67) watched the target stimulus, a short animated movie clip, and

were then given different instructions according to condition. Two factors were manipulated: task order and type of writing. Regarding the first factor, *write-then-rate* conditions completed the writing task and then rated the movie, while *rate-then-write* conditions completed the steps in the opposite order. Regarding the second factor, all participants were asked to generate either a *text review* of the movie or a *filler* (summarizing events of the preceding day). In a follow-up session occurring three weeks later, participants were reminded of the movie clip and asked to recall their evaluation.

Replicating our findings, analyses revealed that at t1, the mean attitude towards the movie was considerably lower for the *review-then-rate* condition than the other three conditions (which did not differ). At t2, this attitude remained basically unchanged. For the *rate-then-review* condition, not only was t2 attitude significantly lower than that of the control groups, but the absolute difference in attitudes between t1 and t2 was significant as well. These findings support our argument that even after initial assessment, attitude was moderated by the process of writing a text review.

In order to examine review content itself, we applied the Linguistic Inquiry and Word Count tool (Pennebaker and Francis ME 2001) to analyze reviews written by the two *text review* conditions. Among other findings, analyses revealed that the *review-first* group wrote significantly more words than the *rate-first* group, indicating more elaboration of the movie experience. In addition, the ratio of positive-to-negative word use was closer to one for the *review-first* group than the *rate-first* group, indicating that the writing of the former was more balanced. Finally, the *review-first* group made greater use of articles, suggesting a more objective writing style.

Study 2 examined how differences in review content influence readers' ability to infer the attitude of the reviewer. Among the reviews written by participants in Study 1, six each were selected from the *review-first* group and the *rate-first* group. Participants (N=68) were asked to read the reviews, estimate what ratings the authors assigned the movie clip, and report their confidence in these estimates.

Rating discrepancies were calculated by taking the absolute difference between a reader's estimated rating and the author's actual rating from Study 1. In support of our prediction, analyses indicated that rating discrepancies were lower for reviews written by the *review-first* group than for the *rate-first* group. Notably, participants were actually more confident in their estimates after reading reviews from the *rate-first* group, despite also being more inaccurate. Given the text analysis results reported above, it is likely that these balanced reviews of the *review-first* group seemed more ambiguous to the readers but actually conveyed the writers' opinion more effectively.

Overall, our results provide initial evidence that reviews written before vs. after global evaluation affect reviewers' attitudes in systematic ways, differ in terms of structure and content, and create different interpretations among downstream readers. These findings bear important implications for those researching the review-writing process, and also for marketing practitioners interested in utilizing consumer-created content.

“The Ratings Paradox: Why We Prefer Reading Negative Reviews, But Then Subsequently Rate These Reviews as Less Useful”

*Kurt Carlson, Georgetown University, USA
Abhijit Guha, Wayne State University, USA*

User reviews, on sites like REI and Amazon, have emerged as an important part of the consumer buying process. In fact, in a recent survey of undergraduate students, 78% of respondents reported that they read one or more user reviews before making an online product purchase. This percentage exceeded all other behaviors, which included talking to friends to get advice (58.5%), reading one or more expert reviews (35.4%), and visiting the store to see the product (20.7%).

User reviews typically include a rating (on a 1-5 scale), coupled with an explanation of the rating (the review) and a report on how useful the review was for previous readers of the review. The usefulness data is generated from those who answer yes or no to the question, “Was this review useful?” Prospective consumers can sort the reviews by valence (e.g., one-star vs. five-star) and by usefulness score (the average usefulness of the review, as reported by those who have previously read the review and answered the usefulness question).

If there is a relatively stable relationship between the number of people who read each review and the number who answer the usefulness question, then the total number of responses to the usefulness question can be used to assess which reviews are read more often. Those reviews with the greatest number of people who answered the usefulness question are those that were most read. When examining the useful ratings, we find the following pattern. Negative (one-star) user reviews are read more often than positive (five-star) reviews, but positive reviews are rated as more useful than negative reviews. We dub this the ratings paradox.

We propose that the ratings paradox can be explained as follows. Consumers who read online product reviews generally have a weak preference for one of the products. Empirical evidence supports this claim. In particular, respondents in a recent survey we conducted reported that (on average) 69.5% of the time that they read user reviews they had a preferred product in mind while reading the reviews. We propose that this preference drives consumers to seek negative reviews about the currently preferred product. It also causes consumers to bias their evaluations of negative reviews, making them subjectively neutral. Having distorted away their diagnosticity, negative reviews are rated as less useful than positive reviews.

We rely on a series of lab studies to test our theory. In the first study, participants (N=53) engage in a choice process involving two hotels. After reading some information about the hotels, participants are asked to report which hotel is leading the choice (i.e. which option they currently prefer). After reporting their leader, participants selected one user review they would like to read about the hotels. The reviews consisted of positive and negative user reviews for each hotel. Results reveal that participants exhibited a strong tendency to seek out the negative review about their weakly preferred hotel. Specifically, 70% participants wanted to read the negative review about their preferred hotel (significantly greater than chance, binomial $z=7.30$, $p<0.001$). Thus, consumers who have a weak preference sought negative reviews about their preferred product, a result that fits with our observation that negative user reviews are read more often than positive user reviews.

We next investigated why consumers rate negative reviews as less useful than positive reviews. We know that consumers who have a weak preference tend to bias the information they encounter to support this preferred option (Carlson 2006; Russo et al 1998). If consumers bias user reviews in this manner, then negative reviews

would be converted into less negative or possibly even neutral reviews. If subjectively seen as “near-neutral” by consumers, negative reviews would rightly be rated as less useful than positive reviews simply because they would be less subjectively diagnostic.

To examine this idea, we conducted two laboratory experiments using undergraduate participants from a US university. In the first experiment (N=60), participants examined one-star reviews and five-star reviews about some products (cameras, TVs, tents etc.) drawn from Amazon and REI. Online, only 18.9% rated the one-star reviews as useful, whereas 87.5% rated the five-star ratings as useful. Laboratory participants, who were not expected to have a preference for either product because they were not shown any information for the products rated the usefulness of the reviews exactly opposite. That is, 86.7% rated the one-star reviews as useful, whereas only 35.0% rated the five-star reviews as useful. These proportions were significantly different from each other ($z>2.5$, $p<0.05$).

We next conducted a laboratory experiment (N=44) to examine whether negative user reviews would be distorted to be subjectively perceived as near neutral. Half of the participants (N=21) were shown the hotel stimuli (described earlier) and were allowed to form a preference for one of the two hotels. Participants were then asked to choose between reading negative information about the preferred hotel or negative information about the other hotel. Consistent with Carlson and Guha (2009), 18 out of 21 chose to read negative information about the preferred hotel (significantly greater than chance, binomial $z=2.17$, $p<0.05$). Participants were then given the negative information they requested. The 18 participants who read the negative information about their preferred hotel rated this information as 4.55 (i.e., near-neutral) on a 1-9 scale, (where 1 indicated negative information and 9 indicated positive information). In contrast, a separate sample of 23 participants, who examined the negative information without first forming a hotel preference rated the negative information as 2.52 (i.e. closer to the negative end) on the same 1-9 scale (2.52 is less than 4.55; $F(1, 40)=9.2$, $p<0.05$), evidencing distortion of negative information. In comparison, the two mean evaluations reveal a strong tendency for those with a preference to convert negative information into near neutral information.

In sum, we find consumers seek negative information about a preferred product and then bias that information making it seem less useful. This pattern of lab results is consistent with our finding that negative user reviews are read more often but rated as less useful, a finding we have dubbed the “ratings paradox.”

“What Determines Customers’ Evaluation of Online Reviews? The Role of Review and Product Characteristics”

*Simon Quaschnig, Ghent University, Belgium
Mario Pandelaere, Ghent University, Belgium
Iris Vermeir, Ghent University, Belgium*

During the last years there has been a huge increase in available choice options for customers (Schwartz et al. 2002), a phenomenon called hyperchoice (Mick, Broniarczyk, and Haidt 2004). But confrontation with extensive options makes decision making more difficult (Schwartz et al. 2002), partly because customers feel more responsible for their choices (Mick et al. 2004). As a result consumers will experience more uncertainty (Anderson 2003). Being confronted with an extensive assortment size may be especially likely in an online context. In addition, products online are intangible which is an additional source of uncertainty (Eggert 2006). According to the uncertainty reduction theory (Berger, and Calabrese 1975), customers will engage in uncertainty reduction efforts to alleviate and eliminate risk caused by uncertainty and to maximize outcome value. Online customer reviews have become

an important source of information and can play a prominent role in this process (Chevalier, and Mayzlin 2006). While previous research has mainly focused on the link between customer reviews and product sales (Chevalier, and Mayzlin 2006; Hu, Liu, and Zhang 2008), this study explores the use of customer reviews in a pre-decision context.

Confronted with an extensive number of alternatives, customers have to make a selection of considered products beforehand for which they subsequently engage in an online search. In an attempt to make an adequate decision, they may consult customer reviews. In the present study we investigate factors that influence customers' evaluation of the helpfulness of reviews. We focus on Amazon.com ratings of helpfulness of reviews. These ratings result from a two-step process. First, customers have to decide whether or not they will rate the helpfulness of a particular review. Second, if they decide to provide a rating, they will have to decide on a positive or negative rating. The current paper investigates whether and how these two decisions are affected by product and review characteristics, like whether the review was positive or negative, the number of words, the position of the review, whether the review is written by credible reviewer, the sales rank of a product, and the type of product.

Our data consists of both product features and customer review characteristics for 260 different products, of which 116 were books and 144 CD's, taken from the public website of Amazon.com. We collected information on the price, the position on the Amazon bestseller list (sales rank) and the number of reviews written for the product. We included products with different sales ranks, with groups ranked from 1 to 25, 101 to 125, 501 to 525, 1001 to 1025, 5001 to 5025 and 10001 to 10025. For each product we took a maximum of 20 reviews into our sample, which resulted in a total of 4229 reviews, of which 1664 (39,3%) were book reviews and 2565 were CD reviews (60,7%). For 40 products there were no reviews, so we did not include them in our analysis. For each review, we counted the number of words in the review, the position the review had on the website, whether it was a top 100-reviewer (i.e. credible reviewer), the score (ranging from 1 to 5) given by the reviewer to the product and also the number of customers that voted on the helpfulness and the percentage of voting customers that found it helpful. To explore which characteristics influence revealed customer appreciation we used multilevel regression analysis.

The present findings suggest that whether the review is positive or negative, its length and position, the reviewer credibility, the sales rank and the type of the product are important predictors for the review to get a helpfulness response by the reader. Whether this response is positive and thus indicating that the reader values this review or not depends on the sales rank (depending on the type of product), number of words and score given by the reviewer.

Customers are responding more to negative reviews, which presumably render them more uncertain about their inclinations to purchase, than to (moderately) positive reviews. At the same time, however, positive reviews are rated as more helpful than negative ones. While the former can be due to the fact that customers react more extensively to inconsistency, the latter can be explained by peoples' tendency to systematically prefer information that is consistent rather than inconsistent with their own standpoint (Festinger 1957). A quadratic relationship with review length shows that moderately long reviews are considered more helpful than short or long reviews. This represents a trade-off between a balanced message with different arguments and too much information. Regarding the position of a review, book reviews further down the website, which happen to be the older reviews, attract more responses. Reviews posted long after the product release will get less attention. For CD reviews, this position effect was not obtained. Consumers tend to

selectively pay more attention to reviews from top 100-reviewers, but no effect was found on the valence of the vote (helpful or not). Obviously, reviews for bestselling products attract more votes than reviews for products with low sales. However, reviews for products further down the sales ranking are perceived as more helpful. Indeed, they may be more unknown products, for which extra information can be more helpful. This relationship cannot be found for CD's. Finally, book reviews attract more votes regarding their helpfulness than CD reviews. Possibly, customers rely more on the opinions of others for books than for CDs. The latter are more subject to personal taste.

To conclude, our results show a significant effect of several product and review characteristics on the evaluation of online reviews. For future research it might be interesting to examine the influence of experts on the evaluation of negative reviews. Also an evaluation of the review content, such as objectivity, and its connection to the valuation of the review by the customer would be interesting. Finally, since we believe that the degree of uncertainty is essential to explain potential buyers' assessment of reviews, a further step would be to test this by manipulating the degree of uncertainty.

“Anonymous and Unanimous: The Impact of Anonymity on Opinion Generalization”

Dilney Goncalves, INSEAD, France

Amitava Chattopadhyay, INSEAD, Singapore

People care about the opinion of others. In particular, the opinion of the majority is often regarded as representing the truth (e.g., Asch, 1951; Festinger, 1954). When consumers search information online, consumers may think that a given review presents a very general opinion about a product or she may think that the reviewer is an outlier and the opinion is very idiosyncratic. Since reviewers are self-selected, the distribution of reviews does not necessarily represent the distribution of opinions in the larger population (Xinxin & Hitt 2008). Thus, before making inferences about product quality, consumers are likely to make inferences about how general the opinion expressed in the review is. Weaver et al. (2007) have shown that people might use metacognitive experiences as information when judging the popularity of an opinion. They showed that more familiar opinions were considered more widespread than less-familiar opinions, even when familiarity was increased by incidental factors—like the number of times the same person expressed an opinion.

A fundamental difference between online word-of-mouth (e.g.: reviews) and traditional word-of-mouth lies in the fact that consumers receive opinions of strangers. More than unknown to the consumer, reviewers can be completely anonymous. We propose that anonymity can influence how general an opinion feels to the reader. In particular, we hypothesize that anonymous reviews will be judged more general than signed reviews.

We assume that people have experience with a variety of opinions, ranging from very idiosyncratic to very general ones. We further assume that opinions and people are linked in memory in a spreading activation network (Anderson, 1983). Thus, people have learned from experience that when an idiosyncratic opinion is activated in memory, activation spreads to the person linked to the opinion and it feels easy to associate person and opinion. Conversely, when a general opinion is activated, because it is connected to many more people, no particular person is easily associated with the opinion. As a result, it feels difficult to associate an opinion to any particular person when the opinion is widespread. We propose that people make the inverse inference: if it feels easy to associate a person to an opinion, then the opinion is probably idiosyncratic. Conversely, if it is difficult to associate a person to an opinion,

then people judge the opinion to be more general. Although this is usually true, factors unrelated to the generality of an opinion can make it easier or more difficult to think of a person. One such factor is the presence of a name accompanying a review. Next, we describe three studies conducted in this research.

In study 1, we asked participants recruited online ($N=251$) to read and evaluate a consumer's opinion about a restaurant. After reading the opinion—which was negative—, participants were asked to estimate the percentage of the restaurant's customers who were dissatisfied. About half the participants saw an anonymous opinion. The other participants saw a signed opinion, which was exactly the same as the anonymous with the addition of a customer's name in the last line of text. In all studies, two names were used. Since there were no differences between the two name conditions and they were aggregated in all studies. The estimates of opinion generality supported our hypothesis: participants reading an anonymous complaint estimated that 53% of the restaurant's customers were dissatisfied while those reading a signed complaint estimated that 43% of customers were dissatisfied ($p<.05$).

To further test our process explanation and to examine whether knowledge about the population would eliminate it, we ran a second study. In this study, participants ($N=338$) read a restaurant review. Prior to reading it, though, participants were informed of the restaurant's average rating (high or low). The reviews were either positive or negative. Finally, reviews were either anonymous or signed—all factors manipulated between-subjects. After reading the review, participants were asked to estimate what percentage of consumers were as satisfied (dissatisfied) as the reviewer and to explain how they reached that estimate. A significant average rating \times review valence showed that participants used the mean information and estimated greater agreement when the review was in line with the average ($p<.001$). More importantly to our hypothesis, a significant main effect of anonymity showed that its effect still persisted even when people had knowledge of the restaurant's average evaluation. Participants were more likely to make attributions to the reviewer when the review was signed (23.5%) than when the review was anonymous (11.5%; $\chi^2=8.26$; $p<.05$). Finally, a mediation test showed that attributions to the reviewer mediated the effect of anonymity on estimates of opinion generality.

In the third study, we examine the effect of reviewer anonymity on choice. Participants ($N=183$) were recruited online to participate in the study. They were randomly assigned to an anonymous- or signed-review condition. Participants read a scenario in which they had to buy a birthday present in a hurry. They were shown a gift-basket and a positive description of it. This was intended to generate a positive first impression of the gift-basket. Then, participants read a negative review which was either signed or anonymous. Participants decided whether or not they would buy the gift-basket and estimated the percentage of people who were dissatisfied with the gift-basket. After reading the negative review, participants were more likely to buy the gift-basket in the signed condition (18.2%) than in the anonymous condition (4.7%). This effect was mediated by estimates of opinion generality.

Our results provide evidence that anonymous opinions are considered more general than signed opinions. This is because it feels easier to associate an opinion to a particular person when the opinion is signed than when it is anonymous. As a result, people are also more likely to comply with anonymous reviews. Besides demonstrating a novel effect of anonymity in online reviews, this research contributes to and extends the literature on social influence and metacognitive experiences (e.g.: Schwarz, 2004; Weaver et al., 2007) and has direct implications for the design of websites.

SPECIAL SESSION

A Broad View of the Notion of Sensory Interaction

Aradhna Krishna, University of Michigan, USA

Joann Peck, University of Wisconsin-Madison, USA

SESSION OVERVIEW

While much research in the area of sensory perception has been done in the areas of cognitive psychology and neuroscience, research on sensory marketing is relatively new with the first academic conference on the subject being organized in 2008. While the field is growing, most of the research in marketing thus far focuses on a single sense – both the antecedents and consequences of sensory perception. However, one sensory input may affect perception of another – for instance, smell may affect haptic perception as one of the papers show. Also, a second temporally distinct sensory input, even belonging to the same sense, may impact perception (and even memory) of the first by creating interference in perception and recall. This session explores the concept of sensory interaction with the four papers synergistically providing a good overview of the kinds of sensory interactions that may exist. The first three papers explore sensory interaction by a second input of the same sense where the interaction is more in the form of interference – the interference is at different times in the first paper, and at the same time in the second and third papers. The fourth paper (and also the third) consider interference by a second sense.

More specifically, the first paper examines the notion of *retroactive interference*, i.e., sensory interference by a second stimuli after exposure to the primary stimuli – if one is first exposed to brand A with smell X and later exposed to brand A with smell Y (or brand B with smell X), what impact does it have on memory for brand A with smell X? The second paper examines the effect of *simultaneous (in time) interference* with a second input of the same sense that is incongruent with the first (subjects imagine one haptic object but actually feel another one that is haptically incongruent with the first). The third paper considers congruence of sensory inputs both from within and across senses. Specifically, it shows that an incongruent size change in one dimension (for example, if one physical dimension of a package is increasing when the two other dimensions are decreasing) as well as incongruence between vision and touch influence consumers' perception of volume change. The fourth paper also considers congruence of sensory inputs, in this case between two different senses, smell and haptics – it focuses on how a semantically congruent versus incongruent smell affect haptic perception (does a rough paper appear rougher when it has a masculine smell?).

Together, the papers provide a big picture overview of sensory interaction with a hope of growing the field in a broad new direction that has many possibilities for future research.

EXTENDED ABSTRACTS

Is Olfactory Memory Unique?

Mimi Morrin, Rutgers University, USA

May Lwin, Nanyang Technological University, Singapore

Aradhna Krishna, University of Michigan, USA

The sense of smell is of critical importance to humans, although it is often the most underrated of all the five senses (Martin, Apena, Chaudry, Mulligan and Nixon 2001). Perhaps not surprisingly, the sense of smell has received less attention from consumer researchers than have the visual and auditory sensory modalities. Yet interest in scent and its effects on consumer behavior is on the rise (e.g., Bone and Jantrania 1992; Bosmans 2006; Mitchell, Kahn and

Knasko 1995; Spangenberg, Crowley and Henderson, 1996). To date, consumer researchers have focused primarily on the conditions under which pleasant scents enhance product, store, and advertising evaluations as well as lingering and variety-seeking behaviors.

Considerably less consumer research has looked at the effects of scent on memory. The few studies that have been conducted provide some initial evidence to suggest that scent enhances recognition and recall of brand information (Morrin and Ratneshwar 2003), and that this information decays only minimally over time (e.g., Krishna, Lwin and Morrin, forthcoming). However, the precise nature of scent's ability to enhance memory is not well understood. Relevant research from the field of experimental cognitive psychology is limited in this respect as well. Indeed, a debate exists regarding whether or not olfactory memory possesses a special capacity to inhibit the forgetting process (Zucco 2003). Some researchers have suggested that olfactory memory possesses unique characteristics that render it distinct from memory based on information acquired from the other senses – specifically, that it is resistant to retroactive interference (Danthiir, Roberts, Pallier and Stankov 2001, Engen 1987). Others disagree (Koster, Degel and Piper 2002, Olsen, Lundgren, Soares and Johansson 2009, Walk and Johns 1984).

We contribute to the debate by exploring the effect of scent on consumer memory over time in a competitive market context. One hundred and twenty-nine undergraduates participated in the study which involved evaluating one or more brands of moisturizer. The study consisted of six different conditions: four interference groups and two non-interference groups. All participants were exposed to a hypothetical brand of moisturizer in the form of an advertisement and product sample at time 1. Two weeks later (at time 2), those in the interference groups were exposed to another moisturizer product (containing either the different brand name, a different scent, or both a different brand and different scent); those in the non-interference groups were exposed to nothing at this time. Two weeks later (at time 3), all participants' memories were tested.

In terms of unaided attribute recall for the first brand encountered, we find that, in the absence of competition, a scented moisturizer's attributes are much better recalled than are those of an unscented moisturizer (23% versus 12%, $p < .01$). This result demonstrates the basic memory-enhancing effects of product scenting. In all three of the scented interference conditions, participants' ability to recall the first brand's attributes was significantly lower than in the no-interference scented condition (all p 's $< .05$). This result provides clear evidence of retroactive interference effects. The specific nature of the scented interfering material did not matter -- thus the second or interfering brand could have the same or a different name, and the same or a different scent. From these results we conclude that product scenting provides no special immunity to retroactive interference.

We also conducted an ANOVA on incremental aided attribute recall (i.e., additional items recalled when provided with a scent-based retrieval cue). Mean comparisons show that when participants were provided with a scented retrieval cue, they recalled a larger proportion of brand attributes (11%) if the brand had been scented and there was no interference, compared to all other conditions (0% to 7%, p 's $< .05$). This result is another demonstration of the overall memory enhancing effects of product scenting. Interestingly, providing the scented retrieval cue produced more incremental recall in

the three scented interference conditions than in the two unscented conditions (all p 's < .05). This result demonstrates that, if provided with an adequate retrieval cue, in this case, the product's scent, much of the information that was retroactively interfered with can nevertheless later again be retrieved – suggesting that such information is available, if not always accessible, in long-term memory.

The pattern of results suggest that scent is indeed an effective memory enhancer, but it appears to be so not because scent-associated information is immune to later exposure to similar information – that is, not due to some special immunity from retroactive interference effects. Rather, it appears to be a function of enhanced olfactory encoding. These enhanced encoding effects were evident in two ways: a) in the fact that unaided recall was nearly double for scented versus unscented products (in the absence of competitive interference), and b) that incremental recall was generated by exposure to a scented retrieval cue even after exposure to the interfering material. Thus, olfactory memory processing can be considered unique or distinct from that based on the other sensory modalities not because the forgetting process is different, but because the encoding process is different. The difference in encoding may be due to a hippocampal resources advantages (Wixted 2004) or to the fact that olfactory information is coded more perceptually than is information from the other sensory modalities (Engen 1987).

That's Not What I Feel:

The Effect of Haptic Imagery and Haptic Interference on Psychological Ownership and Object Valuation

Joann Peck, University of Wisconsin-Madison, USA

Victor Barger, University of Wisconsin-Madison, USA

Andrea Webb, University of Wisconsin-Madison, USA

Previous research has shown that consumers value objects more highly if they own them, a finding commonly known as the endowment effect (Thaler, 1980). This effect is not limited to legal ownership; psychological ownership, characterized by the feeling that something “is mine,” also produces the endowment effect. One antecedent of psychological ownership is the ability of an individual to control an object by touching it. Peck and Shu (2009) show that when individuals are given the opportunity to touch an object (versus not), they report a greater sense of psychological ownership and value the object more highly.

If touch is not available, could the act of visualizing touch act as a surrogate? According to MacInnis and Price (1987), imaging is a resource demanding process in which sensory information is represented in working memory. Bone and Ellen (1992) conjecture that imagery “may involve sight, taste, smell and tactile sensations” (p. 93). Although research on imagery and the tactile system is limited (Klatasky, Lederman & Matula, 1993), there is some evidence for the interdependence of touch and visual imagery (Katz, 1925).

Since imaging requires cognitive resources and the effects of imagery are mediated by resource availability (Bone & Ellen, 1992; Unnava, Agarwal & Haugtvedt, 1996), blocking out perceptual distractions during imaging may enhance its effects. Unnava et al. (1996) found that when imagery and perception compete for the same resources, the positive effects of imaging are reduced. Similarly, Petrova and Cialdini (2005) found that difficulty in imagery generation can reverse the positive effects of imagery appeals. In some instances, consumer behavior researchers have instructed participants to close their eyes when imaging (e.g., Bone & Ellen, 1992; Keller & McGill, 1994 (Experiment 1); Petrova & Cialdini, 2005 (Study 3)), although this was not the focus of these studies. We hypothesize that closing one's eyes while imaging touching an object leads to greater psychological ownership and valuation than imaging touching an object when one's eyes are open.

An experimental study was designed to examine the effect of touch imagery on both psychological ownership and valuation. The design was a 4 (imagery/touch: imagery eyes closed, imagery eyes open, no touch no imagery, touch with no imagery) x 2 (product: Koosh ball, blanket), with the first factor manipulated between subjects, and the second factor varied within subjects. Three hundred and twenty-six individuals participated in the study.

Our first hypothesis predicted that when participants imaged touching the product with their eyes closed, both psychological ownership and valuation would be greater than when participants imaged with their eyes open. We found a main effect of touch/imagery for both psychological and valuation. For psychological ownership, both the touch condition and the touch imagery with eyes closed condition resulted in a significantly stronger sense of ownership than the touch imagery with eyes open condition and the no touch-no imagery condition. Interestingly, there was no significant difference in either psychological ownership or valuation between the touch imagery with eyes closed condition and the condition where actual touch was possible. For valuation as the dependent measure, the results were similar.

We next conducted a second study in order to examine the process in more detail. We hypothesized that when a person closes their eyes to imagine, they are focusing their cognitive resources which results in similar effects to actual touch. In the second study, we had participants imaging touching a product (as in Study 1) but we manipulated whether haptic interference was present and also whether the interference “fit” with the imagined object. The design of this study was a 2 (vision: eyes open, eyes closed) x 3 (haptic stimulus: none, congruent, incongruent) with both factors manipulated between subjects. Three hundred and eighty seven individuals participated and we were able to replicate our first hypothesis. We also found that when a person imagines with their eyes closed, the presence or absence of a haptic stimuli does not significantly impact haptic imaging unless the stimulus is incongruent with the product being imagined.

A final study currently being conducted delves deeper into both the process and the individual difference in Need for Touch (Peck and Childers 2003). While high NFT individuals are more influenced by positive sensory information, low NFT are more affected by negative haptic sensory information (Childers and Peck). In the current study, we examine positive and negative sensory interference by high and low NFT individuals.

How do Consumers Estimate Product Downsizing and How Can they be Helped?

Nailya Ordabayeva, Erasmus University

Pierre Chandon, INSEAD

The supersizing of food portions and packages has been identified as one of the prime drivers of the obesity epidemic (Nielsen and Popkin 2003). Supersizing leads to overeating partly because consumers underestimate just how large supersized portions and packages are (Chandon and Wansink 2007; Krider, Raghuram, and Krishna 2001). Some food companies have started to offer downsized options on their menus (e.g., Ruby Tuesday, TGI Friday's “Right Portion Right Price” menu) but these initiatives have not been very successful because consumers are averse to portion downsizing. To help consumers better monitor their consumption and to help them choose smaller food portions, it is important to understand how consumers perceive package downsizing and to compare the effectiveness of informational, visual, and haptic de-biasing strategies.

Research in psychophysics has shown that estimations of object size follow an inelastic power function of actual object size (estimated size = $a \times \text{actual size}^b$, where $b < 1$), meaning that people

underestimate size increases (Stevens 1986). Research in marketing has found that the underestimation of package size changes is even stronger when an object increases in all three spatial dimensions (height, width, and length) rather than in just one dimension (Chandon and Ordabayeva 2009). However, we don't know why these biases occur, how they can be reduced, and whether these biases, previously reported in the context of size increases, would be similar in the context of size decreases. In this research, we test attentional and computational sources of biased size perceptions, estimate several models of size change, and test informational, visual, and haptic strategies to improve the accuracy of consumers' size estimations in the context of package downsizing.

We hypothesize that people underestimate size decreases not just because they do not pay attention to the fact that the dimensions are changing but because they do not correctly integrate these changes (i.e., there are computational errors not just an attentional errors). We further hypothesize that estimations do not follow the normative model of size estimation which assumes that people multiply the changes in all of the three dimensions. Instead, we compare two models: an additive model which assumes that people just add the change in all of the three dimensions and a "surface area" model which assumes that people respond to changes in the surface area of the object instead of its actual volume.

These hypotheses imply that visual and informational strategies, such as drawing attention to individual dimensions and providing information about perceptual biases would not suffice to correct size estimations. They also predict that facilitating the computational problem by reducing the dimensionality of the size decrease (from 3D to 2D to 1D) or by allowing people to hold and weigh the product (and thus rely on haptic instead of just visual information) should improve the accuracy of size estimations. Another prediction of both the additive and surface models is that product downsizing would be more obvious when one dimension is decreased (1D downsizing) than when one dimension is actually increased while the other two are strongly decreased (elongated downsizing). Finally, because of the height/width illusion, we would expect that size estimations are more sensitive when it is the height of the object which is elongated rather than its width.

In study 1, participants saw four sizes (XL, L, M, and S) of rectangular candles and cylindrical candy boxes which decreased either in 1D (height only), 2D (width and length), or 3D. All participants were given the weight and price of the largest option (XL) and were asked to estimate the weight and to provide their willingness to pay for sizes L, M, and S. Participants in the decomposition condition were also given the height, width and length of size XL and had to estimate the height, width, and length of the other sizes. This manipulation ensured that they would pay attention to the fact that more than one dimension may have been reduced. We found a strong underestimation bias on average ($b = .85$). Reducing the dimensionality of size decrease from 3D to 2D to 1D reduced and eliminated the bias ($b = .67$, $b = .89$, and $b = 1.06$), but drawing attention to individual dimensions did not. We also found that the additive model fit the data better than any other models. This shows that the errors are driven by computational errors and not by attention.

In Study 2, we used a similar design as in Study 1 but manipulated whether the product was downsized in 1D or through elongation because it allows us to better compare the predictions of the additive and surface area models. In addition, some of the participants were asked to hold and weigh the products while others were given information about the feedback on their estimation accuracy in a prior similar task. A control group only saw the products visually and was given no feedback (just like in Study 1). Finally, we

manipulated the dominant dimension of the package by displaying the two products (soap bars or rectangular candles) either on their base (salient height) or on their side (salient width). As predicted, people noticed the size reduction more when only one dimension was changed than when the product was elongated ($b = .81$ vs. $b = .23$). Allowing people to touch and weigh the packs significantly improved estimation accuracy ($b = .59$ vs. $b = .43$). However, providing information and changing the dominant dimension of a package had no effect. Again, we found that the additive model fit the estimation data better than the alternative models.

In the third study, conducted in collaboration with a major consumer good company, we tested the effectiveness of elongated and 1D downsizing of dog food packages. The participants were all dog owners and were asked to choose between a regular-size pack of a competitor brand and a new downsized version of the company's product which was either downsized in 1D or elongated in height or width. As predicted, the choice share of the downsized pack was larger when the pack was downsized by elongation (57% for the height condition and 46% for the width condition) than when it was downsized in 1D (39%).

The Semantic and Aesthetic Impact of Smell on Touch

Cindy Caldara, University of Grenoble, USA

Ryan S. Elder, University of Michigan, USA

Aradhna Krishna, University of Michigan, USA

The marketing literature has received a marked increase in scholarly attention devoted to the impact of sensory perception on consumer behavior (see Peck and Childers 2008). Not surprisingly, much of this exploration has shown the effects of the senses on consumer behavior in isolation from one another. Research on the impact of smell on memory (Morrin and Ratneshwar 2003), music on shopping behavior (Yalch and Spangenberg 2000), and touch on feelings of ownership (Peck and Shu 2009) highlight some of the fascinating results from this primary focus. Despite the need to continue exploring the impact of senses in isolation, the foundation now exists to support studies on the interaction of senses. We contribute to the literature on multisensory interactions by showing the sensory aesthetic (we define sensory aesthetics as the combined hedonically pleasing effects of sensory inputs) and semantic impact of smell on touch. Across two studies we show that the scent of a product can impact haptic perceptions, with these effects being moderated by the level of congruity between the sensory stimuli.

Multisensory Interactions and Consumer Behavior

The overall neural representations of product experiences rely on a combination of all sensory inputs. Recent studies within consumer behavior have explored these cross-modal interactions, including touch and taste (Krishna and Morrin 2008), smell and sound (Matilla and Wirtz 2001), sound and vision (Russell 2002), vision and taste (Hoegg and Alba 2007), as well as multiple sensory inputs and taste (Elder and Krishna 2010). These cross-modal interactions between senses have important consequences on consumer perceptions and behavior.

The specific combination of smell and haptics has not received attention within the marketing literature despite the acknowledgement that both scent and touch in isolation greatly impact consumer behavior (e.g., Morrin and Ratneshwar 2000; Peck and Wiggins 2006). However, recent research within psychology provides preliminary evidence that these sensory inputs do interact. Dematte and colleagues (2006) show that scent can impact touch, wherein a positive scent leads to better fabric perceptions than an unpleasant scent. In addition to this overall halo effect of smell on touch, we anticipate that semantic associations of the scent, as well as the

congruence of these associations and the tactile properties of the stimulus, will further affect perceptions of the product. Whether learned or automatic, scents are not devoid of meaning. Indeed, the meaning of scents can affect not only perceptions, but actual behavior (Holland et al. 2005). Our current work explores not the aesthetic impacts of smell on touch, as well as the importance of semantic congruence within cross-modal interactions. We exhibit our effects across two different dimensions of touch (texture, temperature), and using two sets of fragrances.

Study 1

Study 1 explores the impact of semantic sensory associations and congruity. As we were interested in drawing semantic associations from the smell to the haptic experience, we needed to find a way to match the stimuli. The specific question to be addressed is whether a masculine or feminine smell can impact texture perceptions of paper matched for congruity (rough and smooth paper, respectively). We carefully pretested masculine and feminine smells, as well as rough and smooth paper for equal likeability as well as equal distances from the midpoint on a masculine/feminine scale.

Design and Procedure. Seventy-three undergraduate participants were randomly assigned to one of the four conditions. Each was given a scented piece of paper to evaluate. In contrast to the prior studies, participants were told to touch and also smell the fragrance on the paper. Following ratings of the smell, participants rated the overall texture of the paper.

Results. We found a significant main effect of texture ($p < .001$) as well as a significant interaction of paper type and smell on perceived texture of the paper ($p < .005$). Follow-up contrasts on the interaction revealed that within the smooth paper condition, the feminine smell lead to significantly smoother perceptions than the masculine smell. Similarly, in the rough paper condition, the masculine smell lead to significantly rougher perceptions than the feminine smell. The results support the semantic associations of smell as well as congruence effects. We show that scents do have meanings, and that these meanings can have a significant impact on other sensory inputs, such as touch.

Study 2

In study 2, we replicate and extend the findings of study 1 on semantic congruence to a different dimension of touch, namely temperature. The specific question to be addressed is whether the feel or temperature of a smell can impact evaluations of haptic quality. We again pre-tested fragrances to be equal on overall likeability and familiarity, but to differ on perceived temperature of the smell. We ultimately selected pumpkin cinnamon as a warm smell and sea island cotton as the cool smell, and used therapeutic gel-packs (either hot or cold) as the product to be evaluated haptically.

Design and Procedure. We employed a 2 (fragrance: warm, cool) \times 2 (gel-pack: warm, cool) between subjects design with overall evaluations as the dependent variable. Ninety-eight participants were instructed that they were to evaluate an aromatherapy hot/cold gel-pack. Each participant smelled the gel-pack and then placed the gel-pack on her hand for 15 seconds. Following this procedure, participants rated how well the gel-pack worked (very effective, very quickly, cooled/heated hand well).

Results. We find a significant main effect of gel-pack temperature, whereby the cold gel-pack is perceived as more effective than the warm gel-pack. More importantly, we also find our hypothesized interaction between gel-pack and fragrance temperature ($F(1, 94) = 8.49, p < .005$). Follow up contrasts reveal our anticipated effects as within the cold gel-packs, the cold smell leads to significantly higher evaluations than the warm smell. Similarly, within the warm

gel-pack conditions, the warm smell led to significantly higher evaluations than the cool smell.

The results from study 2 replicate our findings from study 1 and add an additional dimension of touch (temperature). Furthermore, our findings explicate another instance where smell can lead to semantic associations that drive the evaluative consequences of congruence for haptic stimuli.

SPECIAL SESSION

Great Expectations: The Placebo Effect and Consumer Behavior

Eric Hamerman, Tulane University, USA
David Faro, London Business School, UK

EXTENDED ABSTRACTS

“Placebo Responses to Shaken Belief: Detrimental Impact of Consumer Choice on Product Efficacy”

*Baba Shiv, Stanford University, USA
Himanshu Mishra, University of Utah, USA
Ziv Carmon, INSEAD, France*

A large body of research documents the benefits of allowing people to control their fate by exercising choice over experiences they will undergo. In a particularly dramatic example, Langer and Rodin (1976) showed allowing nursing home residents an ability to choose among seemingly inconsequential options, such as on which of two possible dates they will watch a particular movie, dramatically improved both their well being and longevity. From a practical perspective, service providers and retailers are often encouraged to empower consumers to choose for themselves. We propose that such empowerment can backfire and impair the effectiveness of the chosen option. This prediction builds on the theories of Option Attachment (Carmon et al. 2003), and Placebo Effects of Marketing Actions (Shiv et al. 2005).

Research on Option Attachment suggests that empowering consumers to make choices involving significant conflict among the choice alternatives can lead to post-decision discomfort with the chosen option and an increase in the appeal of rejected options. And research on Placebo Effects of Marketing Actions shows that changes in consumer expectations about the effectiveness of products they are to consume can influence the actual efficacy of those products.

In light of those theories, we propose that choosing among choice alternatives can hurt expectations for, and confidence in, the efficacy of the selected option and as a result of a negative placebo effect lessen the actual efficacy of the chosen option.

The basic experimental paradigm was as follows. Participants were informed that some research has shown that caffeinated tea helps with having a focused brain, while tea with extracts from the chamomile flower (Chamomile tea) can calm the brain. However, the results of these studies are not completely definitive and, therefore, the purpose of this study is to examine the effectiveness of caffeinated tea versus chamomile tea. While participants were consuming the tea, they were shown a video purportedly to allow the ingredients to have their effects. After consuming the tea, they were asked to solve a series of word-jumble puzzles, with their goal being to solve as many puzzles as possible in the allotted 30 minutes.

The purpose of Experiment 1 was to document the basic effect and to show that conflict among the choice options is a significant cause of the effect. Our study design was a 2 (choice: participants chose vs. randomly assigned one of the options) x 2 (conflict: the choice options with conflicting vs. similar benefits). Analysis show that the number of puzzles solved was significantly lower in the choice condition than in the no-choice condition, but this was only true when the choice involved a conflict.

In Experiment 2, we sought further support for our option attachment explanation by asking one group of participants to list advantages and disadvantages of each choice alternative. Thus, the study design was a 2 (choice: participants chose vs. randomly assigned one) x (elaboration: before being asked to choose participants listed advantages and disadvantages of each option vs. this was not mentioned). As predicted we found a significant main effect

for choice as well as a significant interaction between elaboration and choice.

In Experiment 3, we sought a different way to evoke a debilitating effect of choice by manipulating participants' confidence in the quality of their choice by using a subtle handedness manipulation that has been shown to influence confidence. Specifically, in a separate study we asked participants to write either with their dominant or their non-dominant hand. Thus, the study design was a 2 (choice: participants chose vs. randomly assigned one) x (handedness: subjects were instructed to write with their dominant hand vs. subjects were instructed to write with their non-dominant hand). The results show the impact of choice as well as for the hand used to write affected the number of puzzles solved. We conclude by discussing the significant managerial and public policy implications of our findings.

“Merely Accessible: Products May be Effective without Actual Consumption”

*David Faro, London Business School, UK
Monika Heller, London Business School, UK
Caglar Irmak, University of South Carolina, USA*

Imagine the following scenario. You wake up with a headache one morning, so on your way to work, you stop by the pharmacy and buy a headache medicine. You put the medicine in your bag and continue your journey to work. When you arrive, you are so busy that you do not take the medicine right away. Would the fact that you purchased the product and had access to it have a positive effect on your headache even though you did not actually consume the product? Would the mere fact that a solution was available and accessible to you suffice to relieve at least part of the problem?

In this paper, we provide evidence for this effect, which is to some extent reminiscent of the placebo effect. In a typical placebo study, a doctor gives a patient a pill that, unbeknownst to the patient, is only a sugar pill. Even though the pill has no inherent power to produce an effect, it has a genuine physiological effect on the patient. Placebo studies therefore show that an active ingredient need not be consumed to produce an effect (e.g., Geers et al. 2005; Irmak, Block, and Fitzsimons 2005; Shiv, Carmon, and Ariely 2005). In our study, we find that actual consumption may sometimes not be necessary either.

