The strength of associations between particular elements of an advertisement was measured with the affinity index. The method of continued associations (Szalay and Deese 1978) provides a foundation from which to build such a measure. Affinities were derived from continued-association tasks. The affinity index value for each pair of elements in each ad was a measure of the conceptual coherence of the advertisement. Kleine and Kernan's (1988) methodology of measuring 'consumption objects meaning' has been applied to the analysis of the conceptual coherence of print advertisement. Affinity refers to the degree to which people see relations of any sort between any two stimuli and is operationalized as the amount of overlap between two response lists (the number of associations two objects have in common). Associations were generated to pictorial as well as verbal elements of the advertisement: all these elements constitute the advertisement and are perceived as a whole. Response words (associations) generated by participants were classified to particular semantic categories. For example, associations 'solid workmanship' and 'durable workmanship' for the brand name of Mercedes could be classified into the same category. These associations which first come to mind are the most readily available in memory and the most important for a subject (Tversky 1977). Since a participant's first responses are assumed to be more dominant (i.e., salient), each response is assigned a dominance score that is a measure of its relative salience. These scores were assigned according to Szalay and Deese's (1978) method: 6 to the first response produced by a participant, 5 to the second response, 4 to the third response, 3 to the fourth through seventh responses, 2 to the eighth and ninth responses, and 1 to each subsequent response. Dominance scores for common responses were summed up across subjects, for each element of the advertisement. This way, five lists of associations were prepared; one list for one element of the advertisement: for the photograph, product illustration, brand name, headline and brand claims. The sums of dominance scores for each element of the advertisement (diagonal values) were used for calculating the affinity index. Calculation of the inter-object affinity index involves summing up the dominance scores across the overlapping elements and across stimuli. This total is then divided by the sum of the total dominance scores of the objects being compared. The resulting index value is the proportion of the combined total dominance scores accounted for by the affinal relations. The index values could vary between 0 and 1 and increases in value as inter-object affinity increases. An example of affinity index between elements of the Honda Accord advertisement is presented in figure 1.

FIGURE 1. AFFINITY INDEX BETWEEN ELEMENTS OF THE HONDA ACCORD ADVERTISEMENT

The sum of the similarities for each of ten pairs of ad's elements was an index of the conceptual coherence of the advertisement. For example, an index of coherence for the Honda advertisement was: $.495 + .349 + .411 + .208 + .361 + .337 + .266 + .237 + .243 + .268 = 3.175$

The higher value of the index the more coherent the advertisement is.

Four pairs of the most coherent versus the less coherent ads were selected for further analyses. For automobiles of familiar brands the most coherent was Honda Accord advertisement and the less coherent Mercedes Class A advertisement. Their equivalents for automobiles of unfamiliar brands were used: Yugo Tourer and Avanti Alsa, respectively. For cosmetics of familiar brands the most coherent was Oxy advertisement and the less coherent Dax

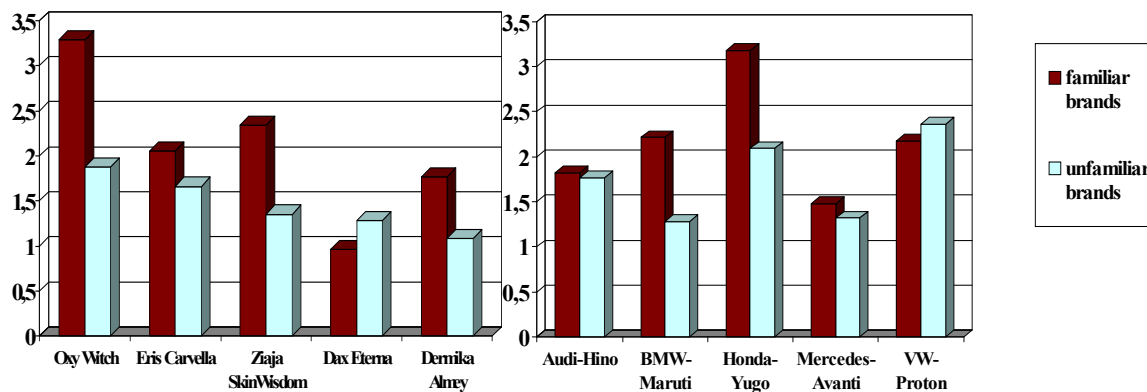

FIGURE 2. BRAND FAMILIARITY AND THE COHERENCE OF ADVERTISEMENT

advertisement. Their equivalents for cosmetics of unfamiliar brands were Witch and Eterna ads, respectively (figure 2).

The differences between the most coherent (Oxy/Witch and Honda/Yugo) and the less coherent (Dax/Eterna and Mercedes/Avanti) advertisements were tested in a one-way ANOVA. Affinity index values for ten pairs of ad's elements (see: figure 1) were used in the analysis of variance. The difference between the most coherent and the less coherent ads, of automobiles and cosmetics altogether, was significant: $F(1, 78) = 23.69; p = .00001$ (for automobiles: $F(1, 36) = 9.70; p = .0036$; for cosmetics: $F(1, 36) = 16.53; p = .00025$).

The differences in coherence of ads for cosmetics and automobiles were tested and turned out to be not significant: $F(1, 38) = .22; p = .65$. Thus, in further analyses ads for cosmetics and automobiles were analyzed in total.

Brand Familiarity and the Coherence of Advertisement

In order to verify hypothesis 1, repeated measurements (familiar-unfamiliar brand) in the analysis of variance were used. Ten indices of similarity for each ad (see: figure 1) were analyzed in ANOVA. Four ads were analyzed: the most and the less coherent for familiar and unfamiliar brand. According to hypothesis 1, advertisements for familiar brands were perceived as more coherent than ads for unfamiliar brands (figure 3).

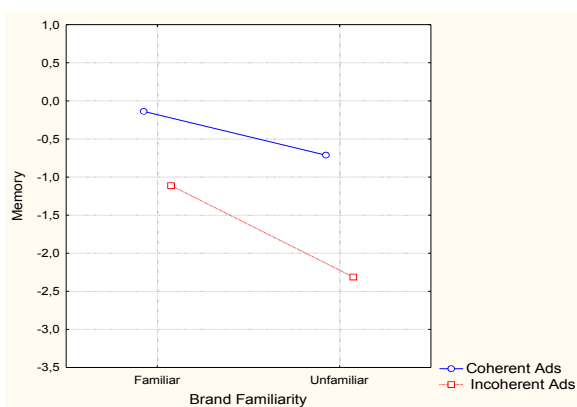

FIGURE 3. COHERENCE OF ADS FOR FAMILIAR AND UNFAMILIAR BRANDS

The results showed that the effect of brand familiarity was statistically significant: $F(1, 39) = 6.43; p = .01$. Ads for familiar brands ($M = .226$) were perceived as more coherent than ads for unfamiliar brands ($M = .163$).

Although layouts of pairs of ads for familiar and unfamiliar brands were very similar, there were salient differences in the perceived coherence of ads.

An advertisement for familiar brand activates a schema – a representation of the brand. An associative network for a familiar brand is well developed and readily accessible in memory. Referring to the theory of conceptual coherence (Murphy and Medin 1985) one can say that knowledge of the brand like ‘theory’ joins together elements of the advertisement in the consumer’s mind.

STUDY 2: THE CONCEPTUAL COHERENCE OF ADVERTISEMENT AND MEMORY DISTORTION

In Study 2 the significance of the conceptual coherence of advertisement in memory distortion was examined. Advertisement’s coherence and brand familiarity were taken into consideration as independent variables. Research was designed in the backward framing paradigm (Braun et al. 1997, 2005). After viewing a coherent versus incoherent print advertisement, participants were presented with a fragment of magazine article about the product they previously saw in the ad. The article acted as a ‘backward frame’, altering how consumers remembered brand claims from the ad.

PARTICIPANTS, MATERIAL, AND PROCEDURE

Three hundred and twenty undergraduates aged 19-28 ($M = 21.76$) participated in the four experiments. In experiment 1 advertisements and magazine articles for cosmetics of familiar brands were used ($N=80$); in experiment 2 ads and magazine articles for cosmetics of unfamiliar brands ($N=80$), in experiment 3 ads and magazine articles for automobiles of familiar brands ($N=80$), and in experiment 4 advertisements and magazine articles for automobiles of unfamiliar brands ($N=80$). Gender differences in each of experimental groups have been controlled.

Print Advertisements. Four pairs of the most coherent versus the less coherent ads were selected from among the ads used in Study 1. For automobiles the most coherent was Honda Accord

advertisement (its equivalent for unfamiliar brand: Yugo Tourer) and the less coherent Mercedes Class A advertisement (its equivalents for unfamiliar brand: Avanti Elsa). For cosmetics of familiar brands the most coherent was Oxy advertisement and the less coherent Dax advertisement. Their equivalents for cosmetics of unfamiliar brands were: Witch and Eterna, respectively.

Postexperience Information. Fragments of magazine articles prepared for the purpose of the experiment were used as post-experience information. Participants viewing advertisements of automobiles were presented with an article containing information of Honda Accord or Mercedes Class A as familiar brands or Yugo Tourer or Avanti Elsa as unfamiliar brands of automobiles, respectively. Participants viewing ads of cosmetics were presented with articles on Oxy or Dax as familiar brands or Witch or Eterna as unfamiliar brands of cosmetics.

Measurement of Memory Distortion. The strength of memory distortion was measured with a memory test consisting of 15 items (brand claims): 5 from the advertisement which participants were presented with, 5 from the magazine article-postexperience information, and 5 additional, not from the ad nor the article. Articles contained brand claims consistent with and similar to these in the advertisement. Additional brand claims were similar to these in the advertisement, too. Participants were asked to recognize which items came from the advertisement they viewed at the beginning of the experiment. Each correct response was scored with 1 point. The index of the memory of brand claims from the advertisement was: $\text{memory} = \text{brand claims from the advertisement} - (\text{brand claims from the magazine article} + \text{brand claims additional})$. This way, the highest score was 5 points and the lowest -10 points. Thus, the higher score, the less memory distortion of brand claims from the advertisement.

Procedure. The study was conducted in quasi-laboratory conditions. At the beginning of the experiment, participants were informed that they participate in the experiment on perception of the advertisement and that their attention and involvement during viewing ads is very important. Then participants were directed to either evaluate the merits of the advertised brand (brand-directed processing) or to judge the merits of the actual advertisement for the brand (ad-directed processing). Thus, each group of participants perceived ads in one of the two contexts. The context of ad perception had to be controlled because consumers never perceive ads 'in vacuo', but in one of these two contexts. Forty seconds were given to view each advertisement. Then participants solved a three-minute distraction task, a puzzle which had no relationship to the present experiment. Next, they were presented with a mock magazine article (postexperience information). Then, they solved another distraction task for three minutes. Finally, participants were asked to solve a memory test on brand claims (measurement of memory distortion).

RESULTS

Memory Distortion of Coherent and Incoherent Advertisements

At the beginning the differences in memory distortion between ads of automobiles and cosmetics were tested. The differences were not significant $F(1, 318) = .25, p = .62$, thus, in further analyses ads of cosmetics and automobiles were tested in total.

It was expected (H2) that brand claims in coherent advertisements are more resistant to memory distortion than brand claims in incoherent ads. The main effect of advertisement coherence in ANOVA was significant, $F(1, 318) = 23.33, p < .000001$ ($M = -.425$ for coherent ads and $M = -1.713$ for incoherent ads). This means that it is more difficult to distort memory of the coherent than incoherent advertisement. The greater amount of similar associations between particular elements of the advertisement, the

better the advertisement is remembered and the less sensitive to memory distortion it is.

FIGURE 4. MEMORY DISTORTION OF BRAND CLAIMS IN COHERENT AND INCOHERENT ADVERTISEMENTS

It can be seen in figure 4 that differences in the strength of memory distortion for incoherent advertisements for familiar and unfamiliar brands are salient, $F(1, 158) = 11.71, p = .0008$. However, in coherent ads such differences have not been observed, $F(1, 158) = 2.18, p = .14$. One can say that the memory of the advertisement and its resistance to memory distortion is determined by the coherence of its elements. Thus, one may refer to the theory of conceptual coherence (Murphy and Medin 1985): Elements of coherent ads are strongly associated with each other and more resistant to distortions.

Brand Familiarity in Memory Distortion of Coherent and Incoherent Advertisements

According to hypothesis 3, it was expected that brand claims in advertisements for familiar brands are more resistant to memory distortion than brand claims in ads for unfamiliar brands. The one-way ANOVA showed that brand claims in ads for familiar brands ($M = -.625$) were less distorted than brand claims in ads for unfamiliar brands ($M = -1.513$), $F(1, 318) = 10.67, p = .001$. A stronger effect of resistance to memory distortion was expected for coherent than incoherent ads. Planned comparisons in the two-way ANOVA showed that in *coherent* advertisements the difference in memory distortion between familiar and unfamiliar brands was not significant: $F(1, 316) = 2.41, p = 0.12$. However, the effect was significant in *incoherent* ads: $F(1, 316) = 10.48, p = .001$. Ads for familiar brands ($M = -1.113$) were less distorted than ads for unfamiliar brands ($M = -2.313$) (figure 5). It is worth noting that layouts of pairs of ads for familiar and unfamiliar brands were very similar, they differed *only* with the brand name (and product illustration in ads of automobiles).

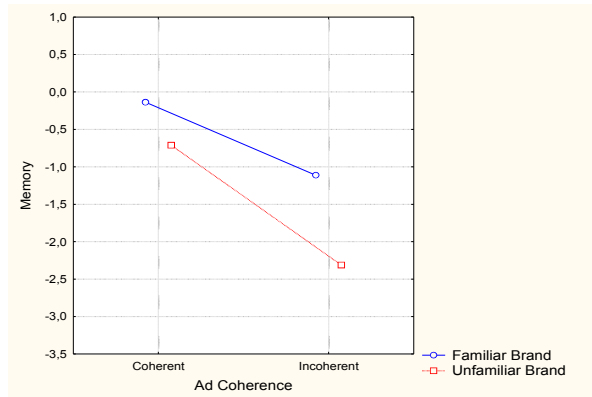

FIGURE 5. MEMORY DISTORTION OF BRAND CLAIMS IN ADS FOR FAMILIAR AND UNFAMILIAR BRANDS

Research showed that familiar brands are more easily detected in advertising clutter. Consumers have well-established brand schemas for familiar brands that may withstand incongruent information (Campbell and Keller 2003; Dahlén and Lange 2004).

Familiar brands are cognitively available and activate a wide area of an associative network. Thus, advertisements for familiar brands are less susceptible to memory distortion as compared to ads for unfamiliar brands. It is more difficult to bring false information into the memory of familiar than unfamiliar brands.

FINAL REMARKS

The presented study, first of all shows rigorous methodology of research on the coherence of ads, sources of that coherence, and its importance for remembering the ads' content. This methodology, well grounded in the contemporary theories of cognitive psychology is, certainly, the stronger argument for accuracy of practical implications derived from the performed research.

First of all brand familiarity turned out to be an important determinant of an ad's coherence, that is, the ads of familiar brands appeared to be considerably more coherent than those of unfamiliar brands. According to Gestalt psychology or the prototype theory of concepts, familiar brands refer to the cognitive schema that is well established in memory. In this sense a coherent ad acquires the ideal features of a „good figure“ (*pragnanz*) or prototype in which separate elements are tightly linked together. Unity achieved in this way is therefore closely related to the general tendency to perceive groupings of elements as an integrated entity. On the other hand it appears that coherent ads are less susceptible to memory distortion than incoherent ads. Such a result is compatible with psychological theories of conceptual coherence and concept formation which point at consolidated memory traces being resistant to distortion.

The essential, practical implication in regard to the creation of ads is to keep or strengthen their coherence. If the brand is familiar then its ad's coherence is intrinsically formed in the consumer's mind. At the same time the process activates psychological mechanisms of retrieving the prototype (good figure) of that product brand from memory. Some attempts to distort the memory of the ad by discrediting the familiar brand, say, in comparative negative ads, will fail because ads of familiar brands are resistant to distortions. The situation is completely different in the case of ads of unfamiliar brands, thus an effort should be put into keeping or strengthening the ad's coherence by carefully selecting its elements. If the coherence is not protected then the ad can be easily distorted in consumer memory, for example in the marketing strategy of competitors who use comparative negative ads. Thus the product of an unfamiliar

brand may appear worse than as it was, in fact, advertised. To protect the ad's coherence is important, initially, to effectively cope with the competitors. Such protection is particularly important for unfamiliar or less known brands.

The results obtained suggest some practical implications for media communication. For example, when TV news are presented by a known presenter, a message is better-remembered and more persuasive; context is not important here. However, when the presenter is unknown, the background is important (coherent context). The results also show how to design a coherent advertisement or how to design an efficient ad for a new brand.

Virtue, Vice, or Both? The Impact of Context-Induced Guilt on Choice and Consumption of Mixed Foods

Sabine Boesen-Mariani, Université Pierre Mendès France, Grenoble, France
Carolina Obino Corrêa Werle, Grenoble Ecole de Management and CERAG, UPMF, France

ABSTRACT

Two studies using real choice settings demonstrate context influence on the choice and consumption of mixed foods (combining hedonic and utilitarian attributes). A hedonic context leads to the choice and reduced consumption of mixed foods for guilt-reducing reasons. A utilitarian context induces less guilt, and leads individuals to choose and consume more of the mixed foods. Priming guilt through nutritional information reverses these effects.

INTRODUCTION

In their daily lives, consumers often confront decisions between hedonic and utilitarian options: for dessert, should I have a delicious chocolate cake or a healthy fruit salad? This kind of dilemma offers a typical example of the hedonic–utilitarian conflict widely studied in consumer behavior literature (for a review see Khan et al. 2005). Various researchers work to understand the consumption of hedonic and utilitarian products and the potential consequences of choosing one over the other (Khan et al. 2005). Yet few consumers choose simply between pure hedonic and pure utilitarian products, especially in the food industry. Rather, expanded choice sets in modern markets mean consumers often consider mixed products, such as such as ice cream, a pure hedonic product that offers low fat or extra calcium, which constitutes utilitarian attributes.

In two studies, we address consumers' choice and consumption of mixed foods according to the choice-set composition. Previous research notes the emotional consequences of deciding between a hedonic and a utilitarian option, in that choosing one or the other prompts mixed emotions (Chitturi et al. 2007). We therefore investigate the role of emotional activation in the choice of mixed foods. Wansink and Chandon (2006) show that “low-fat” nutrition labels reduce the guilt associated with the consumption of hedonic foods; emotion activation thus may be a determinant of choice and consumption. Mixed products may provide a balanced alternative that consumers prefer when they want to regulate their feelings, such as anticipated guilt (study 1).

We also gain some insight in the psychological reasons for the choice of mixed products in different contexts. We propose that presenting mixed food next to a pure hedonic option activates guilt, so the mixed food represents the appealing, guilt-regulating alternative. In contrast, a mixed product that appears beside a utilitarian option induces no guilt, so the choice of a mixed option should reflect pursuit of a hedonic goal. That is, the choice of the mixed food differs according to the context and reflects either the pursuit of pleasure or an attempt to regulate guilt (study 1).

Once they have chosen a mixed product, consumers must decide how much to consume. If the choice of the mixed product results from their trade-off between a hedonic and a mixed option, due to guilt activation, we suggest that the consumption will be reduced in order to address a high-priority goal. However, when the choice of the mixed product results from the trade-off with a pure utilitarian product, the context does not activate the guilt, the motivation is mainly hedonic, and the consumer feels free to eat a larger amount of the mixed option (study 1).

Finally, recent research suggests that low-fat labels can reduce anticipated guilt because they cause calorie misestimations (Wansink and Chandon 2006); consumers should be more likely to consume mixed foods because they perceive them as lower in calories and

fat. The presentation of nutrition information would give a more realistic idea of the guilt associated with each option in the choice set and therefore may attenuate the effect of the presentation context on the consumption of mixed products (study 2).

CONCEPTUAL BACKGROUND

Emotional Reactions to Hedonic and Utilitarian Products

According to Holbrook and Hirschman (1982), people consume products for two main reasons: (1) utilitarian reasons related to the function of the product or (2) hedonic reasons to achieve an affective experience. Hedonic consumption thus is driven by pleasure, emotions, and a sensation-seeking motivation, whereas utilitarian consumption derives from a desire to satisfy a basic need or accomplish a functional task through the practical, and instrumental characteristics of the product (Holbrook and Hirschman 1982). Although the hedonic option generates positive emotions, such as excitement and cheerfulness (Chitturi et al. 2007), its choice is harder to justify because it may have negative consequences in the long run (Hoch and Loewenstein 1991). Therefore, it also can engender negative emotions, such as guilt and anxiety (Giner-Sorolla 2001; Ramanathan and Williams 2007). That is, the consumption of a hedonic product raises mixed emotions: Consumers feel good because they achieve sensory pleasure, but they feel bad because they have succumbed to temptation (Macht and Dettmer 2006; Ramanathan and Williams 2007).

Traditionally, research on consumer decision-making (such as Shiv and Fedorikhin 1999) relies only two dimensions: affect (related of sensorial pleasure) versus cognition (related to the benefits of the products for consumers' health). However, research mentioned above suggests that the dimension related to affect could be formed by two sub-dimensions: positive reflecting the pleasure obtained by the consumption and a negative reflecting emotions such as guilt. Recent research such Wansink and Chandon (2006) and an exploratory study conducted by the authors suggests that a guilt-reducing motivation could determine choice and consumption of mixed products.

Choice Context Effects and Activation of Emotions

Extant research indicates that the choice context can modify consumers' preferences and decision process (Bettman, Luce, and Payne 2008; Hsee et al. 1999). Different elements in the choice environment might activate different constructs in consumer memory and influence preferences and behaviors, as well as four specific systems: perceptual (e.g., stereotypes, traits), evaluative (i.e., attitudes), motivation (i.e., goals), and emotional (Bargh and Morsella 2009). Most research centers on the role of activated goals or traits to explain consumer choice and consumption (for instance: Fishbach et al. 2003; Sela, Berger, and Liu 2009; Wilcox et al. 2009). However, consistent with Bargh and Morsella's (2009) proposal, we suggest that the context activates certain emotions that determine the decision motivation. Specifically, we posit that certain contexts activate more guilt than do others and therefore lead to the choice of less hedonic products, in a sort of balance-seeking strategy (Zemack-Rugar et al. 2007).

When the mixed option appears together with a hedonic option (hedonic context), due to its evaluability the hedonic attribute is highlighted (Hsee et al. 1999). As mentioned earlier, hedonic attributes are not only associated to positive feelings such as plea-

sure but also to negative emotions such as guilt. Consequently, we propose that the hedonic choice-set activates guilt, and the mixed option provides a guilt-regulating mechanism.

Additionally, research on guilt shows that the presence of this emotion makes individuals prioritize utilitarian, long-term motivations (Baumeister and Exline 1999; Baumeister, Stillwell, and Heatherton 1995) and neglect short term motivations such as pleasure-seeking. Taking this into account, we suggest that in the hedonic context, consumers choose the mixed product to avoid feelings of guilt and the choice is driven by a utilitarian motivation. That is,

H1: *When the mixed product appears together with a hedonic product, the choice set activates guilt and leads to the choice of the mixed option (rather than the hedonic product) for utilitarian reasons in comparison with the utilitarian context.*

In contrast, when the mixed option appears with a utilitarian product (utilitarian context), the utilitarian attribute is highlighted, and the context does not activate the same amount of guilt. As a consequence, the choice of the mixed option is not driven by this emotion. The utilitarian context has, in fact, a liberating effect on individuals, encouraging them to indulge due to a health halo effect (Chandon and Wansink 2007a). The consumers will therefore choose the mixed option to satisfy a pleasure-seeking motivation. That is,

H2: *When the mixed product appears together with a utilitarian product, the choice set does not activate guilt and leads to the choice of the mixed option (rather than the utilitarian product) for hedonic reasons in comparison with the hedonic context.*

Wansink and Chandon (2006) also show that low-fat nutrition labels increase food consumption, because consumers increase their perceptions of the appropriate serving size. What happens to perceptions of serving size for mixed products presented together with pure hedonic versus pure utilitarian products? We believe it depends on the motivation behind the mixed product choice. Research on sequential choices indicates that when making similar decisions sequentially in a short period of time, people tend to commit to their first choice through a reinforcement mechanism (Dhar, Huber, and Khan 2007; Huber, Goldsmith, and Mogilner 2008). Therefore, if consumers choose a mixed product in a low-guilt context for hedonic reasons, they should take more of the mixed product to fulfill their pleasure motivation. However, if their choice is motivated by guilt-avoidance, they should tend to serve themselves a smaller portion to continue regulating or even eliminate their guilt. That is,

H3: *In a hedonic context, consumers serve themselves a smaller amount of the mixed product (compared to the utilitarian context).*

H4: *In a utilitarian context, consumers serve themselves a larger amount of the mixed product (compared to the hedonic context).*

The Moderating Effect of Nutrition Information

Previous research demonstrates that providing nutritional information influences perceptions, attitudes, intentions and consumption (Bui et al. 2008; Burton et al. 2006; Garg, Wansink, and Inman 2007; Howlett et al. 2009; Kozup et al. 2003), because

most consumers lack of expertise in estimating the caloric content of foods. They generally underestimate caloric and fat content, especially for large meals (Chandon and Wansink 2007b), which might prompt a mistaken guilt-reducing perception, especially for mixed foods that use health-related claims and induce perceptions of lower caloric and fat content. If so, presenting the nutrition information for all options in the choice set should give consumers a more realistic perception. For mixed foods, the realistic perception may prime guilt especially in the utilitarian context were they are the more hedonic option. The guilt activation should alter the chosen product and amounts.

Specifically, we propose that in the hedonic context guilt is already activated by the characteristics of the choice set and presenting nutrition information only reinforces the presence of this emotion. However, in the utilitarian context guilt is previously absent, therefore, presenting nutrition information highlights guilt and has a strong impact on the amount consumed of the mixed option. As a result, consumers should moderate their consumption of mixed foods in the utilitarian condition with nutrition information to regulate their activated guilt. That is,

H5: *In the presence of a guilt prime (nutrition information), when the mixed product appears together with a utilitarian product, consumers serve themselves less of the mixed product to reduce their feelings of guilt (in comparison to the scenario without nutritional information).*

In the hedonic context, the presentation of nutrition information for both options should reinforce the guilt-reducing characteristics of the mixed food, because its calorie content is less than that of a hedonic food. Therefore, nutritional information in the hedonic context should lead to greater consumption of the mixed food, because the simple fact of choosing the mixed option may already reduce their activated guilt. Therefore,

H6: *In the presence of a guilt prime (nutrition information), when the mixed product appears together with a hedonic product, consumers serve themselves more of the mixed product (in comparison to the scenario without nutritional information).*

We use two experiments to test these hypotheses. First, we explore the impact of the choice context on the choice and consumption of mixed food (study 1). Then, we consider whether the provision of nutritional information might alter the consumption of the mixed option (study 2).

STUDY 1

For study 1, our objective is to test the effects of the presentation context on the evaluation, choice, and consumption of mixed foods. We have predicted that when the mixed food appears beside a hedonic product, the choice set activates guilt, prompts the choice of the mixed option for utilitarian reasons (H1), and leads to the consumption of a smaller amount of the mixed product to continue to regulate guilt (H3). We also argue that when the mixed product is in the same choice set as a utilitarian one, no guilt gets activated, which leads to the choice of the mixed option for hedonic reasons (H2) and the consumption of a large amount of the mixed product to obtain pleasure (H4). Study 1 tests these hypotheses.

METHOD

Study 1 uses a one-factor, two-level (context of presentation: utilitarian option versus hedonic option) between-subjects design, and the 138 undergraduate student participants were randomly assigned to a condition. When they arrived for the study, the participants received a consent form and a participant number and then entered a second room, where they would receive a gift for their participation. In the second room, a research assistant explained that the participants could choose between two snacks. In the utilitarian context, the choice included “fine slices of oven-baked apple” (pure utilitarian product) and “light cocoa cookies enriched with cereal” (mixed product); in the hedonic context, they chose between “shortbread filled with melting chocolate” (pure hedonic product) and the same mixed product. The snacks in large plastic bowls appeared in a counterbalanced order, and participants used a scoop to serve themselves as much as they wanted of the chosen snack in a small plastic bag. The research assistant then identified the bag with the participant’s number and explained that the next stage of the study would take place in the experimental lab, which people could not enter with food. Therefore, they would receive their snack at the end of the experiment. In the lab, participants first completed a lexical decision task (i.e., to measure the accessibility of concepts related to guilt, pleasure, and health), then a questionnaire with measures of their choice, motivations, evaluations of both the snack options, and participant’s profile. While participants were completing this part of the study, a research assistant unobtrusively weighted the plastic bags content to calculate the caloric content of the amount of snack served. Finally, at the end of the experimental session, they received their snack bag, along with a debriefing of the study objectives, and were dismissed.

STIMULI

Each participant considered two different snacks displayed in large plastic bowls and identified by a description (both descriptions contain similar numbers of words). The snacks represented real alternatives, which should increase the vividness of these options and intensify the affect experienced by the respondents (Shiv and Fedorikhin 1999). Although the pure utilitarian option (fine slices of oven-baked apple) was inspired by Shiv and Fedorikhin’s (1999) research, French participants may consider a fresh apple a hedonic product (because it is refreshing), so we decided to use dried apple slices instead. The shortbread filled with melting chocolate provides the pure hedonic option because it contains typically hedonic ingredients (e.g., chocolate). Finally, the mixed option reflects our conceptualization of a hedonic product (cookie) to which we added utilitarian attributes (light and rich in cereals). A pilot study confirms these choices; the data are available from the authors on request. Because one of our dependent measures is the amount that each participant served him- or herself, the chocolate shortbread, cookies, and apple slices are better options than a whole apple or entire chocolate cake. Finally, the size and shape of each unit of the three options is similar (approximately 10 grams per unit), so these characteristics should not influence the participants’ decisions.

MEASURES

Each respondent first responded to the following prompt: “A few moments ago you made a choice from two options, fine slices of oven-baked apple (shortbread filled with melting chocolate) and the light cocoa cookies enriched with cereals. Please indicate below the option you chose.” We confirmed these responses with the choice of snacks registered by the research assistant and find that the choices match across all respondents.

After the choice, in order to measure guilt activation in each context, we asked the participants to complete a lexical decision task on the computer. They considered a series of letter strings and decided, as quickly as possible, whether each letter string was a word. Each word appeared individually in the center of the screen and flashed very briefly. They classified the target letter strings as either words or nonwords, using the D and K keys. Each response was followed by a 1-second pause and then the next trial. After 10 practice trials, which included an equal number of words and nonwords, participants started the main lexical decision task, in which they classified 32 words (4 guilt-related words, 4 pleasure-related words, 4 health-related words, 4 neutral words, and 16 nonwords), which appeared for 50 ms each, followed by a white screen until the participants hit one of the keys, and then the next word. Participants exposed to the hedonic context (versus utilitarian context) should more readily identify words related to guilt, which would confirm the emotion activation effect. Because the latency of incorrect responses would be difficult to interpret, we use only correct responses in our subsequent analyses (Fazio 1990). To minimize the influence of outliers, we first transform all individual reaction times using a natural log transformation, then exclude any that exceed three standard deviations from the cell mean (Fazio 1990).

In line with Shiv and Fedorikhin (1999), we then asked the participants to indicate the basis of his or her choice on five seven-point items: “My choice of snack was driven by “my thoughts (1)/my feelings (7),” “my willpower (1)/my desire (7),” “the rational side of me (1)/the emotional side of me (7),” and “my head (1)/my heart (7).” The Cronbach’s alpha for these items reach .89, and we therefore can average the responses to the five items to form a single index (i.e., Decision Basis). Each respondent also indicated, on seven-point scales, the extent to which hedonic, utilitarian, and guilt-reducing goals bore on their decision: “I was searching for pleasure,” “I was seeking gratification,” “I was trying to avoid guilt,” and “I was trying to make the best choice for my health”.

Next, the participants indicated their familiarity with the different snacks, whether they have consumed this kind of snack, and if they thought these products were innovative. Finally, they indicated their gender, age, weight and height, when they had their last meal, if they were hungry, their knowledge about nutrition, their dietary restrictions (Herman and Polivy 1980), and several other self-perception measures. These measures serve as covariates in the various analyses and only those impacting the results are mentioned below.

RESULTS

Guilt activation. Our hypotheses suggest that the hedonic context activates guilt and that this emotion leads to the choice of the mixed option for utilitarian reasons (H1). Conversely, in the utilitarian context, guilt is not activated and the choice of the mixed option (rather than the utilitarian product) for hedonic reasons (H2). The lexical decision task was used to verify the guilt activation. The results of this task show, as expected, that in the hedonic context, the words related to guilt are more accessible (smaller latency) than in the utilitarian context (528 vs. 544; $F(1, 67) = 6.89, p < .05$). These evidences show that in the hedonic context guilt is more accessible than in the utilitarian context¹. Moreover, our analysis of other self-reported measures indicate that in the hedonic context, the choice of the mixed derives from the intention to avoid feeling guilty (guilt-avoidance motivation_{mixed food choice} = 3.36; guilt avoidance motivation_{hedonic food choice} = 2.48; $F(1, 57) = 5.47, p < .05$). However, in the utilitarian context condition, in accordance with hypothesis

1 The data on the accessibility of pleasure related words and health related words were no statistical significant

3, we find no difference in the guilt-reducing motivation among participants who choose the mixed products versus the utilitarian product (guilt-avoidance motivation_{mixed food choice} = 3.23; guilt avoidance motivation_{utilitarian food choice} = 2.94; $F(1, 58) = .26, p > .10$).

Hedonic and Utilitarian Motivations for choice. Consistent with previous research (Giner-Sorolla 2001; Zemack-Rugar et al. 2007), we find that the guilt activated by the choice context seems to induce a choice of the mixed product due to different motivations. In the hedonic context condition, guilt motivates participants to make a more reasoned choice; yet in the utilitarian context, they choose the mixed snack for affective reasons. Respondents who choose the mixed food rate their choice as reflecting affect in the utilitarian context (Decision Basis_{utilitarian context} = 4.70) more than in the hedonic context (Decision Basis_{hedonic context} = 3.73; $F(1, 73) = 9.89, p < .05$). In the same sense, participants choose the mixed food for their health in the hedonic context condition (health motivation_{utilitarian context} = 2.55; health motivation_{hedonic context} = 4.00; $F(1, 73) = 10.98, p < .05$), but they make this choice for pleasure in the utilitarian context (pleasure motivation_{utilitarian context} = 4.19; pleasure motivation_{hedonic context} = 3.50; $F(1, 73) = 5.73, p < .05$). These results are consistent with hypotheses 1 and 2, which suggest a more utilitarian motivation for the choice of the mixed product in the hedonic context and a more hedonic motivation guiding the choice of the mixed option in the utilitarian context.

Testing the mechanism leading to the choice of the mixed option. Additionally, to test the hypotheses 1 and 2, given the binary dependent variable, a logistic regression was conducted. The choice of the mixed option was coded as « 1 » and the choice of the others products was coded as « 0 ». Product terms were created by multiplying the independent variables (i.e., guilt and motivations). We examined the effects of guilt and hedonic and utilitarian motivation on the choice of snack in each of the context (hedonic and utilitarian). The results indicate that the interaction term between guilt and health motivation was a significant predictor of choice of the mixed option in the hedonic context ($B=0.87$; Wald = 11.41, $p < .05$) and in the utilitarian context the hedonic motivation was a significant predictor of choice of the mixed option ($B= .604$; Wald = 5.409, $p < .05$). The utilitarian motivation was also significant but helped to predict the choice of utilitarian option ($B= -.435$; Wald = 7.026, $p < .05$). These results of logistic regression allow us to confirm H1 and H2.

Amount served. Among participants who choose the mixed snack, those in the utilitarian context serve 54% more than those in the hedonic context (calories in amount served_{utilitarian context} = 317.46; calories in amount served_{hedonic context} = 206.16; $F(1, 74) = 3.86, p < .05$). These results align with the prediction of reinforcement between sequential choices (Huber et al. 2008) and therefore with hypotheses 3 and 4. When guilt is activated, the motivation for choosing the mixed food is utilitarian (in the hedonic context), people control themselves and take only a small amount. Yet, when guilt is absent, their motivation is hedonic (pleasure-seeking motivation in the utilitarian context) therefore they keep searching for pleasure and serve themselves more of the product.

STUDY 2

With study 2, we test hypotheses 5 and 6 regarding the role of a guilt prime (nutritional information) in moderating the effect of the context on the choice of mixed products and the amount served. The presentation of a guilt prime should influence the amount of mixed food they served by participants, such that in the utilitarian context (H5), consumers should serve themselves less to avoid guilt and the hedonic context (H6), consumers serve themselves more because guilt was reduced by the choice of the mixed option.

METHOD

Study 2 relies on a two-factor (context of presentation: with a utilitarian option versus with a hedonic option; guilt prime: nutritional information present versus absent) between-subjects design and the 121 undergraduate student participants were randomly assigned to a condition. The procedure, stimuli, and measures are similar to those in study 1, except that in the conditions with the guilt prime, we present nutritional information (caloric content, sugars, fat, and fiber) for both snack options available. In addition to the measures from study 1, we determine whether participants take into account the caloric content and the nutritional composition of the foods in their choice set, which serve as manipulation checks for the guilt prime. These items were averaged to form an index ($\alpha = .82$).

RESULTS

Manipulation checks. Participants exposed to nutritional information took into account the nutritional characteristics of the product when making their choice to a greater extent than did those who were not exposed to nutritional information ($M = 3.70$ versus $M = 3.00$; $F(1, 121) = 4.25; p < .05$). As we predicted, the presentation of nutrition information emphasizes the guilt associated with the choice in both contexts. Participants exposed to nutrition information declare more feelings of guilt after their choice ($M = 2.41$) than do those who received no exposure to nutritional information ($M = 2.00$; $F(1, 120) = 4.72, p < .05$) after controlling for dietary restrictions.

Amount served. In the hedonic context, the participants who see no nutritional information serve themselves fewer calories of mixed food ($M = 165.7$) than those in the utilitarian context ($M = 264.4$; $F(1, 31) = 6.76, p < .05$). These results are consistent with study 1. However, consumers exposed to nutritional information serve the same amount of the snack, independent of the presentation context (hedonic context = 202.7; utilitarian context = 186.2; $F(1, 33) = .19, p > .10$). Moreover, we find a decrease in the amount of mixed food served in the utilitarian condition when nutritional information appears (utilitarian context: no nutritional information = 264.4; nutritional information = 186.2; $F(1, 40) = 5.51, p < .05$). Consistent with our conceptualization, we find that presenting nutritional information attenuates the effect of the context of presentation on the amount of calories served among the participants who choose a mixed food. These results also indicate that the effect shown in study 1 is being driven by a guilt regulation. In the hedonic condition, however, the results are in expected direction (more consumption with nutritional information) but the difference is not statistically significant ($M_{\text{without information}} = 165.7$ versus $M_{\text{with information}} = 202.7$; $F(1, 24) = .80, p > .10$).

The presentation of nutritional information also influences the amount of mixed food served across conditions. Our analysis of the group of participants choosing the mixed food reveals that the effect observed in study 1 was reversed ($F(1, 40) = 4.63, p < .05$).

GENERAL DISCUSSION

This research examines consumers' choice and consumption of mixed foods and the impact of the context (i.e., choice-set composition) and the presence of nutritional information on those choices. Prior research mainly studies consumers' reactions and behavior with regard to pure hedonic or utilitarian options; we instead focus on mixed options (i.e., a hedonic product that contains one or more utilitarian attributes).

Based on previous research (Giner-Sorolla 2001; Wansink and Chandon 2006), we claim that the mixed product can serve as a guilt reducing option but only in some situations. We suggest that depending on the choice-set composition, guilt can be activated or

not and consequently determine the goal to be fulfilled (utilitarian related to health or hedonic related to pleasure, respectively). Additionally, as nutritional information can change the perception of a food product as well as intentions and consumption (Bui et al. 2008; Burton et al. 2006; Garg et al. 2007; Howlett et al. 2009; Kozup et al. 2003; Wansink and Chandon 2006), we suppose that the presence of nutritional information can activate guilt and reverse the choice-set composition effect described earlier. Through two studies (using real food choices) we demonstrate the role of guilt activation for the choice, and consumption of mixed products.

In study 1, we provide evidence that the context can activate guilt and this emotion influences both the motivation for the choice and the amount consumed of the mixed option. The hedonic context activates guilt and, in order to regulate this emotion, the choice of the mixed option is guided by a utilitarian motivation (i.e., health). Moreover, as a mean to reduce guilt, participants serve themselves a smaller amount of the mixed product. However, in a utilitarian context, we demonstrate that no guilt is activated and the choice and consumption of the mixed option are guided by hedonic motives. Additionally, our results show that these context effects are moderated by the presentation of nutritional information (study 2). More specifically, we found that, in the utilitarian context, consumers reduce their consumption of mixed option when nutritional information appears. This information primes guilt and leads to a reduction of the amount of mixed food consumed in the utilitarian context, reversing the overconsumption observed in study 1.

The results of these studies are consistent with the prediction that environmental stimuli (in that case, the choice-set composition) can activate the emotional system and motivational system that will consequently guide behavioral responses. In that sense, our results complement previous research (such as Fishbach et al. 2003; Wilcox et al. 2009) by putting forward the mediating role of emotion activation (i.e., guilt activation) when people are exposed to temptation. Specifically, the activation of guilt determines the goal to be pursued (hedonic or utilitarian). We empirically demonstrate an alternative path to the one suggested originally by Fishbach et al. (2003); the temptation can, in fact, activate guilt and this emotion will then determine the goal to be pursued. Our findings complement the research by Zemack-Rugar and colleagues (2007) by showing that the activated guilt influence the goals and these goals will then determine the consumers' decisions. Additionally, in our studies we employed different ways to activate guilt that are closer to real-world situations and could actually have an influence in decision making in the everyday consumer environment. We show that choice-set composition and nutritional information can activate guilt; previous research used instead more artificial ways to prime it (e.g., participants were subliminally primed with guilty emotion adjectives).

IMPLICATIONS AND FUTURE RESEARCH

Our findings have important practical implications not only for brand managers but also for policy makers and consumers. For managers, our results indicate that positioning the mixed foods using a guilt-reducing argument can "speak to consumers". In fact, as Fabrigar and Petty (1999) show, persuasive arguments have to match the bases of the attitude toward the product. So, the usual health claims may not be enough to catch consumers; the emotional dimension also needs to be addressed. Moreover, our results help food manufacturers and retail store managers regarding display decisions. Our conclusions indicate that the mixed products sales could be increased by placing them in store shelves surrounded by utilitarian products rather than hedonic product, despite the risks of overconsumption. Moreover, our conclusions have also important

implications for policy makers and consumers assisting them in the context of obesity prevention. Previous research (Geyskens et al. 2007; Wansink and Chandon 2006) alerted to the fact that these mixed options could lead *de facto* to overconsumption. Our findings shed light on the circumstances in which consumers are more vulnerable to overconsumption indicating that placing mixed foods next to hedonic foods might be a good strategy for regulating their consumption. Likewise, our studies show that nutritional information may help consumers control their consumption of this kind of product when it appears in a utilitarian context.

Finally, this research suggests several further questions that additional research could address. First, we investigate the role of guilt activation in the context of choice related to mixed food products. As recent research shows (Keinan, Kivetz, and Netzer 2009), it also would be interesting to test and replicate these results with other mixed products (e.g., luxury clothes made with organic cotton). Second, in our studies the mixed products we used where hedonic product to which utilitarian attributes were added and removed (e.g., light cookies rich in cereals). Further research should explore consumers' reactions to and behavior toward different kinds of mixed products. An important question is whether there is difference between adding a utilitarian attribute (e.g., rich in calcium or fiber) versus removing a hedonic feature (e.g., fat or sugar free)? Similarly, we did not address in this research the fact that these products can have different degrees of "mixture" (more or less hedonic / utilitarian) and it could be relevant to explore the role of guilt in the decision process regarding these different types of mixed products. Third, it would be interesting to test the persistence of the context effects we find in this research and the guilt activation explanation using a more complex choice set (for instance, Sela et al. 2009).

Body Beliefs Shape the Perceived Accuracy of Virtual Models

Ellen Garbarino, University of Sydney, Australia
Jose Antonio Rosa, University of Wyoming, USA

ABSTRACT:

The success of e-tailing highlights the need to understand how perceptions, including body-based beliefs, influence our interpretation of the virtual world. Using an Internet survey, we demonstrate women's body image discrepancy and body boundary aberration influence the perceived accuracy of virtual models, which in turn mediates their usage intentions.

INTRODUCTION

The success of apparel sales online might come as a surprise to many who expected products for which consumption entails a high level of physical involvement would be hard to sell online (Yadav and Varadarajan 2005). Contrary to such expectations, apparel is one of the most dramatic success stories of online retailing, with double digit sales growth in recent years and the largest online sales revenue figures for all physical good (Mui 2007).

As sales volume and competition have increased, online retailers have relied on interactivity and personalization as powerful tools for online differentiation and success (Rust and Lemon 2001). Interactivity and personalization are valued for their ability to enhance involvement, attitudes, and intentions (Fiore, Kim, and Lee 2005; Griffith, Krampf, and Palmer 2001; Kim and Forsythe 2008). Product visualization technologies, such as virtual models, offer some of the most intriguing tools for increasing interactivity and personalization. While product visualization tools have been shown to enhance the retail experience (Daugherty et al. 2008; Kim and Forsythe 2008), most research ignores the potential for individual differences to influence their effectiveness. In product categories with high body involvement, such as apparel, the effectiveness of product visualization may well depend on consumers' perceptions and beliefs about their physical body in ways that potentially limit the accuracy and effectiveness of virtual technologies. To explore this potential influence, we examine how two different belief systems about the body affect consumers' perception of virtual model accuracy and willingness to use them.

BACKGROUND

Product Visualization Technologies and Online Retailing

A number of researchers have explored the ability of product visualization technology to substitute for physical retail experiences. They find that 3D product visualization closely mimics the direct retail experience (Daugherty et al. 2008). 3-D representations have been found to increase psychological processing, involvement, enjoyment, and sense of being there (Li, Daugherty and Biocca 2001). However, this does not always translate into improved brand attitudes or purchase intentions (Li, Daugherty, and Biocca 2003; Westland and Au 1997). Conversely, other research finds that 3-D representations (i.e. virtual apparel models) improve attitudes towards retailers and the retail experience and increase purchase intentions (Daugherty et al. 2008; Fiore et al. 2005).

These conflicting findings may be the result of individual difference factors operating as moderators. A number of individual difference factors, including hedonic orientation (Fiore et al. 2005; Kim and Forsythe 2007), innovativeness (Kim and Forsythe 2008) and preferred level of stimulation (Daugherty et al. 2008), have been shown to moderate consumer responses to product visualization. We propose to explore how individual differences in consumer beliefs about their bodies might moderate the effectiveness of a product visualization tool. While the interrelationship between product

visualization and body beliefs has received little attention, there is some evidence that body beliefs can influence consumers' online purchase intentions. Rosa et al. (Rosa, Garbarino, and Malter 2006) find that people's willingness to purchase apparel online is mediated by their involvement with apparel and their concern with fit, and that these mediators are in turn influenced by the consumers' beliefs about their bodies.

Virtual models simulate the visual aspects of traditional retail experiences, as partial replication of the more conclusive assessment of fit that comes from physically trying on garments. In contrast to traditional stores, however, where consumers can sensorially experience how the product looks and feels, the virtual experience involves an abstract perceptual process where one must mentally extrapolate the consumption experience from a 2-D caricature. The creation of such a mental representation does not merely draw on the consumers' perceptions of the product but also of the caricature and its ability to accurately represent their body as they perceive it. This more complex integration of product, digital rendering, and body information should make the interpretation of electronic representations susceptible to biases generated by the consumer's pre-existing notions about the shape, attractiveness, and adequacy of their bodies. In addition, given the impoverished information available in the Internet context, almost exclusively reliant on two-dimensional representations and text descriptions, it is reasonable to expect that consumers will rely more heavily on information they already hold when making product assessments in this context. Beliefs about one's body are among the sources of information consistently available, and hence likely to exert an exaggerated influence on consumers when shopping in the Internet's low information environment. It is expected that consumers who hold body beliefs that are not well calibrated to the objective reality of their bodies (e.g., see themselves differently than they appear to others) will carry this bias into their interpretation of the accuracy of virtual models, and hence relate differently to the sales tool.

BODY BELIEFS

We focus on how two distinct types of beliefs that consumers hold about their bodies—body image discrepancy (Cash 1994; Cash and Szymanski 1995) and body boundary aberration (Fisher 1986)—affect the perception of a virtual model. Body image discrepancy (BID) is a cognitive evaluation of how well the appearance of various aspects of our body (e.g., hair, skin, muscle tone, body proportions, and weight) aligns with our ideals for those body parts (Cash 1994; Cash and Szymanski 1995). It is captured as a discrepancy between the consumers' perception of each body aspect (e.g., hair, skin, weight, body proportions, and muscle tone) and their ideals for that aspect, weighted for the importance of that aspect to the consumer (Cash 1994; Cash and Szymanski 1995). High body image discrepancy scores indicate a body image that differs from ideals.

Body boundary aberration (BBA) addresses the individual's sense of the location and stability of the edges of his or her body as a container (Fisher 1970, 1973). Most people recognize that they reside in a container, and that a boundary or edge separates them from the outside world. The alignment of this boundary with the skin surface, however, differs between persons, along with how well their boundary can withstand penetration. BBA occurs when an individual's sense of the location of that edge does not align with their skin surface, and when the individual perceives his or her body boundaries as threateningly susceptible to penetration (Fisher 1970,

1986). Initially noted and explored by neurologists in brain-damaged patients (e.g., Head 1926), BBA has also been studied in segments of the general population (Chapman et al. 1978; Fisher 1970, 1986), including consumers (Rosa et al. 2006). In general, perceived body boundary aligns with the skin surface, but it is possible for our sense of body containment to either move inward from the skin surface or extend beyond it to incorporate immediately adjacent objects in contact with the skin. Consumers whose boundaries extend beyond the skin surface sense objects adjacent to their skin (i.e., a tennis racket being held, apparel being worn) as integrated with their bodies, and experience a temporary sense of loss when physical contact ends. One common example of mild BBA is experiencing a general sense of nakedness and vulnerability when a habitually worn accessory (e.g., hat, bra, watch, or ring) is absent. Another example is experiencing an enhanced and generalized sense of power when wearing bold colors or tightly-woven dense fabrics (Fisher 1986). Body boundary aberration affects how people interact with products. Some consumers use products to reinforce their body boundaries (Fisher 1970, 1973), such as by driving autos that feel and sound impenetrable, and strategically choosing colors and fabrics that accentuate their boundaries. It has also been shown that consumers instinctively incorporate the shape and location of products into their body schemas and adjust their behavior accordingly, such as when without thinking they adjust their posture and movement to clear doorways when wearing tall head gear (Blakeslee 2004). BBA has been found to influence how people shop, and that consumers high on BBA are more willing to shop for apparel online (Rosa et al. 2006).

These constructs were chosen to represent different aspects of body belief; body image discrepancy as a consciously evaluative measure, and body boundary aberration as a perception with limited cognitive intrusion. Finding that body beliefs influence accuracy assessments, even when working with such distinct body beliefs, affirms the robustness of the phenomena. Using an online survey, we explore how these body beliefs influence consumer's assessments of virtual models and how their perceptions affect usage intentions.

PROPOSED MODEL

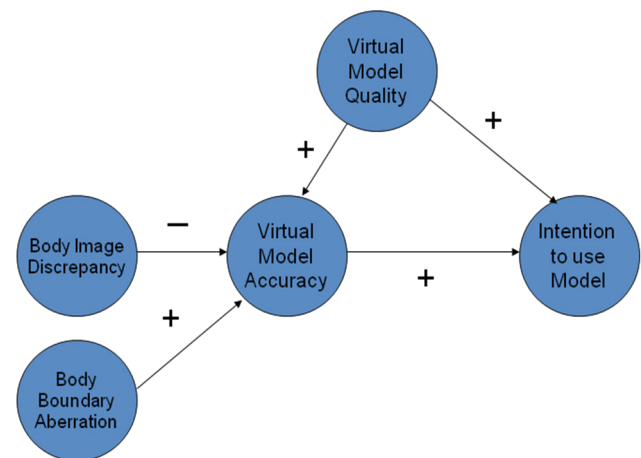

Figure 1 depicts the proposed model of how body beliefs will influence consumer intentions to use virtual models. Because judgments of model accuracy are subjective, we believe they will be influenced by the consumer's body beliefs. Body image discrepancy is expected to have a negative influence on perceived virtual model accuracy. High body image discrepancy exists when consumers believe that aspects of their looks do not meet important standards, suggesting a more critical view of the self in the mirror. Discrepancies are likely to be more salient and influential for high body image discrepancy consumers, and given the evaluative nature of BID, it is reasonable to expect that the same critical eye that highlights discrepancies from the ideal when looking in the mirror will be used to assess the accuracy of any representation that purports to serve the same function. Consequently, body image discrepancy will have a negative relationship to virtual model accuracy.

The influence of Body Boundary Aberration (BBA) stems from the underlying uncertainty about body shape that BBA engenders. Body Boundary Aberration is expected to have a positive influence on the perceived accuracy of virtual models by virtue of the reassurance that comes from seeing a stand-alone representation of the self with unambiguous boundaries. High BBA consumers glean reassurance from seeing their boundaries well-defined, and we expect that a representation of self with well defined edges against a neutral and uniform background will be reassuring to consumers with high BBA.

Perceived model quality is defined as consumers' assessment of how effectively the model can represent how the clothing looks

and fits. It is expected to positively influence both their perception of how accurately the model can represent them and how likely they would be to use it. While we have no theoretical reason to expect that body image discrepancy and body boundary aberration influence quality assessments, we will test this assumption via alternative model testing. The inclusion of perceived model quality as an influence on accuracy assessments and usage intentions allows us to capture the variance in this endogenous variable and reduce the possibility of the paths from body beliefs being inflated by otherwise unaccounted for random variance. Both perceived accuracy and quality are expected to positively influence usage intentions.

Figure 1: The Influence of Body Beliefs

METHODS

An online panel designed to represent the U.S Internet consumer population was used to collect a sample of female respondents (initial invites 8264; N=978; response rate 12%). Since women are the major purchasers of apparel on- and offline, only female consumers were used. This also avoids potential spurious influence due to gender differences in body beliefs (Rosa et al. 2006). The demographics of the sample closely match the U.S. Internet consumer population (ClickZ 2003; Pastore 2001). Average online consumer population versus average sample characteristics, respectively, were as follows: income – \$49,800 versus \$53,600; age – 41 years old versus 44; modal education – college graduate versus college graduate, websites visited per week – 13 versus 12; hours online per week – 6.2 versus 10. All U.S. states and the District of Columbia were represented in the sample. The respondents answered questions about their web usage, interest in apparel, online apparel purchase habits and basic demographics, most notably the respondent's height and weight which were used later to determine which virtual model they were shown. To avoid potential bias in weight responses, we reiterated that we had no way to know their identity and the importance of an honest answer for the integrity of the research. The results do not appear biased, since the weight/height ratio distribution of the sample closely parallels the U.S. distribution of women's weight and height, with a mean of weight/height ratio of 2.40 (as compared to the 2.20 of the national data; Halls 2000), median ratio of 2.30. Respondents were then shown a virtual model based on their body dimensions and wearing a classic black sheath dress in four positions, forward facing, backward facing and right and left side facing (see example in figure 2). The study uses a well-established personalized virtual model, My Virtual Model™, which uses the consumer's dimensions to create a virtual model that allows online shoppers to 'try-on' a wide array of apparel (see Nantel 2004 for a complete description). After

viewing the model, respondents were asked to assess the quality and accuracy of the model, and their interest in using such a model in the future. Finally, they responded to BID and BBA items.