A pilot study was conducted following the first outbreak of swine flu in the UK in late 2009. We tested whether ease of access to Tamiflu (the main drug used in the prevention and treatment of swine flu), would affect participants' self-reports of immune system strength. Participants in an online pool first received basic information about swine flu. Then they received information about Tamiflu and were told that it functions similarly to the immune system by preventing the flu virus from entering body cells and by blocking the release of new copies of the virus. Participants in the high-accessibility condition, who were students, were told that college and university students (along with infants, schoolchildren, pregnant women, and the elderly) would be included in the priority groups to receive Tamiflu. Priority groups in the low-accessibility condition did not include college and university students. Participants then filled out a self-report of current immune system strength (which included items such as: How strong is your immune system in fighting viruses? How often do you get colds and flu? How are your energy levels? My immune system is ... very weak/very

strong. My general health is ... very bad/very good.) Participants in the high-accessibility condition reported their current immune system to be stronger. Moreover, their beliefs about the efficacy of Tamiflu in treating swine flu did not have a significant effect on the results. These results provided initial support for our contention that mere access to a remedy may bring about the claimed effects of the remedy.

In the next study, participants completed two separate concentration tasks. After the first task, participants in the experimental condition were told that coffee was available if they wanted it. On a table behind the participants were a thermos, cups, sugar/sweetener, and milk. In the control condition, coffee was not available and was not mentioned throughout the study. In a third condition aimed to rule out a priming explanation, coffee was mentioned as being available but then was not accessible during the study. The main dependent measure was participants' performance in a second reaction-time task. Participants saw a grid with empty check-boxes presented as a 10 x 10 matrix on a computer screen. We asked participants to click on as many boxes as they could in 20 seconds. We also collected self-reports of stress and perceived control, as well as expectations about coffee's efficacy in improving task performance. Results showed that performance in the coffee-available condition was significantly better than performance in the control and coffee-noted-but-unavailable conditions. Self-reports of stress, perceived control, and expectations about the efficacy of coffee did not show any significant effects.

These results, along with those of the pilot study, suggest that mere access to a product can be as effective as actual consumption and that this effect of accessibility is independent of expectations about product efficacy. Although perceived product efficacy did not have an effect on participants' performance in these experiments, accessibility to a beneficial product may enhance consumers' self-efficacy in accomplishing tasks related to the product's benefits and, as a result, improve task performance. If self-efficacy plays such a role in this process, we would expect to observe a stronger effect of accessibility on performance for participants with low self-efficacy.

Thus, in the final study, we tested the moderating effect of self-efficacy and examined the effect in a new setting. In the main task, participants solved word puzzles. Half the participants had access to a dictionary to which they could refer during the task if they wanted to do so. This was the manipulation of accessibility. For the manipulation of self-efficacy we used a typical procedure of positive or negative feedback in a preceding related task (e.g., Vancouver et al. 2002). Results indicated that for low-self-efficacy participants, the presence of the dictionary significantly improved performance in the word puzzles. For the high-self-efficacy participants we did not find such a difference. Whether participants made use of the dictionary did not change the results.

These results suggest that mere accessibility to a remedy increases consumers' self-efficacy and their task performance. In other words, under certain conditions, products can be effective without being consumed.

“Two Wrongs Sometimes Make a Right: Task Difficulty in Nocebo and Placebo Treatments”

Eric Hamerman, Tulane University, USA

Tor Wager, University of Colorado, USA

Gita V. Johar, Columbia University, USA

The placebo effect is a robust phenomenon in the field of medicine that demonstrates how beliefs and expectations can impact treatment outcomes. When a patient expects to be cured, health often follows (Beecher, 1955). On the flip side, expecting

poor health can lead to illness, which has been termed the “nocebo” effect (Benson, 1997; Hahn, 1997; Spiegel, 1997).

More broadly, negative outcomes tend to occur after individuals are presented with pessimistic suggestions, and vice versa. This is consistent with the idea that performance expectancies—whether positive or negative—are good predictors of actual performance (Wigfield & Eccles, 2000).

However, individuals will sometimes attempt to compensate for lower expectations by increasing their efforts (Fillmore & Vogel-Sprott, 1995; Harrell & Juliano, 2009). This paper attempts to address the issue of when people are most likely to engage in this compensatory response and reverse the nocebo effect.

In two studies, individuals are presented with an energy drink that is framed as either an “enhancement” (placebo treatment) or “impairment” (nocebo treatment) to performance. Additionally, the task which they are asked to perform is presented as either difficult or neutral. Both studies utilized a 2 x 2 between-subjects design, with factors of placebo treatment (placebo or nocebo) and task difficulty (difficult or neutral).

In Study 1, each participant completed a set of analytical reasoning questions (from the LSAT) as a baseline measure of performance, and then was given a placebo or nocebo treatment. In this case, the placebo treatment consisted of an energy drink purported to increase cognitive ability. The nocebo treatment was an energy drink that was said to have a side effect of decreasing cognitive ability. Subsequently, participants completed a second set of analytical reasoning questions, which was framed as either similar to—or more difficult than—the baseline questions.

The dependent variable was the change in number of questions answered correctly between the first and second set of analytical reasoning questions. Results indicated a significant interaction between placebo treatment and task difficulty. In the nocebo condition, framing the task as difficult (vs. neutral) led to a larger increase in performance versus the baseline. In the placebo condition, the results were reversed: a larger improvement in performance over the baseline occurred when the analytical reasoning problems were framed as neutral (vs. difficult).

In order to determine the mechanism by which nocebo respondents performed better when presented with a more difficult task, the experimental paradigm of Study 1 was replicated in Study 2, with a few important additions. After drinking the placebo or nocebo energy drink and being informed of the task difficulty, participants were asked to report their performance expectations, and then completed a threat-challenge scale that measured whether they appraised the analytical reasoning task as a threat or challenge.

Results indicated that in both the placebo and nocebo conditions, participants expected lower performance when the questions were described as difficult (vs. neutral). However, the performance results mirrored that of Study 1. Nocebo participants solved more problems when they were described as difficult (vs. neutral), while placebo respondents solved more problems when they were described as neutral (vs. difficult). As in Study 1, the interaction between placebo treatment and task difficulty was significant for performance.

Respondents were also asked how many additional questions they would be willing to answer at the close of the session for an additional payment. Nocebo participants reported that they would be willing to answer more questions when the questions were framed as difficult (vs. neutral); the reverse was true for the placebo respondents. This was the same interaction that occurred for performance, suggesting that differences in persistence and effort drove the changes in performance.

We hypothesized that the reason for the nocebo participants' performance improvement when faced with a difficult task was a compensatory response to a threatening situation. In support of this prediction, the self-reported measure of "threat" was found to be highest (compared to the other three conditions) in the case of a nocebo treatment combined with a difficult task.

"Explaining the Crossmodal Influence of Color on Odor Identification Responses: An Expectations-Based Approach"

Maya Shankar, Oxford University, UK

Chris Simons, Givaudan Flavors

Baba Shiv, Stanford University, USA

Samuel McClure, Stanford University, USA

Thuan K. Ngo, Oxford University, UK

Charles Spence, Oxford University, UK

In tasks that require us to identify odors just on the basis of (orthonasal) olfactory cues, our performance is quite poor. In fact, we are only able to correctly identify roughly one third of familiar odors when these cues are presented in isolation (e.g., Engen & Ross, 1973; see Zellner et al., 1991, for a review). This is perhaps not so surprising, however, when one considers that under more naturalistic conditions, we rarely have to identify a substance without access to additional information from both higher level cognition and other sensory modalities (see de Araujo et al., 2005; Herz & von Clef, 2001; Zellner et al., 2001). As a result, we often look to the expectations generated by other sensory cues in order to help facilitate correct identification of odors. Crossmodal influences of this kind can help enhance and contribute to a more successful interpretation of those objects in the world around us (e.g., see Cardello, 2007, for a review).

One such cue comes from color. Previous research has shown that the color of a stimulus can generate salient expectations as to its likely properties and identity characteristics (Elliot et al., 2005). Critically, with regards to food and drink acceptance, Cardello (1994) asserts that expectations about the sensory or hedonic properties of food and drink can contribute just as much to a person's final assessments of a stimulus as the physiochemical properties of the food or drink itself (cf. Yeomans et al., 2008; see also Feather, 1982; Tolman, 1951). Given the significant implications of this assertion, it is somewhat surprising that little research has examined whether and in what ways expectations can influence sensory evaluations and identity judgments.

Thus, the current work examined one such unexplored relationship: namely, the role that color cues may play in our (orthonasal) identification of odors. More specifically, it explored the role of color as a generator of flavor-based expectations and the multitude of variables that may modulate whether these expectations exert a significant influence on our odor judgments.

In our procedure, participants were asked to identify—by smell—the flavor of drinks that varied in color. We found that respondents were likely to identify a flavor smell that was consistent with the color of the drink, even when the actual flavor differed. This was especially likely to occur when the discrepancy between the expected and actual flavors was small. We also collected self-reported data on consumer expertise, and found that this factor impacted participants' abilities to correctly identify flavors.

The contributions of this research are three-fold: 1) It introduces a novel methodology for properly measuring individuals' color-flavor associations and expectations prior to testing in order to control for individual differences; 2) It systematically examines variables that may mediate whether expectancy information influences participants' judgments of odor identity (and in the process, reveals that color can have differential effects on odor identification

depending on a number of variables and experimental conditions); and 3) It accounts for the reported results by appealing to a categorical version of the Assimilation/Contrast Theory (Deliza & MacFie, 1992; Zellner et al., 1994). Critically, the model used to explain this data proposes that the confidence with which a participant views his or her color-based expectations may play just as big a role in mediating how participants use their expectations as the stimulus attributes themselves.

“I Have a Feeling It Will Turn Out Fine”: How Social and Emotional Factors Affect Risk Perception

Sara Kim, University of Chicago, USA

Ann L. McGill, University of Chicago, USA

EXTENDED ABSTRACTS

“Gaming with Mr. Slot or Gaming the Slot Machine? Power, Anthropomorphism, and Risk Perception”

Sara Kim, University of Chicago, USA

Ann L. McGill, University of Chicago, USA

Recent research in social psychology has begun to investigate factors that influence people’s tendency to anthropomorphize non-human entities such as objects or animals (Epley et al. 2008). Consumer behavior researchers have been interested in how anthropomorphism in turn affects judgments and behavior (Aggarwal and McGill 2007). To date this work has primarily been interested in how anthropomorphism affects quality assessments and overall liking, and studies have contrasted evaluations of anthropomorphized and non-anthropomorphized products. The present research, by contrast, explores situations in which the same degree of anthropomorphism can color judgments differently depending on how people apply beliefs and expectations of social concepts such as power. Moreover, this research focuses on other types of judgments beyond liking, in particular, risk perception.

The central hypothesis of this research is that anthropomorphizing a product causes consumers to apply social expectations and beliefs they would not normally apply to an inanimate entity. For example, for consumers considering playing a slot machine, our hypothesis is that their perception of risk (and so their willingness to play) would depend on whether they see the machine as being human. If the product is not anthropomorphized, risk assessments should follow from nonsocial considerations. However, if the entity is anthropomorphized, risk assessments should follow from beliefs and expectations about human interaction, such as consumers’ perceived social power over others, their degree of trust in others, their sense of personal need, and their view of others as kind or altruistic. Hence, anthropomorphism may have different effects depending on the model of social interaction brought to mind at the time of the decision.

In this sense, we can view the effect of anthropomorphism on risk assessment as a type of illusion of control. Previous research on illusory control shows that when a task has some characteristics that people associate with personal skill, individuals sometimes behave as if they can influence outcomes that are actually the result of pure chance (Langer 1975). This research proposes that anthropomorphism can also increase or decrease illusory control through the (mis-) application of social factors to outcomes that are based on chance. In this research, we focus in particular on the effect of perceived social power on risk assessments for anthropomorphized products.

In most social psychology studies, power is defined as an individual’s relative controllability to change the states of others in accordance with his or her own will (Thibaut and Kelley, 1959). Further, the causal relationship between perceived power and feelings of control is bidirectional (Thibaut and Kelley, 1959). People believe they have more power over others when they have more control, and people believe they have more control when they feel more powerful. We propose that anthropomorphism increases application of power perception. That is, people who feel very powerful transfer this feeling of mastery to the anthropomorphized entity, believe they can control it, and so feel less risk. In contrast,

people who are low in power feel at the mercy of the entity, and so feel greater risk.

In the first experiment, we showed that participants who felt powerful acted as if they had more control when they anthropomorphized the slot machine (lower risk perception). Anthropomorphism was manipulated by modifying the look of the machine so it appeared to have a face or not. Power was manipulated by asking participants to recall an incident in which they felt powerful or not. Powerful consumers who saw the machine as human were more willing to play a risk-related game, whereas the powerless acted as if they had less control over the outcomes when they anthropomorphized the slot (higher risk perception), decreasing willingness to play the game.

In the second experiment, we used skin cancer as a risk generating entity, a conceptual replication but also one which extends our investigation to a less pleasurable domain than gambling. Again we replicated the interactive effect between anthropomorphism and power on risk perception. In this study, anthropomorphism was manipulated by the message about the disease. In the high anthropomorphism condition, the disease was described as if it has evil intentions to hurt people. Power was manipulated as in the first study. Participants with low power perceived skin cancer as a more risky disease when it was highly anthropomorphized, whereas those with high power showed the opposite pattern. Moreover, this risk perception was positively correlated with liking of a sunscreen which can prevent skin cancer.

In the third experiment, we investigated the reverse effect that perceived risk affected people’s tendency to anthropomorphize depending on their feelings of power. High risk (vs. low risk) increased anthropomorphism for people with low power, while low risk (vs. high risk) increased anthropomorphism for those with high power. Specifically, participants with low power were more likely to anthropomorphize the slot machine after losing than winning the game, whereas those with high power were more likely to anthropomorphize the slot after winning than losing the game. Theoretical implications pertaining to the power and anthropomorphism in judgments and preference construction and managerial implications regarding what managers might be able to do to change risk perception involving with products will be discussed. “Aesthetics as Impetus to Riskier Decision-Making”*Claudia Townsend, University of Miami, USA**Suzanne Shu, University of California, Los Angeles, USA*

We investigate the psychological impact of aesthetics on decision-makers and how this affects propensity to engage in risky behavior. Previous research has shown that the aesthetics of a chosen object can influence a person's thoughts about themselves. Specifically, choice of highly aesthetic options can be a form of self-affirmation and have the same impact on subsequent behavior as does a self-affirmation manipulation (Townsend and Sood 2009). Experimentally induced self-affirmation interventions can lead to positive outcomes such as overcoming confirmation bias and reduced defensiveness (e.g. Cohen, Aronson, and Steele 2000). Townsend and Sood (2009) find that people who choose a highly aesthetic product show subsequent reduced defensiveness, as though they had earlier engaged in self-affirmation. Using this prior literature as a starting point, we examine whether providing the consumer with a personal association with high aesthetics impacts subsequent decision-making and specifically risk taking. Given that association with highly aesthetic objects seems to be a source of self-affirmation, we hypothesize that it will lead to both increased openness to arguments and riskier behavior. The increased risk taking that comes from association with aesthetic objects is consistent with recent findings that individuals with an induced or chronic greater sense of self engage in riskier behavior (Johnson 2000). The primary domain in which we test these predictions is financial decision making and investment in company stocks.

In study 1 we examine whether association with high aesthetics leads to riskier investment behavior. Using a student population we created an association with either high aesthetics or high functionality through hypothetical ownership in a company that either emphasizes aesthetics or functionality. We find that respondents who have previously been associated with high-aesthetics are more likely to invest in a hypothetical risky investment and also offer a higher minimum investment at which they would invest (\$637.23 vs. \$435.60) than respondents who have previously been associated with high functionality. Consistent with the theory that association with high aesthetics is self-affirming and impacts subsequent openness to arguments, participants who had been associated with the high aesthetics company found the pitch for the subsequent risky investment opportunity to be more convincing and reasonable than both the Control and Function-association participants. We also find that participants associated with aesthetics exhibit less risk aversion as measured through willingness to accept a risky gamble than respondents in the other two conditions.

In Study 2 we test this effect using a population with relevant expertise and real financial documents. We examine the investment behavior of respondents with a background in finance who, presumably, are more immune to irrelevant influences on their financial decision-making. Using pairs of actual published company annual reports matched by industry, respondents were told that they were owners of stock in either the companies represented by more aesthetic reports or by the less aesthetic reports within each pair (without explicit referral to aesthetics). After this association we presented respondents with the same risky investment decision and questions on willingness to engage in risky gambles as in study 1. The results confirmed the findings of study 1 revealing that association with high aesthetics leads to riskier investment behavior even among respondents with a background in finance who claim that the aesthetics of the report has no influence on their decisions. Moreover, we find that association with company annual reports alone can provide the aesthetic association needed to self-affirm and cause this effect.

Study 3 replicates the previous results and examines closely the process of self-affirmation through which this occurs. Respondents are told that they own stock in the companies with the aesthetic annual reports used in study 2. We then measure reduced defensiveness and openness to arguments, and show that the effect of high aesthetics on these measures is as strong as a self-affirmation condition, relative to a control group. It is this connection between high aesthetic design and the sense of the self that results in the increased risky behavior. Implications for this are discussed in the realms of self-affirmation theory, risk preferences, and decision-making. (665 words)

“Negative Emotions and Health Messaging: Coping Efficacy and Message Framing Effects”*Adam Duhachek, Indiana University, USA**Nidhi Agrawal, Northwestern University, USA*

Consumer research in recent years has explored how emotional experiences impact consumer attitudes and behaviors. While most research focused on the role of valenced affective states (i.e., positive or negative mood), recent research has begun to look at the role of specific discrete emotional states. A few studies have documented ways in which emotions might affect information processing and persuasion. The current research studies the emotions of shame and guilt in the context of public service messages related to binge drinking. We test the basic proposition that the specific negative emotions of shame and guilt, differ with respect to the efficacy appraisals underlying these emotions and these emotions are differentially responsive to gain versus loss message frames. Building off of theoretical work examining interactions between efficacy and message frame, we postulate the differential effectiveness of these messages are due to differences in the appraisal of coping efficacy, thereby contributing to the literature examining emotions and message framing effects.

Study 1 found that the low efficacy emotion of shame was compatible with a negative message frame, whereas the high efficacy emotion of guilt was compatible with a positive message frame. Not only did this compatibility result in increased persuasion in terms of binge intentions, but also with respect to individual perceptions of risk associated with excessive drinking. Study 2 examined the role of efficacy-based compatibility on subsequent resistance to information that runs counter to the health message. Those experiencing shame (guilt) and exposed to negative (positive) frames were better equipped to resist subsequent pro-alcohol information that ran counter to the health message. In both cases, these individuals were less willing to view alcoholic beverage recipes. Study 3 demonstrated that these compatible conditions resulted in increased efficacy as individuals in the shame (guilt) negative (positive) frames were more persuaded and held subsequently greater activation of the relevant coping strategy. Importantly, this coping strategy-related finding demonstrates the integral role of efficacy in interpreting the effects of message frame on persuasion. Study 4 sought additional evidence of the role of efficacy in driving these effects by testing a problem-focused coping empowerment mechanism to reverse the compatibility-effects of the low efficacy emotion of shame and negative frames. Those experiencing shame, a low efficacy emotion, responded to messages in ways similar to those experiencing

the high efficacy emotion of guilt when they were empowered by problem-focused coping strategies.

This paper makes three main contributions to theory related to message frame and emotions as well as to the substantive domain of consumer health messaging. First, While past research has examined the effect of valenced affective states (positive versus negative mood) on message framing, we make a unique contribution by examining the effects of two discrete negative emotions on message framing. Second, we extend previous research on message frames by articulating an appraisal-based account of emotions that leads to discrepant predictions of message frame for two negative emotions. Finally, we demonstrate a mechanism through which low efficacy emotions can be empowered to mimic high efficacy emotions. This finding is among the first to provide evidence of a positive outcome resulting from a low efficacy emotion like shame. (519 words)

"Uncertainty Exacerbates the Endowment Effect"

Michael J. Liersch, New York University, USA

Yuval Rottenstreich, New York University, USA

Howard Kunreuther, University of Pennsylvania, USA

Min Gong, Columbia University, USA

In standard endowment effect experiments, participants cannot lose their holdings. For instance, Knetsch (1989) gave participants either mugs or candy that they could keep or trade. Regardless of their choice, people walked away from the experiments with one of the items. However, actual endowments are often uncertain. For example, post-Madoff, investors worry their investments will disappear. In this paper, we examine how uncertainty impacts the reluctance to trade. Doing so is of practical significance and may also provide insight into the processes underlying the endowment effect.

In a baseline condition mirroring previous work, participants were endowed with either a mug or a box of highlighters, and given the opportunity to trade. We observed reluctance to trade. A second group of participants underwent the same procedure, but was told that after requested trades were completed, two coins would be flipped. One coin would determine whether participants holding mugs at the end of the experiment would keep their mugs (heads) or lose their mugs (tails); another coin would make the same determination for those endowed with highlighters. Compared to the baseline condition, reluctance to trade was significantly more pronounced when holdings were uncertain.

Researchers have recently suggested that feelings of attachment to an endowed item may underlie reluctance to trade (Strahilevitz and Loewenstein, 1998; Wolf et al., 2008; Johnson et al., 2009). Our results cast doubt on this notion. Because one should presumably be less attached to items that are only tentatively held, attachment accounts imply that certain endowment should yield more pronounced reluctance to trade than uncertain endowment.

It could be argued, however, that anticipatory regret of a "bad" trade engendered our results. For example, consider a mug holder who contemplates trading their mug for highlighters. Under certainty, the individual simply determines their preferences. However, under uncertainty, the individual might be highly averse to the possibility of losing their highlighters in the highlighter coin flip—especially if mug holders were to keep their mug in the coin flip. We ruled-out this possibility in a second uncertainty condition where a single coin was flipped to determine whether both mug and highlighter holders kept or lost their item. Importantly, the level of reluctance to trade was virtually identical in the one and two coin flip conditions.

We also examined whether uncertainty external to the items being traded might impact the reluctance to trade. Participants again received either a mug or highlighters, which they could trade;

in addition, every participant received a Pack of Post-Its, which they could not trade. As expected, people were reluctant to make mug-highlighter trades. We then contrasted this baseline condition with two further conditions: A negative uncertainty condition, in which people could lose their Post-Its via a coin flip, and a positive uncertainty condition, in which people were initially endowed with a mug or highlighter and could win Post-Its via a coin flip. Reluctance to trade mugs and highlighters in the negative and positive uncertainty conditions was virtually identical to the baseline condition. Evidently, to increase reluctance to trade, uncertainty must be associated directly with the tradable items. Thus, we infer that anxiety or other affect arising from the mere presence of uncertainty was not responsible for increased endowment effects in our earlier uncertainty conditions.

In sum, it appears that uncertainty, as long as it is applied to the items to be traded, increases reluctance to trade. These findings indicate that notions of attachment cannot on their own account for endowment effects. Perhaps counter-intuitively, people may be more likely to hold onto their endowments, rather than trade, when holdings are uncertain. (597 words)

New Perspectives on Depletion: Expanding the Boundaries and Nature of Depletion

Nicole Mead, Tilburg University, The Netherlands

EXTENDED ABSTRACTS

“Exercising Self-Control Increases Approach Motivation”*Brandon Schmeichel, Texas A&M University, USA**Cindy Harmon-Jones, Texas A&M University, USA**Eddie Harmon-Jones, Texas A&M University, USA*

Success at self-control is essential for several important aspects of life, from personal concerns such as losing weight and saving money to societal concerns such as reducing drug abuse and preventing violence. Self-control can be construed as a struggle between two competing forces: the force that motivates the expression of an impulse (i.e., impulse strength) versus the countervailing force that overrides the impulse (i.e., self-control strength).

The strength model of self-control posits that the inner mechanism for self-control operates on the basis of a limited resource or strength. The sufficiency of this strength for overriding behavior is determined in part by previous behavior. If the person has recently exercised self-control, then strength may be depleted and further efforts at self-control may be prone to failure.

However, the strength model is mute regarding the other element of the self-control struggle—the strength of the impulse that opposes the control mechanism. Given that both the motivation to act on an impulse and the capacity to control impulses jointly determine self-control outcomes, and given that self-control outcomes are determined in part by recent efforts at self-control, we hypothesized that recent efforts at self-control influence not only self-control strength, but also the motivation to act on impulse.

The present research tested the hypothesis that exercising self-control temporarily increases the strength of approach-motivated impulses. Results in support of this hypothesis would suggest that prior efforts at self-control affect subsequent behavior by increasing impulse strength. The research to be presented in this talk provides the first evidence that initial acts of self-control that have been shown to reduce self-control strength also increase approach-motivated impulse strength.

There are several specific behaviors (e.g., eating, aggression) that are driven both by the impulse that compels the behavior and by the inner mechanism that attempts to control the behavior. For these behaviors, it may be difficult to distinguish the contributions of impulse strength from the contributions of self-control strength. But other approach-motivated behaviors may be unrelated to self-control because the person has no interest or inclination to control them. To distinguish between approach-motivated impulse strength and self-control strength in the current work, we chose to study approach-motivated behaviors that are uninfluenced by self-control. We reasoned that, if exercising self-control causes an increase in approach-motivated behaviors that do not entail self-control, then we can be confident that exercising self-control temporarily increases approach motivation.

Study 1 found that prior efforts at self-control caused an increase in self-reported approach motivation. Study 2a identified a behavior—betting on low-stakes gambles—that is associated with approach motivation but not self-control, and Study 2b found that prior efforts at self-control cause an increase in low-stakes betting behavior. Last, Study 3 found that exercising self-control subsequently facilitates attention toward a reward-relevant symbol but not a reward-irrelevant symbol (Study 3), consistent with the view that self-control increases approach motivation.

Altogether, the current findings suggest that the strength model of self-control be amended to incorporate the other side of the self-control struggle—impulse strength. Prior acts of self-control may increase approach motivation in addition to reducing self-control strength. This amendment to the strength model expands our understanding of self-control failure and may help to explain why prior acts of self-control increase aggression, eating, drinking, profligate spending, and more.

“Prisoners of Their Own Resources: Depletion in Parole Decision by Expert Judges”*Shai Danziger, Ben Gurion University, Israel**Jonathan Levav, Columbia University, USA**Liora Avnaim, Ben Gurion University, Israel*

Highly experienced decision makers, such as judges, doctors, and government officials, often make sequential decisions in a single session. For example, parole board hearings, psychiatric release boards, university acceptance committees, and deportation hearings all involve sequential decisions of individual cases with results that carry significant implications both for the individuals under review as well as the public.

Previous work indicates that making successive decisions is mentally taxing (Vohs et al. 2008), and that decision fatigue leads to simplified decision making, such as accepting default options (Levav et al. 2010). We test whether highly experienced judges who make repeated decisions are susceptible to similar depletion effects.

A substantial body of evidence supports the assumption that experts' judgments are well-calibrated and that they are less susceptible than non-experts to the influence of contextual variables (e.g., Carlson and Bond 2006). Here we examine experts' "decision endurance." Since experts may decide more efficiently and may be mindful of extraneous influences on the quality of their decisions, are they more equipped to make better calibrated decisions over time?

We study parole rulings of expert judges as a function of the temporal order of the rulings. Specifically, we examined whether the probability of granting parole—a deviation from the less effortful option of rejecting parole and maintaining the status quo—decreases for decisions later in the case sequence. Also, following work by Gailliot and colleagues (2007), we examine whether food breaks that separate decision sessions can counteract the negative effects of choice and replenish depleted mental resources. In particular, we test whether cases considered immediately following a break are associated with a greater probability of release than cases considered immediately prior to the break.

Our data include 410 parole cases of Israeli criminals incarcerated for a variety of crimes of differing severity (e.g., theft, assault, rape). Highly experienced justices ($N=13$) consider 15-30 daily cases, in succession. Judges either grant or deny parole. Parole hearings, which continue from morning until early afternoon, are held in three sessions. A 30 minute break that includes a breakfast snack and an hour long lunch break separate the three sessions. The average case duration is approximately 11 minutes long, and does not vary by session.

Results of a logistic regression showed that the probability of granting parole was strongly affected by the temporal order of the rulings. Consistent with the view that choice taxes mental resources and that food and rest may replenish them, we find that parole likelihood is highest at the start of each session and that it gradually decreases throughout a session. The only other predictor

variable that influenced the probability of granting parole was the number of times the prisoner had been incarcerated in the past.

The findings indicate that repeated judgments lead even experienced justices to prefer inaction and preference for the status quo (in this case imprisonment). Furthermore, it appears that these potentially detrimental effects of decision fatigue can be eliminated by a relatively simple intervention.

“Lead Us Not Into Temptation: Depletion Does Not Require Individual Self-control Use”

Joshua Ackerman, MIT, USA

Research on the depleting effects of self-control has typically focused on intrapersonal causes and outcomes (e.g., engaging in thought suppression leads a person to spend more money on luxury goods). However, interpersonal cognition and neuroscience evidence suggests that the self-control actions of other people may elicit depleting effects *even in people who did not use self-control themselves*. This possibility would shed new light on the mechanisms that underlie self-control depletion and on the basic nature of depletion itself. In turn, these would provide new insight into social consumption experiences and the situations in which consumers are likely to benefit (or not) from the presence of other consumers.

Two possibilities emerge from the interpersonal processing literature. First, perceiving others may automatically prime similar cognitions and behaviors. Just as a laugh track can make a mediocre comedy more appealing, perceiving another’s resistance of temptation may prime restraint in the perceivers (e.g., shopping with stingy friends may inspire less impulsive purchasing). An even more full-bodied outcome is suggested by research on mental simulation. Simulation occurs when actions and their downstream consequences are evoked purely through mental recreation of an event. Just as when we grimace watching someone else stub his/her toe, the simulation of one person’s resistance may produce the consequences of self-control use—self-regulatory depletion.

Four studies demonstrate interpersonal consequences of self-control use for two important topics in consumer decision-making—(1) resistance to persuasive messages (Studies 1 and 2) and (2) time perception and impatience (Studies 3 and 4). In each study, I focus on the question: Is there depletion by proxy?

The availability of self-control resources predicts the ability to resist especially persuasive messages (Burkley 2008). In Study 1, participants first read a story about a waiter who came to work at a high quality restaurant without having eaten recently and thus had to exert self-control in order to resist eating food on the job (or else risk being fired). Subsequently, participants viewed an advertisement for a shaving razor that featured either strong or weak messages. The degree to which participants automatically simulated (took the perspective of) the waiter was measured. Automatic perspective-taking was positively associated with favorability towards the ad, primarily when the ad messages were strong, suggesting that participants were no longer able to effectively resist these persuasion attempts. Study 2 used a similar paradigm but actively manipulated perspective-taking. The second task in this study involved reading an essay that advocated changing the school grading system to one that participants initially disliked. Simulating the perspective of the hungry waiter in the first task completely eliminated the negativity towards the grading change and led to a doubling of support for this previously disliked system.

Depleted individuals have also been found to overestimate the passage of time and make more short-term decisions (Vohs and Schmeichel 2003). In Study 3, participants completed a temporal discounting measure after being exposed to another’s self-control use. Those participants who simulated this self-control exhibited

more impatience by discounting the future more strongly (i.e., preferring smaller, sooner rewards to larger, later ones). In Study 4, the actual time spent reading a self-control story was recorded along with participants’ estimates of that time. Additionally, in a separate set of conditions, the waiter story was altered to involve a physically exerting, but self-control free, task. Participants who simulated the waiter’s use of self-control believed that more time had passed than participants who either did not simulate mental self-control or those who mentally simulated physical exertion.

In summary, the results of four studies indicate that self-regulatory depletion can result even when people are not exposed to temptation themselves. These findings raise important theoretical questions for models of depletion that rely on the exhaustion of physical resources. They also suggest interesting consequences for consumers, as when shoppers who exert self-control to avoid buying luxury goods impair the self-control of friends who are shopping with them.

The Effect of an Integrated Virtual Community on The Evaluation of an Online Store: Findings From an Internet Experiment

Peter Domma, Saarland University, Germany
Dirk Morschett, University of Fribourg, Switzerland
Hanna Schramm-Klein, University of Siegen, Germany
Joachim Zentes, Saarland University, Germany

ABSTRACT:

We examined the impact of three characteristics of a virtual community within an online store on consumer evaluations of that store. In particular, we focused on the exertion of retailer influence, the quality of the virtual community and the degree of sociability. An Internet experiment with 477 participants using a professionally designed shopping Web site was conducted, confirming the influence of all three characteristics.

INTRODUCTION

Forrester Research estimates that 74% of Europe's population will be online in 2011, and more than 176 million people will shop online (Dellner 2007). In addition, the use of the Web is changing dramatically. Applications that are summarized under the umbrella term "Web 2.0" used to refer to key concepts such as user empowerment and participation are changing the way consumers use the Web (Cheung, Lee and Rabjohn 2008). Implementing new strategies with regard to Web 2.0 will allow retailers to create competitive advantages. For example, a study by Brown, Tilton and Woodside (2002) showed that customers who participated in a virtual community (VC) provided by a Web site only accounted for about one-third of the visitors but generated two-thirds of the sales. As such, assessing the potential market opportunities in utilizing a VC becomes critical (Kim and Jin 2006).

As the topic of VCs is still at the early stages of research, there is little consensus regarding the definition of a VC (Kim and Jin 2006). Preece (2001) and Preece and Maloney-Krichmar (2005) identified a participatory design and employed the concepts of usability and sociability as the most important elements of a VC. A comprehensive literature review by Lee, Vogel and Limayem (2003) resulted in the working definition that VCs are cyberspaces supported by computer-based information technology centered upon communication and interaction of participants to generate member-driven content, resulting in relationships. The implementation of a VC can combine different aspects with various focuses, such as communities of transaction or communities of interest as described by Armstrong and Hagel III (1996); therefore, VCs can fulfill various types of human needs.

While research on the general concept of VCs is broad (Farquhar and Rowley 2006) and the implementation of a VC is acknowledged as an influential feature of business-to-consumer (B2C) Web sites, there is still a lack of studies investigating the influence of VCs on consumer perceptions of the transactional and relational qualities of a shopping Web site. Only a few exploratory studies have reported on the usefulness of a VC in an e-commerce context (Gupta and Kim 2004). Furthermore, the effects of different VC characteristics on consumer evaluations are widely unknown. We therefore identified three VC characteristics as influencing factors of consumer evaluations from prior literature and practical evidence. These include the exertion of influence by the operator (i.e., the retailer), the quality of the VC and the degree of sociability. We investigate the effects of these determinants on consumer perceptions of the

transactional and relational qualities of a shopping Web site by means of an online experiment.

EFFECTS OF VIRTUAL COMMUNITIES ON CONSUMER EVALUATIONS

We expect that the integration of a VC within the experimental shopping Web site to have a positive effect on consumer evaluations by improving their shopping experience and emotional reactions when visiting the online store. Past research has examined facets of consumer evaluation and acceptance of an information technology from two different perspectives (Dahui, Browne, and Wetherbe 2006). The first perspective, often called the transactional perspective, views a Web site as an information technology and thus focuses on cognitive factors such as perceived usefulness or perceived ease of use. A second perspective refers to the affective or relational components of a Web site such as perceived enjoyment. Recent literature has emphasized the importance of investigating the driving factors of Web site usage beyond cognitive factors, especially because of the changing nature of the Web (Loiacono, Watson, and Goodhue 2007).

Following the research that integrates the transactional and relational perspectives (Gefen and Straub 2004; Moon and Kim 2001), we conceptualize consumer evaluations using six constructs. The transactional perspective in our study includes the key antecedents of the intention to use a technology identified by the Technology Acceptance Model (TAM) (Davis 1989), namely, *Perceived Ease of Use (PEOU)* and *Perceived Usefulness (PU)*. As originally defined by Davis (1989, 320), PEOU refers to "the degree to which the prospective user expects the target system to be free of effort". With regard to e-commerce, PU of a Web site is "the extent to which an individual perceives a web-site to be useful in performing shopping tasks" (Kumar and Benbasat 2006, 428). We add *Perceived Risk (PRisk)* following Mitchell (1999) to comprise two components, namely, the perceived probability of a loss and the subjective evaluation of potential unfavorable consequences.

To capture the relational perspective of consumer evaluations, we consider three dimensions. *Perceived Social Presence (PSP)* is defined as to extent to which a medium is perceived to be warm if it conveys a feeling of human contact and sensitivity to the user (Hassanein and Head 2004). *Perceived Enjoyment (PEn)* refers to the extent to which the activity of using an information technology is perceived to be enjoyable, aside from performance consequences (Davis, Bagozzi, and Warshaw 1992). Following McMillan and Hwang (2002), this study defines *Perceived Interactivity (PInt)* as the extent to which users perceive the online store to enable (many-to-many) communication, to provide control (i.e., in terms of speed, navigation and content), and to respond to user requests.

HYPOTHESES

The investigated determinants of consumer evaluations (i.e., VC characteristics) include the exertion of influence by the operator, the quality of the VC and the degree of sociability.

Concerning the *exertion of influence* on the VC by the operator, this can, on the one hand, be valued positively by members. For example, an operator can establish codes of behavior (i.e., netiquette or guidelines) to contain potential conflict (Leimeister, Sidiras, and Krcmar 2006). Andrews (2002) argued that operators must facilitate the formation of subgroups as well as reward and acknowledge member contributions. In these cases, a certain level of exertion of influence and contribution to the VC by the operator is needed to establish such structural patterns. The positive effect of a higher exertion of influence is supported by the literature on trust, which proposes that an organization must demonstrate its honesty, benevolence and competence to its members (Gefen 2000). In the context of a VC, the operator can show benevolence by being concerned for the welfare of the members of the VC; it can also demonstrate its competence if its contributions to the VC are significant and generate value (Flavián and Guinalú 2006).

On the other hand, a very strong influence by the retailer will make consumers feel that the retailer tries to act in an opportunistic manner and exercises too much control (Flavián and Guinalú 2006). The negative effect can be explained by the elaboration likelihood model (ELM) (Bhattacharjee and Sanford 2006) as a theoretical model of information adoption in computer-mediated communication (CMC) contexts. ELM posits that a message can influence people's attitudes and behaviors with source credibility acting as the peripheral influence (Cheung, Lee, and Rabjohn 2008). Source credibility refers to a message recipient's perception of the credibility of a message source; information provided by highly credible sources is perceived to be useful and reliable (Ko, Kirsch, and King 2005). In the context of CMC, user-generated content has found to be more credible than marketer-generated information (Bickart and Schindler 2001), which means that increasing the exertion of influence by the operator beyond a certain level will lead consumers to evaluate the credibility of information more negatively. Furthermore, reactance theory (Brehm 1966) implies that when people feel that their freedom to choose an action is threatened, they become motivated to reestablish the threatened freedom, which is the case in which content generated by the operator dominates the VC and consumers feel that the retailer acts in an opportunistic manner. Reactance theory also indicates that reactance must reach a certain intensity and thus surpass a threshold point for the perception of threat to take effect. These arguments indicate that a higher exertion of influence by the operator does not in every case lead to a more positive evaluation by the consumers and vice versa. Hence, we assume the effect of the exertion of influence to be nonlinear. This means that given a moderate exertion of influence and either a high or a low exertion, we expect a more positive evaluation from moderate exertion.

We propose that shifting intensity of the exertion of influence by the operator of the VC (i.e., the retailer) will have an effect on consumer PRisk because information from an independent third-party (e.g., other users) is perceived as more credible than information that comes directly from the retailer (Weathers, Sharma, and Wood 2007). We also propose an impact on consumer PU, since information provided by commercial sources is perceived as less useful, as well as on relational factors, that is, PEn and PInt. We expect the latter impact because too much influence by the operator hampers the sense of community among users and their perceived control over their community. Thus, we hypothesize:

Hypothesis 1.1: Compared to a low exertion of influence, a moderate exertion of influence on the VC by the retailer will lead to (a) higher PU, (b) lower PRisk, (c) higher PEn and (d) higher PInt.

Hypothesis 1.2: Compared to a high exertion of influence, a moderate exertion of influence on the VC by the retailer will lead to (a) higher PU, (b) lower PRisk, (c) higher PEn and (d) higher PInt.

As one of the most relevant factors of a VC, the literature highlights the depth, timeliness and quality of content (Farquhar and Rowley 2006). In a recent study by Leimeister, Sidiras and Krcmar (2006), content-related factors were ranked high in terms of relevance by VC members. As mentioned by Preece (2001), the volume, quality and timeliness of the information provided in a VC are factors that affect member engagement in the community, implying that those factors have a huge impact on the positive or negative evaluation by consumers of the VC. We therefore hypothesize a positive effect of high quality information on the perceived usefulness and ease of use. We also expect consumers to perceive the online store as more enjoyable if the depth, timeliness and quality of content are at high levels. As described by Koufaris (2002), product information searches can be fun-seeking experiences. We expect that the use of a comprehensive and lively virtual community can make the shopping experience more fulfilling and enjoyable. Based on our conceptualization of perceived interactivity (i.e., in terms of communication, control and response), we assume that the quality of the VC will affect the perceived possibility of communication as well as the perceived control over navigation and content. Referring to *VC quality*, we therefore hypothesize:

Hypothesis 2: If the integrated VC is of high quality, consumers evaluate the online store more positively as compared to an online store in which the integrated VC is of low quality. In particular, they rate the online store more positively with respect to (a) PEOU, (b) PU, (c) PEn and (d) PInt.

The impersonality of online retailing is still one of the major problems facing this distribution channel, which may be solved by the usage of Web 2.0 instruments. For example, a VC may help substitute for the personal treatment a consumer is given in bricks-and-mortar stores (Flavián and Guinalú 2005). The term *sociability* relates to the development of software, policies and practices to support social interaction online (Preece 2001). One important determinant of success concerning sociability is the provision of information about community members, including, for example, what roles they are taking or how experienced they are (Preece 2001). We therefore assume that increasing sociability by adding more personal information on users will lead to a higher PSP.

The traditional concept of word-of-mouth as relating to personal sources of information takes the relational closeness between a decision maker and a recommendation source as its basis (Brown and Reingen 1987). With the advent of Web 2.0 and the integration of personal information on users within user-generated content, there is the possibility to implement such strong ties in the form of electronic word-of-mouth (eWOM). This can help to create a higher PU of online information and a lower PRisk in the buying decision.

The theory behind the effect of sociability on perceived enjoyment is based on literature that classifies information systems as hedonic (Heijden 2004). We act on the assumption that adding more social cues to the VC will move the nature of the information system toward a hedonic information system, which will be perceived as more enjoyable. Finally, based on the conceptualization of perceived interactivity, we expect a strong impact of sociability on the perceived possibilities to communicate with others:

Hypothesis 3: If the integrated VC provides a higher degree of sociability, then consumers evaluate the online store more positively as compared to an online store in which the integrated VC provides a lower degree of sociability. In particular, they rate the online store more positively with respect to (a) PU, (b) PRisk, (c) PSP, (d) PEn and (e) Plnt.

METHOD

Experimental Design

To test our hypotheses, we used a professionally designed fictitious online-shop. We chose to integrate two different areas into the VC. First, there was an area with a discussion forum, which has been identified as a popular feature of VC Web sites

(Pitta and Fowler 2005). Second, in order to address the aspects of a community of relationships and to manipulate sociability in the experiment, a user profiles section was added. Some screenshots illustrate the Web site and the VC (figure 1). All content within the online store and the VC has been sampled and adapted from real stores, discussion forums and virtual communities on the Web.

A laboratory 3x2x2 between-subject experiment was conducted. Given the need to control for shopping Web site and VC features, this design allowed us to isolate the effects of the different VC aspects on consumer responses.

Exertion of influence. Manipulation of factor 1 (exertion of influence: low/moderate/high) was achieved by varying the number of forum posts by an administrator. Note that the name and picture were chosen in a way that the association between the administrator and the retailer was obvious. In conditions with a low exertion of influence, the retailer did not appear in any forum post, whereas the discussion forum contained posts by the retailer in 50% of threads

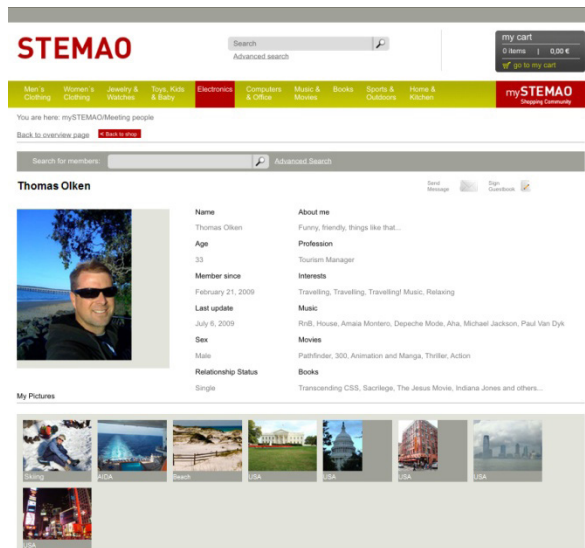

Figure 1: Sample screenshots

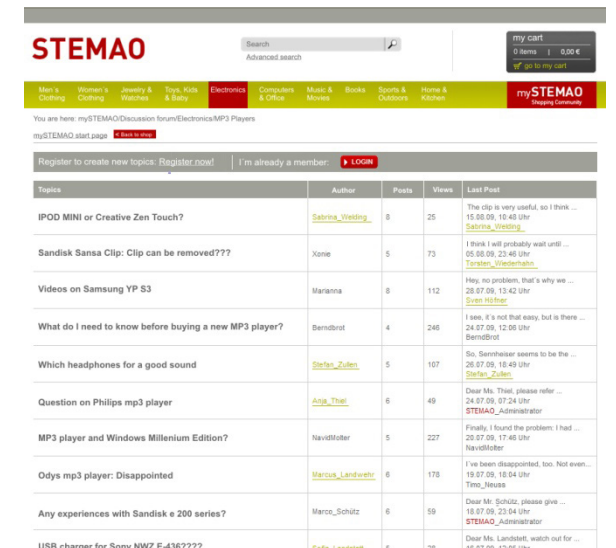

Product page with hyperlink to the VC

Start page of the VC

Example from the user profile section

Discussion forum overview page

for the moderate condition, and posts appeared in every thread for the high condition.

VC quality. The quality of information is evaluated in terms of information content, accuracy, format and timeliness (Cheung, Lee, and Rabjohn 2008). In our study, we focused on comprehensiveness as well as timeliness as grouped under the umbrella term “virtual community quality”. To manipulate the virtual community quality (low/high), we varied the number of contributions to the discussion forum, the comprehensiveness of the content and the timeliness of contributions from group to group. The low quality setting contained very few threads with few posts within the threads; all entries were at least eight months old. We also manipulated the displayed number of views on the forum overview page.

Sociability. To manipulate the sociability (low/high) of the VC, a user profiles section was either present or absent within the VC. Depending on the experimental condition, the community start page contained a section to enter only the section with the discussion forum (conditions 1-6) or the discussion forum *and* the user profiles (conditions 7-12) or. Additionally, respondents who were assigned to conditions 7-12 also had the ability to follow hyperlinks on user aliases in the discussion forum. In the user profiles section, respondents had different ways of accessing the individual profiles (e.g., only the newest profiles or the full list of profiles could be viewed) and information on the profiled person, including profile picture, name, age, interests and his or her personal guestbook. All profiles were checked for plausibility (e.g., fit between age, gender and interest) and conformity with the cover story (e.g., language usage) in a pretest.

Procedure

To avoid participant awareness bias, we chose a non-forced exposure design and developed a cover story to avoid respondents guessing the actual purpose of the study and to induce the impression that they would be examining a portion of a real online store. After a short briefing on the experimental task (i.e., respondents were told to search for information about products in the online store and to choose one product), participants were forwarded to the overview page, which displayed the first three products, namely, mp3 audio players. From this page, participants were able to access the other overview pages as well as the individual product pages containing detailed information about the products. A button with a hyperlink to the VC (labeled “Find out more in our community”) was present on the page header as well as at the end of every product page. Respondents were free to visit the VC. Participants who followed this link were lead to the VC. On every page of the VC, a link was avail-

able to return to the online store and the product pages. Respondents who did not enter the VC were assigned to the control group. After putting the selected product in the shopping cart and confirming their decision to purchase, respondents were forwarded to the online questionnaire. We first surveyed the dependent variables and then the variables for manipulation checks in order to avoid respondents recognizing the actual purpose of the study before answering the questions on the dependent variables.

Measurement

The dependent variables in this study were captured by an online questionnaire assessing constructs on a multiple-item seven-point scale (1=strongly disagree, 7=strongly agree). All measurement scales were pretested. To assess PEOU, we chose five reflective items based on Davis (1989) and Gefen, Karahanna and Straub (2003). The reflective five-item-scale for measuring PU was adopted from past applications of the TAM (Agarwal and Karahanna 2000; Davis 1989; Gefen, Karahanna, and Straub 2003). Both measurement models showed a high level of scale reliability; Cronbach’s Alpha was .91 for PEOU and .93 for PU. We chose a reflective measurement approach for the dimensions of PSP (five indicators, Cronbach’s Alpha = .97), all of which were adapted from validated constructs developed by Cyr et al. (2007). To capture PEn, we followed the conceptualization of Hassanein and Head (2005), Moon and Kim (2001) and van der Heijden (2004) (four indicators, Cronbach’s Alpha = .92). Measures of sampling adequacy values (MSA) and factor loadings for the items of all scales exceeded .50; item-to-total correlations surpassed .40. As AVE for all reflective constructs mentioned above is greater than the squared correlation between that construct and any other construct, discriminant validity is confirmed.

PRisk was operationalized in a formative way to capture functional risk, financial risk as well as the risk of mispurchase (Cunningham 1967). None of the indicators revealed multicollinearity problems (all VIFs were well below 10; condition indices were all below 30). We also assessed nomological validity by analyzing bivariate correlations between the formative construct and a single item of trust, a construct that is closely related to PRisk and has been included as additional construct in the questionnaire. Bivariate correlations were strong and significant ($r = .57, p < .001$). The formative measure of PInt consists of a second-order formative factor composed of three components. Factor analysis of six items selected from past research on interactivity (Jee and Lee 2002) revealed three reflective components, namely, control, response and communication. Based on the theoretical work of McMillan and Hwang (2002), a formative construct of PInt was computed

Table 1: Experimental conditions

Condition	Treatments		
	Factor 1: exertion of influence (3)	Factor 2: VC quality (2)	Factor 3: sociability (2)
1	Low	Low	Low
2	Moderate	Low	Low
3	High	Low	Low
4	Low	High	Low
5	Moderate	High	Low
6	High	High	Low
7	Low	Low	High
8	Moderate	Low	High
9	High	Low	High
10	Low	High	High
11	Moderate	High	High
12	High	High	High

from these three dimensions. None of the indicators revealed multicollinearity problems. Nomological validity was assessed by measuring bivariate correlations between the formative construct of PInt and a single item of interactivity, which also was included in the questionnaire. Bivariate correlations were highly significant ($r = .73, p < .001$).

Sample and Manipulation Checks

The final dataset consists of 477 participants, of which 264 participants visited the VC and 213 did not. Respondents range in age from 16 to 65 years, with a mean age of 32.3 years. 50.3% of participants are female.

Manipulation checks were performed to control for the effectiveness of the treatments. To test for the perceived exertion of retailer influence on the VC, which was measured by a single item, an ANOVA analysis indicated that the three groups were significantly different ($F(2, 263) = 45.516, p < .001$). The results of post-hoc Scheffé tests confirmed that statistically significant differences existed between all groups. Manipulation of VC quality was checked with a variable that was characterized by three indicators, namely, the number of contributions to the message board (threads), the comprehensiveness of content (posts) and the timeliness of contributions. As intended, participants in the low quality sample perceived the VC as of lower quality ($M = 2.64$) than those in the high quality sample ($M = 4.69, F(1, 263) = 221.235, p < .001$). To ensure the successful manipulation of sociability, we removed those respondents from the dataset that were assigned to conditions including the presence of the user profiles section (high sociability) but reported that they did not see that particular part of the VC. Moreover, entering the VC at any point was observed by collecting participant identifications in a SQL database; respondents who actually visited the VC but reported to have not visited the VC were removed from the data set.

RESULTS

The data was analyzed using a 3x2x2 MANCOVA due to the orthogonal between-subject design. Because past research showed a strong influence of *product involvement* and *Internet experience* on consumer behavior in an e-commerce setting, we included both as covariates. We first tested the overall null hypothesis as a screening analysis. The Wilks Lambda multivariate tests of overall group differences were all statistically significant for the main effects ($p < .001$). Regarding interaction effects, *exertion of influence x sociability* was found to be significant (Wilks' Lambda: Multivariate $F =$

1.899, $p < .05$). Referring to factor 1, univariate between-subject tests showed that the exertion of influence was significantly related to PU, PRisk and PInt.

Contrast analysis reveals that statistically significant differences existed among all groups for PU (contrast estimate (c.e.)_{low vs. moderate} = -.333 with $p < .05$; c.e._{moderate vs. high} = .700 with $p < .001$), PRisk (c.e._{low vs. moderate} = .297 with $p < .05$; c.e._{moderate vs. high} = -.601 with $p < .001$) and PInt (c.e._{low vs. moderate} = -.216 with $p < .05$; c.e._{moderate vs. high} = .289 with $p < .01$). All comparisons are in the expected directions. We therefore find support for hypotheses H1.1a, H1.1b, H1.1d, H1.2a, H1.2b and H1.2d. The results show that consumers tend to positively evaluate a moderate exertion of influence by the retailer, whereas a high influence leads to a negative effect on PU, PRisk and PInt. Moreover, respondents in the group with low exertion of influence also rated the online store to be less useful for shopping tasks and perceive a higher risk than respondents in the group with moderate exertion of influence. Furthermore, respondents evaluated the online store to be less interactive. As table 1 reveals, the exertion of influence does not have an effect on PEn, and therefore, hypotheses H1.1c and H1.2c must be rejected. Obviously, the exertion of influence mainly affects transactional factors, especially the risk perceived by respondents.

Because a significant interaction was found between the factors *exertion of influence* and *sociability* by multivariate testing, the main effects were qualified by this interaction. To further examine this interaction, we performed univariate tests and found the interaction to be significant only for PRisk. Even though the interaction effect size was small, apparently the presence of the user profiles section and the linking of aliases to profiles in the discussion forum have some alleviative effect on the negative impact of the high exertion of influence (figure 2).

Whereas respondents perceive a higher risk in purchasing from the online store in the group with high exertion of influence when the user profiles section is absent and sociability is low, this negative effect nearly disappeared when sociability was high and user profiles were present.

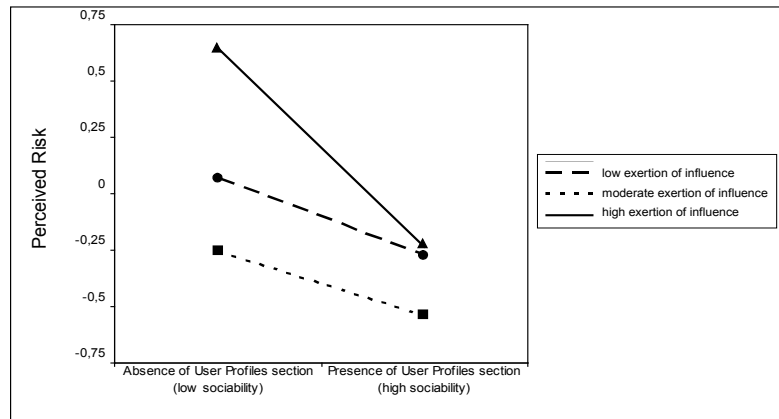

To test hypotheses H2, univariate F-tests showed that the high quality group ($M_{PEOU} = .528; M_{PU} = .369; M_{PEn} = .334$) scored significantly higher than the low quality group ($M_{PEOU} = -.105; M_{PU} = -.149; M_{PEn} = -.018$) with respect to PEOU, PU and PEn. There was no statistically significant difference between the two groups with respect to PInt. These findings supported hypotheses H2a, H2b and H2c, whereas H2d is rejected. The effect of VC quality

Figure 2: Joint effect of exertion of influence and sociability on PRisk

was highly significant for the transactional constructs of PEOU and PU, indicating that comprehensiveness and timeliness of content are effective components of consumer transactional evaluations. With regard to relational components, the results showed that the use of a comprehensive and lively VC makes the shopping task a more enjoyable experience. Further analyses supported hypotheses H3b, H3c, H3d and H3e. The comparison of the effects of high versus low sociability of the VC on PRisk, PSP, PEn and PInt were significant with large effect sizes for PSP and PEn. We found no support for hypothesis H3a ($F(1, 263) = 3.56, p > .05$); that is, the degree of sociability does not affect the perceived usefulness of the online store. Apparently consumers in an online environment tend to disregard the importance of tie strength (i.e., in terms of similarity, expertise and accessibility) as posited by traditional WOM theory, because the presence of user profiles does not lead to a higher PU. With regard to relational factors, the presence of user profiles (i.e., indicating high sociability) seems to be adequate to convey a feeling of human contact and warmth, thus increasing PSP. Moreover, the effect of changing the nature of the online store by adding the user profiles section is clear for PEn and PInt.

IMPLICATIONS

This study investigated how to design an integrated VC within an online store with regard to different characteristics; thus, this study has various implications for marketers. First, retailers should pay attention to the exertion of influence on the VC. We showed that consumers tend to positively react to an increased exertion of influence by the retailer only to a certain point, beyond which an increasing exertion of influence leads to a negative effect on perceived usefulness, risk and interactivity. This effect seems to take the shape of an inverted U-form. However, online marketers may be able to compensate for the negative effect of a high exertion of influence by integrating user generated content areas and social cues within the shopping Web site, as there is a moderating effect of sociability on the effect of a higher exertion of influence with respect to perceived risk. Hence, e-retailers can, for example, boost sales with specific messages regarding new products or sales without consumer reactance if they simultaneously encourage a lively VC with a substantial number of social cues exchanged between members.

As indicated by past research, our study confirms that VC quality is also important in the e-commerce environment with

regard to transactional factors like perceived ease of use or usefulness as well as relational factors like perceived enjoyment. Only if consumers find the information they need and have the feeling that they are part of a vital community the positive effect of the VC appears. Finally, our investigation shows that the existence of the user profiles section of the VC has an enormous impact on relational factors of consumer evaluations of the online store such as perceived social presence or enjoyment, which is demonstrated by the large effect sizes. Referring to the rapid growth of this community type and its impact on the everyday lives of consumers, retailers can be recommended to provide these profiles in their VCs.

Our study provides evidence on re-embedding strategies that utilize social cues to infuse social presence through a Web interface, which can help to make the virtual interaction more similar to traditional shopping environments and thus lead to an enhanced online experience (Cyr et al. 2007). However, there was no effect of adding such social cues on perceived usefulness. This reveals an important difference between offline WOM and eWOM. Research on offline word-of-mouth emphasizes the importance of the closeness of relationship between the decision maker and the recommendation source. This closeness is determined by how the decision maker is able to evaluate similarity between the decision maker and the recommender as well as the expertise and credibility of the recommender. In our study, consumers tend to focus on the benefit of collective intelligence provided by user-generated content in a VC rather than on detailed information about particular recommendation sources.

The Role of Perceived Review Credibility in the Context of Brand Equity Dilution Through Negative Product Reviews on the Internet

Silke Bambauer-Sachse, University of Fribourg, Switzerland
Sabrina Mangold, University of Fribourg, Switzerland

ABSTRACT

In this paper, we examine effects of negative online product reviews on consumer-based brand equity as well as the role of review quality and perceived review credibility. The results of our study show that brand equity dilution increases with increasing review quality and that review credibility plays an important role.

INTRODUCTION

A look at the historical development of the Internet as a source of product-specific information shows that, in a first phase, product-specific information was mainly provided by producers and retailers whereas a more recent phase is characterized by the trend that consumer-based product information in terms of product reviews, as a specific type of online word-of-mouth (WOM) communication, can be increasingly found in addition to company-based information. In the light of this trend, the finding that consumers are more susceptible to WOM communication than to company-based product information (Bickart and Schindler 2001; Herr, Kardes, and Kim 1991; Smith, Menon, and Sivakumar 2005; Trusov, Bucklin, and Pauwels 2009) leads to the assumption that consumer-based online product reviews have a comparatively strong impact on consumer behavior (Chatterjee 2001; Chevalier and Mayzlin 2006; Kiecker and Cowles 2001; Sen and Lerman 2007; Xia and Bechwati 2008). In addition, companies only spread positively valenced information, whereas consumers especially tend to share negative experiences with as many people as possible (Chatterjee 2001) and to look for negative product reviews because negative information is considered as more diagnostic than positive or neutral information and thus is weighted more heavily in judgments (Herr et al. 1991). Consequently, from a company's perspective, negatively valenced online product reviews are very harmful. Regarding the persuasiveness of online product reviews, it is important to consider that, over time, consumers have become more skeptical about consumer generated information that is provided on the Internet. This skepticism is due to news publications about Internet abuses (McKnight and Kacmar 2006) and the fact that people who provide information on the Internet are anonymous. In addition, the fact that such information is unfiltered (Cheung et al. 2009) and that marketers use the anonymity of the Internet to disguise their promotions as consumer recommendations or to pay people for writing negative online reviews about competitor products foster consumer skepticism.

Consequently, it is interesting to analyze whether effects of negatively valenced online product reviews generally exist or whether such effects depend on factors such as review quality and subjectively perceived review credibility. According to Park, Lee, and Han (2007), we refer to review quality as the relevance, understandability, sufficiency, objectivity, and persuasiveness of a review's content. Thus, high-quality reviews provide matter-of-fact information about product characteristics, whereas low-quality reviews are emotional, subjective and do not provide factual information. Perceived review quality is derived from the concept of source credibility which represents the extent to which a person who is processing the information provided by the source evaluates the source as being knowledgeable, qualified, experienced, trustworthy, and able to provide unbiased, objective information (Belch and Belch 2001).

In this paper, we consider the situation where consumers have the intention to purchase a specific product and visit opinion plat-

forms to learn about other consumers' evaluations of this product before making the final purchase decision. We only consider online product reviews posted on opinion platforms that are independent of producers or retailers because this is the most widely used type of online WOM communication (Hennig-Thurau et al. 2004). The target variable with regard to which we examine effects of online product reviews is consumer-based brand equity. Consumer-based brand equity corresponds to consumers' perceptions of a product's additional value that is generated by the brand name (Park and Srinivasan 1994) and is based on associations with the brand which are activated in response to the brand name (Krishnan 1996). These associations are composed of perceived brand attributes and brand benefits such as product quality (Keller and Lehmann 2006; Krishnan 1996). Since the late 1980s, brand equity has been one of the most important marketing concepts in both research and practice (Srinivasan, Park, and Chang 2005). Thus, the objectives of our research are to examine the effects of negative online product reviews on consumer-based brand equity in terms of brand equity dilution depending on review quality and to analyze the mediating role of perceived review credibility in the relation between review quality and brand value perceptions that are a pre-stage of brand equity. This paper adds to the existing body of research because studies on the link between negative online WOM communication and the dilution of consumer-based brand equity are scarce. Moreover, no study has examined in detail the role of perceived review credibility in the relation between review quality and consumer-based brand equity. In addition to addressing researchers, our paper addresses marketers by showing that online product reviews can have negative consequences for companies and by offering insights into the processes that underlie these effects.

EMPIRICAL AND THEORETICAL BACKGROUND Previous Research on Review Quality and the Role of Perceived Review Credibility

Concepts such as message quality and perceived credibility have been subject to several studies in the field of offline communication (Dholakia and Sternthal 1977; Heesacker et al. 1983; Hovland and Weiss 1951-52; Jain and Posavac 2001; Nan 2009; Sternthal, Dholakia, and Leavitt 1978). However, as information processing in online environments differs considerably from offline information processing, we do not consider these studies in more detail. We will instead focus on research on effects of quality/perceived credibility of online product reviews.

In the field of online communication, only three studies cover review quality and/or perceived review credibility. Although none of these studies exactly examines the effects we are interested in, we will shortly summarize them because they still provide interesting aspects with regard to our study purpose. In a basic study, Park et al. (2007) investigated whether the quality of online product reviews can affect consumers' purchase intentions and found that this effect is significant. Note that this study did not include perceived review credibility and only examined effects of positive online product reviews. However, the findings of this study provide the notion that the quality of online product reviews plays an important role with regard to typical marketing response variables.

In another study, McKnight and Kacmar (2006) analyzed the role of perceived information credibility at the example of a legal advice website for consumers. Their results show that perceived

information credibility significantly mediates the relation between factors such as individual characteristics, technology affinity as well as the initial impression of the website, and the willingness to follow the provided legal recommendations. Note that this study did not test effects of consumer-based information, but effects of legal recommendations provided by experts and that this study does not cover negatively valenced information. However, the findings of this study are interesting with regard to our study purpose because they show the mediator effect of perceived credibility in the context of processing information that is provided on the Internet.

A study conducted by Cheung et al. (2009) has most in common with our research purpose. They examined the mediating role of perceived credibility in the relation between the argument strength of positively and negatively valenced online consumer recommendations and the intention to adopt the recommendation. They found that argument strength has a positive effect on perceived credibility which in turn positively influences the intention to adopt the recommendation. Starting from these findings, it is interesting to examine the mediating role of perceived credibility in the relation between review quality and more concrete consumer response variables such as brand value perceptions.

Theoretical Background of Effects of Online Product Reviews on Consumer-Based Brand Equity and the Role of Review Quality and Perceived Review Credibility

In a first step, we will shortly discuss the concepts of brand equity and brand equity dilution. We refer to brand equity as a synonym for consumers' brand beliefs, attitudes and behavioral intentions (Ailawadi, Lehmann, and Neslin 2003; Farquhar 1989; Keller and Lehmann 2006). According to Keller (1993), consumer-based brand equity describes the differential effect brand knowledge has on consumers' value perceptions of brands that are comparable with regard to their major attributes. Consumer-based brand value perceptions as a pre-stage of brand equity comprise aspects such as brand associations, perceived quality (Aaker 1991; Farquhar 1989; Keller 1993; Silverman, Spott, and Pascal 1999; Washburn and Plank 2002) and aspects of consumer behavior such as purchase intentions and willingness to pay (Agarwal and Rao 1996; Faircloth, Capella, and Alford 2001; Yoo, Donthu, and Lee 2000). The concept of brand equity dilution reflects the idea that information processing can result in a revision of brand evaluations (Buchanan, Simmons, and Bickart 1999; Loken and Roedder John 1993; Roedder John, Loken, and Joiner 1998) through the weakening of important brand value perceptions. Such effects can result in lower purchase intentions (Pullig, Simmons, and Netemeyer 2006). Thus, in the context considered here, we refer to brand equity dilution as a revision of consumer-based brand value perceptions that differ across brand knowledge.

Note that brand equity and thus also brand equity dilution can only be examined on an aggregate level if brand knowledge is a between-subjects factor. Consequently, the below derived research hypotheses will contain brand equity as dependent variable if an analysis on an aggregate level is sufficient and brand value perceptions which constitute a pre-stage of brand equity as dependent variable if a more detailed analysis is needed.

In the following, we will first explain theoretically why online product reviews can have considerable strong effects on consumer-based brand equity. Afterwards, we will provide a theoretical explanation for the mediating role of perceived review credibility in the considered context.

In order to build up a theoretical framework for effects of negative online product reviews on brand equity we draw on previous studies on brand equity dilution in different fields of research such as brand extensions (Loken and Roedder John 1993; Milberg, Park,

and McCarthy 1997; Roedder John et al. 1998), retailing (Buchanan et al. 1999), and product-harm crises (Dawar and Pillutla 2000). A theoretical approach that can be found in this type of literature and that can be used to explain effects of negative online product reviews is the so-called search and alignment theory. According to this approach, consumers who initially have positive attribute-specific product information and then are faced with negative attribute-specific product information that challenges the initial impression, tend to revise this impression into the direction of the challenging information (Pham and Muthukrishnan 2002).

In our case, the initially positive attribute-specific product information translates into initially positive brand value perceptions that are due to the fact that consumers who are interested in buying a particular product have formed their intention to purchase the product on the basis of an initially positive evaluation of relevant product attributes. Furthermore, the negative information provided in online product reviews can be interpreted in terms of the negative attribute-specific product information because the authors of such reviews often report their experiences with a particular product in a very detailed way. Consequently, we explain effects of negative online product reviews on brand equity in terms of brand equity dilution as follows. Consumers who are faced with such online product reviews weight negative reviews more heavily than possibly also found positive ones. Processing negative online product reviews further means dealing with attribute-specific product information that is contrary to the initial brand value perceptions. Consequently, consumers are likely to revise their initial brand value perceptions into the direction of the negative online product reviews, which leads to brand equity dilution. The presented arguments lead to our first and basic research hypothesis:

Hypothesis 1: Negative online product reviews have detrimental effects on consumer-based brand equity which occur in terms of brand equity dilution.

With regard to effects of review quality on consumer-based brand equity, we draw on literature in the field of effects of strong versus weak arguments. According to Petty and Cacioppo (1983), strong arguments provided in a message represent high message quality and lead to a stronger attitude change into the direction of the message than do weak arguments that correspond to low message quality. Consequently, we argue in our second hypothesis:

Hypothesis 2: High-quality product reviews have stronger effects on consumer-based brand equity in terms of brand equity dilution than have low-quality product reviews.

The literature provides the following arguments with regard to the role of source credibility in the context of information processing. First, in computer-mediated communication, it is difficult to evaluate attributes such as attractiveness and physical appearance of the information source (Cheung et al. 2009) and thus, cues such as content credibility play a considerable role. Second, the cognitive response hypothesis (Greenwald 1968) proposes that when an issue is personally involving or relevant, people are more motivated to think about the information provided by a highly than by a less credible source. Moreover, attitudes are rather determined by argument quality if a message is presented by a highly credible source (Heesacker, Petty, and Cacioppo 1983).

In the context considered here, we focus on high-involvement products because especially in high involvement contexts, people are motivated to consult opinion platforms before making their

purchase decisions. Thus, the arguments provided by the cognitive response hypothesis can be transferred to the context considered here as follows. The quality of negative online product reviews has an effect on perceived review credibility which in turn has effects on consumer-based brand equity. The latter effect can be explained by the fact that consumers are more motivated to think about the information provided in the online product review and to modify their brand value perceptions into the direction of the evaluation provided in the review if this review seems to be credible. These arguments lead to our third research hypothesis:

Hypothesis 3: Perceived credibility of a negatively valenced online product review mediates the relation between review quality and consumer-based brand value perceptions.

EMPIRICAL STUDY

Test Products

We decided to use different test products to cover several product categories. Thus, we used one utilitarian (computer notebook), one hedonic (digital camera), and one hybrid product (a product with both utilitarian and hedonic features: multimedia mobile phone). We chose high-involvement products that were familiar to the respondents because especially such products are frequently subject to WOM communication (Ha 2002). This phenomenon can be explained by the fact that only in the case of high involvement, consumers are willing to process detailed product-related information and thus are motivated to write and look up online product reviews.

Pretests

We conducted a first pretest to identify the average number of online product reviews people read on opinion platforms before making a purchase decision. In a university computer room, 20 test participants were asked to imagine that they intended to buy a specific product and then received the instruction to spend as much time as they would need in a real situation on an opinion platform to read as many reviews on this product as they thought to be appropriate.

Afterwards, people were asked to indicate the number of online product reviews they had read. The results show that on average, people read 2.6 reviews. Thus, we decided to use three reviews as test stimuli for the main study.

We conducted a second pretest to find high- and low-quality product reviews. In a first step, we looked at several opinion platforms to get an impression of the average length and the typical content of high- and low-quality product reviews on such platforms. We found that high-quality reviews usually have a length of about 350 words and contain attribute-specific information, whereas low-quality reviews have about half the length of high-quality reviews and rather express emotions. We then selected six negatively valenced online product reviews for each product (three reviews that we a-priori judged to be of high quality and three other reviews that we considered as low quality reviews) from a real opinion platform. In order to select the online product reviews, we used the criteria indicated by Belch and Belch (2001) and additionally considered the review quality ratings provided on the platform. The high-quality reviews we chose were more logical and persuasive and gave reasons based on specific facts about the product whereas the low-quality reviews we chose were emotional, subjective, did not offer any factual information, and simply provided a recommendation.

Thirty respondents participated in the pretest on perceived review quality. Each respondent rated the six online reviews for one of the products on the basis of five items that measured review quality (e.g., helpful/informative review, precise information, reviewer has a comprehensive knowledge etc.) on seven-point scales. The five single items were aggregated to an overall value for perceived review quality. The resulting mean values are shown in table 1.

A post-hoc analysis showed that the mean value differences among the online product reviews that were a-priori chosen as low-/high-quality reviews were not significant whereas the mean values of the low-quality reviews and the high-quality reviews differed significantly.

A third pretest was needed to prove that the chosen online product reviews were indeed judged as negatively valenced reviews. Thus, we asked another 30 people to participate in the negativity pretest.

Table 1
Results of the Pretest on Perceived Review Quality

Review	A-priori assigned review quality	Perceived review quality		
		computer notebook	digital camera	mobile phone
1		1.42	1.78	1.58
2	low	2.08	2.34	2.20
3		1.52	1.68	1.54
4		5.16	4.64	4.62
5	high	5.40	5.62	5.50
6		5.86	5.84	5.96

Table 2
Results of the Pretest on Perceived Review Negativity

Review	Review quality	Perceived review negativity		
		computer notebook	digital camera	mobile phone
1		6.10 ($t = 6.03, p < .001$)	6.20 ($t = 8.82, p < .001$)	6.30 ($t = 10.78, p < .001$)
2	low	6.40 ($t = 1.85, p < .001$)	6.30 ($t = 7.67, p < .001$)	5.60 ($t = 7.24, p < .001$)
3		5.70 ($t = 5.08, p < .01$)	5.80 ($t = 6.19, p < .001$)	6.40 ($t = 10.85, p < .001$)
4		5.90 ($t = 6.86, p < .001$)	6.60 ($t = 15.92, p < .001$)	6.50 ($t = 15.00, p < .001$)
5	high	6.00 ($t = 9.49, p < .001$)	6.40 ($t = 10.85, p < .001$)	5.90 ($t = 6.04, p < .001$)
6		6.30 ($t = 10.78, p < .001$)	6.00 ($t = 13.42, p < .001$)	5.70 ($t = 7.97, p < .001$)

Each participant was instructed to read the six reviews for one of the three test products (10 participants per test product) and to evaluate the negativity of each review using the item “the author has a very negative opinion of this product” (scale: 1 = “do not at all agree” to 7 = “totally agree”). The resulting mean values that are summarized in table 2 are significantly higher than the scale midpoint (one sample t-tests) and thus the online product reviews are perceived as being clearly negatively valenced.

The purpose of the fourth pretest was to identify brands about which consumers have more or less comprehensive brand knowledge. For each of the tested products (computer notebook, digital camera, mobile phone), we examined five existing brand names that were

more or less known in the product category. We measured brand knowledge using several items that addressed the most important aspects of the brand knowledge concept. Each of the 45 participants of this pretest evaluated either the computer notebook brands, the digital camera brands, or the mobile phone brands on seven-point rating scales. The tested brand names and the mean values that resulted from the aggregation of the single items to an overall value for brand knowledge are shown in table 3.

We decided to select the brand names that were characterized by the lowest and the highest brand knowledge in the respective product category and thus chose the brand names Axxiv/Dell for computer notebooks, Sigma/Canon for digital cameras, and Glofish/Nokia for mobile phones.

Table 3
Results of the Pretest on Brand Knowledge

Computer notebook (n = 15)	Axxiv 1.07	Packard Bell 3.00	Acer 4.47	Sony 6.60	Dell 6.73
Digital camera (n = 15)	Sigma 1.93	Praktica 2.13	Olympus 4.80	Nikon 5.27	Canon 6.73
Mobile phone (n = 15)	Glofish 1.13	LG 2.47	Samsung 4.67	Sony 6.13	Nokia 6.87

Experimental Design and Measures

Our main study was based on a 2 (low/high review quality) x 2 (poor/comprehensive brand knowledge) x 3 (product type: utilitarian/hedonic/hybrid) between-subjects design. By testing utilitarian, hedonic and hybrid products in the study, we controlled for possible effects of product type.

In order to measure brand value perceptions as a pre-stage of consumer-based brand equity, we used the items shown in table 4 that we chose in accordance with existing literature (Aaker 1991; Agarwal and Rao 1996; Dawar and Pillutlar 2000; Keller 1993).

Furthermore, we measured perceptions of review credibility using four items (“I believe that the product reviews reflect the true experiences of these consumers”, “the authors of these reviews are trustworthy”, “these reviews are credible”, and “if I had the intention to buy a product in this category, I would consider these reviews when making a purchase decision”) according to the recommendations of Cheung et al. (2009) and got a coefficient alpha of 0.89. The high coefficient alpha values for brand value perceptions and perceived review credibility indicate that the chosen items are appropriate to reliably measure the concepts they were intended to measure.

Furthermore, we measured the respondents’ perceptions of the general persuasiveness of online product reviews in order to examine whether the different experimental groups are comparable with regard to this variable. In order to do so, we used two items (“online product reviews have an impact on my purchase decisions”, “before making important purchase decisions, I go to product review websites to learn about other consumers’ opinions”, 7-point rating scales), for which we identified a bivariate correlation of 0.56. As the alpha values and the correlation were sufficiently high, we calculated the overall values for the considered variables as mean values of the respective items.

In addition, we measured the perceived quality of the three presented online product reviews and brand knowledge in order to be able to do manipulation checks. We used the item “the reviews are helpful” (7-point scale) to check for review quality and the item “Please indicate your knowledge with regard to the brand [...]” based on a dichotomous scale (“poor knowledge” vs. “comprehensive knowledge”) to check for brand knowledge. As perceived review quality and brand knowledge have already been subject to pretests, we decided to use these simplified measures to limit questionnaire length.

Table 4
Measures of Brand Value Perceptions

Item	Coefficient alpha (measurement before WOM)	Coefficient alpha (measurement after WOM)
The [product] seems to be of high quality.		
I think that the [product] is reliable.		
I believe that the [product] is a high performance product.		
I like this [product].		
I am interested in this [product].		
I can imagine buying this [product].		
I would recommend this [product] to my friends.		
I would prefer this [product] over others in this product category.	0.93	0.97

Note that we used seven-point rating scales ranging from 1 = totally disagree to 7 = totally agree

Sample and Procedure

Six hundred people participated in the main study (thus 50 people per experimental group). The sample consisted of 55% women and 45% men who were familiar with opinion platforms. The age of the participants ranged from 14 to 60 years, the average age was 25.8 years.

The procedure was as follows. The participants were instructed to imagine that they were planning to buy a product in the respective product category in the near future. Then, they were provided with a picture and a short description of the test product. Afterwards, we measured brand knowledge and a-priori brand value perceptions. Subsequently, the respondents were presented with three negative online product reviews. We varied the order of these reviews from respondent to respondent to counterbalance possible order effects. After having read the online product reviews, the participants were asked to answer the brand value perception scales for a second time. Then, the respondents had to indicate their perceptions of review credibility and to judge review quality. In a final step, the respondents were asked to indicate their perceptions of the general persuasiveness of online product reviews and to provide information about their age and gender.

DATA ANALYSIS AND RESULTS

Before presenting the results of the main study, we prove that the experimental groups are comparable with regard to perceptions of general persuasiveness of online product reviews. An analysis of variance shows that the twelve groups that result from the experimental design described above do not differ with regard to perceptions of persuasiveness ($F = 0.53, p > .10$).

In the next step, we present the results of the manipulation checks for brand knowledge and perceived review quality. As both the brand knowledge manipulation and the brand knowledge measurement are dichotomous, we used a chi-square test. Ninety-four

percent of the respondents indicated poor knowledge about the brand that initially was chosen as a poor knowledge brand and 93% of the respondents agreed to have comprehensive knowledge about the brand that was intended to be the comprehensive knowledge brand ($X^2 = 450.75, p < .001$). Consequently, for the further analyses, we used the manipulated brand knowledge variable.

As perceived review quality was measured as a metric variable, we conducted an independent samples *t*-test with the manipulated review quality as independent variable and the perceived review quality as dependent variable. The results show that the reviews that were used as low-quality reviews were judged as significantly less helpful ($M = 3.86$) than the reviews that were used as high-quality reviews ($M = 5.55, t = 12.90, p < .001$). Therefore, the manipulated review quality variable was used for further analyses.

We now present the results of the main study that aimed to identify the numerical value of brand equity dilution depending on review quality and to examine the mediator effect of perceived review credibility in the relation between review quality and change in brand value perceptions as a pre-stage of brand equity. Based on the theoretical conceptualization, brand equity corresponds to the distance between a comprehensive-knowledge brand and a poor-knowledge brand. The value for this distance that represents brand equity was calculated as a difference by following the recommendations of Smith and Lusch (1976). Thus, we first calculated mean values of brand value perceptions before and after the contact with negative online product reviews, then the differences between comprehensive and poor brand knowledge, and finally the value of brand equity dilution as the difference of brand equity before and brand equity after the contact with the negative online product reviews. These calculations were done separately for low and high review quality. In order to judge whether the brand equity values are based on significant mean value differences and to evaluate brand equity dilution, we calculated independent samples *t*-test statistics. The results are shown in table 5.

Table 5
Brand Equity Dilution in the Case of Low and High Review Quality

	Low review quality ($n = 300$)				High review quality ($n = 300$)			
	VP		E	test	VP		E	test
	K_c	K_p	$(VP_{K_c} - VP_{K_p})$	statistics	K_c	K_p	$(VP_{K_c} - VP_{K_p})$	statistics
Before WOM	4.99	3.99	1.00	$t = 7.64$ ($p < .001$)	5.10	3.95	1.15	$t = 8.99$ ($p < .001$)
After WOM	3.12	2.54	0.58	$t = 4.02$ ($p < .001$)	2.96	2.59	0.37	$t = 2.53$ ($p < .05$)
Difference (before - after)	1.87	1.45	0.42	$t = 2.52$ ($p < .05$)	2.14	1.36	0.78	$t = 4.83$ ($p < .001$)

Note: VP = brand value perceptions, E = brand equity, K_c/K_p = comprehensive/poor brand knowledge

The results presented in table 5 show that the contact with negative online product reviews causes a significant brand equity dilution (low review quality: 0.42, high review quality: 0.78). This result that provides support for H1 shows the destructiveness of negative online product reviews with respect to consumer-based brand equity. The fact that brand equity dilution occurs implies that the deterioration of brand value perceptions is stronger in the case of comprehensive brand knowledge than in the case of poor brand knowledge. Thus, after the contact with negative online product reviews, the distance of brand value perceptions between the comprehensive knowledge brand and the poor knowledge brand is smaller than before. Thinking of findings of research on effects of traditional WOM communication that have shown that effects of WOM communication are weaker for comprehensive-knowledge brands than for poor-knowledge brands (Bone 1995; Sundaram

and Webster 1999), our finding might be surprising. However, an important difference between traditional and online WOM communication that provides an explanation for such a destructive effect of negatively valenced online product reviews even in the case of comprehensive brand knowledge is that traditional WOM communication means transmitting only one piece of information at one point in time whereas online WOM communication is much more voluminous in quantity and available for an indefinite period of time (Chatterjee 2001; Henning-Thurau et al. 2004).