Figure 2: Example My Virtual Model™ Stimuli

Body image discrepancy (BID) was assessed using the scale developed by Cash and Szymanski (Cash and Szymanski 1995); respondents rate how well they match their ideals (i.e., ‘actually are’ against ‘wish you were’) on a 4-point scale (0 = exactly as I am - 3 = very unlike me) for eleven physical characteristics (see table 1 for items). In addition, respondents indicate the importance of these ideals (e.g., how important your ideal weight is to you) on a 4-point scale (0 = not important - 4 = very important). Using Cash’s technique (Cash 1994), a composite score is computed for each characteristic by recoding all ratings of zero (0) for discrepancy and importance to -1, and multiplying the discrepancy rating and the importance rating for each characteristic. This procedure creates a single measure of BID that ranges from -3 to +9; with larger scores reflecting higher actual-to-ideal discrepancies on increasingly important ideals. The 11 items form a single factor ($\alpha = .81$).

Body boundary aberration was assessed using a scale developed by Chapman et al. (1978), subjects responded to 49 statements on a 5-point Likert scale (1 - strongly agree to 5 - strongly disagree). The 10 items pertaining to BBA were interspersed, and later reversed scored such that higher scores signal higher BBA. The 10 items form a single factor ($\alpha = .87$). The average of the ten items was used as a measure of BBA. The BBA scores are widely distributed; 1-1.99 (highest BBA) = 4%, 2-2.99 = 14%, 3-3.99 = 45%, 4-5 (lowest BBA) = 37%. As expected, the two body beliefs are not highly correlated ($r = .11$).

Perceived accuracy and quality of the model and future use intentions were captured on 7-point scales. Perceived accuracy of the model was assessed using two items designed to focus attention on the virtual model’s body (not the face) and the ability of the model to represent the respondent’s body. The items were 1) “Focusing on the body aspects, how much do you feel this model looks like you?” (very much like me – not at all like me), and 2) “How true a representation of you is this model?” (very accurate – very inaccurate). The two items are correlated .88. Perceived quality of the virtual model was captured by three items assessed on 7-point scales: 1) “How well does this representation demonstrate how the clothing would fit?” (very well – very poorly), 2) “How well does this representation depict the clothing?” (very well – very poorly), and 3) “How would you judge the quality of this representation?” (very good – very poor), $\alpha = .93$. The three perceived quality items were designed to focus on how well the model depicts the clothing, rather than how well it depicts the respondent. Intention to use the virtual model was captured by two items: 1) “How interested would you be in using such a model in your future apparel shopping?” (very interested – not at all interested), and 2) “How likely would you be

to use a model like this if it were available?” (very likely – not at all likely), $r = .91$. The three constructs show significant correlation, but no multicollinearity (Qual. – Accur. $r = .52$; Qual. – Use = $r = .61$; Accur. – Use $r = .56$).

Structural equation modeling with maximum likelihood estimation was used to test the relationships shown in figure 1. Correlations were allowed between single-item error terms for some measures of each of latent variable to account for measurement error. Means, standard deviations and correlations of the measures used in the SEM estimation are shown in appendix. Measurement and structural model estimates and model fit statistics are shown in table 1. Although not all body belief items loaded heavily on their hypothesized construct, all loadings were significant at the $p < .000$ level, and hence all items were retained to maintain the integrity of these established body belief measures.

RESULTS

Although the χ^2 goodness of fit statistic is significant ($\chi^2 = 866.6$ df = 311, $p = .00$), as is common with large samples, our fit statistics meet the recommended levels (Hu and Bentler 1999); with the SRMR for the full model of .05, TLI of 0.95, NFI of 0.94, and RMSEA of 0.04, suggesting an acceptable fit for the measurement and structural model. All of the hypothesized structural relationships are statistically significant. Virtual model accuracy ($\gamma = .315$, $p < .00$) has a positive influence on consumer intentions to use virtual models. Moreover, Body Boundary Aberration has a positive influence on virtual model accuracy ($\gamma = .117$, $p < .00$), supporting the notion that consumers high in BBA may consider renditions that highlight the body’s edges more accurate. In contrast, Body Image Discrepancy ($\gamma = -.120$, $p = .00$) has a negative influence on assessed virtual model accuracy, suggesting that consumer whose body attribute image differs substantially from their held ideals are less likely to consider virtual models accurate. As expected, quality perceptions have a positive influence on assessed virtual model accuracy ($\gamma = .507$, $p = .00$) and intentions to use models ($\gamma = .486$, $p = .00$). The SEM results affirm our expectations that body beliefs influence consumer assessments of the accuracy of virtual models even after accounting for quality perceptions.

Secondary SEM analyses were performed to confirm that the influence of body beliefs on consumer intentions to use virtual models is mediated by perceived accuracy and that body beliefs influence the perceived accuracy of virtual models and not their quality. In the first alternative model, perceived accuracy was retained in the model but the paths from body beliefs were redirected to consumer intentions to use virtual models. In this alternative model the paths from body beliefs (BID and BBA) to future use intentions are not significant, and goodness-of-fit deteriorates ($\Delta \chi^2 = 265.6$, df = 1, $p = .000$, $\Delta SRMR = .03$, $\Delta TLI = -.03$, $\Delta NFI = -.03$, $\Delta RMSEA = .01$). These results support the notion that body beliefs affect use intentions through their influence on assessment of virtual model accuracy. In the second alternative model, accuracy is again retained but the paths from body beliefs are redirected to quality of the virtual model. Again we find that the paths from body beliefs, this time from BID and BBA to quality, are not significant. Moreover, the overall goodness-of-fit is again less than for the proposed model ($\Delta \chi^2 = 2359.0$, df = 2, $p = .000$, $\Delta SRMR = .07$, $\Delta TLI = -.20$, $\Delta NFI = -.18$, $\Delta RMSEA = .05$). These results suggest that the influence of body beliefs on consumer intentions to use virtual models is not mediated by quality perceptions. Given the reduced goodness-of-fit of these alternative models, we conclude that the influence of body beliefs of consumer intentions to use virtual model is mediated by perceived accuracy.

Table 1: Measurement and Structural Model Estimates and Fit Statistics

DISCUSSION

The study investigates the influence of body image discrepancy and body boundary aberration on consumer assessments of the accuracy of virtual models, and the subsequent influence that consumers’ perceived accuracy has on their intentions to use such models. The findings argue for an important role for body beliefs in consumer response to the virtual models offered by online retailers. We find that body image discrepancy negatively influences assessments of virtual model accuracy. Consumers who have high discrepancy between held ideals and their self-image are more critical of the accuracy of virtual models and ultimately less likely to use such shopping tools. Moreover, consumers high in body boundary aberration find the models more accurate, and possibly more likely to make mistakes when making online purchases of apparel and using virtual models. This effect might be especially problematic because of earlier findings that high BBA consumers are more likely than low BBA consumers to shop for apparel online (Rosa et al. 2006). If high BBA consumers are concurrently more likely to shop for apparel online and misperceive virtual model accuracy to the positive, they may be among the

consumers most likely to purchase apparel items that result in low satisfaction and higher returns to the online merchant.

Body boundary aberration is a little recognized shaper of consumer perceptions. Prior research found that body boundary aberration can influence concern with fit in electronic shopping environments (Rosa et al. 2006) and we find that it also influences the perceived accuracy of virtual models designed to diminish fit concerns. In contrast to body image discrepancy, however, body boundary aberration is not a factor that is easily addressed through reassuring commentary on a person’s appearance and compliance with social standards, given its unconscious and hard-to-grasp nature. Body boundary aberration, in fact, may be better addressed through subtle manipulations of consumer sensitivity prior to exposing consumers to virtual representations of themselves, such as the bringing of body boundary perceptions to the foreground that arises when persons are exposed to a fractured mirror representation (Fisher 1986). Clearly, a better understanding of body boundary aberration is needed in consumer research, focusing in particular on how it may influence the perceptual mechanisms engaged in the processing on information and the development of mental representations. This will

gain importance as information technology continues to expand the manner in which consumers are exposed to products and services, and encouraged to purchase.

Although consumers spend billions of dollars on apparel and other body-involving products, little research to date has focused on how consumers' attitudes toward their bodies affect consumption behavior. Our work contributes to the theoretical understanding of how body image can influence how consumers respond to technological driven shopping tools. It also contributes to the growing consumer literature addressing how the consumer's physical needs and preferences interact with limited information environment such as the Internet. In contrast to traditional in-store retailing, where the role of body beliefs may be attenuated by the ability to physically experience goods, in the online context such attitudes are likely to play a larger role in determining consumer behaviors because of the limited availability and low diagnosticity of online information. Our research demonstrates that how people see their bodies biases their response to tools that are explicitly designed to help them overcome the lack of physical product experience, and in turn influences how likely they are to use such tools in general. These findings highlight the importance of better understanding how people's pre-existing beliefs affect their responses to this new low body-information environment.

Several limitations in the study should be noted. The data were collected at a single point in time, and it is possible that cumulative practice with Internet shopping will alter these effects. It is hard to predict in what direction experience will have on the influence of body beliefs, given their noted complexity and subtlety, further affirming the need for more research. A limitation related to the indirect data collection method is the potential for misrepresenting the truth about one's body proportions. To minimize this effect we emphasized in the questionnaire both the importance of accurate reporting and the double-blind nature of the survey. However, it is still possible that people misrepresent their height and weight. Encouragingly, our data do not suggest deception by respondents, since the average weight/height ratio in our sample is actually slightly higher than the national averages while the other demographics are very much in line with them. Such limitations notwithstanding, our research has increased the field's understanding of how body beliefs such as body image discrepancy and body boundary aberration can influence consumer assessments of the accuracy of virtual models and their likelihood to use such tools, and moved the field toward a more complete understanding of the role body beliefs in consumer behavior.

Exploring the Everyday Branded Retail Experience- The Consumer Quest for 'Homeyness' in Branded Grocery Stores

Sofia Ulver-Sneistrup, Lund University, Sweden

Ulf Johansson, Lund University, Sweden

ABSTRACT

This paper extends consumer culture theories of branded retail environments by analyzing the consumer experiences of the everyday site of the branded grocery store. The analysis suggests that McCracken's (1989) 'homeyness' framework succeeds to understand the orientations inflected in the everyday branded retail experience, as opposed to the 'mythotypic' (see Kozinets 2002) that explicates the power of the more spectacular. The implications for theoretical transferability in consumer research are discussed.

INTRODUCTION

During the last decade the marketing management literature has paid a lot of attention to the growing impact of branded retail experiences on consumers, and especially to relationships in-between retailers' corporate, store and product brands (Ailawadi & Keller 2004; Burt & Carralero-Encinas 2002; Burt & Sparks 2000; Kotler 1973; Kumar & Kurande 2000; Kankurra & Kang 2007; Pine & Gilmore 1999; McGoldrick 2002; Moore, Fernie and Burt 2000 etc.). The majority of this literature focuses on branded grocery retailers, and quantitatively investigates specific factors that influence the preference of national or retailers' own brands (such as between store aesthetics and the evaluation of private brands (Richardson, Jain and Dick 1996), between quality and feature differentiation from the national brand (Choi, Chan, and Coughlan 2006), or the impact of retailer store image on private brand perception (Collins-Dodd and Lindley 2003)). These measuring exercises result in useful advice to retail managers regarding how to manage very specific components of the consumers' retail brand experience.

In contrast, in a quest for a more holistic understanding of the branded retail experience, consumer researchers inhabiting the marketing research tradition of consumer culture theory, CCT (Arnold & Thompson 2005), have begun to successively contribute to this domain of interest, or as Borghini et al (2009 p. 363) recently expressed it; "in the past few years, retail theory has developed a growing cultural orientation." This has been done by bringing in empirical data and analyzing it through cultural theory in order to understand what is really going on inside the branded retailers' stores from an overarching sociocultural perspective. Instead of testing relationships between already identified variables and factors, this growing cultural orientation has been able to offer cultural accounts that invent radically different concepts and ways to understand the retail brand experience as a whole and from a consumer-centric perspective. For example, Sherry (1998) found parallels to the narrative contents of certain mythologies in consumers' experience of the Nike Town and coined the expression 'brandscape', upon which Thompson and Arsel (2006) built their investigation of the Starbucks (anti)brand experience. Through ethnographic studies, Belk, Sherry and Wallendorf (1988) found dualistic opposites in their investigation of consumers' behavior at a swap meet, McGrath (1989) described consumer gift selection processes in a retail gift store, and McGrath et al. (1993) identified patterns of buyer-seller interactions and farmer/vendor behaviors in the periodic marketplace of a farmers' market. Kozinets et al. (2002) explored the mythological power of a themed flagship brandstore (*ESPN* in Chicago) where a flagship brandstore was defined as a retailer that (1) carries one brand only, (2) owns that brand, and (3) exists to build brand image

rather than make direct profit. Later, Kozinets et al. (2004) explored ludic behavior and identified elements of interagency between the themed brandstore and the consumers at the same spectacular venue. Building upon this themed flagship store framework, Borghini et al (2009) recently presented findings on retail ideologies at the American Girl Place, a themed brandstore claimed by the authors to be so experientially powerful due to its sophisticated play with many different ideological expressions in the same store.

Above examples of cultural analyses of consumer behavior in the physical marketplace provide fruitful insights regarding how consumers experience retailers' environments and branding efforts. However, although the found experiential elements probably can be readily applied to many themed flagship brandstores, to flee markets, swap meets and gift-stores, it is harder to see its transferability to retail sites of a more ordinary kind, e.g. the typical rationalized grocery store.

The grocery store is probably the most common retail experience of consumers in the western world, as it is part of people's everyday activities. Yet it has—despite large focus on the grocery retail brands (such as Tesco, Wholefoods and Carrefour) in more traditional marketing management literature—in the cultural domain of marketing been somewhat neglected in favor for far more spectacular retail brand experiences as seen above. As underlined by Kozinets et al. (2002, p.17); the primary intention of flagship brandstores is to "take the branding concept to an extreme level." But what about less extreme branded retail experiences? Which cultural constellations do consumers immerse when doing their regular everyday grocery shopping?

Thus, the contribution of this paper is to put cultural focus on a somewhat less extreme, yet branded, site; a site of the ordinary and everyday life—the grocery retailer—and to explore its more subtle brand representations through the experience of the consumer. This way, dimensions overarching the entire retailer brand experience (products, store, chain etc) that may be overlooked in the exploration of the spectacular and specific, may be unveiled.

Branded Retail Experience in CCT

The research paradigm in which this investigation takes its departure is consumer culture theory, CCT where consumer experience and meanings have been the central focal point of analysis for more than twenty years (Arnould & Thompson 2005). Here the retail experience has predominantly been analyzed, as mentioned earlier, in terms of brandscapes, myths, narratives and ideologies. *Brandscapes* refer to "consumers' active constructions of personal meanings and lifestyle orientations from the symbolic resources provided by an array of brands" (Sherry 1998, p. 112) and a 'hegemonic brandscape' to "a cultural system of servicescapes that are linked together and structured by discursive, symbolic, and competitive relationships to a dominant (market-driving) experiential brand" (Thompson & Arsel 2004, p.632). Brandscapes are claimed to work as cultural models for consumers' behavior, identity-work and emotional experience on, but in terms of object of reference also off, the specific retail site, and the authors account for the cultural structure (global/local) and anti-branding discourses through which consumers experience these scapes.

Other concepts cultural scholars use to understand retail environment experiences are myths and ideologies that the narratives of these environments convey. *Retail ideology* is by Borghini et al

(2009 p.365) defined as a “retail branding initiative and experience based upon a detailed representation of moral and social values, presented in an extensive and intensive manner through the physical environment and linked to actual moral action in the lives of involved consumers”. They show how the retail environment of American Girl Place conveys narratives with strong ideological imperatives concerning femininity, motherhood and communality. Myths on the other hand “serve ideological agendas” (Thompson 2004) and can for example be spotted as archetypic characters (e.g. the protective man and the fragile woman), through storylines (e.g. the rise and fall of empires). Sensitive to these mythic constructions, Kozinets et al (2004) used Olson’s (1999) ten characteristics (openendedness, verisimilitude, virtuality, negentropy, circularity, ellipticality, archetypal dramatis personae, inclusion, omnipresence and production values) of mythotypic (highly meaningful and emotionally generative symbols) narratives, to analyze ESPN Zone Chicago (a flagship brandstore for the ESPN sport network). They managed to show how spectacular brandstores could become experientially powerful to consumers by delivering on these mythotypic characteristics.

Above concepts make out important corner-stones in consumer culture research, as do concepts related to specific constellations of consumer goods and meanings found in sociocultural research generally. However, these prior conceptualizations of retail environments have largely ignored marketplaces of less mythotypic character, such as the ordinary branded grocery store. As these are probably the most frequent branded retail experiences consumers have on an everyday basis, its symbolic characteristics very likely differ from the mythotypic ones. In this paper we address this gap and propose an alternative analytical model for this everyday branded retail experience.

ETHNOGRAPHIC METHODS

In consumer culture theory (CCT) the lived experience of consumers in the abstract and concrete “marketplace” is of most and common interest (Arnould & Thompson 2005; Thompson, Locander & Pollio 1989; Thompson, Pollio & Locander 1994). In our study, to capture these lived experiences various ethnographic methods (Elliott & Elliott 2003) were used with the aim to find spoken and unspoken meanings:

1. Semi-participant observations of the women shopping for groceries.
2. Unstructured interviews: After the shopping session, long interviews (McCracken 1988) lasting for about 2 hours, were conducted at the womens’ homes.
3. Photo diaries: Each woman was given a disposable camera and a photo diary to fill in during five days over the course of one month. In each diary there were 40

questions and a request to take pictures corresponding to every question in the diary, hence in total at least 240 photos that came out of this exercise. Each question in the diary had a complementary question where the participant was instructed to describe what she has taken a picture of and why.

4. Artefact collection: All food shopping receipts and shopping lists of the household were also collected over the course of the diary month.

The women were instructed to send the diary, photos and receipts after a month, receiving a reward of 1000 Swedish kronor (approx 100 Euros) as compensation for their work.

The respondents were six Swedish women (see table 1), three from an urban area, and three from a suburban/rural area, aged 30-45 years. Three of these women were selected from a pool of approximately 50 women answering an add put up in a large award-winning grocery store with the ICA corporate brand and a local sub brand in the countryside in southern Sweden. These three women also lived in the countryside. The other three women lived in the city area of southern Sweden’s largest town, Malmö, and were selected through the snowball method where we asked people to ask acquaintances’ colleagues’ friends’ (etc) to contact the first author if they were interested in participating in the research project. Out of 30 interested, three were chosen based on certain criteria decided beforehand. The six women should belong to different quintiles of the middle-class and differing from each other in lifestyles, type of work engagements, and family constellations (alone with children or married with children), but should all have children living at home. This because the research project itself had a focus on retail brands and family shoppers.

When doing participant observations during grocery-shopping the first author came along to the store where “they most often go grocery shopping”. However, in the photo diary they were asked to document and take pictures of other visits to other stores during the one-month period. All, except from one, visited many different grocery stores during this time but had one clear favourite for everyday shopping. This way we obtained sufficient variety in each individual’s descriptions and experiences of different formats, chain and product brands, but could still immerse into the meaning structures of the retail environments they preferred the most. Every store that participants referred to in the diaries or interviews, the first author went to visit afterwards in order to see the environment with an ethnographer’s own eyes, to better understand the experiences described by the informants.

The selected womens’ identities were not necessarily bound up around being a mother (as is the case in Moisio, Arnould & Price (2004)) although two of the women’s perhaps were more than the

Table 1. Table of informants

Pseudonym	Age	Sex	Site	Occupation	Education	Family Status
Hanna	29	F	Countryside Southern Sweden	Kindergarden teacher, temporarily home with baby	Child-caring	Married, one child age 1
Madeleine	41	F	Countryside Southern Sweden	Researcher, natural sciences	PhD	Married, two children ages 6 and 9
Stina			Countryside, Southern Sweden	Foster mother	High school	Married, one child + various foster children
Birgit	30	F	Larger town, Southern Sweden	Surgeon, temporarily home with children	Medical doctor	Married, two children ages 1 and 2
Katrin	38	F	Larger town, Southern Sweden	Student and practitioner within HR	BA	Single, one child age 2
Angelica	38	F	Larger town, Southern Sweden	Project manager	BA	Married, two children ages 7 and 9

other four. However, one may still argue that these women were all the main care-takers and family providers, in terms of grocery, whereby the theoretical analysis foremost can be said to have a valid transferability across other “providing” and “care-taking” consumer segments, rather than say women in single households or student dorms. Thompson (1996) called these “caring consumers” juggling in a shared system of conflicting ideologies regarding motherhood, feminism and professional careerism.

‘HOMEYNESS’ IN THE BRANDED RETAIL ENVIRONMENT

While hermeneutically moving back and forth between data and theory (Thompson, Pollio and Locander 1994; Thompson 1997) one specific cultural constellation, excellently described in the consumer cultural literature, namely that of ‘homeyness’, by Grant McCracken (1989), emerged as a readily applicable model to understand what could be discerned in the data analysis. Whereas Kozinets et al. (2002) analyzed the spectacular ESPN brandstore according to Olson’s (1999) ten characteristics of mythotypes, as presented earlier, the more subtly branded retail environments in our investigation, turned out to be much better understood through McCracken’s eight symbolic properties of ‘homeyness’ and how they act upon the environment: (1) *the diminutive property* (small and graspable, making places “good” to think because they are “easy” to think) makes it thinkable; (2) *the variable property* (inconsistent, non-linear, antiuniform/assymetrical, haphazard, made out of sudden passion and desire, far from anonymous calculation e.g. rubblestone) makes it real, (3) *the embracing property* (intimacy, layer on layer enclosing each other, a pattern of descending enclosure, encompassing e.g. the ivy and the books, the “extraordinary intellectual geography for self-construction, memory walls, part-whole logic, takes time to accomplish) makes it cossetting, (4) *the engaging property* (welcoming, draws you in, openness, warmth, invites interaction and playfulness) makes it involving (5) *the mnemonic property* (historical character, significance of objects from the past, deeply personalizing the present circumstances, localized in time) makes it emplacing in time, (6) *the authentic property* (real, natural, personal nature, untouched by the calculated marketplace, “someone lives here”) makes it emplacing in space, (7) *the informal property* (warm and friendly, humble, accessibility, not pretentious, puts people at ease) makes it reassuring and riskless, and finally (8) *the situating property* (the occupant takes on the properties of the surroundings and “becomes” a homey creature) makes it fully capturing.

Before moving forward to the findings, here is a short introduction to the corporate retail brands coming up in the empirical fieldwork; ICA, Willy’s and Netto.

ICA is the biggest retail brand in Sweden, and thereby bigger than Coop and Axfood (owns the retail brand Willy’s) who are number 2 and 3. The Swedish competition authorities have many times warned that ICA is larger than the monopoly regulations allow but due to the franchise format ICA keeps on balancing on the critical 50% market share limit without getting penalties. To consumers in Sweden ICA is famous for its historical presence since the 1950’s in almost every little village and town, its four different retail formats (ICA Nära, ICA Supermarket, ICA Kvantum, ICA Maxi) and not the least, their famous long-lived TV-commercial campaign consisting of the same actors since 2001 with soap opera story line and a new film every week. ICA has their own very successful private labels; ICA Selection (premium), I Love Eco (organic), ICA gott liv (Health), ICA-handlarnas (medium), and Euroshopper (budget). Approximately 20% of ICAs total sales is from private labels.

Willy’s is part of the Axfood Group and is famous for its large, low budget stores and supply. The stores are predominantly situated in the outskirts of city areas. They have a family owned background but were bought by Axfood in 2001. Axfood has since created private labels for Willy’s; Willy’s (medium /budget), Garant (organic) and Eldorado (budget) that make out approximately 20 % of total sales.

Netto, is also mentioned on several occasions by the respondents. It is a relatively new medium-hard discount retailer concept on the Swedish market, with origins in Denmark. The Netto stores are often situated in central areas and offers to the Swedish audience a range of discount brands they don’t see in other stores. They also have lines of baskets with goods quite atypical for concentrated grocery stores in central areas of the stores.

Below follows a categorization of our ethnographic observations and consumer experiences into these characteristics of homeyness. As the experience of a store in many aspects is a different one than of a home (where McCracken did his ethnographic study) we found that every property of homeyness could also complemented by a mythic theme, in terms of how the consumers filled these properties with aesthetic meanings. This meaning content was typically anchored in myths infused in consumer culture regarding the ideal place and the ideal foods. These complementing themes give aesthetic meaning to the homey properties and succeed the property theme in every headline. [Due to the limited space in this conference paper each characteristic doesn’t go as deep as it would in a final journal paper].

The Diminutive Property- The Family Ownership Myth

Entering the large ICA Kvantum Anderssons store in Södra Sandby, a small village on the countryside, is to an outsider like entering most large ICA stores in Sweden. It is quite large and has an open butcher space close to the meat counter. I visit this store with three of the respondents; Stina, Madeleine and Hanna, and even if the store is large the way they describe it is always in a way that emphasizes its diminutive characteristic. They call the store Bröderna Andersson, meaning “The Andersson Brothers”. The store is famous in the larger local area for being well-taken care of by its small, tight family owners and exactly this family reference, rather than ICA reference, is central in observations, interviews and diaries from the participants regularly visiting this store. “I feel like home in this store. Everything is familiar and safe” says Madeleine and smiles. Also Sanna points at this emotional wellness character of ICA Kvantum Anderssons; “It would be a lie if I were to find anything negative in this store. Everything’s perfect here. The staff is so nice, I always feel so good in this store and I’m never stressed when I’m here. It’s top!”. Hanna emphasizes this by saying that “I feel so safe her, and I know exactly what they have and don’t have so [even if its more expensive] why go anywhere else when it’s this great at home?” Thus, despite its relative largesse the store is experientially graspable, it is through experience *thinkable* to the informants. It does not have a diminutive character in terms of material environment, but in the consumers’ minds it has become mentally small and graspable due to its familiarity and warmth.

I go (on different occasions) with Katrin and Birgit to ICA Kvantum Malmborgs Erikslust which is situated in a prosperous middle-class neighborhood in Malmö. The store is playfully infamous in Malmö as the “longest store in Sweden”, and fair enough, yes it is both thin and long in its store layout. Both Katrin and Birgit comment on the unorthodox layout as “oddly narrow” but “funny”. Sometimes “irritating” but more like an annoying sister than an unpleasant stranger. There is a love and hate relationship between my respondents and this pleasantly cramped store. Katrine says; “It is quite different that you really need to know which way you

must walk not to bump into somebody, on the other hand bumping into someone can turn out to be quite amusing as well!". The smallness of the store creates an intimacy with other customers on a physical level, sometimes annoying but also a source of surprise and the spontaneous whims of life.

The Variable Property- The Myth of Mediterranean Life

In the diaries where participants were asked to take pictures of the most inspiring parts of their stores/store experiences and also to describe in what way this was the case, the responses had a certain thing in common. They were all pictures of variable melanges of goods, for example of asymmetrical stacks of French, Italian, Portuguese, Swedish, and Danish cheeses; "Cheese lovers like myself fall head over heels over the grand cheese department. So many kinds—so many jummy cheeses! I quickly run pass them and save them for a more special occasion." Angelica writes about the cheese counter at *ICA Maxi Västra Hamnen* in Malmö. Other accounts on inspiring experiences relate to how the variety is presented, like the shelves with a wide variety of transparent bags with beans and olives, and Madeleine writes about the most inspiring counter at Bröderna Andersson—the cooked meats counter; "these entire chunks of salami and hams everywhere, I get this feeling of the open marketplace, the Mediterranean and other pleasant experiences".

The store aesthetics should offer asymmetrical layers on layers of various goods and brands to live up to this variability ideal, but must not break the rules *too* much; Madeleine, who loved the "Mediterranean" feel at *ICA Kvantum Andersson*, takes pictures of the aisle baskets at *Netto* and writes "It's complete chaos in this store. Tools and food in a terrible mess. I don't feel like home here, it's like being abroad".

The Embracing Property- The Myth of a Loving Market

The diminutive property of is intensified by the embracing property. It has as McCracken writes "a pattern of descending enclosure". At *ICA Kvantum Malmborgs Erikslust* the long and narrow layout literally embraces the customer. She feels "cuddled with" as Katrin expresses it. The opposite is described by all respondents in diaries and interviews, illustrated with photos of empty cartons and shelves. Nothing irritates the respondents as much as when what they have planned to buy is out of stock. Especially if the store normally never is out of stock. As in Fournier's (1998) brand relationship thesis, where brands get anthropomorphized into humans with whom you can have loving and un-loving relationships, here someone you really trusted has betrayed you and it hurts more than if you had counted on it. It is a light shock.

An embrace can be further intensified through marketing tactics, e.g. by ICA's multichannel marketing. The respondents all refer to *ICA Buffé*, ICA's monthly magazine with recipes and inspiring images of happy dinner and lunch guests. To Angelica it is *ICA Buffé* that inspires almost all of her cooking, and *ICA Maxi Västra Hamnen* that inspires her most in store. That way ICA offers an embrace enclosure by providing inspiration from all directions.

The Engaging Property- The Myth of Smalltown Friendliness

The intimacy offered by the diminutive property and the family ownership myth at *ICA Kvantum Andersson* not only feels like an embrace to the respondents, but it also engages them. Hanna and Madeleine both stop at the different counters to chat with the staff, to discuss new deliveries and to get advice for cooking. They also stop to taste at a corner where a store representative cooks meat balls from the store's own minced meat; "I trust ICA again, it could have happened to any of the retailers" Madeleine says (there had just been a national minced meat scandal connected to ICA where

some ICA retailers had been revealed to repack "old" meat in later date packages). Hanna, Madeleine, and Sanna take many pictures of the butcher's space of the store where the meat is cut up. They all express love for this "openness" which seems to draw them in through trustworthiness. The store involves its customers by bringing them into its own making, its core existence and family core, and gets engagement back.

The Mnemonic Property- The Magic of the Past

Three of the respondents have childhood memories in relation to their everyday stores. "I live in the neighbourhood and when I was little my mum used to take me here, it was so exciting because the store is so long!" Birgit recalls about her childhood experiences at the *ICA Kvantum Malmborgs Erikslust*. "I've come here with mum since I was a baby, so I know exactly what I can get and not get. I feel safe with that" Hanna writes about *ICA Kvantum Andersson*.

Madeleine, who has been to *Netto* to buy special protein rich pasta flour, shares one of the brand narratives she connects in relation to the *Netto* logo. "Scottish terriers always make me think of *Netto*, and even more of my youth when we went to Denmark to bargain. At *Netto* there are so many Danish products and brands, like for example cherry marmalade. Odd and exciting! In the brand line "O Sole Mio" there are some odd products, like they used to have dried cranberries. Fun!". In the case of *Netto*, Madeleine does not feel at home at all, as we saw earlier. However, she does find a home for *Netto* in pleasant memories from her youth, that through the magic power of nostalgia somehow compensates for this lack in spatial homeyness.

The Authentic Property- The Myth of a Real and Genuine Market

The women in this investigation have all taken up on the mega trend of authenticity. Authenticity which usually is associated with the tastes of the high cultural capital class (Holt 1998; Ulver-Sneistrup 2008) has since the mainstream market picked up on this winning concept (Pine & Gilmore 2007) proliferated to the mass consumer of western consumer culture. There is a consistent idea of a dichotomy between real and unreal, where the real is considered more morally legitimate than the unreal. *ICA Kvantum Anderssons* get the role of the real and authentic in this investigation. Even if the store in no way is small like a local specialty shop (the stereotypical image of an authentic food market) it manages to play o myths narrating authenticity "here you see how they cut the meat and I mean that's so...nice" Sanna says. In fact, in every tale about *ICA Kvantum Anderssons* it is the story about meat cutting that is persistently told. Apart from the staff's friendliness and the fact that it is two brothers who own the store, the meat-cutting is the genuine proof that these people really love what they do, a prerequisite for true authenticity.

In contrast, Angelica has her roots in northern Sweden and writes that "I would love to buy mushrooms at the store but I just don't trust their origin. I always wait for my mum to come down with freshly picked mushrooms from the Northern Sweden's forests. That's the real thing!".

Authenticity emplaces a store in space, and if the origin is not seen (as the meat-cutting is at *ICA Kvantum Anderssons* or as the mushroom picker is to Angelica) the constellation of homeyness cannot be complete.

The Informal Property- The Myth of the Humble Farmer

As has been abundantly clear in this paper, *ICA Kvantum Anderssons* is a retail case that scores high on every property of homey retail experience. The informal property is another one of these. This store puts its visitors at ease with its down-tuned but friendly

approach to its customers. This in turn creates this embrace feel of well-being seen in many quotes earlier in this paper.

As all our respondents visited many different stores during the month of diary-writing we could compare through which categories they evaluated a shopping experience. In no other store than *ICA Kvantum Anderssons* was the staff mentioned, neither in interviews nor in diaries. It was as if there was no service staff. But at *ICA Kvantum Anderssons* the friendliness among the staff was mentioned at many occasions and in field observations casual conversations between staff and customers were seen at many occasions. Here are fieldnotes from the visit with Sanna:

I am amazed how unpretentious Sanna is and that she is proud, rather than embarrassed, about admitting that she's been abroad once (and only once). How she so casually shares that she doesn't understand much of these new, international, "fashionable" products. When she asks one of the staff (I presume it is the store manager as I recognize him from the website), who is pottering around with the olive oil bottles, what kind of oil this "green liquid is" (olive oil), I expect him to reveal some kind of snobbish latent nature ("dear lord, have you never seen olive oil before?") towards Sanna. But instead he shines up like a sun and enthusiastically brings her with him into the universe of olive oil connoisseurship. He talks of sun, terroir and tree qualities. Of its sublime marriage with ripe tomatoes and parmeggiano cheese. Sanna looks entertained and inspired, however doesn't dare to buy that green liquid. But the man had an air of ease to him. The kind of air that makes people courageous to ask "dumb" questions without having to "lose face". Fieldnotes 11 November 2008

This quality of accessibility and lack of risk comes with the property of informality, and must be mediated through social interaction, hence people, be it the service staff or the other customers. But it must not be *too* informal as we will see in the next paragraph.

The Situating property- The Myth of Hermeneutic Transformation

The last property of homeyness, that also makes this very experience complete, is the situating property. Here, the consumer experiences such involvement with her surroundings that she takes on its properties. She becomes part of the whole—a hermeneutic metamorphosis if you will. Although the experience at the everyday grocery retailer is far from spectacular, such subtle transformation may nevertheless take place. Especially this can be seen in the way respondents comment other customers in the store in the interviews and in the diaries. One can never fully immerse into one's surrounding and *become* homey if one does not identify with the surrounding customers. Katrin shares with me; "I feel so good in this store [*ICA Kvantum Malmborgs Erikslust*]. It's not stressful and everybody looks like they know and can afford to eat good food. I mean it is much nicer than say *Överskottsbolaget* [a hard discount store in a socially troubled neighbourhood in Malmö], ha ha. When I was there there two people were fighting. They had all kinds of technical aid, wheel chairs etc, but suddenly they were perfectly mobile! It's another breed of people there, not nice. But it's cheap. But I'm glad if I never have to go there again."

DISCUSSION

In this paper we have focused on the consumer experiences of branded spaces and environments where there is explicit branding-work going on a but on a radically less extreme level than in themed

flagship stores previously treated in the consumer cultural literature. Whereas the themed flagship brandstore is highly meaningful to a particular audience, and express a combination of "universal emotional states" such as "awe, wonder, purpose, joy and participation" (Kozinets et al 2002), the everyday branded retail environment expresses a somewhat more subdued, but yet very meaningful, experience. This experience turned out to be 'homeyness' among our care-taking grocery consumers.

'Homeyness' as conceptualized by McCracken (1989) is a *constellation* of cultural elements, creating a distinctive feeling of well-being. Hence, one cannot select one or the other specific factor, which the managerial retail literature often tends to do, that makes "the big difference," but it's the whole constellation of expressions that makes the everyday retail experience homey, and therefore inclusive. In addition, this experience can be even more seductive if each property plays on certain myths, supporting Kozinets et al (2002, 2004) and Borghini et al (2009), serving ideologies naturally succumbed in society. Here we could discern myths of the superiority of southern lifestyles, smaller town goodness and the personification of a loving market.

But why was it homeyness, and not, say, sexiness or cosmopolitanism, that encapsulated these consumers? There are probably many alternative explanations to this, but, in the culturally distinctive site of the everyday grocery store, one can imagine that consumers do not seek a transformative experience that fully blows their mind away. In fact, they are shopping for their family household and perhaps therefore need to have surroundings representing or at least supporting an ideal life at home. It is ideally a home outside home where the meanings of goods do not change despite being transported from the one site (shop) to the other (actual home).

One can also reason that the selection of the care-taking (providing for others at home) women in this study may have influenced this quest for homeyness. Do these women want homeyness more than, say men or women without families? McCracken (1989) found that differences could be found between lower and higher status groups (rather than between gender) where lower status groups were more apt to desire the homey atmosphere. A non-supporting pattern was present among Holt's (1998) low and high culture capital consumers where higher status groups preferred formal aesthetics and lower status groups pragmatic solutions, hence 'homeyness' was not an elaborated construct. In our investigation, five women belonged to a typical middle quintile of a large middle class, whereas one (Sanna) to a lower middle class, judging on education and parental background. That no difference was identified between these respondents in terms of homeyness would therefore imply that it very well may be a female, middle-class, local desire, but it may just as well be universally global, at least in the parts of the world that have "home" and "privacy" as cultural constructs in their meaning structures (Rybscynzki 1987). However, to get more comparable examples, this would have to be explored in future research.

This paper contributes to the consumer culture literature on retail by bringing in the culturally distinctive site of the everyday branded grocery store and thereby showing that other analytical models, than have been suggested for more spectacular arenas, are at play here; namely the cultural constellation of 'homeyness.' It also contributes to the more managerial retail literature in that it takes a cultural perspective, and giving this more holistic understanding of what is happening in the interaction between the consumer and the retailer brand, than more evidence based variable-focused work can do. The experience of homeyness consists of a complex but highly meaningful constellation of properties that can be intensified by the immersion into myths supporting the agendas of dominant, rather than emerging (which more spectacular arenas may strive

for in their quest for overwhelming the consumer), ideology. Future research may concentrate on exploring further theoretical transferability options for the constellation of homeyness in branded retail environments across industrialized/less industrialized contexts, across gender, ethnicity and class. Homeyness may very well change character across settings, peoples and times, and there may also be contexts where other cultural constellations are of equal importance. However, in this investigation it stood clear that homeyness was highly meaningful as the fundament for the ideal everyday retail experience, and the lack of it was the fundament for avoidance. Or as Hanna so succinctly put it; "why go anywhere else when it's this great at home?"

An Exploration Into The Religious and Symbolic Meanings of Gendered Spaces in an Arab Gulf Home

Rana Sobh, Qatar University
Russell Belk, York University

ABSTRACT

Houses are rich symbols representative of culture, self and identity (Marcus 1995). The current research provides a comparative perspective on Arab-Islamic (Qatari) and Western values as encoded in the home and use of spaces within it. Our ethnographic study involved observation and in-depth interviews with twenty four middleclass home-owning Qatari families living in Doha. We found gendered areas as well as visual and non-visual domains of privacy. Furthermore, we found a parallel between the home and the woman's body as these both relate to the notions of sanctity, purity, and reserve. Both also seem to embody and mediate global and local cultural controversies Qataris are subject to as a result of the increased influence of Western consumption patterns.

INTRODUCTION

Houses are rich symbols representative of culture, self and identity (Marcus 1995). Differences in the use and sense of ownership of various spaces within the home by individual family members especially the adult males and females articulate social relations and define gender relationships in a particular society (Altman 1975). The home is conventionally understood as the foundation of the private sphere (Allan and Crow 1989). However, notions of privacy and separate public and private spaces within the home have emerged only within the last few hundred years (Tuan, 1982). Notions of private space are also encoded architecturally (Sommer 1969) and intimacy within the nuclear family is a concept that has grown as the presence of extended families sharing the same home has diminished (Rybczynski 1986).

While the home provides a more private space to the family compared to the public domain, it does not necessarily secure private spaces for individual family members from each other (Allan and Crow 1989). Such concepts have been extensively studied in the West, but little comparable work has been done in non-Western homes. Definitions of private and public spheres are different in Islam than those in Western paradigms. Privacy in the West refers to people's rights to non-intrusion and might be linked to the notion of individualism and individual rights to property. However, in the Arab-Islamic world, privacy is very much based on the notion of sanctity and concerns both women and the home (El Guindi, 1999). The current research provides a comparative perspective on Middle Eastern (Qatari) and Western values as encoded in the home and use of spaces within it. We found a parallel between the home and the woman's body as these both relate to the notions of sanctity, purity, and reserve. Both also seem to embody and mediate global and local cultural controversies Qataris are subject to as a result of the increased influence of Western consumption patterns. The domestic sphere seems to bind the past to the present.

We locate our research in the Gulf region and Qatar in particular where dramatic changes are occurring. Qatar and the Gulf States in general offer a context unique for several reasons: 1) Society requires strong adherence to traditional values and social norms, 2) There is an omnipresent awareness of Islam and religious values in shaping identities and informing behavior, 3) There is an abundance of financial resources available to locals and a significant growth of financial, educational, and media centers, and 4) There has been a significant dilution of local populations by the expatriates and guest workers who comprise more than 80% of local populations.

This influx of expatriates coupled with an influx of global mass media and other forms of popular culture resulted in the increasing adoption of Western lifestyles and tensions between the desire to embrace the modern and a desire to preserve local identity. Such tensions are reflected in many aspects of consumption including clothing (of both men and women),

DATA COLLECTION AND ANALYSIS

Our ethnographic study involved observation and in-depth interviews with twenty four middleclass home-owning Qatari families living in Doha. Our sample involved families across different life stages (e.g., young married without children, families with young children, and families with older children). In addition, the researchers interviewed a Qatari architect, a real estate agent, and a religious scholar. Interviews lasted between 60 and 90 minutes. The interviews discussed meanings of home, favorite areas of the home, situations in which these spaces are used, favorite objects within the home, the meanings of these objects, and usage patterns by other family members, who makes decisions regarding home decorating in each room and how the house was selected or designed. As a stimulant for these interviews we used projective stimuli (e.g., metaphorical descriptions such as "If my home were an animal, it would be...") and visual elicitation (based on photographs of various areas of the home taken, with informant permission). Audio and video recordings of interviews and observations were made and transcribed. The analysis followed the logic of hermeneutic research in that we sought to identify shared cultural meanings underlying expressed meanings by individual consumers (Thompson, Pollio, and Locander 1994).

HOME SANCTITY, PRIVACY, AND DIFFERENTIATED AREAS IN QATARI DOMESTIC SPACES

Qatari architecture and home design are influenced by characteristics inherent in Islam. For instance, because there is lack of emphasis on external appearance in Islam as compared to inner self, Islamic architecture generally focuses on interior space as opposed to the exterior space or façade. The dominant form of Islamic architecture is inward facing; the facade rarely gives an indication of the structure's richness of inner design. In other words, architecture must be experienced from within. Thus, a Muslim person should be simple in the facade of his home just as in his personal appearance; yet both should rich with faith, wisdom, and beauty inside. This is why in Qatar there is generally little variation between homes' facades compared to enriching and differentiated interior designs. However, this has been changing recently and the exteriors of new homes in Qatar are becoming more richly designed and differentiated. It is also evident that Qatari people are increasingly becoming extravagant in their appearances compared to a decade earlier (Sobh, Belk, and Gressel forthcoming).

Privacy in Qatari Homes

The Qatari architecture in our study emphasized that the importance of inner spaces in Muslim architecture is also tied to an Islamic focus on privacy. There is much emphasis in Islam on the importance of respecting privacy for both males and females

and on the sacredness of the home (Campo 1991). Surrounded by a simple facade, the courtyard which is the house's most private space is kept hidden. The inward design is used in traditional Arab Muslim homes including traditional Qatari homes. Such a courtyard house has high walls or facades and the courtyard or family spaces are in the back of the house, or at least not directly accessible from the front door. This design expresses the need to keep the public sphere from intruding or interfering with the family's privacy and the inner life. This is visually encoded by the sharp distinction between public and private spaces. Having an inward home structure that excludes and protects the private from the public is not only intended to protect family members' privacy, but also to protect neighbors' privacy.

Abdullah (architect): Privacy and religious considerations have always been taken into consideration in Qatari homes. Qatari architecture reflects people's life style and values. Being respectful of Islamic religious values in Qatar, Bahrain, Saudi Arabia, the Middle East, Iran, and even Turkey has influenced architecture in these countries and regions. The difference lies in the building materials used. The architectural style in Qatar, Bahrain and Saudi Arabia is similar. There're a lot of windows but they are equipped with screens, like a woman with veil. She can see but cannot be seen. Even in Afghanistan, little openings in the face cover are used. The whole body is covered but there are two small openings for the eyes.

So why are people's privacy, male or female, and the sacredness of their homes so highly emphasized in Islam? The Westerner's conception of privacy is coterminous with individualism, whereas the Middle Easterner's is not. Hurma (best translated to sanctity in English) denotes the concept closest to the notion of privacy in Arab-Islamic culture. What is private in Islam is any personal domain that should be concealed from others and within which individuals have freedom of action. In a spatial/physical sense, the home is par excellence a private space as well as the body or parts of the body that should be concealed in public 'Awra'.

In Islam, intruding into a person's private space, trying to gain information about a sin an individual conceals behind a closed door of his/her home is itself considered a sin (Mottahaedeth and Stilt 2003). As such, people are completely free in the private space like home. But as soon as the person enters the public domain he/she is constrained by the law prevalent in society with regard to clothing, eating and drinking, sexual behavior, and some forms of social conduct (Kadivar 2003).

The significant need for privacy within Qatari homes is also related to the concept of modesty in Islam. Modesty underpins the Muslim self and particularly the woman's self and her relation to private and public spaces and regulates gender relationships. Modesty (*haya'* in Arabic) is not limited to a person's dress in public (physical modesty); it is also reflected in speech, conduct and thoughts. Dress requirements have necessitated a unique convenient style whereby women's living quarters are separated from men's quarters so that they do not have to veil while in their homes, even if male guests are present elsewhere in the house.

While there are gendered areas within Western households (e.g., Chevalier 2002; Munro and Madigan 1999; Taylor 1999), there is a sharper distinction and more formally drawn boundaries between men's and women's spaces as well as transitional spaces in moving from one gendered area to another within Arab Muslim homes. In all visited homes, the space designated as private was for the family (husband, wife and children) and close male relatives

from the *mahrem* category (those in a degree of sanguinity precluding marriage), as well as female visitors. The public or communal areas were for men and their male visitors – *majles* (the place for sitting). These have separate entrances for males and females from the main street. Men's quarters emphasize openness to the public domain; their entrances are usually close to the street and the windows overlook the street, while the family or women quarters emphasize enclosure away from the public gaze; usually in the back of the house and are further separated from the street by high perimeter walls which visually encode a sharp distinction between private and public spaces. There is no permeability or internal link between these two domains which indicates that gender sociability is controlled and restricted (Farah and Klarqvist 2001).

Non-visual Domains of Privacy

Our findings reveal that the concept of good smell is of great significance in Qatari homes as well as in other countries in the Arab Gulf. *Oud* – a very expensive type of wooden pieces is frequently burned in scentors to remove home odors, especially before and after receiving guests. The following quote illustrates the importance of smell in Qatari homes and the frequent use of *oud* to fumigate the house and prevent it from being contaminated with cooking smell as well as the presence of domestic helpers.

Um Hussein: Because the number of dishes is large and there are the cooking smells. Our kitchen, the housemaid's room and washing room are isolated but are close to us so as to monitor what goes on. To prevent cooking smells from spreading we close the doors and use a ventilator. In addition, we always use incenses. They are nice to smell. Gulf people used them even in the past. I sometimes cook and I feel there is smell in my clothes and so incenses are needed. We also wash clothes every day, but the abaya is not washed every day [Thus it benefits from incense more].

The significance of good smell in Qatari homes is inherent in the requirement of cleanness and purity (*taharah*) in the Islamic faith, both physical and spiritual. A good smell is associated with cleanness, angels, purity, good deeds and thus God's blessing and benediction. In contrast, bad smell is associated with what is dirty, the evil, bad deeds, and God's curse. A pleasant smelling person is considered pure and ready to enter a mosque, while someone who smells of food or other unpleasant odors is impure and contaminated.

Participants made statements associating perfuming and home fumigating with worshipping: "God will bless a man who washes himself, uses the best perfumes and dresses nicely, especially on Friday" (Saleh). "A smelly and dirty place will be vulnerable to devils and a scented place will be inviting to angels" (Rawdha).

Good smell is also an integral part of Arab hospitality rituals. Guests are traditionally welcomed for up to three days without question, but neither they nor the house should be contaminated by each others' presence. Not only the bedroom, but the entire house is sacred. The threshold of the door where the guest enters is a liminal space within which rites of transition (Gennep 1960) and rites of incorporation (Kanafani 1993) take place. In this case rites of transition (removing shoes, eating, and drinking coffee) transform what was profane into something sacred, with the threshold being the transitional space. The guest remains a stranger, even if they are a close relative or a friend, until they are incorporated into the host's home and thereby decontaminated and sacralized. In addition to fumigating the home before guests' arrival and departure, a special flask (*mrash*) is sometimes used for perfuming guests after eating and before leaving the house. Most visited homes, had a tray

of scents and expensive perfumes used to create pleasant smelling spaces and people and to denote status and prestige of the hostess. Guests make ample use of these perfumes, placing certain scents on certain parts of the body. As Aubaille-Sallenave (2006) notes, these odors than become a part of the guests sacred “armor” as he or she goes out into the profane world.

The centrality of good smell in Qatari homes can as such be related to the strong value placed on privacy and home sanctity in Muslim home, as discussed earlier. There is a marked attempt to keep the smells of homes and guests from contaminating one another. Given the dry desert heritage of Bedouin predecessors in Qatar, Qataris use not only physical separation in rooms of the house, but various olfactory barriers and perfume and incense purifications rather than ablution rites to maintain purity. In a culture where water is at a premium, the use of perfume and incense is an important ritual. The separation of the exterior kitchen (and often the driver’s and maid’s quarters) from the home is another attempt to maintain the purity of the Qatari home.

The Home: A Place for Freedom and Control for women

Our findings reveal that women dominate the family quarters in different ways. First, the wife or the female in charge in the household decides whom to allow in the home and whom not allow. For instance men from the non-mahrem category are generally not allowed. The husband and other male family members (sons) are expected to respect their mother and sisters’ privacy and usually leave the home when they have female visitors. Having control of whom to allow and when to allow them gives women a sense of control over their domestic space and a sense of freedom within it. A home free from non-mahrem males is physically and symbolically liberating for women. Not only do they not have to bear the inconvenience of covering, but they can also show their ostentatious outfits, hair styles, jewelry and beauty to female guests to ‘provoke their envy’ and make statements about their status, taste and affinity for fashion.

Mariam: My home is my kingdom. It’s not big and others may consider it small. I wanted a small house with a good plan, reasonable size, easy to control. The important thing is to own my freedom, because we had been fed up with closed places. In many houses in Qatar, the swimming pool is indoors, i.e. without freedom. Ours is outdoors [i.e., not visible to neighbors], yet I enjoy both freedom and privacy in it.

Um Hussein: At home I feel in control and free. My favorite place to sit and spend time with my family is the family sitting room. It’s comfortable from it I can monitor everything taking place within the house, children, husband and housemaids. I can call anyone from there. I can see and hear everyone from my place. I always sit at a strategic position by the window to monitor who comes in and who goes out during the day.

The home thus appears to be an uncontrolled space for self expression as opposed to the more controlled public space. Women can move freely between rooms and different areas in the home. While people in all cultures experience, which is not necessarily to say enjoy, more privacy and freedom in their domestic environment, for Qatari women the freedom they experience in their homes is above and beyond the general sense of individual privacy that Westerners may enjoy in the domestic spaces. It is related to the convenience of gender privacy that reduces or eliminates the need

for bodily covering and modest self-presentation and conduct that is required of them in public.

Abdullah: Qatari women control their households. This makes up for their lack of control outside. Yet, with a veil a woman can wear any make-up and type of dress underneath which also gives her a sense of freedom outside her home. The veil is like a mobile privacy for women.

As emphasized by this Qatari architect, a woman’s dominance of the domestic space diminishes as she moves out of her domestic space to enter the male dominated public sphere. Her sense of control and freedom within the public space is restricted. Nevertheless, women covering with the abaya, shayla, and sometimes a face cover in public creates a personal sense of privacy that a woman carries along with her as she moves into the public sphere. In many public domains like public schools, universities, banks, and hospitals, gender segregation is institutionalized to various degrees to accommodate women need for gender privacy. For instance, Qatar National University has different buildings for female and male students and public hospitals have different entrances for men and women and gender-differentiated waiting areas. Such attempts to control gender relationships in public through institutionalizing gender differentiated areas are an attempt by local governments to reach a compromise between ensuring respect of traditions and women’s need for empowerment.

The religious scholar in our study explained how gender segregation in the home and public in the Gulf region is more of a local cultural practice than a religious requirement:

Mutassim: Islam defines privacy between man and man, man and woman, woman and woman through the concept of Awra—body parts that can’t be exposed or shown to others. This relationship is an important issue in Islam, which prohibits its encroachment. Islam does not impose full separation between men and women, as it is sometimes the case now. In fact, this is governed by cultural heritage, which is different in Egypt than in Syria or Lebanon, for instance. Shariaa does not impose full separation. On the contrary, during the Prophet’s life, women took part in military expeditions and men and women ate together. Traditions are influential. Islam does not impose a specific space for a woman inside the home. Neither Christianity or Judaism does so. There is nothing in Islam that suggests that women and non mahrems or visitors can’t sit and talk together. As I noted earlier, in the prophet Muhammad’s era, women and men used to pray together and eat together. There was not the kind of separation we see nowadays in the Gulf society. As long as the woman observes Muslim dress code and manners, she can interact with men. Actually this is the purpose of the Muslim dress code for men and women. It aims to de-sexualize and prevents seduction so that they can interact (work, talk, study etc. together) without the possible drawbacks of such interaction.

Nevertheless, the more traditional of our informants would never socialize together as two couples, for example. Only same sex gatherings took place within their homes. Although this obviously makes it difficult for young people to meet a potential husband or wife, the practice of arranged marriages and the off chance of a surreptitious meeting at a mall, co-educational university, or place of employment do provide opportunities to find partners.

While the home provides women in the family with gender privacy, bedrooms and parents' bedroom in particular, seem to be women's special safe heaven. The perception of the bedroom as the most private and exclusive place for the adult couple in the home is not exclusive to the Qatari culture (e.g., Chevalier 1999; Spain 1992). However, in Qatari homes, bedrooms and especially parents' bedrooms were found to be an especially sacred retreat for women. While some of the interviewees allowed the female researcher to see their bedrooms, many did not allow photos as they did for the rest of the house. Evidently the bedroom as an extension of self is an equally sensitive area as the body.

Maids usually have restricted access and some of participants prefer to clean their own bedrooms in order to prevent their room from being contaminated by their domestic helpers' presence. The bedroom for these women is not just a place to sleep, but a place to be themselves. Most of the female participants said that their bedroom is their most private space in the home and within it lie their favorite possessions and most sacred corner. This sacredness is by no means solely because of the intimate relationship between the husband and wife that takes place in it.

Um Hussein: Bedrooms are never entered by strangers, sometimes not even by relatives. Visitors for the first time may be shown the house but bedrooms are private places inside the house and may not be entered by anybody.

While bedrooms usually have a view of the courtyard or street, it is strictly one way—using mirrored window glass and in some cases meshherabia (filigree panels on windows) means that the woman can look out, but others may not see in. There is often a television, phone, and computer, so there is an indirect connection to the world outside. The woman's bedroom is the largest in the house and furnished to her taste, generally with chairs, sofas, a large bed, mirrors, lamps, and decorative flourishes. Many had large walk-in clothes closets, attached spa bathrooms, dressing rooms, makeup tables, and sometimes exercise equipment and a fireplace (decorative only, given the warm climate). There may be family photos, religious objects, and paintings. Oriental rugs and carpets are common on the floor. Inasmuch as women are excluded from many of the local mosques, it is not just metaphorically a sacred space, but also literally the place where the woman prays and worships.