The differentiation between low and high review quality further shows that brand equity dilution is significantly stronger in the case of high review quality ($t_{0.78-0.42} = 2.33, p < .05$). Thus, the results provide support for H2 and show that the danger of brand equity dilution as a consequence of the contact with negative online

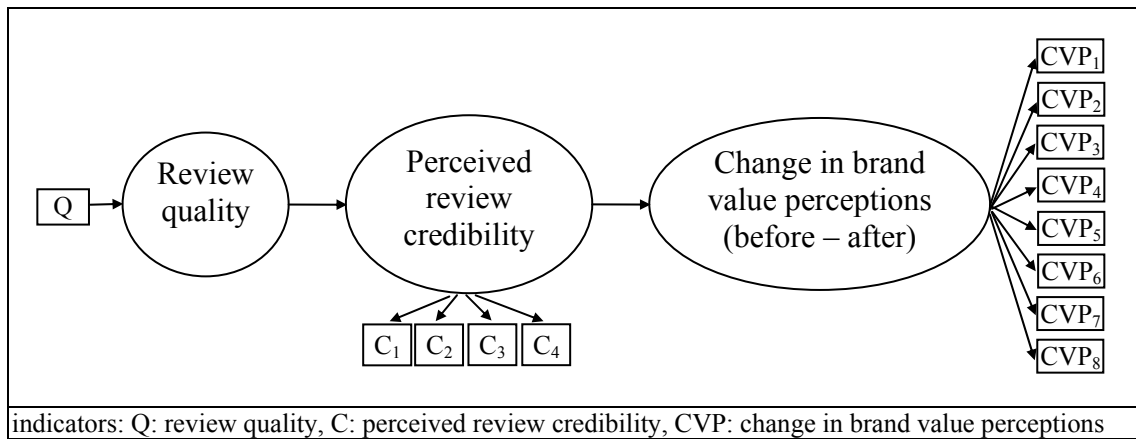

product reviews is much higher in the case of high quality reviews than in the case of low quality reviews.

In the second step of our analysis, we examined the mediator effect of perceived review credibility in the relation between review quality and the change in brand value perceptions. We did not use brand equity as dependent variable for this analysis because numerical values for brand equity can only be calculated on an aggregate data level whereas we needed data on the individual level to be able to accurately examine the mediator effect of perceived review credibility. Choosing brand value perceptions that constitute a pre-stage of the concept of brand equity should not pose a problem because in the first step of our analysis, we have shown that brand equity is calculated on the basis of brand value perceptions and thus both concepts are closely related. We used the SmartPLS procedure to determine the role of perceived review credibility in the relation between review quality and change in brand value perceptions. We estimated the model shown in figure 1.

The estimated path coefficients and the associated t-values as well as the factor loadings are summarized in table 6.

The significantly high factor loadings show that the chosen single items are appropriate to measure the model constructs. Furthermore, the estimated path coefficients are significant with plausible signs and thus provide support for the assumed relations. In more detail, the path coefficients indicate that a higher review quality leads to more positive perceptions of review credibility which in turn lead to a larger difference between brand value perceptions before and after the contact with negative online product reviews. Consequently, the data provide support for the assumed mediator effect of perceived review credibility and thus for the assumption of H3. As the differences have been calculated as brand value perceptions_{before} – brand value perceptions_{after}, a larger difference means a stronger detrimental effect of negative online product reviews on brand value perceptions. Thus, the analysis has shown that perceptions of review credibility play an important role in the context of effects of negative online product reviews on brand value perceptions.

FIGURE 1
PLS MODEL

indicators: Q: review quality, C: perceived review credibility, CVP: change in brand value perceptions

Table 6
Results of the PLS Analysis

Effect	Path coefficient	T-value
review quality à perceived review credibility	0.42	4.77
perceived review credibility à change in brand value perceptions	0.34	3.93
	Factor loading	T-value
perceived review credibility → C ₁	0.81	18.64

change in brand value perceptions → CVP ₈	0.81	17.43

indicators: Q: review quality, C: perceived review credibility, CVP: change in brand value perceptions

CONCLUSION

The starting point of this paper has been the observation that opinion platforms where consumers publish their product reviews become increasingly popular, from both the reviewers' and the readers' perspective. Moreover, both practical experience and previous research let assume that consumers are especially interested in writing and reading negative online product reviews. Additional important observations have been that such reviews vary considerably in quality and that consumers show an increasing skepticism toward online product reviews. Consequently, from a marketer's perspective, the questions arose which effects especially negatively valenced online product reviews might have on consumer-based brand equity, whether these effects exist for all negative product reviews or depend on review quality, and which processes underlie these effects. Therefore, it stood to reason to extend the existing body of research in the field of effects of online WOM communication which only consists of a small number of studies by introducing the concept of dilution of consumer-based brand equity as dependent variable, by examining possible effects of negative product reviews depending on review quality, and by shedding light on the processes that underlie these effects.

The findings of the empirical study show that negative online product reviews have considerable detrimental effects on consumer-based brand equity and that these effects increase with higher review quality. A more detailed analysis of the role of perceived review credibility shows that this variable mediates the relation between review quality and brand value perceptions that are a pre-stage of consumer-based brand equity.

Consequently, marketers should start considering such negative consequences that they might have neglected up to now when planning their communication strategies. Thus, marketers should continuously monitor the relation of high- and low-quality reviews on their brands that can be found on the most important opinion platforms. In addition, most of the leading opinion platforms provide information about the number of hits per review. Out of these two types of information, marketers can estimate the likelihood that potential customers will be faced with a comparatively large number of negatively valenced high-quality reviews. If this likelihood is considerably high, they should try hard to develop appropriate coping strategies.

“Grandma’s Fridge is Cool” – The Meaning of Retro Brands for Young Consumers

Andrea Hemetsberger, University of Innsbruck, Austria

Christine Kittinger-Rosanelli, University of Innsbruck, Austria

Barbara Mueller, University of Innsbruck, Austria

ABSTRACT

This article addresses the question why young consumers favor retro brands although they had no consumption experience with the original counterpart. Interviews with young consumers revealed that retro brands are perceived to be special possessions which help young consumers coping with ambiguities in their search for identity. Retro brands are perceived as nostalgic and authentic objects reflecting continuity and discontinuity; retro brands help negotiating young consumers’ individual identity and search for belongingness and are used as fashion icons that reflect young consumers’ aspiration for social acceptance and non-conformism.

THEORETICAL BACKGROUND

Literature has brought forward an abundance of explanations for the consumption of retro brand. Nostalgia has been the most prominent, so far. Holbrook and Schindler’s view of nostalgia is closely related to what Davis (1979) was one of the first to distinguish among personal and communal nostalgia, where ‘personal nostalgia’ depicts a nostalgic feeling towards object-related experiences that have somehow been lost. Communal nostalgia occurs at the societal level and is often related to social turmoil, great depressions and other discontinuing moments in history.

Turner (1987) provided some additional thoughts on nostalgia that go beyond personal and communal nostalgia. He claims that nostalgia involves a sense of loss and decline, a melancholic vision of the contemporary world based on a perceived crisis in our civilization, a sense of loss of individual freedom and autonomy; and the idea of a loss of simplicity, authenticity and emotional spontaneity in a mass consumption culture. Similarly, Brown, Kozinets and Sherry (2003) found that retro brands allow referring to a particular past time and its ethos. Consumers, therefore, use retro brands to return to an imagined era of moral certainty.

As young consumers’ lives are strongly determined by a search for identity and a period of conscious reflections on issues related to one’s identity (Adamson, Hartman and Lyxell, 1999), identity formation and how individual and social identity go together in this critical period might provide another explanation for young consumers’ liking of retro brands (Cooley, 1902; Mead, 1934; Erikson, 1968; Kroger, 1989; Mittal, 2006). It is our aim to find out how these quintessential questions are related to the meaning of retro brands for young consumers.

Our empirical work followed a 2-step process. First we identified young consumers who owned and liked retro brands using theoretical sampling (Glaser und Strauss 1967). In a second step we conducted narrative interviews (Schütze, 1987). A constant comparative method was applied for analysis (Charmaz, 2006).

FINDINGS

Young consumers are also nostalgic. Although some of these feelings reflect derivative experiences with things owned by their grandparents or parents, young consumers do report about personal nostalgia through *memories from their childhood*, and *meaningful moments*, early experiences and habits that they had come to love. Retro brands are favored because they symbolize deep relationships but also when they help standing for one’s own opinion and taste. Therefore, young consumers also alter traditional rituals that come

with nostalgic brands and *re-interpret its meaning* for their own communal purposes. Retro brands also reflect communal nostalgia, *romanticizing the past and old values* but not in order to bring back the good old days but rather to set a counterpart to current societal developments that young consumers dislike. Retro brands help in this respect by their inherent stability and authenticity.

Our findings show that retro brands help overcome tensions between the defined inner self and the social roles that young consumers are beginning to take over (Mittal, 2006). Retro brands seem to work particularly well in expressing *personal values and attitude towards life* and the social self-concept (Sirgy, 1982), as they are considered as authentic, credible and expressive. Young consumers put particular emphasis on the differentiating elements of their favorite brands in order to underline their *individuality and personality* and at the same time draw a coherent picture of a young consumer’s personality *for others to mirror*. Retro brands help communicate these values and also convey a particular aesthetic component.

Retro consumers commonly describe themselves as fashion-conscious and non-conformist, which marks retro brands as a symbol for fashion and style. Young consumers consider themselves as real non-conformists as all others go with the masses. Young consumers express this attitude by drawing a clear distinction among ‘retros’ and ‘fashion victims’ thus also strongly relating to his peer group and a certain communal spirit of like-minded consumers in search of autonomy. This way, retro brands allow young consumers to overcome the tension between non-conformity and social acceptance.

DISCUSSION

Our research contributes to theory in many ways. First and most important, our findings show that retro brands do have deep meaning for young consumers. They provide meaning from a time perspective in that they embody history, childhood memory, nostalgia, and timelessness. At the same time, the discontinuities young consumers are facing in their lives, their striving for autonomy, their idealism that clashes with in-authenticities in contemporary political and market systems contributes to their choice of retro brands.

Retro brands are not just nostalgic objects for young consumers. They are consumed so as to define young consumers’ self-concept at the crossroads of individual and social identity. Retro brands are identity-building in that they provide strong historical value systems to identify with. They have a high differentiating potential in that they are not marketed to the masses and embody authenticity and originality.

In a similar vein, retro brands are used to negotiate the distance-proximity tension in young consumers’ lives (Adamson, Hartman and Lyxell, 1999). Young consumers’ identity seeking processes are strongly related to processes of autonomy-seeking, which means distancing from particular values and societal developments, and social acceptance, which is necessary for any individual’s psychological well-being. By successfully demonstrating autonomy, they fight established consumption patterns and gain acceptance among their peers as non-conformist consumption heroes.

“Grandma’s Fridge is Cool” – The Meaning of Retro Brands for Young Consumers

‘Wow, this green grandma fridge is absolutely cool, Mum! Would be perfect for my new little apartment.’ Mum agrees and smiles. This is quite common scenery, except that it seems quite counter-intuitive that mothers and their daughters are delighted by the same new, old-fashioned styles. As for mothers we can imagine that it would remind them of their childhood but what about their daughters?

Retro branding has become quite popular before and after the turn of the century and researchers recognized this (Brown, 2001). Most researchers base their assumptions and empirical accounts of retro brand consumption on feelings of nostalgia (Holbrook 1993; Holbrook and Schindler, 1989; 2003; Brown, Kozinets and Sherry, 2003). Some studies have related nostalgia to age and developmental changes that occur at a particular age. Davis (1979) was probably first to state that nostalgic feelings typically relate to times of adolescence and early adulthood in Western societies. Holbrook and Schindler (1989) and Schumann and Scott (1989) concordantly concluded from their studies that memories are structured by age whereby preferences typically peaked for things that were popular when individuals are in their early 20s. In stressing the role of experiences associated with objects that were common when one was younger, Holbrook and Schindler (1991) primarily provide explanations for the baby boom generation who have now grown old enough to have something to be nostalgic about. However, the question why their children or young consumers in general favor retro brands over others is yet to be studied. We define young adults as children of the baby boomer generation of Generation Y, who are between 20 and 30 years of age, the age group that Holbrook and Schindler (1991) have studied, and exactly the formative period (Erikson, 1968) where first important independent life-changing choices are made.

As consumers of a younger age cohort have no experience with the original counterpart of a retro brand, nostalgia as an explanation for retro brand consumption seems counterintuitive. Yet, young consumers might be nostalgia prone, have childhood memories or derivative experiences stemming from their older relatives’ stories and narratives. Furthermore, Davis (1979) contended that discontinuities in life, which are very common at the respective age, influence individuals’ sense for continuity and the past.

In this article we try to go beyond obvious explanations of nostalgia and derivative experiences. We aim to research and theorize about the deeper meaning of retro brands for young consumers who had no consumption experience with the original brands. To this end we review the literature on retro branding and nostalgia. We introduce additional explanations for retro brand consumption and young consumers’ identity development as a search field for explanation, and provide empirical insights into young consumers’ narratives about their retro brands. In the discussion section we carve out the meaning of retro brands for young consumers’ coping strategies with tensions in their identity search.

RETRO BRANDS AND NOSTALGIA

Brown et al. (2003) defined Retro Branding as “*the revival or relaunch of a product or service brand from a prior historical period, which is usually but not always updated to contemporary standards of performance, functioning, or taste*” (Brown et al. 2003, 20). Retro brands combine designs from a prior period with innovative functionality thus creating a harmonious offer that unites the contemporary with the past. Usually marketers emphasize the nostalgic elements of retro brands, which are valuable sources of meaning for consumers. Retro brands include various forms of

relation to the past, ranging from exact reproductions of former brands (e.g.: Converse sneakers) to so called ‘nostalgic’ or ‘vintage brands’ that use designs from past times to technologically upgraded products with nostalgic designs (e.g.: the PT Cruiser and the VW New Beetle).

Particularly for older consumers, special possessions serve as materializations of memory and evoke a powerful sense of the past (Belk, 1991). Holbrook and Schindler (1989, 1994, 1996, 2003) intensely researched nostalgia and nostalgia proneness in various consumption contexts and related it to particular age cohorts. The authors define nostalgia as “A preference [...] towards experiences associated with objects [...] that were more common [...] when one was younger...” (Holbrook and Schindler, 1991, 330). Via a process called nostalgic bonding, a consumer’s history of consumption of particular brands during a critical period of preference formation can create a lifelong preference for those brands. Holbrook and Schindler (2003) were particularly interested in the baby boom generation and how they collectively memorize and celebrate their common history when they were in their early 20s (Holbrook and Schindler, 1989, 1993, 1994, 1996). Holbrook and Schindler’s view of nostalgia is closely related to what Davis (1979) and Stern (1992) have described as ‘personal nostalgia’, a nostalgic feeling towards object-related experiences that have somehow been lost.

Relating these observations to young consumers in their early 20s, we can state that they are currently forming their preferences and nostalgic bonds with particular objects, rather than being nostalgic about preferred brands of their youth. However, Holbrook and Schindler (1993) found that some individuals are more nostalgia prone than others, where nostalgia proneness is independent from age-determined preferences. Furthermore, young consumers might refer to their childhood memories (Belk et al. 2003; Brown-La Tour, La Tour and Zinkhan, 2007) with brands that are preferred due to a sheer familiarity effect (Chaplin and Roedder John, 2005).

A second common facet of nostalgia refers to the collective memory of historical periods and styles that are commonly described as ‘communal nostalgia’ (Davis, 1979). Communal nostalgia occurs at the societal level and is often related to social turmoil, great depressions and other discontinuing moments in history. Stern (1992) has diagnosed a fin de siècle effect, which describes the tendency to retrospect as the turn of the century comes close. Communal or ‘historical nostalgia’, as depicted by Stern (1992), “expresses the desire to retreat from contemporary life by returning to a time in the past viewed as superior to the present.” (Stern 1992, 13). In view of contemporary postmodern fragmentation, young consumers might well experience their upcoming life as adults as challenging and use retro brand consumption experiences as escape from unwanted societal developments and market hegemony and dive into the myths of past times. Movies and songs from the past are especially suited to serve this kind of temporary escapism from the disenchanting everyday life (Holbrook and Schindler, 1989, 1996).

BEYOND PERSONAL AND COMMUNAL NOSTALGIA

Turner (1987) provided some additional thoughts on nostalgia. He claims that nostalgia involves a sense of loss and decline, a melancholic vision of the contemporary world based on a perceived crisis in our civilization, a sense of loss of individual freedom and autonomy; and the idea of a loss of simplicity, authenticity and emotional spontaneity in a mass consumption culture. In an attempt to summarize and differentiate Turner’s writings, Kessous and Roux (2008) develop a semiotic square that describes different qualities and triggers of nostalgia, which could be long-lasting or just one significant event, reflecting two dimensions: ‘continuity’ and ‘dis-

continuity'. Based on these dimensions they describe continuity as everyday past childhood memories as opposed to non-continuity which reflects transitional periods of ambiguity and unanchored identity. Discontinuity, on the other hand relates back to unique moments in life whereas non-continuity is related to traditional brand use for ritual occasions.

Brown, Kozinets and Sherry (2003) present yet another explanation for the success of retro brands, which is communal in its approach. Based on the philosophical concepts of allegory (symbolic stories), arcadia (a utopian sense of past worlds), aura (brand essence) and antimony (brand paradox), the authors found that retro brands allow referring to a particular past time and its ethos. The retro brand concretizes important symbolic elements of the past. Consumers, therefore, use retro brands to return to an imagined era of moral certainty. Retro brand consumers also emphasize the utopian and moral character of its fan communities. Retro brands which still exist as a brand story; that have a vital essence; are able to mobilize a utopian vision for a consumer cohort; and positively address opposing desires, are likely to constitute strong sources for consumer identity search.

As young consumers' lives are strongly determined by a search for identity and a period of conscious reflections on issues related to one's identity (Adamson, Hartman and Lyxell, 1999), identity formation in this critical period might provide another explanation for young consumers' liking of retro brands. Theories of understanding the self can be organized around two major themes: the self as a subject/object and the self in relation to others (Cooley, 1902; Mead, 1934). These major themes roughly reflect theories of individual and social identity, or the 'I' and the 'me' as depicted in current consumer behavior literature (Mittal, 2006), and how those identities are going together (Kroger, 1989). Erikson (1968) proclaimed the view that identity formation is a reciprocal process between the psychological interior of the individual and her/his socio-cultural environment. Especially in late adolescence and early adulthood, individuals consciously reflect on themselves as subjects and in relation to others. This identity formation process has many facets, one of them being related to existential questions and ideology. Adamson and Lyxell (1996) found that questions about the future, the meaning of life in general, death, and finally questions about one's own identity are the most crucial questions in late adolescence. It is our aim to find out how these quintessential questions are related to the meaning of retro brands for young consumers.

METHOD

Our empirical work followed a 2-step process. First we identified young consumers who owned and liked retro brands using "theoretical sampling" as described in grounded theory (Glaser und Strauss 1967; Strauss und Corbin 1990). In our questionnaire we first presented a brief definition and examples for retro brands to ensure a shared understanding of retro brands. Participants then indicated on a 7-point-scale whether they owned retro brands and how much they liked them, in general and their own retro brands, in particular. We used snowball sampling to find appropriate informants, most of whom matched our criteria right away. Informants, who possessed retro brands, showed strong liking, and considered retro brands "very cool" or "cool" qualified for the main study. The final sample consisted of 5 female and 5 male respondents with an age range of 20 to 29 with varying professional backgrounds and a set of more or less well-known retro brands in fashion (Adidas and Puma retro fashion), cars (PT Cruiser, BMW Mini), motorbikes (Aprilia), beverages (Afri-Cola), entertainment and furnishing (wallpapers, lamps, and similar). Most of the respondents owned one to five retro or retro style brands.

In the second step we conducted narrative interviews (Schütze, 1987). We chose this qualitative and inductive approach to reveal meaning of retro brands to young consumers which has not yet been researched systematically. The interviewers used an open interview guideline, including photo-elicitation (Banks, 2007; Heisley und Levy 1991) and projective techniques (e.g. projective questioning, story completion, choice ordering, Haire 1950). A few days before the interview, respondents were equipped with a camera and invited to take pictures of their favorite retro brands. These pictures together with pre-selected pictures by the researchers were used during the interview to stimulate narratives and reveal meaning structures. Respondents were first, asked to talk about their relationship to their most favored retro brand, how they 'met', what kind of relationship they had, and how important they were for them. A second set of question related to the personality of the brand. In a subsequent set of questions, we asked respondents about reactions of their peers to their retro brands, before we turned to the respondents' opinions towards contemporary societal developments to uncover whether retro consumers are critical and past-oriented in that respect. The interviews took place at respondents' homes to ensure a natural setting. They lasted between 35 and 90 minutes and produced a total of 7h and 50 min. of information.

We tape-recorded the interviews and transcribed them verbatim. An idiographic analysis documented the individual retro-brand meanings based on personal and social backgrounds (Thompson, Locander and Pollio, 1989; 1994). To integrate and systematize themes and experiences in the individual cases we used "constant comparative analysis" (Strauss and Corbin, 1990; Charmaz, 2006) and the analysis software MaxQda.

FINDINGS

Our interviews with young consumers reveal that the consumption of retro brands definitely entails feelings and experiences of nostalgia. However, nostalgia is not in the foreground but rather symbolizes a common striving among young adults that is related to their search for what is important in their lives. Retro brand consumption actually reflects young consumers' coping strategies, which helps balance their developing individuality with social attributions, their aspiration for stability and security with their attempts to flee the ordinary, and their aspiration for social acceptance and belongingness with anti-conformism. In the following, we will carve out these contradictions and discuss how retro brands help young consumers negotiating their developing identities within society.

Continuity and discontinuity

Young consumers are also nostalgic. Although some of these feelings reflect derivative experiences with things owned by their grandparents or parents, young consumers do report about personal nostalgia through memories from their childhood, early experiences and habits that they had come to love. Continuity and discontinuity also reflects communal nostalgia, romanticizing the past and old values but not in order to bring back the good old days but rather to set a counterpart to current societal developments that young consumers dislike or protest against. Continuity and discontinuity are not contradictory but rather emanate from the deep desire for stability and security which they experienced in childhood, in times of accelerated pace of life and materialism, which young retro consumers opposed.

Childhood and Derivative Brand Experience

Young consumers' childhood memories are deeply influenced by grandparents, their houses, objects, and stories. These memories are engraved in their brains and provide feelings of warmth,

security and comfort. As young consumers are confronted with more and more opportunities and freedom to construct their own life stories, they are also facing more uncertainties and feelings of insecurity. Retro brands have a history, reflect continuity in times of fast changes and are safely grounded in grandmother's wealth of experience (Kessous and Roux 2008).

"Yeah, and these old signs, they sure are beautiful [...]; over there we have these old Lindt chocolate signs and also Sarotti retro-signs, and this one how grandma cooked, from good old times and so on, [...]. Well you know, I mean this feeling of security: grandma is cooking for you and you are the hero in her world and you can wish for anything [...] somehow that is just cool..."
(Daniel)

Although young consumer never decided to consume these brands themselves, we know from Chaplin and Roedder John (2005) that children at the age 8-9 years connect to brands on a more concrete level related to their familiarity or ownership of the brand. They incorporate brands into their self on an un-reflected, highly affective basis. Young consumers also report about the memories of their parents as if those memories were their own. Through the deep empathic feelings with relatives and their narratives, young consumers seem to incorporate these derivative experiences into their own memory thus enriching brand meaning and its connection to the past.

Meaningful Moments

Even if we consider young consumers' life times as being quite short, their memories and meaningful moments are by no means less intense. Meaningful moments do not need time to develop into nostalgia; similar to what Kessous and Roux (2008) described as discontinuity, young consumers refer to those unique reference points as a reason to favor retro brands. Our findings corroborate Davis' (1977) contention that those moments are connected with joyful experiences and mastery of life. Retro brands are favored because they symbolize relationships with good friends, exciting trips and parties, nice little gifts but also when they help standing for one's own opinion and taste. As young consumers are constantly exposed to social expectations, instances of successful emancipation from others' opinions mark their lives on their way to self-standing personalities. Retro brands help in this respect by their inherent stability and uncompromising idiosyncrasy.

Re-interpretation of Traditional Objects of Bygone Times

As many contemporary brands have rather short life cycles, retro brands are symbols for continuity, reflecting long-lasting quality and historical heritage. Young consumers who like retro brands use them as stable anchors that reflect tradition and authenticity in a world of many materialistic, fake, and uninspiring objects. Respondents report about the genuine and superior quality and their trustful relationship with those brands. Furthermore, many retro brands are used for ritualistic practices among young consumers, which disconnect the brand from the mundane world. By ascribing retro brands the qualities of a genuine, disinterested object purified from persuasive marketing practices, those objects also become cult objects for young consumers. As Belk and Tumbat (2005) reported, cult brands often pass a period of deterioration (satanic myth) and resurrection (myth), which likens the development of many retro brands that gain cult status. Contrary to nostalgia based on non-discontinuity as described by Kessous and Roux (2008), young consumers do not pursue traditional acts and habits like their

ancestors but instead interpret those acts differently and use them for community-building rituals among young consumers.

Romanticizing the Past and its Values

Retro brands not just represent tradition and lay the grounds for new interpretations of retro brands as cult objects; they also serve as powerful symbols of collective memory. Retro brands are not only perceived as authentic, they also embody past times and values of those times yet in a quite distorted manner. Even if young consumers are aware of some of their misperceptions, they nevertheless buy into the romantic view of the good old days as described by Davis (1979), in order to contrast it with what they feel is going in the wrong direction in contemporary society. As reported by Stern (1992), those romantic feelings are often based on idealized and imagined views of golden eras in order to transcend one's discrete existence in time, using retro brands as a sanctuary from contemporary meaninglessness, a transfiguration of the world of everyday consumption.

"A whole lot of families visit farms again, because they want to bring their children back to nature, they somehow want to get back to some place, back to something they consider to be better."
(Carina)

"Yeah, basically I think I was born too late anyway, ...well it is a certain feeling that you... not quite crave for the past, which sounds quite up the pole, because you were not even born then ... but you imagine that everything used to be a little more romantic then and they had only good music and fancy cars and that it would just be great to have it this way again. Well sure you don't want to have back everything, that's why you have a computer in your room. But at the same time, maybe by creating your own look, you want to get a little bit of that feeling."
(Emily)

Similar to Brown, Kozinets and Sherry's (2003) findings, consumers use traditional qualities of retro brands as reference to a past ethos thereby rebelling against contemporary developments. In absence of an own life history, this non-continuity tendency may relate to the current transitional period young consumers are living through, and their respective search for identity.

Individual and social identity

Identity formation processes are full of troubles, uncertainties, but also successes and empowering moments. Our findings show that retro brands help overcome ambiguities between the defined inner self and the social roles that young consumers are beginning to take over (Mittal, 2006). Retro brands seem to work particularly well in expressing specific personality characteristics and the social self-concept (Sirgy, 1982), as they are considered as authentic, credible and expressive. Retro brands ease the task of finding one's own style as they remain stable, timeless, stay always true to themselves and, therefore, easy to hold on.

Personal Values and the Art of Life

Late adolescence and early adulthood is the time for defining what young consumers want to achieve in life and how they want to live their lives. Early adulthood is a formative period as young adults usually make decisive decisions for their lives and form their attitudes and value systems. Respondents report about the art of living in a particular past period and relate to that in their

descriptions of their attitude towards life and how they want to be seen. Retro brands help communicate these values and also convey a particular aesthetic component.

„I am not a fan of all retro-products, but as it is, I hope that values from former times can be put across. I like most the music of the 60ies and 70ies, and I am super fond of bell-bottoms [.....]; they also evoke former times and maybe other priorities that one can identify with, at least I can; and maybe you can also get that across.”
(Finn)

As demonstrated above, retro brands not only help depicting a person's attitudes and values; they also address and emphasize the differences between the contemporary social value system and that of a past era. Therefore, using retro brands is also a means of criticizing contemporary social values and thus self-definition (Mittal, 2006). Consuming retro brands is also expressive in that they reflect a consumer's particular way of life. According to the respondents they carry the aura of the respective decade that young consumers ascribe to the retro brand. Although some attributions are not accurate, young consumers favor those brands for the meaning ascribed to the respective time period.

Emphasizing Individuality and Personality

Particularly in times of identity formation and definition, young consumers are keen to act in a congruent manner in order to achieve a positive self-worth and approach their ideal self (Sirgy, 1982). An even stronger motivation to use retro brands for self definition is that they enable to differentiate from the masses. Young retro brand consumers put particular emphasis on the differentiating elements of their favorite brands; the fact that young consumers are usually early adopters of new fashion trends helps retro brand consumers sharpening the difference between themselves as retro style consumers and others, who buy into the persuasive tactics of the fashion industry.

“[.....] I am simply a person, who I mean I don't like it if ... if everything is more or less the same,... if I cannot stand out with my belongings; not in the sense of standing above it, rather more to personify, to add a bit of character, that I can make a statement. I mean this car, according to my personal opinion, stands for more than a Polo [Volkswagen] and I simply enjoy that it is timeless.”
(Anna)

Paradoxically, and antithetical to typical youth brands, Anna emphasizes the stability and timelessness of her car that supports her need for individuality. Other respondents are creatively mixing and matching retro and more contemporary styles in an attempt to emphasize their creativity and uniqueness. Retro brands are often ascribed stronger personality characteristics than other brands. The historical aura of retro brands adds to this personality and enables young consumers to express a strong personality and to live in between times, a strategy to escape fragmentation and alleviate the boredom of contemporary life.

Contrasting the “I” and the “Me”

Young retro consumers like to contrast what they consider their individual personality with their social roles. Individuals steadily define themselves according to their own self-definition and their social roles, which often creates tensions (Mittal, 2006). Retro brands help bridge this gap in that they communicate continuity, authenticity,

originality, expressivity, and aesthetic design. As indicated above, they help the “I” to differentiate from the masses and at the same time draw a coherent picture of a young consumer's personality for others to mirror. For retro consumers early adulthood is also the time to emancipate from peer pressure and rather engage in constructing a reflected “I” that is mirrored in a social self-concept “Me”, constructed with the help of favored retro brands.

“Well, I think it heavily depends on age, let's say, if you are younger; you are completely dependent on your “peer group” ... [...] ,... you had to go by the group just to be cool, no matter if you yourself considered it cool. But very soon after you enter a stage where you realize, ok, they can tell me lots of sh..., they are not quite that awesome, now I make my own style, and then you start,... then I started to consider what do I want.”
(Daniel)

Mittal (2006) proposes three broad approaches to resolving the tension between self and social identity, namely switching reference group, educating others, or modifying consumption. Usually these strategies are adopting strategies to the social ‘Me’. In the case of retro brands, consumers rather educate the others to bring the core self more to the forefront.

Social acceptance and non-conformism

Retro consumers commonly describe themselves as fashion-conscious and non-conformist, which marks retro brands as a symbol for fashion and style. Jana describes them as balanced and ‘laid back’ personalities, rather than whimsical early adopters of the various hype youth brands. By describing retro consumers as being different, young consumers do not want to portray themselves as conservative; on the contrary. They consider themselves as the real non-conformists as all others go with the masses but by consuming retro brands they act against hegemonic norms of consumption. As depicted above, retro brands shall help them adjusting the social self-concept to the reflected self identity. Yet social acceptance is still crucial. Without being accepted at some point, a non-conformist strategy would not work. Retro brand consumption is not to be thought of as resistive consumer behavior but rather as a successful attempt to resist conformity of fashion trends and taste.

Non-Conformism

Non-conformity through retro brand consumption has many facets. Non-conformity is demonstrated best by fashion and other conspicuous objects of consumption. Some young consumers report that they are bored by particular social norms in social arenas, such as professional life, and similar social situations. They simply like being different, a little provocative, and introduce a more casual look. Others emphasize the slightly anti-commercial meaning that comes with retro consumption as retro is ‘recycled’ design which is longer lasting. Julian expresses this unconventional attitude by drawing a clear distinction among ‘retros’ and ‘fashion victims’ thus also strongly relating to his peer group and a certain communal spirit of like-minded consumers in search of autonomy.

“[.....] with some products I sure have the feeling that you are sick of it after putting it on twice; you see it another ten times in the subway and then you are finally done with it; there is nothing individual left in it. This also happens to my friends, they are rather relaxed people who do not bow to clichés, there is like no Polo-shirt-carrier with collars up or like the absolute “Mega-Fashion-Victim”, well I'd

say just normal people and not—even if it might sound a bit exaggerated—total victims of consumerism.”
(Julian)

Non-conformism is also strongly connected to the mix and match style of retro brand consumers. Mixing and matching is actually a strategy to get the best out of both in that young consumers avoid being trendy and mainstream but aspire to be authentic, bring the ‘old charm’ of retro brands to the foreground.

Social Acceptance and Coolness

The ‘old charm’ of retro brands often creates retro brand cults. The dramatic change of society in Germany, for instance, has brought forward a strong wave of ‘Ostalgia’, a nostalgic cult related to the bygone times of Eastern Germany (Eigler, 2004). Even if retro brands do not achieve cult status, they have the ingredients of being cool. As coolness is defined by the in-group, coolness cannot be created but is rather defined by young consumers. In the case of retro brands, our respondents emphasized that retro brands are cool but they would lose this attribute if they go mainstream. Thus, what is considered as cool in a younger age cohort that extensively consumes trendy retro brands is un-cool and unacceptable for young adults.

“Especially those “Emos”, all of them carrying Chucks, they are all Chucks-zealot; or like these “tapered pants-zealots” and the like. I mean there are some bands or famous idols, who create certain styles that are readily adopted by Teenies with maybe lower self esteem and they think that is really cool. They jump on the bandwagon and the industry is right there to seduce them ‘hey, give us your pocket money’ [...].”
(Daniel)

Young consumers’ coolness is inextricably interwoven with their striving for independence. This is exactly what unites them with other members of their age cohort. Gaining social acceptance means being non-conform, fighting mainstream. Hence, these findings point to the importance to discriminate among groups with different definitions of ‘coolness’ as being cool means belonging to a particular social group. This way, retro brands allow young consumers to overcome the tension between non-conformity and social acceptance.

DISCUSSION

Our research contributes to theory in many ways. First and most important, our findings show that retro brands do have deep meaning for young consumers. They provide meaning from a time perspective in that they embody history, memory, nostalgia, and timelessness. Although young consumers often do not know the original counterparts of their favorite retro brands, they borrow from the collective memory, or gain derivative experience from parents’ and grandparents’ consumption habits. Contrary to their parents, young consumers experience retro brands in childhood rather than in their 20s, which is by no means less impactful on their emotional bonding with retro brands. The close-knit bonds with their families and the brands young consumers associate with family life strongly connect young consumers to original brands that later become their favorite retro brands. In connecting them with the ‘safe haven’ of family life they provide continuity in young consumers’ lives. At the same time, the discontinuities young consumers are facing in their lives, their striving for autonomy, their idealism that clashes with in-authenticities in contemporary political and market systems contributes to their choice of retro brands.

Hence, retro brands, on the other hand, are not just nostalgic objects for young consumers. They are consumed so as to define young consumers’ self-concept at the crossroads of individual and social identity. Retro brands are identity-building in that they provide strong historical value systems to, at least partly, identify with. They have a high differentiating potential in that they are not marketed to the masses and embody authenticity and originality. Therefore, retro brands enable young consumers to clearly communicate their identity for others to mirror. By defining retro brands as cool within the peer group, retro brands help coping with the ambiguity between ‘the self’ and ‘the other’ (Adamson, Hartman and Lyxell, 1999).

In a similar vein, retro brands are used to negotiate the distance-proximity tension in young consumers’ lives (Adamson, Hartman and Lyxell, 1999). Young consumers’ identity seeking processes are strongly related to processes of autonomy-seeking, which means distancing from particular values and societal developments, and social acceptance, which is necessary for any individual’s psychological well-being. Combining new and old is a strong antidote to contemporary fashion dictates, used by young consumers to demonstrate autonomy. By successfully demonstrating autonomy, they fight established consumption patterns and gain acceptance among their peers as non-conformist consumption heroes.

Figure 1 summarizes how retro brands are consumed as expressive objects used for coping with tensions that are related to young consumers’ life statuses.

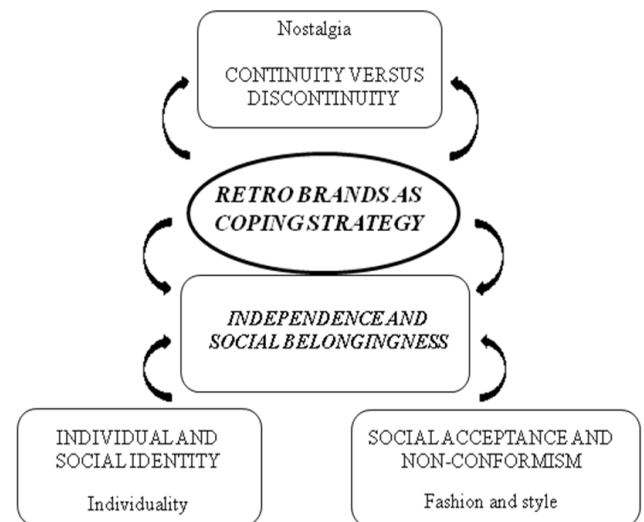

Figure 1: Retro Brands as Coping Strategy

Particularly in times of market turbulences and political promises of “change”, retro brands constitute materializations of idealized forms of consumption for a particular young age cohort. Retro brands are pastiche forms of authentic, historical, value-laden objects that enchant contemporary technologically engineered and marketed objects. Retro brands are no less engineered and marketed than any other brand but they successfully serve young consumers’ aspiration for continuity and stability in an age-related period of discontinuities and insecurity but also freedom to choose. At the same time and similarly paradox as Benjamin’s antinomy (Brown, Kozinets and Sherry, 2003), retro brands are subject to the same fashion cycles as other fashion brands. They are perceived as highly individual and fashionable yet—contrary to new fashion brands—with retro brands individualized styles are created by young consumers, not just bought. It is the mix and match quality, the malleable historical context of retro brands that serves as a means of creating unique, fashionable artwork-like styles among young consumers.

Does Advertising Based on Gender Equality Work and Which Consumer Groups Should be Addressed?

Silke Bambauer-Sachse, University of Fribourg, Switzerland
Zoltan Horvath, University of Fribourg, Switzerland

ABSTRACT

In this paper, we examine gender equality as one aspect of CSR that can be used for innovative image advertising. We identify two consumer groups that differ with regard to their internalization of gender equality and thus regarding their reactions to an image campaign that is based on gender equality.

INTRODUCTION

A general trend in corporate communication is that companies increasingly move away from traditional communication messages that focus on exchangeable product attributes, which can easily be copied by competitors within the same industry. Instead, companies are increasingly looking for communication messages that are image-focused, unique, innovative and able to differentiate them from competitors (Kotler and Armstrong 2006). One such topic that companies increasingly cover in communication strategies is corporate social responsibility (CSR) (Brown and Dacin 1997). Corporate social responsibility refers to a company's status and voluntary activities with respect to its perceived societal obligations (Brown and Dacin 1997; Sen and Bhattacharya 2001). CSR activities are characterized by a long-term perspective and a proactive view of responsibility (McGee 1998). Aspects of CSR are for example environmental protection (e.g., environment friendly products, pollution control, recycling), customer orientation and care (responsibility for product safety), respecting business ethics, responsibility for economic development, community support (e.g., support of arts and health programs, educational and housing initiatives for the economically disadvantaged, generous/innovative giving), and employee support (e.g., job security, profit sharing, union relations, employee involvement, equal career opportunities for men and women) (Sen and Bhattacharya 2001).

Thus, announcing a corporate commitment to gender equality in terms of treating male and female employees equally could be part of a CSR communication strategy. Gender equality is given if equality between men and women is ensured in all areas including employment, work and payment. Despite broad and intensive efforts during the last decades, factual gender equality has not been realized to an acceptable extent in many European countries. Especially labor markets are often characterized by a clear gender-specific segregation. In addition, gender roles in private life do often not mirror the idea of gender equality. In many societies, women are still considered as being responsible for the family (Kirton and Green 2005; Mikkola 2005; Nentwich 2006; Royo-Vela et al. 2007).

Although talking about corporate commitment to gender equality in advertising strategies could be an innovative approach for an image advertising campaign that is built on CSR, gender equality has only been ascribed minor importance as a part of corporate communication strategies up to now (Grosser and Moon 2005). Consequently, the purpose of this paper is to pick out corporate commitment to gender equality (in terms of treating female and male employees equally) as one possible aspect of innovative image advertising and to identify different groups of consumers such advertising could be addressed to. The consumer group identification will be done on the basis of the extent of social internalization of gender equality as a personal norm because previous research provides the notion that the effectiveness of CSR strategies depends on the extent to which people within a society have internalized

the concept that is subject to a certain CSR strategy as a personal norm (Lichtenstein, Drumwright, and Braig 2004; Osterhus 1997).

An examination of this research topic can add to the existing body of consumer research by considering an aspect of CSR that has not been analyzed in consumer research contexts before as well as by providing insights in characteristics of possible consumer segments that differ both with regard to the extent of internalization of gender equality as a personal norm and to their evaluation of relevant marketing response variables.

A practical benefit of our paper is that companies might have a higher motivation to pursue the implementation of gender equality with more effort than they have done in the past when they learn that they can profit from such measures in terms of generating positive consumer reactions by talking about the implementation in image advertising campaigns that address appropriate consumer groups. Moreover, our research will show that the communication of a clear commitment to gender equality to appropriate consumer groups can provide an added value for companies, which goes beyond satisfying increasing expectations from both government/legislation and society. Furthermore, motivating companies to go about implementing clear commitments to gender equality will lead to a stronger presence of this topic in both working and consumer life and hopefully finally to a stronger internalization of gender equality as a social and a personal norm.

THEORETICAL BACKGROUND

Basic Effects of Communicating a Clear Commitment to Gender Equality

As the commitment to gender equality is a part of CSR strategies, we draw on research in the field of CSR as well as on research in the field of gender equality to build up the theoretical background.

Literature on CSR indicates that high CSR efforts have positive effects on customer satisfaction, product evaluation, and corporate image (Brown and Dacin 1997; Lichtenstein, Drumwright, and Braig 2004). In addition, literature on social advertising provides the notion that communication strategies with a social dimension have positive effects on consumer response variables such as purchase intentions and attitudes toward the communication campaign (Drumwright 1996).