Mariam: I feel completely free and comfortable in my bedroom. When I'm not with my children, I prefer to be in my bedroom. I do my hair and nails, pray and recite the Quran there.

Um Hind: When I want to relax and have privacy and be on my own, I stay in my bedroom. My bedroom has a TV, a walk-in wardrobe, bathroom and Jacuzzi. I pray, reflect and recite the Quran in this private place.

For these women their bedroom is a place where they can enact their most inner selves and perform spirituality. It is where they pray and recite Quran. As these participants suggest, the bedroom is not only for prayer, but also for reflection, for consolidating the self.

The Home as a Place for Expression

Besides being a place for freedom and control for women, the domestic space in Qatar is also used to make statements about taste and status. This is particularly the case in the design and furnishing of the female guest room, although such home features as elevators, swimming pools, and elaborate men's majleses also serve this purpose.

Interviewer: If someone entered your house, what would be his/her impression about it?

Mariam: He/she would think we have a high style, and that while other people don't usually care for details, we do.

Other people may pay the same amount but they don't get a fine home like this. It's a matter of how you utilize the budget... I'm proud of my home, mainly because I designed it.

Even the quality of oud and other incenses used to perfume the home and guests make a difference. The outcome of a visit is usually evaluated based on the smell carried by the visitor and detected by others outside the host or hostess's home. The nicer the smell the higher the prestige of the absent hostess whose prestige and reputation are thereby extended (Kanafani 1983). Some participants noted that they would know the social class of the home owner from its oud smells as there are different types of oud scents and combinations that can be quite variable in price. This is different from western homes where only material objects (i.e. furnishing and design) convey meanings, denote status, and generate aesthetic experience. This may derive from the traditional Arab environment of desert with little water for use in cleaning and purification rituals, as has been common in the West (Shove 2003; Smith 2007). For men the home also appears to be a source of pride and fulfillment. It is a place of peace and safety for the family that the husband is expected to provide materially. Providing a home and being in charge financially are considered to be a husband's duty in Islam. It is related to the concept of *kivama*--being in charge and responsible for the wife or women in the family. A woman, even if she has an income, has no obligation to spend it on the home or family.

Interviewer: If your home were an animal. Which animal would it be?

Jamal: I'm fascinated with marine life. The whale is big, graceful and my home gives such [an] impression.

Abu Khalid: Though we don't like animals, a horse may represent it. It's strong and proud.

Not only home design, but also furnishings were cited as points of pride. Furniture from Italy, fine oriental carpets, and original artwork were among the objects cited as being "unique." Likewise lush elaborate landscaping in the inner courtyard of one home made it hard to appreciate that it was located in an arid country of sand and deserts.

The Men's Majles: A place for Pride and Honor

The men's majles is a communal male space where the husband and other male family members, receive and entertain their male guests. It is a space that binds Qataris to their past and expresses cultural authenticity. It is the most prominent site for enacting Arab hospitality and a source of pride and honor that brings praise and supports the family or tribe reputation and prestige.

Salah: In [the] majlises I meet my friends and old classmates and cousins. [The] Majles is a place of prestige and a place of heritage. It has traditions surrounding it. It's large (6x10 meters) to accommodate as a large number of guests as possible. Not only is the size and magnificence of the majles important, it also brings honor and status to the host if many guests come, especially if they are prominent. Its significance is reflected in the type of treatment and generosity found in it, as well as implied cultural heritage. It's also reflected in the age of people present there [with older men being higher in status].

People often have their meals on the floor and don't use chairs in the majles. Coffee has major importance in a majles. It's essential for hospitality. Guests are welcomed with incenses and *Oud*. Coffee is prepared from green grains following special rituals.

Objects and traditions from the Bedouin past are also an important part of the display in Qatari Majleses. We found that Qatari male favorite objects tend to be objects that represent a proud and prosperous heritage linked to the past and the traditions that are revered in the Arab Gulf region (e.g., heirloom swords, coffee pots, grandfather's photos) and these objects tend to be on prominent display for other men to see in the majles.

Jassim: We have started to long for the past. You observe a lot of the old features in [the] Almannai [a prominent family with two majleses we visited] Majles: Old style doors and windows, rawashin [special places] where [they] display coffee pots, weapons, etc..

Some would bring their falcons to the majleses they visit. When a falconer comes to majles with his falcon(s) he wants to demonstrate his skills in falconry. He also comes armed with his guns and daggers. Old swords and guns are currently used for decoration, together with other things used in the past such as the pump used in coffee-making. People used to express their pride in being a member of a specific tribe, family or district. [The] Majles in the Qatari and Gulf societies means honor. It's everything.... In the past tribal issues were discussed: politics, economics, etc.

Although the majles is an exclusive space for men, it could be occasionally used for a big women gathering. As such, the most public area in the domestic sphere can be temporarily converted to a women private sphere. This space mutability is inherent to the characteristic feature of the Islamic construction of space. For instance, a public space like a street can be temporarily altered into a private sacred space by occupying it for prayer by men or women (El Guindi 1999). The home could also be converted to a public space for women with the entrance of a man from the non-mahrem category.

Embracing the Modern and Longing for the Traditional

Despite a cultural pride in Qatar's Bedouins and the Bedouin heritage of many Qataris, there is no doubt that contemporary conveniences are embraced as well. Land Rovers have replaced camels, homes and majleses have air conditioning and big screen televisions, and foods are prepared in kitchens equipped with all the latest conveniences. For these things are marks of status as much as links to past traditions and heritage are. The real estate agent in our study explained how the modern and the traditional co-exist:

Agent: Now people like to have a beautiful garden, swimming-pool, Jacuzzi, marble, excellent decoration and central air-conditioning as well as an external majles and a separate space for a tent. People like to sit on the floor in the tent where they feel comfortable, while [the] majles is usually used for formal receptions. The tent is especially used in Ramadan. People prefer the tent during winter, listening to the sound of rain. Tents are air-conditioned now. It's a psychological need rooted in Qatari customs. To Qataris, tents may still be more beautiful than palaces! Even with the largest and finest majles, the tent is considered necessary. The tent is mainly for men. It is usually set up in the open space close to the house or within the house enclosure and is supplied with electricity. ... Some families set up tents in the desert and some set up their tents close

to the sea. People like to go to the desert and if it rains wild plants grow and people enjoy the scenery.

As noted by the real estate agent, tensions between the traditional and modern are evident in the configuration of homes and objects within them. Opulent two or three storey villas are replacing traditional, one story inward facing Qatari homes. Yet, many Qatari homes have an external Bedouin tent in their front yard usually used by male family members and their guests as part of a proud connection to prior roots. Although traditional furnishings like floor seating is increasingly being replaced by modern furniture in Qatari homes, some Qatari families still have a traditional space or corner in their homes with floor seating where family members sit and eat meals. Many Qatari families also have permanent tents in the desert where they go and spend the weekend away from the modern urban lifestyle in Doha. These and other examples show how Qataris embrace Western goods and symbols of modernity and at the same time use traditional goods and symbols as a way of preserving or reviving traditional roots. This process of creolization (Hannerez 1992) of blending the local with the global results in a new synthesis of consumption patterns with an increasing incorporation of modern, Western lifestyles and goods into traditional ways of life (Ger and Belk, 1996).

A part of the status of a family also comes from their membership in a prominent tribe. Although belonging to a prominent family can also still convey status in the West, in Qatari society family and clan reputations are more dependent on the moral reputations of family members. This is more similar to Asian notions of face than it is with Western concepts of new and old wealth. Conspicuous consumption, however is increasingly important in the Gulf as Qataris as well as Saudis, Emiratis, Bahrainis, Kuwaitis, and Omanis turn the inward focus of traditional housing more outward and as subtle signs of wealth (e.g., designer abayas, luxury watches, sunglasses, and purses, and expensive automobiles and SUVs become commonplace, even among teenagers. This part of Qatari culture is inflected by the combination of increased wealth and greater presence of global forces.

DISCUSSION

At first glance it is tempting to see the simultaneous longing for the traditional in Qataris' preferences for traditional hospitality rituals, dress, tribal affiliation, high exterior walls around homes, and at least a room or corner with floor seating, as a reaction to the threat of too much foreign influence too quickly. There is some truth to this, but it is important to appreciate that it is given added emphasis by the status of Qataris as minorities in their own country. Coupled with a pan-Islamic embrace of overt Islamism in an era of various perceived and actual hostility to Muslims since September 11, 2001, there is a strong desire to assert a uniquely Muslim and Arab identity in Qatar and other Gulf States.

It is also tempting to see gender segregation in Qatari households as confining women to the home and veil. The public/private paradigm has been commonly used to describe gender segregation in an Arab-Islamic cultural space. However, we found that the privacy of family/women quarters give a woman a sense of freedom and mobility in the domestic space, just as bodily covering gives her a sense of freedom and mobility in the public space. The veil can be seen as a woman's mobile privacy that she transports with her as she moves from the private to the public sphere. *Hurma* is an Arabic term that refers at once to a woman or wife, to the sanctity of religious sites, and also to the sanctity of the home. In essence, it is that which is sacred and pure.

Without attempting to in any way suggest that Qatar is at an earlier stage of "development," it is also well to remember that

similar degrees of gender segregation found in Qatari domestic spaces could be found in some Western spaces as recently as a century ago. Some even find that women's seclusion is more rooted in Western European traditions reflecting a "bourgeois conception of society" (Sciama 1993: 110). And as in the Gulf today, the ability to maintain gender segregation in the Western home was itself a demonstration of wealth and status.

The majles—is a space where roots and traditions are revived and where collective and tribal identities are enacted by men. However, the women's space is more expressive of individual identity and denotes personal status and wealth. Women's domain can be seen as an embodiment of individual identity, mobility and change, whereas men's domain can be seen as an embodiment of collective identity, stability and perseverance of roots. The majles has kept the horizontal traditional building architecture, design and furnishing whereas family homes are increasingly adopting a modern vertical structure (two or three storey villas) and use modern interior designs and furnishing. According to Tuan (1974), vertical elements of the landscape symbolize transcendence and evoke a sense of striving, while horizontal ones symbolize the ideal of roots identification and acceptance. The majles thus encompasses elements of stability and resistance to change, while women's space encompasses mobility and represents what is culturally changeable. Having both spaces in each Qatari household helps locals negotiate and reconcile the conflicting demands of modernity and tradition and to mediate the major social and cultural changes the country has been undergoing.

A similar dichotomy is seen in local personal adornment, where women's garments and grooming are becoming much more expressive while men's garments have changed little. The black, plain and modest abaya that Qatari women traditionally wear in public is increasingly assuming a modern fashionable appearance, accessorized with jewelry, designer handbags, and high heel shoes (Sobh, Belk, Gressel forthcoming). Whether in the configuration of their domestic spaces or appearance in the public space, women seem to capture the ambivalence and conflicting imperative of traditional norms and the temptations of the modern. Women carry the burden of their nation's culture and traditional norms but they also seem to carry change and transformation in their society; their challenge is to reconcile the two.

Consumers' Attachment and Commitment to Brands and Media Titles: The role of Emotions

Rita Valette-Florence, IMUS & IREGE, France
Imene Becheur, Wesford School of Business, France
Virginie de Barnier, IAE Aix en Provence, France
Pierre Valette-Florence, IAE & CERAG, France

ABSTRACT

In this research, we develop a new emotion scale that applies to both media titles and advertiser brands. The dimensions include a positive affective dimension, plenitude; a negative dimension fear; and a mixed dimension, possession, which includes a rather negative facet, envy, and a rather positive one, love. This research also studies the effects of emotions on affective relational variables, namely attachment and emotional commitment, and the potential mediating role of attachment on emotional commitment. Overall, results show a partial mediating effect of attachment between possession and commitment. Both fear and plenitude are complete mediators.

INTRODUCTION

In this research, we develop a new emotion scale that applies to both media titles and advertiser brands. This research also studies the effects of emotions on affective relational variables, namely attachment and emotional commitment, and the potential mediating role of attachment on emotional commitment.

Considering the criticisms addressed to existing emotion scales, this study attempts to construct a new scale of emotions (applicable to advertiser brands and media brands) by combining elements of both Holbrook and Batra's (1987) and Richins's (1997) scales.

The qualitative study allowed us to collect emotion-type items that could describe magazines, and to verify the collected items and validate Richins's (1997) and Holbrook and Batra's (1987) scale items for magazines. Then, in our quantitative study, we relied on five media titles: *Le Monde* (national daily), *Télérama* (Television), *Elle* (Feminine), *Géo* (Tourism) and *L'Equipe* (Sport national daily), and four advertised brands: *Apple* (Computer), *Carte Noire* (Coffee), *Benetton* (Clothes) and *Ferrari* (Cars). After a series of analyses with CSA (covariance structure analysis) and PLS (partial least squares) (PLS) estimation model, we obtained a 10 variable solution, which clustered into three second-order dimensions: fear, possession, and plenitude. Some of these dimensions match those in Holbrook and Batra (1987) and Richins (1997), including scepticism, surprise, tranquillity, and envy, whereas other dimensions, such as distress, are new. The proposed scale therefore offers a specific measure of emotions that apply to both media titles and advertiser brands. The dimensions include a positive affective dimension, plenitude; the negative dimension fear; and a mixed dimension, possession, which includes a rather negative facet, envy, and a rather positive one, love.

The research model specifies relationships between emotions and two relational consequences, attachment and emotional commitment by magazine readers and brand consumers. We test the following hypotheses:

- H1:** *Fear has a negative impact on (a) attachment and (b) commitment toward the brand or magazine.*
- H2:** *Possession has a positive or negative impact on (a) attachment and (b) commitment toward the brand and magazine.*
- H3:** *Plenitude has a positive impact on (a) attachment and (b) commitment toward the brand and magazine.*

- H4:** *Attachment to the brand or magazine mediates the relationship between emotions and commitment to this brand or magazine.*

Magazines

The fear dimension negatively influences attachment and commitment to magazines, in support of H1a and H1b. In contrast, plenitude has a positive impact on attachment and commitment toward magazines, in support of H3a and H3b. Possession negatively influences attachment and commitment to magazines, in support of H2a and H2b.

In the test of the model with attachment as an antecedent of commitment, the results indicate a partial mediating effect of attachment between possession and commitment. Both fear and plenitude are completely mediated by attachment, in support of H4. Globally, plenitude is the main determinant of attachment and commitment toward magazines. The negative influence of fear seems legitimate, whereas impact of possession is more paradoxical. This result suggests the need for a refined analysis for each magazine individually.

The mediating role of attachment for *Elle* is complete for plenitude and possession (the latter has a positive impact on attachment) and partial for fear. The path coefficient, though weaker, is statistically significant. More than 90 percent of the explicative power (i.e., contribution to R²) pertains to attachment, despite the partial mediation. This specific analysis of every press title also indicates that the negative influence of possession on all titles is due to the newspaper *Le Monde* (-.227)

Brands

The impact of possession is positive on attachment and commitment. These results support recent findings regarding the concept of brand love (Albert, Merunka, and Valette-Florence 2008). Yet this mediating role is complete for brands. The influence of all second-order emotional dimensions on brand commitment is overrode by attachment.

As we did for media titles, it seems interesting to test the model with regard to each brand. For example, the analysis of Apple shows a complete mediating effect of attachment. Again, more than 90 percent of the explanatory power is due to the influence of attachment on commitment. In turn, the emotional commitment of Apple consumers to the brand occurs only if they are emotionally attached to the brand. The corresponding possession path coefficient for Apple is approximately .309 (.210 for all the titles). Further analyses of the direct impact of the possession first-order dimensions on attachment reveal that only the love dimension has a positive and significant influence (.314, .046 for envy). This result reemphasizes the role of brand love for Apple consumers (Albert et al., 2008).

An analysis of variance of the latent factor scores for the different brands and magazines assesses the differentiating power of the proposed scale. Results confirm the differentiating power of all scale dimensions. Love and surprise are the most differentiating dimensions.

Moreover, Duncan's test (not shown here to preserve space) identifies, for each dimension, the brands and magazines that have the same, different, or close profiles. The brands reflect various different means; for example, *Benetton* achieves a strong profile on fear, whereas *Apple* and *Carte Noire* score higher on possession (due to consumers' strong emotional commitment to *Apple* and the seduction-based advertising strategy of *Carte Noire*). In contrast, the magazine profiles are generally similar, except that *Elle* and *Géo* are stronger on love and envy. The

informational character of *Le Monde* distinguishes it on all dimensions, and *L'Equipe* appears close to the other magazines.

Finally, in terms of their emotional proximity, *Apple* coexists better with *Géo* rather than *Le Monde*. However, only a study of *Apple* consumers who are also *Géo* or *Le Monde* readers could confirm this claim.

Emotional elements constitute the basis of the relationship between the consumer and brand, and various studies consider the length and content of that relationship (Hakansson 1982; Morgan and Hunt 1994). The relational paradigm insists on the attachment concept (Thomson, MacInnis, and Park 2005), which relates to emotional commitment (Chaudhuri and Holbrook 2001, 2002).

Such emotional reactions are among the various responses to advertising, though exposure to any media appears to provoke emotions (Murry and Dacin 1996). These emotions in turn affect people's intentions (Adelaar et al. 2003). But does this link mean that the medium used to promote a brand also influences the audience's emotional reaction? For example, if a consumer experiences certain emotions and feels attached to a brand, does that person also feel emotions and attachment to the magazine in which an ad for the brand appears? On a more general level, this study investigates a critical question: Is it legitimate to apply the same emotion scale to brands and to specific media titles? The answer is important on both theoretical and managerial levels. This research also examines the extent to which emotions influence attachment and emotional commitment towards press titles and commercial brands.

The remainder of this article first describes the development of a new emotion scale that applies for both press titles and commercial brands. Then, it presents a research model that modelizes the influence of emotions on attachment and emotional commitment, along with the test of the mediating effect of attachment. Finally, the findings, limitations, and further research opportunities appear in the conclusion.

1. A new emotion scale

We first underline the importance of emotions in consumer-brand relationships. Then, we review the existing emotion scales. After developing a new scale that assesses emotions elicited while reading a magazine, or consuming a brand, we show its superiority over existing emotion scales.

1.1. Importance of emotions in consumer-brand relationships

"Emotions are ubiquitous in marketing: They influence information processing, mediate responses to persuasive appeals, measure the effects of marketing stimuli, initiate goal setting, enact goal-directed behaviours, and serve as ends and measures of consumer welfare" (Bagozzi, Gopinath, and Nyer 1999, 202). Zajonc (1980) and Zajonc and Markus (1982) furthered recognition of the importance of emotional reactions, prompting the elaboration of a new approach described as "experiential" (Holbrook and Hirschman 1982).

For the defenders of this approach, consumption represents an experience and therefore entails a range of emotional reactions, including feelings, sensations, emotions, and so on. These theorists also argue that emotions influence information processing, stimuli evaluations, and satisfaction. In particular, Westbrook and Oliver (1991) identify three emotional responses as important antecedents of satisfaction with newly purchased automobiles: pleasant surprise, interest, and hostility. Oliver (1992) expands these determinants of satisfaction to include positive affect (interest and joy) and negative affect (anger, disgust, contempt, shame, guilt, fear, sadness), as well as disconfirmation beliefs (Bagozzi, Gopinath, and Nyer 1999).

1.2. Previous emotion measurements

This research study focuses on measuring emotions linked to consumption. The consumption emotion scale (CES) proposed by

Richins (1997) can capture emotions during consumption experiences, and recent studies show that the CES applies in a French context (Ferrandi, De Barnier, and Valette-Florence 2003).

This scale may be appropriate for measuring emotions during brand consumption, but advertising pages in publications, such as magazines, also may affect emotions, whether directly or indirectly, and therefore the readers' emotions toward the subsequently consumed brand. Approximately 30 percent of magazine pages contain advertising or publicity, so other measurement scales may be necessary or beneficial in this context.

Measures that assume discrete emotions suggest that emotions belong to identifiable and independent categories (Aaker, Stayman, and Vezina 1988; Batra and Holbrook 1990; Batra and Ray 1986). Those that adopt a continuous approach instead imagine that emotions combine two or more dimensions (Holbrook and Batra 1987). The discrete approach suffers two important limitations, in the sense that, first it cannot identify relations between basic emotions and therefore cannot investigate combinatory effects, and second, no general agreement exists regarding basic emotions or listings of emotions, which makes it difficult to synthesize any results.

Considering these criticisms, this research adopts a continuous approach to emotions.

Among the existing emotion scales, the standardized emotion profile (SEP) scale by Holbrook and Batra (1987) seems to offer the best and most valid measure of emotional reactions stimulated by exposure to printed advertising stimuli. In comparison with other scales, it provides the double advantage of a precise factorial structure and easily understandable items. In addition, French magazines such as *Géo* and *Elle* correspond better to the emotions measured by Holbrook and Batra's scale, whereas dailies such as *Le Monde* or magazines like *Capital*, which include less intrusive advertising, might register better with Richins's measured emotions.

Based on Holbrook and Batra's (1987) and Richins's (1997) scales, this study attempts to develop a new emotion scale for commercial brands and press titles.

1.3. Scale development

The scale construction process consists of two parts: a qualitative study and a quantitative study, with exploratory and confirmatory factor analyses.

Qualitative studies

From a managerial point of view, magazines are brands. However, magazines also entail some particularities when presented as brands. Therefore, the scale development process must generate groups of items related to the emotions activated when people read magazines to identify any missing items from prior scales.

Focus groups provide an effective means for doing so (Edmunds 1999), because they combine social interaction and group influence phenomena. Following Derbaix and Poncin (2005), this step includes projective and classical qualitative studies that explore respondents' conscious and subconscious minds.

The qualitative study consists of two steps. First, the "discovery step" attempted to collect emotion-type items that could describe magazines. Second, the confirmation step (classical method) intended to verify the collected items and validate Richins's (1997) and Holbrook and Batra's (1987) scale items for magazines. Both expert analyses and synonym checking confirmed that the retained items could all be regrouped into Holbrook and Batra's and Richins's scales.

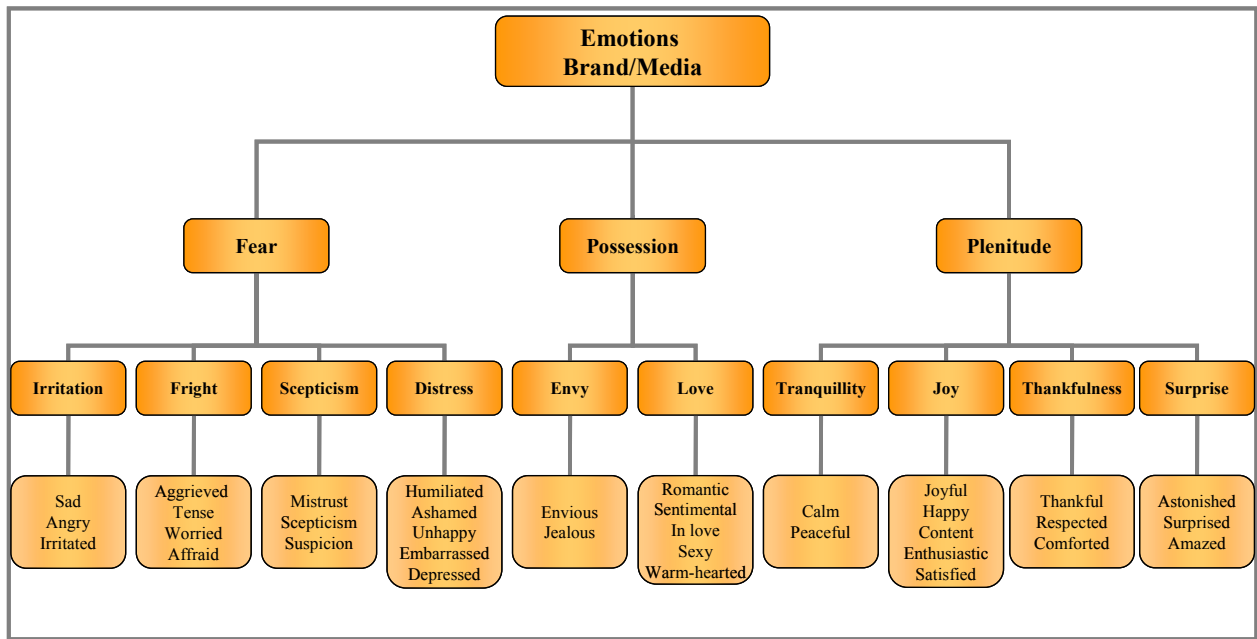

Quantitative study

The selection of publications was based on the number of printings in France, as well as the possibility that the titles would induce

Table 1: Scale's structure and validity

Figure 1: Emotions scale

different emotions, such as “fear” or “interest” (the daily newspaper *Le Monde*), “sadness” or “joy” (sport magazine *L’Equipe*), and “jealousy” (fashion magazine *Elle*). All in all, we relied on five media titles: *Le Monde* (national daily), *Télérama* (Television), *Elle* (Feminine), *Géo* (Tourism) and *L’Equipe* (Sport national daily)

The selection of advertised brands includes well-known brand names that would induce a wide range of emotions. For example, *Carte Noire* (a very famous coffee brand in France) likely provokes “sentimentality” or “romanticism”. In that survey, we selected four brands, namely *Apple* (Computer), *Carte Noire* (Coffee), *Benetton* (Clothes) and *Ferrari* (Cars).

Respondents were either brand consumers (to support measures of the impacts on attachment and brand commitment) or brand experts (to build a reliable emotion scale). The questionnaire included items from our newly developed emotion scale, as well as from Lacoquilhe’s attachment scale (2000) and Fullerton’s emotional commitment scale (2003). The convenience, non representative sample (498 respondents) contains a range of social and professional classes and age groups.

Two types of confirmatory factor analyses validate the scale’s structure, namely, a classical covariance structure analysis (CSA) and a partial least squares (PLS) estimation model (Tenenhaus et al., 2005). Considering the non-normality of the measurement variables and the relatively small size of the sample, these analyses relied on a systematic bootstrap procedure (500 replications for CSA and 250 replications for PLS). The CSA approach tests and validates the adequacy of the model according to the fit indexes recommended in the literature (Hu and Bentler 1998). The root mean squared error of approximation (RMSEA) is .0565; the goodness-of-fit (GFI) and adjusted goodness-of-fit (AGFI) indices are .914 and .895, respectively. In the PLS model, the GoF (goodness of fit) index proposed by Tenenhaus et al. (2005) reaches .821 for internal GoF and .997 for external GoF. This model therefore is satisfactory, because GoF is close to 1.

Convergent validity, reliability, and discriminant validity tests consider the specific quality of each scale’s dimension. As Table 1 shows, all t-tests in the CSA are significant. The loadings also are important, and the extracted variance is greater than 50 percent (close to .50 for “possession”) (Fornell and Larcker 1981). The reliability of every latent variable, according to Joreskog’s coefficient, is satisfactory,

particularly for second-order dimensions. All 10 variables clustered into three second-order dimensions: fear, possession, and plenitude.

Finally, a series of sequential tests that compare free with constrained models (i.e., correlations between two latent variables fixed to 1) confirm that the free models exhibit better fit with the data, in support of discriminant validity (also proved for the PLS model). These results confirm a 10-dimensional first-order structure and a three-dimensional second-order structure (Figure 1). Some of these dimensions match those in Holbrook and Batra (1987) and Richins (1997), including scepticism, surprise, tranquillity, and envy, whereas other dimensions, such as distress, are new.

The proposed scale therefore offers a specific measure of emotions that apply to both media titles and advertiser brands. We also checked by means of a multi-group confirmatory factor analysis that the scale structure remained invariant between press titles and commercial brands. This result confirms the universal nature of emotions, which don’t depend on the domain of inquiry. Overall, the dimensions include a positive affective dimension, plenitude; the negative dimension fear; and a mixed dimension, possession, which includes a rather negative facet, envy, and a rather positive one, love.

Finally, by means of series of discriminant analyses, we compared the predictive power of our new emotion scale with than of Richins (1997) and Holbrook and Batra (1987). For all three scales, we used PLS latent scores as independent predictive variables, and six of the studied brands (*Apple*, *Carte noire*, *Elle*, *Le Monde*, *L’equipe*, and *Geo*) as the dependent variable. Results show that the new developed scale outperform the two other scales as for the overall classification rate (namely 56 percent vs. 51 percent for Holbrook and Batra’s scale, and 50 percent for Richins’s scale).

2. The effects of emotions on attachment and emotional commitment

McQueen, Foley, and Deighton (1993) illustrate the emotional development between brands and consumers with the notion of attachment, which can lead to brand commitment. Moreover, Chaudhuri (2006) underlines the importance of affect, which binds the antecedents of emotions to their manifestations, such as attachment and commitment, considered as two key brand relational variables (Thomson, MacInnis, and Park, 2005).

2.1 Relational variables

The relational perspective shows that attachment linked to attitudinal loyalty and brand commitment is now considered as an independent construct with its own measures (Thomson, MacInnis, and Park, 2005; Lacoëuilhe 2000). In the marketing field, brand attachment reportedly results from nostalgic connections with life events or image congruence (real or ideal) between the consumer and brand (Lacoëuilhe 2000). Attachment represents a strong emotional relation to the brand (Aaker and Fournier 1995), which one can define as a strong, interactive and lasting psychological and emotional relation between consumer and brand that can be manifested by dependency and friendship.

Lacoëuilhe's (2000) definition also considers brand attachment "a psychological variable that translates a lasting and changeless emotional relation (separation is painful) towards brand and that expresses a relation of psychological closeness to it." This author therefore argues that emotions, though similar to attachment, differ from it, in that emotions are more intense, shorter, and related to an event's nature, whereas attachment is a long-term, evaluative reaction. This study adopts both Lacoëuilhe's (2000) definition and his four-item measurement scale, rather than Thomson and colleagues' (2005) attachment scale, which includes items linked to emotions such as love.

Early commitment studies in the organizational field (Meyer and Allen 1991; Mowday, Steers, and Porter 1979) include a measurement scale based on three dimensions: emotional commitment, cognitive or calculated commitment, and normative commitment (Allen and Meyer 1990a, 1990b). Various researchers apply this concept to marketing, particularly in the field of relationship marketing (Bansal, Irving, and Taylor 2004; Fullerton 2003, 2005; Gundlach, Achrol, and Mentzer 1995; Morgan and Hunt 1994). In this research, we define commitment as a firm's willingness to support a relation with the brand. This study focuses particularly on emotional commitment, which reflects the degree of involvement and identification with the organization (Meyer and Allen 1991), which in turn leads to a sense of membership. In marketing, it leads to consumer loyalty, because commitment causes a favourable attitude toward the brand, along with an intention to re-purchase it (Fullerton 2005). According to Fournier (1998), consumers develop relations with the brands they use. In this sense, commitment creates the benevolent will to sustain a satisfactory relationship over the long term, which involves accepting short-term, necessary sacrifices and creating obstacles to the dissolution of the relationship.

Fullerton (2005) also argues that commitment constitutes the heart of such relationships, because it leads customers to develop positive affect toward the brand. For example, in consumption communities, consumers share or feel positive emotions toward the object of consumption, both on their own and together with the community members. (McAlexander, Kim, and Roberts, 2003). Finally, emotional commitment relates closely to the expressive function of brands, a source of emotions and feelings. Consequently, this research assesses the impact of emotions activated when people consider a brand or read a publication on their attachment and emotional commitment to those brands and media titles.

2.2. Research model & Hypotheses

The research model tests the effects of emotions on affective relational variables, namely attachment and emotional commitment, and the potential mediating role of attachment on emotional commitment. Strong relations between consumers and brands underlie schemata and emotion-laden memories. In effect, interactions between consumers and objects lead to strong emotions, which create strong attachments toward those objects (Thomson, MacInnis, and Park 2005). Therefore, emotional items from prior attachment scales, such as emotional, delighted, passionate, or cheerful (Lacoëuilhe 2000; Thomson, MacInnis, and Park 2005) should characterize attachments toward the brand. These

emotions are positively valenced, in that they reflect a positive, nice, and intense evaluation of the object (brand) (Lazarus 1991; Roseman 1991). Indeed, brands create emotional attraction and have the capacity to activate strong feelings, emotions, and pleasure. Therefore, emotions should affect brand attachment positively.

In social psychology, Simpson et al. (2007) show that positive emotions affect positively attachment to one's partner, whereas negative emotions affect it negatively. Similarly, positive emotions should reinforce emotional attachments to the brand or publication, whereas negative emotions should influence them negatively. The effect of possession may be mixed, because this dimension consists of two first-order variables, one positive (love) and one negative (envy) (Pines and Friedman 1998; Richins 1997).

Therefore, positive (negative) emotions should favour (inhibit) commitment toward the brand or magazine. In turn,

H1: *Fear has a negative impact on (a) attachment and (b) commitment toward the brand or magazine.*

H2: *Possession has a positive or negative impact on (a) attachment and (b) commitment toward the brand and magazine.*

H3: *Plenitude has a positive impact on (a) attachment and (b) commitment toward the brand and magazine.*

The intensity of an emotional attachment with an object may be associated the consumers' willingness to abandon their immediate interests to promote a stronger relationship with the object (Thomson, MacInnis, and Park 2005). That is, "Consumers' brand emotional attachment predicts their commitment towards this brand and their willingness to make financial sacrifices in order to acquire it". Lacoëuilhe (2000) also considers attachment a determinant of commitment toward brand, with an emphasis on the importance of dissociating calculated commitment from emotional commitment. Emotional commitment appears more likely to explain the effect of attachment on customer loyalty to brand. Therefore,

H4: *Attachment to the brand or magazine mediates the relationship between emotions and commitment to this brand or magazine.*

Figure 2 summarizes these hypotheses.

2.3. Methodology & results

To test our model, we used a PLS approach (Tenenhaus et al., 2005). The GoF index reaches .832 for press titles, and .829 for commercial brands. All in all, the total predictive power of attachment, at 49.1 percent and 52.5 percent for magazines and brands, respectively, is much less than that of emotional commitment. Specifically, commitment's predictive power reaches 71.1 percent for magazine readers and 86.3 percent for brand consumers. This result further suggests that brand consumers are more attached and committed to their brands than are magazine readers. Further analyses of *Elle* magazine and the Apple brand, discussed subsequently, support this result.

Press titles

In Figure 3, the path coefficients appear in red. The fear dimension negatively influences attachment and commitment to magazines, in support of H1a and H1b. In contrast, plenitude has a positive impact on attachment and commitment toward magazines, in support of H3a and H3b. Possession negatively influences attachment and commitment to magazines, in support of H2a and H2b.

Figure 2: Research model

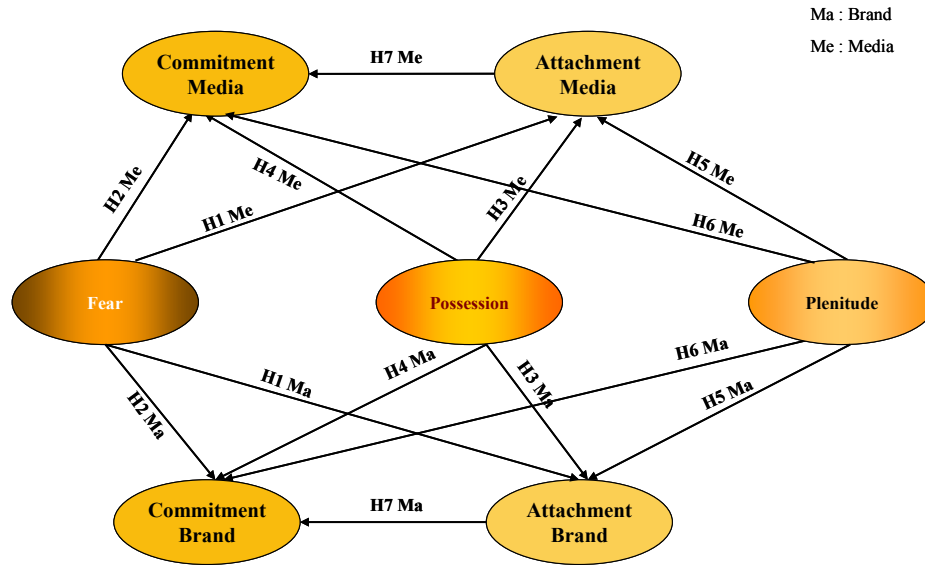

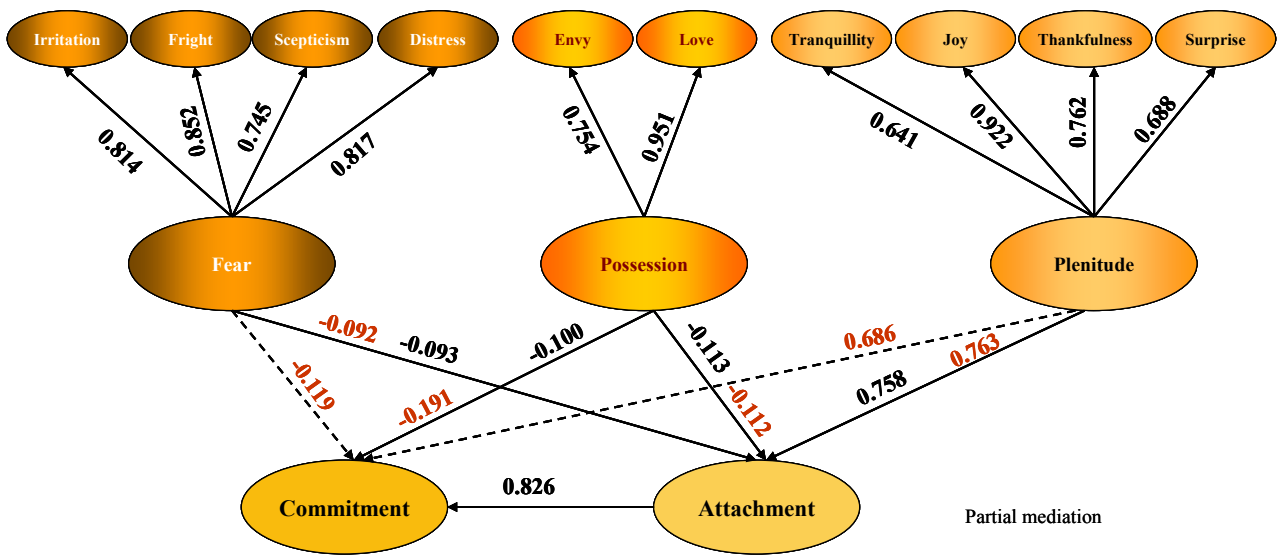

Figure 3: Path coefficients for media

In red : Path coefficients after bootstrap with attachment on one side and commitment on the other side
In black : Path coefficients after bootstrap with attachment antecedent of commitment

In the test of the model with attachment as an antecedent of commitment (path coefficients in black) (Lacoeuille 2000), the results indicate a partial mediating effect of attachment between possession and commitment. Specifically, possession still has a direct influence on commitment to the magazine.

Both fear and plenitude are completely mediated by attachment, in support of H4. Globally, plenitude is the main determinant of attachment and commitment toward magazines. The negative influence of fear seems legitimate, whereas impact of possession is more paradoxical. This result suggests the need for a refined analysis for each magazine individually.

The mediating role of attachment for *Elle* is complete for plenitude and possession (the latter has a positive impact on attachment) and partial for fear. The path coefficient, though weaker, is statistically significant. More than 90 percent of the explicative power

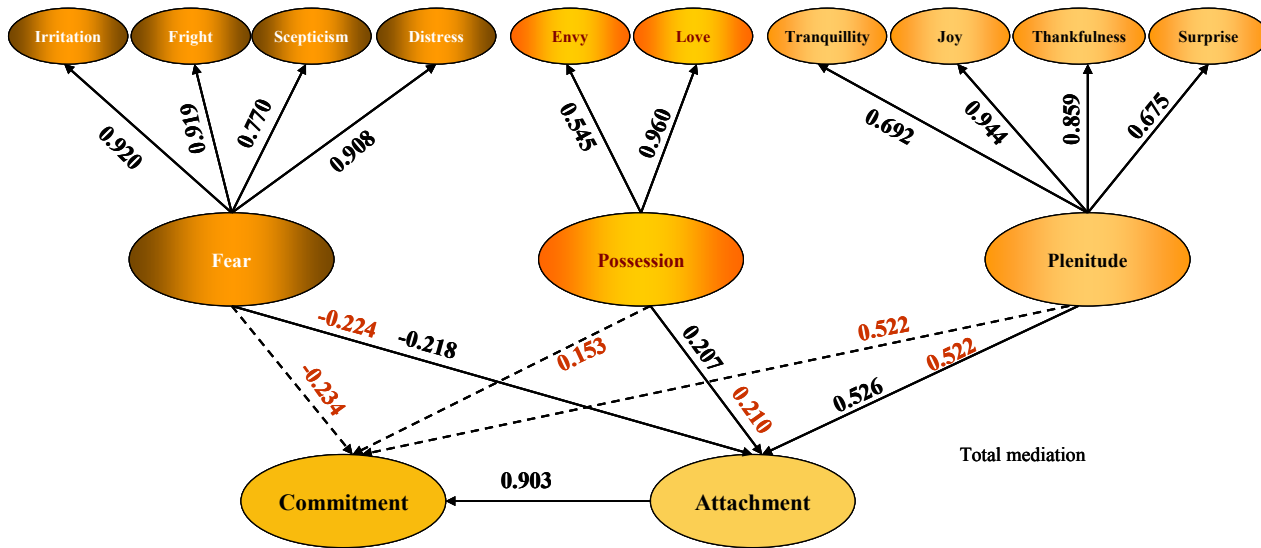

(i.e., contribution to R²) pertains to attachment, despite the partial mediation. This specific analysis of every press title also indicates that the negative influence of possession on all titles is due to the newspaper *Le Monde* (-.227)

Commercial brands

Similar to the magazine model, the hypotheses receive validation for brands (path coefficients in red in Figure 4). The impact of possession is positive on attachment and commitment. These results support recent findings regarding the concept of brand love (Albert, Merunka, and Valette-Florence 2008).

Yet this mediating role is complete for brands. The influence of all second-order emotional dimensions on brand commitment indirectly goes through attachment (Figure 4).

Figure 4: Path coefficients for brands

In red : Path coefficients after bootstrap with attachment on one side and commitment on the other side
 In black : Path coefficients after bootstrap with attachment antecedent of commitment

As we did for media titles, it seems interesting to test the model with regard to each brand. For example, the analysis of Apple shows a complete mediating effect of attachment. Again, more than 90 percent of the explanatory power is due to the influence of attachment on commitment. In turn, the emotional commitment of Apple consumers to the brand occurs only if they are emotionally attached to the brand. The corresponding possession path coefficient for Apple is approximately .309 (.210 for all the titles). Further analyses of the direct impact of the possession first-order dimensions on attachment reveal that only the love dimension has a positive and significant influence (.314, .046 for envy). This result reemphasizes the role of brand love for Apple consumers (Albert et al., 2008).

Commercial brands & press title profiles

Because the purpose of this research also involves the operational appeal of the proposed emotion scale, this section confirms the strong differentiating power of this scale. Table 2 shows the results of latent factor scores variance analysis for the different brands and magazines. They confirm the differentiating power of all scale dimensions. Love and surprise are the most differentiating ones.

Table 2: Variance analyses, F-tests (p < .05)

Dimensions	Love	Surprise	Joy	Scepticism	Fright	Irritation	Envy	Thankfulness	Tranquillity	Distress
F	17,44	8,09	7,18	5,95	5,74	5,10	4,41	4,37	3,36	2,92

Finally, in terms of their emotional proximity, *Apple* coexists better with *Géo* rather than *Le Monde* (Figure 6). However, only a study of *Apple* consumers who are also *Géo* or *Le Monde* readers could confirm this claim.

4. Discussion, limitations & future research

This research attempts to confirm that brands generate emotions, which could constitute the basis of an affective route (emotions–attachment–emotional commitment). This research also reveals that specific media titles, as brands, can prompt emotions. An empirical approach creates and validates an emotion scale applicable to both

Moreover, Duncan’s test (not shown here to preserve space) identifies, for each dimension, the brands and magazines that have the same, different, or close profiles. The brands reflect various different means; for example, *Benetton* achieves a strong profile on fear, whereas *Apple* and *Carte Noire* score higher on possession (due to consumers’ strong emotional commitment to *Apple* and the seduction-based advertising strategy of *Carte Noire*). In contrast, the magazine profiles are generally similar, except that *Elle* and *Géo* are stronger on love and envy. The informational character of *Le Monde* distinguishes it on all dimensions, and *L’Equipe* appears close to the other magazines.

Figure 5 reveals that consumers perceive irritation, fear, scepticism, and distress as less predominantly emotional traits, but that surprise, thankfulness, love, tranquillity, and especially joy are the most important emotional traits. Consumers’ emotional brand profiles are identical to their emotional magazine profiles, though some differences appear, especially for the second-order dimensions of fear, which consists of fright, scepticism, irritation, and distress. These dimensions have greater impacts on magazines than on brands, whereas all the other dimensions, especially love, are more important for brands than for magazine titles.

brands and media titles that outperforms existing emotion scales (Holbrook and Batra 1987; Richins 1997).

In addition, the test of the research model reveals the partial or total mediating effect of attachment on emotional commitment, as well as the role of positive (plenitude) and negative (fear) emotions on attachment and emotional commitment for each brand and media title studied. Moreover, the validated emotions scale suggests a variety of applications. Brand and media managers now have a new, qualitative instrument with real action levers that they can use to enhance customer’s attachment and commitment towards brands. Measuring the emotions provoked while reading a magazine title and assessing their coherence with the emotions activated by exposure

Figure 5: Brands and magazine profiles

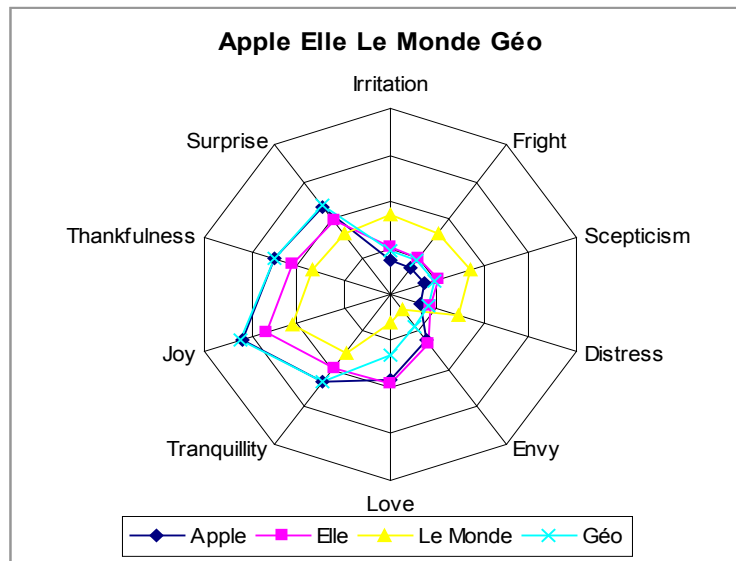

Figure 6: Comparison of Apple, Le Monde, Elle, and Géo profiles

to advertised brands offers a valid measure of the qualitative affinity between media titles and brands. Finally, managers should opt for strategies that emphasize the positive emotions activated during brand consumption or media reading to compete better.

As usual, this research suffers from several limitations, including the small sample size and questions of its representativeness. Other affective relational concepts, such as brand love (Albert, Merunka and Valette-Florence, 2008) or identification (Escalas, 2004) also could have been integrated into our model. Additional research therefore should attempt to advance understanding of the emotional qualitative affinity between brands and media (i.e., when people are both brand consumers and media readers). It also will be important to test various publications and media categories, including different forms such as radio and television. This extension could suggest better and more precise media selections for advertisers.

Another interesting avenue for future research would be to explicitly test that the media context of a given ad may lead to different emotions, and hence to changes in attachment and commitment. In addition, an experiment could show that the same ad may elicit

different feelings or emotions when printed in different outlets. For instance, it could be interesting to compare Ab and Aad for an *Apple* ad incorporated within *Elle* vs. *Geo*.

Consumer's Perceived Control

A Critical Review and a Research Agenda

Renaud Lunardo, Troyes Champagne School of Management, France

ABSTRACT

The inconsistent results about the influence of perceived control on consumer behavior raised questions regarding its conceptualization and the need to consider desire for control when modeling its influence. This paper presents a review of past research on perceived control and offers a propositional agenda for further research.

INTRODUCTION

There is virtual consensus among researchers that individuals' understanding of how much control they can exert over their behavior has been shown to affect how they behave and how they evaluate themselves and the environment (Rotter 1966). Despite the term "control" has been used and defined in a multitude of ways, it is often referred to as "the belief that one can determine one's own internal states and behavior, influence one's environment, and/or bring about desired outcomes" (Wallston et al. 1987, 5). As such, perceived control has been studied in a wide number of fields, from psychology to medicine (Skinner 1996). It has been demonstrated to be an important driver of behavior, resulting in more performance of behavior. For instance, in the field of psychology, empirical evidence testing prominent theories, including the theory of reasoned action (Fishbein 1967) and the learned helplessness model (Seligman 1975), has shown that perceived control exerts a significant influence on human well-being (Langer and Rodin, 1976), task performance (Geer, Davison, and Gatchel 1970), anxiety (Staub, Tursky and Schwartz 1971) and stress (Lazarus and Folkman 1984; Paterson and Neufeld 1995).

It was not until the 1990s that perceived control made its first appearance in consumer-related studies (Hui and Bateson 1991). Relying on Mehrabian and Russell's (1974) approach to environmental psychology by conceptualizing perceived control as an affective response to the environment – the emotion of dominance – the study of perceived control in consumer research intensified with the emergence of emotions as a component of the consumer experience (Holbrook and Hirschman, 1982) and new conceptualizations of servicescapes (Bitner 1992). Despite a high criticism of the most frequently used perceived control measure – the Dominance subscale of the PAD (Mehrabian and Russell 1974) – inclusion of perceived control in consumer research continued unabated.

However, significant perceived control findings in consumer research have sometimes been rare or contradictory, leading some suggest that the inclusion of perceived control in consumer research is unproductive and should be abandoned (Russell and Pratt 1980; Yani-de-Soriano and Foxall 2006). Several reasons have emerged to explain the lack of significant findings. For example, some have suggested that the problems may come from the inappropriate use of terms resulting in conceptual ambiguity.

Given these concerns, the purpose of this paper is to present a thorough review of consumer behavior studies in the marketing literature that have examined perceived control. The review is grounded in the theoretical models from several fields, from social psychology to marketing, with the specific goal of providing a framework to address the question: "To what extent are differences in perceived control useful in explaining meaningful variations among consumer behaviors?" Addressing this question will help clarify whether enthusiasm or skepticism about perceived control research in consumer behavior is warranted, and, if warranted, what direction(s) future research should take.

PERCEIVED CONTROL AS A PSYCHOLOGICAL CONSTRUCT

A wide set of different terms, signifying essentially the same thing, have been used over the course of perceived control research. The perceived control construct has been called by "many different things, including, besides control, self-directedness, choice, decision freedom, agency, mastery, autonomy, self-efficacy, and self-determination" (Rodin 1990, 1). Meanwhile, as the definition has broadened, the precision of the meaning has lessened, leading to a surprising heterogeneity among the constructs researchers use to describe perceived control (Skinner 1996). Thus, a literature review is needed to provide a clear and unambiguous definition of the subject under analysis. With respect to this particular literature review, it requires not only understanding what perceived control is, but also understanding how it is related to, yet different from, other control terminology.

Contributing to the inconsistent use of terminology is the fact that the term "control" is not similarly treated in both psychology and marketing. In psychology, the history of research on perceived control is a long one, involving many different general theoretical frameworks and a host of specific constructs, including locus of control, causal attributions, and self-efficacy (Skinner 1995). From Rotter's (1966) general social learning theory came the construct of locus of control (LOC), which refers to people's perceptions about whether or not their behaviors are reliably linked to outcomes. An internal locus of control is the belief that they are, and an external locus of control is the belief that they are not. Despite hundreds of studies dealing with the influence of the LOC on behavior, theorists have pointed out that perceptions of control may not only result from the contingency between their actions and the outcomes, but also from the explanation one gives for why that is so. In other words, it is not uncontrollability per se, but the attributions individuals make for a perceived noncontingency between actions and outcomes that influence behavior (Weiner et al. 1972). Thus, locus of control and causal attributions are quite similar by both referring to control in terms of subjective beliefs about the extent to which certain causes lead to success and failure. However, they must not be confounded since they differ in terms of stability. Indeed, the causes to which individuals attribute events can be arrayed along three main dimensions: internality, stability and controllability, and while locus of control only relies on the dimension of internality, attribution relies also on stability. During the attribution process, the more an outcome is attributed to stable causes, the greater the weight that will be given to that outcome in determining predictions for the future.

Although in both of the preceding conceptualizations perceptions of control are products of external conditions (here, the degree of contingency between actions and outcomes), they also can refer to individual actions. In this case, perceived control results from individual efforts to achieve a goal (White 1959). These perceptions of control are sometimes referred to as feelings of efficacy (Bandura 1977). Self-efficacy appears to be similar to the perceived behavioral facet of control, one of the three facets of control identified by Averill (1973) who distinguished between behavioral, cognitive, and decisional control. Referring here to "the availability of a response which may directly influence or modify the objective characteristics of a threatening event" (286-287), it can also refer to the ease or difficulty of performing a behavior,

or to the confidence in one's ability to perform, as in the Theory of Planned Behavior (Ajzen 1991, 2002). In a review of papers that have assessed perceived control, Ajzen (2002, 6) highlights that a common operationalization is "for me to perform behavior x would be very easy / difficult". When also reviewing papers that contrasted self-efficacy and perceived control, self-efficacy is frequently operationalized as "for me to engage in behavior x would be easy/difficult", which is the same as the definition of perceived control. As noted by Ajzen (2002), perceived behavioral control and self-efficacy are quite similar since both are concerned with perceived ability to perform a behavior, leading to a considerable conceptual overlap in the operationalizations of both the constructs of self-efficacy and perceived control. Thus, a challenge to addressing the question of the role of perceived behavioral control concerns the imprecision with which this construct and self-efficacy are used in research. It seems clear that most researchers tend to use these terms interchangeably, even if they have distinctive qualities.

Despite those numerous conceptualizations discussed in psychology, perceived control is in marketing surprisingly often referred to as an emotion. In contrast with conceptualizations that see control as a durable learning process – such as the LOC – the perceived control literature in consumer research explicitly defines control in terms of dominance, an affective response to the environment (Mehrabian and Russell 1974). As such, dominance represents "the extent a person feels powerful vis-a-vis the environment that surrounds him" (Russell and Mehrabian 1976, 6), ranging from extreme feelings of lack of control upon one's surroundings to feelings of being influential and powerful, or in control. In other words, the positive pole is defined as the disposition to assume the lead, to take control, and to direct or influence others. The opposite pole represents the disposition to submit to authority, to follow orders and to comply with demands (Lorr 1991). People experience control in a particular setting when they feel that the environment facilitates goal achievement, whereas they feel a lack of control when the environment prevents them from achieving their goals (Lunardo and Mbengue 2009; Ward and Barnes 2001).

PERCEIVED CONTROL: AN IMPORTANT DRIVER OF CONSUMER BEHAVIOR

The Theory of Learned Helplessness (Seligman 1975) and the Theory of Planned Behavior (Ajzen 1991, 2002) have widely been used in psychology to explain the consequences of control on behavior. They both posit that a perception of control can motivate individuals to engage in a behavior. As a result of the use of these theories, a large body of theory and evidence is available to show that perceived control is a powerful predictor of emotions and behavior. The purposes of this section are to draw upon these theories and marketing research to identify antecedents of perceived control and to demonstrate how perceived control can motivate consumers to engage in a behavior.

Perceived Control as the Consequence of Predictability, Choice and Crowding

Existing literature suggests that the most prominent antecedents of perceived control are predictability and choice (Skinner 1996). In fact, some theorists so strongly believe that these constructs are antecedents of control that they have labeled them predictive control and decisional control.

The ability to predict events in the environment has been found to be important for the comfort and safety of organisms. Predictability refers to being informed about things, anticipating what may happen, feeling certain about the outcome, or anticipating potential problems (Troup and Dewe 2002). Existing evidence in psychol-

ogy shows that the ability to predict events increases feelings of control and in turn reduces tension or anxiety (Staub et al. 1971). In consumer research, Holt (1995) has showed how predictability of action by spectators in professional Baseball enhances perceptions of control: by predicting action on the field, spectators enhance the perception that they are involved in the game's production and so how they interject some control over the game.

Unlike predictability, choice as an antecedent of perceived control has been studied in research examining the mediating role of perceived control on the effect of density and choice on consumer's emotional feelings during the service encounter (Hui and Bateson 1991). As found out by the authors from an experiment including two service settings, a bank and a bar, results showed that when consumers have choice (the perception that an outcome is caused by a person's own decision, Hui and Bateson 1991, 175), it increases decisional control and results in positive outcomes, leading authors to conclude that "perceived control is a powerful concept in explaining the consumer's reactions to consumer density in the service environment" (182). Other studies also demonstrate that consumer choice in the traditional retail setting results in more consumer's perceived control (Chang, 2006). However, studies indicate that the relationship between choice and perceived control is complex, and that giving control through more choice may not be as desirable as it seems at first. For instance, Wathieu et al. (2002) suggest that choice can be considered a predictor of perceived control only if the consumer has the ability to specify and adjust the choice context.

In a more setting-specific point of view, perceived control has also been seen as resulting from density. Because density can facilitate or obstruct desired behaviors, it can determine the individual's perceptions of crowding which in turn negatively affect perceived control (Schmidt and Keating 1979; Hui and Bateson 1991). A study conducted by Langer and Saegart (1977) showed that those negative effects of crowding can be reduced by information that give individuals cognitive control of the situation. In contrast to the negative relationship between perceived crowding and perceived control, the sign of the relationship between density and perceived control can vary according to settings. For instance, Hui and Bateson (1991) found out that in a bank setting, high density is associated with lower perceived control, while in a bar setting it is associated with higher control. Such results give support to the assumption that perceived control can be used to explain the emotional and behavioral effects of density according to settings.

The Wide Range of Effects of Perceived Control on Consumer's Behavior

Perceived control in psychological research has been found to exert influence on a wide set of responses. As noted by Skinner (1996, 556), "when people perceive that they have a high degree of control, they exert effort, try hard, initiate action, and persist in the face of failures and setbacks (...). When people perceive control as impossible, they withdraw, retreat, escape, or otherwise become passive; they become fearful, depressed, pessimistic, and distressed." Briefly, it is acknowledged that when people are exposed to uncontrollable environments, they exhibit a variety of negative behavioral responses. In contrast, when they believe that they can personally control the environment, their performance is less affected.

As a multidimensional concept, perceived control in consumer research has been related to many constructs. When referring to the LOC, it has been found to have a significant influence on search (Srinivasan and Tikoo 1992), internals perceiving greater benefits to search and find the purchase process less stressful. It also has influence of the service encounter evaluation: when customers

perceive the cause of service failure to be within the control of the firm, they will be more dissatisfied than when the firm is perceived to have less control (Leong, Ang and Hui Lin Low 1997; Van Raaij and Pruyn 1998).

Despite studies referring as perceived control through the LOC or through the more specific perceived behavioral facet (Kidwell and Jewell 2003; Lwin and Williams 2003; Nysveen, Pedersen and Thorbjornsen 2005; Kang et al. 2006), the largest segment of consumer research on perceived control refers to dominance, especially in retail and service setting literatures. Perceived control has been found to have an impact on consumer self-confidence (Bearden, Hardesty and Rose 2001), pleasure (Hui and Bateson 1991), mood, involvement (Ward and Barnes 2001), satisfaction (Wathieu et al. 2002; Navasimayam and Hinkin 2003) and intention to behave (Mathur 1998). In retail studies involving either crowding (Dion 2004; Van Rompay et al. 2008) or arousal (Lunardo and Mbengue 2009) as aversive stimuli, perceived control has also been proved to be related to stress and coping strategies. Results show that no simple relationship exists between perceived control and stress, along with Averill (1973, 300-301) who suggested that "the stress-inducing or stress-reducing properties of personal control depend upon the meaning of the control response for the individual".

Although significant results have been found out, two major criticisms can be raised. First, studies rely on measures of dominance that have been rejected by several researchers due to lack of psychometric qualities. Second, quite surprisingly, studies investigating the effect of control do not consider if the control is actually desired by consumers. The next section addresses these issues.

THE NEED FOR FURTHER RESEARCH

Given that perceived control is not well understood, and often misunderstood, there is a pressing need for further research. The remainder of this article sets forth a series of issues that collectively can serve as the foundation for a perceived control research agenda. Two main future research directions are presented. The first relates to the conceptualization and operationalization of perceived control, the second to the need to consider individual differences in the desire for control. These issues impact the theoretical framework within which future studies will be designed.

Beyond Perceived Control as an Emotion in Consumer Research: Interests and Limitations

Although the dominance has proved useful in the contexts for which it was developed, several limitations in its application to the consumer research must be recognized. It is our position and the position of other authors (Russell and Pratt 1980; Yani-de-Soriano and Foxall 2006) that dominance is not always an appropriate operationalization of the perceived control concept. This conclusion is based on four main considerations, all relying on that perceived can not only be viewed as an emotion.

First, in the wide range of usages of the expression "perceived control", it is often referred to as a belief. According to Skinner (1995), the term "belief" is appropriate since it is open to revision. Beliefs can refer to the future or the past, and be used at any level of generality from the most situation specific to the most global. Since emotions are transient phenomena, they cannot refer to such beliefs, and thus can not refer to perceived control.

Second, when defined as an emotion, perceived control is not seen global but rather context specific, and would differ according to contexts. As such, it can only refer to specific situations and not at a more general level. Thus, while general consumer's perceived control should be able to predict tendencies, consumer's dominance would only predict more specific responses.

Third, Clore, Ortony, and Foss (1987) excluded from the domain of emotion those descriptors that refer to subjective evaluations of people. However, in the psychological literature, perceived control widely refers to subjective evaluations. For instance, locus of control can be seen as subjective beliefs about the extent to which certain causes lead to success and failure, and perceived behavioral control refers to the subjective evaluation of being able to adopt a behavior. Thus, if subjective evaluation can not be conceptualized as emotions, nor can perceived control.

Fourth, when perceived control is considered an emotion, researchers use the 6-item dominance subscale of the Mehrabian and Russell's (1974) PAD model (Pleasure-Arousal-Dominance). Notwithstanding its popularity and widespread application, the dominance subscale has been subjected to a number of theoretical and operational criticisms (Yani-de-Soriano and Foxall 2006). Two main problems regarding the use of dominance as a measure of perceived control remain unresolved. First, as mentioned by Yani-de-Soriano and Foxall (2006), Russell (1978) did not find support for dominance. About 46% of the variance in dominance could be predicted from the other two emotions (pleasure and arousal), leading to consider dominance as confounded with pleasure. This overlap between dominance and pleasure makes dominance be in the PAD the factor that contributes the least to variance in approach-avoidance behavior, accounting only for 14% of the total variance while pleasure accounted for 27% and arousal for 23%. Those problems have led numerous researchers to eliminate the semantic differential format (Babin and Darden 1995), to delete items from the original scale to replace them by ad hoc items (Donovan and Rossiter 1982), to create their own scale (Hui and Bateson 1991), or even to delete the variable in their study (Donovan et al. 1994). Second, the validity of the scale in assessing emotional responses to other stimuli, as interpersonal aspects of shopping, is not assumed (Yani-de-Soriano and Foxall 2006).

Thus, the conceptualization of perceived control as dominance poses research directions. It does not capture the complex nature of the perceived control concept, and its measure has not been proven of quality. However, operationalizing perceived control not as dominance but as a multidimensional concept would also pose research directions. First, because of the multiplicity of perceived control constructs, people may have complex understandings of the many facets of control. Thus, in terms of measurement, researchers should be explicit in their assessments of control if they want to operationalize their constructs successfully. For instance, researchers may be willing to use items like "Did you have any control over outcome Y?" or "To what extent did you feel you had control over outcome Y". Such measures may result in answers that reflect different constructs, such as perceptions of control, a sense of effectiveness, or even, when the outcome is negative, feelings of responsibility or self-blame (Skinner 1996). Thus, researchers should precise if they aim at measuring global or specific dimensions of perceived control. To cope with this problem, researchers may use one of the different measures of facets of perceived control. Among the three distinct dimensions of perceived control identified by Averill (1973), behavioral and cognitive controls are dimensions for which a scale already exists. Regarding perceived behavioral control, Ajzen (2002, 6) provides a list of scales for which the internal consistencies or reliabilities range from 0.61 to 0.90. Concerning cognitive control, Faranda (2001) developed a 7-item, two-dimensional and reliable scale (a dimension of self-control with an alpha of 0.82 and a dimension of informational control with an alpha of 0.93). To date, only the decisional dimension cannot yet be measured due to a lack of measure of quality. This analysis of marketing studies that assessed perceived control suggests that it is possible

to obtain reliable and valid measures of perceived control, but this is not assured and care must be taken in the formative stages of the research to explicitly formulate what form of perceived control the researchers aims at measuring.

Does Everybody Want to Control? The Need to Include Individual Differences Variables in the Desire for Control

Not all individuals react identically to issues of personal control. Although most individuals have a strong desire to obtain control over important environmental outcomes, individual differences in the motivation for control exist. As noted by Burger (1989), consumers may sometimes not desire feeling in control over specific situations. This desire for control has been defined as “a stable personality trait reflecting the extent to which individuals generally are motivated to control events in their lives” (Burger 1985, 1520). As pointed out by Burger and Cooper (1979), these individual differences in the motivation for control should help account for variation in behavior. According to them, individuals high in the desire for control are more assertive, decisive, active, and seek to influence others when such influence is advantageous. They prefer to avoid unpleasant situations or failures by manipulating events to ensure desired outcomes. On the contrary, individuals low in the desire for control are generally nonassertive, passive, indecisive, and are less likely to attempt to influence others and may prefer that many of their daily decisions be made by others.

In consumer research, desire for control has been shown to affect behavior, especially when linked to locus of control. For instance, in a lottery context, because individuals with an internal locus think they have the ability to affect the outcomes of events in their lives, they are more likely to perceive ability to influence lottery outcomes by choosing winning numbers. As a result, they are more likely to continue to play a lottery in the face of losses (Sprott, Brumbaugh and Miyazaki 2001).

However, only a few researchers included desire for control in their studies. For example, in the study of the impact of human and spatial density on the consumer's emotional and behavioral responses, only the study of Van Rompay et al. (2008) among a wide number of studies on this topic (Dion 2004; Eroglu and Harrell 1986; Eroglu and Machleit 1990; Eroglu, Machleit and Chebat 2005; Machleit, Eroglu and Mantel 2000) explicitly included the desire for control to explain the influence of control. The authors showed that the effects of human and spatial density vary with consumers' desire for control: consumers high in desire for control react to high human density with negative affect and less approach behaviors, whereas consumers low in desire for control do not respond with negative affect. Not explicitly including the desire for control construct but the motivational orientation, Lunardo and Mbengue (2009) found out similar results in a study examining the impact of perceived control on shopping behavior. Since utilitarian consumer behavior has been described as task related, the authors suggest that utilitarian-oriented consumers prefer stores in which the environmental stimuli enhance their feeling of control. From a field study, their results showed that for highly utilitarian-oriented consumers, a perception of lack of control leads to an increase in stress, while this effect is not exhibited for low utilitarian-oriented shoppers.

CONCLUSION

Even though widely discussed, perceived control is not well understood, and the term itself is often abused and misused. In psychology, the expression “perceived control” can either refer to locus of control, self-efficacy or the multidimensional concept of perceived control. Such a case in which the same term is used

to refer to very different constructs is confusing, and may lead to ambiguous results in research. In consumer behavior, researchers mostly rely on Mehrabian and Russell's (1974) dominance, the extent to which an individual feels in control over his environment. By defining perceived control in this manner, the definition can be used by retailers for which the influence of the store environment on consumer's perceived control can be of great importance. However, problems related to this conceptualization still exist. Thus, the purpose of this paper was to outline an agenda for further research around the theme of consumer's perceived control.

Two future research directions were presented, one dealing with the emotional conceptualization of control, the other addressing the need to include individual differences in the “desire for control”. Considering the issue of measure, future research should address an underestimated aspect of perceived control in consumer research, the discriminant validity of the construct. Research should explore how perceived control differs from a number of similar constructs already under scrutiny in consumer behavior, such as self-confidence, or persuasion knowledge. The development of scales aiming at measuring perceived control over specific stimuli also warrants consideration. This would allow perceived control to be included in consumer research to explain how marketing stimuli may lead to a feeling of being controlled offers an interesting area for additional research. In retailing research, it would lead to a better understanding of the conditions under which atmospheric stimuli such as music, color or scents may increase consumer's feeling of being controlled by the retailer through the atmosphere. This issue is especially important considering the numerous stimuli used by retailers to control consumer's behavior in the servicescapes (Bitner 1992).

Considering the individual differences in the desire for control, Von Rompay et al. (2008) found that desire for control moderates the effects of human and spatial density on perceived control, which in turns affects consumer's behavior. It would be of interest to determine whether consumers with higher desire for control, as compared to those with lower levels of desire for control, are more willing to adopt approach-behavior when feeling in control over other stimuli than density in retail settings. Further, the effect of stimuli in online settings could be investigated to get a deep understanding on their effects on perceived control and behavior.

Exploring Consumer Forgiveness In Service Failures

Yelena Tsarenko, Monash University, Australia

Yuliya Strizhakova, Rutgers University, USA

ABSTRACT

Despite the significant increase in service failures, little attention is given to understanding the notion of consumer forgiveness. Drawing upon 15 in-depth interviews with consumers across three service industries, we discuss three main discourses of consumer forgiveness. Our research offers a novel perspective on the way consumers frame and interpret unsatisfactory service incidents.

INTRODUCTION

Instances of services failures have become more abundant and severe in recent years, resulting in traumatizing experiences for consumers. Companies dealing with failures utilize their best PR practices to mitigate public criticism; however, much less attention is given to consumers and their experience of failures in such circumstances. Specifically, the question that business practice and research has been largely neglecting is: how do consumers forgive service providers for their mistakes? Although forgiveness has attracted a growing line of inquiry within such fields as psychology, moral development, philosophy, psychotherapy and political studies (Mellor, Bretherton, & Firth, 2007; Rosser, 2008; Shriver, 1995), consumer forgiveness still remains largely unexplored.

What stands behind such a familiar and at the same time elusive concept as forgiveness? There are various conceptualizations of forgiveness; yet, no accepted definition has been consistently adopted. One definition of forgiveness proffered by Enright, Gassin and Wu (1992) states: "as the injured party ceases fighting against the other and gives him or her the unconditional gift of acceptance as a human being, the former is said to be forgiving" (p.101). Forgiveness is understood to be a process of decreasing "inter-related negative resentment-based emotions" (Malcolm & Greenberg, 2000), associated with "motivation/behavior" (McCullough, Sandage, & Worthington, 1997) and "cognition" (DiBlasio, 1998) and is predominantly studied as one of the ways by which individuals respond to stress.

There is a general consensus that forgiveness is a complex process that evolves over time rather than a straightforward response to an incident. It forms a part of the life cycle of an incident that involves many steps (Thoresen, Harris, & Luskin, 1999). The main component of this complex process of forgiveness is the transformation of negative emotions, although debates exist about the extent of this transformation (Exline, Worthington Jr., Hill, & McCullough, 2003). Forgiveness is also regarded as an intended, deliberate activity and not merely a dissipation of negative emotions (Karremans & Aarts, 2007; McCullough, Fincham, & Tsang, 2003), driven by decreased intentions to avoid the offender and seek revenge and by increased good-will toward the transgressor. The main motivational drive of forgiveness lies within the offended party: it is one's intention to rediscover self and reclaim the future for oneself (Holloway, 2002). Forgiveness is also distinct from forgivingness: the former is a transgression-driven process, whereas the latter is one's general predisposition to forgive. In addition, the complexity of the forgiveness process varies based on the type of relationship, the nature of a transgression and steps undertaken by a transgressor to seek forgiveness.

The primary goal of our research is to explore the role of consumer forgiveness with a deeper focus on how consumers understand, conceptualize and practice forgiveness in business settings. Even though we situate consumer forgiveness within

the broader process models of forgiveness discussed above, we contribute to prior research by examining forgiveness as a distinct consumer process. Specifically, we develop a theoretical framework of consumer forgiveness by identifying three idiosyncratic discourses of consumer forgiveness. Discourses reflect the social and political aspects of language and subjectivity as well as influence an individual's interpretation of the world and its phenomena (Bristol & Fischer, 1993). Drawing upon in-depth interviews with 15 victims of service failures, we highlight three interpretive meanings – self-healing, reconciliation, and disappointment – that guide consumer discourses of forgiveness. Not only does our research bring the concept of forgiveness to the consumer domain, but also, and most importantly, it develops distinct interpretations of *consumer forgiveness*, derived from the nature of provider-consumer relationships and marketplace constraints. The three discourses of consumer forgiveness identified in our research provide a basis for the theory of consumer forgiveness and have vital implications for future academic research and managerial practice

METHOD

Data was collected through in-depth interviews with informants recruited by a market research agency. The screening criterion for the interview was that participants had experienced a service failure at least six months prior to the interview. Service failures were drawn from three service sectors with a varying complexity and risk factors for consumers: healthcare, finance and retail sectors. A total of 15 in-depth interviews were conducted: fourteen interviews in the healthcare, thirteen interviews in the finance sector and seventeen in the retail sector. Written consent was obtained prior to the interviews; all interviews were audiotaped and documented by a professional transcription service.

The sample selected for our study was configured to provide a contribution to the generalization of the theory rather than to satisfy statistical principles. The process of recruiting additional respondents ended when theoretical saturation was achieved (Strauss & Corbin, 1998). Recognizing that human feelings, cognitions and motives are complex and ambiguous, the interview process required special preparation and structure to maximize the value of elicited information (McCracken, 1988). To avoid priming our interviewees on the subject of forgiveness, we constructed the dialogue in such a way as to gradually arrive at the topic of forgiveness. Each interview started with some general stories of consumer preferences and dislikes that allowed informants to naturally move to the second stage of the discussion, i.e., their experience of a service transgression. Interviewees exposed details of a negative encounter from its beginning to a resolution or its ongoing 'limbo' state. In some instances, satisfactory transgression resolution either did not exist or was not possible to achieve. The next stage of the interview involved a dialogical encounter between the interviewer and interviewee to obtain an understanding of the concept of forgiveness and its meaning and interpretation (Schwandt, 2000). To achieve such an understanding, we aimed to elicit a conceptualization of forgiveness that was produced by the informants (rather than reproduced as a normative conceptualization) through a detailed conversation with informants about the feelings and emotions they experienced when facing issues in their daily lives. Because respondents were not primed in advance to discuss 'forgiveness', the ensuing conversations about emotions and forgiveness very often prompted them to

share personal and sometimes very private accounts of situations in which they had offered or withheld forgiveness or had sought (successfully or otherwise) forgiveness from another party. This approach enabled participants to produce an account of 'forgiveness' according to the particular interpretation and meaning they ascribed to the concept.

Preliminary analyses were undertaken after documenting the initial verbatim transcripts to inform and modify subsequent interviews. This process involved assessment of transcripts to gain an insight into the scope of the content and emerging themes. Initially, two researchers independently read, reflected upon, and conducted a preliminary interpretation of concepts derived from the transcripts. Subsequently, after extensive discussions, a detailed data analysis and classification of categories were carried out using NVivo 8.0. Themes and concepts that had emerged were subsequently refined for axial coding. We undertook an iterative process that involved consulting multidisciplinary literature on forgiveness and interpreting the concepts and themes constructed by participants.

FINDINGS

Individuals' striving for an emotional balance and harmony guides their trajectory of forgiveness. Boundary conditions that are pertinent to business settings (e.g. extended service recovery, ease of switching to another service provider, allocation and distribution of power in the business relationship, etc.) shape and determine the way in which consumers deal with transgressions. In this section, we highlight similarities and emphasize differences in the process of consumer forgiveness by elaborating on three idiosyncratic discourses of consumer forgiveness.

The Discourse of Self-Healing

The discourse of self-healing suggests that self is a dynamic concept that is central to internal organizing principles of psychological functioning (Wilson, 2006). In the modern, fast-paced, hyper-active Western society, filled with stress and constant uncertainty, self-healing courses and mediation programs have attracted an unprecedented interest (Askegaard & Kjeldgaard, 2008). The popularity of these self-healing courses stems from a biological desire for self-preservation and survival. It also explains why many informants approach forgiveness as a healing process which does not always result in a restoration of relationships with service providers, but rather has an enormous self-healing impact upon the injured party.

I read a lot of books on positive thinking and self help and there're hundreds of books at home. So in the books they sort of say that if you forgive others, you can forgive yourself because you're only hurting yourself and I realise that "well ,hang on, that's true" because they're probably running off doing their own thing in their own life and not thinking two thoughts about you. But you're here two years later with things that are holding you back...so even if you don't get that apology, you have to do a bit of work and say "I'm hurting myself here" because you're not setting yourself free.[Linda]

Linda's statement succinctly summarizes three prevailing aspects of the self-healing discourse of forgiveness: the injured party's strong internal focus on self-healing, an unsatisfactory outcome with the transgressor, and the salient role of spirituality. Many informants concur that forgiveness is inextricably intertwined with the healing process. Susan, a physiotherapist, offers her professional perspective on the healing virtue of forgiveness when discussing

her dealings with an insurance company that refused coverage of some medical expenses.

I suppose you can say that I have forgiven it; I've just let it go. When people don't forgive, they get very bitter and hold on to negative feelings or thoughts, which can become destructive. Life's too short to be holding negative anger. People get really bitter and I know from a health perspective with my industry that a lot of illnesses and disease can come if people bottle things up and store it inside and get angry and don't forgive and let go. [Susan]

She acknowledges her expectations of the service recovery and emphasizes the fact that no recovery was offered in her case.

Nothing was given to me. They didn't address the fact that this girl told me the wrong information and it was her first day. She sort of acknowledged that but didn't say "I'm sorry". There was actually no apology. [Susan]

Many informants agree that the forgiveness process is a result of an internal motivation to maintain positive physical and psychological well-being. Forgiveness emerges as pursuant to mending the consequences of harm. The self-healing power of forgiveness is evident in Karen's account of dealing with her mother's hospice care. It resonates with her other strategies in life driven by the same goal of self-preservation, such as her active engagement in water aerobics and other exercises, the value she places on slimming and toning, and growing her own vegetables.

I think it's better for you to forgive. I think because if you don't forgive after a while, you will make yourself into a harder person ... but I don't always put that into practice but that's what I think. I think first of all you get angry and then you think to yourself, it's better for you if you can forgive. I think you have a better type of life if you can forgive people and realise that everybody has got their business.[Karen]

Karen's discourse is filled with juxtapositions of the self-healing virtue of forgiveness with reflections on how hard it is for her to arrive at forgiveness. Karen has learned to forgive but it does not come naturally to her. She also believes that being "a happy person" makes people forgive easier.

Informants who express the self-healing discourse of forgiveness often emphasize that spiritual/ religious beliefs and practices are central to their attitudes, motivations and behaviors when dealing with stressful service failures. For example, Sandra who faced a dilemma with the return of merchandise recognizes that it is easier for her to forgive now than it was several years ago.

It's a little bit easier for me the last few years, because I'm a member of a religion which is called [...]. It's one of the spiritual teachings that you don't hold things against another person and you actually try to find out the reason in yourself. [Sandra]

The post-injury phase and the question of how to deal with the transgression lead to an introspective analysis of one's internal state that includes values, desires, beliefs, and emotions. At this point, one's system of organization of self is challenged; i.e., an individual faces the dilemma of finding the meaning of self in a

stressful encounter and initially seeks remedies to maintain or preserve the status quo. However, as the stressful encounter unfolds, the process of reconstruction of self begins. Such notions as self-worth and self-confidence are at a crossroads, marking a new stage of rediscovering self. In light of this, the self has the capacity to change the existing situation either via positive transformations or by engaging in self-defeating or self-destructive behaviors. Forgiveness often becomes the only remedy, the only self-healing tool when a customer's stress is not appropriately addressed by the provider.

The Discourse of Reconciliation

The second discourse of forgiveness reflects consumer reconciliation of experienced negative emotions with justifications for the transgression. In other words, reconciliation is an internal process driven by one's emotional states and cognitive elaborations rather than an external reconciliation between parties. It should further be noted that forgiveness, while not equivalent to reconciliation between parties can, in some instances, promote it. In this case, forgiveness as a coping strategy helps to reduce stressful reactions to a transgression and may increase one's motivation to pursue relationship-constructive actions toward the offender.

Well, [forgiveness] means that I've got a compassionate side to me or an understanding side to me, things aren't just black and white, things can be grey. Because I understood the overall situation. You can't blame one person, unless it was a personal fault or they did something on purpose. That's when I don't like it, but if they simply forgot something, well, that's human. Yes, everyone has emotional problems and just because I was treated badly on one occasion doesn't mean that I wouldn't use them again. I'm not like that. [Frank]

Frank's statement summarizes several salient aspects of forgiveness as reconciliation of self and the transgression: attribution of blame for the transgression, cognitive elaborations on the transgression, and the role of one's personality in this process. As evident from Frank's account, forgiveness is achieved by understanding and weighing all possible causes for the wrong and accepting that wrong was unintentional. Frank maintains a broader perspective on his mishap with a malfunctioning new TV set that cost him extra money to have delivered to his house and back to the retailer for the repair: the failure was a result of a combination of factors that extended beyond one person's negligence. Frank does not attribute blame for the mishap to the retailer or the manufacturer. Controlling his impulse to respond to the service failure with an emotional response and engage in name-calling the transgressor, Frank combats his negative feelings and replaces them with cognitive elaborations that reflect his intention to internally reconcile the issue. In reconciling his anger with the transgressor's role in the incident, Frank recognizes the role of human factors in the service failure; however, he is not quick to jump to the conclusion that his relationship with the service provider is over. He takes a balanced approach whereby he controls his emotion and is trying to keep the situation in perspective.

The discourse of forgiveness as reconciliation is particularly prominent among informants who discuss their experiences with transgressions in the healthcare industry. On the one hand, hospital overcrowding and nursing understaffing have been frequently cited as a classic area of service failures where problems can only be exacerbated (Berry & Bendapudi, 2007). On the other hand, the nature of health services is involuntary; in itself healthcare is already associated with greater uncertainty, fear and vulnerability. In addi-

tion, the stakes of errors are very high and may be life-changing. This apparent controversy influences the way individuals differ in their attribution of blame. While some are ready to pursue litigation, others attempt to transform their negative experience and take a more balanced approach in their evaluation.

I forgive because I know people are human and I know they don't have enough funding, I know they don't have much money and I know that a lot of them are doing the best they can do but when you – I think a lot of people can forgive but you don't forget; it stays with you so if it happens again, it's always there and it's always that worry that you're going to get stressed; are they going to look after my kids? [Carol]

Despite forgiving, informants in the health industry are not capable of forgetting the incidents because of the very high stakes of such errors. Unless constrained by insurance or geographic location, most informants do not envision seeking future services with providers at fault. Carol's discourse is filled with reconciling themes: empathy for the provider driven by her knowledge and respect for the doctors and anxiety about her future with the provider. Similar to many other informants, Carol reconciles the transgression and forgives the provider both cognitively and emotionally; however, her behavior toward the provider is likely to remain avoidant because of the experienced high stakes of the transgression. Carol's excerpt reveals not only the ubiquitous nature of forgiveness in modern life, but also separates forgiveness as a motivational process, distinct from forgetting.

The most complex cognitive elaboration on the provider failure is found in Sharon's account:

I just need some answers and I respect you [surgeon] enough to provide that in a way that I can understand. So yeah, it wasn't going anywhere making me feel with the intent to degrade his ability or his knowledge or his experience. It wasn't that at all because we're talking about one of the most prominent brain surgeons in the state, I guess. It was more his attitude wasn't very nice but at the end of the day, I think he respected me for that and we had a nice sort of – we understood each other. I think he respected me for taking him on but not on a professional level otherwise I would never have done it. [Sharon]

Sharon's family was shocked when her father had a stroke during his surgery that left him half-paralyzed. In order to come to grips with and comprehend that trauma, Sharon and her family needed a detailed explanation of what had happened during the surgery. However, the elicited information was clouded by medical jargon without any proper acknowledgment of their loss. In her account of forgiveness, Sharon faced the dilemma of having to acknowledge the skills and expertise of the surgeon while challenging his interpersonal skills and his attitude to the members of patient's family. Despite the surgeon's apparent lack of empathy and the transactional nature of the business relationship, Sharon was attempting to relinquish her self-righteous and judgmental attitude that separates the injured party from the transgressor (Exline, Campbell, et al., 2004; Tangney, 2002).

In thinking about forgiveness, our informants often discussed their understanding of the positions of the transgressors, which in Amy's case comes from her observation and contemplation of the positions of the service providers:

But then again, the customer probably doesn't understand what they've [personnel] been through in the day. I think that a lot of customers do feel like they're the only customer and they expect to be treated like they're the only person but I suppose well, they're supposed to be serving you or whatever and maybe people have got a right to feel a bit special but then some people expect too much, I think [Amy]

Amy is able to empathize with the pharmacy and its personnel in particular, despite the loss of her prescription. Being sick and elderly, she felt very frustrated with her situation but she made a conscious attempt to remain positive and retain some compassion and understanding of the service personnel. In other words, she was reconciling her frustration with the failure with her empathetic feelings toward the provider.

The Discourse of Disappointment

Some consumers projected feelings of disappointment with service providers at large onto a given failure; hence, one failure resonated with a spectrum of failures they expected from providers and resulted in lowered negative emotions. Consumer forgiveness in such cases is driven by one's disappointment with the whole service provider system and is achieved through cognitive elaborations that compare an individual incident with one's expectations of the general social system. In other words, metaphorically, forgiveness as disappointment is "when goodness goes beyond virtue and evil beyond vice" (Arendt, 1963).

I went back [to the lab] and it was convenient and I did forgive. I thought it's happened once, okay, they probably didn't fulfil my obligations of how I would have rectified the situation, but then I didn't have high expectations of them being a health provider. I'm not really happy with the health care. On the other side, I probably need them more than they need me. So it's a little bit different so hence going back and forgiving them and to be honest, I'm glad that I did. [Irene]

Consumer discourse of forgiveness as disappointment was driven by a feeling of inequitable power between self and the "big institution", marketplace constraints and an astute sense of betrayal. Irene's path to forgiveness lies in a web of ambiguous thoughts driven by her disappointment with the whole healthcare system. Because of a mix-up of blood test results, she was given a false positive diagnosis that caused anxiety and fear. She had to undergo the whole process all over again. Undoubtedly, Irene questioned the accuracy of results each subsequent time. Moreover, she was sent an invoice at home stating that she had to pay \$80 for this test which was supposed to be covered through the government-sponsored healthcare system. Irene acknowledges the mishap, but further elaborates that recovery did not meet her standards. However, she did not have high expectations; instead she replaced them with her diminished view of the importance of the system. Forgiveness stems from Irene's disappointment with the whole system and her greater need of this particular service provider in contrast to her own value to the provider. In Irene's statement, it is evident that forgiveness is a highly motivational process which occurs as an integration of strategies designed to produce a desired outcome but this motivational process is marked by an asymmetrical relationship and market constraints rather than by gracious and dignified feelings.

In the passage below, Brett who did not receive an appropriate explanation about fees on his account describes his forgiveness of a financial institution as a "selfish act". His disappointment with the banking system resonates with broader consumer descriptions of banking services: traditional and ordinary but, as Arendt (1963) puts it, "banality evil". Financial institutions are services where customers often feel alienated, unprotected and without much control over their relationships with them. The provider-customer inequality is further aggravated by the sheer size and monetary power of these establishments.

...but it's just a small guy fighting a big bank. I didn't feel like I was treated as an individual. They don't have to fight for your, um - loyalty, I suppose and retention. I've forgiven for sure - selfish once again, you know, okay, but if I've had a bad experience, I'm going to tell people through conversation. I wouldn't recommend them to go to that - that shop, that branch, whatever. But I'd forgive only on a monetary, selfish way. I mean, I've still got my credit card with them and the savings account with them, you know. So I've probably forgiven the bank indirectly. [Brett]

The impersonal service that is provided when consumers do not feel valued or cared about is largely a norm rather than an exception, it is a default mode of operandi underlying the asymmetry in this relationship (La Caze, 2008; Young, 1997). While service provider-customer relationships remain unproblematic, there is no explicit need to re-evaluate the positions of each party. Once the conflict emerges, the differences between parties become more salient and their positions become more diverging. Such a state leaves the consumer with little to no choice but to embrace forgiveness as a defensive mechanism to retain their own human side. Brett considers his forgiveness as a selfish behavior, emphasizing the monetary, not emotional, value of his forgiveness (i.e., his ability to continue using the credit card and earning interest on a savings account).

Assessment of market constraints, particularly in the health service industry where the number of options is relatively limited, forces consumers to embrace forgiveness in light of their needs. Jane explicitly states that she not only contemplates forgiveness but also her preparedness for further patronage of this particular hospital. This sense that you need the service more than the service needs you dominates the approach of how consumers forgive the service failure.

I can forgive and I will consider going back there because there's not many other hospitals to go to. [Jane]

In contrast, Harry's path to forgiveness is driven by his disappointment with the whole banking system and is overshadowed with the feeling of betrayal. His debit card was not returned by an ATM machine in a foreign county and his bank was not able to replace it in a timely manner, leaving him only with one credit card but no access to his bank account on a multi-country trip

When I was overseas when I needed them the most - that's what I said to her "when I needed you the most, you let me down" so it would have been nice to have the bank help me when I needed them. I'm still banking with them and I've been banking with them for a very long time as well, so I haven't decided to take my business elsewhere. I think I would only be replacing them with

pretty much the same thing because it's probably the same. So obviously, I've forgiven. [Harry]

Harry doubts the efficiency of other financial institutions. He does not see the point of replacing one "locked-in" relationship with another one of the same quality and value. Harry declares his forgiveness; however, this is no more or less than a discrepancy-reduction strategy.

DISCUSSION

Consumer forgiveness is a complex process that involves emotional transformations, cognitive elaborations and behavioral expressions. Through three distinct discourses, we show how consumers intrinsically deal with negative incidents in their consumption practice. Affective, cognitive and behavioral aspects of forgiveness are untangled through delineating three main discourses of forgiveness as self-healing, reconciliation and disappointment. Discourses unveil how consumers construct, understand, and interpret their forgiveness process.

Our findings demonstrate that consumer forgiveness, apart from being internal, is a highly motivational process that is influenced by both internal and external forces. For example, self-healing and reconciliation are driven by internal motives when consumers rely on internal strength, values and beliefs in their accounts of forgiveness. The influence of the service provider is important but not essential in order for consumers to forgive. These discourses at large correspond with both emotional and unconditional forgiveness in psychological research (Worthington, 2006). Self-healing discourse is associated with the way consumers replace their negative emotions with neutral or positive ones, regardless of the actual problem resolution. In a similar vein, reconciliation is aimed at one's emotions and the incident at hand. Reconciliation of negative emotions elicited by the transgression and their transformation into more empathetic feelings occurs through extensive cognitive elaborations, attribution of blame, and appreciation of a personal factor in which the offended party steps beyond the transgression in an attempt to justify it. It is based upon available body of knowledge on human mistakes and their causes. Hence, the discourse of forgiveness as reconciliation is characterized by elaborated cognitive processes that reconcile one's negative affective states with one's humanity to understand why mistakes happen in the first place.

Finally, the discourse of disappointment is likely to be unique and relevant to institutional relationships: it is driven by marketplace constraints, a sense of betrayal and a perceived asymmetry of the relationship. Consumer forgiveness stems from a resonance of one transgression with an overall view on business relationships that are shaped by inequality and betrayal. In contrast to other discourses of forgiveness, forgiveness as disappointment does not result in any positive emotions, but rather, reduces immediate anger and frustration with less negative disappointment. Forgiveness emerges as an individual's survival response to external constraints and institutional powers rather than as an internal virtue.

It should be noted that although in this study discourses of consumer forgiveness are presented as distinctive interpretive frameworks, in reality more than one discourse may shape the consumer forgiveness process. Service failure contexts, marketplace constraints, and individual differences impact the salience of each discourse in individual accounts. Overall, by situating our research within broader process models of forgiveness in psychology and applying the discourse analysis methodology to our interviews, we are able to highlight the multi-faceted nature of consumer forgiveness and provide a foundation for future theoretical advances in this new frontier.

Big Ideas on the Contribution of Brands to Consumers' Lives

Sandy Bulmer, Massey University, New Zealand

Margo Buchanan-Oliver, University of Auckland, New Zealand

ABSTRACT

Concepts from adjacent fields are used to show that brands contribute to feelings of belonging to national communities. We propose that national identity is a significant, overlooked form of community. Studies of brands and national identity have clear potential for adding new insights into how consumers use brands.

INTRODUCTION

Brands are ubiquitous. It is almost impossible for consumers to avoid exposure to brands via traditional advertising media, publicity/public relations activities or in-store display and promotional programs. Furthermore, new digital models of communication are extending the reach of brands into consumers' lives through social media, user generated content, brand websites, advergames, e-mail based viral marketing, SMS and mobile marketing etc. Despite being pervasive, brands are not usually considered to affect society in any significant way. Certainly, brands are not commonly credited with contributing to productive and enabling forces within society, and in the popular media little is heard about any positive contributions that brands make to society in general. Indeed, for many consumers, admitting that brands have social use or cultural relevance is tantamount to declaring moral bankruptcy and intellectual shallowness.

Within consumer research literature, there is still much to be learned of what consumers DO with brands, and the experiential dimensions of brands are poorly understood. Many scholars and researchers deploying diverse methodologies have contributed to understanding concepts of branding (see, for example, Aaker 1991; Fournier 1998; Kapferer 1997; Keller 2003; Muñiz and O'Guinn 2001; Schouten and McAlexander 1995). Fournier's landmark article on consumer-brand relationships (1998) boosted the process of addressing these issues. Nevertheless, the contribution of brands to the lives of consumers—and the communities they are part of—is under-researched, although concepts of community have been popular amongst consumer researchers in the past 15 years (Arnould and Price 2000; Cayla and Eckhardt 2008; Cova 1997; Fournier 1998; Kates 2004; Kozinets 2002; Mathwick, Wiertz, and de Ruyter 2008; Muñiz and O'Guinn 2001; Schau, Muñiz, and Arnould forthcoming; Thompson 2005).

New forms of community enabled by technology, such as online brand communities, have been documented (Cova and Pace 2006; Muñiz and Schau 2005). These exemplify the kinds of imagined communities originally described by Benedict Anderson in his reflections on the origin and spread of nationalism (Anderson 1983). Anderson developed his ideas based on the impact of print media, particularly newspapers, and added to Marshall McLuhan's media thesis that widely disseminated standardized stories, consumed in common, serve to unite people (McLuhan 1962).

The power of mass media to both constitute nations and draw communities together is widely accepted in cultural studies, political science, journalism and mass-communication literature (Askew and Wilk 2002; Frosh 2007; Millard et al. 2002; Moreno 2003; Prideaux 2009). These researchers are in no doubt that advertising produces nationalism and informs the process of conceptualizing a nation. In essence, other literatures suggest that advertisements contribute to national identity. However, researchers in consumer research and marketing have not yet made the logical extension of this argument. If brands typically sponsor such advertisements, then

how do brands affect national identity? And why might national identity matter to marketers and consumer researchers anyway?

A popular position taken by observers is that national identity is an irrelevant construct nowadays, since many consumers (at least in advanced economy countries) have an external focus and global outlook. Globalization commentators such as Stalnaker (2002) suggest that national identity is an outmoded concept and posit that today's urban consumers belong to a global class not limited by race or dominated by national identity, but by what they like, what they want, and what they are willing to pay for. However, others suggest that the very processes of globalization are partly responsible for an apparent increase in the importance and significance of ethnic and national identities. Paradoxically, consumers have multiple allegiances, simultaneously belonging to a stateless global class and having a heightened sensibility of national identity.

Multiple quests by consumers for local, trans-national and global identities are explained by the post-modern perspective. Firat and Dholakia (2004) suggest that the chaotic fragmented lives that people lead give rise to a desire for meaning and substance. "The consumer transforms from someone who belongs to a culture, society or a lifestyle to someone who actively negotiates one or more communities—an active cultural constructor" (Firat and Dholakia 2004, 10). According to this view, national identity is a dynamic collaboration between community members that is not reliant on tradition but is built using resources from the imagined present. It is assumed that people hold multiple identities and utilize each as required, so that simultaneous membership of nations within nations, ethnic and racial groups is not discounted. There is no necessity to commit oneself to a single way of being; individuals will take on various identities at different times and situations as it suits their needs.

Ethnic and national identities are key elements in social identity and categorization today, essential for maintaining self-respect, belonging, a sense of security and giving people meaning in their lives. In some national communities there is a long established and confident sense of national identity. In these communities national identity is not necessarily subject to widespread commentary but, as Billig (1995) suggests, reference to national identity may be so embedded, familiar and continual that it is not consciously registered.

A review of the literature in several specialist journals devoted to the study of nations and identity including *National Identities*, *Nationalities Papers: The Journal of Nationalism and Ethnicity* and *Social Identities: Journal for the Study of Race, Nation and Culture* points to numerous contemporary contexts where national identity is being actively negotiated and is relevant and important. Clearly, many national communities struggle with their unique identity, possibly grappling with issues of colonization and indigenous populations, recent establishment and linkages with other nations or economic communities, ethnic diversity and the effects of biases in immigration policies—in this we include the European Union countries and others once part of the USSR and Yugoslavia, many African nations and countries such as Australia, Canada and New Zealand which are part of the (British) Commonwealth.

National identity is a creditable and relevant contemporary form of identification. Furthermore, a well developed and strong sense of national identity has the power to be a productive and enabling force within society providing positive social capital with benefits such as improved cooperation with others, improved information

flows and more effective, better functioning government and other democratic institutions (Aldridge 2002). With this in mind, government policy makers in many countries are actively looking for opportunities of building social capital by way of developing some shared sense of national identity and common talking points. The 'Picturing America' Program made available to schools and libraries across the United States through the National Endowment for the Humanities (NEH) is one such initiative. In other countries strategies such as 1) better funding public service broadcasting and the development of local programming and 2) expanding and enhancing the museum and library sectors to develop insights into national identity (including digital strategies for creation, preservation and protection of content) have been deployed in an attempt to assist community members to define who they are, what they believe in, and why they live in the place that they do. Ultimately, these strategies are underpinned by the provision of relevant narratives and imagery and by facilitating discourse within society—a default role that is played by brand communications.

In addressing the conference theme of big phenomena that are of real importance to consumers' lives, we present an argument that consumers use brands in hitherto unrecognized ways. We utilize conversations in other branches of social science to assist in drawing the reader's attention to an aspect of consumer experience that has not been considered in our field, despite the clear potential for adding insight (Deighton et al. 2010). The strategy of "poach[ing] and cross-fertiliz[ing] ideas, methods, and contexts from a variety of theoretical conversations that differentially address core topics" has much to recommend it as "theoretical insights and constructs from one paradigmatic conversation are reconceptualized and reworked in relationship to a different paradigmatic vernacular" (Arnould and Thompson 2005, 869). Our claim is that brands, through their marketing communications, contribute to important personal and collective identities, and to feelings of belonging to over-arching communities such as national communities. We provide support for the proposition that national identity is a significant but overlooked form of community and suggest that future studies relating to brands and national identity have clear potential for adding insight into the broad question of what consumers do with brands, particularly concerning brands as the focus of advertisements.

THEORETICAL BACKGROUND

Consumption, Symbolism and Experiences

Consumption, and the cultural symbolism surrounding it, is inextricably linked with aspects of self-identity and other dimensions of community, as has been shown in the consumer research literature for many years. Consumption is essentially a symbolic activity (Douglas and Isherwood 1979) and goods are consumed, in part at least, for the role they play in mediating and communicating meaning. The meanings assigned to goods whether simple or complex, perform a major function in key social and psychological activities such as identity formation, the maintenance of kin relations, belongingness and class structure (Jackson 2004). Consumption practices designed to enable communication between consumers are common to all social groups and communities. Social signaling is at the heart of consumption rituals such as those observed at special occasions, such as weddings (Otnes and Scott 1996), and in everyday activities, such as drinking a favored brand of beer with friends (Pettigrew 2002). Image management through consumption is maintained through scripted behaviors that hold special meaning for the participants and unique consumption practices ranging from gift giving to the use/wearing of particular objects and clothing (Otnes and Scott 1996).

The brands one consumes help define the self and therefore can help in the quest to be someone different and to be part of a group (Schouten and McAlexander 1995). The depth and power of the consumed brand's symbolic meaning within a social group can be seen when teenagers insist on wearing particular branded trainers that symbolize their desired personality, characteristics and reference group affiliation (Chaplin et al. 2005). Similarly, within the Harley Davidson owners' group (HOG), brand consumers authenticate their identity by performing a role and sharing experiences within a particular community of consumption (Schouten and McAlexander 1995). Furthermore, through their stories and symbolism, brands can assist communities other than those whose focus is consumption, helping in the outward expression and celebration of key values (Kates 2006).

Brands are experienced in many different ways and live as stories in the minds of consumers which contribute to "the range of identities that people can use to think of themselves" (Cayla and Eckhardt 2008, 226). According to Elliott and Wattanasuwan's (1998) model of Consumption and the Symbolic Project of the Self, brand purchase and usage experiences (lived experiences of brands) are complemented by brand advertising and other types of brand marketing communications (mediated experiences of brands). It is this mediated experience of the brand and indirect consumption, via storied audio/visual representations that we now focus on. For the purposes of this paper the argument we develop refers to brand advertising. However, other types of brand marketing communications are also anticipated to impact on national identity, especially publicity and sponsorship programs.

Brands as Resources

Brand communications are intended by producers, not only to provide information but, to enhance the direct experience of brand purchase and usage. Underpinning this view of advertising is the understanding that meaning is co-created. Using insights obtained from cultural anthropology McCracken (1986) advanced the view that advertising works by bringing the product and a representation of the culturally constituted world together in an advertisement, emphasizing the importance of the societal context that an advertisement is embedded in. The advertising consumer completes the work of the advertising producer and is the final author of the brand advertisement (McCracken 1986); thus consumers actualize the meaning of advertisements (presupposing that they make assumptions and have the knowledge to make texts meaningful) (Mick and Buhl 1992). The process of advertising meaning co-creation, mediated by the influences of the social and individual realm, is dependent on the consumer's unique life experiences and plans, and the uses they have for the interpreted meaning (Ritson and Elliott 1995).

One of the ways that mediated brand experiences are able to supplement consumption is by providing a scripted story or by articulating loosely constructed thoughts about a brand (Elliott and Wattanasuwan 1998). While we certainly do not suggest that consumers always accept the narratives provided (and indeed they may reject the brand stories developed by advertising agencies), these advertising stories are conceptualized as a resource that the consumer can use for her/his own purposes (Elliott and Wattanasuwan 1998). Furthermore, if mass media are used in a brand's marketing communication program, then advertising stories become a common resource that is available to everyone in an advertising audience, as Ritson and Elliott described in their study of adolescents (1999); consuming advertising is a joint, communal activity.

Linking Value

Ongoing social interactions and communal events have been shown to be facilitated within groups of advertising consumers (Ritson and Elliott 1999). Advertisements can provide a focal point for consumer to consumer contact that is valued for reasons beyond product recommendation, decision-making and the purchasing process. The concept of social connections, the establishment and/or reinforcement of bonds between individuals, facilitated by marketing activities has also been highlighted by Cova (1997) and this approach is encompassed by Consumer Culture Theory (Arnould and Thompson 2005). Consumer culture necessarily implies a role for brands in creating and re-creating a sense of self, personal purpose and belonging. Cova (1997) introduced the idea of the linking value of products and services that in some way permit and support social connections between consumers and forge feelings of solidarity through the pursuit of common consumption interests. Cova and Cova note, "such linking value is rarely intentionally embedded in the use value of the product/service concept, yet it is a quality that merits our careful attention" (2001, 70).

Brand advertising provides the means for uniting consumers within communities, providing a focal point for consumer to consumer contact and for imagining belonging to a community of individuals linked through commonality of some sort. The combination of Elliott and Wattanasuwan's (1998) concept of mediated experiences of brands as resources, and Cova's (1997) linking value, provides a neat framework for the argument that identity projects and community connections are supported by brands as experienced through marketing communications. That is, the literature provides a theoretical basis for the claim that brand advertising has a linking value in communities. Furthermore, the linking value extends beyond word-of-mouth effects, product recommendations and assistance in the decision-making/purchasing process. Brand marketing communications have a vital role to play in striking a chord within the isolated consumer, connecting people with each other through the "lifestyles, stories, experiences, and emotions" conveyed (Leach 2000, 18).

Community

Connections between people are central to the ideas of community, and as discussed earlier, the construct of community is well-established in consumer research studies. Communities are social groups that help define an individual within society—community implies a consciousness of kind where there is a collective sense of difference from others not in the community. Consumer research publications have focused on many notions of community, including brand communities (Muñiz and O'Guinn 2001), new communities (Goulding, Shankar, and Elliott 2002), virtual communities (Mathwick et al. 2008), and the struggle for self and community (Arnould and Price 2000). However, there has been little published regarding national communities and the linkages between consumers who share the same national identity, despite strong evidence that membership of national communities remains a matter of relevance, as discussed earlier.

National Identity

National identity refers to a shared perception of self within a national community, and is characterized by the belief that there are commonalities which unite members of a nation (Kirloskar-Steinbach 2004). National identity is not just about shared culture; it is about the feeling of belonging (Grimson 2010). This social phenomenon assists individuals to understand their place in the world and necessarily emphasizes similarities and differences between people. National identity is not a fixed view, but one that is an act

of imagination, such that it is most unlikely that a group of fellow community members will imagine exactly the same thing—there is "no such thing as the one and only national identity" (de Cillia, Reisigl, and Wodak 1999, 154). Thus, within a nation and amongst different generational cohorts, various national identities develop which claim to express the same national past but in fact envisage it in different ways.

National identity is flagged in everyday life and is embodied in habits of thinking and using language (Billig 1995). In effect, it is a dynamic collaboration between community members that is not reliant on tradition but is built from usable pasts (Brooks 1915) and the imagined present (Humphrey 2004; Spangler 2002; Squire 1996). As Denny et al. (2005, 20) suggest "only through the imaginations and activities of many can the idea of a nation and national culture be achieved". Without even realizing it, brand owners contribute to national identity through the provision of usable pasts and visions of the imagined present in advertisements.

The concept of usable pasts was first introduced in the book 'America's Coming of Age' to capture the move towards reconstructions of history that served to unite the nation, emphasizing defining moments of the past (Staples 2003). More recently, usable past has been conceptualized as what we ought to elect to remember, signaling the "desire to make sense of national experiences in ways that unify rather than separate us" (Carnegie Council 2001). Conscious attempts to draw a nation together in this way are seen in the official commissioning of murals, statues and other monuments in public spaces, postage stamps, coins, anthems and flags that serve to make visible the myths, historical memories and common mass culture.

Construction of the nation also occurs through media culture and especially through cinema; national identity may be apprehended in the narratives, iconography and recurring motifs of popular culture (Elsaesser 2005). The term national cinema is used to distinguish the cinema tradition and style of a country (in contrast with Hollywood and the cinema of the United States). In addressing how national cinema expresses national identity in the French context, Hayward (2005) proposes seven typologies—Narratives (where the narrative is an adaptation of an indigenous text); Genres (certain types are characteristic of particular nations); Codes and Conventions (production practices become typical); Gesturality and morphology (intonations, attitudes and postures are rooted in a nation's culture); The star as sign (actors embody national cultural codes); Cinema of the centre and of the periphery (mainstream, heartland cinema in one country contrasts with its less conventional, avant-garde and narrow-interest films); Cinema as the mobilizer of the nation's myths and of the myth of the nation (the texture of society is reflected in cinema as political, social and economic changes occur). On a more compressed scale, brand advertisements (especially television commercials) also provide these types of stories and imagery, reflecting society and commonly held values, showcasing beloved geographic locations and personalities, and highlighting myths and representations of the way we are and used to be—utilizing the unifying experiences of a nation.

We know advertising is culturally anchored and the idea that society is reflected by advertising is not new—although Elliott (1997, 291) notes that the extent to which "advertising reflects reality or actually creates it is problematic." We further note that brand communications are embedded with visual representations and narratives which form part of the visual landscape (Schroeder 2002; Schroeder and Salzer-Mörling 2006). However, our argument is not that culture is shown in advertisements. We posit that consuming brand advertisements that offer imagery and stories that in some way reflect the nation, contributes to the feeling of belong-

ing to that collective. Consuming brand advertising is a widespread community practice that affects national identity.

Social Identities

Having presented the argument that brands affect national identity we now discuss the self and the construction of personal and social identities, the I/we negotiations of consumer identity projects. Self-concept refers to a person's own mental image or perception of her/himself as an object; each person holds numerous perceptions regarding their personal existence and each perception is integrated with the others (Reed 2002). Individuals are motivated to keep a positive self-image, assimilating new ideas and excluding old ones, in a continuous process of self-concept development. Thus, self-concept is not static; individuals engage in perpetual reconstruction of identity as a result of social experience (Mead 1934).

The self is socially constructed; we understand ourselves in relation to others around us, and because of the similarities or differences between ourselves and others. Schroeder and Salzer-Mörling, in discussing brand culture, note that rather than being 'authentic, coherent and deep,' selfhood can be construed as being "constructed, contingent and performed" (2006, 121). Sense of self evolves and develops, both consciously and in an automatic or unconscious fashion, throughout the lifetime and is not present at birth (Mead 1934). Activities and interactions with other individuals in society are essential to the development of self (Mead 1934). The young adult attempts to validate the simple series of factual events that have shaped the self so far and to craft a meaningful life-story; as a child matures s/he begins to "discover the self through story in historical and biographical terms" (Cardillo 1998). Interaction with a wider range of society also presents opportunities for a wider range of the self to become apparent.

Selfhood is one of many identities, including gender and ethnicity, which is neither fixed nor timeless. Jenkins' thesis, building on the foundational sociological and social anthropological works of Mead, Goffman and Barth, is that the "self is an ongoing, simultaneous synthesis of (internal) self definition and the (external) definitions of oneself offered by others" (Jenkins 1996, 20). Identity exists and is maintained through relational processes of interconnectedness (Barth 1969). There is an ongoing to and fro process of constructing and re-negotiating identity according to the responses of others within society, which Jenkins calls the internal—external dialectic of identification. Membership of multiple social groups leads to the existence of not one, 'personal self', but rather several selves according to the Theory of Social Identity, developed by Tajfel and Turner (1979). Various social situations trigger an individual to think, feel and act according to their personal, family or national level of self (Turner et al. 1987).

Using Brand Resources to Negotiate Identities

Consumers of brand resources are bricoleurs—that is to say, in constructing stories and identities they pick and choose, drawing on a wide range of things that happen to be available (Lévi-Strauss 1962). This type of thinking and development of ideas involves manipulating and making resourceful use of materials, irrespective of their original purpose. Further explanation of this is given by Ritson and Elliott (1995, 1036) who present a view of the advertising audience "as not passive, homogenous receivers of ads containing pre-specifiable, intended meanings but as active co-creators of meaning who display an ability to read, co-create then act on polysemic meanings from ads that they view." Consumer use and interpretation of advertising is idiosyncratic and uncontrollable and research shows that consumers' interpretations of advertisements are more wide ranging than intended by advertising creators (Phillips 1997).