Although studies on gender-specific aspects have been conducted in different fields (e.g., Alreck, Settle, and Belch 1982; Chichilnisky, Hermann, and Frederiksen 2008; Gunkel et al. 2007; Hoerber 2007), no scientific studies exist on effects of communicating a clear commitment to gender equality in the context of corporate communication. However, several arguments coming from this stream of literature can be applied to our research. A first finding that might play a role is that brand gendering through stereotypical portrayal may alienate consumers and cause resentment and rejection of the brand, advertiser or media (Alreck, Settle, and Belch 1982). A more general interpretation of this finding is that stereotypical gendering may have negative effects. Put vice versa, a clear commitment to gender equality in the context of CSR strategies might at least avoid such negative effects on corporate image or even have positive effects. Other research has shown that men (women) do not necessarily ascribe major importance to traditionally stereotypical masculine (feminine) factors (Gunkel, Lusk, Wolff, and Li 2007).

Thus, this finding also supports the assumption of positive effects of communicating gender equality in the context of CSR strategies.

Literature on gender differences also provides a counter-argument. The notion that men often have difficulty accepting the gender changes that are occurring in their environment (Connell 2006) leads to the assumption of negative effects of communicating a clear commitment to gender equality.

The application of these contradictory findings to our research context leads to the assumption that openness to communication strategies that are based on gender equality might differ among consumers. Consequently, an analysis that aims to differentiate between several groups might lead to the identification of consumer groups that show very positive reactions to advertising strategies that are based on a clear commitment to gender equality and other groups that show less positive reactions to such strategies.

The Role of the Internalization of Gender Equality

As it is the objective of this paper to pick out one specific dimension of CSR, namely gender equality, and to identify consumer groups on the basis of the internalization of gender equality as a personal norm, we will subsequently go more into the theoretical details of internalization in terms of transforming a social norm into a personal norm.

Social norms are characterized by perceptions about the nature and content of a prevailing social sentiment (Schwartz 1977). Individuals associate social norms with the importance of taking a specific action (Malhotra 2005). Thus, if the idea of treating women and men equally is considered as a social norm, people might associate this norm with the importance of implementing gender equality in daily life.

Internalization basically refers to the incorporation of a concept as part of one's own belief structure so that it becomes a personal norm (Kelman 1958; Lewis, Agarwal, and Sambamurthy 2003). In other words, internalization consists of transforming a social norm into a personal norm. In the context considered here, internalization can be referred to as the transformation of the concept of gender equality that is established as a social norm on a society level into a personal norm on the individual level.

According to Kelman (1958), individuals show different levels of changes in behavior as a consequence of an internalization of a social norm. These differences can be explained by different processes whereby individuals accept influence. The internalization of a specific idea and the behavior that is associated with this idea lead to satisfaction (Kelman 1958; Venkatesh and Davis 2000). Consequently, the internalization of a concept is closely associated with typical response variables that are subject to consumer research. Therefore, we argue that the internalization of gender equality might also be closely associated with other consumer response variables such as acceptability of an advertising campaign, interest in a company, or purchase intention when gender equality is used as an advertising topic. Therefore, we assume in our first research hypothesis:

H1: *The higher the extent of internalization of the social norm of treating women and men equally, the higher are the acceptability of an advertising strategy that broaches the issue of gender equality, the interest in the company, and the purchase intention toward the products offered by this company.*

In order to make the idea of internalization more tangible, it is important to have a more detailed look at concepts that are related to internalization. As internalization means that a social norm is

transformed into a personal norm, we will have a closer look at the concept of personal norms. According to Schwartz (1977) personal norms are mainly activated and translated into behavior by the awareness of consequences that are associated with a certain behavior. Awareness of consequences refers to whether someone is aware of the negative consequences for the case of not acting according to the internalized norm (Schwartz 1977). In the context considered here, the idea of awareness of consequences means that individuals are aware of negative consequences for the case of not adopting gender equality as a personal norm and implementing gender equality in their everyday life.

From the theoretical considerations presented above, we can derive two criteria upon which we will try to identify different consumer groups: the extent to which an individual has transformed a social norm into a personal norm and the awareness of consequences for the case of not behaving according to the norm. As people seem to be different with regard to these criteria, we argue in our second research hypothesis:

H2: *Using the transformation of a social into a personal norm and the awareness of consequences as segmentation criteria will lead to the identification of at least two different segments of consumers.*

Applying the rationale that underlies hypothesis 1 to the context of hypothesis 2, we additionally assume:

H3: *The segments that can be identified on the basis of the dimensions of internalization will differ significantly with regard to consumer response variables such as acceptability of an advertising strategy that broaches the issue of gender equality, interest in the company, and purchase intention toward the products offered by this company.*

EMPIRICAL STUDY

Study Overview

We conducted two empirical studies to cover two research purposes. The objective of the first study was to show that a relation between the internalization of gender equality as a personal norm and the evaluation of consumer response variables exists, thus to examine whether the dimensions of internalization determine consumer response variables such as purchase intention, interest in the company, and acceptability of gender equality as a topic of an advertising campaign. The objective of the second study was to identify different groups of consumers that differ with regard to the internalization of gender equality as a personal norm, to examine these groups in more detail with regard to demographics, and to analyze differences of these groups in their reactions to an advertising strategy that broaches the issue of gender equality.

As we used the same measures and the same procedure in both studies, we will describe these aspects first below and then present the results of the two studies.

MEASURES

The statements used to measure the two dimensions of internalization (transformation of a social norm into a personal norm and awareness of consequences) were derived from literature in the fields of the internalization of norms (De Groot and Steg 2009; Osterhus 1997; Wall, Devine-Wright, and Mill 2007) and gender equality (Fletcher et al. 2007; Rubery et al. 2003). In order to measure the consumer response variables (purchase intention,

interest in the company, and acceptability of gender equality as a topic of an advertising strategy), we created statements by looking at previous studies in consumer research where these variables have been operationalized (e.g., Brown and Dacin 1997; Webb and Mohr 1998). Table 1 gives an overview of the items we used to measure the respective variables and the alpha coefficients per variable and study. The alpha coefficients indicate that the respective items reliably measure the concept they were intended to measure. The sufficiently high alpha values allow for calculating the overall construct values as arithmetical means of the single indicators for each construct. These arithmetical means are used in the analyses presented subsequently.

PROCEDURE AND SAMPLES

We created questionnaires that contained the measures shown in table 1 as well as age, gender, and educational qualification. In order to recruit the samples, we used official mailing lists of a Swiss university that contained the email addresses of students as well as of scientific and administrative staff to send out emails that informed about the purpose of one of the studies and provided a link to the respective questionnaire.

With regard to the generalizability of the results that were based on the samples described above, it is important to mention that Switzerland is generally characterized by a wide cultural diversity (Swiss Federal Statistical Office 2009). Moreover, especially Swiss

Table 1
Measures

Variable	Item	Coefficient alpha	
		study 1	study 2
Transformation of a social norm into a personal norm	I feel bad when I do nothing while other people take action against gender inequality. (T1)	.79	.80
	I would do everything to prevent unequal treatment of women and men. (T2)		
	Each individual in our society is responsible if women and men are treated unequally. (T3)		
	Each individual should feel personally obliged to take actions to improve equal treatment of women and men. (T4)		
Awareness of consequences	If a society denies gender inequalities, this can lead to even higher inequality. (C1)	.84	.86
	In my opinion, a sustainable implementation of gender equality can contribute to solving gender inequality problems such as gender pay gaps. (C2)		
	I think that ongoing gender inequalities can cause social tensions. (C3)		
	If children will be better educated in terms of gender equality, this will lead to a more tolerant generation. (C4)		
	I know that treating women and men unequally will foster discriminating tendencies in our society. (C5)		
Purchase intention	If a company's advertising campaign broached the issue of sustainably implementing gender equality91	.91
	... I would be motivated to buy products from this company. (P1)		
	... this would have a positive effect on my purchase decision in favor of this company's products. (P2)		
	... this would positively influence my loyalty toward this company. (P3)		
Interest in the company	... I would become curious to learn more about this company. (I)		-
Acceptability of gender equality as an advertising topic	... I would recognize it as an interesting new advertising strategy. (A)		-

Note: the items were measured on 7-point rating scales ranging from 1 (do not at all agree) to 7 (totally agree)

universities are characterized by the fact that both administrative and scientific staff as well as students come from all over the world (Swiss Federal Statistical Office 2009). Consequently, the results coming from these data are not only Switzerland-specific, but can also be transferred to other countries.

Results of study 1

Based on a sample of 186 questionnaires that we received in the context of the first study, we examined whether the extent of the internalization of gender equality can explain consumer response variables such as purchase intention, interest in the company, and acceptability of gender equality as a topic of an advertising strategy. Therefore, we conducted regression analyses with the two dimensions of internalization (transformation of a social norm into a personal norm and awareness of consequences)

as independent variables and the consumer response variables as dependent variables. The results of these regression analyses are summarized in table 2.

The results show that the dimensions of internalization have significantly positive effects on the three considered response variables and thus provide support for H1. Consequently, the more people have transformed the social norm of treating men and women equally into a personal norm and the more they are aware of positive consequences of implementing such a norm into daily life, the higher are their purchase intentions toward products of a company that broaches the issue of gender equality in its advertising campaign, the higher is their interest in such a company, and the more likely they are to accept gender equality as a topic of an advertising strategy.

Table 2
Effects of Internalization on Consumer Response Variables

Independent variables	Dependent variables		
	purchase intention	interest in the company	acceptability of gender equality as an advertising topic
Transformation of a social into a personal norm	$\beta_1 = .62$ ($t = 7.04, p < .001$)	$\beta_1 = .50$ ($t = 4.34, p < .001$)	$\beta_1 = .60$ ($t = 5.32, p < .001$)
Awareness of consequences	$\beta_1 = .48$ ($t = 5.09, p < .001$)	$\beta_1 = .47$ ($t = 3.77, p < .001$)	$\beta_1 = .43$ ($t = 3.51, p < .01$)
R ²	.67	.47	.52

Results of study 2

The data collection in the context of study 2 led to an initial number of 1209 questionnaires that were completely filled in. However, we had to exclude several questionnaires from the data analyses because they proved to contain inconsistent answers as will be further explained below.

In a first step, we used the initial data set that contained 1209 respondents and conducted a hierarchical cluster analysis (which is commonly used to determine the optimal number of clusters) based on the method “between-groups linkage” with the variables T1-T4 and C1-C5 (listed in table 1) as input variables. We used the heterogeneity coefficients from the agglomeration schedule to identify the optimal number of clusters. The relation between the heterogeneity coefficients and the number of clusters is shown in figure 1.

FIGURE 1
OPTIMAL NUMBER OF CLUSTERS

Figure 1 clearly shows that a two-cluster solution is optimal. Based on this notion, we used K-means cluster analysis (which is used for large samples) to assign the respondents to the clusters. In order to be able to identify respondents with inconsistent response patterns at the same time, we conducted two separate analyses, one based on the variables that were intended to measure the transformation of a social norm into a personal norm and one based on the variables that were used to measure the awareness of consequences. We then generated a cross-tab to examine to what extent each respondent was assigned to the same cluster when differentiating between the two factors. The cross-tab indicates that 87 (256) respondents who were assigned to cluster 1 (2) based on the extent of a transformation of a social into a personal norm were assigned to cluster 2 (1) based on their awareness of consequences. The fact that a person has been assigned to two different clusters based on two sets of cluster variables that are correlated means that this person has not provided consistent answers with regard to the two sets of variables. In our research context, such bias might come from a tendency to (inconsistently) provide socially desirable answers which is typical for such fields of research. Thus, we eliminated 343 people who provided inconsistent answers from our initial data set and were left with two clusters of which cluster 1 has more than double the size of cluster 2 (see table 3).

Based on the remaining data set of 866 respondents, we determined the cluster centers based on the person-to-cluster-assignment that resulted from the K-means cluster analyses. In order to examine the discriminatory power of the identified segments, we conducted independent samples t-tests for the cluster variables. The cluster centers and the t-test results are presented in table 3.

Table 3
Cluster Centers of the K-Means Procedure and t-Test Results

Aspect	Item	Mean values		t-test results
		cluster 1 (n = 618)	cluster 2 (n = 248)	
Transformation of a social into a personal norm	T1	6.46	4.23	$t = 20.27 (p < .001)$
	T2	5.04	2.46	$t = 23.48 (p < .001)$
	T3	5.92	3.05	$t = 29.13 (p < .001)$
	T4	5.75	3.23	$t = 20.16 (p < .001)$
Awareness of consequences	C1	6.67	4.44	$t = 19.29 (p < .001)$
	C2	6.60	4.22	$t = 20.17 (p < .001)$
	C3	6.14	3.62	$t = 21.43 (p < .001)$
	C4	6.47	4.22	$t = 19.84 (p < .001)$
	C5	6.52	4.20	$t = 18.95 (p < .001)$

The highly significant t-values show that the two identified clusters can be clearly separated with regard to the cluster variables and thus provide support for H2. A look at the cluster centers shows that the extent of the internalization of gender equality is much higher in cluster 1 than in cluster 2. In order to make the resulting clusters more tangible, we additionally examined differences of the clusters with regard to age, gender, and education. The results of an independent samples t-test for age and chi-square tests for gender and education are shown in table 4.

The results of the age comparison show that people in cluster 1, which is characterized by a higher extent of internalization, are older on average (28.56 years) than people in cluster 2 (25.38 years). Although one might criticize that, descriptively, the age difference is not considerable, it can be stated, that these two age values characterize two different periods of life (people at the age of around 25 years are completing their education whereas people at the age of around 30 years are starting their professional lives and are founding a family). Moreover, cluster 1 is characterized by a clear dominance of women over men (81% vs. 19%), whereas in cluster 2, the percentage of men slightly dominates the one of women (55% vs. 45%). However, with regard to education, there are no significant differences between the two clusters. Thus, the extent of the internalization of gender equality obviously does not depend on education.

Finally, we analyzed whether the identified clusters differ with regard to the consumer response variables that have been used as dependent variables in the regression analyses of study 1 and that have also been measured in study 2. The mean values of these variables per cluster and the results of independent samples t-tests for the mean value differences are summarized in table 5.

The highly significant mean value differences of the considered variables show that cluster 1, which is characterized by a significantly higher extent of internalization is also characterized by significantly more positive reactions in terms of consumer response variables than is cluster 2. Thus, H3 is supported.

CONCLUSION

The starting point of this paper has been the observation that CSR topics are becoming more and more popular in advertising campaigns and that many CSR-based advertising campaigns cover similar topics such as environmental protection. Consequently, the basic research interest that finally led to doing the studies presented above, was to find other CSR topics that might attract more attention and that could also be used in advertising campaigns. Therefore, from a consumer research perspective, we found it interesting to pick out gender equality as one rarely considered CSR topic and to examine whether the internalization of gender equality as a personal norm can be related to consumer reactions to an advertising strategy that is based on gender equality. Furthermore, we were interested in identifying different consumer segments based on the extent of the internalization of gender equality as well as in examining whether the identified segments differ with regard to typical consumer response variables such as acceptability of the advertising strategy, interest in the company, and purchase intention.

Consequently, we built up a new theoretical framework by bringing together literature from the fields of CSR/social advertising, gender equality and internalization in terms of the transformation of social into personal norms. Based on this theoretical framework, we conducted two empirical studies.

The findings of the first empirical study show that the extent of internalization (represented by the two dimensions transformation of a social into a personal norm and awareness of consequences) positively influences purchase intention toward the products of a company that broaches the issue of gender equality in its advertising campaign, the interest in such a company, and the acceptability of gender equality as a topic of an advertising strategy.

The results of the second study indicate that two consumer segments that differ significantly with regard to the aspects of internalization can be identified. The first segment has more than double the size of the second segment and it is characterized by a higher degree of internalization of gender equality. Thus, transferring

Table 4
Cluster Differences with Regard to Age, Gender and Education

Variable		Cluster 1 (n = 618)	Cluster 2 (n = 248)	Test results
Age		28.56	25.38	$t = 5.06 (p < .001)$
Gender	male	19%	55%	$\chi^2 = 60.86 (p < .001)$
	female	81%	45%	
Education	secondary school	3%	2%	$\chi^2 = 2.41 (p > .10)$
	high school	27%	31%	
	college/university	70%	67%	

Note: for gender and education, we report percentages because given the large difference in sample sizes, percentages are more meaningful than absolute values

Table 5
Cluster Differences with Regard to Consumer Response Variables

Variable	Cluster 1 (n = 618)	Cluster 2 (n = 248)	T-test results
Purchase intention	5.22	3.00	$t = 20.44 (p < .001)$
Interest in the company	5.42	3.47	$t = 14.56 (p < .001)$
Acceptability as an advertising strategy	5.40	4.00	$t = 10.80 (p < .001)$

these findings to a larger population means that about two thirds of people in a society have internalized the concept of gender equality as a personal norm to a considerable extent, whereas about one third of people in this society are characterized by a much lower degree of internalization. Furthermore, the results provide the notion that people who are characterized by a high degree of internalization of the concept of gender equality are older on average than people that rate lower on the internalization scale. An additional finding has been that the high-internalization segment is clearly dominated by women, whereas the low-internalization segment is slightly dominated by men. In addition, we found that education does not play a role with regard to the internalization of gender equality. Relating the identified clusters additionally to the consumer response variables that capture reactions to an advertising strategy that broaches the issue of gender equality provided the notion that the consumers in segment 1 responded much more favorably than did consumers in segment 2.

The managerial implications of our findings can be summarized as follows. First of all, our results have shown that it might be an innovative approach to base an image campaign on the CSR topic of gender equality because such a campaign might be accepted and would generate a higher interest in the company as well as positive effects on purchase intention. However, the results show at the same time that the target group addressed by such an advertising campaign should be carefully chosen. Only if the major target group is characterized by a high degree of internalization of gender equality, if it has an average age of about 28 years and consists mainly of female consumers, the reactions to such an advertising campaign will be favorable.

Starting points for future research could be to investigate in more detail the finding that gender equality does not depend on education as well as to examine possible effects of the respondents' country of origin because cultural aspects might also play a role in the considered context.

Hiding in Plain Sight: 'Secret' Anorexia Nervosa Communities on YouTube™

Ekant Veer, University of Canterbury, New Zealand

ABSTRACT

This research investigates the way in which online public forums are being utilized as a means of sharing ones experiences with Anorexia Nervosa. What is particularly fascinating as well as simultaneously being horrifying, is that many of these accounts are pro-anorexia and used as encouragement for other sufferers to continue with their own eating disorders. With the ease of access to online video logging (vlogging) the role of the 'Vlogosphere' is growing in importance as a medium for public exhibitionism, even when the content of the posts are of an extremely sensitive nature. By adopting a netnographic research approach and Hermeneutic analysis method this research explores the role that personal video logs (vlogs) are being used as a means of public exhibitionism for five sufferers of Anorexia Nervosa. The findings show that the community that evolves around the sufferers act to maintain the vlogger's disease by encouraging her in her disorder and simultaneously defending her from attackers who disagree with her actions and vlogs.

INTRODUCTION

The use of web logging (blogging) and video logging (vlogging) as a means of self expression has increased exponentially in recent years (Nardi, Schiano, and Gumbrecht 2004) with the number of active blogs doubling every 6 months between 2003 and 2006 (Green 2007). Universal McCann estimate that 59% of internet users either read or own a blog of some form and 75% watch video clips online (Smith 2008). The potential that online media has as a portal for individual self expression appears limitless. This research focuses specifically on one aspect of online self expression many would define being stigmatized and outside mainstream consumer society. This research examines the way in which sufferers of Anorexia Nervosa use YouTube™ as a medium for expressing thoughts, fears, progress with their therapy, self identity, and other highly personal and sensitive topics to a relatively anonymous public audience with little control over the privacy of their posts.

Blood (2002) refers to a blog as a "coffee house conversation in text" (p.1) whilst other researchers define blogging by its format. Walker (2005) defines a blog as being a frequently updated web site consisting of dated entries in reverse chronological order so that the most recent post appears first. Blogs are typically posted by individuals having a personal or informal style and wish to produce an online diary (Walker 2005).

Some research has been done on the need for consumers to express their multiple selves through a variety of channels (Lee, Im, and Taylor 2008), whilst others have examined the motives behind 'online diaries' (Nardi et al. 2004). One area of interest in the literature is the need for stigmatized users to find ways of expressing themselves freely without judgment as a means of searching for belonging (Baumeister and Leary 1995). However, relatively little research has been conducted on the recent developments of video blogging and the motivations behind its use by internet users, with stigmatized identities such as Anorexia Nervosa. Therefore the research question presented here is: how does video blogging technology, and the community that it has created, motivate those with highly stigmatized identities, such as Anorexia Nervosa, to express their identity to complete strangers?

In achieving this aim we undertake a netnographic methodology (Kozinets 2002) to investigate five YouTube™ vloggers as they post their thoughts and feelings on the public forum. This

research comprises data collected from vlogs themselves, viewer, and producer generated comments to specific vlogs and forum posts made by participants about their vlog posts. Hermeneutic analysis is used to explicate the underlying meanings associated with the vlogs as well as to derive a fuller understanding of the context in which the participants choose to adopt vlogging as a means of self expression. Preceding the findings and discussion is a brief review of the extant literature on exhibitionism its role in consumer culture.

BACKGROUND

Self-expression and exhibitionism

The notion of consumers having and expressing multiple selves is well founded in consumer research and psychology (Markus and Kunda 1986; McGuire et al. 1978; Onkvisit and Shaw 1987; Wylie et al. 1979). The pressure associated with public expectation can lead to self-impersonation and as such, it is argued that consumers carry an arsenal of different masks that reveal different aspects of our 'self' (Markus and Nurius 1986). This research focuses more on a specific form of self-expression, that of public exhibitionism of a self that is often stigmatized by mainstream society. Holbrook (2000) defines consumer exhibitionism as going hand in hand with consumer voyeurism. Exhibitionism, as used in this research, is the need for consumers to display, express, and expose a form of themselves (whether it is real or not) so that others (consumer voyeurs) may watch. It is the act of purposefully exposing a part of the self in order for it to be seen. Similar acts that may be concealed from others would not, in this case, be seen as exhibitionism. Therefore, had this research looked at the private diaries of Anorexia Nervosa sufferers for which the only audience is the writer, then the concept of exhibitionism would not be valid.

Much of the psychological literature on exhibitionism defines it as a deviant and abnormal act. The main bodies of research look at sexual exhibitionism and means of treatment (Marshall, Eccles, and Barbaree 1991; Zohar, Kaplan, and Benjamin 1994) and focus heavily on the irrational nature of the behavior. One interesting area of research looks at how sexual exhibitionism in adolescents may not be a psychological disorder, but rather a "strategic interaction" in a search for acceptance and engagement with others (Green 1987). This desire to interact through 'showing off' has been linked with an abusive history (Hold-Cavell 1985). More recently, Baslam (2008) shows that female exhibitionism may not necessarily be related to abnormal sexual deviancy but a "normative spectrum for pleasurable active sex seeking and pleasurable procreative desire and fantasy" (pp. 99). Baslam continues by describing how female exhibitionism can be designed not to interact, but to engage onlookers with a sense of envy and yearning, which further affirms the female performer in her role as exhibitionist (Baslam 2008). Again, although motives may be different, the purpose is to engage the voyeur in some way.

Beyond the sexual context of exhibitionism there remains a raft of literature on 'show off's that has not permeated into consumer research. Bal (1992) describes the use of displays in museums as a means of asserting dominance of a culture. That is, by showing ones wares as a culture one is really showing off as to the superior nature of one culture over another. This notion of exhibitionism as a means of control, power, and even defence of ones identity is found in many contexts. Wilson and Daly's (1985) research on Detroit youth posits that violence in young men is often incited when a conflict in power exists between perceived competitors and such power struggles are further incensed when competitors show

off their power, whether it be through their physical strength, peer support or weaponry. One could argue that such behaviors found throughout society, from the youth in city streets, to adults in halls of power. Showing off and exhibitionism are, in many cases, about control and power. The following section will look at the relationship between control, power and Anorexia Nervosa in young women.

Anorexia Nervosa and Control

Although the focus of this research is not the etiology of Anorexia Nervosa, it is important to understand some of the basic causes associated with the disorder if we are to fully understand the context associated with the participants in question (Palmer 1969). The DSM-IV classifies Anorexia as being an inability to maintain a healthy body weight combined with a fear of losing control over the sufferer's weight and becoming 'fat'. Sufferers often come from abusive and *controlling* families whereby nurturance is significantly lacking (American Psychiatric Association 2000). Although many treatment plans are effective if the sufferer is diagnosed in time, many are reluctant to undertake treatment as it does mean relinquishing control (American Psychiatric Association 2000). This theme of control is reiterated in a number of studies on anorexia. Indeed, Garner, Olmstead, and Polivy's (1983) eating disorder inventory includes subscales on both striving for effectiveness (desire to find methods or solutions that are effective in meeting necessary weight-loss goals) as well as idealized perfectionism (searching for a physical perfection, which may be a distorted reality of one's actual size), both items heavily related to control over one's physical self. Latterly, Morgan, Reid, and Lacey's (1999) measurement of eating disorders also puts a heavy emphasis on the impact of lost control with regard to the severity of the sufferer's condition. One of the earliest pieces of psychoanalytic work on Anorexia also notes that the nature of the disease is when a person "embarks on her [his] relentless pursuit of thinness and absolute control over her [his] body" (Sours 1974, p 567). It is clear that control over oneself, one's body, and a desire for self-control away from a parental control system are all key factors in understanding sufferers of the disease, which links openly with the desire for control by the exhibitionist. Although of significant interest, this research will not focus on understanding why some sufferers of Anorexia Nervosa choose to be exhibitionists whilst others do not – the focus here is to understand their behaviors and actions as exhibitionists. The following section outlines the methodology employed and the findings from the research.

METHODOLOGY

This research utilized a netnographic approach (Kozinets 2002) as it offers significant advantages in this particular context. In particular it aids in researching sensitive subject areas as the researcher can covertly collect and analyse data without the vlogger feeling subjected to undue inquiry they may not be comfortable with (Langer and Beckmann 2005). This covert approach naturally raises issues of ethicality as participants may not wish their posts to be analysed and disseminated for public academic audiences. Netnography allows researchers to engage in stories presented on a freely available public forum without influencing the research participants. However, the nature of the posts and the research at hand on a public forum also allows the researcher (and anyone else surfing the web) to freely access the posts and ensure that ethicality is maintained as long as the participants is kept anonymous. As such, participants in this study will not be referred to by their actual user names and titles of posts will not be disclosed in this paper.

As much of the data being analysed is freely available on YouTube™ it was deemed appropriate to begin data collection by

finding participants [vloggers] who displayed characteristics akin to those suffering from Anorexia (Morgan et al. 1999). The search began by using search terms for "weight loss" which revealed a total of 212 individual vloggers. This search was then further refined with a search for "fast" or "fasting" which resulted in 13 individual vloggers being identified. By examining their initial posts all 13 displayed some characteristics of Anorexia, with 5 specifically mentioned that they have been diagnosed with the disorder. Although the other 8 vloggers may indeed be sufferers it would be imprudent of the researchers to assume the condition without formal psychoanalytic assessment of the vlogger by a specialist. As this is not available at this time these remaining 8 vloggers are not formally analysed as part of this study.

All five of the remaining vloggers were women aged between 20 and 31 at the time of analysis; however, logs made by diagnosed sufferers were identified by girls as young as 8 years old. Although a small proportion of Anorexia Nervosa sufferers are male the sample here are all female. All of the women had a steady partner and either lived at home with their parents or with their partner and (and any children they may have). The netnography began by watching all the vlogs made by the five vloggers, transcribing text and copying any comments made by viewers or vloggers. In total, 249 vlogs were viewed ranging in length from 45 seconds to 15:13 minutes covering a range of topics. The number of views for each vlog varies from vlogger to vlogger. As an indication of the volume of data provided by the vlog creator [vlogger] and vlog voyeurs [viewer] the most prolific vlogger had created 92 vlogs, which were viewed over 190,000 times (as at January 2009) and had over 2,700 regular subscribers who were alerted to any new vlogs being posted. Although these numbers may pale in comparison to the millions of videos available online, it still shows an area of high usage and of importance to online community research.

For interpretation of the collected data a hermeneutic approach was adopted as it offers a greater insight of the stories being told by the vloggers by examining the underlying meanings and context associated with the stories (Palmer 1969; Thompson 1997). By adopting hermeneutic analysis the researcher requires an understanding of the personal history of the textual stories in order to help understand the meanings associated with the stories generated by respondents. This research will therefore look to understand historical notions of control from participants' perspectives and focus on their own processual desire for greater control through their YouTube™ vlogs. However, themes from other, interrelated subjects will also be drawn into the analysis as it is seen appropriate.

FINDINGS

A number of themes emerged from the analysis of the data. However, due to the limited space associated with this submission we will only concentrate on three major themes, that of acceptance through self-validation, community and control. Other themes not discussed here include the vloggers' struggle with depression, anxiety, and validation. It is hoped these themes can be elucidated further in a future manuscript.

Acceptance Through Self-Validation

Based on the data collected, YouTube™ seems to be providing those that suffer from Anorexia Nervosa the possibility to express their real selves as well as control the level of expression associated with the posts. YouTube™ provides vloggers with a space in which their identity can be expressed without fear of being unaccepted or misunderstood; something that these vloggers express is impossible outside this setting. Vloggers maintain a heavy control over their posts by enabling the right to delete posts that invalidate their expression or damage their identities. Many of the vloggers express

that their fasting and Anorexia like behaviors are an important aspect of their lives and they feel unable to share it with those that matter to them the most. This indicates that they are fully aware of the controversy that surrounds their behavior but find that through the consumption of YouTube™, they do not risk the possibility of being unloved and unaccepted, as Vlogger A demonstrates here:

“ No one really understands what I go through, my parents would think I've gone crazy and send me to THAT clinic but it makes me feel so tired sometimes, and suppressed, and alone. They just don't understand what it feels like to want something so bad.....thank you guys so much, I mean it... all my subscribers.....it's nice to have someone that I can relate to and talk to....love you all and thanks for all your supportive messages... it's such a relief to finally be able to discuss this without people thinking that I'm a freak! ” (Vlogger A, 31, engaged with one child – fasting for her wedding).

Here Vlogger A offers a clear example of a need for belonging and validation (Baumeister and Leary 1995). When a lack of interpersonal belonging exists in real life for these vloggers they attempt to seek validation and belonging elsewhere. Some vloggers continue to build this need for belonging by further displacing themselves from their real life friends and families. Without a feeling of being understood by their friends and families and a deep sense of vulnerability, they crave the understanding of those on YouTube™. Therefore, as close relationships are formed on YouTube™, face to face relationships progressively diminish:

“I have to spend time with my mother today....not only is she going to complain how I'm not eating but I have to actually have a CONVERSATION with her....I really don't want to go and want to spend time with you guys....what's the point anyway?! It's not like she is going to understand any of my problems or issues; she is just going to start crying and complaining that she doesn't know how to help me...I DON'T NEED HELP! What's wrong with her?! Anyway...I can't avoid going so I might as well and just have some form of civil conversation...I promise to let you guys know how it went and will be making a video sooon!” (Vlogger C, 24, living with long-term boyfriend - fasting to lose her “hips”)

The above not only shows the lack of enthusiasm towards face to face interaction but also reveals the closeness of the relationships formed online. The vloggers studied here all show a desire to spend time with their online viewers rather than with their families. This indicates that, YouTube™ users form online relationships that can be of more value than those formed over many years with their parents or partners as the vlogger finds themselves expressing their ‘true’ selves to online viewers, resulting in the formation of a stronger connection and therefore high levels of affection and closeness. This can be also shown in the specific videos made:

“Just wanted to say hi to [name of viewer deleted], thank you for all your nice messages. You are so sweet. I saw recently that you're going through a bit of depression....you will be fine. You're amazing and such an inspiration to me. I hope you will pull through and I'm always here for you if you need to discuss anything. You have helped me stay motivated throughout my fasts and it's so sad when I see you upset. Please, PLEASE feel better soon.....hugs and kisses,

love you lots!” (Vlogger B, 22, living at home with parents – fasting to lose weight)

These bonds with the viewing audience forms a sense of community online that the vloggers crave as a means of offering validation for their situation and endeavors to lose weight.

Community

The more the vlogger engages with the YouTube™ community she has created the greater the ties between her online in-group and the weaker the ties with her offline friends and family (Batson et al. 1997; Tajfel 1982; Turner 1987). Such a creation results in greater reliance on YouTube™ itself and therefore provides a space whereby control of their identity becomes possible:

“It's so nice to be able to talk to people who know what I'm going through...it's funny...I spend all day hiding having this eating disorder from people around me and getting stressed about it....and then on here you can actually talk so freely about it... YOU WANT PEOPLE TO KNOW! [Laughs]...I guess it's because you guys know what I'm on about...you won't just think oh my god she needs help... thanks sweethearts!” (Vlogger C, 24, living with long-term boyfriend - fasting to lose her “hips”).

Consequently, this reliance results in strong levels of attachment between users and therefore, the need for approval. All of these examples offer evidence of a need for community, acceptance and the exertion of control by the vlogger. Many of the vloggers admit their need for control stems from the lack of control they felt as they grew up:

“It's not as if it's something I could have done anything about...HE was just a fucking monster now I think about it...HE was the one who did this to me and now HE's the one who thinks I'm a perfect angel...well it's not like that [long pause]. I couldn't change 'that' but I can change 'this'...this and NOW” [vlogger holds herself and squeezes stomach in so as to appear thinner] (Vlogger E, 21, living at home with parents – fasting to appear more attractive to a boy she likes).

The historical context of the stories offers a greater insight into the way in which the vloggers use exhibitionism as an extension of their need for control, which is again, symptomatic of Anorexia Nervosa sufferers. Vloggers perceive their YouTube™ vlogs as being a portal to an identity and community where they are offered acceptance and protection from the reality of their everyday lives (Noble and Walker 1997; Turner 1964).

As previously discussed, results have shown that vloggers feel that YouTube™ is a place for self expression without judgment. Therefore, they feel at ease with expressing issues of concern and frustration that are related to their weight loss. It is the fact that such expression is directed at viewers that have similar interests and concerns that allows for high levels of support and encouragement in times of distress for the vlogger. Not only does such expression allow for a release of anxiety, but the support it generates allows the video bloggers to feel loved and cared about. This evidently allows for emotions of affiliation and belonging to be experienced:

“I broke my fast today...I'm so angry with myself....IM A FAILURE!!! I ate so much....I'm so disappointed in myself....WHY??? I know this is probably boring for you, but I

need to get this feeling out!! I know you guys will understand...ITS SO FRUSTRATING!! I hope I haven't put on any weight! I don't want to step on the scales....." (Vlogger C, 24, living with long-term boyfriend - fasting to lose her "hips").

In response to this, a viewer commented:

"Don't worry hunnie, we all have made mistakes. I know you are strong and can cope with this. Don't let it put you down, keep motivated. I swear you are such an inspiration to me and even though you feel really bad and like a disappointment, you are not! Keep up the fast and you will feel better, don't let yourself slip and most importantly remember, we have ALL broken a fast at some time or another and what you did is normal. Love you and wish you the best"

Participant C went on to thank the viewer in her next video:

"Thank you so much for your comments!! It's nice that I can have someone to talk to that relates to my problems.... you made me feel a million times better, you're a sweet heart and I wish that your fast is going well! Thanks for caring!"

All of these interactions aid the vlogger to exert greater strength and control over her situation and lead her further down the road of fasting as a means of losing weight. It is clear that the online communities offer much needed validation for these 'private' fasts and is only exaggerating the effects of the disease through greater need for control and greater desire to lose weight.

Control

In order to control their identity without it being challenged, users tend to lie to friends and family about their eating disorder. In line with this they try just as hard to keep their video blogging activities a secret from those that know them:

"... sorry....I have to keep my voice down....my parents are in the other room and they don't know about this video making...they would go really mad if they found out...and they would also find out a lot of things that I really don't want them to know, as you can imagine (sighs)....it's good that way.....I get to have my own little world with you guys that's far away from the day to day crap" (Vlogger D, 21, living at home - fasting to look beautiful).

The use of YouTube™ allows for strong levels of supportive interaction, but it also provides many of these women with a form of 'thinspiration' through the viewing of other similar online journals:

"I was bored the other day...well I couldn't sleep....so I went on YouTube™ and watched some videos....I mean.... some of you girls are amazing...your so motivated and strong willed...I also watched a video on a fast and I decided that's what I need to do...so I'm starting a fast!!! Thanks for the inspiration (deleted word)....I realized how much weight you're losing and if you can do it....well it just gave me the motivation to try fasting" (Vlogger A, 31, engaged with one child - fasting for her wedding).

This once again emphasises the strong sense of community provided by the consumption of YouTube™, but also shows how

the vloggers engage with coping mechanisms to continue their individual fasts. Conversely, when control is lost, the outcome often results in frustration, anger, depression, but also, more heightened levels of exhibitionism. This is shown by one vlogger's flamboyant outburst online after losing control of her fast:

"...feeling like SHIT right now...really depressed...I mean, I weighed myself this morning and I've lost NOTHING!! NOTHING!!.....I'm just really frustrated, I know it's a bit silly but I just needed to get it out and I cant seem to sleep... ..I don't know...I guess this really has nothing to do with anything....I just wish I could zone out or disappear"(Vlogger B, 22, living at home with parents - fasting to lose weight).

And again, the sense of frustration comes through with another vlogger, completely unrelated to the first but with a very similar narrative:

"I am so fucking angry!!!! I weighed myself and nothing! NOTHING! (screams).....that's it I'm not going to post another video till I've lost some weight...this is just pathetic and I'm PATHETIC to watch.... I'm so sorry you guys... you've been so sweet to me and all I've done is let you down.....just watch me I will loose the weight!" (Vlogger E, 21, living at home with parents - fasting to appear more attractive to a boy she likes).

The frustration through lost control is symptomatic of sufferers of Anorexia Nervosa; however, their public, exuberant displays of anger are often not seen due to their fear of losing acceptance (Vitousek and Manke 1994). Sufferers are more likely to reclude from those not in favor of their behavior; but when a support network, such as the YouTube™ communities, exist, the vlogger is able to vent their emotional frustration and draw strength from viewer comments and responses to their situation.

DISCUSSION

This research has looked at the role in which YouTube™ offers sufferers of Anorexia Nervosa the opportunity to seek acceptance, form communities of similarly minded supporters of their behavior and exert greater control over their lives. This research does not aim to offer an understanding for what may have caused their eating disorders nor does it offer contributions for understanding a cure for the disease. What this research is able to show is that technologically savvy consumers are able to find emotional catharsis through exhibitionist behaviors. The loss of control with one side of the vlogger's life is exaggerated with more and more extroverted presentations of self online. This is in line with Schau and Gilly's (1995) investigations into online presentational behavior and the desire to show one's self online in a way that may appeal to viewers. In this case the vloggers are presenting a sign that draws attention and sympathy from viewers, allowing the vloggers to further validate their decision to fast.

The findings here show that the expression of self using vlogs is a form of hyper-expression or exhibitionism compared with personal websites or even blogs. This could be indicative of a coping mechanism to generate validation for their actions and draw encouragement from the community they have created, or it is an extension of their disorder whereby a loss of control in one aspect of the vlogger's life leads to a need to gain of control by drawing attention to their plight through exhibitionism.

The paradox in this research lies with the fact that many of these sufferers act as though they are sharing their private thoughts in a private setting. The revelations of self they offer become more and more detailed and private in nature, similar to that of a private diary (Nardi et al. 2004), but in a public forum. The desire to exhibit themselves to the outside world, whilst still keeping their affliction hidden from their loved ones offers a significant area of interest for both consumer culture theorists and eating disorder therapists.

The Catharsis Hypothesis suggests that venting one's emotions can aid in alleviating the emotional anger or pain one is feeling (Feshbach 1956). However, more recent evidence has shown that vented anger does not often relieve tension, but rather increases anger levels (Bushman 2002; Bushman, Baumeister, and Phillips 2001). But, it appears that when the vented emotions are subsequently validated by a strong community spirit to continue unhealthy behavior the vlogger reacts positively to the feeling of catharsis through the support she receives from YouTube™. This cathartic experience is thus harnessed as a means of mood repair. However, the result is a continuation of thoughts and behaviors that further validate the triggers of Anorexia Nervosa.

This research may offer more questions about vlogging behavior than it does answers, but it does highlight the need for awareness of the role that online communities play in self formation and self validation. What is known is that these women are suffering, but they are not suffering in silence and they are not suffering alone. The support rich environment offered by YouTube™ means that sufferers are able to be a 'validated self' and it is this 'self' that may continue to slowly kill them in the privacy of their webcams, computer screens and hundreds of thousands of online voyeurs.

Sacred Places: An Exploratory Investigation of Consuming Pilgrimage

Leighanne Higgins, University of Strathclyde, UK

Kathy Hamilton, University of Strathclyde, UK

ABSTRACT

In line with the growing commercialization of religion, this paper focuses on the consumption of sacred place within the context of the Christian pilgrimage. Theoretically, we raise the profile of place within consumer research and contribute to understandings of the relationship between the sacred and the profane.

INTRODUCTION

The aim of this paper is to explore the religious consumption experience of pilgrims within sacred places. The interplay between economics and spirituality has been well documented within consumer research literature with regards to the sacralization of consumer culture (O'Guinn 1991, Kozinets 2001, Muniz and Schau, 2005). However, there is less research interest on the secularization of the sacred in relation to the commercialization of religion. We contribute to this research stream by exploring the context of the Christian pilgrimage.

Previous research on the interaction between the spiritual and the material has focused on people (O'Guinn 1991), possessions (Muniz and Schau 2005) and activities (Celsi, Rose and Leigh 1993, Arnould and Price 1993). Our focus brings the issue of place to the forefront, highlighting that place is central to our understandings and experiences. We begin by discussing the concept of pilgrimage to help contextualize the study.

DEFINING PILGRIMAGE

The traditional definition of pilgrimage relates to "a physical and spiritual journey in search of truth, in search of what is sacred and holy" (Vulkonic 1996 cited in Timothy and Olsen 2006). This perspective prioritizes religious and spiritual fulfillment whereby pilgrims journey to a holy site where the earth and the divine are believed to meet. Within contemporary consumer culture the definition of pilgrimage has evolved to encompass more than holy sites alone. As Morinis (1992) suggested, a pilgrimage site can be any place where an individual finds enlightenment, clarity or happiness. Following this approach, pilgrimage can be discussed within the context of dark tourism to places like Auschwitz or celebrity pilgrimages such as a trip to Graceland.

Pilgrimage sites become sacralized because of events that have taken place there. In this paper we focus on Christian pilgrimage sites. For example, Lourdes in France is seen as one of the most celebrated Roman Catholic shrines in the world, with a yearly intake of approximately 5 million pilgrims, travelling to worship the apparition of the Virgin Mary in 1858. Similarly, Fatima in Portugal receives approximately a million pilgrims between May and October each year, honoring the apparition of the Virgin Mary to three children in 1917. A typical Christian pilgrimage involves processions, individual prayer, meditation, and collective worship during religious services.

Given the growing commercialization of religion, a consumption vocabulary surrounds Christian pilgrimage discourse. The pilgrim is increasingly viewed as a tourist and the pilgrimage site becomes the marketplace where hotels, souvenir shops, restaurants and tour operators all compete to attract the lucrative pilgrim consumer. In this respect, pilgrimage sites provide an overlapping of the sacred and the profane, offering an appropriate context to explore and seek understanding of the complex relationship between religion and consumerism.

RELIGION AND RELIGIOSITY WITHIN CONSUMER CULTURE

Statistics point to the global decline of religious practice and belief. In Scotland, where the research was conducted, the 2001 population census found that thirty percent of the Scottish population had no religious affiliation whatsoever (Voas 2006). A similar trend is present in the USA with the "American Religious Identification Survey" discovering a nine percent drop in the number of citizens identifying themselves with a religion, and with Christianity seeing a twenty percent drop in following between the years 1990 and 2001 (Kosmin and Mayer 2001). In contrast, consumers are moving towards the production and reworking of their own religions (Scott and Maclaran 2009), implying that individual beliefs have more significance in everyday life than the social structures and institutions that support them. For example, in Ireland, despite falling Church attendance, Palmer and Gallagher (2007) argued that the ideology of religion remains important, thereby reinforcing the multidimensionality of religiosity. Religious institutions may have particular difficulty in appealing to younger age groups who seek innovative non-traditional approaches (Davis and Yip 2004). Equally, while we have witnessed a decline in traditional religious beliefs, there has been a proliferation of New Age spiritual thinkers, who according to Rindfleisch (2005, 343) position New Age spirituality as "'social products" for consumption."

SACRED CONSUMPTION

Following a Durkheimian approach, Belk, Wallendorf and Sherry (1989, 13) distinguished the sacred in contrast to the profane. They argued that sacred occurrences may be "ecstatic" and "self-transcending" and are often "aided by a social context involving fellow believers who also revere the object or experience." In opposition, the profane is "ordinary and lacks the ability to induce ecstatic, self-transcending, extraordinary experiences." However, research has acknowledged a blurring and narrowing of the boundaries between the sacred and the profane. This is evident through two parallel trends in relation to religion and consumption, first, the secularization of the sacred and second, the sacralization of the secular (Belk, Wallendorf and Sherry 1989).

The sacred experience is no longer confined to the religious arena, rather consumption activities offer the possibility of transcendence (Arnould and Price 1993, Celsi, Rose and Leigh 1993, Hamilton and Hewer 2009), filling the void left by the less central role of religion in everyday life. Shopping malls are seen as "cathedrals of consumption" that offer "enchanted settings" where consumers can gain a sense of community (Ritzer 2005, 7). Fans worship and imbue celebrities with god-like powers and fan clubs serve important social functions, facilitating sharing and bonding (O'Guinn 1991). "Cherished possessions" or "inalienable wealth" (Curasi, Price and Arnould 2004, 609) account for an important part of the self. The religiosity of brand communities highlights the transformation of seemingly profane and functional consumer goods into objects that offer emancipation and liberation (Muniz and Schau 2005). This use of religious themes and narratives in marketplace discussions points to "the continued presence, vitality, and relevance of religious connections" (Muniz and Schau 2005, 745). Through consumption practices "the material world can become the seat of the sacred again; consumption can become (re) ensouled" (Kozinets 2002, 32).

Equally, religious commercialization is growing as religious souvenirs, devotional objects, music and home decorations objectify the sacred (Ger and Wilk 2005) while religious theme parks merge the sacred and profane (O’Guinn and Belk 1989). Trends such as these draw attention to the expanding reach of market capitalism, supporting the idea of a consumer civilization (Campbell 2004).

METHOD

This exploratory study was conducted in order to understand the experiences and opinions of visitors to Christian shrines. Ten one-to-one in-depth interviews formed the basis of data collection. A total of eight interviews were conducted with respondents who identified themselves as Christian and who had participated in a Christian pilgrimage. Access to five of the respondents was negotiated with the assistance of a parish priest from a local Catholic church. Following a snowball method, the parish priest then aided an introduction with a local Episcopalian minister which led to three further respondents. All of these respondents practiced their religion on a regular basis. Although not included in the current paper, we also conducted two interviews with respondents who identified themselves as Atheist. As shown in table 1, respondents were mixed in terms of gender and age.

The interviews were conducted in a social room within the Catholic Church hall and lasted up to 100 minutes. Interview topics focused on accessing the lived experience of respondents’ understandings of pilgrimage. Discussion centered on defining pilgrimage, personal meaning of pilgrimage and the role of marketing in the pilgrimage experience. Interviews were audio-recorded and transcribed for data analysis. We adopted a hermeneutic approach to data analysis by first seeking an idiographic understanding of each transcript and second, seeking a holistic understanding by exploring common patterns and themes (Thompson, Pollio and Locander 1994).

FINDINGS

The findings are presented in relation to three emergent themes; understanding pilgrimage, the social context, and pilgrimage as a consumption experience versus pilgrimage as a spiritual experience.

UNDERSTANDING PILGRIMAGE

Belhassen, Caton and Stewart (2008) suggested that a fully comprehensive understanding of place cannot be obtained without consideration of physical environments, experiences and meanings. This provides an appropriate framework to deconstruct the meaning

Table 1: Profile of Respondents

Pseudonym	Gender	Age	Occupation	Religious Belief	Pilgrimage Experience
Daniel	Male	58	Retired	Episcopalian	Jerusalem, Rome
David	Male	53	Taxi Driver	Catholic	Lourdes (several times)
Mark	Male	18	Student	Catholic	Lourdes (several times)
Robert	Male	55	Manager	Episcopalian	Lourdes (several times)
Fiona	Female	51	Clerical work	Catholic	Lourdes (once)
Isabelle	Female	56	Retired	Episcopalian	Lourdes, Walsingham
Katy	Female	57	House-wife	Catholic	Lourdes , Jerusalem
Penny	Female	52	House-wife	Catholic	Lourdes

of pilgrimage and present this section of the findings. Although each aspect is discussed separately, it should be apparent that physical environment, experience and meaning are interrelated.

PHYSICAL ENVIRONMENT

Given the centrality of place to the pilgrim experience, the aspects of physical location were frequently mentioned during interview discussions. For respondents, a pilgrimage site is somewhere that something “special” or “miraculous” has occurred. Put simply, it is “a holy site.”

Mark: “I feel that it has to have some type of spiritual core to it, some type of pull that makes people deem it as special enough to visit.”

Daniel: “certain locations have this, what experts call, a numinous feel to it, where you actually feel when you are in a place that there is something special about it.”

Whilst the idea of specialness derives from shared social and cultural understandings relating to historical sacred occurrences, some referred to more personal events. For example, Mark considered his pilgrimage to Lourdes “as being one of the curers for my illness” reinforcing the powerful, self-transcendent nature of the sacred (Belk, Sherry and Wallendorf 1989). Irene described a pilgrimage as “a personal mission” while Katy commented:

Katy: “I think it has to have something special to the individual. For me Lourdes is very special, not because I have seen huge miracles occurring there, but I truly believe that little miracles happen there every-day. And to see small children who are seriously ill and people seriously ill, but who still belief and smile, and laugh, that is humbling and puts life in perspective for you, makes you wonder what am I worrying for? So for me, that humbling aspect is a miracle in itself.”

Such social and personal understandings result in the pilgrimage site being viewed as “a place of worship,” or “a place of prayer” where pilgrims can celebrate their faith in a spiritual centre.

Another key theme that emerged in relation to the physical environment was the way a pilgrimage must involve a “journey” and consequently, somewhere away from one’s everyday domain. As Fiona commented, “a pilgrimage for me is travelling out with your normal environment and everyday life.” For all of our respondents, the pilgrim had necessitated significant travel, normally involving a trip from the UK to continental Europe. However, further analysis of this idea reveals that the physical distance travelled is not the most important criteria of the journey:

Katy: “I think the problem is we have got it into our minds that by going further afield we are making more of an effort, but I think that we all journey, and can all make good pilgrimages, as long as we set out and achieve the goal

that we aimed for, no matter where we actually made the journey. I would not say you have to leave the county to make a pilgrimage, I mean it is all about a journey. And for some people it might be a hard journey just getting into the door of the church, or going to mass, so in that way yes I think for some it could be a pilgrimage. But for me mass, and prayer are my everyday norms, so going to Lourdes and other pilgrimage places, I feel helps me learn more about my faith and allows me to broaden my spiritual and faith journey."

This further suggests that pilgrimages are individualistic experiences that involve a distancing from one's daily routines and realities. This physical distancing or escapism provides the additional benefit of time, or as one respondent puts it, "time for thoughts and prayer." Although from the above, it is evident that the physical environment is important, for many this is not the only or central aspect to a pilgrimage. Indeed, for some, the emotional journey becomes far more significant. This is explored further in the following section on the meanings of pilgrimage.

MEANINGS

Given the personalized nature of pilgrimage, it can have many layers of meaning. Some see it as "enlightening," and a time for "spiritual growth in your inner faith." In this sense, it offers a reminder of the nature of existence:

Daniel: "The basis of pilgrimage as far as I can understand it is the notion that our life on earth is transient, that we are all pilgrims in the sense that we have come, and we are moving and we are going, we cannot settle down here forever, we are on a pilgrimage. And the notion of going to holy places is to in a way, for many people anyway, is to bring that realization.to bring people to an awareness of the spiritual image of human existence."

A common theme for many respondents was the potential of pilgrimage in relation to "the liberation of emotions." Particularly significant, was the idea of mixed emotions. While respondents mentioned "enjoyment," "pleasure" and "fulfilment," they also talked about "sacrifice," "effort," "tiredness," "exhaustion" and a "testing," "pushing" and "draining" of the self. Some respondents employ exchange terminology in an attempt to explain such mixed emotions. In other words, while the experience "can be quite exhausting both physically and mentally," this is "in exchange for spiritual fulfilment" and the achievement of other personal spiritual goals. As such, pilgrims are content to endure the "emotional cost" in order to reap individual benefits.

For some respondents it was this exchange aspect that differentiates a pilgrimage from a holiday:

Mark: "there are times you will be in blasting heat and you think wow if I was on holiday I would be sunbathing or having a drink, but that is not why you're there, you're there to help the sick and to gain better spirituality yourself. So yes I agree there is and always should be a level of penance involved, I think that's what makes it worthwhile, and what separates normal holidays from pilgrimage."

Robert: "going on your holidays is solely to relax, but I think if you go on a pilgrimage you look to test yourself too, and it is not all about relaxing so I believe there is a level of penance and servitude involved."

Fiona: "A tourist is there to take pictures and do their nosy and see what the hype is and then move on, and to buy the tack, to buy the flashing Our lady and the huge tacky rosaries and all that. The pilgrim I feel is there for his or her purpose, you are there for your spiritual need, for you to take your time to pray the way you want to pray, to light your candles and all the things you want to do."

Previous consumer research on experiential activities tends to adopt a positive tone in that they afford consumers the opportunity for relaxation, fun and pleasure (Goulding et al. 2008), and even in some cases a kind of flow experience (Celsi, Rose and Leigh 1993). In contrast, this study highlights the dual and complex nature of emotional release within the pilgrimage context. Alongside consumption and enjoyment, pilgrimages require "effort," "hard work" and "penance." These multiple meanings produce differential but complementing pilgrimage experiences, to which we now turn.

EXPERIENCE

This section focuses on the various different roles played and performed by the pilgrim. These different roles can be partly explained by individual motivations behind the pilgrimage:

Daniel: "In my case, when I go to a place it is more for historical reasons, more because I am interested in the history of religion, I am interested in where it comes from if you like, where its sources are, it was for this reason that I went to Jerusalem and Rome. It is maybe a bit idiosyncratic, I don't go for the usual reasons, I don't feel obliged to go as a kind of religious duty, I go out of interest to search out the underlying sort of historical meaning or truth behind the Christian faith."

Mark: "For me I have been to Lourdes as a member of the sick twice and as a helper once also. I feel that you get different things from the experience each time you go. When I went as a sick person, I found that it was meeting people and the generosity of people that moved me most, but as you go as a helper it changes as it is much more rigid and you have to do certain things. Making it more difficult at times, but also incredibly rewarding, as you know you are helping bring some peace to others who are now in a situation I was in before."

The pilgrim site thus provides a stage where pilgrims are helpers, cultural and historical enthusiasts, worshippers or in search of healing.

Findings reveal that within the pilgrimage site, individuals often perform a dual role fluctuating between pilgrim and tourist. Despite these overlaps respondents are clear that "it is not by any means a holiday" and underlying motivation separate the pilgrim and the tourist.

Pilgrimages are often presented in a similar fashion as package holidays making it difficult to make a clear distinction between the two. We suggest that a distinction between journey and destination may be appropriate. Tourists consider the pilgrimage site as a destination, somewhere to explore while for pilgrims, the site is part of a journey. This calls to mind Belk, Ger and Askegaard's (2003) research on consumer desire. They argued that the journey towards aspirational consumption goals can be enjoyable in itself, sometimes outweighing the benefits that are achieved once the goal is realized. Within the context of pilgrimage, it is the journey itself that pilgrims value and in this respect it is pilgrims who gain

the deepest satisfaction from the pilgrim site. This reinforces the need to think of place as comprising different elements; while the physical environment remains the same, individual experiences will differ (Belhassen, Caton and Stewart 2008).

THE SOCIAL CONTEXT

Pilgrims can make their journey individually or as a part of an organized tour group, both of which provide slightly different experiences.

Robert: "On your own you have the freedom to do as you wish meaning you can tailor your journey to suit you, your pilgrimage is to benefit you the way you want and need, extra prayer time, etc. But also on the organized trips you have more structure and routine, which can limit you, but you have comradeship, which can be nice and spiritual in its own way."

Even those who make an individual pilgrimage are surrounded by other people, an issue that appeared to be central and "vital" to the pilgrimage experience for our respondents. Through a "common thirst for the some kind of spiritual reality," people from diverse nationalities and cultures are connected.

Daniel: "I think it enhances or it should enhance the notion of human solidarity, and belonging and it should do away with the normal prejudices, like prejudices of race, etc..... I think that one of the great benefits of pilgrimage should be to see other people and realize that being human is what is important."

Isabelle: I also found that the mixing with the different nationalities was extremely rewarding and even though you don't speak the same language you all have a common understanding and can make yourself understood in the pilgrimage situation for you are there for the same purpose, searching and worshipping together.... I believe that it is about brotherhood and sisterhood, about realizing that we are all connected, about coming together."

The idea of sharing a common purpose was something that several of the respondents mentioned. This creates a strong feeling of integration and togetherness and an environment where "there is so much love" and no barriers created by language or race. As Belk (2010) suggested, unlike economic exchange, such sharing helps to create a sense of community. The dissolution of boundaries between pilgrims creates a liminal state and strong evidence of *communitas* (Turner 1969).

While the common purpose often results in "a group of similarly minded people," pilgrimage also provides the opportunity to meet people with different religious beliefs and backgrounds. As Mark suggested, "there are so many that may not even come from a religious background, but they return year after year due to gaining something from the experience." Similarly, one of our respondents discussed an encounter with someone from a non-Catholic background:

Penny/David: "one of the times I went to Lourdes, I met a man who was Grand Masonic Leader in Scotland, and he went just to see what all the hype was about at Lourdes, and felt so much passion and feeling when he entered the site, that he returned three times following from that, well he was on his fourth visit when I met him and he planned to return every year till as he put it "God allowed.""

This provides an example of the way in which the pilgrimage site can incite the sharing of personal narratives creating unity even amongst strangers. To seasoned pilgrims, stories such as this serve to reinforce and confirm the miraculous and special nature of the pilgrimage site. Muniz and Schau (2005, 740) reported a somewhat similar situation in their investigation of the Apple Newton brand community where the telling of stories was identified as a form of "consumer magic." The emphasis on sociality contrasts with Palmer and Gallagher (2007) who found that the social support offered through religious institutions plays a less significant role in everyday life. Instead, it reinforces the importance of self-other relations with spatial environments.

CONSUMPTION EXPERIENCE OR SPIRITUAL EXPERIENCE?

In this section we explore the interplay between religion and consumption, investigating whether respondents view pilgrim sites as truly sacred or if they have become contaminated by commercialization. Many of our respondents accepted that marketing, consumption and tourism are inevitable elements of pilgrimages and indeed, several simply explained marketing as an "everyday norm"

David: "consumerism is a part of everyday life, so why would religion, which let's face it is a huge part of peoples' lives not also be included in this consumerism. It is just that when people think religion, they automatically believe it should be neutral from all changes, but it evolves and changes with life like everything."

Nevertheless this does not appear to detract from the benefits of the pilgrimage and some even highlighted the resulting economic benefits of pilgrimage to towns surrounding the shrines. However, this perspective depends on the creation of certain boundary lines over which marketing cannot intrude. Several respondents discussed this idea in relation to Lourdes, arguing that as long as the grotto (where the visions of the Virgin Mary were seen) itself remains sacred, they do not object to commercialization outside the gates:

Fiona: "to be honest at the grotto it is like another world, the grotto and the basilica is like another place completely, the minute you go through the gates it is the strangest thing, but it is almost like a presence enters you, and it stays with you throughout the domain, and it happens every time you go through the gates not just the first time. You see something different every time you go into the domain. They have managed to keep the bustle and tack of the commercial side of Lourdes away from the domain."

Similarly, Penny suggested that "once you enter the domain, there is just so much relaxation, there is none of the bustle, or the buying and the selling." The movement from "busy streets" to "tranquility" allows for a change in mindset and complete absorption in the task at hand so that "you are not thinking about anything other than your faith and Our Lady." O'Guinn and Belk (1989) noted that visitors experienced a similar feeling of other-worldliness in Heritage Village, USA, the religious theme park, despite the presence of a shopping mall and other forms of entertainment. However, in the present study, findings suggest that the Christian pilgrim site can provide a complete and temporary escape from the marketplace as it is free from "tackiness" and "commercialization." In this respect, it can remain pure, outside the domain of contemporary consumer culture. Reminiscent of Belk's (2010, 730) conclusion on sharing, we can argue that an understanding of pilgrimage challenges "the

encroachment of the perspective that all the world is a market and everything and everyone within it is an exchangeable commodity."

A few respondents discussed the way in which the surrounding consumer culture inadvertently contributed to a more intense pilgrimage experience:

Daniel: "I believe that you just have to cling to your faith and ignore all the tackiness, and all the nonsensical things that happen around you whilst on your pilgrimage. I suppose you could say that is new form of penance in modern day pilgrimage that you have to eradicate from your mind, all the irrelevant things happening around you."

Likewise, Irene concurred that an aim of pilgrimage is to "challenge myself to block out the everyday live and focus on my faith and religion." Others discussed more straight-forward benefits of the consumerist element, for example, some respondents appear to get enjoyment from the consumer environment that surrounds pilgrimage sites such as the opportunity to "go for dinner and maybe have a glass of wine or whatever with my friends." Others also like to shops for souvenirs:

Isabelle: "I got a lot of enjoyment picking presents to take back for people in my church, you just had to watch where you went for them, obviously there are the tacky shops but there are also some really lovely and very spiritual shops which sell some lovely religious tokens."

Katy: "And I also think that brining back a small souvenir for people from a holy pilgrimage site can mean the world to the person, allows them to feel a part of that pilgrimage themselves and allows them to know they are thought about and loved."

Souvenirs appear to provide a tangible memento or symbol of the journey both for the pilgrim or a way of spreading the sacredness to others. For some pilgrims, the opportunity to consume and relax is essential. Indeed one respondent argued that without escapism through the tourist market, "it would be torture." This supports the earlier discussion on the fuzzy boundaries surrounding the tourist and pilgrim roles.

CONCLUSIONS

This paper focuses on the consumption of sacred place within the context of the Christian pilgrimage. In relation to theoretical contributions, we raise the profile of place within consumer research, addressing Sherry's (2000, 277) concern that consumption theory often neglects "place as a lived experience." Increased mobility, alongside technological advances, has resulted in a lack of embeddedness or indeed, placelessness appearing as a central feature of consumer culture (Cushman 1990). However, we demonstrate that place can have significant meaning in our lives, indeed, the spiritual and emotional release achieved by our respondents cannot be decontextualized from the physical places in which they occur. In this respect, place is central to our understandings and experiences.

We also contribute to understandings of sacred consumption, in particular the relationship between the sacred and the profane, discussions which have only a marginal place within consumer research literature (Arnould 2004). Much of the research in this area tends to focus on the sacralization process, whereby sacred and secular meanings intertwine as consumption extends far beyond a core commercial purpose. We attempt to redress this balance by exploring the issue of secularization and the way in which spiritual

and religious meanings have become increasingly commercialized. We began this paper wondering if "consuming pilgrimage" was an appropriate phrase to use in the title. However, throughout the findings we have highlighted the fuzzy boundaries between the sacred and the profane and illustrated that places can combine both sacred and profane elements. We suggest that religion can have a place within consumer culture and that the presence of commercialization does not appear to reduce or dampen the religious or spiritual experience. Despite commercialization, pilgrimages still offer the opportunity to "transcend existence as a mere biological being coping with the everyday world" (Belk, Wallendorf and Sherry 1989, 2).

Place attachment theory is often considered in relation to our homes or places that we visit on a regular basis. However, through an examination of the physical environment, experiences and meanings of pilgrimage sites, we demonstrate how consumers can also experience strong attachment to places that are far from our place of residence yet places that are deemed to deserve reverence. Our findings reveal that the combination of sacred space and special activity or practices creates a sense of utopia (Maclaran and Brown 2005). Sacred sites place the consumer, providing a welcome feeling of belonging in light of the increasing displacement associated with consumer culture. Visiting such sites of enhancement can have important spiritual benefits. Within consumer culture theory there has been much debate surrounding rationality and emotion. We suggest that what is missing from this discussion is spirituality. As well as receiving functional and emotional benefits through consumption, spiritual benefits are also achievable. Indeed, as humans it could be argued that we need and seek some form of connection with the spiritual side of existence.

Consumer Reactions to Corporate Decisions to Outsource Labor Abroad

Silvia Grappi, University of Modena and Reggio Emilia, Italy

Simona Romani, Luiss Guido Carli, Italy

ABSTRACT

This paper analyzes consumer reactions in the form of word of mouth communication to positive, negative, and hybrid (i.e. both positive and negative at the same time) CSR information. We also examine the mediating role of emotions in explaining these reactions, while controlling for the moderating role of consumer ethnocentrism.

Fiat SpA, the Italian Turin-based car-manufacturer, is forging ahead with its decision to close its Termini Imerese plant in Sicily. Fiat's head of institutional relations has informed labor unions that the company has no intention of altering their plans to halt this facility's production after 2011. In fact, Fiat is currently in the process of gradually off-shoring production in countries where wage rates are a fraction of those in Italy, claiming that it is no longer competitive to keep the Termini Imerese plant going. The Italian government has held off on a decision regarding new "cash-for-clunkers" incentives, as the Minister for Industry insists that Fiat must maintain current levels of production and employment. Although Fiat does anticipate a "significant" drop in sales, its Chief Executive Officer stated that the company will not defer its plans and would fully agree with not renewing these incentives. The decision to close the Termini Imerese plant, which currently employs 1,658 full-time employees, is a model example of corporate decisions to outsource jobs abroad, which leave domestic workers in great difficulty, with no regard for the economical and social implications for that community, or indeed the whole country. In fact, this town is situated in Southern Italy where unemployment rates are extremely high and there are few alternatives available besides emigration. Fiat's essentially financially motivated decision has attracted much attention throughout Italy, especially because of the impact this is having and will continue to have on the workers and entire Termini Imerese community.

Research available on consumers' responses to a company's Corporate Social Responsibility (CSR) record generally focuses on either positive or negative information. However, in the marketplace it is possible at times for consumers to be simultaneously exposed to different valenced CSR information on the same company in one or more domains.

This paper attempts to examine this situation with the aim of analyzing consumer reactions, in the form of word of mouth communication, to CSR information that is positive, negative, and hybrid – i.e. both positive and negative at the same time. In detail, we investigate the mediating role of emotions in explaining consumers' reactions to a company's CSR practices, controlling for the moderating role of consumer ethnocentrism.

The CSR context selected for the purposes of this study is the company decision to either source man-power from within the home market (positive CSR information) or totally/partially outsource these jobs abroad (negative/hybrid CSR information). The practice of outsourcing labor abroad has attracted much attention over recent years and been heavily criticized for the associated ethical issues. It is possible for consumers to perceive this choice as a sign of the ethical and/or moral commitment of the company to its

home country; outsourcing sends a message to consumers that the company no longer supports the local or even national community and/or economy. Therefore, the locating of production abroad has CSR implications that can extend well beyond awareness on a local level and notably even come to backfire on the brand. Consumers may well conclude "Why should I sustain them? They don't support us anymore!"

BACKGROUND AND CONCEPTUAL FRAMEWORK

Corporate Social Responsibility (CSR) is defined as a company's "status and activities with respect to its perceived social obligation" (Brown and Dacin 1997: 68). A number of studies show how information on CSR practices can influence consumer evaluations in terms of their attitude towards the company (Brown and Dacin 1997; Mohr and Webb 2005; Sen and Bhattacharya 2001; Sen, Bhattacharya, Korschun 2006), purchasing behavior (Sen and Bhattacharya 2001; Klein and Dawar 2004), and identification with the corporation (Sen and Bhattacharya 2001). It has also been demonstrated that consumers are more sensitive to irresponsible than responsible corporate behavior. In other words, we witness an asymmetric effect where doing bad harms more than doing good helps (e.g., Sen and Battacharya 2001, Battacharya and Sen 2004).

Although the extant research has examined the impact on consumer evaluations of either positive or negative CSR information as well as, more recently, the inconsistencies between a company's claimed CSR standards and their actual behavior (Wagner, Luz, and Weitz 2009), there is a lack of studies on reactions to hybrid CSR behavior (both responsible and irresponsible at the same time) and the possible role played by emotions in these responses. This paper introduces a conceptual framework to examine the specific consumer reaction of word of mouth to CSR behavior as well as taking into consideration the moderating role of individual ethnocentrism and mediating effects of emotions.

Corporate policy and practice on outsourcing jobs abroad provides an ideal context for investigating these effects. Companies are faced with the choice of either maintaining a domestic workforce in the aim of supporting the national economy (positive CSR behavior), or outsourcing domestic jobs abroad for opportunistic reasons (negative CSR behavior), or opting for a partial outsourcing of labor (hybrid CSR behavior).

In order to define these various CSR contexts it is possible to consider the literature on Country of Origin (CO) (Guran-Canli and Maheswaran 2000a, 2000b; Verlegh, Steenkamp and Meulenberg 2005), and, in particular, the critical distinction between the concept of country of design (CD) and country of manufacture (CM) (Ahmed and d' Astous 2008). Given that products can be designed in one country and manufactured or assembled in another, the CD and CM are both important elements in the analysis of responsible/irresponsible CSR behavior.

One factor that can play a key role in reactions to companies' outsourcing decisions is ethnocentrism. This expresses the point of view that the group to which one belongs is the center of everything (i.e. the home country) with all other groups (i.e. foreign countries) judged against this standard. Consumer ethnocentrism is the tendency to overestimate the quality of domestic products (Sharma, Shimp, and Shin 1995; Shimp and Sharma 1987) and favor products originating from one's own country over those

imported (Ouellet 2007). The purchase of foreign products can be viewed as improper because it costs domestic jobs and harms the economy, or even as simply unpatriotic (Sharma, Shimp, & Shin, 1995; Shimp & Sharma, 1987).

Consideration should also be given to the mediating role of emotions in the relationship between CSR practices and consumer behavior. It is reasonable to expect that negative emotions play a central role in the CSR negative context, and likewise that positive emotions feature prominently in the CSR positive context, with both being associated in CSR hybrid contexts. An explanation for these responses may be found in the category of moral emotions. Morality can be defined as judgments that “must bear on the interest or welfare either of society as a whole or at least of persons other than the judge or agent” (Gewirth 1984: 978). Moral emotions are therefore those activated in moral contexts that prompt individual moral behavior, clearly connected to the interests of others (Haidt 2003). For the negative situation we have chosen to focus on the emotion anger, given that it is a typical reaction to unjustified insult and can be triggered on one’s own or other’s behalves (Haidt 2003), while for the positive context we concentrate on gratitude, in being a classic example of a positive valenced affect experienced in response to the benevolence of another. Gratitude is experienced especially when the recipient considers the benefits received as unexpected and/or costly to the “benefactor” (Tangney, Stuewig, and Mashek 2007).

RESEARCH HYPOTHESES

We hypothesize that ethnocentrism plays a central role in moderating the overall effect of CSR practices on consumers’ word of mouth behavior in contexts characterized by total or partial outsourcing of domestic jobs abroad (negative and hybrid CSR practices). Given that in these contexts ethnocentric consumers can perceive a threat to them as well as the group they belong to (home country), we predict that their evaluation of the company’s decision is heavily influenced by their level of ethnocentrism.

H1: *The negative effect of the decision to outsource domestic jobs abroad (negative CSR practice) on consumers’ word of mouth is moderated by consumers’ ethnocentrism.*

H2: *The negative effect of the decision to partially outsource domestic jobs abroad (hybrid CSR practices) on consumers’ word of mouth is moderated by consumers’ ethnocentrism.*

We also predict that a company’s decisions on outsourcing often give rise to moral emotions. Given that these choices closely relate to consumers’ sense of national belonging and what they perceive to be in the interests of their country, we hypothesize that these moral emotions play a mediating role in the moderated effect between the “CSR practices–to–word of mouth” connection. We examine the role of the negative moral emotion of anger in the negative CSR context, and both anger and the positive moral emotion of gratitude in hybrid CSR contexts, where the appraisal of situations characterized by both positive and negative corporate practices can activate mixed feelings (Ruth, Brunel, and Otnes 2002).

H3: *The negative moral emotion of anger has a mediating role in the moderated negative effect of the decision to outsource domestic jobs abroad (negative CSR practice) on consumers’ word of mouth.*

H4: *The moral emotions of gratitude and anger have a mediating role in the moderated negative effect of the decision to partially outsource domestic jobs abroad (hybrid CSR practices) on consumers’ word of mouth.*

We can hypothesize that the role of ethnocentrism differs in the positive CSR context. In this case, the lack of a direct “threat” to domestic jobs would suggest an absence of the overall moderation of ethnocentrism. Here, we would expect the positive moral emotion of gratitude to have a mediating role in the “CSR practices–to–word of mouth” connection. Although we can expect ethnocentrism to have a reduced role in the positive context compared to that negative or hybrid, it may still have an influence on eliciting moral emotions and/or consumer actions.

H5: *The positive moral emotion of gratitude has a mediating role in the positive effect of the decision to support the national economy (positive CSR practice) on consumers’ word of mouth. Consumers’ ethnocentrism moderates this mediating process.*

METHOD

The methodological approach adopted for testing the above hypotheses involves the use of an experimental design, conducted on Italian consumers. Pretests were conducted in order to select both the product and foreign country where the manufacture and/or design of the product is/are delocalized.

Pretests. First, subjects were asked to rate their overall level of knowledge of three different products chosen as representative of three diverse product categories (so as to ensure a wide range of initial possible options): a digital camera (electronic); a pair of sunglasses (fashion); and ceramic tiles (technical). In each pretest, performed separately on each of the products, the consumers rated their knowledge on a seven-point scale: sunglasses ($n = 30$; $M = 4.00$, $std = 0.95$); digital camera ($n = 30$; $M = 3.57$, $std = 1.19$); ceramic tiles ($n = 30$; $M = 3.23$; $std = 0.94$). In conclusion, the final product selected, with the highest level of knowledge among respondents, was sunglasses. Regarding the choice of foreign setting for the product’s delocalized manufacture and/or design, we asked respondents to rate, on a seven-point scale, ten countries (Australia, Belgium, China, France, Japan, the UK, Morocco, Russia, Spain, and the USA) in terms of their ability in the manufacturing and, independently, design of the product ($n = 30$). The country selected, resulting as being considered the least skilled in both fields, was Morocco ($M = 2.03$, $std = 1.10$ as manufacturer; $M = 1.33$, $std = 0.61$ as designer). This choice is based on the need to put emphasis on the negative aspects of corporate behavior related to the outsourcing of labor (the company decision is motivated by purely economic motives and unrelated to workers’ skills).

Procedure and subjects. In order to cover the relevant CSR contexts - (1) positive CSR: support of national economy (CD Italy/ CM Italy); (2) negative CSR: total outsourcing of domestic jobs abroad (CD Morocco / CM Morocco); (3) hybrid CSR: partial outsourcing of domestic jobs abroad (CD Italy / CM Morocco; CD Morocco / CM Italy) - and to test our hypotheses, we employed a 2 (CDs) \times 2 (CMs) between-subjects design.

Initially, participants were provided with some background information about a fictitious company that produces and sells sunglasses, and then presented with a scenario of this company’s CSR policies regarding support of the national economy. After reading this description, participants completed the relevant questionnaire, were debriefed and then thanked.

The participant group, randomly assigned to conditions, consisted of a sample of 339 consumers, both male (49.6%) and female (50.4%), with a mean age of 39. Of this sample, 70 questionnaires were collected for the control condition (without information on the company's outsourcing practices).

Dependent variables. All dependent variables were assessed using a scale from one to seven. First, subjects were asked to express the degree to which they felt given emotions based on the information they had just read, and then rate their intentions to practice word of mouth about the company. Subjects then responded to questions designed to measure their level of ethnocentrism and check for manipulation, and indicated their age and gender.

Moral emotions. Subjects were asked to express the degree to which they felt each of the given emotion descriptors on the basis of the information they had just read, using measures selected from the literature (Laros and Steenkamp 2005; Richins 1997; Shaver et al. 1987). The items used for anger are angry and very annoyed ($r = 0.94$), and for gratitude, thankful and feeling appreciation ($r = 0.78$). The items measuring the same emotions were averaged to form the emotions indexes.

Consumer worth of mouth. Subjects were asked to express their degree of agreement with various statements, aimed at measuring their intention to practice word of mouth: "I intend to recommend this company's products to friends, relatives, and acquaintances," "I intend to talk well of this company to friends, relatives, and acquaintances," and "I intend to mention this company to friends, relatives, and acquaintances" ($\alpha = 0.96$).

Ethnocentrism. Following Ouellet (2007), ethnocentrism was measured using four items selected from the CET scale (Shimp and Sharma 1987): "A good citizen does not buy foreign products," "It is not right to purchase foreign products because it puts us out of jobs," "We should purchase products manufactured in our country instead of letting other countries get rich off us," and "We should buy from foreign countries only those products that we cannot obtain within our own country" ($\alpha = 0.93$).

Manipulation checks. The final section of the questionnaire controls for manipulation, by asking respondents to recall where the product in question was designed and manufactured, and rate their perception of the company's CSR practices regarding outsourcing.

RESULTS

A comparison was made between the experimental and control groups (Gurhan-Canli and Maheswaran 2000a), and no systematic effects were observed with gender and age as covariates.

Manipulation checks. Participants correctly recalled the product's CD and CM in each experimental condition. An ANOVA on the perception of the company's CSR practices (Tab. 1) revealed a clear differentiation between the four groups ($F(3, 265) = 68.56, p < .005$). Post hoc analysis revealed significant differences between the negative condition (CM Morocco / CD Morocco) and all the other (hybrid and positive) conditions; the positive condition (CM Italy / CD Italy) and all the other (hybrid and negative) conditions; and no differences between the two hybrid conditions (CM Morocco / CD Italy; CM Italy / CD Morocco) ($t = .421; p = 0.67$).

Table 1. Means (std deviations) of consumers' perceptions of the company's CSR practices

	CD Italy	CD Morocco
CM Italy	6.31 (0.85)	4.19 (1.12)
CM Morocco	4.27 (1.16)	3.42 (1.45)

Note – cell size ranges from $n = 59$ to $n = 70$

Word of mouth. First, we tested the bearing of CSR practices on consumers' word of mouth by comparing two groups: one corresponding exclusively to the control condition (with no information on the company's CSR practices); and a second, complete with all the other conditions. A t-test on the consumers' word of mouth index revealed that CSR decisions do indeed have a significant impact ($t = 5.34, P < .005$). An ANOVA on negative word of mouth revealed a great differentiation between the groups ($F(4, 334) = 50.28, p < .005$). Post hoc analysis revealed significant differences between the negative CSR condition (CM Morocco / CD Morocco) and all the other (hybrid and positive) conditions; the positive CSR condition (CM Italy / CD Italy) and all the other (hybrid and positive) conditions; and no differences between the two hybrid conditions (CM Morocco / CD Italy; CM Italy / CD Morocco) ($t = 1.38; p = 0.17$).

We then tested our research hypotheses by analyzing the role of moral emotions in the "CSR practices-to-word of mouth" connection. Tables 2 and 3 present the resulting means and standard deviations of the dependent variable and moral emotions for each experimental condition.

Table 2. Means (standard deviations) of word of mouth

	CD Italy	CD Morocco
CM Italy	5.73 (1.17)	3.35 (1.40)
CM Morocco	3.67 (1.33)	2.85 (1.45)
Control group	5.01 (1.44)	

Note – cell size ranges from $n = 59$ to $n = 70$

Table 3. Means (standard deviations) of moral emotions

		CD Italy	CD Morocco
anger	CM Italy	1.38 (.73)	3.19 (1.97)
gratitude		5.32 (1.50)	2.41 (1.59)
anger	CM Morocco	2.71 (1.88)	3.52 (2.24)
gratitude		2.96 (1.72)	1.80 (1.08)
anger	Control group (no CO information)	1.69 (1.14)	
gratitude		3.74 (1.81)	

Note – cell size ranges from $n = 59$ to $n = 70$

In order to detect the role of moral emotions in explaining consumers' word of mouth within the experimental sets, we followed the approach of Muller, Judd, and Yzerbyt (2005) in analyzing the moderated mediation and mediated moderation processes. The relevant variables are: (1) the manipulated independent variable X (the company's outsourcing policies: the product's CM and CD), indicating the different experimental conditions; (2) the outcome variable Y (word of mouth), measuring the response of participants presumed to be affected by the treatment; (3) the mediating variables Me (moral emotions), which are also responses expected to be influenced by the treatment; and (4) the continuously measured moderating variable, Mo (ethnocentrism), an individual difference variable assumed to be unaffected by the treatment.

The *mediated moderation* process can only occur when moderation takes place. Given that the magnitude of the overall treatment effect on the outcome depends on an individual difference (in this case, ethnocentrism), then the question of mediated moderation is concerned with the mediating process that is responsible for that moderation. The *moderated mediation* process occurs if the mediating process responsible for producing the effect of the treatment on the outcome depends on the moderator variable value. Given that the moderator is an individual difference variable, in this case the mediating process that intervenes between the treatment and outcome varies according to people's different levels of ethnocentrism.

There are three models that underlie both these processes (Muller, Judd, and Yzerbyt 2005). The first assesses the moderation of the overall treatment effect:

$$Y = \beta_{10} + \beta_{11}X + \beta_{12}Mo + \beta_{13}XMo + \epsilon_1 \quad (1)$$

The second allows the treatment effect on the mediator to be moderated:

$$Me = \beta_{20} + \beta_{21}X + \beta_{22}Mo + \beta_{23}XMo + \epsilon_2 \quad (2)$$

And the third allows both the mediator's (partial) effect on the outcome and the residual effect of the treatment on the outcome, controlling for the mediator, to be moderated:

$$Y = \beta_{30} + \beta_{31}X + \beta_{32}Mo + \beta_{33}XMo + \beta_{34}Me + \beta_{35}MeMo + \epsilon_3 \quad (3)$$

In all three models, *X* and *Mo* are uncorrelated and all the variables are centered at their mean, with the exception of the outcome (Muller et al. 2005). In distinct analyses for each moral emotion (gratitude and anger) we estimated models 1 through 3 to demonstrate mediated moderation and moderated mediation processes.