Advertisements are assemblages of resources, drawing on words, pictures, movement, sounds and colors which refer to cultural texts, pre-existing knowledge about products and consumption practices, long running campaigns and historical precedents in advertising, cultural myths, other tacit cultural knowledge and utilize language derived rhetorical devices (McQuarrie and Mick 1996). Images, stories and other fragments of advertisements provide resources used by consumers as they negotiate their identities. Brands provide triggers for thinking about how I see myself, how others see themselves, how I feel I have something in common with others, how we have a sense of shared experiences and feelings about the nation. A disjointed group of individual consumers can recognize themselves as individuals and as part of a nation; they can imagine the national community because they recognize shared feelings of commonality and belonging.

Brands, through their marketing communications offer views of what we as a nation did, what we value, who we honor, where we consider special places, and what characteristics as individuals we share. They are a pervasive source of ideas that allow us to imagine and negotiate I/we, our internal self identity but also more overarching types of social identities, including national identity. (We acknowledge that this argument is not limited to national identity and is relevant to all sorts of social identities, tribes and communities. However, one of the purposes of this paper is to put the focus on national identity as an under-researched form of identity that is surprisingly relevant in contemporary society).

Many brands unwittingly incorporate elements of myth into brand marketing communications. We note also the reported deliberate and cynical use of existing cultural myths, not as a component of an advertisement but, as an entire brand foundation in a few exceptional cases (Holt 2006). Some advertisements are not very rich in resources for national identity projects, but the use of visual coding and recognizable national and cultural markers in brand advertising is widespread in some product/service types and is more apparent in some nations. Nostalgia is one type of appeal that is often rich in elements of a mythic golden age—referring to imagined moments of peace, harmony, stability, and prosperity. Although the mythic components do not necessarily communicate the main message enunciated in a brand advertising brief, there is clear evidence of myths in many marketing communications—see, for example, the study of Wal-Mart advertising flyers (Arnold, Kozinets, and Handelman 2001).

In summary, we have presented an argument that others in different disciplines know that advertisements affect national identity. We have argued that national identity is a relevant contemporary form of identification and a construct worthy of further investigation. Overall, we have taken a consumer experience perspective and focused on examining the literature regarding how the brands that are the sponsors of advertisements affect national identity. Conceptualizations of the linking value of brands, brands as resources, the provision of usable pasts, socially constructed identities and the advertising consumer as bricoleur have been employed in the construction of our case.

DISCUSSION AND CONCLUSION

We stated at the beginning of this paper that brands have not been credited with contributing to productive and enabling forces within society, and yet there is evidence that brands contribute to national identity and that strong national identity is a stabilizing force that contributes a sense of security and meaning to consumers' lives. The idea that brands, through their marketing communications, might be useful to consumers in negotiating and imagining a national community is new and raises many interesting questions.

It also poses new opportunities for brand owners and their advertising agencies as they consider how they might be more sensitive to consumption experiences and consumer uses of brand advertising.

Creatives and others involved in the process of developing advertisements would benefit from utilizing more socio-cultural readings of brands as resources and understanding elements of national identity that are central to a national community. So far, most brands have only unwittingly contributed to national identities. A more informed and deliberate approach might be of real benefit to both consumers and brand owners. Government agencies and organizations such as the Carnegie Council have already understood the benefit of utilizing a usable past in drawing a nation together. The construct of a usable past is contingent on the times and mores, and subject to change. If advertisers were to understand which parts of usable past could be used or conceived as being usable at any particular time, that would also benefit brands. Some studies have been reported that analyze advertisements from an expert perspective (Arnold et al. 2001). However, we believe that more research into consumer responses to advertisements, conceived as assemblages that act as resources in the construction and negotiation of national identity, would also be useful.

Feelings of belonging to a collective that shares advertising consumption experiences and holding a strong sense of national identity are important to many consumers throughout the world today, yet these dimensions of consumer experience have not been examined in the consumer research literature. The contribution of this paper is in tying together concepts from the literatures of history, sociology, cultural studies, film, television, and media—which are purely conceptual but have importance and potency—with marketing and consumer research on brands, communities and identities. The unique perspective we offer combines all these concepts, and moves forward by considering the insights on national identity and brands from the point of view of the consumer.

We believe that our big idea on the contribution of brands to consumers' lives has the potential to stimulate new and useful insights in consumer research. The ideas articulated in our paper (cross-fertilized by concepts from several other disciplines) offer many opportunities for future research. Further studies should be undertaken to answer questions such as: What is the relationship between national identity and the brands that are advertised? What are the mechanisms by which brands affect national identity? How do consumers experience national identity in brand advertisements? There are broad questions to be answered regarding the role that the entire range of a brand's marketing communication program plays in creating value for consumers and for brands. More work is needed to address the role of brand marketing communications in offering fragments which form part of the wider social milieu of resources that surround consumers and contribute to identity projects. Such research would add to the clarification of what consumers do with brands.

Research into the relationship between communications and national identity might include mapping those elements that provide the richest resources for national identity in different countries. A catalogue of the most significant elements (visual, aural and behavioral) that contribute to national identity would offer marketing communicators useful insights into the potential links that could be made between brands, consumers and their national identity. Obtaining consumer insights into how well a brand's communications conform to expectations of what national identity is would be of use to marketers. Studies might also consider the types of stories that are most effectively employed by communications that contribute significantly to national identity.

The practitioner relevance and contribution of such future studies would be to provide a clearer understanding of how aspects of marketing communications can impact on brand value; to contribute towards better understanding global brand advertising; to generate insights that make for improved brand marketing communications experiences that resonate with aspects of national identity and to provide insights for brand owners into leveraging brands further through intensifying brand messages and enhancing consumer reception. Finally, we suggest that this new perspective is particularly relevant to US brands as they look outside their own borders and seek to understand the power of their brands in other national markets.

Consuming Label Information in Product Series

Lin Huang, University of Michigan, USA

ABSTRACT

This research examines the psychological avenues in processing extrinsic numerical cues and its verbal counterpart in the context of product series evaluation, which is affected by the mere choice of product labels on a newer generation with the membership being indexed either numerically or verbally. A theoretical model is proposed to account for this “label effect” which posits that numerical labels activate an expectancy mode to unconsciously search outward for information compatible with the expected product specification, while equivalent descriptive labels activate a self-fit mode to unconsciously search inward for incidental goals congruent with the anticipated product experience.

INTRODUCTION

Consumers are known to attend to extrinsic cues, such as brand names, during consumption experiences (Dodds et al., 1991) and are sensitive to the presentation format of such marketing information (Biehal and Chakravarti, 1982; Levin and Gaeth, 1988), sometimes in a nonconscious manner (Fitzsimons and Shiv, 2001; Shiv et al., 2005; Chartrand, 2005; Chartrand et al., 2008). Therefore, the manufacturer’s decision to assign a brand name or a label to a product in general is certainly strategic (Keller, 1993; Robertson, 1989; Pavia and Costa, 1993). A manufacturer typically carries a line of related products (a product series) as a result of innovations over time. Subsequently, when naming a product from a later generation in this series, the manufacturer oftentimes adopts the original brand name of its predecessor from an earlier generation to take advantage of the established brand equity, and adds a new component to index membership. This new component in the brand name is mostly seen in either numerical forms (e.g., Airbus 320, 330, 380; Acrobat Reader 7, 8, 9) or descriptive/verbal forms (e.g., Nike Air Max *Light* preceded by Nike Air Max).

While the use of this umbrella branding strategy is deliberate, the choice between a numerical and an equivalent descriptive form seems more idiosyncratic and largely interchangeable, at least as seen in the eyes of the consumers. One of the best illustrations of such perceived random choice in naming schemes comes from the Microsoft Windows OS series. The latest generation Windows 7, released in 2009, only surprisingly has its most immediate predecessor in terms of the same numerical naming scheme back in 1990 (Windows 3). During almost two decades in between, several descriptive names, among others, were dragged to fill in the seemingly odd blanks (e.g., Windows XP, Windows Vista). Please note that I am not claiming that manufacturers are always reckless in choosing between numerical and descriptive naming schemes for their product series. It is only that the decision criterion behind such choices, which may or may not be effective, is usually unknown to consumers and researchers alike. The focus of this research, however, is to understand how consumers process numerical and (equivalent) verbal information, and the resulting patterns in judgment and evaluation. In the end, manufacturers should be more able to design appropriate brand names for a product series if they have such additional knowledge about consumers at hand.

I contend that consumers have a consistent yet nonconscious pattern in processing the inter-product information (such as innovation) embedded in an extrinsic cue, whether such information is conveyed through numerical or verbal components in product

series brand names. Specifically, numerical information in a product series brand name (henceforth *numerical label*) activates an expectancy mode in which consumers nonconsciously search outward for product specifications compatible with the expected outcome; and verbal information in a product series brand name (henceforth *descriptive label*) activates a self-fit mode in which consumers nonconsciously search inward for motivational constructs (such as goals) congruent with the anticipated product experience.

ALPHA-NUMERIC BRANDING AND COMPARATIVE JUDGMENT

To motivate the discussions of including a numerical or descriptive (verbal) component in a product series label, I draw theoretical background from the literatures on alpha-numeric branding and comparative judgment. First, there is a small cohort of research studying optimal brand name design. Robertson (1989) provides a list of desirable brand name characteristics based on phonetic and semantic appeals. More specifically, research shows that consumers perceive alpha-numeric brand names favorably (Boyd, 1985; Pavia and Costa, 1993; King and Janiszewski, 2009) whenever appropriate. Alpha-numeric brand name is defined as “a (brand) name that contains one or more numbers” (Pavia and Costa, 1993), equivalent to the term of *numerical label* adopted in this research. People are known to interpret number information through multiple cognitive channels, such as stereotyping of certain “good” or “bad” numbers (Simmons and Schindler, 2003) and classical conditioning of certain “special” numbers (Goodman and Irwin, 2006) without relying on the conscious belief in the associative systems. Therefore, using numbers in brand names has proved its theoretical relevance. Pavia and Costa (1993) opt for an exploratory research via focus groups to identify common reactions towards alpha-numeric brand names. They find respondents generally agree that alpha-numeric brand names are suggestive of product series and are more appropriate for functional/technical products than for fun/sensual products. However, the authors do not specify the cognitive foundations behind their findings. More recently, King and Janiszewski (2009) find that certain numbers are favored more than others due to the differences in metacognitive experiences of fluency. Therefore, brands with such numbers are evaluated more favorably than those who do not.

Then, it should be noted that the product series paradigm used in this present research has its root from the law of comparative judgment (Thurstone, 1927), which focuses on measuring the perceived intensity of stimuli through pairwise comparisons rather than measuring the standalone physical properties. In this spirit, a product is judged by its membership in a product series rather than just by its own features. Hsee and colleagues started a line of research on separate and joint evaluations of product options (please see Hsee et al. 1999 for a review) which posits that some types of product features are easier to evaluate than others in a joint evaluation mode. This finding speaks for an interesting class of preference reversal effects. The inter-product relation within a product series, such as innovation, is inherently easier to evaluate in a joint evaluation mode (i.e., joint evaluation across product generations). So the use of this product series paradigm should predict novel (and potentially different) patterns of preferences compared to the use of a single-product paradigm.

Given the product series paradigm, it is natural to go beyond *numerical labels* (i.e., alpha-numeric brand names) and include *descriptive/verbal labels* into the model, since it is also a widely

1 Henceforth, “*verbal*” and “*descriptive*” are used as equivalent terms.

accepted candidate to denote membership in a product series. In this research, I define this descriptive component in the product label as an adjective quantifier, such as [brand name] *Elite Edition* or [brand name] *Xtra*. Previous research that explicitly contrasts the use of numerical and verbal information is scarce. The most relevant work in this line focuses on the memory representation and distortion of such information (Viswanathan and Childers, 1996). They study the product attribute domain where either numerical or verbal information is used to express magnitude (e.g., 10 calories versus *low* calories) and find that numerical attribute information is more prone to memory distortion and is therefore easier to deviate from its original representation than numerical information. Then, they conclude that numerical information is generally more preferable for memory tasks (such as recall or recognition) than its verbal counterpart. They also argue that numerical information does not have meaning by itself unless being compared against each other while verbal information is inherently descriptive.

NONCONSCIOUS CONSUMPTION OF EXPECTANCY AND FIT

Previous research on cognitive elaboration suggests that peripheral cues are less important in persuasion when there is sufficient motivation or ability to process the true merits of the stimulus (Petty and Cacioppo, 1986). However, there is also ample evidence that, holding the physical consumption constant, the consumption of information (such as the information embedded in peripheral/extrinsic cues) can redirect the whole consumption experience (Shiv et al., 2005; Ariely and Levav, 2000; Morales and Fitzsimons, 2007). To generalize the role of consuming information, Ariely and Norton (2009) propose a *conceptual consumption* account to pin down this independent effect “over and above utility from physical consumption”. The conceptual consumption account posits that consumers may forgo positive physical consumption or choose negative physical consumption when the information compatible with certain psychological avenues becomes available. Two such psychological avenues that are most relevant to this present research are *expectancy* and *regulatory fit*.

There has been lots of evidence that expectancy can influence consumptions and this stream of research in psychology/marketing is analogous to the medical research on the placebo effect of medical treatments (please see Price et al. 2008 for a review). Shiv et al. (2005) study the placebo effect of price and find subjects who consume an energy drink bought at a discounted price perform worse on a follow-up puzzle solving task compared to those who consume the same drink at a regular price. They propose that the expectancy on the price-quality association leads to this effect. Besides price, brand is also documented as a stimulus that alters expectancy. Allison and Uhl (1964) find that consumers believe their favorite brand beer tastes better when they see the brand displayed, however they report it tastes just the same as any other beer when there is no brand information.

As for regulatory fit, it is natural to view it as a class of conceptual consumption because this is basically a metacognitive experience of feeling right and all metacognitive experiences involve “the interplay of declarative and experiential information” (Schwarz, 2004 & 2006). Higgins and colleagues study the regulatory fit effect in a set of research, positing that the fit is experienced when there is a manner of decision making (e.g., eager or vigilant) that sustains the goal orientation (e.g., promotion/prevention focus). Avnet and Higgins (2006) explore the use of feelings/reasons as psychological equivalence to the use of explicitly manipulated (eager/vigilant) manners. Borrowing from Viswanathan and Childers (1996), it is consistent in this present research to deduce that numerical labels are

perceived as reason-intensive while descriptive labels are perceived as feeling-intensive; meanwhile, the incidental goal priming in the present research for the shrift/prestige focus (see Chartrand et al., 2008) is induced through an item listing task adapted from Idson et al. (2000) & Cesario et al. (2004). I use the “unrelated studies” paradigm (Avnet and Higgins, 2006) in this present research so the goal priming is seemingly unrelated to label conditions in order to allow the possibility of nonconscious processes. Finally, it should be noted that the automated choice of a psychological avenue (expectancy/fit) in conceptual consumptions is situational and dependent on the availability of relevant information (Schwarz, 2006), such as the numerical/verbal cues in the present research.

Interestingly, both classes of conceptual consumption may be potentially experienced in a nonconscious manner. Shiv et al. (2005) find that the expectancy on price-quality association is processed out of the awareness of consumers. Analogously, Jones et al. (2002) find the fit between the preference for letters used in self name and self-esteem level is experienced unconsciously. Extant research on nonconscious goals (Chartrand et al., 2008; Chartrand, 2005; Fitzsimons et al., 2002; Fitzsimons and Shiv, 2001; Janiszewski and van Osselaer, 2005) suggests that incidental goals can be activated by extrinsic cues, such as brand names. Although consumers are generally aware of the outcome of the goal once it is fulfilled, they can be nonconscious of the source and/or process of this goal. Also, certain metacognitive experiences (such as fit or fluency) may actually be due to nonconscious processes (Fitzsimons et al., 2002). The nonconscious property is examined through extensive debriefing (Chartrand, 2005) and/or mediation tests (Shiv et al., 2005). The present research focuses on the latter, but collects some qualitative evidence as well.

Hypotheses

Taken together, the number processing, conceptual consumption, and nonconscious goal literatures provide the following insights for this present research. First, numerical labels are easier to compare against each other due to the fact that numbers are inherently ordinal. In the product series paradigm, numerical labels facilitate direct specification comparison across product generations, where the gains in utility (or, innovations) are distributed along declarative (utilitarian) dimensions. However, descriptive/verbal labels are easier to trigger subjective interpretation of an anticipated product experience due to the fact that adjective quantifiers are inherently descriptive. In the product series paradigm, descriptive labels help appreciate the gains in utility (or, innovations) that are distributed along experiential (hedonic) dimensions. This distinction in innovation judgment due to labels shall become blurred when the numerical or descriptive information in the labels becomes less diagnostic.

Hypothesis 1a: Consumers judge a product belonging to a product series with numerical labels more favorably when the judgment is on the utilitarian dimensions. They judge descriptive labels more favorably when the judgment is on the hedonic dimensions.

Hypothesis 1b: The judgment shall converge once the numerical or descriptive information in the labels becomes less diagnostic.

Second, a natural conjecture from the above hypotheses is that the label effect shall be moderated by the type of product messages available to consumers (presumably during various chances of exposures to marketing campaigns). To be specific, declarative

product messages that meet expectations of certain product specification improvement shall be more appreciated when paired with numerical labels. On the flip side, experiential product messages that meet an incidental goal orientation shall be more appreciated when paired with descriptive labels.

Hypothesis 2: *Consumers prefer a product belonging to a product series with numerical labels when they observe declarative product information. They prefer descriptive labels when observing experiential product information.*

Third, since labels are basically extrinsic cues, consumers may be unaware of this information in forming judgment. They can be clueless if they ever use this information or how to use such information. In the product series paradigm, they can be unaware of the changes in expectancy (in the case of numerical labels) or feeling right (in the case of descriptive labels) that is attributable to labels. Alternatively, consumers might also consciously and intentionally make inferences from the labels like they typically make from many product features. I hypothesize that:

Hypothesis 3: *Consumers engage in a nonconscious processing of certain extrinsic cues, particularly product series labels.*

And finally, this present research aims to pin down the psychological factors that are likely to influence this label effect. Based on previous findings on expectancy and regulatory fit (e.g., Shiv et al., 2005; Avnet and Higgins, 2006), expectancy strength and incidental goal priming are two promising candidates for this purpose and I will further elaborate on these in the respective experiments. Here, I hypothesize that:

Hypothesis 4: *Consumers prefer a product belonging to a product series with numerical labels when they are in a high expectancy strength condition (versus a low expectancy strength condition); Expectancy strength has no effect on descriptive labels.*

Hypothesis 5: *Consumers prefer a product belonging to a product series with descriptive labels when they are primed with a prestige orientation. They prefer numerical labels when primed with a thrift orientation.*

STUDY 1

The goal of study 1 was to test the hypothesis that numerical labels lead to different product series judgment compared to descriptive labels, depending on whether the judgment is on the utilitarian or hedonic dimensions (hypothesis 1a). Participants were asked to state their judgment on a new generation automobile belonging to an automobile series with either a numerical label or a descriptive label to index its generation. Each participant made judgment on both utilitarian and hedonic measures. It was expected that participants in the numerical label condition would judge this new generation automobile more favorably on utilitarian measures while those in the descriptive condition would judge the automobile more favorably on the hedonic measures.

Design and Procedure

Study 1 used a between-subject manipulation of the label conditions (numerical, descriptive). One hundred and fifteen undergraduate students from a large Midwestern university participated in this study for course credit. Participants were invited into a behavioral lab and were told that the study investigated “product design in the automobile industry”. They were instructed that a fictitious model XYZ is a popular automobile model made by an anonymous automobile manufacturer. Now the manufacturer is in the process of designing a new generation of this model. For the participants in the numerical condition, they were instructed that the manufacturer is to market the new generation as model XYZ 2 and put it into production next year. For the participants in the descriptive condition, everything was similar except that they were instructed that the new generation will be marketed as XYZ SE (*Special Edition*). No other information was given to the participants.

Then the participants were instructed that, at this stage, the public knew very little about this new generation automobile and they were asked to offer their best intuitive guess on this new model by using 7-point scales (1 = *strongly disagree* and 7 = *strongly agree*) on the following statements – “The new model is *fun*”; “The new model is *entertaining*”; “The new model is *exciting*”; “The new model is *well designed*”; “The new model is *functional*”; and “The new model is *practical*”. The order of these statements was randomized. “Fun”, “entertaining” and “exciting” statements were designed to make hedonic judgment. And “well designed”, “functional” and “practical” statements were designed to make utilitarian judgment. Finally, the participants were asked how likely they would like the new model by a 7-point scale (1 = *least likely* and 7 = *most likely*) and they were invited to write down their other free thoughts about the new model (if there was any).

Results

The results from three utilitarian statements (well-designed/functional/practical) were combined to form a utilitarian measure (Cronbach’s $\alpha = .93$) and the results from three hedonic statements (fun/entertaining/exciting) were combined to form a hedonic measure (Cronbach’s $\alpha = .95$). The data were analyzed using a one-way between-subject ANOVA with the label as the between-subject factor. The main effect of the label on the utilitarian measure was significant ($F(1, 113) = 25.22, p < .001$), and the main effect of the label on the hedonic measure was also significant ($F(1, 113) = 7.86, p < .05$). Participants in the numerical label condition judged the new model more favorably on the utilitarian measure ($M = 4.96$) than participants in the descriptive label condition ($M = 4.02; t(113) = 3.73, p < .001$). In contrast, participants in the descriptive label condition judged the new model more favorably on the hedonic measure ($M = 5.28$) than participants in the numerical label condition ($M = 4.76; t(113) = 1.97, p < .05$).

Supplemental Analysis. When using a more inclusive judgment variable “like”, it turned out that the label effect was insignificant ($F(1, 113) = 2.17, p > .10$). In fact, participants liked the new model similarly, no matter they were in the numerical label condition ($M = 4.93$) or in the descriptive label condition ($M = 4.59; t(113) = 1.47, p > .10$).

Discussion

Study 1 demonstrates that consumers have more favorable utilitarian judgment on the product series using numerical labels. And they have more favorable hedonic judgment on the product series using descriptive labels. This pattern provides evidence in support of hypothesis 1a. Since there was no other product information available in this study except for the label condition

itself, the resultant effect should be clearly attributable to the label manipulations. The findings in this study are generally in line with Pavia and Costa (1993) where they posit that functional or technical products are more appropriate to use alpha-numeric brand names than fun or sensual products.

Interestingly, the label effect is insignificant on the inclusive judgment variable “like” when this “like” is not projected onto a more specific hedonic or utilitarian dimension. This finding confirms that people have no hardwired preferences for either kind of label when used in a product series. In other words, neither numerical nor descriptive labels have an absolute advantage over its counterpart in terms of the holistic preferences. However, study 1 suggests that different types of labels are indeed advantageous on different facets of preferences. The next question is, naturally, what might be the relevant information that is more conducive to utilitarian (versus hedonic) judgment when a numerical (versus descriptive) label is used in a product series?

STUDY 2

Study 1 found that consumers favor product series with numerical labels during utilitarian judgment and favor descriptive labels during hedonic judgment. If this is so, it is then possible to identify a particular type of informative product message that is conducive to a particular dimension of judgment. The goal of study 2 was two folded. First, I wanted to test the hypothesis that consumers prefer a product series with numerical labels when they have access to the declarative product message. On the flip side, they prefer descriptive labels when having access to the experiential product message (hypothesis 2). Second, I wanted to additionally test the hypothesis that consumers make use of the product series label information in a nonconscious manner (hypothesis 3). Participants were asked to state their preference for the sequel to an animation movie. The membership of the sequel in this movie series was indexed either with a numerical label or with a descriptive label. Unlike the generic brand in study 1, here I used an actual movie title. It was expected that the participants in the numerical label condition would favor the sequel more than those in the descriptive label condition when they were presented with declarative movie information on its plot; and participants in the descriptive label condition would favor the sequel more than those in the numerical label condition when they were presented with experiential movie information on 3D enhancement.

Design and Procedure

Study 2 used between-subject manipulations on both factors - the label conditions (numerical, descriptive) and the movie information conditions (declarative message on plot, experiential message on 3D enhancement). Two hundred and fifty-six undergraduate students from a large Midwestern university participated in this study for course credit. Participants were invited into a behavior lab and were told that the study was to investigate consumer preferences for the sequel of *Up*, a 2009 American computer-animated film.

For the participants in the numerical label condition, they were told that the sequel will be named as *Up 2*. For those in the descriptive label condition, they were told that the sequel will be named as *Up: Russell's Special Mission*. For the participants in the declarative message condition, they were told that “Pixar recently announced that the screen writer of *Up* will write the sequel. And the studio plans to bring back the producing team from *Up*. The voice actors for the two main characters will reprise their roles in the sequel.” For those in the experiential message condition, they were told that “the sequel will be one of the world's most expensive animation movies and will be the first full-length movie in the history to use the latest Digital 3D IMAX technology, which can

significantly improve the 3D viewing experience especially for viewers sitting closer to the screen, a major unsatisfying problem for many traditional 3D movies)”.

Participants were randomly assigned to one of the four combinations of these conditions. They provided responses on 7-point scales for two dependent measures: “liking of the sequel”, and “the intention to watch this sequel”. Additionally, I recorded data on two covariate measures: “how do you like animation movies in general (on a 7-point scale)”, and “have you watched the original title *Up* before? (binary)”.

Finally, I did two things for the nonconscious process hypothesis. One was to design a mediation test adapted from Shiv et al. (2005). At the end of the study, I asked the participants to rate how relevant that they felt the name of the sequel was to their preferences of the sequel on a 7-point scale ranging from 1 (“not at all relevant”) to 7 (“very relevant”). The rationale was that if the participants were nonconscious of this process, this relevance measure should not mediate the effects of the independent variables on the dependent measures. The other thing that I also did was to ask the participants to write down their thoughts on the potential hidden agenda of this study (if there was any) or any other thoughts about this study in general. This was not as rigorous as the extensive debriefing proposed by Chartrand (2005), but was designed as a mini version to accommodate administrative constraints during the study.

Results

The data were analyzed using a two-way between-subject ANCOVA with the label and message as the two between-subject factors and with the two covariate measures as mentioned earlier. The label by message interaction was significant as expected ($F(1, 249) = 59.54, p < .001$) for the “liking” dependent measure and ($F(1, 249) = 54.18, p < .001$) for the “intention to watch” dependent measure. Furthermore, participants in the numerical label condition liked the sequel more when they were presented with declarative messages ($M = 4.48$) than with experiential messages ($M = 3.57; t(134) = 2.81, p < .005$). On the flip side, participants in the descriptive label condition liked the sequel more when they were presented with experiential messages ($M = 4.50$) than with declarative messages ($M = 3.49; t(118) = 3.71, p < .001$). With the “intention to watch” dependent measure, I also got the similar crossover pattern. Specifically, participants in the numerical label condition were more likely to watch the sequel when they were presented with declarative messages ($M = 4.31$) than with experiential messages ($M = 3.41; t(134) = 2.73, p < .01$). In contrast, participants in the descriptive label condition were more likely to watch the sequel when they were presented with experiential messages ($M = 4.20$) than with declarative messages ($M = 3.26; t(118) = 3.30, p < .001$). Additionally, “watched the original title before” was the only significant covariate on the “intention to watch” dependent measure ($F(1, 249) = 73.83, p < .001$). No other covariates were significant in any other cases.

Nonconscious Processing. As discussed earlier, I used a mediation approach to address this issue. Recall that at the end of the study, I asked the participants to rate how relevant that they felt the name of the sequel was to their preferences of the sequel on a 7-point scale ranging from 1 (“not at all relevant”) to 7 (“very relevant”). Had the participants been conscious of this process, this relevance measure should have mediated the effects of the independent variables on the dependent measures. Sobel tests on both dependent measures failed to support such mediations (Sobel $z = .32, p = .37$ for the “liking” dependent measure; Sobel $z = .28, p = .38$ for the “intention to watch” measure). This result suggests the nonconscious processing hypothesis. Additionally, on the hidden

Figure 1

agenda thoughts elicitation task, none of the participants correctly guessed the purpose of this study or suggested that their preferences were resultant of the sequel name. This also provides another piece of evidence that the participants were unaware of the process.

STUDY 3

Study 3 was designed to focus on the expectancy mode and address three issues. First, I wanted to test the hypothesis that the numerical label effect is stronger when consumers have a strong expectation (that an improved specification in the new generation leads to gains in utility) than when they have a mild expectation. This prediction should not hold for the descriptive label effect (hypothesis 4). Second, I wanted to test the hypothesis that numerical labels are evaluated similarly as descriptive labels whenever the numerical information becomes less diagnostic for comparative judgment (hypothesis 1b). And third, I wanted to continue investigating the nonconscious nature of the label effect (hypothesis 3). Participants were asked to state their preference for a new model of portable media player from the family of such players. The membership of this new model in its family was indexed with a typical (diagnostic) numerical label, an atypical (non-diagnostic) numerical label, or a descriptive label.

Design and Procedure

Study 3 used between-subject manipulations on the two factors – the label conditions (typical numerical, atypical numerical, descriptive) and the expectancy strength conditions (high, low). Three hundred and six national adult samples from an online paid subject pool were recruited for this study. They were told that the study was meant as a survey for portable media player designs and read the following instructions – “Creative Labs is a portable media player producer with a strong foothold in European and Asian markets. Its flagship player, Creative ZEN, was released in 2008. It was the world’s first 32 GB flash memory based player. Now the company’s top priority is to get a more substantial market share in North America where it plans to launch a successor to the popular

Creative ZEN next year. This next generation player will set a new world record of 64 GB capacity with an additional SDHC card slot for even bigger storages”.

The participants were then instructed that the new generation player would be marketed as Creative ZEN 2 (for typical numerical label condition), Creative ZEN 200 (for atypical numerical label condition), or Creative ZEN Pro (for descriptive label condition). Meanwhile, the expectancy strength conditions were manipulated as suggested in Shiv et al. (2005). Particularly, participants in the high expectancy strength condition were instructed that “according to a preliminary marketing analysis, the new features in this next generation player will *definitely* help attract *significant* attention from a *large* number of North American consumers”. Those in the low expectancy strength condition were instructed that “according to a preliminary marketing analysis, the new features in this new generation player *might* help attract *some* attention from *certain* North American consumers”.

Participants were randomly assigned to one of the six combinations of these conditions. They provided responses on 7-point scales for a set of three dependent measures: “liking of the new player”, “intention to buy the new player”, and “worth recommending the new player to friends”. I also use 7-point scales for a set of three utilitarian statements as I did in study 1 and collected data on routine demographic covariates as I did in study 2. For the nonconscious process hypothesis, the data collection procedures were similar to study 2 where I used a relevance scale for the mediation test and a mini debriefing for qualitative evidence. However, the relevance scale in this study was designed as more nuanced in that I did not ask for the relevance of label per se; instead, I asked for the relevance of the expectancy to the preference – “How relevant that you feel the preliminary marketing analysis was to your preference for this new player?” This change should make the relevance scale less susceptible to demand artifacts and more straightforward to identify if the non-consciousness of interest was due to the nonconscious process of expectancy.

Results

The data were analyzed using a 3 (typical, atypical numerical labels & descriptive label) by 2 (high & low expectancy strengths) factorial between-subject ANOVA. The demographic covariates turned out insignificant and were eventually dropped in the analysis. The three dependent variables (“liking of the new player”, “intention to buy the new player”, and “worth recommending the new player to friends”) were combined to form a preference measure (Cronbach’s $\alpha = .85$). Consistent with study 1, the three utilitarian statements (“well-designed”, “functional”, and “practical”) were combined to form a utilitarian measure (Cronbach’s $\alpha = .91$). The main finding was that the label by expectancy strength interaction was significant as expected ($F(2,300) = 3.48, p < .05$) for the preference measure. Particularly, participants in the typical numerical label condition prefer the new player more ($M = 5.01$) than those in the atypical numerical label condition ($M = 4.53; t(101) = 1.65, p < .1$) or those in the descriptive label condition ($M = 4.49; t(104) = 1.97, p < .05$) when they had high expectancy strengths (Note: the difference between the latter two means was insignificant; $t(115) = .21, p = .84$). Besides, the only significant preference change between high and low expectancy strengths happened in those assigned to the typical numerical condition ($M_{\text{high expect}} = 5.01, M_{\text{low expect}} = 4.18; t(85) = 2.71, p < .01$). There were no significant preference changes in the remaining two label conditions (p 's $> .65$) between high and low expectancy strengths.

Nonconscious Processing. The results were consistent with study 2 in support of the nonconscious hypothesis. As discussed earlier, I used a modified relevance scale for the mediation test. Recall that at the end of the study, I asked the participants to rate how relevant that they felt the preliminary marketing analysis was to their preferences of the new player on a 7-point scale ranging from 1 (“not at all relevant”) to 7 (“very relevant”). Had the participants been conscious of the role of expectancy, this relevance measure should have mediated the effects of the independent variables on the dependent measure. A Sobel test failed to support such mediations (Sobel $z = -.10, p = .39$). This result suggests the nonconscious processing of expectancy. Additionally, on the hidden agenda thoughts elicitation task, none of the participants correctly guessed the purpose of this study or suggested that their preferences were resultant of the marketing analysis. This also provides another piece of evidence that the participants were unaware of the role of expectancy.

Discussion

Study 3 demonstrates that consumers prefer a product series with (diagnostic) numerical labels when they have high expectancy strength. Expectancy strength has no effect on descriptive labels or (non-diagnostic) numerical labels alike. This pattern provides evidence in support of hypothesis 4 in that numerical labels (rather than descriptive labels) distinctly activate an expectancy mode as a psychological avenue to process extrinsic cues. The resultant effect is stronger when the expectancy of a specification-induced outcome is stronger (for instance, in the high expectancy strength condition, the marketing analysis speculated that the new player would be hugely successful due to specification improvement over the older generation).

The fact that the non-diagnostic (atypical) numerical labels were treated as if they were descriptive labels supports hypothesis 1b. The diagnosticity of the numerical information in this product series paradigm is simply the sufficiency of the input for a comparative judgment task.

Finally, study 3 also confirms the nonconscious process prediction in hypothesis 3. This is consistent with the finding in study 2. Particularly, I find that consumers handle the expectancy of a specification-induced outcome in a nonconscious manner, which is in line with the finding in Shiv et al. (2005) that consumers process price-quality associations unconsciously. Next, I switch gears to study regulatory fit as the other psychological avenue to process extrinsic cues and perform an analogous process analysis with respect to nonconscious goals.

STUDY 4

Study 4 was designed to complement study 3, and focused on investigating the role of regulatory fit as another means (versus expectancy) to process extrinsic cues. There were two purposes for this study. First, I wanted to test the hypothesis that a product series with a descriptive label is preferred when consumers are primed with a prestige focus. In contrast, a numerical label is preferred when they are primed with a thrift focus (hypothesis 5). And second, I wanted to continue investigating the nonconscious processing perspectives (hypothesis 3) and I focused on the aspect of nonconscious goals in this study.

Design and Procedure

Study 4 used a between-subject design with two factors – the label conditions (numerical, descriptive) and the goal priming conditions (thrift, prestige). Two hundred and twenty-seven national adult samples from an online paid subject pool were recruited for this study.

At the beginning of the study, the participants were randomly primed with a thrift or prestige goal through an item listing task suggested by Idson et al. (2000) & Cesario et al. (2004). For participants in the prestige priming condition, they were given the following instructions – “Suppose you get your dream job and you are in great financial conditions, how you would spend your money in the next five years to make you feel happy and fulfilling? Please list five such spending”. For those in the thrift priming condition, the instruction was – “Let’s think broadly about the future. What might be your most concerned financial problems or general economic situations in the next five years? Please list five such concerns”. Then, the participants were assigned to a short unrelated filler task to help set up the “unrelated studies” paradigm (Avnet and Higgins, 2006), which better allowed the possibility of processing nonconscious goals because the goal priming was seemingly separate from the later label conditions.

Next, the participants were told that they were invited to take a survey for e-book reader designs with the following instructions – “Kindle is an e-book reader developed by Amazon. The original Kindle was released in November 2007. It was sold out on the first day and the device remained out of stock until April 2008. Earlier this year, Amazon just released a new generation of Kindle. This next generation Kindle model had a trendy facelift with an overall thickness of mere .36 inches”. They were then instructed that the new generation was marketed as Kindle 2 (for the numerical label condition), or Kindle *DX* (for the descriptive label condition).

Participants were therefore randomly induced into one of the four label-by-prime conditions. The types of dependent variables collected were analogous to study 3. The setup on the non-consciousness investigation was also analogous to study 3, except that the wording in the relevance scale was modified to examine the nonconscious goals – “How relevant that you feel your hypothetical future financial well-beings were to your preference for this new Kindle model?”

Results

The data were analyzed using a two-way between-subject ANCOVA with the label and goal priming as the two between-subject factors and with a scale covariate (“how do you feel a consumer electronic product representative of you being who you are?”) that turned out marginally significant ($p = .06$). Analogous to study 3, the three preference variables were combined to form a preference measure (Cronbach’s $\alpha = .90$) and the three hedonic statements were combined as a hedonic measure (Cronbach’s $\alpha = .97$). I found the label by goal prime interaction was significant as expected ($F(1, 220) = 6.24, p < .05$) on the preference measure. Particularly, when primed with a prestige goal, the participants preferred descriptive labels more ($M = 4.60$) than numerical labels ($M = 4.12; t(104) = 1.72, p < .1$). However, I did not find the predicted crossover pattern with the thrift goal priming. It turned out that when primed with a thrift goal, the participants had similar preferences between numerical ($M = 4.26$) and descriptive label conditions ($M = 3.91, t(119) = 1.35, p = .18$). Moreover, the preference for numerical labels was insensitive to the goal priming ($p = .51$).

Nonconscious Processing. Recall that at the end of the study, I asked the participants to rate how relevant that they felt your hypothetical future financial well-beings were to their preferences of the new Kindle model on a 7-point scale ranging from 1 (“not at all relevant”) to 7 (“very relevant”). Had the participants been conscious of the role of goal priming, this relevance measure should have mediated the effects of the independent variables on the dependent measure. A Sobel test failed to support such mediations (Sobel $z = .22, p = .38$). This result suggests the nonconscious goal hypothesis. Additionally, on the hidden agenda thoughts elicitation task, none of the participants correctly guessed the purpose of this study or suggested that their preferences were resultant of the earlier item listing task for the goal priming.

Discussion

Study 4 partially supports hypothesis 5 in that descriptive labels are indeed advantageous under the prestige priming. But there is no parallel pattern for the numerical labels under the thrift priming. In fact, a new product generation indexed with the numerical label is insensitive to goal priming in general. Although all these results do suggest that that descriptive labels (rather than numerical labels) distinctly activate a fit mode as a psychological avenue to process extrinsic cues (e.g., when primed with a prestige goal, consumers may feel right to interpret the descriptive label, such as *DX* (deluxe) in this study; and such an interpretation is facilitated by the portrayal of the trendy thin look in the product message), the lack of the crossover pattern for the numerical label under the thrift priming is somehow surprising.

Previous literature posits that there is “feeling right (i.e., fit)” when the reason-intensive stimulus (such as the numerical label) sustains a thrift focus, or when the feeling-extensive stimulus (such as the descriptive label) sustains a prestige focus. Subsequently, the conceptual consumption of such a stimulus becomes more favorable when this “fit” is met (Avnet and Higgins, 2006; Viswanathan and Childers, 1996; Chartrand et al., 2008). In this study, the effect due to descriptive-label-prestige-goal fit is congruent with the previous literatures. However, the lack of the effect under numerical-label-thrift-goal fit is probably due to the fact that, within a product series paradigm, the numerical label is not sufficient to sustain a thrift goal. In a single-product paradigm, recall that the numerical information in the brand name suggests a number-magnitude-quality association, and may provide a basis of justification for purchase. For example, seeing the number 57 in Heinz 57 sauce may make the consumer feel the product has good quality and therefore like it more when

she has a need for thrift. However, the numerical information has very different roles in the product series paradigm where it suggests membership in a particular product generation and may no longer sustain a thrift goal (unless this number information is accompanied by a declarative product message that suggests a utilitarian product specification improvement to meet the need for thrift, which was not the case in this study). That being said, this interesting finding that the numerical label tends to be irresponsive to goal priming remains consistent with the focal conclusion that numerical and descriptive extrinsic cues activate distinct psychological avenues – expectancy and fit, respectively – to process such information.

Like the results in the previous study, study 4 also confirms the nonconscious process prediction in hypothesis 3. Particularly, I find that the incidental goal priming is processed in a nonconscious manner, which is in line with the rich literature on nonconscious goals (Chartrand et al., 2008; Chartrand, 2005; Fitzsimons et al., 2002; Fitzsimons and Shiv, 2001).

GENERAL DISCUSSION

This research mainly attempts to contribute to three theoretical topics. The first issue concerns the conceptualization of distinct processing patterns between parallel information sources. Schwarz (2006) proposes that cognitions are inherently situational and adaptive. The findings in this present research are consistent with this theorizing in that when consumers face the numerical labels in a product series, they are hardwired to distinctly activate an expectancy mode to search outward for information on the expected product specification improvement. When they face the parallel descriptive labels, they are instead hardwired to distinctly activate a fit mode to search inward for incidental goals that facilitate the interpretation of the anticipated product experience. Meanwhile, the experimental results here suggest that a numerical extrinsic cue is not conducive to a regulatory fit pathway while a descriptive extrinsic cue is not conducive to an expectancy pathway.

This research furthers the understanding of the conceptual consumption account (Ariely and Norton, 2009) since the pattern here speaks for a *distinctness* property between competing conceptual consumption classes. Therefore, it may be interesting to investigate in the future what causes the compatibility between certain types of information and certain classes of conceptual consumption. Correspondingly, it is advisable to study other sources of parallel information that are capable of activating distinct conceptual consumption modes.

The second theoretical issue concerns nonconscious processing of extrinsic cues. This research offers evidence in support of the perspective that extrinsic cues may be processed unconsciously and certain metacognitive experiences have their nonconscious foundations (e.g., Fitzsimons et al., 2002; Chartrand et al., 2008). Particularly, this research identifies the nature of the non-consciousness in the label effect. I find that consumers are unaware of the activation of this nonconscious process because they cannot identify the label as a source of the process. Moreover, consumers are oblivious of the process itself – they cannot tell that either the expectation on the specification-induced outcome (when they are in the expectancy mode) or the incidental goal (when they are in the fit mode) is the actual force behind this process.

The third theoretical issue concerns the consumption of inter-product concepts. Even within the school of the conceptual consumption research, I argue that the inter-product concepts are very under-researched. The efforts have been disproportionately focused on a single-product paradigm to study how the extrinsic cues for this product (e.g., price, brand) lead to various psychological effects. However, the same extrinsic cues could lead to different

predictions when used in a product series paradigm where there is a whole new class of (inter-product) concepts, such as innovation. In summary, the *distinctness*, *non-consciousness*, and *interdependence* properties in consuming information have significant merits on their own and warrant further attentions from the academia and the practitioners alike.

Approaching God: Proxy and Proximity of Brand Heroes to the Brand Community

Toni Eagar, Australian National University, Australia

ABSTRACT

An ethnographic exploration of a brand community and their hero was conducted to understand the outcomes of greatness through proxy and proximity. Proxy allowed an idealized mythology of the hero to form, which was enhanced by the possibility of proximity. However, proximity can expose the hero's feet of clay.

INTRODUCTION

Narratives form a central component to brand communities, where story telling by and about the community form identity and mythology. Included in these narratives is the heroic figure that brings success to the brand through the conquering of the commercial world. However, there is a difference between achieving reflected greatness through the proxy of the brand and attempting to achieve greatness through proximity to the hero (Schau and Muniz 2007). This paper contrasts the Schau and Muniz (2007) findings of proxy being the dominant method for approaching the hero with a community that desires both. The tension between proxy and proximity is explored and the impact on community narratives is outlined. For marketers the management of proximity encounters between the community and the hero becomes important as the hero in the flesh can reveal feet of clay.

THE HEROISM OF THE BRAND HERO

Not all employees of a brand are heroes; this paper focuses on those that have been identified by the community for their special association with the brand, product and community. The definition of a hero is somewhat fluid but it is a person, either real or fictional "who has given his or her life to something bigger than oneself" (Campbell 1988, p.123). The hero narrative generally revolves around a figure that either experiences trials and attains a physical deed through performing an act of courage or who has a revelation and through a spiritual deed learns to experience the supernatural. In either heroic narrative the hero sacrifices something of themselves for the benefit of society. The role of these heroic tales is to provide the steps that the ordinary man can take to be "liberated from his personal impotence and misery and be endowed (at least temporarily) with an almost superhuman quality" (Jung 1964, p.79). So the tales of heroes are for the purpose of giving the ordinary human being the hope or the method of becoming more than their current condition. In a sense the hero is a social archetype of the desired perfect citizen as the hero embodies or becomes those aspects that a society admires most.

The study of comparative mythology has established a common myth structure for the narratives of heroes. Jung (1964) proposed that the traditional hero myth structure had the following basic story line:

1. The hero has a humble birth
2. Early proof of superhuman strength
3. A rapid rise to prominence or power
4. A triumphant struggle with the forces of evil
5. The hero suffers the fallibility through the sin of pride
6. The hero falls through betrayal or makes a 'heroic' sacrifice in death

The above basic story of the hero encapsulates the role of the hero as more than human, the basic role of the hero in ridding society of a negative element, be it evil, monsters or sin, and the ultimate destruction or sacrifice of the hero. In Jung's psychological perspective the role of these heroic symbols is to strengthen

the ego and make a person feel they are or can be more than their current self. Campbell (1949, 1988) takes a similar perspective of the role of hero myths to individual psychology but he expands on the hero myth narrative through what he terms the monomyth (Campbell 1949). The monomyth is the formula of separation – initiation – return, where:

"A hero ventures forth from the world of common day into a region of supernatural wonder, fabulous forces are there encountered and a decisive victory is won, the hero comes back from this mysterious adventure with the power to bestow boons on his fellow man" (Campbell 1949, p.23)

For the brand hero this would be encompassed with the hero leaving the non-commercial world of the ordinary man and entering the marketplace and overcoming the competitive forces and the negative aspect of 'the opposition' and either creating the brand to bring forth to the brand community or increasing the brand's success or value which is considered a boon by the community. The brand hero monomyth narrative reads:

A brand hero ventures forth from the non-producer world of the consumer into the unknown and inexplicable world of the commercial producer where fabulous forces of the market are encountered and a decisive victory is won over other brands. The brand hero then delivers the brand and its value to the brand community.

This commercialization of the world in which the hero enters is a reflection of the norms of modern society and as such the attributes that the brand hero embraces are those of market success and is entrenched in the capitalist paradigm of the free market that seeks success over the competition (Csapo 2005).

An alternate view to the synthesization of modern worship as discussed above is the study of the sacred in what would appear to be the profane setting of consumption (Belk, Wallendorf, and Sherry 1989). The underlying assumption of this perspective is that consumption has become a secular ritual through which transcendent experience is sought (Belk et al. 1989; Hirschman and Holbrook 1982; Muniz and Schau 2005; O'Guinn and Belk 1989; Schouten, McAlexander, and Koenig 2007; Wallendorf and Arnould 1988). This research has indicated that with the rise of individualism and the move away from formal religions in modern society, individuals are using consumption practices and purchases to attain the sacred and achieve transcendence (Belk et al. 1989; Schouten et al. 2007). The marketplace has become central to society, so the heroes of the market are as appropriate figures of worship as those from history.

PROXY VERSUS PROXIMITY OF THE BRAND HERO

The tribal perspective has seen the consideration of mythology and religiosity in stigmatized (Kozinets 2001; Muniz and Schau 2005) and non-stigmatized brand communities (Schau and Muniz 2007). In one of the closest references to brand heroes found in the literature Schau and Muniz (2007) discuss the impact of Tom Petty on the values, myths and rituals enacted by the brand community of Tom Petty and the Heartbreakers (TPATH). Their work focused on the similarities across brand communities and proposed that a brand community did not need to be marginalized or stigmatized for

magico-religious myth and ritual to manifest. This work highlights the idealized nature in which Tom Petty is held as “god by proxy not proximity”. The TPATH community represent and actively defend the ideas that Tom Petty displays; this identity is built on the ideas of temperance, family, friends, the environment, anti-commercialism and the USA. These ideals result in the community defending Tom Petty against claims that contradict this persona, such as claims of infidelity and drug use. There is also enforcement of the norms of community behavior, restricting or reprimanding references to sexually explicit material or drug references besides alcohol and marijuana. This is a clear indication that the idealized version of the brand hero becomes a model of correct behavior and core to the identity of the brand community.

The other key finding from the study of TPATH is the distinction of the relationship between the brand hero as a god by proxy rather than proximity. The authors distinguish between the proxy role which views brand hero as god and as source of greatness as it is bestowed through the brand’s product versus the proximity role which seeks greatness through contact. The brand community seeks greatness through camaraderie with the product which is a crucial difference in the motivation of brand community members and celebrity worshippers. This paper extends Schau and Muniz’s work by comparing a community seeking proxy with a community that has the tension of seeking both proxy and proximity.

METHOD

Qualitative methods were applied, using both a grounded theory approach, particularly the principles of building theory from data through constant comparison and theoretical sampling (Glaser and Strauss 1967), and ethnography, and its concern for culturally based patterns of behavior (Goulding 2005). These were considered the most appropriate method as mythological narratives about the brand hero were constantly generated, negotiated and perpetuated by the brand community. Using Nvivo the analysis method applied was to open-code data, build categories and through systematic comparison develop theoretical constructs and relationships. Data gathering involved an embedded ethnographic study of three online forums, 25 real world interviews, 30 online interviews, attendance at a three-day convention, and three book-signing events, as well as informal community meet-ups in Australia, the UK, and Germany.

The investigation was conducted in the Discworld brand community, with Terry Pratchett as the author of the Discworld books representing the brand hero. Discworld is a fantasy-comedy series that has sold over 40 million books worldwide. There are 38 books in the series, which is aimed at an adult readership. While, the researcher had read some of the Discworld books prior to the commencement of this study they were not involved in the brand community. Discworld was selected because of the nature of book marketing, with limited use of advertising, the marketing efforts of the author, including book signings and readings, and the strong, long-running brand community. The brand community’s greater access to the brand hero provided the opportunity to explore the narratives that emerged from the community’s stories and encounters with Terry Pratchett.

FINDINGS

The Brand Community

The most central tenet of the Discworld community’s identity is that they are the one’s that “get it”. This is tied to the core value of the Discworld brand, “the joke”, which will be discussed in the following section. For community members being one of those that understand the value of Discworld mean that are, in a sense, more educated, smarter, and have a more sophisticated sense of

humour than those that do not read Discworld. This is a way of differentiating fans from non-fans but it also relates to how fans see themselves as somehow similar to the brand hero.

“What’s a normal fan of Pratchett? I don’t ... I know most of my family and a whole range of people. I think the only thing you can say about a Terry Pratchett fan is that most of them have above average IQ’s, it’s about the only thing I can think of to say about Terry Pratchett fans” (David, Social Network, Personal Interview)

David saw others that would ‘get it’ as being of above average intelligence. His friend Chris described David as an ‘intellectual snob’ for this statement but others have expressed a similar view of Discworld fans. Sharon described Discworld fans as:

“We are intelligent, literate and social people” (Sharon, AusDWCon attendee, Personal Interview)

As can be seen from the quotes regarding how the community perceives other Discworld fans there are clear indicators that the community perceive themselves to be ‘intelligent’ and ‘literate’. Those people interviewed that had attended real-life Discworld events such as book singings, public lectures or conventions, stated that they thought that the other people in attendance were like themselves with one respondent referring to the people at a Pratchett signing as; “People in the queue? Very much like the people I was hanging around with at the time the nerdy geeky uni type” (Judy, Social Network, Personal Interview).

The Brand

The core value that the community identified with the Discworld brand was “the joke”. This is associated with the nature of the Discworld story. Discworld is predominantly a satire in a fantasy setting; there are many references to real world ancient and modern history, as well as, puns, word plays and the twisting of the everyday or expected language forms. These many references to the real world as a basis for “the joke” mean that the reader has to be aware of the real world reference in order to get the Discworld joke.

“You can read it on so many levels depending on what you actually know about the world, its history and things like that. You actually understand different stuff. So, you can read a different book that you haven’t read for years and get different things in it because over that time you’ve grown yourself. And it makes fun of the world. It makes fun of everything of things that people think are so important and sort of puts it in perspective. I like the fact that it makes fun of everyone. At the same time there’s a note of seriousness in it too...”

“He took things that really happened in history, like to the witches and things like that, there’s stuff about witchcraft except the witch trials instead of burning witches at the stake its actually this fantastic time when they all [witches] got together and had fun and compared spells and stuff.” (Alison, Personal interview)

This understanding of the real world that is used to create “the joke” forms an important aspect of the interpretive function of the community. “The joke” was a recurring theme in how the Discworld community saw themselves and also as how they viewed Terry Pratchett. There was a strong element that he created and

continues Discworld to share “the joke” rather than for commercial motivations. This narrative proved to be problematic when the community came into proximity with the brand hero, commercial motivations were Terry Pratchett’s feet of clay.

The Brand Hero

The perception of Terry Pratchett as the mythical hero of the brand community versus the profane self-promoter with his own agenda was heavily influenced by the proximity of Pratchett to the community member. There is a great tension between being perceived as accessible with the disappointment in meeting the hero to find that he does not fit the mythology. This adds an additional dimension to Schau and Muniz’s (2007) religiosity through proxy rather than proximity. In the Discworld case it was found that while community member’s desired greatness through proxy, they also desired a certain level of proximity. This section will explore the community reactions to the perception of proximity, actual proximity and how this influences the narratives of Terry Pratchett as a sacred and as a profane figure.

Besides the proxy narratives there was evidence that proximity played an important role in the creation of the hero narratives and perceptions of sacredness. The transcendent religious experience of the brand hero was most strongly experienced in the convention setting where Pratchett was present. This communal interaction with Pratchett was the basis for many of the narratives of his accessibility. The accessibility myth relies on interpretations of proximity that if Pratchett was nearby community members could approach him in conversation. Terry Pratchett was considered a credible Discworld community member because he would behave just like any other fan at community events.

“Now, the question is, why does he do it? Why give up three days of precious free time to spend them in a field with people who would buy your books anyway? Even if it did increase sales, the amount would be a drop in the ocean compared to what he’s selling already. So I’m left with the notion that he enjoys it. He walks around, chatting to fans, occasionally being photographed but not, I hope, being hassled too much. He doesn’t appear to have an entourage (we saw him walking down from the top barn to his car on Sunday morning, presumably to pick up something) or to have any security worries (if he had any ‘mindes’, they were very well hidden) and because he acts like a ‘regular person’, that’s how he gets treated. It might be that he feels he ‘owes’ it to the fans to turn up at events like this. In the Q&A, he was asked whether he was going to be at the Australian Convention, and after saying that the date had been changed a couple of times already, he said that whatever date it finally ended up on, he’d be there, because “they’ve gone to so much trouble” (and that he never misses a chance to go to Australia). I don’t know of any author with a comparable level of sales who gives so much time to keeping fans happy.” (Diane L, alt.fan.Pratchett, 05.08.2005)

For this Discworld brand community member they perceive that Terry Pratchett is motivated by enjoyment of fan contact rather than by commercial concerns. In her mind this gives added credibility and appeal to Pratchett as a brand hero. The ‘regular person’ aspect of his credibility presents a persona that the brand community is able to identify as someone similarly committed to the community and the brand. The brand community perceived that they and the brand hero were working together for the benefit of the brand.

Another example was at the AusDWCon Pratchett sat with up to 50 attendees in conversation outside of the formal sessions. These conversations ranged from the shepherds hut that Pratchett had built as his library to the various ancient sites of interest around England, such as the Long Man, and the White Horse, which are referred to in Discworld books. The conversation I witnessed at the convention lasted for 2 hours and is not the only reported interaction between Pratchett and the community, with mentions being made of long interactions in bars and pubs at other events. These examples create and reinforce narratives of the hero’s accessibility and approachability. These are values that the Discworld community believes to be part of their ethos, with inclusive practices such as only using proper English instead of netspeak in online interactions. Proximity in communal interactions provides evidence of Pratchett’s character and has formed an important basis for heroic mythology and community ethos. However, proximity can have negative consequences which will be discussed next.

The issue that proximity to Pratchett raises is around the revelation of the hero as profane and ordinary. There were two instances within the Discworld community that illustrated the dangers of proximity between members and the hero. The first relates to Pratchett making rude comments to a respondent at a book signing, the second was an attendant at the AusDWCon who after a small group discussion with Pratchett was disillusioned with the market motives that underlied his behavior. These incidences indicate that there are issues with proximity leading to the hero revealing himself as profane rather than mythic.

The first incident that revealed the issues of proximity between the hero and the community was in an interview with Judy, who describes meeting Terry Pratchett twice, the first in a large group setting for a public lecture and the second in a book signing. The book signing meeting was quite confrontational, she described it in the following way:

“At that particular signing I also got a Discworld magic cards signed. I was playing Discworld magic deck, I don’t know if you know them...it is just a card game basically of dungeons and dragons sort of thing... Cardboard, expensive bits of cardboard. Anyway there’s an orangutan card there’s a wizards card and a Terry Pratchett thing. When I gave them to him to be signed he was quiet scathing about the amount of money people spent on silly pieces of cardboard.”

The second meeting at a book signing event was also perceived as negative.

“The one with the cards which I said he was quite scathing about silly card games the way people spent masses amounts of money on etc. And the other was probably entirely my fault I got up to the table and hadn’t really been thinking “what can I say to this man”, I got to the table put the books down and foolishly made a reference to banana daiquiris. He says ‘couldn’t people come up with something original’ or something like that. He was a fraction rude so like his books, but as a person I find him quiet abrasive.”

Judy’s experience with Terry Pratchett indicates an antithesis to the open and friendly hero figure described in previous narratives. For her he was scathing, rude and abrasive. Interestingly these apparently negative character flaws were justified by their reflection in “the joke” at the core of the brand. So in this case if the hero is

perceived as negative this is what makes their contribution to the brand so special. Also, evident in Judy's description of the meeting with Pratchett is the need to think about and plan the interaction prior to the event. This was reflected in a number of respondents who felt intimidated by the pressure of the formal meeting situation that book signings provided. Community members didn't want to appear gushing or clichéd but wanted to express their appreciation for the books. Many described their encounters as brief:

"What happened, I went up said "I'm a big fan" he said "Thank you" and I got my books signed." (Chris, Personal interview)

Others described wanting to meet Pratchett in a more informal setting, with the implication that both parties could more accurately represent themselves. There was also a sense that a long informal "chat" with Pratchett would in some way validate them as an interesting and therefore worthy individual.

"I guess it would be cool to just run into him by accident. Like, you know, in a pub or something and wind up talking and it's a situation where he could genuinely walk away and say I've had enough of talking to you but didn't. So if you actually were able to hold you own in a real life conversation with him that would be cool because, like, I said I think of his intellect as being, you know, somewhere up there, you know. So having a real life conversation with him would be cool." (Tegan, Personal interview)

This respondent sees an informal meeting as being on a more level playing field where it is an opportunity to match intellects with Pratchett. Where the formal book signing meeting seems to attract the community, with most respondents attending one, there is a desire or the fantasy for the personal meeting between equals. The formal meetings, especially the book signing events, place the hero and the community within prescribed roles. It would seem that these roles do not sit comfortably with either party, with Pratchett appearing occasionally abrasive and fans uncomfortable with appearing gushing and deferential. So for the community the ideal form of proximity is in an idealized informal scenario rather than the stilted actual interactions available.

The second negative outcome that proximity caused was to draw attention to the commercial motives of the hero. These were in conflict with the mythology and the community's values. This proved to be an area of conflict between the commercial-based mythology of the hero bringing success to the brand in the market and the belief that the hero does this out of love of the brand and affinity for the community. The second encounter that was reported as negative was where the perception of Pratchett's motives as love and affinity was undermined. Vanessa an attendee at the AusDW-Con was one of a few attendees who won the opportunity to meet with Terry Pratchett in a small group meeting. She describes the experience as disillusioning:

"You have all sorts of ideas about what Terry's going to be like. But I was disappointed. Terry Pratchett really is in it for Terry Pratchett." (Vanessa, informal conversation at a post-AusDW-Con meet-up)

For Vanessa the meeting with Pratchett undermined her idealized ideas of who he was as a person with the reality that he is motivated by his own desire for commercial success. Within

this encounter lies a central problem of the community – hero relationship, it is idealized myth couched within a commercial and profane environment. This tension between the fantasy and the reality can be exposed when the community is placed within proximity of the hero.

A certain level of positive proximity can create and reinforce myths about a hero, as approachable and as having affinity for the community. The wrong kind of proximity, or a negative encounter, can expose feet of clay and bring the hero back into the real-world and a profane commercial 'sell out'. In this context the idea of Pratchett 'selling out' was in the belief that he was motivated by money rather than a love of the brand and a kinship with the fans. The Discworld community wants to believe that he loves what he does, from writing the books to meeting the fans. The commercial side is a by-product of this love rather than the motivation for it.

DISCUSSION

For the brand hero their role is to provide a norm of behaviour for the community to aspire to and replicate and to reflect back to the community the qualities that they believe themselves to possess. The heart of the impact of the brand hero in brand communities is in the co-creation of identity, where Terry Pratchett is "intelligent, literate and well-mannered"; the brand community believes itself to reflect those qualities. In reinforcement, Pratchett tells them that they reflect these qualities also. For the brand hero to be effective they must continue to embody these qualities or risk the undermining of the core of the community's ethos. This is a major challenge as the hero is a commercial figure, up against a community who believes them to be motivated by non-commercial objectives and who is ultimately human. The feet of clay that the community does not want to see is the commercial imperative of the modern brand hero.

For brand communities the touching of god through proxy is a process of negotiating identity, where the brand hero reflects the ideal identity and provides an outline for members to achieve the same ideal state. In the case of the brand community this ideal state is in getting "the joke" and in being intelligent enough to match the joke's creator. This sense of identity is not reliant on actual interactions with the brand hero. However, the sense of community is enhanced when there is the possibility of brand hero proximity. So in this case the greatness of the proxy was improved by the hope of proximity, which is the first tension that exists between proxy and proximity. For marketers, the issue becomes how much access to allow between brand heroes and the community where the hero is seen as accessible but retains their mythology.

The dangers of proximity were also found with the brand hero revealing that instead of being the idealized inclusive and nice figure of the mythology he can be abrasive and rude. This encounter formed a negative impression for the respondent of the hero. This was relayed to her friends who when I spoke to them they were all familiar with her experience. While they were familiar with the incident they seemed to not believe it, the community members were unwilling to attribute an actual negative encounter over their idealized idea of the hero. For Judy she explained Pratchett's behaviour as a reflection of "the joke", so rather than negatively effecting her perception of the brand it reinforced her reasons for liking Discworld. This suggests that isolated negative encounters do not eclipse idealized mythologies of the hero. More research is needed into when and how many negative brand hero experiences cause a shift in a positive idealized brand hero myth.

Another important issue found when brand community members came into proximity with the brand hero was in the realization of the community that the brand hero is a commercial figure. The

brand hero forms an intersection between the market imperatives of the brand and the non-commercial religiosity of the brand community. While the mythology of the brand hero is couched in the marketplace the assumption of the community is that their motivation is non-commercial. Within the Discworld community there is the belief that Pratchett is motivated by a love of the brand and a respect for the community. Proximity with the brand hero may reveal that they are motivated by market forces or self-promotion. The ongoing tension for communities and brand heroes is in their desire for the celebration of ownership while balancing alternate motivations for profit (Muniz and O'Guinn 2001; Muniz and Schau 2005). This tension between marketers need to make profits and brand communities' desire for a non-commercial magico-religious experience has been recognized in previous research (Muniz and Schau 2005; Schau and Muniz 2007). Unlike previous research that has considered the commercial nature of the products, this study has focused on the perceived marketization of the brand's creators and managers. In brand community settings marketers need to minimize proximity that highlights the commercial nature of the brand hero.

LIMITATIONS AND FUTURE RESEARCH

The current study explores the issues with encountering brand hero greatness through proxy and proximity. While proxy builds an idealized mythology of the hero, proximity can create a sense of affinity with the community. However, this proximity can have negative outcomes in revealing the hero's feet of clay and the unwelcome reminder market motives. There is a need for more research into the balance between proxy and proximity, what are the optimal amounts and is there a qualitative difference in the types of proximity. For instance, the Discworld community has the option of book signing events, conventions, online and real-world question and answer sessions. Marketers would be better able to manage the relationship between the community and hero if there was more information about the effectiveness of the different encounters.

Limitations exist in this study as it explores only one fan community that has one brand hero. Other brand communities will have multiple brand heroes that have different functions within the brand. For instance, a football team has the players, coaches, and management who may be considered heroes of the brand. These different types of heroes may form alternate relationships with the community with different expectations as to ideal behaviors. Comparing the expectations of ideal brand hero behaviors would reveal the underlying drivers of commercial heroic mythology. It is in understanding the heroic that we can form an understanding of community aspirations.

The Attractiveness of New Zealand as a University Study Destination: A COO Study of Chinese Students

Sussie Celna Morrish, University of Canterbury, New Zealand
Jia Guo, Xi'an Xiang Rui Real Estate Co. Ltd., China

ABSTRACT

The development of global markets and the growth of international trade have increased interest in COO effects on consumers' perceptions and intentions but traditionally focused on goods more than services (such as providing international education). This study develops a model of COO factors affecting choices of study destination. Using in-depth interviews with Chinese students intending to study overseas, it finds that COO variables influencing their evaluation include: reputation, language, economic, social, legal, and geographic factors.

INTRODUCTION

Country of origin (COO) effects refers to how consumers perceive products coming from a particular country (Roth and Romeo, 1992). From a marketing perspective, COO may strengthen or weaken a product's position (Srikatanyoo and Gnoth 2002). In general, COO has been used as a country stereotype, an extrinsic cue to product attributes, and a halo/summary constructs. While it is widely acknowledged that COO plays an important role in information processing and has an impact on product evaluations (Al-Sulaiti and Baker 1998), there has been limited research on COO effects on choice of services. The increasing importance of global trade in services urges marketers to gain insights into the underlying factors considered by consumers when evaluating services. Given that services are typically characterized by significant interpersonal contact, complexity, divergence, and customization than other products, its quality attributes cannot be perceived, felt or possessed in advance. For example, the quality of higher education may vary distinctly from country to country, year to year, class to class, lecturer to lecturer, and student to student (Patterson, Romm and Hill 1998). In particular, international tertiary education (ITE) is a high involvement service that requires high costs, personal relevance, and time for international students' decision making (Gray 1991). As global trends within the field of higher education have brought new competitors (Ivy 2001), it is extremely important for international educational institutions, to understand how international students evaluate and choose service providers in order to maintain their competitive advantage and develop distinctive images.

BACKGROUND LITERATURE

COO effects refer to how consumers perceive products originating from a particular country. Since first studied (Schooler 1965), numerous practical and theoretical implications of COO effects have made it one of the most fruitful areas in marketing research. In many cases it has been found to play a more important role in foreign product evaluations than price and brand (Wall, Liefeld and Heslop 1991). From a marketing perspective, COO has important strategic implications for firms manufacturing and exporting products because it is a way to differentiate products from competitors especially in their promotional campaigns and packaging or brand decisions (Papadopoulos, 1993). From a consumer's perspective, COO affects not only the evaluation of product quality, but most importantly the likelihood of purchase.

Like many other extrinsic cues, COO may become part of a product's total image to reduce potential risks. Reiersen (1966) suggests that while consumers have preconceived notions about foreign products, attitudes are really national stereotypes. Country

stereotyping has been found to be universal with studies showing that developing countries receive unfavorable judgments of their product quality because consumers have biased stereotyping information of their country's images (Nagashima 1977; Nes and Bilky 1993). Consumers are different in the extent to which they use country stereotypes (Chiou, 2003) given that perceptions regarding products from a given country seem positively correlated with the degree of the source country's economic development, stability of political climate and the perceived similarity with its belief system (Wang, 1978).

Roth and Romeo (1992) report that consumers from certain countries have different beliefs regarding products made in a given country compared with consumers from other countries but tend to evaluate their own countries' products comparatively more favorably than that of foreigners (Nagashima 1970). Some researchers however found that the impact of COO on product evaluation is moderated by the consumer's prior knowledge of product categories and their ability to analyze and elaborate the product information (Chiou 2003). Thus, increasing consumer knowledge and awareness could have positive COO effects.

Demographic variables also play a role in differences in COO effects. For example, there is a tendency for older consumers to rate foreign products relatively higher than would younger consumers; female consumers evaluate foreign products more favorably than male consumers; and consumers with a high level of education have more favorable attitudes towards foreign products than those with limited education (Schooler 1965). Wang (1978) found that consumers with a higher income level favor foreign products more than those with lower income.

An often raised criticism of early COO studies is their reliance on a single cue context whereby COO is the only available information that respondents rely on for product evaluations. This is of course problematic given that a real-life purchasing situation is more complex and often involves multiple cues that help consumers' decision-making. Agrawal and KamaKura (1999) in fact suggest that the impact of COO as a single cue may be weaker in real world situations. Another criticism of early COO studies relates to sample selection where students were usually the main participants. Further, Bilkey and Nes (1982) observed that COO effects were often studied under a controlled experiment environment where respondents were given only verbal descriptions of products, with no sample or visual representation. There has also been a primary focus on COO effects on product evaluation and nationality differences in the consumption of a product in more developed countries (Bilkey and Nes 1982). Reliability and validity were seldom demonstrated in earlier studies and it was not until the 1990s that scholars began to address these concerns (Papadopoulos 1993).

Although studies indicate that COO does indeed affect product evaluations both in general and in specific classes, types of products, and brands (Javalgi, Cutler and Winans 2001), these had mainly focused on goods. Very few studies have investigated the way consumers react to the country of origin of a service and whether COO has a similar effect on service evaluation. Overall, there has been a very few studies that have examined the impact of COO effects on the consumption and evaluation of services, and most of these studies examined consumers' perceptions towards services in western or developed countries (Al-Sulaiti and Baker 1998).

COO Effects on Evaluation of Services

Despite the importance of global trade in services, relatively few studies have considered COO issues on international services. For this reason, Javalgi, et al. (2001) reviewed the literature that specifically applies to services. They identified three primary categories of studies namely: a) core services, such as medical care or travel services; b) supplementary services provided to enhance the value of a product, such as a warranty or guarantee; or c) cross-national service comparisons, where services produced and consumed in individual countries are compared. Extant literature suggests that findings of COO research also apply to services whereby COO does appear to be an important informational cue for consumers of services. Javalgi, et al. (2001) suggest that the relationship between COO and services appears to be similar to the relationship between COO and manufactured products. For example, COO was found to have effects in specific service areas such as European ski vacations (Ofir and Lehman 1986), choice of ophthalmology service providers (Harrison-Walker 1995), retail services (Lascu and Giese 1995) and airline selection (Al-Sulaiti and Baker 1997; Bruning 1997). Overall, these studies report that COO is more important when brand names are not well known (Ofir and Lehman 1986), but less important when price is a consideration (Al-Sulaiti and Baker 1997; Bruning 1997). There is also a perception that offerings in more developed countries such as Germany are better than in less developed ones like Mexico (Lascu and Giese 1995), where prices are expected to be discounted. While perceptions of quality are higher for foreign carriers (Al-Sulaiti and Baker (1997), consumers are quite happy to switch to another nation's carrier if there were price or service advantages Bruning (1997).

Ahmed and Johnson (2002) examined COO and brand effects on consumers' evaluations of cruise lines. They found that COO effects played a more important role than brand effects for quality and attitude ratings, while brand was more significantly correlated with purchase intentions. Therefore, a positive country image is necessary to bring about a positive attitude and a favorable image of service providers.

However, it is questionable whether the findings from studies of core services by COO are directly applicable to international tertiary education. Consequently, it is essential to understand the unique characteristics of international tertiary education in order to explore the impact that COO has on the evaluation of New Zealand universities.

Export Education in New Zealand

New Zealand export education has been a rapidly growing industry that has brought and continues to bring many economic, educational and cultural benefits to the country and its educational institutions. The total economic benefits to New Zealand position the industry in fourth place, between the export values of the timber and fishing industries (Asia-NZ 2000 Foundation of New Zealand 2003). International students attending New Zealand educational institutions are the main mode of New Zealand export education services. New Zealand educational institutions consider it strategically desirable to strive to increase the number of international students (Smith and Rae 2006).

The export education industry is a sustainable 'green' export, which fits well with New Zealand's vision of developing a knowledge-based economy. International students can potentially contribute to New Zealand's economic and social development, and its future trade opportunities (Asia-NZ 2000 Foundation of New Zealand). According to New Zealand international enrolments, the overall economic contribution of the international education sector including tuition fees paid, living costs for students, and multiplier

factors for the wider economy amounted to \$2.21 billion in 2004, \$2.034 billion in 2005 and \$1.9 billion in 2006 (NZ Ministry of Education 2007).

From an academic perspective, New Zealand's international relationships are further strengthened through educational partnerships. New Zealand research benefits from increased international collaboration, funding, and commercialization. There is greater uptake of New Zealand educational intellectual property and services overseas. International education is also well linked with other New Zealand business activities. Additionally, the New Zealand export education industry is estimated to have created up to 20,000 jobs (NZ Ministry of Education 2007).

Competitors in the Global Market

In the more globalized world of tertiary education, New Zealand is an active and visible player with several strengths in the area of internationalization (Goedegebuure 2007). When compared to its main competitor nations, New Zealand appears to have a heavy weighting towards onshore delivery of education for international students. In other words, its focus is on students who travel to New Zealand and live in the country in order to study (Education NZ 2005). New Zealand is an attractive destination for international students because it is English-speaking and perceived as clean, green, and increasingly important these days, safe. New Zealand's education system is considered to be of a high standard, and it is a cheaper destination to complete a bachelor's degree (in relation to tuition fees and living costs,) than Australia, the UK, Canada and the US (Asia-NZ 2000 Foundation of New Zealand 2003). Five countries received 60% of all foreign students in 2006 – the United States (23%), the United Kingdom (12%), Germany (11%), France (10%) and Australia (7%).

The numbers of students worldwide seeking education outside of their home country is expected to grow from 1.8 million students in 2000 to 7.2 million by 2025 (Bohm et al. 2002). New Zealand is ranked third in terms of growth in international students, and is second only to Australia in terms of export earnings from foreign students as a percentage of total export earnings from services (Patterson 2005). New Zealand international enrolments indicate that in 2006 the majority of international tertiary students came from the three main North Asian countries: China, Japan, and South Korea (69%), followed by Europe (9%) and North America (7%). Most Asian enrolments were in undergraduate courses (51%), as were most North American enrolments (57%). European enrolments had the highest proportion of postgraduate courses (27%). China dominates enrolments in universities (55%) and other public tertiary institutions (46%). Since the peak in 2002, there has been a 40 % decline in Chinese enrolments to 31,905 in 2006. This decline has usually been ascribed to factors like negative publicity, due partly to the high-profile failure of a number of private education providers in New Zealand. There has been much greater competition from other countries for Chinese students (notably universities in Australia, United Kingdom, and Canada), a greatly increased provision of tertiary education opportunities in China, and an increase in costs due to the rising value of the New Zealand dollar (NZ Ministry of Education 2007).

COO and NZ Education Services

Compared with the purchase of manufactured products, services tend to be more heterogeneous, more intangible, and more difficult to evaluate than manufactured products. Consumers may rely more on COO in evaluating services, where purchase and consumption are usually simultaneous and where they constitute a higher risk for consumers (Ahmed and Johnson, 2002). This is especially the case

for international tertiary education. Heterogeneity makes it difficult to control and standardize the quality of education. Intangibility makes it difficult to display or communicate the quality of education service to prospective students (Mazzarol, 1998). Consequently, students find it difficult to evaluate the quality of education in advance of their purchase and consumption.

Tertiary education has become less nationally and more internationally oriented (Srikatanyoo and Gnoth 2002) and only a handful of studies have been conducted on the marketing of education within international markets (Mazzarol 1998). Existing literature that has examined the decision-making process of prospective international students has tended to focus on the study of factors relating to the institution itself, ignoring the influence of the country of origin (Cubillo, Sanchez and Cervino 2006).

In view of the findings from Srikatanyoo and Gnoth (2002), prospective students may evaluate the quality of international tertiary education by using the image of host country. It is important to explore how international students perceive New Zealand as a study destination, and how its universities are influenced by its country-specific factors. Further analysis of the determining factors in the decision-making process of the prospective international students would allow educational institutions, as well as national governments interested in attracting international students to strengthen their image, to minimize their perceived weaknesses, and hence, to increase the possibility of being chosen as a destination for international tertiary education.

Decision-making Process

The decision to study abroad is one of the most significant and expensive initiatives that students may ever undertake (Mazzarol 1998). Because of high costs and the complex decision, students are involved in deep purchase consideration. Many models of decision-making in relation to high involvement purchases suggest that consumers make a decision by moving through the three stages, namely problem recognition, information search, and alternative evaluation. Theoretically, this is applicable to educational choice, too (Engel Kolatt and Blackwell 1995). *Problem recognition* occurs when international students realize that they need to study abroad (Pimpa 1999). The most common reasons motivating students to study overseas are to gain an internationally recognized qualification, to improve their English and communication skills, to experience Western culture, and to get permanent residence (Davey 2005). Previous study suggests that this stage becomes more complex after students make the decision to go abroad. They start to consider problems like which country to go to, which university to choose, and what subjects to study. They may deal with these three problems all at once (Patterson et al. 1998).

Prospective students usually *search information* of countries, universities, and courses from both personal sources (parents, relatives, friends, agents) and non-personal sources (newspaper and television advertisements, international education fairs). A number of studies suggest that recommendations from family or friends who have previously experienced a similar type of service are the most important information sources since they can reduce risk for a high involvement purchase and provide clarification and feedback for consumers (Pimpa 1999). Comparably, students rely less on non-personal sources (e.g. mass media) than on word-of-mouth communication. *Alternative evaluation* is the last stage in the consumer decision-making process. Hill, et al. (1992) found that engaging in alternative evaluation, the customer organizes the information gathered from the search stage, chooses appropriate criteria, and compares various alternatives according to their recog-

nized needs. In this case, each student's decision criteria may vary from another because of different individual motivations and needs.

Factors Influencing Choice of Destination

The literature indicates that the choice of destination for studying overseas depends on many different factors. Mazzarol and Soutar (2002) found that the most important determinants for student's choice of a particular host country are knowledge and awareness of the host country, recommendations from friends and relatives, the cost of education and living, the local environment, social links and geographic proximity, and other institutional factors, such as the recognition of the academic qualifications and the quality of the institution's staff. In their study of international students' decision-making process, Cubillo, et al. (2006) identified four factors influencing the preferential choices of prospective students: personal reasons, country image effect, institution's image and program evaluation. Both studies suggest that country image played an important role in the choice of a study destination. Bourke (2000) found that prospective students tend to choose a country first, and then select an institution. Srikatanyoo and Gnoth (2002) indicate that while country image may directly influence student's attitudes towards its academic institutions, students' beliefs about the institutions may also change their perceptions of a country.

In relation to the selection of a particular host institution, the most important variables include the quality and *reputation of the institution*, the recognition of the institution's qualifications, and the quality of the institution's expertise and teaching faculty (Mazzarol and Soutar 2002). Further, Price, et al. (2003) found that teaching and studying facilities also influence the image of the institution. Moreover, Mazzarol (1998) suggests that the ability to offer a broad range of courses and programs plays an important role as well.

Country Image and Education Quality

Previous studies show that the country's image affects the evaluation of education services (Lawley, 1998; Srikatanyoo and Gnoth, 2002; Cubillo et al., 2006). Since the country's image is assumed to be the first factor that consumers consider in product evaluation, it plays a much more important role than other factors which influence the evaluation of a product or service (Wall, Liefeld and Heslop 1991). *Language* is an important COO consideration with English being one of the dominant languages in global communication, business, and science. For many Asian students, international study is an opportunity to improve English proficiency and skills. English speaking countries therefore become popular choices. Additionally, *cost* is considered an important factor that influences student destination choice (Mazzarol and Soutar 2002) as well as safe environment (Mazzarol, et al. 2001) and visa/residency regulations (Davey 2005). Mazzarol, et al. (2001) also found that Chinese students who choose to study in New Zealand and Australia are more likely to be influenced by geographic proximity than other students who choose different host countries. In addition, students from other Asian countries are also attracted to New Zealand due to geographic motivations (Malcolm, Ling and Sherry 2004).

METHODOLOGY

The overall research goal is to explore COO effects on the choice of an international education provider. Since the research question of interest is how international students evaluate and choose the country and institution when making the decision to study abroad, previous research is used to guide the factors and issues explored in this study. We deemed qualitative research an appropriate method to obtain insights into the motivation, emotional, attitudinal, and personality factors that influence decision-making.

Telephone interviews were conducted with ten Chinese students (five males and five females) from three major cities (Bei Jing, Shang Hai, and Cheng Du) in China. Eight of them were still in China and had the intention to go overseas for tertiary education; another two were currently studying in middle school and high school in New Zealand. An interview protocol was designed consisting of open ended questions to allow interviewees to expand on their answers.

RESULTS

Problem Recognition

The participants were asked to reflect on the reasons on wanting to study overseas. Even though they each have distinctive motivations for studying abroad, in general, these motivations fall into four categories: 1) belief that a qualification from international tertiary institutions enjoys world-class recognition, 2) to get an independent life experience and obtain a better perspective and understanding of the world, 3) international qualification may help them to gain work experience and benefit their future career and 4) improve their English proficiency and communication skills.

Information Search

Beside the country they had already applied to, they were asked to indicate the other countries they had actively considered in this process. Five countries, U.S., U.K., Canada, Australia, and New Zealand, were mentioned. Students searched information of these countries and relevant institutions from both personal and non-personal sources. The most often-used source was personal sources, such as recommendations from families and friends. These students trusted word-of-mouth information more than information from non-personal sources, a finding consistent with literature. As the purchase of international tertiary education is a high-risk decision making process, students were willing to spend a large amount of time and effort for information search. They would rely on information from people who had real experiences and their feedback in order to reduce possible risks. Some non-personal sources used by students include the internet, intermediary agents, TV programs, education fairs and books. Information from these sources was less powerful than personal information because the students believe they were commercially promoted. However, the main function of media information is to provide preliminary impressions of countries or institutions and then direct students to personal source for further confirmation.

Alternative Evaluation

Six out of ten students chose New Zealand as their study destination after comparing all possible options. Those who did not choose New Zealand preferred to study in the US. Of main concern however is the US visa requirement. Failing this, UK and Canada would be their second choice. The findings indicate that lack of knowledge and awareness of New Zealand is a universal phenomenon for most of the students, who had not considered this country on their initial list or as the preferred destination. The level of knowledge by the two students who already studied in New Zealand at secondary school was obviously higher than that of the other eight. Their living and studying experiences generated for them a positive perception of New Zealand, specifically as a quality education provider, its relatively lower costs, ease of getting a visa and so on.

Understandably, a majority believes that a country's economic development level was related to its educational level. Therefore, the US and UK were their first preference. In general, the most frequently-mentioned factors in selecting the alternative countries

are costs, language of the host country, the university's reputation, visa application, and work opportunities.

Factors Influencing Destination Choice

Students who chose to study in New Zealand regarded the relatively lower costs of studying and living, world-recognized universities, English speaking country, safe society, the ease of getting a visa, and the opportunity of finding part-time jobs as the most significant factors in their decision. Of secondary importance were: geographic environment and lifestyle and enjoyment. We capture these factors in a COO-based model in Figure 1.

Although six out of ten students who participated in the in-depth interviews chose New Zealand as their final destination, nine students had considered other countries as their most preferred destination in the beginning. Among these, the US and UK were always considered first for overseas study. Students held positive perceptions of these two countries as quality education providers. They believed that large countries have a longer history of good educational background, world-class universities, and higher academic standard. All the participants suggested that they only considered English-speaking countries as their study destination. The major economic issues of concern to students are expensive tuition fees that are significantly higher than domestic rates and living expenses. Unless students are offered scholarships or the students' families are wealthy, the cost of studying overseas is always a serious concern for prospective students. More than half the participants who would like to study in the US or the UK in the beginning finally changed their mind and chose New Zealand as their study destination because of the higher costs in those other two countries.

While some students did not consider safety as a major decision issue, parents were more concerned about it. As a result, being safe is a fundamental consideration for students who intend to pursue education abroad especially for families of female students in this study. They believe that safety is very important and it was the reason for them to choose New Zealand in the end.

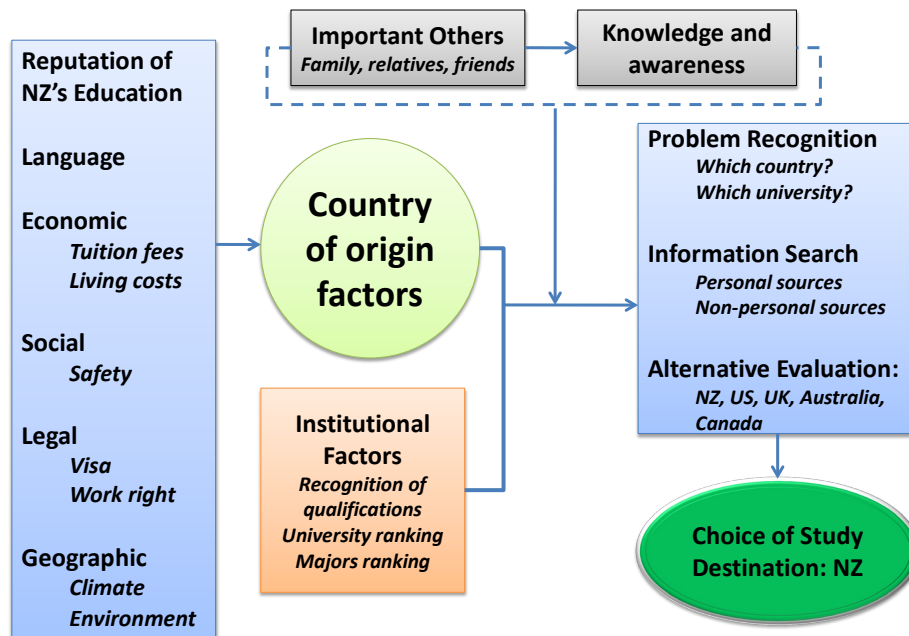

Life style and enjoyment in the host country did not appear to be important to most of these students. They generally believe that living in a country with different life style is not an issue because they were going abroad to have different life experience and they could get used to new things very fast. Secondly, it would always be good to have entertainment, but they preferred not to have much of it because the reason to go overseas was mainly for study. Their parents believed that New Zealand was calm and relaxing and the US by comparison has lots of temptations.

Eight out of ten students have considered the difficulty of applying for a visa, an important factor in their final decision. Some students gave up their preferred countries (e.g. US and Canada) because it was too difficult to get a visa or some of them had been rejected several times. In comparison, they thought it was easier to get a visa to New Zealand, a factor that puts New Zealand in a favorable position to attract students. Half of the participants indicated that while the natural environment of the host country is not the most important factor, it still plays a role in evaluating alternatives in overseas tertiary study. Thus, countries which have a clean and beautiful environment are more attractive than others.

Institution and Moderating Factors

Recognition of qualifications acts as the most important criterion for students to choose a university. All of them emphasized that a qualification from a world-famous university is desirable for future work opportunities therefore qualifications need to be recognized both internationally and by future employees. University ranking

Figure 1: COO Model

is perceived to be desirable such that studying in a world famous university will make it easier for students to find a job in China after graduation. In addition, the ranking of majors is also deemed important because they realize the overall ranking of a university is not necessarily equal to the quality of a certain major offering. Therefore, they chose the major first and then the university next.

Knowledge and awareness of New Zealand and its institutions as well as the influence of other important people moderated the final choice of destination. Except for the two students with good knowledge of New Zealand, the information on New Zealand was generally sourced from friends and agents.

CONCLUSION, IMPLICATIONS AND CONTRIBUTION

This study does not aim to draw definitive conclusions. Rather it serves to provide valuable insights of how COO factors affect the choice of international tertiary education in a New Zealand context. The findings of this study suggest that country reputation, language, economic, social, legal, and geographic factors play significant roles in evaluating alternative countries as a study destination. Students are concerned most about the recognition of their qualification, cost of studying and living, the safety of the host country, and difficulties of visa application. Their family and friends influence their knowledge and awareness of the host countries and eventually the final choice of study destination.

This study fills a much-needed gap in the literature relating to how COO affects consumer's evaluation of services, in this case, international tertiary education. It identified country-specific factors that might influence the prospective international students' perception and choice of study destination, and developed a conceptual model of how Chinese students select New Zealand to pursue their overseas study. This was based on both relevant literature and the findings from interviews.

The rapid development of international tertiary education requires that we understand the characteristics of the market it tries

to tap. This study will be important to academics, administrators and practitioners who are involved in international tertiary education. The conceptual model may help achieve an understanding of the true characteristics of the Chinese study abroad student market, and develop appropriate strategies to enhance the image of New Zealand's education quality. The findings will also benefit institutions by contributing to the use of their competitive advantages for international student recruitment.

There are two significant limitations to this study that prevent generalization of these findings to broader contexts. First, this study has focused on a modest sample of Chinese students and reflects only one destination country. Students from other countries living under different social contexts may show differences in the primary beliefs that affect their decision-making in regard to their choice of overseas study destination. Second, participants were interviewed using qualitative methods, whereas the use of quantitative methods, inferential statistical analysis, and longitudinal studies might have revealed further details.

The marketplace for international tertiary education is dynamic and will change over time. Therefore, further work should also consider conducting a cross-nation study of other overseas destinations, and selecting participants from different source countries to comprehend the decision-making stages and the variety of types of international students.

The Emperor's New Clothes: Are We Seeing our Subjects Clearly?

Simone Pettigrew, University of Western Australia, Australia

ABSTRACT

Referencing consumption-related themes in popular music, this paper playfully and provocatively suggests that transformative consumer research could boldly refuse to adopt the underlying assumptions of much previous consumer research and instead consider an alternative interpretation of the consumer.

INTRODUCTION

Imagine that we could forget our roles as scientists commissioned with identifying and measuring constructs relating to consumer behavior. Imagine that we could forget our duties as educators where we teach students to view consumption through the lens of theoretical concepts and profit maximization. If we could look at consumption through uninitiated eyes, what would we see? Would everything we behold support our learned interpretations, or is it possible that the metaphorical emperor, our consumer as king, would no longer be swathed in layers of fine clothes but instead appear naked to us? In other words, would the consumer whom we primarily depict as an agentic decision-making unit turn out to be a bewildered and put-upon individual who has a vague awareness of his or her subordination in the marketplace but lacks the knowledge and skills to redress the situation?

It is difficult to adopt a *tabula rasa* perspective retrospectively, but perhaps if we accessed views on consumption that are offered up in contexts outside of laboratories and formal interviews we could tap into different interpretations that provide alternative views on how consumption 'works' in consumers' everyday lives. Increasingly, consumer researchers are turning to the Internet and social media for insights, but there is an older medium that has been long communicating attitudes about consumption and its role in society. For decades, popular music has been an avenue for consumers to make statements about their relationships with specific consumer goods and the marketplace in general. With the occasional use of lyrics from some of these songs as a loose framework, this paper playfully and provocatively suggests that transformative consumer research could boldly refuse to adopt the underlying assumptions of much previous consumer research and instead consider the implications of an alternative interpretation of the consumer. Given that the task of TCR is to engage in "investigations that are framed by a fundamental problem or opportunity, and that strive to respect, uphold, and improve life in relation to the myriad conditions, demands, potentialities, and effects of consumption" (Mick 2006, p2), the perspective adopted in relation to the role of the consumer will be critical in ensuring that research results achieve their potential to improve consumer welfare.

I AM A WEAPON OF MASSIVE CONSUMPTION AND IT'S NOT MY FAULT, IT'S HOW I'M PROGRAMMED TO FUNCTION

LILY ALLEN, "THE FEAR", 2009

In most consumer behavior research, consumers are viewed as active (as opposed to passive) in their consumption decisions (e.g., Baumeister, Sparks, Stillman, and Vohs, 2008; McCracken 1990; Wallendorf and Arnould 1988; Wright 2002). According to this perspective, consumers are able to make complex consumption decisions with a view to meeting their functional and symbolic needs (Baumgartner 2002; Hirschman and Thompson 1997; Holt 1995). Consumers are described as thinking, feeling subjects who imbue

the consumption process with many different levels of meaning (Tetreault and Kleine 1990). They are seen to be self-directed in their consumption projects (McCracken 1987), choosing alternatives that will maximize their happiness and wellbeing (Thompson and Troester 2002). Throughout this process, they actively employ products in the fashioning of their self-determined self-images (Holt 1995; McCracken 1990). Consumption is viewed as an enjoyable activity that can be appreciated in its own right as well as being a means to an end (Belk 1996).

Based on assumptions of agency and rationality, this prevailing view considers consumers to be largely in control of their own identity projects (Elliott 1997; Schau, Gilly, and Wolfinbarger 2009). The use of objects to assist in the construction and maintenance of the self-concept is seen as a conscious, controllable process in which consumers engage to maximize their satisfaction (McCracken 1989; Walker and Olson 1997). This enables them to shop for a self-identity much as they would for a consumer good (Hirschman and Thompson 1997). In this scenario, consumers deliberately consider symbolism in their consumption decisions and make informed choices about which self out of numerous optional selves they wish to communicate at a particular point in time (Hirschman and Thompson 1997; McCracken 1990).

But what if Lily Allen is on to something? What if today's consumers are effectively programmed to consume at high levels and in ways that are largely beyond their individual control? Could growing up in a materialistic environment (Giddens, Schermer, and Vernon 2009) and exposure to more than 3,000 advertisements per day (Kalkbrenner 2004) result in consumers being effectively programmed to abide by the requirements of the marketplace, whether they want to or not?

While less frequently explicitly articulated in the consumer behavior literature, Lily's idea of programmed consumption can be found in numerous accounts of consumer behavior that attribute decisions and activities to elements other than consumers' conscious decision-making processes. Repetition of messages, unintended exposure to advertising, and associative learning are recognized as producing lasting effects that circumvent consumers' conscious barriers to persuasion (Ajzen 2001; Bettman Luce, and Payne 1998; Fitzsimons, Chartrand and Fitzsimons 2008; Shapiro 1999; Shimp, Stuart, and Engle 1991; Tybout and Artz 1994). In addition, over the years researchers have identified age, gender, social class, stage of the family life cycle, personality traits, mood, aspects of the physical environment, methods of information presentation, time pressures, marketing communications, situational factors, other social actors, and broad cultural forces as having significant impacts on consumer behavior (Bearden, Hardesty, and Rose 2001; Bettman et al. 1998; Klein and Lansing 1955; Lury 1996; Mick 2008; O'Guinn and Faber 1989; Raghunathan, Pham, and Corfman 2006; Wallendorf and Arnould 1988). These factors are largely beyond consumers' direct control and therefore can be expected to exert influence over consumption decisions and activities in ways that reduce consumers' agency. Other factors, such as existing product knowledge, are only partially under the consumer's direct control but are also influential (Celsi and Olsen 1988). This begs the question: To what extent can behavior be considered volitional in the wake of so many influencing variables? How much 'space' is left for truly individual, conscious, and deliberate consumption decisions?

**YOU KNOW THAT WE ARE LIVING IN A
MATERIAL WORLD AND I AM A MATERIAL
GIRL**

MADONNA, "MATERIAL GIRL", 1984

Madonna sensitizes us to the tendency for individuals to adapt their behaviors in accordance with the requirements of the external environment in order to survive and thrive. While advertisements might be promoting different products, it is possible that in aggregate they are advocating a culture of acquisitiveness (Tybout and Artz 1994), which in turn prevents the visualization or contemplation of alternative lifestyles (Waide 1987). In this situation, the healthy doses of skepticism towards advertising often attributed to consumers (e.g., Kivetz 2005; Scott 1990) are of less relevance because the consumer culture produces an overall orientation to consumption that is unconsciously assimilated.

Murray (2002) has outlined in detail how symbolic meanings resident in consumer goods are pre-determined by the capitalist system. Consumption codes are assimilated from childhood onwards, resulting in an internalized set of consumption priorities that typically prevents consumers from recognizing the pre-programmed nature of their desires. Any resistance only occurs within the system and is merely cosmetic. The result, according to Murray, is consumers who are merely participating in the construction of a reality that has been pre-determined and thus are unwittingly reinforcing the prevailing market system (see also Baudrillard 1988; Firat and Dholakia 1998).

In recent years there has been an increasing focus in consumer research on consumer creativity (Burroughs and Mick 2004; DeBerry-Spence 2008; Moreau and Dahl 2005). In this research stream, the ways in which consumers manipulate meanings and craft individual assortments of objects are seen to be confirmation of their ability to control their consumption behaviors in deliberate ways that are meaningful and satisfying. However, the strategies that have been interpreted by consumer researchers as masterly and creative could be considered reactive and compromised if they are viewed as consumer responses to market-produced tensions (Murray 2002). This is particularly the case where the role of such strategies is to reduce negative emotions rather than to maximize positive outcomes (Luce et al. 2001).

**OH LORD, WON'T YOU BUY ME A MERCEDES
BENZ? MY FRIENDS ALL DRIVE PORCHES,
I MUST MAKE AMENDS**

JANIS JOPLIN, "MERCEDES BENZ", 1971

As appreciated by Janis, conformity pressures place substantial limits on consumer agency. The instinctive need to create and maintain meaningful relationships with others ensures humans are tuned in to the expectations of other consumers (Cialdini and Goldstein 2004). To effectively achieve their desire for social fit, consumers are compelled to continually monitor the consumption behaviors of others and of themselves (Firat 1994). They observe others' consumption behaviors and reactions to their own consumption choices, and through these monitoring processes they attempt to conform to socially-prescribed forms of consumption (Hormuth 1990; Lury 1996). Advertising can encourage this behavior by alerting people to the ridicule or rejection they may experience if they consume inappropriately (Waide 1987).

Similarities in consumption patterns at the societal level demonstrate that sociocultural forces are very effective in prescribing behavior (Firat and Dholakia 1982). Consumers continually attempt

to utilize the most appropriate behavioral models for their social grouping(s) (Firat 1991), with any differences in behaviors the likely result of differences in "cultural expertise" (Roth and Moorman 1988, p403). Bourdieu (1984) notes that the taste structures taught to members of subcultures form cultural capital that provides an unconscious guide to decision making. The result is that apparent extensive choice in consumer markets conceals the reality that alternatives are constrained at the macro level to a relative few that are socially and culturally acceptable (Csikszentmihalyi and Rochberg-Halton 1981; Droge, Calantone, Agrawal, and Mackoy 1993). Individual differences in behaviors between consumers are considered to be negligible at the macro level of analysis (Firat and Dholakia 1982; Levy 1981).

**SQUARE-CUT OR PEAR-SHAPED THESE ROCKS
DON'T LOSE THEIR SHAPE DIAMONDS ARE A
GIRL'S BEST FRIEND**

MARILYN MONROE, "DIAMONDS ARE A GIRL'S BEST FRIEND", 1953

Marilyn's emphasis on diamonds over relationships reflects the view that objects can be more constant and reliable than people. The withering of the social structures and growing anonymity of most modern marketplaces have been described as resulting in an empty self that is insatiable for consumer goods that fail to satisfy because they cannot replicate the fulfillment that comes with satisfying human relationships (Cushman 1990). In contexts where relationships are superficial, consumers can be highly dependent on consumption for communication, to the point that they have no choice but to employ products in their social interactions (Firat and Dholakia 1998; Hormuth 1990). Consumers have an underlying awareness that they judge others and in return are judged according to their consumption behaviors (Firat 1995). This results in a heightened need to possess certain types of products to facilitate image management (Baudrillard 1988; Pettigrew 2001).

Another consequence of the relative anonymity of modern societies is the need to present oneself differently in different contexts (Firat 1995; Lury 1996). Although most consumers are more comfortable with a stable sense of self, this is difficult to achieve in a social environment that requires them to perform multiple and sometimes competing roles. Attempts to synthesize competing aspects of self can be unsustainable and result in ongoing effortful identity work for the individual (Ahuvia 2005).

Other complications can also occur in the process of integrating objects into the extended self. The individual wishes to feel unique in consumption, thus supposedly selecting objects that are somehow special or unique (Csikszentmihalyi and Rochberg-Halton 1981; Hirschman and Thompson 1997). Paradoxically, the objects selected are often mass-produced and common to many other consumers (Hormuth 1990). Consumers are encouraged to believe that their consumption assortments are distinctive and constitute genuine expressions of individuality (Baudrillard 1988; Firat 1991). For some analysts, this belief is legitimate as small differences in product combinations are considered to be adequate to claim uniqueness (Murphy and Miller 1997). However, others consider it a form of self-delusion as small differences only camouflage the over-riding similarity between the consumption patterns of individuals (Droge et al. 1993).

**I'VE LOOKED AT LIFE FROM BOTH SIDES NOW
FROM UP AND DOWN, AND STILL SOMEHOW
IT'S LIFE'S ILLUSIONS I RECALL, I REALLY
DON'T KNOW LIFE AT ALL**

JONI MITCHELL, "BOTH SIDES NOW", 1969

Joni's description of extensive experience failing to provide definitive answers about the nature of life resonates with the TCR task of attempting to address intractable problems that have resisted resolution despite much effort to understand and address them. We need to acknowledge that existing knowledge structures, and especially the dominant assumptions of consumer agency, will constrain our activities in this area of research (Murray and Ozanne 1991). As Joni alludes to above, if we're not careful our attention will be drawn to the illusions on show (our emperor's clothes) rather than the underlying substance.

Consumer researchers are often located in marketing or management schools, and as such these researchers typically approach consumption from the perspective that market-based consumption is a liberating, enjoyable, and largely optional pastime in which individuals engage at their discretion. This interpretation justifies the activities of marketers and the academics who assist them in their quest to generate profit from the marketplace. However, adopting a TCR perspective calls for a different approach to consumer research and its intended uses. In particular, it highlights the defensive position of consumers in modern markets and the need to empower them to improve their position relative to other actors in the marketplace (Atherton and Wells 1998). The relatively small amount of attention given to consumer empowerment in the consumer behavior literature has focused on the potential for consumer education to assist individuals in achieving their goals and protecting their interests in the market place (Bazerman 2001; Luce et al. 2001; Wathieu et al. 2002; Wright 2002). It is suggested that consumer education should commence early in life and constitute a formalized component of the school curriculum (Benn 2002; Ringold 2002). The underlying belief is that education will assist consumers to act more rationally and thereby enhance their welfare (Atherton and Wells 1998; Bazerman 2001).

Some researchers have pointed to the failure of consumer education initiatives in the past to illustrate that education alone cannot be the answer (Loewenstein 2001). In the case of alcohol consumption, for example, past studies have shown that supply-side factors such as limiting access through minimum age stipulation, restricting store opening hours, and enforcing price increases have been more effective at modifying demand than attempts to educate consumers about the dangers of excessive consumption (Bentzen, Eriksson, and Smith 1999; Wagenaar et al. 2000). At a different level, Seitz (1972) argued that consumer education is inherently futile in dynamic marketplaces where the number of products available is large and growing and where organizations have infinitely more resources at their disposal to obtain and analyze market information. According to this view, consumers will always be in catch-up mode and as a result the power distribution will remain permanently unequal, leaving consumers vulnerable to the actions of those with dominant market power.

Given the inadequacies of education as an all-encompassing path to consumer empowerment, other realms of influence must also be considered if consumers are to be empowered beyond their current position in the marketplace. The important role of social and cultural forces points to the need to address these factors, but they are extremely difficult to change. Influencing the sociocultural environment via upstream initiatives is thus one of the greatest challenges facing transformative consumer researchers. Choices must

be made about which aspects of the sociocultural environment to target and how they will be modified. A first step may be to focus on assisting public policy makers to empower consumers through the development and implementation of consumer-focused regulations and legislation (Hollander, Keep, and Dickinson 1999). Some consumer researchers are already active in this area (e.g., Friedman 1998; Karpatkin 1999; Sommer 1994). Such an approach would acknowledge the limited abilities of individual consumers to change the environments in which they live and recognize the necessity of political intervention to achieve large-scale changes (Benn 2002; Seitz 1972). This approach would respond to Murray and Ozanne's (1991) call for consumer researchers to actively attempt to change social structures to improve consumers' lives. However, upstream initiatives are still likely to face difficulties in achieving consumer empowerment due to the ability of commercial lobby groups to effectively protest government initiatives that have the capacity to diminish their market power (Pal and Byrom 2005).

Another alternative would be to tame the consumer culture of some of its materialistic ways. The enormity of this task is overwhelming, but just as government-induced cultural change has been effective in the past (such as is currently occurring in the area of attitudes to the environment in many countries), there is potential to alter consumers' attitudes regarding their ideal lifestyles. For example, it is theoretically possible for public service announcements (PSAs) to be increased in number to equal or even eclipse commercial advertising. PSAs could actively encourage consumers to create meaning in their lives without an over-reliance on goods and services, such as by cultivating those personal virtues that are ultimately more fulfilling and being less concerned with accumulation (Waide 1987). Of course, such an approach would require decisions relating to which values and virtues should be prioritized, an inherently difficult and contentious task.

A further option is to use our skills and expertise to assist consumer associations and activist groups in achieving their goals. These groups attempt to address the imbalance of market power between consumers and organizations by representing consumers in general and disadvantaged consumers in particular (Karpatkin 1999). Alliance with such groups would allow consumer researchers access to those who have some ability to communicate with and resolve issues for individual consumers and groups of consumers. Such an alliance could also empower consumer groups to interact with governments and industry lobby groups on a more equal footing.

To conclude, researchers seeking to transform consumers' lives in positive and enduring ways may need to step back from current conceptualizations of the consumer that emphasize agency and rational decision-making. Instead, it may be productive to take a more critical view that explicitly recognizes the many and varied forces impacting both researchers' and consumers' interpretations of the consumption process. Stripping back the layers of previously learned and implicitly accepted understandings may hold the key to generating new answers to age-old questions.

Men, Bags and The City - Male's Adoption of Non-Traditional Gender Aesthetics

Ralf Weinberger, University of Innsbruck, Austria

Andrea Hemetsberger, University of Innsbruck, Austria

ABSTRACT

This article studies male's overt consumption of non-traditional gender aesthetics. Phenomenological interviews revealed that consumers use these items to build a unique aesthetic gender identity. Consumers apply strategies of differentiation and contrasting to safeguard their aesthetic individuality and set themselves apart from communal forms of consumption.

INTRODUCTION

"Look, this guy carries a handbag..." Whereas several years ago such a whisper would have led to surprised glances at the guy with the handbag, men carrying handbags in cities are not that much of a surprise anymore. Rather, when taking a walk through cities one can see an increasing number of men carrying handbags in their hands, in the crook of their arms or draped over one shoulder. Uninformed observers may ask themselves "Aren't handbags for women? Have guys become the new gals?"

In recent years males have been increasingly in researchers' foci, since males started to participate in what we denominate here as non-traditional gender aesthetic consumption. We define non-traditional gender aesthetic consumption as forms of aesthetic consumption which break with long held aesthetic conceptions of a certain gender in Western societies. Since the advent of the metrosexual trend (Simpson, 2002), different studies researched such male consumption practices intended for the stylistic and aesthetic display. Changes on the macro-social, social and individual level, caused a reshaping of male identities (Schroeder and Zwick, 2004; Simpson, 2002; Patterson and Elliott, 2002; Nyeck et al, 2002).

Schroeder and Zwick (2004) and Patterson and Elliott (2002) argue that advertising portrayals of men led to a renegotiation of male identities in society. Bakewell et al. (2006) regard women's emancipation and the gay liberation movement as impacting factors on the increasing aesthetic discourse among men. Subcultural communities and peer groups also set boundaries of male's legitimate consumption of grooming products (Rinallo, 2007; Nyeck et al, 2002). An increased male narcissism (Sturrock and Pioch, 1998, Ourahmoune and Nyeck., 2008), rebellions against societal conventions (Nyeck et al., 2002) or transitional lifetimes (Ourahmoune and Nyeck, 2008) were found to be influencing factors on males' embellishing consumptions. However, particularly heterosexual males still fear stigmatization and engage in avoidance behavior (Ourahmoune and Nyeck, 2008, Kimmel and Tissier-Desbordes, 1999). Non-traditional gender aesthetic items go beyond male narcissism, beauty rituals, and new male aesthetics as norms of gendered consumption seem to be relevant here as well. Furthermore, fear of stigmatization and avoidance behavior runs counter overt displays of non-traditional gender objects as fashion items and aesthetic statements of male consumers. We draw on Nietzsche (1969), Featherstone (2004) and Venkatesh and Meamber's (2008) assertion that, by consuming in a non-traditional manner, consumers are creating their lives and selves as aesthetic identity projects.

We aim to research and theorize about deeper seated individual meanings of non-traditional gender aesthetic consumption for consumers' identity projects as well as consumers' patterns of aesthetic consumption. We start with a literature review on aesthetic consumption and identity construction. Following the empirical data we elaborate the relevance and meanings of non-traditional gender aesthetic consumption for consumers. In the discussion

section we work out deviations from present knowledge in the literature and present strategies consumer undertake to manage aesthetic identity projects.

AESTHETIC THEORY

Aesthetics is often perceived as an ambiguous concept of meanings of the beautiful, which can either relate to experiences, sensory characteristics, the arts, or consumption activities (Venkatesh and Meamber, 2008). In this article we understand aesthetics as consumer's interpretation, evaluation and meaning production, which define the beauty of consumption items. We use Nietzsche's contribution as a theoretical introduction into aesthetic theory. Nietzsche's nihilism, the denial of objectivity and persistent truth, renders aesthetics into the sphere of the individual and its interpretations and meaning creations. Nietzsche claims that people are active producers of their (aesthetic) worlds and realities (Welsch, 1997). Aesthetics is understood as being formed by people's individual perception, understanding and interpretation of the world.

Postmodernism resumes this notion of the subjectivity in aesthetics. Aesthetics and Postmodernism are particularly closely tied together, since Postmodernism is *inter alia* born out of fundamental aesthetic changes, such as the collapse of the boundaries between art and everyday life, between high art and the mass/popular culture or an overall promiscuity of styles (Featherstone, 2004). A postmodern approach to aesthetics deems that aesthetics is mixed and strongly interrelated with aspects of the everyday lives, where facets of the political and social life, popular arts or everyday aesthetic issues, such as environmentalism, fashion, and lifestyles, are constituted by aesthetics. A Postmodern aesthetic understanding also implies a plurality of styles and diverse aesthetic notions that exist next to each other, without claiming that a particular style is more important or meaningful (Welsch, 1997).

Featherstone (2004) argues that the consumer culture contributes heavily to an ongoing aestheticization quest of people. People constantly consume and strive for new styles and tastes in order to construct different lifestyles. Consumers aspire aesthetically constructed lifestyles, since aesthetics is the only principle, which still holds in a world where norms and conceptions are in flux. Since modern conventions of "right and wrong" behaviors or styles macerated, people need to individually make sense of what they consider as beautiful and aesthetic (Featherstone, 2004, Welsch, 1997, Firat and Venkatesh, 1995). This aestheticization trend is particularly lived out in urban areas by a young middle class, who is usually more active in the stylization of their lives. The urban context provides people with a style plurality from which they can individually make use of. Aestheticization manifests itself in accumulations of expressive goods such as clothing, furniture, in bodily alterations, and other aesthetic projects, which help people demonstrate their individuality and aesthetic differentiation (Featherstone, 2004; Firat and Venkatesh, 1995; Veryzer, 1995).