Mediated moderation. In model 1, we would expect β_{13} to be significant, indicating overall treatment moderation; in models 2 and 3, either (or both) of two patterns should exist: both β_{23} and β_{34} and/or both β_{21} and β_{35} are significant. In addition, the moderation of the residual treatment effect β_{33} should be reduced in magnitude compared with that of the overall treatment effect. In order to understand the mediated moderation effect, the following calculations prove useful:

the simple effects of treatment on the mediator (emotion) at values of one *SD* above and below the moderator (ethnocentrism) mean score: $\beta_{21} + (\beta_{23} * \pm SD_{Mo})$ (4)

the simple effect of the mediator on word of mouth at values of one *SD* above and below the ethnocentrism mean score: $\beta_{34} + (\beta_{35} * \pm SD_{Mo})$ (5)

the total indirect effects through the mediator (emotion), taking the product of the two simple effects (4) and (5) for each of the two ethnocentrism values

Moderated mediation. In model 1, we would expect β_{11} to be significant, whereas not β_{13} . In models 2 and 3, either (or both) of two patterns should exist: both β_{23} and β_{34} and/or both β_{21} and β_{35} are significant. In consequence the residual treatment effect

should now be moderated, that is, β_{33} may be significant, but this is not a necessary condition for establishing moderated mediation (Muller et al. 2005). It also proves useful to consider the following calculations:

the simple effects of the manipulation on the mediator (emotion) at one *SD* above and below the moderator mean using the following equation: $\beta_{21} + (\beta_{23} * \pm SD_{Mo})$ (4)

the simple effect of the mediator on word of mouth at values of one *SD* above and below the ethnocentrism mean score: $\beta_{34} + (\beta_{35} * \pm SD_{Mo})$ (5)

the total indirect effects through the mediator, taking the product of the two simple effects (4) and (5) for each of the two ethnocentrism values

the simple residual treatment effects at the two ethnocentrism levels: $\beta_{31} + (\beta_{33} * \pm SD_{Mo})$ (6)

Our findings, presented in Tables 4 and 5, demonstrate that consumers' ethnocentrism is capable of moderating the overall negative effect of corporate decisions regarding the total/partial outsourcing of domestic jobs abroad (negative/hybrid CSR practices) on consumers' word of mouth behavior, supporting H1 and H2.

We can also observe that, in the negative CSR context, the negative moral emotion of anger is capable of influencing word of mouth communication through a mediated moderation process, thus supporting H3. The effect of negative CSR practice on negative word of mouth interacting with the emotion of anger, is greater when the level of ethnocentrism is high (-0.57) compared to low (-0.39). After controlling for the mediator and its interaction with the moderator the residual direct effect of the manipulation on the outcome results as -0.57 (reduced from -0.63).

In the two hybrid CSR contexts both the moral emotions of gratitude and anger prove capable of affecting word of mouth through mediated moderation processes, thus supporting H4. In the first (CM Morocco / CD Italy), the effect of mixed CSR practices on word of mouth, interacting with the emotion of anger, is greater when the level of ethnocentrism is high (-0.46) compared to low (-0.04). After controlling for the mediator and its interaction with the moderator, the residual direct effect of the manipulation on the outcome is less moderated by ethnocentrism at -0.38 (reduced from -0.49). In the case of gratitude, the effect can also be seen to be greater when the level of ethnocentrism is high (-0.37) compared to low (-0.01), with the residual effect reduced from -0.49 to -0.41. In the second hybrid CSR context (CM Italy / CD Morocco), the effect on word of mouth interacting with the emotion of anger, is greater when the level of ethnocentrism is high (-0.62) compared to low (-0.14), with the residual effect reduced from -0.55 to -0.43. And again for gratitude the effect is greater when the level of ethnocentrism is high (-0.45) rather than low (-0.25), the residual effect is reduced from -0.55 to -0.49.

Table 4. The mediated moderation and moderated mediation processes

	Process	Emotions	
		Gratitude	Anger
Set 1 – positive CSR (CM Italy / CD Italy)	$b_{13} = -.01$, sig.=ns Moderated Mediation	$b_{21} \neq 0$ and $b_{35} \neq 0$	No hypothesized effect
Set 2 – hybrid CSR (CM Italy / CD Morocco)	$b_{13} = -.55$, sig.=.00 Mediated Moderation	$b_{23} \neq 0$ and $b_{34} \neq 0$	$b_{23} \neq 0$ and $b_{34} \neq 0$
Set 3 – hybrid CSR (CM Morocco / CD Italy)	$b_{13} = -.49$, sig.=.00 Mediated Moderation	$b_{23} \neq 0$ and $b_{34} \neq 0$	$b_{23} \neq 0$ and $b_{34} \neq 0$
Set 4 – negative CSR (CM Morocco / CD Morocco)	$b_{13} = -.63$, sig.=.00 Mediated Moderation	No hypothesized effect	$b_{23} \neq 0$ and $b_{34} \neq 0$

Table 5. Simple and total effects in mediated moderation and moderated mediation processes

		High ethnocentrism	Low ethnocentrism
Set 1 - CM Italy / CD Italy			
Gratitude	simple effect of the manipulation on the mediator	$1.47 + (0.04 \cdot 1.75) = \mathbf{1.54}$	$1.48 + (0.04 \cdot -1.75) = \mathbf{1.40}$
	simple effect of the emotion on WOM	$0.30 + (-0.04 \cdot 1.75) = \mathbf{0.23}$	$0.30 + (-0.04 \cdot -1.75) = \mathbf{0.37}$
	total indirect effect	$1.54 \cdot 0.23 = \mathbf{0.35}$	$1.40 \cdot 0.37 = \mathbf{0.52}$
	simple residual treatment effect	$0.17 + (0.04 \cdot 1.75) = \mathbf{0.24}$	$0.17 + (0.04 \cdot -1.75) = \mathbf{0.10}$
Set 2 - CM Italy / CD Morocco			
Gratitude	simple effect of the manipulation on the mediator	$-1.36 + (-0.37 \cdot 1.90) = \mathbf{-2.06}$	$-1.36 + (-0.37 \cdot -1.90) = \mathbf{-0.66}$
	simple effect of the emotion on WOM	$0.30 + (-0.04 \cdot 1.90) = \mathbf{0.22}$	$0.30 + (-0.04 \cdot -1.90) = \mathbf{0.38}$
	total indirect effect	$-2.06 \cdot 0.22 = \mathbf{-0.45}$	$-0.66 \cdot 0.38 = \mathbf{-0.25}$
Anger	simple effect of the manipulation on the mediator	$1.62 + (0.63 \cdot 1.90) = \mathbf{2.82}$	$1.62 + (0.63 \cdot -1.90) = \mathbf{0.42}$
	simple effect of the emotion on WOM	$-0.28 + (0.03 \cdot 1.90) = \mathbf{-0.22}$	$-0.28 + (0.03 \cdot -1.90) = \mathbf{-0.34}$
	total indirect effect	$2.82 \cdot -0.22 = \mathbf{-0.62}$	$0.42 \cdot -0.34 = \mathbf{-0.14}$
Set 3 - CM Morocco / CD Italy			
Gratitude	simple effect of the manipulation on the mediator	$-0.82 + (-0.43 \cdot 1.84) = \mathbf{-1.61}$	$-0.82 + (-0.43 \cdot -1.84) = \mathbf{-0.03}$
	Simple effect of the emotion on WOM	$0.30 + (-0.04 \cdot 1.84) = \mathbf{0.23}$	$0.30 + (-0.04 \cdot -1.84) = \mathbf{0.37}$
	total indirect effect	$-1.61 \cdot 0.23 = \mathbf{-0.37}$	$-0.03 \cdot 0.37 = \mathbf{-0.01}$
Anger	simple effect of the manipulation on the mediator	$1.10 + (0.53 \cdot 1.84) = \mathbf{2.08}$	$1.10 + (0.53 \cdot -1.84) = \mathbf{0.12}$
	Simple effect of the emotion on WOM	$-0.28 + (0.03 \cdot 1.84) = \mathbf{-0.22}$	$-0.28 + (0.03 \cdot -1.84) = \mathbf{-0.34}$
	total indirect effect	$2.08 \cdot -0.22 = \mathbf{-0.46}$	$0.12 \cdot -0.34 = \mathbf{-0.04}$
Set 4 - CM Morocco / CD Morocco			
Anger	simple effect of the manipulation on the mediator	$1.86 + (0.37 \cdot 1.96) = \mathbf{2.59}$	$1.86 + (0.37 \cdot -1.96) = \mathbf{1.14}$
	simple effect of the emotion on WOM	$-0.28 + (0.03 \cdot 1.96) = \mathbf{-0.22}$	$-0.28 + (0.03 \cdot -1.96) = \mathbf{-0.34}$
	total indirect effect	$2.59 \cdot -0.22 = \mathbf{-0.57}$	$1.14 \cdot -0.34 = \mathbf{-0.39}$

In the positive CSR context, findings show that consumers' ethnocentrism is not capable of moderating the overall positive effect of the company decision to support the national economy on consumers' word of mouth. The moral emotion of gratitude results as affecting consumers' word of mouth through a moderated mediation process, and consumer ethnocentrism is capable of moderating this mediating process, thus supporting H5. In this context, the simple effects of the manipulation on the mediator gratitude, regardless of the ethnocentrism level, reveal that this emotion is increased (1.54 for high ethnocentrism; 1.40 for low ethnocentrism). We also calculated the simple effects of gratitude on word of mouth (0.23 for high ethnocentrism; 0.37 for low ethnocentrism). By taking the product of the two simple effects for each of the levels of ethnocentrism, we were able to calculate the overall indirect effect through gratitude (0.35 for high ethnocentrism; 0.52 for low ethnocentrism). The simple residual treatment effect for the high ethnocentrism condition is 0.24 and 0.10 for the low. These results reveal that the indirect effect, through the mediator, is greater when ethnocentrism is low rather than high. In fact, the experimental treatment has a greater effect on gratitude in the high rather than low ethnocentrism condition, whereas the effect of this emotion on word of mouth is stronger in the presence of low ethnocentrism.

DISCUSSION

This research attempts to increase our understanding of consumer reactions in terms of word of mouth to different CSR decisions regarding the outsourcing of domestic jobs abroad, while taking account of the mediating role of positive and negative moral emotions and the moderating role of consumer ethnocentrism. Notably, our analysis of emotions and ethnocentrism is completely new in the CSR research field, and furthermore, we include a rare

examination of hybrid CSR contexts in addition to those typically positive and negative.

We are able to verify a model linking CSR practices to consumers' word of mouth behavior, adopting the approach of Muller, Judd, and Yzerbyt (2005) in analyzing the moderated mediation and mediated moderation processes. In the positive CSR context, the emotion gratitude proves important in explaining the impact of company practices on consumer word of mouth through a moderated mediation process, with ethnocentrism playing a significant role in influencing the effect of gratitude on the outcome. Subjects with high levels of ethnocentrism result as being less likely to engage in word of mouth compared to those with low levels. This would appear to suggest that the company decision to support the national economy in maintaining a domestic work-force is seen quite simply as fair practice and not worthy of particular "celebration" for highly ethnocentric individuals, whereas it is more note-worthy for those with low levels of ethnocentrism, making them more likely to engage in word of mouth about the company.

In the negative and hybrid CSR contexts (total/partial outsourcing of domestic jobs abroad), findings show that ethnocentrism does have a moderating role in the "CSR practices-to-word of mouth" connection. Notably, individuals with high levels of ethnocentrism result as having less intention of engaging in word of mouth compared to those with low levels. In the negative CSR context, the emotion anger proves important in explaining the moderated influence of company practices on consumer word of mouth behavior. In the two hybrid CSR contexts, both anger and gratitude play a mediating role in the moderated influence of company practices on consumer word of mouth. It is interesting to note a difference that emerges between these two hybrid contexts. In the case of Morocco as the CM and Italy as the CD, the negative effect on word of mouth for consumers with low levels of ethnocentrism is negligible, whereas

in the reverse condition (CD Morocco / CM Italy) it is manifest, even for this group of subjects. The explanation for this possibly lies in the different consumers' perceptions of these two hybrid conditions. It appears that the outsourcing of design is perceived as a greater threat to the home country than manufacturing. The context used for analysis probably determines this specific result. The fact that Italy boasts a long tradition in fashion and design makes it possible to speculate that Italian consumers perceive the outsourcing of product design to Morocco as more negative than the manufacturing alone, and are thus more likely to react to it.

Another interesting result warranting further discussion concerns the presence of both positive and negative emotions in the hybrid contexts. How consumers act in the presence of mixed emotions remains an open issue in consumer research and marketing (Ruth et al. 2002). This situation can lead to inconsistent behavioral responses, but our findings suggest that consumers tend to reduce their intention to make word of mouth, overcoming the conflict and favoring the negative reaction. The only CRS context in which these mixed emotions are capable of inhibiting action in individuals with low levels of ethnocentrism is, as mentioned above, that where Morocco is the CM and Italy the CD. This preliminary evidence merits further examination in future research.

There are a number of intrinsic limits to this study which suggest possible directions for additional research. One such limitation regards our scenario-based approach, with participants giving their reactions to various descriptions of CSR practices under experimental conditions. It is likely that subjects pay more attention to these descriptions than if they had come across them in an everyday context such as a newspaper or magazine. Furthermore, respondents were prompted to express their emotional reactions and intentions regarding word of mouth immediately after reading these descriptions. Both these aspects suggest that the possible effect of CSR practices would be stronger in this artificial situation compared to in real life. Replicating this study under more natural conditions would undoubtedly provide a more conservative test. Another limitation relates to the fact that this paper focuses on a selected sub-area of CSR practices. The taking of other CSR domains into consideration would certainly broaden the perspective examined here. And lastly, future research on consumers' reactions to corporate outsourcing decisions from an intercultural and not purely Italian perspective would probably also prove to be of great relevance.

On Consuming Celebrities: The Case of the Kylie E-Community

Paul Hewer, Strathclyde University, UK
Kathy Hamilton, University of Strathclyde, UK

ABSTRACT

In this paper, we seek to move beyond the standard endorsement and communications approach to celebrity so perceptively critiqued by McCracken (1989). To build upon the insights of O'Guinn (1991) and Penaloza (2004) gleaned from cultural analysis of the singular celebrity case through attention to computer-mediated fan communities. Our analysis reveals that celebrities offer consumers vital dreams of survival and escape achieved through consumer exchanges in the emerging digitalscape of online fan communities. Here celebrity functions as a form of collective therapy practiced through celebrity e-forums. In this way, we demonstrate how commercial domains are reappropriated and de commodified by fans as unique repositories for the exchange of empathetic understanding the collective display of affective emotional investments.

INTRODUCTION

The labours of consumption operate in uncertain times; while stocks, shares and our beloved brands from yesteryear tumble and fall, those theories which purport to explain consumers as solely economic agents lose their appeal and credibility. Consumers lives, punctuated by news of the daily downturns of firms and organizations, seek other forms of solace and salvation. In this critical context of disenchantment the labours of consumption gains a more social and sacred character, enlivened and revitalized by the hyperreal vitality and presence of all manner of celebrity hopefuls. In this paper we seek to instigate a *celebrity turn* within consumer research and consumer culture theory (Arnould and Thompson 2005) to augment our understanding of consumers and the sacred character of the investments and identifications they make in celebrity culture. In this paper, we seek to move beyond the standard endorsement and communications approach so perceptively critiqued by McCracken (1989) and to build upon the insights of O'Guinn (1991) and Peñaloza (2004) gleaned from cultural analyses of the singular celebrity case. To advance such approaches we turn to the vital dreams of survival and escape which celebrities offer and the possibilities of transformation which they afford consumers in computer-mediated fan communities. As a context for this discussion we use the case of Kylie Konnect and Kylie forums to explore the vitality of consumer to consumer interactions - fan to fan conversations around the loved object (Ahuvia 2005) of Kylie.

On the face of it there would appear to be little of uniqueness about the case of Kylie¹; little to merit concerted academic debate and discussion. But this would overlook the ingredients of Kylie which make her exactly the right context and imaginary resource for countless popular discussions on blogs and social networking sites centring upon the trials, tribulations and fascinations of celebrity affairs. In this paper we take seriously the vitality of such cyber interactions within contemporary culture to argue that consumer fascinations around the continuing appeal and resourcefulness of celebrities often resides in their storytelling potential; a potential

which accounts for the productive social aspects of those interactions where fans debate and come together over issues like their treatment by the media, their thwarted love affairs and music/fashion/celebrity appeal. In this respect we explore Kylie as a *loved object* (Ahuvia 2005); seeking to unpack the forms of love and sacralisation (O'Guinn and Belk 1989), that are made possible in consumer to consumer (fan to fan) celebrity brand communities (Muniz & O'Guinn 2001).

THE CELEBRITY TURN

The turn to celebrity within consumer research is necessary to further contextualise and problematise consumer to consumer exchanges in the emerging digitalscape. The problem being that in writing about the pervasiveness of celebrity culture it is all too tempting to see them as simply existing at the level of the image; that is as flawless and airbrushed products of media representation and production. Such a perspective is evident within the celebrity endorsement literature which advocates the use of aspirational celebrities to help sell products (Silvera and Austad 2003). For us, it is necessary to go beyond such understanding to problematise celebrities as 'carriers of meaning', or 'role models' but from 'below' (Turner 2004). To instigate a grassroots cultural approach that considers them from the perspective of consumers themselves, to permit understanding of the significance they play in the consumption, but also production, of celebrity. Celebrity needs to be conceptualised as Cashmore and Parker suggest as: "a commodification of the human form, the epitome of economic fetishism. It is the process by which people are turned into "things," things to be adored, respected, worshipped, idolized, but perhaps most importantly, things which are themselves produced and consumed" (Cashmore and Parker 2003, 215). Such a perspective draws our attention to the types of investments consumers express and project upon celebrities, highlighting the everyday 'work' which consumers enact through their icons. Moreover, Maffesoli (2007) draws attention to the role of such persona within the tribal aesthetic: "They recreate what already exists... and it is by communing with their repeated stagings and identifying with them that we all...transcend ourselves and explode creatively, breaking free from our enclosures and throwing off the shackles of our small individual ids." (2007, 33).

Such promise of transcendence parallels research on sacred consumption (Belk, Wallendorf and Sherry 1989). Investments in consumption activities can transform seemingly profane consumer goods such as the Apple Newton into objects that offer potential for emancipation and liberation (Muniz and Schau 2005). Similarly, devotion to media brands such as Star Trek sometimes transcends mere entertainment to become a "profoundly motivating vision of the future" (Kozinets 2001, 77). In this way a religious metaphor becomes "adaptable in a consumer-centred world...[where] some of the same forces that drive many religions may drive the religiosity of brand communities (Muniz and Schau 2005, 746). Through such consumption practices we witness how "the material world can become the seat of the sacred again; consumption can [thus] become (re)ensouled" (Kozinets 2002, 32).

In establishing this point we seek in this paper to make explicit the character of consumers' investments in celebrity culture, but also the particular sacred appeal of celebrities to consumers. Sometimes as Jauss (cited by Marshall 1997, 69) reveals this connection is not only sympathetic or admiring, sometimes it is ironic and playful

1 We appreciate that to some to some audiences/markets, Kylie may be relatively unknown but since beginning her musical career in 1988, Kylie has enjoyed the success of 52 singles, 10 studio albums and countless awards and accolades including the prestigious BRIT, Grammy and MTV Europe music awards. For a fuller resume of her achievements we encourage readers to take a look at the wikipedia entry for Kylie as space restrictions prevent us from detailing these here.

but sometimes gains in momentum and investment, becoming associative (celebratory and participative) and even cathartic, so that fans gain a sense of emancipation from their affinity with the celebrity brand community.

Theoretically the notion of the 'fan' has previously been ascribed a type of passivity, defined in response to celebrity system (Jenkins 2006a). However, fans should be conceptualised as actively producing cultural meanings around celebrity (Peñaloza 2004; Grossberg 2005; Turner 2004); to embrace the move from a representational culture to a presentational culture where celebrities are reworked in terms of their value and utility by audiences and users (Marshall 2005). Celebrities, as Maffesoli suggests, exist as "Archetypes...[within] this creative unveiling...revelators trying to bring out what already exists." (Maffesoli 2007, 32). Similar to other consumer tribes, "fan communities move among corporate landscape, occupying them ideologically and affectively, 'poaching' and appropriating ideas, myths and memes, living with them, making them their own, and moving on" (Kozinets 2007, 195).

Writing about the 1920s star system, Firat and Dholakia (1998), comment that: "The people of fortune were celebrities and (almost) everyone wanted to know them, and to be acquainted (for most, of course, vicariously) with them. Celebrities, stars and others, who became the acquaintances of all, sold things.... ideas, values and attitudes." (1998, 47). Pringle in *Celebrity Sells* (2004) makes a similar point. And in this respect we witness how the marriage between celebrity culture, consumption and everyday life is firmly cemented and established. And as marriages go, it ain't a bad one since celebrities are part and parcel of consumer culture, their longevity and appeal expressive of the social forces which converge around the Entertainment-Marketing Complex (c.f. C.W. Mills 1959).

Online fan communities are thus ideal platforms to explore the emerging participatory culture which is taking shape as people are learning how to live and collaborate within such knowledge communities (Jenkins 2006a, 2006b, 26). Kozinets (1997) suggests that identification with a virtual community of consumption depends largely on two factors, both we argue, are clearly evident in online fan communities. First is the relationship that the person has with the consumption activity. In comparison with other consumption contexts, experiences with celebrities involve a high level of intensity and emotion often appearing central to a fan's self-concept and indeed, the guiding heuristic is often a religious one as celebrities are said to perform some of the functions of gods who are worshipped by fans (O'Guinn 1991). In particular pop stars generate and instigate investments of time and energy as we are drawn "into affective and emotional alliances with the performers and with the performers' other fans" in search of "opportunities to make meanings of their social identities and social experiences that are self-interested and functional" (Frith 1987, 35-37). Second is the intensity of the social relationships and emotional interactions the consumer expresses and shares with other members of the virtual community. Given that fans are typically associated with cultural tastes that are denigrated by the dominant value system (Fiske 1992), the internet can thus provide a forum where the fan attempts to make up for an "absence of 'authentic' relationships... [a] perceived personal lack of autonomy, absence of community, incomplete identity, lack of power and lack of recognition" (Jenson 2002, 16-17).

In taking account of the social uses of celebrity, we do not deny that the celebrity is also "a manufactured commodity" that demands "commercially strategic" development (Turner 2004, 26). Here the commercial value of celebrity collides with, and feeds off, its cultural value to produce a regime of connections, investments

and effects. The challenge for marketers is to create a fusion between consumers; a fusion which begins with understanding the consumption rituals and practices which fans initiate (Sandvoss 2005; Hogg and Bannister 2000; Holt, 1995). For as, Taylor 1999, 161) suggests: "fans are not true cultists unless they pose their fandom as a resistance activity, one that keeps them one step ahead of those forces which would try to market their resistant taste back to them." So on the one hand, fans are seen as ideal consumers as their consumption habits can be highly predicted by the culture industry but they also express anti-commercial beliefs indicating a co-existence between commercial ideologies and commodity-completist practices (Hills 2002). The focus of our paper thus becomes to achieve a deeper understanding of online celebrity fan practices: What investments do they project upon celebrities through these e-forums? What significance does celebrity play in their lives? How is the celebrity brand re-imagined and reworked by fans in their communal exchanges?

METHODOLOGY

To explore the richness and diversity of the emergent digital landscape demands a particular style of method. A methodology capable of taking seriously the social interactions and conversations consumers engage in through such new technologies. Our analysis took the form of a digital ethnography (Murthy 2008); and drew upon the insightful work of Kozinets (1997, 1998, 2001, 2002b) and Kozinets et al (2008). Such an approach provides researchers with "a window into naturally occurring behaviours", in relation to the "language, motivations, consumption linkages, and symbols of consumption-oriented online communities" (Kozinets 2002b, 62 & 70). Such "connected research" allows us to learn from social dynamics between participants (Schillewaert, De Ruyck and Verhaeghe 2009) as we increasingly witness a shift towards the "public display of private worlds" (Beer 2008, 624).

Textual and visual material in the form of conversations, images and blogs were thus collected through two online forums devoted to talk around Kylie (<http://forums.kylie.com/> and <http://kylieconnect.com/>). *Kylie.com* is an international forum with 15,687 registered users (as of 2/03/09). Over the 12 month period of our analysis 2052 discussion threads generating a total of 58,525 postings were made. The forum provides an arena for members to discuss Kylie's music, live appearances, TV appearances and press from around the world. *KylieConnect* launched in November 2007 was the first artist social networking site for music fans. It allows members from around the world to create profiles, upload images and blogs; but also to connect and interact with other Kylie fans. The forum element² of the site is made up of 648 threads, totalling 8007 postings covering a variety of Kylie-related chat. Subsequent to the collection of this data, we attempted to code our material to organize our ideas into a set of thematic insights. These codes were based upon the collected material and the theoretical lens which surrounded our study. Analysis and interpretation was constructed around moving between individual postings, chunks of postings, entire discussion threads and the emergent understanding of the complete data set (de Valck 2007; Muniz and Schau 2005; Schau & Gilly 2003). Analysis of social interaction between participants in the form of naturally occurring discourse proved particularly insightful (Ritson and Elliott 1999). We adopted a number of techniques proposed by Wallendorf and Belk (1989) to establish the trustworthiness of the data including triangulation across researchers and forums, observation over time and negative case analysis. We also acknowledge that analysis is based on the communicative acts of only a small percentage of Kylie's fan base rather than the complete set of behaviours of all fans in the community (Kozinets 2002b). Our results are organized in terms of the follow-

² Other elements of the site include a gallery of Kylie images and Kylie's latest blog (which by blog standards is highly commercial with the emphasis on updating fans on her latest performances, cds and perfume range); along with links to Kylie.com the official retail site where fans can view lyrics, download wallpaper, watch her performances and purchase CDs, DVDs, ringtones, widgets etc.

ing three themes: Exploring the Kylie community; the Othering of Kylie and finally, the theme of Knowing Kylie.

UNPACKING THE KYLIE E-COMMUNITY

For O'Guinn (1991) the organising logic for celebrity worship is that of religion, as sometimes fans imbue celebrities with god-like powers and in this section we explore the ways in which the sacralisation of celebrity manifests itself on online fan communities like Kylie Konnect and the Kylie forum.

Members appear to emphasise the sense and awareness of themselves as being part of a brand community (Muniz & O'Guinn 2002; Muniz and Schau 2005). Fans in this respect talk of the role of the forum in social and sacred terms: "As Kylie fans, we are here to share everything about her. As forum users, to critique as an audience of Kylie and other users' thoughts but as whole, we are here to support each other." In terms of summing up and expressing the happenings of such forums we might concur with O'Guinn when he suggests: "They get together and talk, reminisce, and share one another's joys and sorrows... They gather in his[her] name, but for each other." (1991, 8). The sense of camaraderie and the stress upon the value of forum membership is thus palpable, with members suggesting: "I love KK [Kylie Konnect] it is the friendliest forum I have found anywhere and people here understand what you are saying and everything is taken as it is meant." Moreover, they clarify the nature of the celebrity communion, one which transgresses global boundaries and traditional markers such as age and gender, rather as they affirm: "it's not about age, it's about taste." Here we see the promise of *communitas* in online fan forums; where *communitas* is pivotal to sacred consumption (Belk et al. 1989) and therein sometimes "consumption can become (re) ensouled" (Kozinets 2002a, 32).

The importance of the emerging digitalscape and the connections it makes possible is further emphasised when fans speak of how in their more mundane lives devotion to Kylie is not always met with such positive affirmation. For example, some forum members voiced their disappointment that their social contacts did not understand the appeal of Kylie: "All of my friends hate her.... they don't understand how good she is live". Such awareness of the negative associations she brings forth in others, reveals the significance of the virtual forum as a space where such talk has little place. In this respect the e-forum provides a relief and platform to compensate for this absence of a Kylie community in their everyday lives (Jenson 1992)³. Instead, we witnessed a developing sense of shared taste and fellowship (O'Guinn 1989) that helps to explain the almost confessional character of many of the conversations around Kylie's appeal (c.f. Beer 2008 and Bauman 2007).

THE OTHERING OF KYLIE

On the forums we witness the constant referencing to Kylie as akin to an *absent other* -where as an imaginary resource she makes possible threads of quasi-religious character and sentiment to be expressed. For example one of the forums sections is titled: "Do we know whether Kylie is aware of our conversations?" -responses ranged from the "I can't say for sure if she checks in to see what her humble subjects are doing, but you never know...she could be here right now and we would be none the wiser."; to the: "I wonder does she even have a username". While some are sceptical about Kylie's presence, their questioning would suggest to us that they want to

believe that she is party to their conversations - overhearing their 'gifts' of praise and devotion which they offer through the forum.

In this respect we witness how participants seek to transform themselves and the sense of their own identities through the narratives they construct around their shared devotion and adoration to Kylie. For example, one of the sections is entitled: *Kylie is a new super hero?* Here we find creative renditions of authoring themselves through her appeal: "Yes because she saves me from boredom and gets me all happy!" to another fan who suggests:

"I wrote a story...about a Princess named Kylie that took place far into the future where the Earth is finally at peace and KYLIE is the heir to Earths thrown (sic). But then Evil arise from the depths of space and KYLIE has to become KYBORG (the thing she was dressed as at the beginning of the Fever Tour) to fight off the evil. It was kinda cheesy but still good."

Forum members' expressions of their devotion to Kylie are littered throughout the forum. Two threads were particularly insightful: First, Kylie's 40th birthday in May 2008 was accompanied by the creation of a special area for postings of birthday wishes where expressions of gratitude dominated. Second, a thread titled: "What has Kylie done for you?" appeared to encourage the offering of survival and salvation tales (cf. Muniz and Schau 2005). For some, the appeal of her music runs deep and goes far beyond the derogatory view of it as 'pop' or mere 'entertainment'. Rather it generates strong emotional sentiment from fans keen to express their gratitude in relation to the help and comfort they gain from experiencing her music:

I just wanted to thank you for being such an inspiration for me, your beautiful voice is always like a light that shines even in the darkest places, and the most obscure moments of my life. I feel like i have no words to describe how happy your work makes me.

Such sacralisation harks back to Belk's discussion of the domains of sacred consumption (1989); we witness how celebrities are through fans co-creation endeavours sometimes "set apart from others" (Belk 1989, 11): or, as another member echoes:

Thank- you for everything you have done for me, inspiring me and giving me courage to come through the most difficult part of my life. For that and for you being you and your music and everything about you, I love you.

The forum in this instance enables us to glimpse the process of celebrity sacralisation in the making. In this way, expressions of 'love' were expressive of the emotional nature of the community (cf. Maffesoli 1996). For some, such declarations can be encouraged by feelings of sexual attraction towards Kylie; but for some treatment of Kylie as a 'loved object' (Ahuvia 2005) is perhaps generated through the affectual benefits that being a Kylie fan provides. As Rojek (2001, 52) suggests "the celebrity is an imaginary resource to turn to in the midst of life's hardships or triumphs, to gain solace from, to beseech for wisdom and joy". Here we see parallels with religious devotion (Muniz and Schau 2005) as fans employ the language and rhetoric of religious sentiment to express their reverence and respect for Kylie for fulfilling "a need to believe in something significantly more powerful and extraordinary than the self" (Belk, Wallendorf and Sherry 1989, 2). Or as one of her fans describes Kylie:

3 On the basis of our own participant observation (June 2008) we can suggest that her performances also represent a significant community gathering enabling disparate fans to come together and share their passions.

For me she has not only been an inspiration, I look up to her and see her as a role model, I think her music is great and I love the personality she lets us see. She has always been very special to me. Because I started having panic attacks when I 8, I had had them before but they came back when I was 8 that was the same time I became a fan and for me I think she was meant to come and help me and she has, she has been a support. She came when I needed her and it makes me feel happy when I see her because has not just been an idol but she has been a support.

Seeing Kylie in such redemptive and enduring terms was a common theme amongst forum conversations. Many fans appreciate that she is not making the headlines for “driving too fast”, “being drunk” “using drugs” or “doing other bad things”. Fans, in this way, strive to distance Kylie from other less sacred celebrities, especially those who invite and encourage media speculation for their inappropriate or immoral behaviour. Rather Kylie becomes a sacred ideal in comparison to her profane rival celebrities (Pimentel and Reynolds 2004).

KNOWING KYLIE WITHIN THE E-ECONOMY

In this section, we reveal how fans strive through their narratives to express their identifications with Kylie. Emblematic of this desire by fans are their attempts to collect Kylie memorabilia. Such collecting we argue permits fans to perpetuate and make tangible this sacredness (cf. Belk 1989, 21). For example, one of the most popular threads on the forum with a total of 2273 posts (as of 10/03/2009) was that devoted to “Your Kylie Collection”. Discussions on this thread typically took the form of members ‘listing’ and displaying their collections to others members of her music, merchandising from posters to annuals etc, through such interactions we glimpse how fans attempt to make explicit the strength of their devotion through the ritual of collecting (Belk, 1989) but also through the act of constructing narratives and sharing those with others around their memorabilia we witness how the community imagines itself but also signifies the strength of its devotion within the e-community.

In this sense fans are keen to not only collect tangible objects which bring them closer to their heroes, but also to use the forums to strive for a proximity with others who share their own life-worlds and views. In this respect, what has touched audiences most is Kylie’s recent battle with breast cancer (something that has inspired some of the songs from Kylie’s most recent album). Fans appear to relate to Kylie on this level and the experience of her music then becomes an experience of identity formation in that “we absorb songs into our own lives and rhythm into our own bodies; they have a looseness of reference that makes them immediately accessible” (Frith 1996, 121). For fans, music and experience can become so intertwined that it is difficult to locate the music’s meanings without talking about their own personal lives (Cavicchi 1998). This is in evidence through forum postings where fans narrate their own personal experiences of dealing with cancer. For example “*I lost my Mother last week to cancer and your wonderful “feel good” music did help me cope*” and “*I too have recently been diagnosed with cancer; only being 33 years old... What I love about her is she still puts her diamonds and lippy on and if it’s good enough for Kylie then it’s good enough for me.*” For others, it extends beyond experiences with cancer, to also include coping with other illnesses.

Kylie to me is a constant light in my life, I admire her so much, I’m proud to be a fan. at the moment she is helping me a lot !! I’m having a big operation on 5th Nov and right now

kylie and her music are keeping me together. I’ve been a fan for 20 yrs and kylie is in my heart for sure. 😊

On the 31st of March this year, I gave birth to stillborn twin daughters, 3 days before I was booked in for my c-section. Although the better days outnumber them now, I still have my bad days and listening to Kylie cheers me up a bit. Also, what I have been through and breast cancer are two completely different things, but I find it inspirational that Kylie has publicly been through a very dark time, and something that would have been very traumatic, and she did it with dignity and picked herself up and is back, better than ever. She is living, breathing proof that there is light at the end of the tunnel.

As illustrated, fans have been dedicated followers of Kylie throughout her long career; such commitment is another key ingredient of sacred consumption (Belk et al. 1989). Kylie’s music can be seen as having *transformative power* for fans and in this way it becomes part of the “care of the self” (DeNora 1999, 37). The religious theme is thus foregrounded and conventional thinking dictates that during times of illness people turn to religion to improve their emotional well-being or pray for healing and redemption. What we witness on the forum is fans putting their ‘faith’ in Kylie as an imaginary resource of hope, comfort and salvation, but also this connection enables them to link with like-minded others. De Nora (1999, 45) argues that “Music is a device or resource to which people turn in order to regulate themselves as aesthetic agents, as feeling, thinking and acting beings in their day-to-day lives.” As one fan suggests, “*As for me personally, she changed my life completely, she made me believe in my own power, possibilities and dreams, in my own future - and she’s done it just through her music, her behavior and just simply by being a real woman!*”

The Kylie forum thus becomes a sacred space⁴ wherein fans can come together to understand, make sense and manage the stress and anxieties that confront them in contemporary consumer culture. It is at these moments perhaps that communities take a ‘sharing and caring’ form (cf. Kozinets 2002a, 22).

It would be wrong, however, to suggest that all fans experienced the quasi-religious character of this style of devotion to Kylie, as the community is also noteworthy for its divergent character. For some fans, the appeal of Kylie is simply that of the enjoyment they receive from listening to her music, which provides “*lots and lots and lots of fun and entertainment*”. While another suggested, “*she hasn’t really done anything for me, she is only a singer nothing more than that to me. although some of her songs do make me happy when I feel sad, but that’s all really.*” Another forum member was quick to agree “*Voice of reason once again. Second that.*” At times, Kylie’s music can therefore be enjoyed as an end in itself, a hedonistic soundtrack to fun, dance and laughter, rather than as a means to some other personal or social goal (Holbrook 1987). Another noteworthy posting adopts a more critical stance towards such devotion suggesting that although it offers to many escapism, sometimes this may border on the “unhealthy”:

⁴ It was Emile Durkheim who envisaged religion as the symbolic self-consciousness of society. Such a view places especial importance on the channels of communication with which society constructs itself. It was also Durkheim who confidently pronounced that “...If there is one truth that history teaches us beyond doubt, it is that religion tends to embrace a smaller and smaller sector of social life...this shows that there is a decreasing number of collective beliefs and sentiments which are both collective and strong enough to assume a religious character.” (1987, 245). He did however draw our attention to the enduringness of such religious sentiment.

Hmmm... I was half-tempted to go for the she hasn't done anything for me route, because, in all fairness, she hasn't. But I am in the mood to pay a kind of tribute to my younger years. Kylie kept me occupied during the hardest time of my life. I didn't have to think about my problems when I was being a "Kylie fan". Like a second identity I could escape to from real life. From this point, I know how unhealthy this was, and I also know it wasn't because it was Kylie, it could have happened with any celebrity. But it happened with her.

Given these opposing and divergent uses - Kylie can be seen as a malleable and fragmented brand community. While some fans sacralise Kylie seeing her as possessing inspirational god-like qualities and seeking personalised meanings reflective of their own life experiences, others are more playful (dare we say postmodern) in terms of the ways they weave Kylie into the fabric of everyday life merely for fun and escapism.

THE ALTERNATIVE THERAPIES FOR CONSUMING CELEBRITIES - DISCUSSION

In this paper we foreground what consumers share with other consumers on celebrity e-forums to demonstrate the sacred qualities of such spaces to highlight the consumption and identity 'work' that takes place through talk on celebrity mattering. Our analysis of the Kylie Brand Community reveals the forms of collective therapy and sacralisation being practiced on such celebrity e-forums. Here we might concur with Kozinets, who you might recall spoke of Star Trek as a, "moral compass around which fans centre their lives, one as all-encompassing as a religion." (2001, 77). Or even paraphrase Maffesoli to consider celebrity, through the sacred lens of religion which he defines as simply "that which unites us as a community" (1996, 38). To speak of consumers as fans places emphasis squarely upon Weber's concept of 'emotional communities' as ephemeral, changeable and ill-defined (cf. Maffesoli 1996, 12), and through attention to their illusive and ephemeral character we start to glimpse the extent to which celebrities are useful resources for rethinking ourselves and our forms of togetherness.

These commercial domains⁵ are thus reappropriated and de commodified as 'inalienable' (cf Wallendorf and Arnould 1991) by fans as unique and cherished repositories for the exchange of forms of empathetic understandings and the collective display of affective emotional investments. Celebrities are then for consumers 'good to think with' (Levi-Strauss 1966), and the internet forums initiate a particular form of at-a-distance proximity between fans and on celebrities.

Moreover an unintended consequence of such proximity appears to be that they operate as *stages* for the construction of debates around celebrity, be they of an ethical, moral or sacred kind. Here we emphasise the narratives constructed and participation engendered around celebrities in such internet spaces. Spaces which make possible the emergence of identity, communal and transcendental value. But which also serve to make explicit to consumers the difficulties and tactics of negotiating ways of life within contemporary consumer culture. For as Dyer commented in the work *Heavenly Bodies* (1986), "the stars articulate what it is

to be a human being in contemporary society; that is, they express the particular notion we hold of the person, of the 'individual'." (quoted in Turner 2004: 104). Such a view suggests that sometimes celebrities be understood as 'moral beacons' (Porpora 1996, 210); or as Boorstin advocated, back in the 1960s: "receptacles into which we pour our own purposelessness." (*ibid*, 214). Here then we start to glimpse the importance of celebrities in an age of anxiety and uncertainty, without recourse to 'metanarratives' (Lyotard 1984; Firat and Venkatesh 1995); an age of "playing with the pieces of identity" (Baudrillard 1993); an age where as Marx prophetically pronounced "All that is solid melts into air" (cf. Berman 1983). In such a critical context of disenchantment our intense and emotional connection with celebrities, be it from afar or virtual means, starts to then make sense, for we witness how they permit us to enter into intense moral and social dilemmas. In some senses what is unique, in contrast to earlier eras, is the internet platform itself as a space wherein consumers weave and spin, through their interactions and narratives, their own 'threads' of significance (cf. Geertz 1973) which unite them and sometimes leads them into producing emergent understandings. Here we concur with Firat and Dholakia (1998) on the almost theatrical character of such spaces and spacings: "... instead of the stage, the backstage and the audience, the theater is composed only of the stage. All interaction across all dimensions - economic, social, political - occur on this stage. This means that everyone is a player, an actor. On a stage, different groups of actors may be engaged in different interactions simultaneously. They all contribute to what is happening on the stage." (1999, 154-155). The value of such stages and the stagings therein, is revealed as a site wherein consumers "put them to work" (McCracken, 1989). And sometimes such consumption work is trivial and mundane, sometimes merely driven by distraction and diversion, but sometimes it becomes re-enchanting, and at other times it becomes playful and emancipative in character making possible catharsis. It is in such moments that the sacred character of such spaces is revealed - as communal spaces of revelation and insight.

In such commercial contexts, especially given the nature of the internet connection we witness how celebrity functions as a site for organizing social identity, a vessel for identity formation and group transformation. The liminality of celebrity thus takes centre-stage, for as Turner suggested: "In liminality people 'play' with the elements of the familiar and defamiliarise them" (1982, 27). And as a means for organizing identity (du Gay 2007), and for reorganizing such constituent parts, roles and characters, we might finally explore the value of what we might term *celebritopias*⁶ - that is as a land of myth, magic and fairytale princes and princesses. The mythological space of *celebritopia* then presents itself to consumers as a neverending staging, a soap opera rich and ripe in potential for interaction, participation and collaboration. A neverending story of opportunity and possibility which punctuates our own more domestic, prosaic and profane everyday lives; an opportunity which in some senses renders our own lives and meanings as sharable; and a narrative which as we have sought to demonstrate provides our own lives with a sense of meaningfulness and sacralisation. When we start to see the social importance of *celebritopias* we see how celebrities are important sites for

5 See 1 above, but to save you the effort we note that Kylie Konnect is unashamedly commercial with the emphasis placed on updating fans on her latest performances, cds and perfume ranges); along with links to Kylie.com the official retail site where fans can view lyrics, download wallpaper, watch her performances and purchase CDs, DVDs, ringtones, widgets etc.