Venkatesh and Meamber (2008) argue that consumers are constantly seeking aesthetics in their everyday consumption, highlighting the centrality of aesthetics for people's lives. Venkatesh and Meamber (2008) further contend that aesthetics in people's lives and in consumption practices impact not only on people's taste formations, but also on their emotions and feelings, which are central for people's identity formation. Based on these findings, Venkatesh and Meamber (2008) conceive consumers as aesthetic subjects,

who use meanings of various aesthetics in their identity creations (Thompson and Hirschmann, 1995, Venkatesh and Meamber, 2006). Non-traditional gender aesthetics add to identity creations, which is not limited to the adoption of styles, or to idiosyncratic consumption styles but derives much of its meaning from ‘gendered’ consumption. Gender aesthetics are playfully mixed and matched so as to define one’s gender identity on the continuum between femininity and masculinity.

CONSUMER GENDER IDENTITY PROJECTS

Thompson and Haytko (1997) define identity as a sense of the consumer of who s/he is, which is constantly (re)defined, negotiated and created. In contrast to the postmodern identity conception (Firat and Venkatesh, 1995) or the empty self concept (Cushman, 1990), we assume that consumers actively construct identity narratives in which personal histories and conceptions of the social and cultural environment are interwoven. Consumers refer to market offerings by negotiating meanings and symbols via which they further develop their identity narratives. Nevertheless, consumers try to forge a coherent, if diversified identity narrative (Arnould and Thompson, 2005; Schau and Gilly, 2003; Thompson and Hirschmann, 1995).

Consumption patterns and objects provide people with means to create not only desired, utopian identities, but also to foster the development of consumer’s individual identity narratives (Kozinets, 2001). In the case of transitional life episodes, for instance, consumption objects, such as loved objects also help people to give meaning to these episodes or/and to stay “true” to their own identity. Similarly, certain consumption objects stand for specific personal meanings to which people refer to and by which they construct their subjective individual identity narratives (Ahuvia, 2005). Consumption objects also serve the purpose of socializing and categorization (Holt, 1995). Furthermore, recent research has shown that consumption is also deeply interlinked with individual’s self-understanding of their gender identity.

Fischer and Arnould (1994) define gender identity as the extent to which people think of themselves as masculine or feminine. Connell (2002) conceives gender as a project, where personal and society’s gender understandings are negotiated. Patterson and Elliott (2002) assume that males are currently reevaluating their gender identity understandings since advertising increasingly promotes the groomed, slim and sexy male, attributes which were formerly regarded as feminine. Nyeck et al. (2002) found that the extent of consuming non-traditional gender aesthetics also depends upon the different gender identity understandings of gays and straights. Males consume these items either to blend into their reference or peer groups, thus adhering to the reference groups’ gender understandings or to rebel against gendered conventions and norms of society. In a similar vein, Rinallo (2007) concludes that peer groups of males set boundaries of legitimate male consumption behaviors. Ourahmoune and Nyeck (2008) found that males participate in

clandestine consumption to overcome stigmatizations and social sanction due to their deviation from their peer’s or society’s gender conception. Male’s gender identity understandings are in flux, which is why males have become more involved in their aesthetic appearance. However, males still use non-traditional gender aesthetic items primarily to hide bodily imperfections or to act out their narcissistic needs (Ourahmoune and Nyeck, 2008; Nyeck et al, 2002). These findings run counter empirical observations of overt, public display of traditionally feminine items, such as handbags, which are neither hidden, nor just serve to compensate imperfections or narcissistic needs. It is the aim of our study to address this specific form of non-traditional gender aesthetics consumption and its role in male’s identity narratives.

METHOD

Our empirical study followed a two step process. First, male handbag wearers were observed and approached online, or personally approached on the streets in urban areas. Our purposive sample followed the principles of snowball sampling (Patton, 1991). However, snowball sampling turned out problematic as handbag users rarely knew other handbag consumers. Hence, we adapted our methodology accordingly and followed the technique of criterion sampling (Patton, 1991) which focused a male handbag usage and did not address other characteristics such as e.g. sexual orientations. People, who agreed to participate in our study were asked to write a diary over a period of 2.5 to 3 weeks in which they were asked to write freely about their usage of handbags (Alaszewski, 2006). In addition, informants were asked to take pictures of items of which they particularly liked for their design. In total, 14 participants took part in our study. All of them live in urban areas in Central Europe, with ages ranging from 25 to 42.

In a second step we conducted phenomenological interviews (Thompson et al, 1989) with the participants at their homes or in their offices if participants did not feel comfortable being interviewed at home. Informant’s home and office styles were also observed. We chose phenomenological interviews to learn about the participants’ experiences with non-traditional gender aesthetics and to reveal the deeper meanings of non-traditional gender aesthetics consumption. The interviews started with broad general questions about consumers’ lives and then focused on their experiences with aesthetics and non-traditional gender aesthetics. Secondly, we asked for other experiences with other non-traditional gender aesthetics to reveal the overall importance of non-traditional gender aesthetic consumption to their lives. Subsequently, our questions focused on perceived societal changes and on a self estimation of masculine and feminine traits. We asked about other people’s reactions to the participant’s usage of non-traditional gender aesthetic consumption to reveal stigmatization experiences and behaviors. Additionally, a set of questions aimed at the identification of situations when appearance and style are particularly important to the informants.

Table 1: sample characteristics

Interview 1: Daniel, teacher, 29	Interview 8: Patrick, designer, 30
Interview 2: Marcus, company owner, 28	Interview 9: Simon, editor, 31
Interview 3: Steve, student, 25	Interview 10: Marc, student, 25
Interview 4 : Robert, student, 27	Interview 11: Oliver, make up artist, 24
Interview 5: Peter, hairdresser, 29	Interview 12: Richard, social worker, 27
Interview 6: Thomas, employee, 28	Interview 13: Nico, self employed, 35
Interview 7: Michael, employee, 42	Interview 14: Lukas, student/ marketer, 28

Diaries were not only used to identify important usage situations of handbags but also stimulated stories and narrations about experiences with non-traditional gender aesthetics and about the informant's general aesthetic preferences. Photo-elicitation (Heisley and Levy, 1991) also helped with eliciting relevant stories of non-traditional gender aesthetic consumption.

Interviews lasted between 1h 30 min and 2h 45 min and accounted to a total of a bit less than 30 hours of information. The interviews were transcribed and accounted to 290 single spaced pages of interview transcription. A hermeneutic-phenomenological analysis according to the principles of phenomenological analysis by Thompson et al. (1989) was conducted. An idiographic analysis documented the individual life stories and meaning of non-traditional gender aesthetics. Integrative analysis revealed similarities and differences and allowed us to formulate themes, and relate them to processes of identity construction and differentiation through aesthetic consumption.

FINDINGS

Defining individual gender identity through non-traditional gender aesthetics

The findings revealed that the male handbag usage is not a singular, restricted activity, but it joins the ranks of a personal history of activities related to non-traditional gender aesthetic consumption. Male handbag consumption and usage is merely a continuation of such consumption activities and starts as a search for an aesthetic gender identity.

"In the past it was more colorful, more flashy, also items from the women's collection. Well, my favorite designer in the 1990's was Helmut Lang. I changed between a woman's trousers with a sash ... and also the tops were all for women when I went out"
(Simon)

"[...] or make up, I also used make up back then and that kind of stuff [...] even as a child and I always wore handbags. Male bags, those real ... men bags, like the Freitag ones, I never wore them."
(Patrick)

These verbatims demonstrate that consumers used non-traditional gender aesthetics already in their youth and teenage years when these items were not at all advertised in the media (Schroeder and Zwick, 2004). We assume that a history with non-traditional gender aesthetics facilitates an easier adoption of other or further non-traditional gender aesthetic consumption activities in their later lives. Gendered forms of consumption usually follow a certain path until they become part of an individual's self understanding. The meaning of non-traditional gender aesthetics consumption is not homogenous and changes over the course of lifetime. Some meanings may become dominant for the individual consumer during a specific phase of life. Other meanings may add to the overall pattern of consuming non-traditional gender aesthetics as a part of their aesthetic life project.

Coming out phase

While Ourahmoune et al. (2008), Rinallo (2007) or Nyeck et al. (2002) highlight the distinction between a heterosexual and homosexual involvement, usage, and personal history with non-traditional gender aesthetics, our findings contradicted these results. Both, heterosexual and homosexual males were equally involved in non-traditional gender aesthetic consumptions, yet the purpose of

these consumption activities is different between gay and straight males. Gay informants heavily use non-traditional gender aesthetics for their coming out.

B: sparkling, colorful skirts for males... very, very much so, yes; and deliberately taking them to the countryside to go out. Yes, yes,

A: for what purpose?

*B: To show that this here is a gay guy.
(Daniel)*

B: [...] then it happened very quickly - my coming out phase. Flashy, wrap around skirts, I was bleached blond [...] I also wore handbags then, well such nylon ones.

A: What did you want to express here?

*B: that I was gay.... apparently...
(Simon)*

During this coming out phase non-traditional gender aesthetics help gay males not only to demonstrate their sexual orientation, but also assisted them to define themselves as gay and to negotiate a gay identity during a time when gayness is a central topic for them. As the next respondent demonstrates, these non-traditional gender aesthetics can also fulfill a social-political purpose during the coming out phase. Using non-traditional gender aesthetics is a public statement to the public that being gay is not a problem, and normal.

"[...] I am different, I am gay, I am that obviously gay; look, you can all notice that I am gay, because I don't have a problem with that. I publically demonstrate that I don't have a problem with it. That everyone, the world may know it."
(Daniel)

During the coming out phase respondents also reported that non-traditional gender aesthetics are extensively consumed and applied as the gay scene offers a liminal zone for such activities and aesthetics. When this coming out phase is over, the extent of the usage of non-traditional gender aesthetics often decreases. Hence, we assume that non-traditional gender aesthetics for gay males is also a coping strategy with these turbulent times of defining one's own sexual orientation on the one hand, and dealing with publicity on the other hand.

Urban change and freedom

Some respondents mentioned that they were more heavily involved in this form of consumption when they either moved to a city (Ourahmoune and Nyeck, 2008) or started to spend most of their time there. Here, the contrast between the city and countryside, where the respondents felt constrained in their possibilities, becomes apparent.

A: You mentioned that you wanted to move to a bigger city, why was that?

*B: I don't know, I am just like that. A lot of people say "Listen Alex, you just belong to a big city". In the village I was always the odd duck, and therefore I thought that I needed to go to a big city [...] well and I was being looked at in an odd way. Particularly when you are not coming from a big city, where there are different people like you. And that is why I am feeling quite comfortable here."
(Oliver)*

The city liberates and provides freedom to act out one's own identity and to consume products, such as non-traditional gender aesthetics, which would render the individual as the odd one out on the countryside. However, respondents also used non-traditional gender aesthetics to symbolize their transition from the rural area to the city and to establish a stark contrast to the rural social environment. Non-traditional gender aesthetics are used as a strong sign of a genuine urban lifestyle identity.

"For a country bumpkin, XXXX was a metropolis par excellence. Then it was also to show your friends from the countryside "look I have been to the city and I have become really city-like", because I wear glittering clothes...."
(Daniel)

Individual gender understanding

The responses concerning the gender understandings of the respondents supported the notions that male identity conceptions are currently changing drastically (Ourahmoune and Nyeck, 2008, Schroeder and Zwick, 2005). On a continuum contrasting of what the individual respondent connects with masculinity on the one hand and femininity on the other hand, informants rated themselves as being somewhere in between the masculine – feminine continuum. In describing themselves, respondents also referred to attributes which they used to describe femininity.

"Yes, well, probably something in between a bit. Yes, because, since I am not embodying what I consider as masculine, yes, well I am rather ... a bit androgynous."
(Simon)

"Puh, I would say somewhere in between these two. Well in between these two, I don't hope that I am appearing too feminine, but I also don't feel the need to appear too masculine...."
(Marc)

These findings also highlight that the respondents, gay and straight, do not have a problem to incorporate feminine traits into their self understanding. Heterosexual and homosexual males do equally not try to neglect them and spoke freely about aspects of their identity which could be rated as feminine. Male's gender identity understandings are not set in opposition to feminine attributes but rather combine attributes of both genders into their aesthetic identity.

(Non)stigmatized

In contrast to the results by Kimmel and Tissier-Desbordes, (2000), Ourahmoune and Nyeck (2008) or Rinallo (2007) that non-traditional gender consumption behaviors are stigmatized and that males, in particular heterosexual males, enact avoidance behaviors due to fears of social sanctions such as ridicule, our study rather supports the opposite. Informants are quite bold in their public display of non-traditional gender aesthetics and did not fear social sanctions or stigmatization. Several informants, heterosexual as well as homosexual, already experienced some forms of sanctions such as name calling or ridicule, but instead of avoiding carrying non-traditional gender aesthetic items, they vehemently defend their individual identity project.

B: "why are you running about with a bag like a fairy?"
A: Who said that?
B: These were close acquaintances.

A: And what did you think when you heard that?

B: Bite me! [laughs]

A: So would you abstain from using the bag?

B: No. No. No. No. When I need it, then I need it. I am not here to ... satisfy any aesthetic or social requirements of other people.

(Nico)

Not only did the informants not refrain from using non-traditional gender aesthetic objects when they experienced social sanctions but some also reported that they actively fight against such ridicule. Although the participants were sampled in urban areas of different population size (from 130.000 inhabitants to 1.3 million), larger urban areas are not different in that regard. Nevertheless, respondents reported that such social sanctions are quite rare.

Stigmatizations and social sanctions do occur, however our study did not support previous findings of avoidance behavior and fear of stigmatization. Also heterosexual's fear of being judged as gay (Ourahmoune and Nyeck, 2008) was not supported, which gives rise to the assumption that non-traditional gender aesthetics consumption is rather a deliberate, bold statement of one's uniqueness and individuality as a male consumer.

Constructing aesthetic individuality

Uniqueness and Otherness

Non-traditional gender aesthetics facilitate differentiation from others and from mainstream consumption. Respondents report a particularly strong desire to demonstrate their otherness within their surrounding social environment. Non-traditional gender aesthetics provide the means to construct a unique individuality even at the odds of being totally out of fashion, or far ahead of any fashion trends.

"I even have more extreme ones[watches], the one is pink with turquoise and has in the centre a diamond, which is rotating, such a... everyone would think that I am nuts. No one would wear anything like that."

(Steve)

"The lacquered shoes, the bags, be it the normal shoulder bag or the handbag, doesn't matter, because no one in my environment wears any bags like that. Ahm sunglasses, huge Dior sunglasses, Ray Ban, whatever, ahm jewellery, ...everything that the XXX newspaper is spreading as styling tips, that is, yes, well, that is for people who do not want to draw attention, these are people who are satisfied with what society tells them to do. I am different."

(Robert)

Apart from the creation of aesthetic boundaries from the surrounding environment (Featherstone, 2004), individuals thereby also negotiate their individual need for attention or blending in. Using non-traditional gender aesthetics does not only facilitate differentiation, but due to this purposeful public display individuals draw attention to themselves as aesthetic subjects. Yet throughout the interviews it became obvious that non-traditional gender aesthetics are not geared at provoking others. Rather, respondents emphasize their aspiration to differentiate themselves from the masses. Individuals sort of participate in a tightrope walk between catching attention and blending into contexts such as events, job environment or leisure time activities. They also indicated that they did not have a history of provocation, oftentimes not even during puberty or teenage years.

"I am a person who needs a tremendous lot of attention. Ahm ... probably that's also one of the reasons why I am dressed like this and buying those things. Not to boost my ego, but to ... simply...I am against this group thinking, this collective thinking. Ahm I am rather, I was born as an individual and I don't need to be like everyone else. That means that I also don't need to please everyone."
(Robert)

Non-traditional gender aesthetics help people create their self as non conformist. Respondents repeatedly judge the mainstream as negative from which they want to distance themselves. Perceived narrow-mindedness, constrained thinking or collectivism were noted characteristics of their environment from which the individuals want to (aesthetically) distance themselves. Hence, respondents in most cases were the only ones in their environment to carry handbags and only few knew other males who used handbags. Informants also did not participate in handbag consumer communities. None of the informants would be active or know about handbag communities as this would run counter to their deep inner aspiration to be unique; different; interesting.

Self branding

In a similar vein, people use non-traditional gender aesthetics for the purpose of "self branding". They purposefully display their handbags and /or extravagant outfits to portray themselves as unique and to generate a lasting impression. Self branding with non-traditional gender aesthetics means to ease the identification and recognition of people at social events, or in business situations. This form of self branding was particularly widespread among individuals who run their own (fashion) business.

"Yes, there are always looks and laughter that he has his bag with him that's an identifying feature [...] yes, people know you because you always have the bag with you [...]"

A: How is that...?

"Actually that's pleasant, positive. And it supports the brand. Hm... the ego"
(Marcus)

"I also wear one from my collection in the evening when I go out, then I wear the clutch I have my business cards, the cigarettes, the money and the cell phone and that is often the first topic when I am talking. With the rich women, when they ask me where I got that great bag from then I say "from my own collection" and you strike up a conversation like that."
(Patrick)

Here, non-traditional gender aesthetics are used in a business context for self branding and for branding the business. Hence, non-traditional gender aesthetics are part of the fashion system, and are used to demonstrate uniqueness and innovativeness.

"You get attention in certain circles and you develop an own brand and it is prototypical for someone that he always appears like that, that's important [...]", Marcus).

In this context the personal identity project coalesces with the company purpose and serves to build a strong (self and corporate)

brand identity. Individuals purposefully select the appropriate handbag and outfit to draw attention to their specific business idea.

Contrasting

Individuals create their own aesthetic identity by consuming aesthetically unique or exceptional items. When a certain style, which they liked at the onset, is taken over by several people, the same style can become unaesthetic to them.

"The funny thing is that there are products that are beautiful in my opinion and which I like, but when a lot of people wear them, they become ugly."
(Steve)

"I would say indeed that I would not wear something that a lot of people are wearing. If there are one or two then it is okay [...]"
(Thomas)

Consumers actively search for styled products, such as clothes which few other people consume. This quest for consumer individuality is not restricted to fashion but is also to be found in other areas of aesthetic consumption, such as food or hairstyles. It can even pervade a consumer's whole consumption behavior, where items are actively avoided as soon as other people possess them.

*A: when did you start to search for your very own style?
"it started... it has actually always been like that that I always wanted the items that others did not have."*
(Steve)

This aesthetic life projects are not restricted to consumption in a narrow sense. For certain consumers this aesthetic striving is central to their lives and extends into other life areas, such as their choice of partners or friends.

"I have to admit that the particular look - being particular, also applies to my girlfriends. [A: yes?] Well I don't like normal girlfriends; they are too boring for me. They need to be special in a way. I had completely different types. But they always draw attention. They always stand out."
(Steve)

Another way to achieve one's aesthetic goals is not by avoiding consuming mass aesthetics but by avoiding items that are in fashion. Instead of using purchased fashion items, they are stowed away until it is out of fashion and other people do not use or wear it. Individuality becomes the dogma of consumption, even at the expense of not being able to use new fashion items and being totally out of fashion.

"Right, it will become old and shabby and then in ten years no one will wear such a thing, but it is classic enough to look okay and in ten years I can wear it. No one will wear a thing like that and then it will just be fine"
(Nico)

One way of understanding the desire for individuality is that respondents feel an intrusion into their private sphere when other people are similarly dressed or have similar aesthetic understandings.

“When there is a point where you are converging, and clothes are one example of that, then you need to deal with this person and this may cause, well not anxieties, because nothing is happening, but ah... well.. it's a strange feeling”
(Richard)

Similar to the striving for uniqueness and otherness, contrasting serves the need for individuality. Contrasting, though, goes beyond just using non-traditional gender items, and is psychologically distinct. Whereas uniqueness supports the extended self, contrasting helps delineating individual identity from collective identity and sameness.

Non-traditional gender aesthetic consumers also had recurring aesthetic styles in their consumption behaviors. Thus we assume that consumers have certain aesthetic styles according to which they, inter alia, choose products and base their consumption decisions on. However, this does not mean that consumers have only one specific style but they deliberately choose different ones, which they can use to contrast their aesthetic style with others. In an aesthetic context, respondents evaluate authenticity based on mass consumption of items (=unauthentic) or on individually used, unique products. Aesthetic authenticity can be achieved when very few or no other people possess the same items, or are unable to copy a particular aesthetic style mix. Whereas Beverland (2005) contends that authenticity is socially constructed, our findings rather indicate that non-traditional gender aesthetics serve the purpose of highly individualized aesthetic authentication.

DISCUSSION

The findings of our study contribute to theory in at least two important ways. First, they show that consumers use non-traditional gender aesthetic items to deal with important life projects, such as the negotiations of gay, of urban and of gendered self understandings and to create a unique and authentic self. Our study highlights that rather consumer's gender identity than their sexual orientation influences non-traditional gender aesthetic consumption. Second, by contrasting consumption behavior and styles with those of others and emphasizing otherness, respondents also contrast the current emphasis of communal forms of consumption in consumer research. Instead, they highlight the necessity to redress the balance between highly individual and highly communal forms of consumption.

Our findings address motivations and strategies to achieve individuality by participating in individual aesthetic identity projects. Consumers of non-traditional gender aesthetics demonstrate a particularly high need to deviate from common, mass consumption. Similar to Nietzsche's (1969) and Featherstone's (2004) notion of the individual aesthetic self, individuality is expressed by a constant quest for uniqueness and otherness and the creation of an authentic, inasmuch individual, aesthetic identity. For this purpose consumers pursue different strategies to aesthetically escape commoditization. One strategy refers to the creation of distinct consumption activities by public display of non-traditional gender aesthetic items. Contrary to prior findings (e.g. Ourahmoune and Nyeck, 2008, Kimmel and Tissier-Desbordes, 1999) stigmatization is not an issue, as being different is the prime motivator for non-traditional gender aesthetics.

A further strategy is the creation of aesthetic contrasts. People create contrasts in their personal, individual styles so as to emphasize otherness. Furthermore, contrasts are created through the application of diverse styles to facilitate an aesthetic break from the ordinary. A third strategy relates to the individualization of consumer objects. Consumers either remove parts, redesign or olden consumer articles to distinguish themselves from the masses.

Contrasting is also used to negotiate consumers' individual place in society. Rather than provoking and standing out at any rate, they try to style themselves appropriately (e.g. not in tutu for opera) to contexts and occasions. However, within this context dependent aesthetic range, aesthetic individuality is emphasized through non-traditional gender aesthetics. By contrasting context-dependent with non-traditional consumption, individuals sharply distinguish themselves from others.

Three different indicators also support our assumption that non-traditional gender aesthetics are a highly individual rather than communal form of consumption. First, snowball sampling technique could not be successfully applied to recruit interview partners and respondents frequently mentioned the individuality of their aesthetic behavior. Second, to our knowledge participants did not participate in internet communities of male handbag wearers. Third, a lacking of a consciousness of kind (Muniz and O'Guinn, 2001) became obvious in respondents narratives. Male handbag users rather emphasized their uniqueness and striving to set themselves apart from the masses. Based on these indicators, we may conclude that non-traditional gender aesthetics are a genuinely individual life project which runs counter communal forms of consumption in brand communities (Muniz and O'Guinn, 2001). When items, which consumers judge as expressive for their individual aesthetic identity, are copied or become fashionable, their aesthetic identities are endangered. Consumers, again, seek to contrast communal forms of mass aesthetics by seeking for the non-traditional. Interestingly, non-traditional gender aesthetics does not oppose social norms or communal forms of consumption in a resistive manner but rather seeks to authenticate a unique and distinct aesthetic gender identity.

Do Foreign Brand Preferences Lead to Counterfeiting? Cross-Country Insights

Bernhard Swoboda, Trier University, Germany

ABSTRACT

Foreign brand preferences matter when explaining consumers' counterfeiting behavior. The study examines the indirect impact of foreign brand preferences on purchase intention toward counterfeits for developing and developed countries. These impacts are moderated by price consciousness and integrity. Results show that price consciousness is more crucial in developing countries.

INTRODUCTION

Many international companies selling branded goods suffer losses of up to 10% of their revenue due to counterfeits (Business Standard 2009). Not only is consumers' demand diverted, but counterfeits also devalue the genuine foreign brand and thus jeopardize the brand's equity (Green and Smith 2002). Now that 'Louis Vuitton' handbags are sold for ten dollars at the wayside, the unique brand's style appears on thousands of consumers, undermining the foreign brand's exclusiveness. Counterfeits are a cheap way to embellish oneself with admired symbols. However, the way in which consumers' illicit behavior is driven by foreign brand preferences is unclear. Foreign brand preferences have been investigated in the context of the country-of-origin (COO) effect, which is related to the country's level of economic development (Bilkey and Nes 1982). Foreign products from developed countries are preferred to products from developing countries (Ger, Belk, and Lascu 1993). Especially in developing countries, quality and prestige are ascribed to foreign brands (Batra et al. 2000). Thus, not only foreign brands, but also counterfeits allow consumers to display status brands, but without paying a premium price (Grossman and Shapiro 1988) when choosing the latter. Chuchinprakarn (2003) shows that taste for Western products and materialism predict the use of counterfeits.

The purpose of this paper is to analyze the relation between foreign brand preferences and purchase intention toward counterfeits. Such a cross-country investigation broadens the understanding of consumer behavior and gives insights for actions implemented internationally that are aimed at tackling companies' losses caused by counterfeits. We examine whether or not foreign brand prefer-

ences (FBPs) indirectly impact the purchase intention toward counterfeits (PItC) through attitude toward counterfeits (AtC) and attitude toward originals (AtO). As the most crucial antecedents for purchasing and against purchasing counterfeits, price consciousness (PC) (Bloch, Bush, and Campell 1993) and integrity (IN) (Ang et al. 2001) are tested as moderators. In detail, we examine the following research questions:

1. Do FBPs indirectly impact PItC?
2. Does the impact differ between developing and developed countries?
3. Is the impact moderated by price consciousness and integrity?
4. Are there different strengths between developed and developing countries for those moderating effects?

The remainder of this study is organized as follows: referring to the theory of reasoned action, we derived hypotheses linking FBPs and PItC indirectly through AtC and AtO. Beside this basic model, additional moderators are tested which stimulate and impede the purchase of counterfeits. The analysis is based on consumer data from China, Romania, and Germany, applying multi-group structural equation modeling. Results are presented and discussed before limitations and further research are addressed.

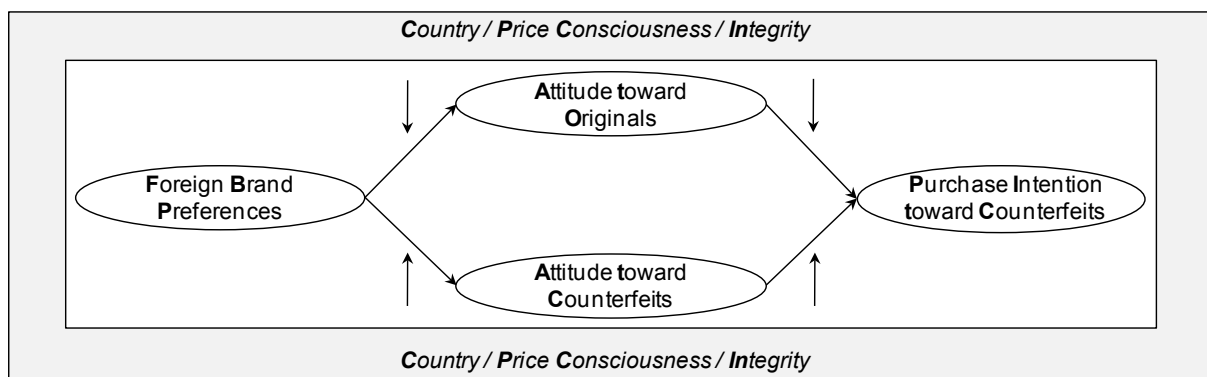

CONCEPTUAL FRAMEWORK AND HYPOTHESES

The conceptual model underlying our research is twofold (see Figure 1). Firstly, we build upon the work of Batra et al. (2000) and Ger et al. (1993) when outlining how FBPs are indirectly linked with PItC. Based on the theory of reasoned action (Ajzen and Fishbein 1980), we focus on the basic model indirectly linking FBPs and PItC through AtC and AtO. Secondly, we outline the moderating variables of country, price consciousness, and integrity.

Foreign Brand Preferences

Consumers base their purchasing decisions on intrinsic as well as extrinsic information cues. Extrinsic cues (e.g. brand name, brand's COO) are used especially when intrinsic cues are not immediately accessible (Jacoby, Olsen, and Haddock 1971).

Figure 1: Conceptual Framework

Consumers' preferences for foreign brands are strongly linked to the COO effect, which has been studied intensively in academic literature (for literature reviews see Bilkey and Nes 1982; Peterson and Jolibert 1995; Verlegh and Steenkamp 1999). Schooler (1965) showed that consumers evaluate identical products differently when the products' COO is varied. Thus, the brand's origin serves as a cue for product evaluation (Bilkey and Nes 1982; Han 1989), as well as for social status and prestige (Batra et al. 2000). Foreign brands, especially Western brands in developing countries, have a positive effect on brand attitudes (Ger et al. 1993). This has become apparent in developing countries like China and Romania, where - in times of communism - foreign brands had restricted market access (Ger et al. 1993). Since the rapid influx of foreign brands in developing countries (Walters and Samiee 2003), foreign brands' origin is mainly associated with developed countries and therefore used as extrinsic cue for brand evaluation.

Counterfeits

As mentioned previously, not only foreign brands, but also counterfeits allow consumers to display status brands, but without paying a premium price (Grossman and Shapiro 1988). Thus, counterfeits are the cheap way to embellish oneself with admired symbols. Following Lai and Zaichowski (1999) and Cordell, Wongtada, and Kieschnick (1996), counterfeits are illegally made products that copy a trademark, but are typically of lower quality and price. Research findings show that consumers' purchase intention is influenced by their attitude toward counterfeits (De Matos, Ituassu, and Rossi 2007), which in turn is affected by object-related factors, such as brand image, price, and COO (Bian and Moutinho 2008; Bloch et al. 1993; Chakraborty, Allred, and Bristol 1996), as well as by psychographic factors, such as moral beliefs and materialism (Wee, Tan, and Cheok 1995; Wilcox et al. 2009). Materialism and the taste for Western products predict the use of counterfeits (Chuchinprakarn 2003), thereby taste is described as the concept of brand preferences and materialism.

Theory of Reasoned Action

The conceptual model is based on the theory of reasoned action (Ajzen and Fishbein 1980) whereupon a person's attitude predicts behavioral intention, which in turn predicts actual behavior. In their study of drug consumption, Bentler and Speckart (1997) found that attitude is a more accurate predictor for intention than for actual behavior. We therefore apply this attitude-intention relationship to our model, which also uses criminal intention as an outcome variable. This outcome variable $PItC$ is explained by AtC on the one hand and by AtO on the other. Cronan and Al-Rafee (2008) and Cordell et al. (1996) showed that AtC affects consumers' $PItC$. Although AtO has received less attention in the literature, it is not necessarily less important when explaining consumers' $PItC$. Consumers' choice between the original (genuine brand) and the counterfeit is influenced, for example, by the genuine brand's equity (Yoo and Lee 2005) or the consumers' fairness (Ang et al. 2001) toward the original. Consumers' behavioral intention is based on the attitude toward the behavioral options to buy the original or the counterfeit.

As mentioned above, there are common drivers, such as materialism (Wilcox et al. 2009) and conspicuous consumption (Phau and Teah 2009; Wang and Chen 2004), that link FBPs with $PItC$. Since brands offer an identity, consuming of brands is motivated by achieving status and social prestige (Eastman, Goldsmith, and Flynn 1999). Foreign brands carry symbolic meanings of quality and social status which have been widely acknowledged in developing countries (Batra et al. 2000). "Counterfeiting unbundles the status and quality aspects of a product" (Grossman and Shapiro 1988, 82), thus consumers holding FBPs are supposed to favor genuine

brands on the one hand or counterfeits on the other. Summing up, we hypothesize:

Hypothesis 1-Basic: The stronger the consumers' FBPs, the more positive their AtO .

Hypothesis 2-Basic: The stronger the consumers' FBPs, the more positive their AtC .

Hypothesis 3-Basic: The more positive the consumers' AtO , the lower their $PItC$.

Hypothesis 4-Basic: The more positive the consumers' AtC , the higher their $PItC$.

Moderating Effects

A **moderator** addresses the question of 'when' a variable most strongly predicts or causes an outcome variable (Fraizer, Tix, and Barron 2004). It can be hypothesized that the relations of the basic model vary across the context variable country, as well as across the psychographic antecedents price consciousness and integrity. Including these moderators in the basic model will give a deeper understanding of 'when' consumers who prefer foreign brands favor either the original or the counterfeit.

Differences between developed and developing countries. Bilkey and Nes (1982) extracted several differences between developed and developing countries from prior research and suggested a positive relationship between the level of economic development and product evaluations. A significant body of research has studied products' COO in developing countries, where their origin serves as a symbol for status and therefore suggests overall quality (Batra et al. 2000). This has been examined for developing countries such as China (Sklair 1994), where "everything foreign had an automatic cachet" (Sklair, 269), as well as for Romania, where "status goods are nearly inevitably foreign" (Ger et al. 1993, 104). Developing countries provide an environment where interpersonal relationships play an important role (Ger et al. 1993) and status mobility is high (Kottak 1990, 49). Thus, in developing countries, foreign brands are used to display status and to participate in the global consumer culture (Venkatesh and Swamy 1994, 207). Studies in Western developed countries show that foreign brands were favored only when product quality was perceived as superior (Knight 1999; Gürhan-Canli and Maneswaran 2000). One can suggest that foreign brands are not automatically a signal of quality and prestige for consumers in developed countries.

Hypothesis 1-4-C: The suggested paths differ between developed and developing countries.

Price consciousness. From a consumer's point of view, a price premium signals prestige and exclusiveness. While prices are kept high, the brand is available exclusively to a special customer group that can afford to pay a premium. Counterfeits are alternatives for consumers with limited purchasing power. According to Bloch et al. (1993, 31), "people buy counterfeits because they are getting prestige without paying for it." Price consciousness can be defined as "the degree to which the consumer focuses exclusively on paying low prices" (Lichtenstein, Ridgway, and Netemeyer 1993) and has been shown to be crucial in explaining consumers' purchase intention toward counterfeits (Albers-Miller 1999; Bloch et al. 1993; Cordell et al. 1996). Thus, we assume that:

Hypothesis 1-4-PC: The suggested paths differ between consumers with high and low price consciousness.

Integrity. While price is discussed predominantly in the literature on what drives the purchase of counterfeits, integrity is a much investigated variable that prevents consumers from purchasing counterfeits. Ang et al. (2001) found integrity to be the best predictor for attitude toward piracy. Lawful-minded consumers who place importance on ethical standards have a less favorable attitude toward piracy (Ang et al. 2001). Also Kwong et al. (2003) found that ethical belief has the highest impact on attitude toward piracy. Integrity refers to lawful and moral beliefs. According to Kohlberg's (1976) moral competence theory, individuals' intentions are affected by their personal sense of justice. Cordell et al. (1996) found that lawfully guided consumers are less likely to purchase counterfeits. Therefore we assume that:

Hypothesis 1-4-IN: The suggested paths differ between consumers with high and low integrity.

Price consciousness and country differences. Several studies (e.g. Watchravesringkan, Yan, and Yurchisin 2008) examine cross-country differences in price perception. According to the

economic disparity of the countries of investigation, consumers' price consciousness might be influenced by the home country's level of economic development. Consumers from developing countries are more price conscious (Fan and Xiao 1998) than consumers from developed countries. Thus, we assume:

*Hypothesis 1-4-C*PC:* The suggested paths are moderated by the country's economic development and consumers' price consciousness.

Integrity and country differences. When investigating counterfeiting, national legal settings and public policies are highly relevant as antecedents for lawful attitudes and intentions (Cordell et al. 1996). Comparing the countries of investigation, they differ in their tradition of trademark protection. Thus public visibility and acceptance of counterfeiting differ between the countries. In contrast to the developing countries, developed countries such as Germany have long-established trademark legislation (Germany since 1874). Generally speaking, law and social norms are related: norms can be a source of or a substitute for law (Posner 1977). In view of the

Table 1: Sample Characteristics

Table 3: Measurements: Operationalization and Reliability

Foreign Brand Preferences (FBPs) ($\alpha = .807$; AVE = .667) Reference	
I prefer to buy foreign brands if I want to give the product away as a gift.	Adopted from Staack and Schramm (2005)
When I invite friends, I try to offer foreign brands.	
I choose foreign brands because they are cool and hip.	
It's best to buy foreign brands because they are of high quality.	
Attitude toward Originals (AtO) ($\alpha = .625$; AVE = .596)	
I want to support the brands I like.	Adapted from Wang et al. (2005) and Ang et al. (2001)
If I cannot distinguish between the original and counterfeit, I won't buy any of them.	
I always choose brands because they grant a guarantee.	
Attitude toward Counterfeits (AtC) ($\alpha = .676$; AVE = .727)	
Because fashion changes so fast, I would not mind buying fake brands.	Adapted from Ang et al. (2001)
I buy fakes because they copy the newest version of the brand which is not available here.	
Purchase Intention toward Counterfeits (PitC)	
I intend to purchase counterfeits in fashion and clothing.	Adapted from Ajzen and Fishbein (1980)
Price Consciousness (PC) ($\alpha = .713$; AVE = .776)	
I am willing to pay a premium for my favorite brand (r).	Adapted from Huang, Lee and Ho (2004), developed by Lichtenstein et al. (1993)
Generally I am willing to pay more for brands (r).	
Integrity (IN) ($\alpha = .670$; AVE = .771)	
It is illegal to buy fakes.	Adapted from Ang et al. (2001)
It is immoral to buy fakes.	
GFI = .982; AGFI = .966; TLI = .948; CFI = .965; RMSEA = .051; $\chi^2/df = 196.678$ (d.f. = 30); $c2/df = 6.556$ α = Cronbach's Coefficient Alpha; AVE = Average Variance Explained.	

facts, we assume that consumers in developed countries are more lawfully and morally guided toward counterfeits than consumers from developing countries. Thus, we hypothesize:

Hypothesis 1-4^{C9IN}: The suggested paths are moderated by the countries' economic development and integrity.

EMPIRICAL STUDY AND MAIN RESULTS

Sample Design

Some 2700 face-to-face interviews were conducted in three urban areas in China, Romania, and Germany. Random samples of 700 questionnaires per country were included in the analysis to compare equal sized country samples, as can be seen in Table 1. The survey was based on quota sampling modeled on age and sex, according to the national distribution of the population.

Anonymity was assured and an explanation was given on how counterfeits should be understood according to Lai and Zaichowski (1999) and Cordell, Wongtada, and Kieschnick (1996). In order to enhance the generalizability of the study (Alden, Steenkamp, and Batra 1999), we chose the countries of investigation according to their level of economic development. Based on the GDP per capita, China and Romania are among the developing countries, whereas Germany belongs to the developed countries, as illustrated in Table 2.

Measurements

The measurements were drawn from established scales using five-point Likert-type scales.

The dependent single item measure PltC asks about clothing and fashion goods, thus our results are limited to this product category. We performed confirmatory factor analysis (CFA) to

verify the measurement (Gerbing and Anderson 1988,) as can be seen in Table 3.

In addition to the classic tests for checking validity and reliability (e.g. Fornell and Larcker's 1981 procedure for assessing discriminant validity), verification of equivalence and measurement invariance are especially important in cross-cultural studies. Firstly, we applied the forward translation and back translation method to ensure semantic equivalence (Berry 1980). In a second step, assessment of the content-related equivalence, i.e. measurement invariance, was conducted in three checking stages (Steenkamp and Baumgartner 1998): tests for configural, metric, and scalar invariance. According to Cheng and Rensvold (2002), partial scalar invariance is largely confirmed for all constructs between the countries, as illustrated in Table 4.

Method

The analysis is based on multi-group structural equation modeling. Three moderating factors are tested within the model: (1) country, (2) price consciousness, and (3) integrity. The first moderator includes China and Romania as developing countries and Germany as developed country. The latter two moderators were conducted by splitting each country sample into two groups according to their mean: high versus low price consciousness and high versus low integrity.

The moderating factors price consciousness and integrity are compared using the model fit ($\chi^2/d.f.$, AIC, and MECVI) to access which moderator is most crucial. Absolute fit measures like Chi-Square/degrees of freedom judge a model per se, without any alternative, and are not sufficient criteria in our case. Akaike Information Criterion (Akaike 1987) and Maximum Likelihood ECVI (Browne and Cudeck 1989, 1993) are based on information

Table 4: Measurement Invariance Testing

Countries		χ^2	$\Delta\chi^2$ (p-value)	CFI Δ CFI	TLI Δ TLI	RMSEA Δ RMSEA

theory and used when choosing between different models with non-nested data, as in our case.

Results

Our basic model using no moderating factor is accepted. The results (Table 5) reveal that proposed impacts are significant and signs are correct. However, the model fit Chi-Square/degrees of freedom (7.287 > 2.5) exceeds the threshold (Hinkin 1995), but Comparative Fit Index (.958) and Root Mean Square Error of Approximation (.055) are within the acceptable range (Brown and Cudeck 1993).

Adding country as a moderator to the basic model, the results (Table 6) show that eight out of twelve paths within the country comparison differ significantly. However, there was no evidence that developed and developing countries differ significantly from each other. Hypotheses 1-C to 4-C are rejected because we found differences between the developing countries.

Examining the results of the moderating factor price consciousness, hypothesis 1-PC is rejected, but hypotheses 2-PC, 3-PC, and 4-PC can be partly supported: Hypotheses are supported for Romania, but not for Germany, and only hypothesis 2-PC for China. Investigating the results of the moderating factor integrity, hypothesis 1-IN is supported for China and hypothesis 2-IN is supported for Germany.

For Romania, there were no significant differences found between individuals scoring high in integrity versus those scoring low.

The findings of the moderating effect of country and price consciousness ($H_{1-4-C*PC}$), as well as country and integrity ($H_{1-4-C*IN}$), revealed that differences between developed and developing countries regarding the moderators price consciousness and integrity can be rejected.

Nevertheless, we found interesting results when comparing these two moderator models: We tested the moderators country and price consciousness, as well as country and integrity, within competing models to access which model achieves the best model fit. The model applying country and price consciousness as moderators (Table 7) reveals a better model fit than the model incorporating country and integrity as moderators ($\Delta\chi^2(0) = 55.395$; $\Delta AIC = 55.395$; $\Delta MECVI = .026$).

Finally, we also tested other plausible rival models (Steenkamp, Batra, and Alden 2003) which achieve a poorer model fit. When testing reverse causal direction, the model fit reveals a significant 22% poorer model fit ($\chi^2(32) = 299,789$, $p < .001$, $RMSEA = .063$, $CFI = .944$, $TLI = .921$) compared to our proposed basic model ($\Delta\chi^2(0) = 66.619$). Additionally, we provide strong support for the indirect impact of FBPs on PltC. Modeling the direct effect of FBPs on PltC,

c2=486.234 (d.f.=192); c2/d.f.=2.532							
* p<.1; ** p<.05; *** p<.01; n.s. = not significant.							

the rival model fit ($\chi^2(31) = 231,531$, $p < .001$, RMSEA = .056, CFI = .958, TLI = .936) shows a poorer Root Mean Square Error of Approximation, Comparative Fit Index and Tucker-Lewis Index, in addition to a non-significant different model fit ($\Delta\chi^2(1) = 1.639$, n.s.). Based on these results, our proposed basic model is supported.

DISCUSSION

Theoretical Implication

Huang et al. (2004) called for further research investigating the relationship between price consciousness and attitude toward gray market goods. Pursuing this call, the present study reveals insights in the importance of price consciousness and integrity as moderating factors combining two streams of research: foreign brand preferences and counterfeits. After evaluation of the competing models that differ in terms of their moderator, the results indicate the best model fit for the model incorporating country and price consciousness. These results are in line with Bloch et al. (1993), who found that people purchasing counterfeits rely heavily on price. In addition, the competing model using country and integrity as moderators examines the antecedent that was previously found to have the highest impact in lowering PI_TC (Ang et al. 200; Kwong et al. 2003), but in the present study achieves a slightly poorer model fit than the model incorporating country and price consciousness. Especially in Romania, as a developing country, price consciousness plays a crucial role. The impact of FBPs on AtC was not only moderated in strength, but also in direction. For individuals that score low in price consciousness, FBPs impact negatively AtC ($\beta = -.243$, $p < .001$), whereas for their peers that score high in price consciousness, FBPs impact positively AtC ($\beta = .262$, $p < .05$). For China, the moderating effect can be confirmed for only one path, and in Germany for no path. We conclude that price consciousness in such developing countries influences consumer behavior much more than values and norms, like integrity. In Romania, people scoring high or low on integrity did not significantly differ from each other in the proposed relationships. This could not be observed for developed countries, such as Germany, where consumers that score high in integrity have FBPs that lead less to a positive AtC than the FBPs of consumers scoring low in integrity. Thus, integrity in developed countries serves as an inner state that averts a positive AtC, which cannot be observed for developing countries.

Moreover, the findings show that the moderators differ in strength between the countries, but these differences are not due to their economic development alone. Differences might be derived from inherent country-specific patterns, such as cultural differences. The Chinese culture has emphasized the sharing of one's developments with the society. The Chinese understanding of copying and its honor to the master differs from Western beliefs (Swinyard, Rinne, and Keng Kau 1990).

Managerial Implications

Apart from such a theoretical contribution, some interesting insights from a manager's point of view can be drawn from this study. In China and Romania, there are insufficient legal regulations to constrain a rising appreciation for the society's integrity that might disregard counterfeiting. For such regulations, firms must work hand in hand with local authorities. Once counterfeiting is socially disregarded, especially in such collectivistic societies, counterfeits will not be used any more to display status and prestige. Thus, brands' investments should not only target the brand and its intangible value, but also its physical uniqueness, which makes cost-effective counterfeiting difficult.

Limitations and Further Research

Our study does have some limitations: In the dependent variable PI_TC, we ask about clothing and fashion goods, which constrains the results to this product category. Further research should investigate other product categories and especially additional countries to generalize and broaden the results. Although country differences appeared to be significant the data set should be extended to discover the relevance of countries' level of economic development. Examining the influence of culture, further studies should include a direct measurement for cultural dimensions to state culture-specific hypotheses. This might shed some light on the country differences discovered. We also suggest a revision of measurement to include at least four items in order to obtain more scope for eliminating items that have no cross-cultural equivalent.

Gamerz: A Videographic Study of Hardcore Xbox 360 Game Players

João Fleck, Universidade Federal do Rio Grande do Sul, Brazil

Stefânia Almeida, Pontifícia Universidade Católica, Brazil

Marlon Dalmoro, Universidade Federal do Rio Grande do Sul, Brazil

José Mazzon, Universidade de São Paulo, Brazil

ABSTRACT

We utilized a videographic approach to analyze and understand the peculiarities of video game consumption in the context of hardcore players that interact in Microsoft Xbox 360 virtual communities. The results allowed us to infer that the virtual experience and the online interaction are key elements presently in the consumption of games.

INTRODUCTION

The dawn of the video games era is linked to consoles such as Atari and Nintendo 8-bit in the decade of the 1980s (Shankar and Bayus 2003); however, the explosive growth in sales of this equipment is more recent. From 1996 to 2007, video games sales presented a growth of 700% and in 2008, in the United States, the games industry made a profit of \$21.3 billion (Matthews 2009).

The growth of the games market is a result of the considerable improvement in the quality of consoles and systems. Since the 1980s, games producers have released new gaming systems, at five years interval on average, satisfying the desire of consumers that search constantly for more potent games (Clements and Ohashi 2005). It is also noticeable that the advent of the internet in the gaming world has altered the ways in which the interaction occurs, not only among consumers but also among consumers and the producers (Evans et al. 2001). Games with online interaction present an exponential growth and win popularity, including computer games, online games, and video games. These kinds of games are usually multiplayer allowing users to fantasize and to be entertained through interaction in a virtual world (Hsu and Lu 2004).

This virtual gaming world results in a new social and marketable structure with the sprouting of virtual communities of consumption. In these communities, the commitment and the trust can be considered as supporting the relationship structure amongst consumers themselves and also between the consumers and the organization, because the active members tend to be loyal and engaged to the product (McAlexander, Schouten, and Koenig 2002; Algesheimer and Dholakia 2006).

In the video gaming industry, consoles are the mainstream and they represent a mature and competitive market (Williams 2002). This competition allows consumers to develop an optional loyalty. One of the leading companies in consoles is Microsoft with the Xbox/Xbox 360 platform (Matthews 2009). This product already has solid market participation, representing 18.6% of the video game market in 2007 and more than 100 million consoles sold (Orry 2008). Besides the configuration of virtual communities around its product, the Xbox has a hedonic nature: its consumption is involved in stories, myths and rituals, and games are an entertainment product to group consumption. Since the dawn of the video game era, the consumption forms of these products have gone through profound changes, especially regarding the interconnection of players through the internet and the formation of virtual communities. Having this new scenery as our premise, our goal is to understand and analyze the peculiarities of video games consumption from the perspective of hardcore players that interact in a virtual community of Microsoft Xbox 360. We believe that our results are pertinent, because the study focused on users highly involved with the product and

also due to our interpretative approach that allowed the reaching of broader results.

THE GAMES, THE GAMERZ, THE SOCIAL INTERACTION, AND THE FORMATION OF VIRTUAL COMMUNITIES

Online games are a type of entertainment based on the web and on IT. They are multiplayer games that allow the users to fantasize and to be entertained, more specifically the role-playing ones, that are similar to Multi-User Dungeons (MUDs) based on text, and are a hybrid of adventure games and chat. The online players appreciate friendlier interfaces and multimedia effects that are available on traditional MUDs. Besides, the internet allows virtual players to fulfill a series of roles in the fantasy world, interact with others and even to create their own virtual worlds (Hsu and Lu 2004).

According to Mendenhall, Napomuceno and Saad (2010), the characters in games can be analyzed as a form of escapism, because they have abilities that are incongruent with human biology such as the ability to fly. The escapism of virtual games leads to users completely immerse in their cyberspace activities, which characterizes a flow experience (Shin and Kim 2008).

In the flow state, the consumer experiences a sensation of happiness, followed by a feeling of trust and a desire for exploration. A consumer in a flow state also may have his vision of the passing of time distorted, once there is no temporal pressure conducting the specific activity that gives a positive feedback. As a result of this process, the time allocated for such activity tends to increase exponentially (Chou and Ting 2003).

According to Csikszentmihalyi (1991), the flow experience can be defined as the “the holistic experience that people feel when they act with total involvement”. In the vision of Hsu and Lu (2004), this definition suggests that flow consists of four components: control, attention, curiosity and intrinsic interest. When they experience a flow state, people remain absorbed in the activity, their senses are focused on the activity itself, they lose consciousness, and they feel in control of the environment. Using similar reasoning, Hoffman and Novak (1996) characterize the flow state on the web as a cognitive status that occurs during virtual experience, involving: (1) high levels of ability and control, (2) high levels of challenge and activation; and (3) focused attention. This experience is also elevated due to interactivity and telepresence. In an analysis of the virtual gaming world, Hsu and Lu (2004, p.857) defined flow as “an extremely enjoyable experience, where an individual engages in an online game activity with total involvement, enjoyment, control, concentration and intrinsic interest”.

According to Holt (2000), players evaluate video games based on the fact that they provide a flow experience or not. To Chen (2007), the majority of current video games include flow components, delivering a sensorial and instant feedback, and offering clear objectives that the player reaches through specific abilities. Accordingly, a well designed game transports the players to their personal flow zones, arousing genuine feelings of joy and happiness (Chen 2007). The flow experience, social norms and attitudes explains approximately 80% of intentions of online gaming (Hsu and Lu 2004).

Regarding norms and social influences in virtual interactions, Hsu and Lu (2004) argued that interpersonal interaction among players leads to the creation of virtual communities that may increase the business value through the propitiated participation and the loyalty of users. Using the same reasoning, Schubert and Ginsburg (2000) considers virtual communities as social aggregations that emerge on the internet when a sufficient number of individuals carry discussions for a sufficient period, with a sufficient human feeling, to develop networks of personal relationships in the virtual space. In the view of Dholakia, Bagozzi, and Pearo (2004), consumers encounter and interact online for the purpose of reaching personal objectives, as well as objectives shared with other members. Therefore, the aim of virtual communities is to create value and knowledge to all its members (Bagozzi and Dholakia 2002). One of the advantages of such communities for consumers is that they recognize others as themselves (McWilliam 2000). In this way, virtual communities can be understood as networks of interpersonal bonds that provide sociability, support, information, belongingness, and social identity. Also, it is important to emphasize that these communities are “becoming defined socially and not spatially” (Wellman 2005, p.53).

According to Ellemers, Kortekaas and Ouwerkerk (1999) and Bagozzi (2000), social identity is formed by three elements: (1) a cognitive component, formed based on the consciousness of belonging to the group (also defined as self-categorization); (2) an emotional or affective component, created from the sense of emotional involvement with the group and the affective commitment; and (3) an evaluative component, created by the connotation of positive or negative value connected to the feeling of belonging to the group, in other words, the self-esteem based on the group. It is important to highlight that the process of self-categorization accentuates similarities among the individuals and other group members as well as dissimilarities between non-members.

People tend to choose activities that are congruent with the salient aspects of their identities, as well as to support institutions that represent these identities (Ashforth and Mael 1989). They tend to find organizations attractive when their social identities are perceived with a sense of distinction. The higher the level of involvement of a person with an organization, the higher the level of attractiveness the organizational identity over this individual will be (Dutton, Dukerich, and Harquail 1994). A strong identification with an organization makes the cooperative behavior towards group members to be elevated due to: (1) the sense of trust and reciprocity in the community, (2) the higher social attraction among group members and (3) the presentation of a favorable image of the organization for himself and for others (Dutton et al. 1994).

In the view of Hsu and Lu (2004), when players play virtually, the interaction with other users creates a connection of continually growing strength. In that sense, usability through dialogue and social interaction, access and connection is the key to the successful management of a gaming online community (Hsu and Lu 2004). The key to success is the desire of consumers to interact among them, keeping an active community. One of the main difficulties to create and sustain a virtual community of any size is the time, energy and the commitment of consumers around one specific brand or product. This tends to occur only if the brand or product is really a determinant of the lifestyle of consumers, passion or hobby (Achrol and Kotler 1999).

METHOD

In this study we used an interpretative approach through the accomplishment of in-depth filmed interviews with hardcore players of Microsoft XBOX 360. The interviews were held inside the Microsoft headquarters in Brazil, in an event that assembled members

of one of the largest Xbox communities of users in the world, the Portalxbox. We conducted eight in-depth interviews applying an 18 question semi-structured questionnaire with questions regarding two main themes – communities and gaming. The choice of the subjects is due to their profound involvement with the Microsoft console as well as their active participation in the Portalxbox community. The interviews were transcribed and analyzed, afterwards we edited a 42 minute videography, and, based on this videography we re-analyzed the data for this paper. In consonance with the pragmatic perspective, to interpret the data gathered, we used discourse analysis following the guidance of Pêcheux (1969).

In the past, consumer behavior researchers had the tendency to minimize or simply to ignore the importance of the audiovisual aspect of their studies (Kozinets and Belk 2006). However, this atmosphere is changing. The use of videographies as a research method in marketing academic studies is being disseminated recently. In the consumer behavior area, we can cite the studies of Smith, Fisher and Cole (2007), Kimura and Belk (2005) and Bengtsson, Ostberg and Kjeldgaard (2005) among others.