6 Here we might quote Porpora when he suggests: "Traditionally, heroes are the protagonists of myths - that is, metaphorical or figurative accounts that are addressed to the ultimate questions: Who are we? Where did we come from? Why are we here? Addressed to ultimate questions as they are, myths relate to a sacred plane of existence, a plane that transcends profane, everyday life. In the sacred plane, heroes personify transcendent ideals and transcendent visions of the good." (1996, 227)

the negotiation, revitalization and transformation of our public and private selves. Celebrity it would appear in its technological guise currently makes possible a space in our lives for sacredness to emerge, a space for innovation and interrogations to disturb and unsettle the eversame (cf. de Certeau 1984).

Helping or hindering? Sibling interaction in child influence strategies

Ben Kerrane, Bradford University, UK

Margaret K. Hogg, Lancaster University, UK

ABSTRACT

In this paper we explore the process of child influence, explicitly focussing on how sibling relationships ('sibship'), as one component of the family environment, shape the influence strategies which children direct towards their parents. Our findings point towards the ambivalent nature of sibling relationships, and suggest that sibling behaviours work to both help and hinder fellow siblings utilize influence strategies on their parents' consumption choices.

INTRODUCTION

Understanding the influence that children exert in family consumption decisions remains a prominent area of concern for consumer researchers. Children influence up to \$1.88 trillion of family expenditure globally (Lindstrom and Seybold, 2003), and yet we still lack a complete understanding of child influence processes (Cotte and Wood, 2004; Flurry, 2007). Whilst we do have a comprehensive account of the repertoire of strategies which children utilize in their attempts to get their own way from their parents, we know little about the motivations that lie behind strategy usage (Palan and Wilkes, 1997) or how contextual factors, such as the family setting and intra-family relationships, shape the influence strategies which children utilize (Cotte and Wood, 2004).

In this paper we specifically explore sibling relationships within the family setting. Sibling relationships have tended to be overlooked within existing consumer research (Cotte and Wood, 2004) which has usually focused on dyadic parent-child interaction. Our contribution is thus twofold. First we seek to better understand sibling relationships, which remain largely under explored in consumer research; and second, to investigate how sibling relationships shape the influence strategies which children employ within the family setting. Our study responds to Cotte and Wood's (2004) and Flurry's (2007) call for further research into the purchase influence of children in families, specifically by exploring how one aspect of the family environment (sibling interaction and relationships) affects the influence strategies that children employ.

Child influence strategies: The research context

Research over the past forty years has established that "*purchase decisions within the family are not always the outcome of individual choice, but rather, family members influence each other*" (Hamilton and Catterall 2006, p.1032). The examination of children's influence strategies began with a study of cereal choices which identified that both the child's assertiveness and the mother's child-centeredness were central to a mother's susceptibility to her child's requests (Berey and Pollay 1968). In another study of cereal choice within a supermarket setting, children were more successful if they told their mothers to buy their preferred cereal, or if they demanded their choice, rather than if they simply asked their mother for it, or requested the item (Atkin 1978).

Another study specifically asked adolescents to write a series of essays entitled "How I get my way with my mother ... father ... best friend". Fifteen influence strategies were identified, sub divided by whether the strategies used were direct or indirect (Cowan, Drinkard and MacGavin 1984). Direct strategies included the use of more overt behaviours (asking, begging and pleading, telling or asserting, reasoning, demanding or arguing, stating importance, bargaining and persistence), whereas indirect strategies are believed to occur when "*the influencer acts as if the person on the receiving*

end is not aware of the influence" (Johnson 1976, p. 100). Indirect influence strategies included the use of negative affect (such as the use of crying, sadness and anger), positive affect (including the use of sweetness and innocence), verbal manipulation (often involving telling lies), eliciting reciprocity, using an advocate, evasion and laissez-faire (taking independent action, regardless) (Cowan *et al.* 1984). Adolescents directed more influence strategies towards their mothers than their fathers, and of those strategies directed towards mothers most involved the use of negative affect.

Examining explicitly the mother-child dyad, twelve child influence strategies were identified by Cowan and Avants (1988). These included: ask, bargain, show positive feelings, do as I please, show negative affect, persistence, beg and plead, perform good deeds, reason, cry and get angry. What is significant from this study is that strategies were related to the level of parental resistance that the children expected to encounter: high (anticipating non-compliance strategies e.g. beg and plead, cry) or low (autonomous strategies e.g. tell), and whether or not an equal power relationship existed between the parent and child (egalitarian strategies e.g. bargain and reason).

A study of the power strategies of popular and rejected black South African children identified four dimensions of influence strategies: direct and indirect influence strategies (as identified by Cowan *et al.* 1984), and bilateral and unilateral strategies (Bonn 1995). Falbo and Peplau (1980) had earlier identified the concept of bilateral and unilateral dimensions within influence strategies in their study of intimate relationships. Whereas bilateral strategies require the cooperation and responsiveness of the target (e.g. bargaining), unilateral strategies do not. Bonn (1995), through interviews with children involving hypothetical situations, identified a range of strategies, including persuasion, bargaining and compromise (bilateral, direct strategies); suggesting, ingratiating, and deception (bilateral, indirect strategies); sadness, crying and anger (unilateral, indirect strategies); and asking, threatening and coercion (unilateral, direct influence strategies). Rejected children often used unilateral influence strategies, frequently involving the use of aggression (Bonn 1995).

More recent work on adolescents and their parents identified four classes of influence strategies: bargaining, persuasion, emotional, and request strategies (Palan and Wilkes 1997). In a diary study which applied Palan and Wilkes' (1997) influence strategy framework focussing on children's impact on innovative decision-making, children were subsequently found to employ persuasion strategies most often, followed by request and bargaining strategies (Götze, Prange and Uhrovská 2009). In only a few cases were children found to utilise emotion based strategies (Götze *et al.* 2009).

Lee and Collins (2000) and Lee and Beatty (2002), through videotaped recordings of family interactions during a simulated decision-making situation, recognised the potential for coalitions to form within families. Five main influence strategy types were identified: experience strategies (using experience and knowledge as a source of information to influence the outcome of a decision), legitimate strategies (which emphasise positional power and ste-

1 It should be noted that Palan and Wilkes (1997) identified seven influence strategies, although the latter three (expert, legitimate and directive) were strategies solely utilised by parents in response to their adolescent's use of an influence strategy.

reotypes), emotion strategies, bargaining strategies and coalition strategies (Lee and Collins 2000). Seven dimensions of children's direct influence strategies, ask nicely, bargain, show affection, just ask, beg and plead, show anger and con, have also been identified (Williams and Burns 2000). More recently the child influence strategies of justifying and highlighting the benefits of purchases, forming coalitions, compromising and remaining persistent, have also been documented (Thompson, Laing and McKee 2007).

In addition to the types of child influence strategies, a number of studies have also assessed children's influence on family decision processes in terms of the amount of influence children exert. Factors such as product classification and usage patterns (Belch *et al.* 1985; Shoham and Dalakas, 2003); the stage in the decision-making process (Szybillo and Sosanie 1977; Belch *et al.* 1985; Lee and Beatty 2002; Götze *et al.* 2009; Wang *et al.*, 2007); child demographics, such as age (John, 1999) and gender (Flurry 2007; Wang *et al.*, 2007); and family variables, such as family size (Jenkins 1979; Ahuja and Stinson 1993; Beatty and Talpade, 1994; Geuens, Mast and De Pelsmacker, 2002), income and social class (Ekström 2007; Jenkins 1979; Hamilton and Catterall, 2006; Moschis and Mitchell 1986; Lee and Beatty, 2002), and family type (Bates and Gentry 1994; Hall *et al.* 1995; Mangleburg and Grewal, 1999) are suggested to affect the amount of influence children exert.

Children appear to make informed choices about which influence strategy they will employ (Williams and Burns 2000). Their decisions are informed by the historical success or failure of utilizing such strategies in previous decision-making situations (Bao *et al.* 2007; Götze *et al.* 2009; Thompson *et al.* 2007). Ultimately, however, whilst we do know a great deal about the types of influence strategies which children utilize, and the amount of influence children have, we do not know how environmental variables (such as the family setting) shape the influence strategies which children direct towards their parents (Cotte and Wood, 2004). In this paper

we explicitly focus on how sibling relationships, as one component of the family environment, shape the influence strategies which children utilize.

METHODOLOGY

Phenomenological interviews (Thompson, Locander and Pollio 1989) were conducted with six families living in the North West of England, capturing the stories of twenty-nine family respondents. Following calls for family research which captures the dynamics of family purchase decision-making (Hamilton and Catterall 2006; Tinson and Nancarrow 2005) interviews were conducted with both children and their parents. In line with other interpretivist studies (see for instance Thompson and Troester 2002) purposive sampling (Miles and Huberman 1984) was used to identify and recruit a range of family types and not just nuclear family forms. Detailed profiles of the six families recruited are presented in Table 1. An emphasis on studying consumers in-depth necessitated a smaller sample size to be used to allow thick descriptions to emerge (Carrigan and Szmi-gin 2006) which is common for interpretivist consumer research.

The families were recruited partly through personal contacts; partly through placing online appeals for participants in family newspapers and publications; and partly by contacting relevant family organisations in the North West region. The interviews were conducted in the family home, usually in the kitchen at the dining table. Each family was visited between three and five times and interviews were conducted over a period ranging from four to twelve months. Respondents were first asked for their consent to participate in the research process, assured of anonymity, told about the purpose of the research and then asked for permission to record the conversations.

Consent was sought from parents and guardians to approach their children in order to then seek the children's consent to be involved in the data collection process (Mandell 1991). Methods by

Table 1: Respondents' details

Family Pseudonym	Family Type/Comments	Parents/ Guardians	Working status of Parents/ Guardians	Children/ Ages	Number of interviews	Time period of interviews
Jones Family	Cohabiting couple headed family; Debbie and Paul are not married and have four children together	Debbie Paul	Childminder Plumber	Michael (14) Anna (12) Adam (9) Tina (7)	5	11 months
Baldwin Family	Blended; Carole and Ray have one biological child together (Nina), and Jessica (Ray's step-daughter, Carole's biological child) also lives in the family home. Carole and Ray also have non-resident children from previous relationships	Carole Ray	Sales Assistant Plumber	Jessica (14) Nina (5)	4	12 months
Harrison Family	Single parent family	Natalie	Unemployed	Mark Peters (21) David Peters (18) Luke Harrison (13)	3	6 months
Francis/ Akua Family	Lesbian headed family	Fante Francis Barbara Akua	Office Manager Senior Civil Servant	Kwame Akua (19) Helen Akua (17) Ashanti Francis (5) Kaya Francis (3)	3	4 months
White Family	Nuclear	Claire Brian	Administrator Sales Rep	Robert (12) Lee and Kevin (10)	4	6 months
Bright Family	Blended	Pat Tom	Housewife Company Director	Zara (11) Jack (9)	3	6 months

which valid consent can be obtained from children were adhered to (Mason 2004). Recognising that children are potentially vulnerable research participants (Morrow and Richards 1996) the children were interviewed within the family home where an adult was always present, although not necessarily within earshot.

Interviews were tape recorded in full, lasted between 60 and 130 minutes, and were transcribed verbatim. The interviews with family members were conducted over three stages and explored themes such as family history, intra-family relationships and how family members got their own way. In stage one an interview was conducted with the parents/guardians. Following this initial interview, stage two involved interviews with the children. Given that children, particularly younger children, may feel uncomfortable in a one-on-one interview situation (Mayall 2001) the children were given the option to have another sibling present during their interview. Indeed in the second stage of the interviewing process the membership of the interviews was very fluid. Some children preferred to be interviewed individually, whereas in other families the children freely left and returned to the interview as other siblings joined and departed. Accordingly with some of the families one longer style visit was conducted with the children (comprising several shorter interviews with single and multiple children, often with overlapping attendance), whereas in other families the children preferred to have a much more contained interview. A semi participatory researcher role was adopted with the children (Mandell, 1991). Following this stage of interviewing, a final family group interview was conducted at stage three.

The interpretation of the interview texts was undertaken using a hermeneutical process (Thompson 1991; Thompson, Locander and Pollio 1990) which involved moving iteratively, back and forth between interview texts (within and across family cases) and the literature. Emerging themes in the data drove subsequent reading in the literature (Thompson 1996). Following hermeneutical principles (at the methodological level) a constant shift when reading between individual transcripts and the entire data set enabled a greater emergent understanding to develop in which elements of the part gave further meaning to the whole. Each family case was analysed on an idiographic basis which allowed for categorization of data from which larger conceptual classes emerged. These concepts were then compared across family cases, following Spiggle's (1994) initial steps for qualitative data analysis.

FINDINGS

We have chosen to present, in a similar vein to Thompson (2005), two family cases which illuminate the global themes found across all the families in this study. Two family stories are used to emphasize the depth of the data which was collected and to show the complex and ambivalent nature of sibling relationships within the family setting. Our exploratory study highlights the ways in which children tried to help their siblings when they attempted to get their own way from their parents (*helping behaviours*, for example, expressing to parents the unfairness of not buying a product for a sibling; or voluntarily, or unwittingly, offering support to a sibling through coalition formation), and also the behaviours of siblings when they decided to counter the influence strategies of their brother(s)/sister(s) (*hindering behaviours*, such as using threats and violence to stop a child employing an influence strategy; or sabotaging their influence attempt). Primacy is placed on child accounts of sibling relationships.

Across each family story the children were aware that certain siblings within families were favoured by parents. Unequal parent-child relations, and parental favouritism of specific children, are suggested to be common characteristics of family life (McIntosh

and Punch 2009; Sutor et al. 2008) and this strongly emerged within our data. The siblings and parents alike highlighted within each family the children who were favoured by parents, which was particularly acute in the blended Baldwin family. Here Jessica Baldwin highlights her step-father, Ray's, favouritism of his biological child, Nina, supporting earlier research that step-parents often favour their biological children (Sutor et al., 2008):

Jessica: Nina. Yeah (...) she's their angel, she like, like gets all the time, she doesn't even have to ask for things, she just gets them from Ray, he buys her things all the time ... It doesn't work like that for me (...) I have to put money to the things I want, or just go without, but I do try and work on them.

A sense of the unfairness of parental favouritism emerged from the family stories which highlighted the relative ease with which certain siblings could influence their parents. Such ease antagonised the other siblings, particularly those siblings who felt that they had to work much harder in order to get their own way, as Anna Jones comments:

Anna: It's so unfair. Michael gets everything, computer stuff, guitars, money to go out with his mates, Mum won't give me any extra money because I get my spends, and that's it.

Michael Jones' preferential parental treatment results in volatile relationships between him and his fellow siblings, with parental differential treatment (PDT) giving rise to sibling rivalry and competitiveness amongst siblings (Tucker, McHale and Crouter 2005). Whilst PDT worked to help certain children influence their parents in attempts to get their own way (facing minimal parental resistance), it could also work to the disadvantage of the favoured children in relation to sibling interaction because PDT often represented an obstacle for certain children to overcome. Parental favouritism affected sibling relationships, as Michael Jones, described as his mother's "golden boy" by his father, explains:

Michael: I suppose Mum does buy me more things (...) I can tell Anna's not happy about that, but what can I do? It's kind of a good thing, but a bad thing as well ... yes I can get what I want from Mum, but I've got to watch my back a bit with Anna. She doesn't like it.

Ultimately what emerges from the family stories is that parent-child relationships can affect sibling-sibling relationships, resulting in a spill-over of behaviours (i.e. that differing parent-child relations are manifest in, and shape, sibling-sibling relationships). Moreover, sibling-sibling relationships can also help or hinder a child's success in influencing parental decisions. Helping behaviours and hindering behaviours were evident amongst siblings in terms of facilitating or impeding another sibling's utilization of influence strategies on their parents.

Sibling relationships and helping behaviours

Just as parent-child coalitions exist (Lee and Collins, 2000), sibling-sibling coalitions were also apparent (Thompson et al., 2007) within each family story. Nina Baldwin, for example, frequently recognises the unfairness of her parent's resistance to her half sister's influence strategies. Fairness has been reported as a characteristic of sibling interaction and exchanges (McIntosh and

Punch, 2009), and Nina explains how she offers her help to Jessica in an effort to get her half-sister what she wants:

Nina: Mummy and Daddy just get me what I want (...) Jess doesn't get many things, so I help her ... I'll say to Mummy that I want something when really I don't, but it's for Jess.

Nina likes spending time with her older half-sister, but frequently this is not reciprocated by Jessica. Although Jessica is often annoyed by Nina, with older siblings keen to distance themselves from younger siblings (Punch, 2008), Jessica does attempt to recruit Nina when utilizing an influence strategy directed towards her parents:

Jessica: I try just to ask them for things, but they're having none of it, they keep, they just say that I've had too much, and that they can't afford it. That's what they always say to me, we've got no money (...) but they get stuff for Nina, they buy her loads of stuff ... so I'll get Nina to ask them for things for me. They don't say no to her.

Although Jessica is often annoyed by her half sister's actions and Nina's desires to spend time with her, Jessica also manipulates this relationship for her own gain – and recruits Nina to employ influence strategies on Jessica's behalf. Through promises to play with Nina and to spend time with her, which often do not materialise, Jessica recruits an ally who is skilled and successful in influencing her parents. Ultimately Nina's influence success and power is exploited by Jessica, and younger siblings are reportedly easily manipulated by older siblings in deal making situations (McIntosh and Punch, 2009). Such manipulation was also evident within the Jones family, with Michael's siblings often forming temporary coalitions with him to strengthen their chances of success when employing an influence strategy. Whilst his siblings report that they do not have a favourable opinion of Michael, largely because of PDT, they too recognise the minimal parental resistance that he faces when influencing their parents:

Anna: Michael's the good one, the favourite (...) the one that gets everything. He's dull, a swot, good at school. I don't hang out with him, I wouldn't (...) but then he's good to have on side if you want something from Mum and Dad.

We feel that the above quotation is significant as it highlights the ambivalence and fluidity within sibling relationships (Edwards, Mauthner and Hadfield, 2005; Punch, 2008). Sibling relationships are far from static and fluctuate across contexts and influence strategy attempts, and are often manipulated and exploited by children to assist them in achieving their own ends. However, such manipulation is recognised by older siblings – and it does not always appear that they are totally duped by their fellow siblings into offering help – as Michael Jones comments:

Michael: I know what they're doing, I know that they want to use me so they can get something from Mum. But then I don't know when I might need them to help me get something (...) so I just go along with it, sort of bank it in case I need their help later.

Tag-team sibling influence was also apparent. The Jones siblings discussed how they each took turns to help influence their parents buy products which they all wanted. Parents are more responsive to the influence of their children when multiple children argue for

the purchase (Tinson and Nancarrow, 2007). Here Adam and Tina Jones discuss their actions when they approached their parents to get cable television:

Adam: We all wanted to get cable, so we just went on and on and on at them. We took it in turns to mither them

Tina: We all helped to get that, everyone had at go (...) Michael helped, too, so we knew we would break them and get it because he wanted it

Across the family stories, as Thompson *et al.* (2007) similarly report, the siblings did not formally or explicitly discuss the types of influence strategy that they would utilize. Rather the siblings used the influence strategy which they knew had proved to be most effective for them to use in the past. This lends support to the notion that children engage in a trial and error process to understand which strategy is most effective for them to utilize (Bao *et al.*, 2007):

Michael: I don't have to try too hard to get what I want (...) usually I just put my arms around Mum and tell her what I want. That usually does it.

Ultimately siblings can work to help fellow siblings to get what they want from their parents. At times, however, younger children appeared to be easily manipulated by older children. Sibling relationships are often ambivalent, as Nina Baldwin comments. Here Nina highlights that although she does like her half-sister, and often freely offers her help to Jessica to influence their parents, at times the relationship between Nina and Jessica sours. It is at this point, as experienced by other siblings across the families, that violence is used to gain the 'help' of other siblings:

Nina: Sometimes I don't like Jessica, and Jessica doesn't like me. If she doesn't play with me I won't help her (...) she doesn't like that, and sometimes she says she'll hurt me if I don't help her, or she'll say she'll (...) she'll say she'll kick me if I don't help.

Conflict is a common feature of sibship (Edwards *et al.*, 2006). Violence was also a way in which siblings could hinder another child's utilization of an influence strategy, as the follow section describes.

Sibling relationships and hindering behaviours

Threats of violence were also identified by the child respondents as ways in which siblings tried to block and hinder the use of influence strategies by their brother(s)/sister(s). Often siblings would tell one another what they were going to approach their parents for, before employing a given influence strategy. The siblings, however, were often very aware that their parents' resources were limited and that, because of this, there was a rush to be bought something first. Parents were also reported to justify non-compliance to their children's earlier influence strategies on the grounds of limited financial resources, as Palan and Wilkes (1997) also found, and so the children felt a heightened sense of urgency to get what they wanted before their siblings:

Jessica: The thing with Nina is that she gets all the time, she gets bought loads of things from Mum and Ray. I don't think that's fair, and when she comes to me saying that she's going to ask them for a new mobile or coat or whatever I try and stop her ... I might threaten her or something just to get her not to ask them. If she doesn't ask them for things then they can't use the excuse of having no money to me.

Another related way in which children attempted to counter the influence strategies of their siblings was to directly emphasize to parents how often they [the parents] yielded to their sibling's influence strategies. This frequently concerned the children who the siblings felt were favoured the most by their parents due to PDT. As Anna Jones explains, Michael's success in influencing his mother and father antagonises her and her siblings, and as a result Anna stresses to her parents the unfairness and frequency with which they yield to Michael:

Anna: Michael gets what he wants, he asks and he just gets, so that's when I say to Mum you bought him something last week (.) last time. I don't think she realizes how often she buys him things, so I let her know to stop him getting more stuff (..) I point it out to her, he shouldn't get anything else, it's not fair.

Often multiple siblings would unite in larger families to highlight such unfairness to their parents, as Tina further explains:

Tina: I think (..) I think if I just said it wasn't fair, that Michael gets things all the time Mum wouldn't believe me, not just me. But then if Adam and Anna says it too, then (.) then they believe us more.

Siblings, either individually or in coalition with other siblings, would also attempt to sabotage the chances of their brother's or sister's influence success through suggesting to parents that buying him or her a given product would be a waste of their money. Such behaviour was obviously dependent on inter-sibling relationships and the quality of such relationships at a given point in time. Often siblings approached parents to cast a seed of doubt in their mind as to whether a child would use the requested product to block sibling influence attempts:

Adam: I say to Mum and Dad that they won't use it, or they already have it (..) or that I know someone at school that has it, and they say it's no good (..) so don't get them it. I might not even know, but I say it to stop them getting things.

A similar technique was also used by children to block and hinder the influence strategies employed by their siblings. Rather than deceive their parents, as the above extract illustrates, in some instances elder children would use the internet to research what their siblings were asking their parents for. Through the internet the children found negative information about the products that their siblings wanted, and used this information as a basis to inform their parents and sway their decisions. Here Jessica discusses using this technique when her younger half-sister asked her parents for a Nintendo DS™:

Jessica: Nina wanted a pink DS (.) but I didn't want her to get one 'cos she gets too much. So I went online and found a bad review and showed it to Mum, I showed it to her, and told her that she'd get headaches using it, and she didn't buy it in the end.

Rather than this being a selfless and supporting sibling act, we feel that Jessica acted in this way to stop her half-sister being bought an expensive item. Alongside Jessica feeling that Nina is bought too many things by her mother and step-father, Jessica is also aware that her parents have limited financial resources. Whilst children using the internet to gather information to support influence strategies is

documented elsewhere (Belch, Krentler and Willis-Flurry, 2005; Thomson and Laing, 2003), with parents responding favourably to children who are well informed, here siblings actively use the internet to gather information to hinder the influence strategies of their brother(s)/sister(s).

Again, the ambivalent nature of sibling relationships was also apparent in terms of hindering behaviours. Siblings who had once worked together to influence their parents would often work against each other in union with other siblings. Here Adam discusses a family decision of deciding where to eat out in which he united with his older brother, Michael, to get his own way. Adam often works in coalition with Tina and Anna to stop Michael getting his own way, but here Adam joined forces with Michael:

Adam: Anna was on about us going to Nando's², but I didn't want to, I wanted a Chinese. Michael wasn't bothered where we went, so I got him to say he wanted a Chinese as well (.) I said he could lend my [computer] games, so in the end Mum said we should go for a Chinese.

The above quotation from Adam again works to underline the ambivalent nature of sibling relationships, and also the power that certain children have within the family. In this decision making scenario Adam persuaded Michael to agree with his restaurant choice, with siblings often using products and monetary exchanges as currency to sway the decisions of other siblings (McIntosh and Punch, 2009), despite a volatile relationship existing between the brothers.

DISCUSSION

Whilst we know a great deal about the types of influence strategies which children direct towards their parents, and the variables which affect the amount of influence that children exert in family consumption decision making, we do not have a thorough understanding of the *processes* of child influence itself. Our paper has attempted to fill an element of this gap by focussing attention on how one component of the family environment, sibling interaction and relationships, shapes the child influence process. Sibling relationships have largely been ignored by consumer researchers (Cotte and Wood, 2004) and sociologists alike (McIntosh and Punch, 2009), and our paper offers some insight into the ambivalent nature of sibship.

As our family stories suggest, sibling relationships are far from static, with sibling alliances and coalitions contested and negotiated by children, largely for their own gain. Within the Jones family, for example, Michael's strong relationship with his parents and the resulting parental differential treatment that he receives antagonizes his siblings, Anna, Tina and Adam. However, the siblings recognise Michael's strong position within this family, and the minimal parental resistance which Michael faces when utilizing influence strategies, and they will often work with Michael to bolster their own chances of influence success. Although Michael does not always lend his support to his siblings to strengthen their chances of influence success, he often does, largely because of the use of bribes (e.g. Adam's offer to Michael of lending Michael his computer games if Michael agreed with his choice of restaurant for the family meal) or because Michael feels he may need to recoup this help from his siblings at a later time.

Jessica Baldwin also recognises the ease in which her half-sister influences the decisions of her mother and step-father.

² Nando's is a restaurant in the United Kingdom which specializes in chicken dishes

Despite Jessica being annoyed by her half-sister, with Nina enjoying spending time with Jessica and playing with her, Jessica will often attempt to recruit Nina to employ influence strategies on her behalf towards their parents. At times Nina will do this voluntarily, with Nina recognising the unfair parental resistance which Jessica faces when utilizing influence strategies. However, often Jessica will manipulate Nina into offering her help through threatening to hurt her if she doesn't, or making deals with her to encourage her to help (and these deals often do not materialize) when this relationship sours.

Children can help their siblings to get what they want from their parents through helping behaviours i.e. emphasizing to parents the unfairness of not yielding to a sibling's influence strategy; utilizing an influence strategy on parents on behalf of another sibling; or through working in coalition with siblings, either through their own free will or because they have been coerced into lending their support due to threats of violence. Largely we feel that these children chose to help a sibling because they expected to gain something back from doing so. The children reported that their parents responded well to displays of supposedly altruistic behaviour, and that selfless acts often resulted in material gain for the children (with parents rewarding such behaviour).

Children also displayed hindering behaviours, and would use violence; highlight to parents the unfairness of yielding to a child's influence strategy; form coalitions; and sabotage a child's chances of influence success (e.g. by informing parents that the item a child wants is not a good product, or that they wouldn't use it) to stop siblings getting their own way from their parents. The children were aware that their parents had limited financial resources, a feeling very much heightened given the current economic climate, and as such there was stiff competition amongst the siblings to get what they wanted first from their parents.

Siblings, therefore, can play an important role in helping or hindering the influence strategies which children utilize, offering insight into the process of child influence. Equally our study lends support to the notion that children utilize complex and sophisticated influence strategies in attempts to get what they want from their parents (Götze *et al.*, 2009; Thompson *et al.*, 2007). Whilst coalition formation has been documented elsewhere within family decision making (Lee and Collins, 2000), and in relation to sibling coalitions (see, for instance Thompson *et al.*, 2007), our study extends this body of literature by highlighting the fluidity of sibling coalition formation. Sibling coalitions appear ambivalent, and future research should further explore how such different coalition patterns form and re-form, coalescing around different family members and various combinations of influence strategies.

Our study was limited to examining the influence strategies children utilize on their parents, however scope also exists to explore the different ways in which children attempt to influence the behaviours of their siblings (intra-generational influence). The main focus of our paper was to explore how sibship affects child influence strategies, however we already have early findings that suggest that family type also affects the process (cf. Jessica's relationship with her step-father) which could be usefully explored further. Our paper has also, because of space constraints, focussed on the voice of siblings alone, although the stories and themes presented here through the voices of the children recruited are very much rooted in the accounts of family life from both children and parents. It is also recognised that the setting for the interviews was largely dictated by parents who initially granted access to their home. We also acknowledge that the family group interview could have produced socially acceptable results i.e. children may have felt constrained in this setting, and presented their family in a harmonious light, for

example. However, an individual interview format was also offered to the children in an attempt to take account of such potential bias.

Opportunities exist to explore the influence strategies of children across a greater range of family types, and also to explore in further depth whether children direct different types of influence strategies towards different family members (e.g. siblings, grandparents, step-parents). Similarly opportunities exist to explore firstly, multiple family consumption sites (e.g. do children switch their use of influence strategy in different family settings, or homes); and secondly families of different cultures, in order to investigate whether such factors (as sibling relationships) also influence the choice processes involved in selecting which influence strategy to employ in families from different cultural settings.

Construction of Print Advertisement in the Context of Conceptual Coherence and Memory Distortion

Alicja Grochowska, Warsaw School of Social Sciences and Humanities, Poland
Andrzej Falkowski, Warsaw School of Social Sciences and Humanities, Poland

ABSTRACT

Conceptual coherence of print advertisements and memory distortion of coherent-incoherent ads, considering brand familiarity is examined. The theoretical background are network models of the mind and theories of concepts. Results showed the significance of the coherence of ads in their resistance to memory distortion, examined in the backward framing paradigm.

INTRODUCTION

Construction of Print Advertisement in the Context of Conceptual Coherence and Memory Distortion

It is important for marketers that their advertisements be well remembered and resistant to memory distortion. Consumers receive information about different products from different sources, for example from internet, the press, TV, or comparative advertisements created by competitors. One of the most important determinants of the effectiveness of an advertisement is its construction – in such a way that the structure of the ad is not sensitive to memory distortion. The goal of our research is to show that persuasive messages, such as print advertisements, are resistant to memory distortion only if they are conceptually coherent.

CONCEPTUAL COHERENCE OF PRINT ADVERTISEMENT

Effects of information congruency versus incongruency in advertisements have been investigated in several empirical studies but the results are inconclusive. Discrepant results of the research on the memory and evaluation of ads in the context of (in)congruency seems to stem from different approaches to this problem.

Incongruency resulted in better evaluation and memory of an ad or product when (in)congruency between *different* marketing objects was investigated (e.g. ad-brand, product-celebrity, ad-magazine). Dahlén et al. (2005) found that ad-brand incongruency produced *more sophisticated* associations. However, it is worth noting that *similar* associations result in better memory of objects. Ad-brand incongruency had positive effects on credibility of ads, and product-celebrity mild incongruency had positive effects on product evaluation, but the memory has not been investigated in this context (Dahlen and Lange 2004; Lee and Thorson 2008). Dahlén et al. (2008) showed that ads placed in thematically incongruent media were better-remembered. It is worth noting that ads were incoherent with their external context and could draw consumers' attention (but incongruency *within* the ad has not been investigated). For example, an ad of automobile in a furniture magazine is incongruent and as a discrepant element it draws attention.

However, research in which (in)congruency *within* the advertisement or other marketing objects was investigated shows that congruent objects are better-remembered and evaluated (e.g. a dentist presenting a toothpaste). Incongruent objects are classified to the other category and it is hard to remember them. For example, Nedungadi and Hutchinson (1985) found that products classified into categories where they did not fit 'naturally' had more in common with contrasting categories and were far less typical, resulting in poor associations with the category concept and poor recall. According to Sujana and Bettman (1989) strong discrepancy of the focal attribute of the brand from the overall category schema, as compared to moderate discrepancy, resulted in higher recall of

discrepant features. The brand in the strongly discrepant condition was perceived as a distinct subtype. On the other hand, interproduct similarity was correlated positively with the number of common usages shared by the particular pair of products and negatively with the number of distinctive usages associated with the two products. Thus, the probability of recall of a category instance from memory was associated strongly with its typicality (Ratneshwar and Shocker 1991). Heckler and Childers (1992) found that unexpected and relevant information in the advertisement was remembered better than unexpected and irrelevant. One can say that relevant information is associated with the content of advertisement and is perceived as an integral part of an ad.

Findings presented above show that incongruency results in a better evaluation and memory of an advertisement when (in)congruency between *different* marketing objects is investigated (e.g. ad-brand, ad-magazine). However, congruent ads are better-remembered and evaluated when (in)congruency *within* the advertisement is examined. Congruent elements constituting an advertisement are associated with each other and easily recalled. We investigate the (in)congruency between different elements *within* the advertisement.

THEORETICAL BACKGROUND

One may refer at this point to network models of the mind in which encoded information is stored in memory as a network structure, consisting of nodes representing concepts and links representing associations among concepts. The stronger associations among nodes, the easier connected pieces of information are retrieved (Anderson 1983; McClelland 1995). These findings are also confirmed by psychological theories of conceptual coherence (Murphy and Medin 1985) and theories of concepts (Smith 1995). One of the crucial theories explaining what makes a category seem coherent is Murphy and Medin's (1985) theory of conceptual coherence: Similarity of category members, correlated attributes, and knowledge about the word ('private theories'), as well as needs, goals are determinants of conceptual coherence. According to Murphy and Medin (1985) 'conceptual coherence derives from having a theory': representations of concepts are thought to be embedded in knowledge that embodies theories about the world. In further studies the importance of theories for conceptual coherence has been elaborated by Medin (1989), and Margoli (1999). Both authors provide additional evidence that the notion of similarity is too unconstrained to give an account of conceptual coherence, and that concepts are organized around theories. In this theoretical context the following issues are considered, and important for the present article: what makes a concept efficient, useful, and informative, and what makes a set of objects form a single category. In the marketing domain the conceptual coherence has been developing around the brand image. Lau and Phau (2007) carried out the research which showed that the mediating role of brand image fit between brand personality fit and dilution of brand affect is explained by using conceptual coherence theory.

Therefore, a coherence of print advertisement can be defined by the amount of similar associations provided by particular elements of an advertisement. These associations and their strength result from the knowledge about the advertisement. This means that the greater amount of similar associations between particular elements of the advertisement, the more coherent it is. According to this approach

one may expect that the elements of an incoherent advertisement are remembered better when they are unusual and/or untypical but they can be remembered in *isolation* from other elements of the ad. On the other hand, memory is an active constructive process. Research conducted in the backward framing paradigm showed that information acquired *after* an experience can transform the memory of that experience. Postexperience information is most likely to distort memories when it is very similar to the actual experienced information (Braun et al. 1997, 2005). Thus, we can expect that coherent elements, strongly associated with each other, are more resistant to memory distortion than incoherent.

In Study 1 we propose the operationalization of the conceptual coherence of print advertisement. We also show the significance of brand familiarity in perceiving the coherence of ads. In Study 2 we demonstrate the importance of an advertisement coherence for its resistance to memory distortion, considering the moderating role of the brand familiarity.

OPERATIONALIZATION OF CONCEPTUAL COHERENCE OF ADVERTISEMENT

According to network models of memory, the encoded information is stored in memory as a network structure, consisting of nodes representing concepts and links representing associations among concepts. The frequency with which a node is activated, as well as the duration with which activation spreads in the network, are also measures of connection strength (Anderson 1983; McClelland 1995). These assumptions about the network nature of the mind allow to operationalize the conceptual coherence of print advertisement. Shank's (1991) research showed that the extent to which a feature is associated with a category depends not only on the number of pairings of the feature with the category but also on the relative predictiveness of the feature for the category, which in turn illustrates the operation of a selectional process that determines the way in which the feature and the category are associated. This approach to the processes of categorization is a theoretical basis for operationalization of conceptual coherence of print advertisement. The strength of associations between particular elements of an advertisement is a measure of the ad's coherence. Kleine and Kernan's (1988) method of measuring 'consumption objects meaning' (affinity index) has been applied to analysis of conceptual coherence of print advertisement. In our research the effects of the coherence and memory distortion of advertisements are moderated by brand familiarity.

BRAND FAMILIARITY AND PERCEPTION OF AD COHERENCE

Familiar brands are more easily detected in advertising clutter. Moreover, familiar brands are less affected by competing claims from other brands (Kent and Allen 1994; Pechmann and Stewart 1990) and have a more persuasive power of sources of claims (Snyder 1989). At the same time, consumers have well-established brand schemas for familiar brands, which leads them to expect a certain kind of communication from the brand (Campbell and Keller 2003; Dahlén and Lange 2004). Familiar brands have a well developed brand schema that may withstand incongruent information, whereas unfamiliar brand schemas are more sensitive to incongruity. Familiar brands are cognitively available and activate a wide area of an associative network. Thus, conceptual coherence of advertisements is moderated by brand familiarity. One can refer to the theory of conceptual coherence here (Murphy and Medin 1985): Knowledge of familiar brands, like knowledge, theories about the world, joins together elements of an advertisement in a consumer's mind.

H1: *Advertisements for familiar brands are perceived as more coherent than ads for unfamiliar brands: Advertisements for familiar brands elicit more similar associations between particular elements than ads for unfamiliar brands.*

The conceptual coherence of ads determines a way of storing information about an advertisement in memory. Coherent ads, as compared to incoherent, should be better remembered and more resistant to memory distortion.

AD COHERENCE AND MEMORY DISTORTION

One of the important determinants of the effectiveness of an advertisement is a good memory for its elements. The advertisement is one of many sources of product information received by consumers. Coherent ads are better remembered: Particular elements of an advertisement are associated in a network in memory. Recalling one of its elements facilitates recalling other elements. On the other hand, memory can be distorted because of its constructive nature. That is why it is important for information in an advertisement to be resistant to memory distortion.

One of the most intriguing forms of memory distortion: when the memory of a previous experience with a product is altered by the actual information about the product, has been examined by Kathryn Braun-LaTour and colleagues (Braun and Zaltman 1997; Braun-LaTour and LaTour 2005) in the field of consumer behavior in the backward framing paradigm. An advertising misinformation effect was obtained for color memory of a previously seen candy bar wrapper (Braun and Loftus 1998). In other research, Braun found that a bad orange juice experience could be remembered as being better in retrospect if advertising were received after-the-fact. The advertising acted as a 'backward frame', altering how consumers remembered their sensory experience with the juice. In recall, consumers incorporated the language of the advertising to express their own experiences (Braun 1999). Moreover, advertising had an effect on how consumers remembered their past experiences. An autobiographical ad for Disney altered how consumers remembered their own childhood experiences – identifying Bugs Bunny as having been part of their original experience (Braun-LaTour et al. 2004).

In the same way any memory of a previously seen advertisement can be distorted by postexperience information. In this situation, it is not the memory of a previous experience with a product altered by actual experience with an ad but rather the memory of a previously experienced advertisement altered by the other sources of information. Thus, information presented after an experience alters how consumers remember their experience. The more similar the suggested post-experience activity is to what people actually experienced, the more likely source confusion may occur and result in memory distortion (McClelland 1995; Roediger and McDermott 1995). However, if pieces of information are strongly associated in memory networks, then they are more resistant to distortions. Therefore, one can expect that conceptually coherent advertisements are more resistant to memory distortion than incoherent ads. We examined to what extent brand claims in coherent ads are resistant to distortions in memory.

H 2: *Brand claims in coherent advertisements are more resistant to memory distortion than brand claims in incoherent ads.*

The effect of memory distortion of advertisements is moderated by brand familiarity as the research presented above has shown (Campbell and Keller 2003; Dahlén and Lange 2004).

H 3: Advertisements for familiar brands are more resistant to memory distortion than ads for unfamiliar brands. The effect is moderated by the coherence of ads: A stronger resistance to memory distortion is expected for coherent than incoherent ads.

STUDY 1: CONCEPTUAL COHERENCE OF ADVERTISEMENT

Participants, Material, and Procedure

Fifty undergraduates, aged 19-27 (*M* = 23.41) participated in each of four experiments (N=200). In each of experimental groups gender differences have been controlled (Males = 50%, Females = 50%).

Stimuli. Four series of print advertisements were used: (1) Ads for familiar brands of not expensive cosmetics: Eris, Ziaja, Dax, Dermika, Oxy; (2) Ads for unfamiliar brands of cosmetics: Carvella, Skin Wisdom, Eterna, Almey, Witch (these brands were unfamiliar in the country participants came from); (3) Ads for familiar brands of automobiles: Honda Accord, Volkswagen Golf Plus, Mercedes Class A, BMW 3 Series, Audi A6 Avant; (4) Ads for unfamiliar brands of automobiles: Yugo Tourer, Proton Plus, Avanti Also, Maruti Nerii, Hino Vant. The same ads were used for familiar and unfamiliar brands, only brand names have been changed in ads of cosmetics and brand names and product illustrations in ads of automobiles. Familiarity of all brands was checked in pretests: familiar brands were well known to all of 20 participants of the pretest, and unfamiliar brands were unknown to all of them. Each ad consisted of the following elements: the photograph, product illustration, brand claims, brand name, headline (Keller 1987). Advertisements for two different products (automobiles and inexpensive cosmetics) were used to be sure that the analyzed effects are replicable.

Procedure. Participants were asked to generate as many response words (associations) as they could in one minute, for each of five elements of the advertisement (the photograph, product illustration, brand claims, brand name, headline). This way, instructions referred to participants' 'private theories' of the advertisement, and associations essential for the advertisement were activated. The participants were asked to list their associations in the order that first came to mind. Each participant viewed one advertisement. Additionally, particular elements of the ad were presented on an instruction sheet. Finally, control questions were asked regarding participants' knowledge of advertising and the given brand.

RESULTS

Affinity Index as a Measure of Conceptual Coherence of the Print Advertisement