The filmed interview has strong advantages over the one that is audio-recorded or directly transcribed (Belk and Kozinets 2005). It allows the researcher to analyze the body language of the interviewee and also to analyze the tone of a determined answer, generating a better content analysis. According to Spanjaard and Freeman (2006), the videography allows a bigger understanding and richer results than conventional in-depth interviews.

Another advantage of the videographic technique is that it opens more interpretative venues than the written analysis (Smith et al. 2007). Regarding consumer behavior research it is a given fact the visual information are cognitively more complex than textual, and that the learning is facilitated when information is presented in a varied form. Therefore, studies that combine visual and textual elements are more comprehensive for knowledge dissemination (Heisley 2001).

Using the same reasoning, Sherry and Schouten (2002) inferred that one of the most convincing advantages of the validity of this method is its ability to engage the audience in a multisensory set of materials, facilitating the gain of knowledge, not only cognitive, but also emotional and resonant. Last but not least, the videography allows that a study initially intended for the academic audience reaches a broader audience, working as a bridge between the academia and the world outside its boundaries.

RESULTS

To advance on the understanding on videogames and their hardcore players, specifically the users of Xbox 360, we now present the analysis of the eight filmed interviews. It is important to consider that the respondents José, Maurício and Paulo are the administrators and the creators of the community. The other subjects are active users.

THE BEGINNING OF EVERYTHING

The video games industry had its boom in the decade of 1970. In the first development phases, the industry was characterized by very low performance consoles, until 1974, when Sears released the Atari Pong, pioneering a new market. In 1977, the popular Atari Video Computer System was released, creating a new gaming concept. According to the interviewees, the video game culture is directly linked to Atari, since these was the first console of several gamers.

In the beginning, playing video games was susceptible to prejudice and even taboo. In the view of our informants some prejudices endures until today. Maurício comments that, when he started to play, he used to it hidden from his parents:

[...] at that time there was some prejudice [...] even today there still is some [...] but at that time existed not only prejudice, but also some tales, like the one that said that the video game damages the television... so, when my parents went out, we used that free time to play and since then I've been playing [...] since the Atari I had almost all the video games consoles [Maurício]

Another taboo related to games consumption highlighted by the interviewees is the fact that it is related to a childish entertainment. One informant talks about these taboos, especially in the view of his fathers and how they considered video games as something meant for children and that adults playing would be a sign of regression to childhood.

However, it is noticeable that since the acquisition of the first console, the interviewees evolved along with the games industry of games – the childish play stayed behind and the systems evolved to become an entertainment form full of diverse meanings. We observed that the majority of our subjects tried to follow the evolution of the video games industry – when a new product was released, they bought it, and experimented new forms of play. However, in front of the diversity of options aroused preferences related to games forms, types and brands. In the view of the interviewees, specific functionalities of the Xbox strengthen the preference for this console.

Therefore, the Xbox community consists in an attribute for the users of the Microsoft console. The online interaction enabled by the *Live* environment of the Xbox 360 conquered users since its releasing, what is noteworthy, given the fact that Microsoft had no tradition in video games.

The Xbox online environment enabled the creation of bonds among users and generated affinity to the brand. The integration promoted by *Live* results in virtual communities that imply in value for the product given the participation that the environment creates and users loyalty, an outcome of identification with the product, because this congregates users with mutual interest around one community.

SOCIAL BONDING

The social relationships that are developed in the Xbox 360 made the video game more than just a gaming environment. It became an interaction environment, developing social bonding and emotion sharing. This new dynamics provided by the console, attract consumers to beyond the game, as for instance, the online chat, that even can become more important than the game itself:

You can ask several players why they turned their video games on the past week and several of them will tell that they did so just to chat [Bruno]

It is also noticeable the strength of the friendships that are created in *Live*, especially due to the sharing of references, as in the solving of doubts regarding the games. This social interaction sometimes even surpasses the technical questions of a game, for instance, the low graphic quality being minimized due to a good interaction environment. Also, it even surpasses the dissatisfaction with the console itself:

I already lost a console due to its defects and I bought another due to the friends that I've made [...] I have more contact with the friends that I've made in the Xbox than with my so-called physical friends [Alessandro]

It is obvious the extension of the utility of the game as a tool of social interaction. This interaction is a tendency of current video games, making the game a social experience and not an individual one. Allied to that, through the formation of communities, the interaction with other users creates a connection of continually growing strength.

Talking about this belongingness feeling regarding the community – that even utilizes a common language – the interviewees emphasized the fact that on the moment that the game became a social experience, this experience is transposed beyond the playing moment. Due to the involvement in the online games communities, the user encounters commonalities with other users that are interested in sharing feelings towards the game. The socialization through the communities creates the opportunity to performing activities online and offline, information exchange, recommendation and knowledge dissemination.

The involvement with the game became a fundamental element of its consumption. One informant even mentioned that, in his view, to quantify the game consumption nowadays it is impossible just to take into account the time that the player is playing, but how much time in life of a player is related to the game. Commonly, it is perceivable that the users play daily, with a signifying increase of gaming time during the weekends. The concern regarding the excess of time dedicated to the game is constant in their lives, even with some self-imposed limits.

One interesting discovery is that the interviewees consider the game as a healthy form of spending their time, an escape valve and not an addiction:

[...] I simply love it [...] today I play more as an escape valve of the real life, the work, the stress, the financial difficulties [Felipe].

Games nowadays demand a bigger dedication, because they are becoming more complexes and requiring more gaming time. In this way, it is possible to observe a thin line that separates being a hardcore gamer and an addict gamer. The interviewees demonstrated concern regarding being in the limit of addiction and not to exchange real life for the digital one, using reasons to justify their long time of use as well as the complacency of people of their social circle outside the game.

MARKET COMPETITION

The video game market is a multimillionaire industry. Currently, in the configuration of this market, three companies are predominant: Microsoft, with the Xbox 360, Sony, with the Playstation 3 and Nintendo, with the Wii.

In this market configuration, the Xbox 360 and the Playstation 3 are preferred by hardcore players, and both platforms have a similar quality, while the Nintendo Wii is preferred by casual players:

I place the Wii in a relatively inferior level, precisely due to the fact that it has a different focus [...] it is a casual console. You invite some friends over, you take that controllers and shake them. It's a group experience that can be boring individually [Fábio].

Among the differences in consoles, the subjects also emphasized the option of playing online existent in the Xbox 360 and in the Playstation 3, that is not available on the Wii. On the other hand, one interviewee analyzed that the Nintendo console is directly towards a different social interaction, the one that happens physically. The

Wii is considered a product directed to have fun with friends, in a reunion or a party.

We noticed that the users consider the three main options of consoles available in the market to be in two distinct segments. While the Xbox and the Playstation is directed at the hardcore gamer, that demand more complex and long games, with better graphic quality, the Wii satisfy casual gamers that use it as a tool to have fun, mainly with friends.

These differences are confirmed in the games. In the view of the gamers, the Playstation and the Xbox titles have similarities in their libraries and also similar characteristics and quality. The Wii, however is highlighted to have a broader games library, however, with worst games and a stronger focus on games for children.

The Playstation 3 and the Xbox 360 are consoles with similar characteristics. Given the fact that they are directed at a hardcore audience, the companies choose not to do announce in the traditional mass media, while Nintendo use it to publicize the Wii. Due to the focus on the casual user, the promotion of the Wii helps to boost its sales, while the other consoles rely on their network of users to spread the word on their product, generating a positive effect on their consumption.

This element distinguishes even more the difference among the profile of users. In the case of video games, the relationship of the users to the brand is heightened, especially due to the community that it is formed around the product, once that, in this interaction they recognize others as themselves and the formation of a group. In this way, products directed towards a large-scale of users, such as Xbox and Playstation, the building of a network of users guarantees a relationship with the brand and the perennality of the product consumption.

GAME EXPERIENCE

Games are designed in a way that make consumers feel so strongly involved with them to the point that they perceive the games as reality (Mendenhall, Nepomuceno, and Saad 2010). The insertion in the gaming environment incorporates feelings of the real life in the virtual environment. The experience suppresses passions, desires and dreams:

[...] driving games are my favorites, they suppress my desires [...] I strongly value the immersion that outcomes from the game [...] in the moment you turn your TV volume up, you feel yourself as if you were a driver [Bruno]

[...] my biggest passion are cars and the video game is a form of living, at least partially, this passion, because I don't have the money to afford a high performance car, so at least I can drive one virtually [Fábio]

Conversely, the experiences provided by the game are also transposed to outside the virtual world. One subject mentioned that the simulation games brings several elements from reality, as for instance, the racing games in which you have to adjust your car to improve its performance and that they are very similar to the real competition environment. Consequently, the gamers end up searching for information on the real racing environment in order to apply them in the game.

In the view of the interviewees, the consumption experience provided by the video game takes the gamer on a travel to a parallel world and to forget everything else. This is a characteristic of the post-modern consumer in the conception of Firat and Dholakia (1998). The immersion in consumption experiences that differ from the quotidian that enables the opportunity to experience lifestyles

different from the ones daily lived and difficult to bare. These experiences enables the creation of an imaginary in a world of fantasy beyond the real one, creating their own virtual worlds that up to a point may be incongruent with the human abilities.

The experience enabled by the game also arouses memories associated with determined moments of life, as well as feelings and emotion for the players. These feelings are aroused not only by the gaming context, but also by sound and visual effects that are part of the game; especially when they aggregate elements of interactivity:

[...] this is a game that I consider to be a great art, as if it were a film. They managed to create such a unique gaming environment that you end up involved in it, wanting or not, you will be involved with the story and it is very difficult to turn off and go to sleep [...] when that specific music plays, it boost up your energy, not your character's but your own [Renato]

The stimulation of feelings and emotions proportionate to the players a flow experience. During a flow experience an individual act with total involvement with the experience, having in mind anything except overcoming a determined challenge. The diverse element existent in current games, such as music and interactive elements, allied to the fast growing competence of game developers have enabled more intense flow experiences through means of greater demands of learning and high levels of challenge, strengthening constantly the playing desire.

This desire can even overcome the individual rationality in front of what is socially accepted, generating behaviors that are strange even for the gamers themselves. Several interviewees talked about situations in which they felt the urge to play.

A newly released game arrived in the afternoon at work and then you went out to play. It's nothing that will compromise your work performance, but you manage somehow to flee from work to enjoy the new game [Alessandro]

It is clear that the gamers have an exorbitant consumption desire, having the constant need to immediately have in their hands the latest version of their favorite games. But in their conception, this attitude are not characteristics of addiction, because a gamer would only be and addict in the moment that he started to bring emotions from the game to the real world.

The consumption experience is connected to social interaction. In the analysis of the interviews we observed that actions such as stay up all night playing is a social moment, in which, the interaction with the friends group has a great amount of importance. One subject mentioned that the social group creates the propitious environment for the gaming consumption, eliminating possible apprehensiveness and prejudices from others, in other words, during the game, everyone, no matter how different they may be, is sharing the same experiences, probably with a similar intensity.

FINAL DISCUSSION

Our goal in this study was to analyze and understand the peculiarities of video game consumption in the view of hardcore gamers that interact in Xbox 360 virtual communities. We used an interpretative approach through a videography to capture the nuances of this form of consumption.

Based on what was aforementioned, we may conclude that the interaction and the insertion in a specific environment such as the one that exists in the current generation of video games (Playstation

3 and Microsoft Xbox 360) has consequences on the feelings and emotions of players through mechanisms such as social interaction, imaginary construction and flow experience. Nevertheless, the virtual communities that sprout from the online environment aggregate and enhance several artifacts in the use of video games.

The video games – that were initially produced with the objective of entertain solely individuals, or sometimes groups, as long as they were in the same place – evolved in the last years to become one of the main tools of social interaction, creating strong bonds among users, sometimes even stronger than the physical ones. In the view of our informants, we can infer that gone are the days in which video games were an individual entertainment, now it is the era in which they became a social interaction tool.

This form of entertainment, once considered to be designed for children, finds today its main target among youngsters of A and B classes, reaching a profitability of US\$18 bi in the year of 2007 only in the U.S. (Matthews 2009). This figure is even more impressive if we compare it to the profitability from the movies industry in the U.S. in the same period: US\$ 9.6 bi (MPAA 2007).

The characteristics that we use in the present study do not allow us to extrapolate its results and are limited to players of Microsoft Xbox 360. New researches should be conducted along with hardcore players of other consoles or of PC games, aiming at understanding similarities and differences among platforms. We also instigate others to conduct consumer behavior videographies, given its power to capture non-verbal elements that may help in broadening the scope of the studied phenomenon.

Last but not least, it is important to emphasize that leisure, play and entertainment are themes of high importance nowadays and in order to offer a greater comprehension on these sub-areas more researches should be carried, aiming not only at understanding the consumer experience but also using this understanding to support advances in the production side that fulfill the desire of consumers.

“Fine Feathers Make Fine Birds” – Community Brands and Branded Communities

Roland Schroll, University of Innsbruck, Austria

Andrea Hemetsberger, University of Innsbruck, Austria

Johann Füller, University of Innsbruck, Austria

ABSTRACT

This article introduces the concept of branded communities. A qualitative study of Apache, an Open Source software community, revealed that creative communities not only create brands but have become brands themselves. We conclude that we should incorporate branded communities and their members in an extended theory of brands and branding.

ACKNOWLEDGEMENTS

We would like to thank Sally Khudairi and the Apache community for their support, for their willingness to serve as interview partners, and the kind reception at the ApacheCon 2009.

INTRODUCTION

Consumers create brands. With the diffusion of network technologies, consumer innovation and creation is taking on new forms that are radically transforming the nature of consumption and production, branding and meaning creation. This paper elaborates on the notion of many well-recognized scholars that the predominant branding concept needs to catch up with reality and that our current understanding of brands is ripe for review (Holt 2002; Kozinets 2002; Pitt et al. 2006; Prahalad and Ramaswamy 2004b). Especially in the last decade of the previous century technological innovations, such as the mobile phone, the Internet and social software portals such as Facebook, have fundamentally changed our lifestyles and created opportunities for collaboration, participation in the market system, and sharing (Belk 2010; Giesler 2006; Kozinets, Hemetsberger, and Schau 2008; von Krogh et al. 2008).

Similarly, for brands and branding new opportunities arise. Due to an increasing availability of worldwide communication and production capabilities and a general revival of community and tribes in our postmodern society (Cova 1997; Maffesoli 1996), communities are given the means to create community brands (Füller, Lüdicke, and Jawecki 2007) and become brands in and of themselves that members as well as consumers identify with. Meanwhile, grassroots community activities have taken on institutionalized forms of communal production, such as the Open-source organization and the Apache Foundation, and gradually developed into the realm of marketing and branding.

Linux and Apache are well known examples where community members not only develop their software but also create strong brands (Pitt et al. 2006). Community-driven brands like Apache – comprising the leading open source web server and other software products, or Mozilla with their main sub-brands Firefox, Thunderbird, Sunbird, and many others, are initiated, created, owned, and driven by user communities and not by companies and their marketing departments. Community brands, in general, are gaining momentum. They emerge in a wide range of consumer goods as well. Members of consumer communities, for example interested in gaming, skiing, or beer-brewing create, brand, and market their own products - games, skis, or beer, respectively (Kozinets et al. 2008). Those brands create significant brand value. Recent research in this area has studied the value of community brands as compared to commercial brands (Füller et al. 2007), and how brand community practices create value (Schau, Muniz and Arnould 2009).

However, how communities are creating brands and the value of the community itself is yet to be studied.

To this end, we first problematize traditional views of brands and brand creation, and argue that theories of co-creation and customer integration fall short to explain the dynamics of branded communities. Second, we aim to show that communities have taken over important brand functionalities typically fulfilled by brands. By introducing the concept of branded communities we argue that creative communities have become brands in themselves, offering significant meaning for members and non-members alike. Based on our findings, we discuss community brands and branded communities in the context of existing theory and theorize on how community brands may impact markets currently dominated by company brands.

BRANDS AND BRANDING

From proprietary towards open brands

Over the years, brands had transformed from simple markers of identification attached to products to complex social phenomena (Berthon et al. 2007; Mühlbacher et al. 2006). Furthermore, as brands are increasingly perceived as cultural agents that are also expected to give back to the society and fulfill civic obligations (Holt 2002). According to Holt (2002), it is this recurring mismatch between the predominant branding concept and consumer's expectations which results in an ongoing advancement of brands and branding. It is the inefficiency of the predominant branding paradigm, which creates the necessity for brands and branding to move it one step further. However, consumers according to Holt “are revolutionary only insofar as they assist entrepreneurial firms to tear down the old branding paradigm and create opportunities for companies that understand emerging new principles.” (Holt 2002, 89). Holt's view implies that consumers depend on branding efforts of corporations. Only then the advancement of brands and branding under corporate control will continue.

One exception to this is the Open Source (OS) movement. Pitt et al. (2006) argue that, in relation to the Open Source movement, brands and branding are moving towards a fourth and final phase, in which brands will provide the same functions for consumers, but it is unclear which benefits these brands provide for ‘producers’. This does not mean that profit-seeking corporations cannot benefit from OS brands but rather that some of the traditional functions of brands for producers, such as financial incentives, vanish when brands are nonproprietary (Pitt et al. 2006). Indeed, the proliferation of information and communication technologies, together with the re-emergence of new forms of communities (Cova 1997; Maffesoli 1996), challenges the predominant understanding of the roles of corporations in building brand value. For instance, the benefit of reducing consumer's search costs is challenged by the increasing availability of search technologies. Similarly, the risk of buying the wrong product or brand is reduced by the open access to other consumer's reviews and ratings. Many of the benefits brands provided in terms of risk reduction and limitation of search costs proved very valuable at a time when communication and sharing was limited. In an open environment, such as the Internet, sources of brand value have changed (Schau et al. 2009).

Active Consumers and the Brand

Recently, the active role of the consumer in the creation process of brand meaning has attracted scholars' attention. While traditionally the consumer was ascribed a rather passive role, the advantage of integrating the consumer as a co-creator of value has been stressed by several scholars (Payne et al. 2009; Prahalad and Ramaswamy 2004a; Vargo and Lusch 2004). A recent study shows that „where consumers are given large degrees of freedom to create or co-create with organizers, they feel authenticity, a type of soulfulness and meaning, and they respond with enthusiasm, energy, and action” (Sherry, Kozinets, and Borghini 2007, 30). Today, it is widely accepted that consumers can and often do shape, appropriate, and co-create the meaning of commercial brands (Cova and Pace 2006; Kozinets et al. 2004; Muniz and Schau 2005; Thompson and Arsel 2004; Thompson, Rindfleisch, and Arsel 2006). Producers may develop and introduce a brand on the marketplace, but consumers and other stakeholders, then, may modify its meaning in unexpected ways. Consumers may openly denounce brands (Klein 2000), challenge the producer-intended meaning (Kates 2004; Thompson et al. 2006), decide upon legitimate brand ownership (Kirmani, Sood, and Bridges 1999), or even hijack a brand (Muniz and Schau 2005; Wipperfurth 2005).

Despite the influence consumers have on existing brands, an increasing desire among consumers to interact with the market in new ways has been observed (Cova and Rémy 2007; Szmigin, Carrigan, and Bekin 2007). Modernity has widely alienated workers from production processes (Slater 1997), workers lost ownership of the products they produced (Bocock 1993). This is a profound detachment of work from workers. Following Marx, the process of production is an important means for self-expression and advancement (Marx, Engels, and Arthur 1970), which led consumers to act out their creativity within their own private domain. New media technology has fundamentally altered consumers' possibilities to create and has taken much of the constraints of organized, de-enchanted work. Producers' lack of willingness to give off control and integrate the consumer in the production process resulted in the emergence of new, emancipated consumption communities. These communities have a strong influence on existing brands, as shown above, but more importantly, they can also become active players on the market themselves (Thompson and Coskuner-Balli 2007).

It is our aim to carve out the specific idiosyncrasies of community brands and branded communities. Communities as developers of brands are a very recent phenomenon which has not yet been studied. Hence, if we are to study the value of those community brands we first need to explore how the community perceives their brand; whether they think of their creations as a brand at all; and how they describe the inner values of the brand of itself and in comparison with other non-community brands. To this end, we researched a prominent and successful 'creative crowd', members of the Apache Foundation and its contributor community.

METHOD

For our study we applied qualitative-inductive methodology (Denzin and Lincoln 1994) in order to gain rich insights into the phenomenon studied (Creswell 1998; Maxwell 2005). First, we identified informants from the Apache foundation using "theoretical sampling" as described in grounded theory literature (Glaser and Strauss 1967; Strauss and Corbin 1990). All together 12 interviews were conducted. All of our respondents were between 29 and 48 years of age and male due to the predominance of male community members. We only interviewed community members, since we were interested in the brand's and the community's development and were dependent on first hand information of people inside the community.

In order to look at the phenomenon from different perspectives, respondents were chosen based on several criteria. Degree of community involvement was the first criterion. While some respondents took over central roles within the community (e.g. President of the ASF), others were only loosely connected to the community through their day-time job. Four of the interviewees have either founded their own company based on Apache products or were working for such a company. Second, we looked at the duration of community involvement. While four of the respondents were members of the initial Apache Group or involved with the software shortly after and thus community members since the very beginning, others could not look back on such a long history of community membership. The status role respondents held in the community was a third criterion. While nine out of the 12 interviewees were members of the Apache Software Foundation, four respondents additionally were members of the Board of Directors, which has the social oversight over the communities' development. Other roles of respondents included project chairman, documentation contributor, Vice President for conference planning, and simple code committers (see Table 1 for interviewee profiles).

We used a semi-structured interview guide composed of four parts. Interviewees were first asked to introduce themselves and report about their commitment and current role within the Apache community. In a second part we asked for the respondents' view of the historical development of the community. The main part of the interview revolved around Apache as a brand; whether community members perceived it as a brand; about the uniqueness of Apache as a brand; their motives to contribute; and the perceived overall meaning of Apache. Finally, we focused on the relationship of the Apache brands with other brands such as Microsoft, as well as possible future developments of the community and the brand.

All interviews took place at the „ApacheCon Europe”, the official conference of the Apache Software Foundation. The conference provided a perfect context to interview prominent community members in their natural setting of discussing strategically important future perspectives of Apache. The interviews lasted between 35 and 90 minutes and produced a total of 7h and 50 min. of information. We tape-recorded the interviews and transcribed them verbatim. The interviews were content-analyzed and interpreted until theoretical saturation (Goulding 2002) was achieved. Typical verbatims were selected to demonstrate our main findings.

FINDINGS

The meaning of the Apache brand

At first sight, the Apache brand does not differ from any commercial brand. In this part of the paper we describe the brand's social, symbolic, and commercial value and demonstrate that the community itself embodies a great part of the Apache brand value. An important aspect of the brand's social value is its ability to connect like-minded people, create a sense of community, and provide a platform for exchange as the following statements demonstrate:

“It's an immediate connection that we have ... So when I meet someone now there is little chance that we actually have commonality on the project we are involved with. But we are part of that larger community and there is an immediate connection.” (Steven)

In this regard Apache is not very different from many commercial brands which also create a sense of community among members, such as for instance Harley Davidson. However, in contrast to many other brand communities, it is not the product which is at the centre of the Apache community. The “community over code” principle

present in the community demonstrates that it is the community and the social relations between members which are valued above everything else; or as the following interviewee put it:

"... there is this slogan that the community is more important than the code. And that's more than a slogan. If there are technical decision there is a real effort to resolve the community issues before solving the code issues. It's interesting to see these folks putting aside technical issues in favor of interpersonal issues." (Steven)

In contrast to Apache, many other OS communities did not survive,

"...because they did not put community first. This is where Apache has got it right. They talk about the community ... and then the code. ... That's one reason why Apache survived ..." (Peter)

The importance of the community and the social relations between the individual members fits well to Cova (1997)'s notion that the link is more important than the thing, and further corroborates Schau et al.'s (2009) notion of value creation through community practices. In their search of meaningful relationships to others consumers are increasingly looking for brands, which enable them to connect with others and enable them to engage in meaningful activities.

"...there is also a community of experts within the Microsoft community. But I definitely think that we have the upper hand in terms of giving something back to society ... our software can make a difference in life and I believe that is more Apache than it is Microsoft." (Thomas)

It is evidenced here that the Apache brand has much more to offer than many commercial brands; much more than just functional and hedonic benefits. The Apache brand derives much of its meaning from the motivation to give something back to society and thus find meaning in life. Being a member of the Apache community is not just a personal expression of preferences and social belongingness. The Apache brand can be seen as a lifetime partner, a valuable companion for one's identity construction and something that is worth living for. This idealistic and ethical notion is hardly found in traditional, commercial brands. Whereas the value of many commercial brands becomes evident in specific situations, such as the reduction of search costs in a shopping situation or the display of a specific personality in a social situation, the value of the Apache brand is less static and not only tied to specific moments in time. The brand stands for a life-time project which enables community members to constantly derive meaning from. It is primarily the connectedness and this self-transcending quality that differentiates community brands from commercial endeavors.

Personal Branding - The value of community membership

Most commercial brands just need to be bought in order to provide symbolic and social value; membership in brand communities is usually just a matter of brand ownership and expertise. However, in the case of the Apache brand it is a bit more complex. The community has installed a strict member selection process, which does not only demand significant effort on the side of potential members but also gives the community control over who is being associated with the brand and with whom the brand is associated with.

"It's very hard to become a committer. You need to show quality over a long period of time and also show commitment to the community. So there is this process in place that guarantees the quality. That is also important to us. We do not want to constantly check everything." (Justin)

"You contribute and at some point someone tells you: 'Ok, become one of us!' And that's it." (Chris)

"... the way the people become members is through peer recognition. You have to contribute for a certain amount of time and then someone might nominate you for membership and as the members we vote on that membership." (Steven)

Membership has to be earned by excellent contributions and commitment. The only way to become a member is by acceptance of the existing members. During their first involvement with the community, not only their work is under constant review but also their personality to determine whether they fit the community and the so called "Apache Way".

"But I think what is difficult is to teach the new comitters the 'Apache Way', the way you have to behave when you are in a project." (Chris)

The „Apache Way" does not only guarantee that projects are executed in a specific way but also safeguard the special community culture by teaching new members how to behave. While many commercial brands have to deal with a rather heterogeneous user group and the resulting conflict about who is a legitimate brand owner and who is not, this is different with the Apache brand. As the brand cannot be separated from the individual community member it is essential for the brand that the right people are chosen to represent the brand. The brand is the community, and the individual members are the brand. What the brand stands for is not prescribed but rather evolves through everyday community interaction, communal practices, and the behavioral patterns of its members.

A series of benefits arise from the member selection process described above. These benefits result from the fact that group membership and thus brand association is not open to everyone, as it is the case with most commercial brands, but rather a number of qualities need to be fulfilled in order to be accepted as a member.

"The other side of the brand is personal branding. The fact that I am a member of the Apache Software Foundation opens lots of doors." (Bill)

"... they said: 'You are just a contractor, we do not care what you say!' Then I sent an e-mail using my apache.org account and afterwards all the technical guys came to me and said: 'Oh you work for Apache. You said something yesterday?' So it changes perception." (Chris)

As the above statements demonstrate, being associated with the Apache community does carry a lot of value in the IT area. Community membership can be transformed into individual assets in the workplace and beyond. This strict and extensive process of becoming a community member upholds the high status and prestige associated with Apache. Referring to Simmel (1906), especially in communities with restricted access, membership is perceived as more valuable. The prestige and status associated with membership

of the Apache community manifest itself in various situations, such as for instance during job interviews.

"... there are stories, like people going to job interviews and mentioning that they are a community member... It makes the people listen, because it does carry some value." (Roland)

Just as with commercial brands, members make us of the Apache brand to communicate their identity. However with most commercial brands, use of a specific brand does only provide limited information about the true personality of the brand owner. One might wear designer shoes in order to be perceived as classy or elegant, however the receiver of the message has only limited possibilities to check for the validity of these claims. Due to the members selection process this is somehow different with the Apache brand. The receiver of the message can draw conclusions on the person's behavior and skills, his sub-cultural background, work ethics and morality. Hence, not only the *community brand* creates value for its creators and users but also membership in the *branded community* of Apache, in particular.

DISCUSSION

This paper explores the phenomenon of community-created brands using the example of Apache, an open-source software community well known for its expertise in programming and its market-leading web server. Our findings contribute to theory in at least two important ways. First, we were able to show that brand development is not restricted to managerial strategy and action but in reality emerges as a grassroots activity of communities. Contrary to commercial brands, community branding processes naturally evolve as side effect of the communities' natural, everyday activities. Freely available software can be monetized. Apache's market share and the amount of sponsorship for Apache demonstrate its market value. Second, voluntary community work pays back in a number of ways, which are beneficial and of enormous value for the community, the individual, and society at large.

In the case of Apache, every community member is able to and actually engages in communicating about the brand and community identity. Every single member becomes a marketer of the Apache brand. As identification with and self-expression through Apache membership is much stronger for community members than for employees of traditional companies, Apache members turn out to be true and credible evangelists of the Apache brand. Additionally, the Apache foundation gives some guidance to members how to communicate, thus ensuring that the values of the Apache community brand are passed on. This stands in stark contrast to profit-oriented companies where usually not all employees consider themselves being ambassadors of their brands. The Apache foundation constitutes a platform where all members actively contribute to the brand. In companies brands are usually crafted and executed by marketing departments, or even outsourced to agencies. The average employee plays a minor role and is often a rather passive stakeholder. Admittedly, brands as Apache are not faced with pricing or distribution issues as the brand is distributed via the Internet and for free. Hence the community concentrates on product development and market communication tasks. Yet, they provide a role model for authentic and sustainable brand buzz and cult as depicted by Holt (2002) and others.

In addition to the unique brand building process, Apache offers an attractive and unique brand meaning and value for its members and non members to identify with. Apache stands for high quality software and a group of very knowledgeable, highly intellectual,

self-motivated computer geeks who aim to write the best software. The prestige and status granted from outsiders manifests this position. Community values, such as "community over code", demonstrate their orientation towards the human element, which is solidly based in community philosophy. The genuine belief in what they are doing, their independence and non-commercial interest considerably enhance credibility and authenticity. As Apache is not following the dominant market logic of increasing revenue and profit it is not forced to run after quantitative growth but rather concentrates on fulfilling user expectations. With community brands consumers are able to escape the branding mill of commercial brands who try to exploit the brand's value by attracting more and more customers thus diluting the brand's power as a source of identification for its consumers. Instead, as we have shown above, the Apache brand carefully selects its members and thus determines who is associated with the brand and who represents the brand. On the one hand this increases the value of community membership and on the other hand endows the community with some control over how the brand is perceived. This stands in contrast to many commercial brands, where brand association is largely determined through the market.

Previous research (Schau et al. 2009) already demonstrates that brand community practices create value. However the value created in these communities can almost exclusively be retrieved inside the community and is mostly limited to the consumption of the brand. Our study contributes to research in this area by showing that brand community practices can also create value outside of the community and in contexts not related to consumption situations, for instance on the job market. Due to careful member selection processes, Apache community membership equals a strong 'employer brand'. Also in traditional brand communities issues evolving around members or brand user selection in the form of brand user legitimacy struggles can be observed (Kirmani et al. 1999). As communities such as Apache do not only provide desired meanings as citizen artists, but also provide consumable products, they may become true alternatives to commercial and profit-oriented organizations, and build a new form of self-organized and volunteer-based organization, not only in terms of product innovation but also in terms of branding.

Recognizing the concept of community-created brands, we can draw several implications. Similar to the concept of community-based and user-based innovation we touch on new community-based marketing approaches that may emerge by trying to leverage the value of community brands. Like open innovation concepts are trying to leverage the creativity and innovative capabilities of users for new product development, open marketing concepts are able to leverage the branding activities of communities. Community brands are much more organic and holistic entities, marketed by the community, by its sponsors and users in a process of constant mutual exchange of economic, financial, social, emotional and intellectual value. Consumers' ability and capability to do so pose new challenges onto commercial brands in terms of authenticity and customer proximity.

Community brands have radically changed our view of brands and branding. The phenomenon of community brands shows that the concept of brands and branding is not limited to the product domain and that it is much better described as a complex social phenomenon including community membership into a new understanding of contemporary branded communities.

What Happens between the Memory Option and the Stimulus Option? Attribute Valence and Information Retrieval in Mixed Choice

Mauricio Palmeira, Monash University, Australia
Shuoyang Zhang, Colorado State University, USA
Shanker Krishnan, Indiana University, USA

ABSTRACT

Previous research on mixed choice has focused on attractive options and suggested a conservative bias. The current study investigates the role of attribute valence and shows in three experiments that consumers tend to prefer the stimulus option when the options are described by attractive attributes and the memory option when they are described by negative attributes. Further, the preference patterns can be explained by consumers' imperfect memory retrieval.

INTRODUCTION

Unlike the ideal scenarios often seen in decision making experiments, consumers usually do not have all the options presented in their consideration set at the same time. Instead, consumers often find themselves in mixed choice settings, in which the information of a certain brand is directly observable, while that of another brand is available only in memory. For instance, when Lynda visits Sears, finds a viable washer/dryer combo, continues to search in Lows for alternatives, and ends up seeing another qualified combo, she must rely on the information in memory of the previously considered option in order to compare with the physically present one. This type of scenario has been described as mixed choice (Lynch and Srull 1982), as opposed to solely stimulus-based choice, where all the information about brands or attributes is directly observable at the time of choice, or solely memory-based choice, where all the information must be recalled from memory and not physically present. Mixed choice is very common in the marketplace because the range of products one store can carry is very limited, especially for products that imply high financial risks (Alba, Marmorstein, and Chattopadhyay 1992).

Among the handful of studies that have examined mixed choice, (Alba et al., 1992; Biehal and Chakravarti 1983, 1986; Dick, Chakravarti, and Biehal 1990; Lynch, Marmorstein, and Weigold 1988), most has relied exclusively on choice tasks involving brands with attractive attributes and largely ignored the ones with unattractive attributes. This somewhat narrow focus is understandable given that in advertising and marketing context it is prevalent to emphasize on the positive features. However, consumers with limited resource in real life often find themselves in situations where they face the choice between two undesirable options. For example, first time home buyers Sam and his wife Carol can only afford houses in a certain price range even after both taking multiple part-time jobs. They have to take a relatively older house in a less than ideal neighbourhood in order to take advantage of the tax credit before its deadline. Therefore, they must decide whether to select the open house that just came to the market today or the previous house that they remembered from an earlier visit. Apparently constrained by time, money, and energy, consumers may have to choose between the bad options when the good ones are simply not available. Further, consumers may use the comparison between the undesirable attributes as their strategy in considering the tradeoffs and choosing products that are similar in terms of positive attributes.

The current research adds to the body of mixed choice research by investigating the role of attribute valence in consumers' preferences on both positive and negative tasks. Valence has been

shown to play an important role in shaping theories of consumer behavior (e.g. Ahluwalia 2002; Brenner, Rottenstreich, Sood, and Bilgin 2007; Dhar and Simonson 1992; Nicolao, Irwin, and Goodman 2008). We predict that consumers' choice pattern is contingent upon the valence of attributes used to describe the options in the consideration set. Specifically, consumers are more likely to prefer the stimulus option over the memory option when they are described by attractive attribute, which is consistent with the conservative bias suggested in prior research (Alba et al. 1992; Biehal and Chakravarti 1983, 1986). In contrast, consumers are more likely to prefer the memory option over the stimulus option when the options are described by negative attributes. This is because consumers' inability to recollect the complete information of the memory option decreases the extremity of either positive or negative attribute. Therefore the imperfect memory makes the positive memory option less positive, leading consumers to prefer the stimulus option; and makes the negative memory option less negative, leading them to prefer the memory option.

In the next section we elaborate on how attribute valence may influence consumer preference in mixed choice through memory imperfection. We then test the hypotheses and the mechanism in three experiments using different mixed choice scenarios. We conclude by discussing the findings and directions for future research.

Biehal and Chakravarti (1983) represents the first formal investigation of situations in which information of different options in a consideration set is partly externally available and partly in one's memory. They found that when consumers did not have the perfect memory for all the aspects of a previously encountered brand, they tended to favor the fully observable brand, often leading to suboptimal choices. Specifically, they attribute the differences in choice outcomes to the differences in memory accessibility induced by manipulating learning goals at information encoding. Alba et al. (1992) referred to this finding as a conservative bias. In their examination, they found that this tendency to "overvalue" externally present information at the time of choice can be reversed when characteristics of the alternatives lead to a superior retrospective evaluation. Specifically, when abstract claims or a large number of attributes are used, consumers form superior evaluations about the memory brand, because abstract beliefs and number of arguments are easier to recall than detailed attribute information.

The current research investigates the role of attribute valence in mixed choice and suggests that consumers' choice pattern is contingent upon the valence of attributes used to describe the options in the consideration set that that the preference pattern is explained by imperfect memory retrieval. Specifically, we predict that consumers are more likely to prefer the stimulus option over the memory option when they are described by attractive attribute, which is consistent with the conservative bias suggested in prior research (Alba et al. 1992; Biehal and Chakravarti 1983, 1986). In contrast, consumers are more likely to prefer the memory option over the stimulus option when the options are described by negative attributes. This is because consumers' inability to recollect the complete information of the memory option decreases the extremity of either positive or negative attribute. Therefore the imperfect memory retrieval makes the positive memory option less positive, leading consumers to prefer the stimulus option; and makes the

negative memory option less negative, leading them to prefer the memory option.

EXPERIMENT 1

Experiment 1 provides an initial investigation into the effects of attribute valence in a mixed choice situation. Participants read information about two used cars described either in terms of attractive or unattractive features. We reasoned that while participants have full information about the stimulus option, they have only imperfect information about the memory option. By that we mean that participants can only recall some, but not all the features of the memory option. When options are described in terms of attractive features, not remembering some of the features decrease the relative attractiveness of the memory option, as participants would see fewer reasons to choose it. This in turn should lead to a preference for the stimulus option. Conversely, when options are described by unattractive features, this imperfect recollection actually helps the memory option, as it gives fewer reasons to reject it. In this case, participants can see all the unattractive features of stimulus option, but can only access some of the unattractive features of the memory option.

Stimuli and pre-test

One-hundred and twelve business undergraduate students from a large Midwestern University evaluated the attractiveness or unattractiveness of 15 fifteen possible features of a used car. Half of the participants were asked to consider they were buying a car in a tight budget and evaluated how much each of the negative features presented (e.g., “the passenger door does only open from the inside,” “the heater is very weak and helps very little in winter,” “there is a crack in the windshield (but no leak)”) would bother them in a nine point scale from “1-would not bother me at all” to “9-would be a complete deal breaker.” The other half considered a series of positive features (e.g., “it has a sliding glass sunroof,” “the painting has a beautiful finish”) and rated how much each would please them on a nine point scale from “1-I wouldn’t mind at all” to “9-This would be really good”.

Based on these ratings, we created two profiles for attractive used cars, each described by six desirable features (all averages between 5.0 and 7.5). Conversely, we combined two sets of six undesirable features (all averages between 5.0 and 7.5) to create two unattractive used car profiles. The complete stimuli are presented in the Appendix.

In the attractive cars condition, participants were told that the car was a little beyond their budget, but it had a series of nice features. In the unattractive cars condition, participants were told that they were on a tight budget and despite these inconveniences, their mechanic had guaranteed that the car would last at least until they graduated.

Method

Design. We employed a 2 (features attractiveness: positive vs. negative) x 2 (order of presentation: A → B vs. B → A) between-subject design.

Participants and Procedure. Eighty-nine business undergraduate students from a large Midwestern University completed this experiment in partial fulfillment of a course research requirement. The experiment was conducted on computer stations using the Medialab interface. Participants were directed to a computer station to complete the experiment and randomly assigned to one of the four conditions. Participants read a scenario in which they were asked to consider the purchase of a used car. They read the description of the first car at their own pace and clicked to continue to an unrelated study,

which served as a filler task for our experiment. After completing the filler task, which took approximately 10 minutes, participants were presented with a second used car and asked to make a choice between the option they saw in the beginning of the session and the one presented at the time of choice. Finally, they were asked to type all they could remember about the first alternative.

Results

We ran a logit model to predict choice of alternative A using valence of features and order of presentation (i.e. whether option A was presented first or second) as independent factors. There was a marginally significant effect for valence ($X^2(1) = 2.93, p = .087$) and marginally significant effect for order ($X^2(1) = 3.10, p = .078$). More importantly, we found a significant interaction ($X^2(1) = 9.65, p < .01$), indicating that the effect of order is moderated by valence of the attributes.

In order to understand the nature of this moderation, we looked at choice pattern in each set. In the attractive features condition, replicating the finding of previous research (Alba et al. 1992; Biehal and Chakravarti 1983), we found a tendency to prefer the stimulus option, as the choice share of option A increased from 50% when it was the memory option to 63% when it was the present option (consequently the share of option B increased from 37% to 50% as it shifted from memory to present). In other words, on average, a stimulus option was chosen 57% of the times. This difference however, failed to reach significance ($\chi^2(1) = .73, n.s.$). More importantly, in the unattractive features condition, we found support for our hypothesis. The choice share of option A shifted from 37% when it was the stimulus option to 84% when it was the memory option ($\chi^2(1) = 14.77, p < .01$). Thus, on average, a memory alternative was chosen 74% of the time.

In order to be able to attribute this pattern to memory, as opposed to mere order of presentation, we turned to the analysis of the free recall measure. If our theory is correct, we should find stronger effects for those with worse memory. For each set, we counted the number of items recalled by each participant and created two groups based on a median-split. Those in the poor memory group ($n = 44$) recalled up to 2 features, while those in the good memory group ($n = 45$) recalled 3 or more features. For each set, we ran a logit model using order and recall group as independent factors. For the attractive set, we found a significant interaction ($\chi^2(1) = 3.83, p < .05$) between order and recall, indicating that participants with better memory behaved differently than those with worse memory. Specifically, in the good memory group ($n = 26$), only 40% of participants chose the stimulus option, while 70% of those in the poor memory group ($n = 15$) did the same, suggesting that those with worse memory are more likely to choose a stimulus option. Order of presentation had no effect ($\chi^2(1) = .41, n.s.$) and there was a marginal main effect for recall group, which has no theoretical significance ($\chi^2(1) = 2.81, p = .094$). For the unattractive set, we fail to find an interaction between order and recall group ($\chi^2(1) = .13, n.s.$).

Discussion

Results from our first experiment provided initial support for our hypothesis about the role of attribute valence on mixed choice. We hypothesized that a preference for a stimulus option observed in previous research would only manifest when attributes were attractive, while the reverse would occur when attributes were unattractive. Consistent with our hypothesis, our data showed a strong preference for the memory option in the unattractive set (74%). Results from the attractive set were consistent with those observed in previous research, indicating a preference for the stimulus

option. However, our analysis based on memory performance failed to establish the role of memory in the unattractive set, as those with poor memory were just as likely to choose the memory option as those with good memory. In addition, we found evidence for the role of memory, as the tendency to prefer the stimulus option only manifested in the group with poor memory.

EXPERIMENT 2

We designed Experiment 2 with two goals. First, we sought to replicate the choice pattern obtained in Experiment 1 using a different choice category. Second, the initial experiment only showed evidence for the role of memory in the attractive set condition. In this second experiment, we looked for the corresponding evidence for the unattractive set.

Stimulus and pre-test

For this experiment, we used a set of jobs as the stimuli. We believe this is a relevant consumer behavior context to the extent that successful companies try to market themselves to prospective employees that face a choice between two or more jobs. This category has also been used in previous consumer behavior research (Brenner et al. 2007, Tversky and Kahneman 1991) and provides a good test for the generalizability of the effect.

We followed the same procedure used in Experiment 1 pre-testing the stimuli. Participants evaluated the attractiveness or unattractiveness of fifteen possible features of a job they would take upon graduation. Based on these ratings, we created two sets of profiles. As in Experiment 1, none of the profiles was completely attractive or completely unattractive. In the unattractive set, each job was described by five unattractive features, but it had a nice salary. The attractive set on the other hand, was described on five attractive features, but had a lower salary. All options are described in the Appendix.

Method

Design. We employed a 2 (valence of features: attractive vs. unattractive) \times 2 (order of presentation: A \rightarrow B vs. B \rightarrow A) between-subject design.

Participants and Procedure. Eighty-three business undergraduate students from a large Midwestern University completed this experiment in partial fulfillment of a course research requirement. The experiment was conducted on computer stations using the Medialab interface. Participants were directed to a computer station to complete the experiment and randomly assigned to one of the four conditions. Participants read a scenario in which they were about to graduate and were considering a choice between two job offers. They read the description of the first job at their own pace and clicked to continue to an unrelated study, which served as a filler task for our experiment. After completing the filler task, which took approximately 10 minutes, participants were presented with a second job offer and asked to make a choice between the option they saw in the beginning of the session and the one presented at the time of choice. After this selection, participants were asked to type as much as they could remember about the first offer.

Results

Following the analysis of Experiment 1, we ran a logit model to predict choice of A using order and valence as the predictors. As hypothesized, we found a significant interaction effect between order and valence ($\chi^2(1) = 12.11, p < .001$). The effect of valence was marginally significant ($\chi^2(1) = 3.11, p = .078$) and there was no effect for order ($\chi^2(1) = .66, n.s.$).

In the attractive features set, the choice share of option A increased from 33% to 60% as it shifted from memory to present ($\chi^2(1) = 3.16, p = .075$), representing an average of 63% choice share for the stimulus option. In the unattractive features set, the pattern was reversed: the choice share of option A shifted from 43% when it was the present option to 86% when it was the memory option ($\chi^2(1) = 10.50, p < .01$). Thus, on average, the memory option received 71% of the choices. These results replicate those of Experiment 1 showing the conservative bias for attractive features, but the reverse for the unattractive ones.

As in Experiment 1, we coded the number of items participants recalled and performed a median-split to create two groups for each set. Participants that recalled fewer than 3 features were considered the poor memory group ($n = 37$), whereas those that recalled 3 or more made up the good memory group ($n = 46$). For each set, we ran a logit model using recall group, order and their interaction as the predictors. In the attractive set, we found a significant interaction ($\chi^2(1) = 11.16, p < .001$). Participants in the good memory group ($n = 17$) selected the stimulus option only 57% of the time, compared to an 88% selection from the poor memory group ($n = 24$). There was also significant main effect for order ($\chi^2(1) = 6.12, p < .05$), indicating an overall tendency to prefer the stimulus option, and a main effect of recall group ($\chi^2(1) = 5.28, p < .05$), which has no theoretical significance. For the unattractive set, although there was a tendency for a stronger effect in the poor memory group compared to the good memory group (77% vs. 88%), the interaction failed to reach significance ($\chi^2(1) = .92, n.s.$).

Discussion

Experiment 2 had two purposes. First, it aimed to provide a test of our hypothesis in a new context, namely choice between job offers. Results replicated those observed in experiment 1. That is, participants tend to prefer the stimulus option over the memory option when considering attractive attributes; where as they tend to prefer the memory option when considering unattractive attributes. Second, we sought evidence that poor memory for the initial option was driving the effect in both sets. As in Experiment 1, we found evidence of it for the attractive features set, as only those in the poor memory group (recall below median) displayed the effect. However, in the unattractive features set, the predicted pattern was not significant.

Although our first two experiments showed a strong reversal in the conservative bias, we have yet to demonstrate the role of memory. In addition, there is an important alternative explanation that deserves attention. As we reasoned before, in a mixed choice scenario, consumers have full information about the stimulus option, but unless one has perfect memory, there is only limited information about a memory option. This asymmetry of information may be interpreted as a choice between a safe option, for which all information is available, and a risky one for which only partial information is available. In fact, the term "conservative bias" given by Alba et al. (1992) to the pattern obtained by Biehal and Chakravarti (1983) suggests a risk avoidance interpretation of the phenomenon.

In the development of prospect theory, Kahneman and Tversky (1979) showed that individuals tend to be risk averse in the domain of gains, but risk seeking in the domain of losses. If participants interpret a mixed choice situation as a risky decision, this pattern of risk aversion and risk seeking would lead to the exact same pattern that we observed in our experiments. When consumers face a choice between attractive features, they are assumed to be choosing in the domain of gains, and therefore should be risk averse and choose the safe option, which would be the stimulus option in our study. However, when consumers face a decision involving negative

features, they should be risk seeking and prefer safe option, which would be the memory option. Although our hypothesis stays the same, this could be an alternative explanation. We examine this risk-based explanation in the next experiment.

EXPERIMENT 3

We designed Experiment 3 with three goals in mind. First, we wanted to test the risk-based alternative explanation. Second, we sought to obtain evidence for the role of memory in the negative set that was not shown in the previous experiments. To that end, we decided to use recognition task as a more sensitive memory measure as opposed to the free recall used in Experiments 1 and 2. In addition, we doubled the sample size to make sure that there would be enough power for the analysis. Third, we wanted to provide further test of generalizability using a different choice category.

Stimulus and pre-test

Thirty-seven business undergraduate students from a large Midwestern University completed this experiment in partial fulfillment of a course research requirement. The procedure followed those of Experiments 1 and 2 with participants evaluating 15 positive and 15 negative characteristics of apartments that they would be renting. Based on these ratings we created two attractive profiles, which were described on seven positive features, but had the disadvantage of being expensive. Conversely, two unattractive profiles were created in which each apartment had seven undesirable features, but had a good price. All descriptions are presented in the Appendix.

Method

Design. We employed a 2 (features attractiveness: positive vs. negative) \times 2 (order of presentation: A \rightarrow B vs. B \rightarrow A) between-subject design.

Participants and Procedure. One-hundred and ninety-two business undergraduate students from a large Midwestern University completed this experiment in partial fulfillment of a course research requirement. Participants were directed to a computer station to complete the experiment and were randomly assigned to one of the four conditions. Participants read a scenario in which they had just graduated and were moving to a big and expensive city. They were looking for an apartment, but didn't have much time. They were presented with the description of the first apartment, which they read at their own pace. They then continued to the next unrelated study, which took approximately 10 minutes and served as a filler task for our experiment. After completing the filler task, participants read the description of the second apartment. In the next screen, while they could still read the description of the second apartment, participants were asked to choose one of the two apartments that they have seen. After that, as a test of the risk explanation, participants rated their agreement with the following statements on a seven-point scale: "choosing the first option is riskier," "choosing the first option involves more uncertainty," and "choosing the second option is safer." Then, participants were asked to explain what went through their minds as they made their choice. Finally, participants performed a recognition task. In a series of 13 screens, we randomly presented the seven attributes that were used to describe the first apartment and the six foil attributes that were not used to describe either apartment. Participants were asked to indicate whether each attribute described the first apartment and their confidence on a five-point scale: "1-completely confident it is true;" "2-somewhat confident it is true;" "3-completely unsure;" "4-somewhat confident it is false;" "5-completely confident it is false".

Results

Choice. As in Experiments 1 and 2, we ran a logit model to predict choice of A using order and valence as the independent variables. As predicted, we found a significant interaction between order and valence ($\chi^2(1) = 22.54, p < .001$). None of the main effects were significant (order: $\chi^2(1) = .33, p > .70$; valence: $\chi^2(1) = .70, p > .40$).

Despite our efforts to create equally attractive options in each set through the pre-test, there was clear preference for option B in each set. In extreme cases, an unbalanced set, in which one option is much more attractive than another, decreases the power of any manipulation due to the formation of strong preferences. Choice effects are easier to detect when options are perceived as similarly attractive, so that experimental manipulations can tip preferences one way or the other. However, we note that although this unbalance may decrease the power of our experiment, it does not affect the conclusions from our analyses, as we are not interested in the overall preference for a given option, but how this preference differs when it is the memory option versus when it is the stimulus option.

In the attractive features set, we found that the choice share of option A increased from 12% to 39% as it shifted from memory to present ($\chi^2(1) = 9.73, p < .01$), representing an average of 64% choice share for the stimulus option. In the unattractive features set, the pattern was reversed: the choice share of option A shifted from 15% when it was the present option to 47% when it was the memory option ($\chi^2(1) = 12.94, p < .01$). In other words, a memory option received 66% of the choices. These results replicate the pattern observed in the previous experiments.

Memory. We computed a recognition index by summing the scores for the true attributes, subtracting the scores for the false attributes and inverting the sign of the score. A person with a perfect memory should be completely confident that attributes that described the first option are true, and completely confident that attributes that do not describe the first option are false. Therefore, this person should answer "1-completely confident it is true" for all seven attributes of the memory option and "5-completely confident it is false" for every false attribute. This person would have a score of 1×7 (7 real attributes) $- 5 \times 6$ (6 foil attributes) $= -23$. We invert the sign of the score, so that better memory coincides with higher scores. A perfect memory gets a score of 23. On the other extreme, a person that was completely confident and wrong in all attributes would get a score of $-5 \times 7 - 1 \times 6 = -29$. In our data, the scores ranged from -11 to 23 with a median of 12.

For each set we ran a model using order and the recognition score to predict choice of option A. In the attractive features set, consistent with the pattern obtained in our previous experiments using free recall, we found a significant interaction between memory and order ($X^2(16) = 35.99, p < .001$). More importantly, in the unattractive features set, we also obtained a significant interaction ($X^2(16) = 34.76, p < .001$). We can illustrate the nature of this interaction comparing the group with recognition score below the median to the group with scores above the median. In the attractive features set, 56% of participants in the good memory group ($n = 44$) preferred the stimulus option compared to 70% from the poor memory group ($n = 45$). In the unattractive features set, the memory option was preferred by only 56% of those in the good memory group ($n = 50$), compared to 74% of those from the poor memory group ($n = 43$).

Risk statements. We used four statements to capture the extent to which participants viewed this situation as a risky decision. Participants rated their agreement on seven-point scales and we tested whether the average was significantly different from the midpoint of the scale. For each statement in each set, we mean-centered

the answers and ran an ANOVA using order as the independent factor. For ease of exposure, we report the means using the original seven-point scales.

In the attractive features condition, there was no support for a risk perspective. On average, participants disagreed that “choosing the first option is riskier” ($M = 3.55$, $F(1,88) = 10.81$, $p < .01$) and displayed no significant tendency for the other two statements (“choosing the first option involves more uncertainty”, $M = 3.84$, $F(1,88) = 1.09$, $p > .3$; “choosing the second option is safer”, $M = 4.13$, $F(1,88) = .89$, $p > .3$). In every analysis, the order was significant, which means that in addition to considering whether an option was the memory or the stimulus one, participants’ answers were also affected by the specific alternative. All answers were consistent with the higher attractiveness of option B, which as discussed before has no theoretical value. As indicated, the analyses reported here control for this difference in attractiveness.

In the unattractive features condition, there was also no support for a risk perspective. In all three statements, the average was not significantly different from the midpoint of the scale (“choosing the first option is riskier,” $M = 3.84$, $F(1,92) = 1.10$, $p > .29$; “choosing the first option involves more uncertainty,” $M = 3.89$, $F(1,92) = .38$, $p > .50$). There was a marginally significant disagreement with one statement (“choosing the second option is safer,” $M = 3.74$, $F(1,92) = 2.89$, $p = .092$), which is also not consistent with a risk interpretation. Order was significant for all statements except for “choosing the second option is safer,” but as discussed before, this has no theoretical relevance.

Discussion

Results from Experiment 3 successfully replicate the pattern observed in the previous experiments using apartment as a new category for the mixed choice situation. In other words, participants are more likely to choose the stimulus option rather than the memory option when they are exposed to options described by attractive attributes, while the reverse would occur when attributes were unattractive. This experiment further strengthened our hypothesis from four aspects. First, it served as another test of our hypothesis in a new context, namely choice between job offers, and replicated the findings observed in experiments 1 and 2. Second, it provides further evidence that poor memory for the initial option was driving the effect in both attractive and unattractive sets. Moreover, using a more sensitive memory measure (recognition), this experiment showed significant evidence for the role of memory in the unattractive features set, which we had not found in previous experiments using free recall. Last but not least, the results in support of our memory-based hypothesis rejected the alternative risk-based explanation. We asked participants to rate their agreement with statements that framed the decision as a risky choice. The results showed that there was no tendency of agreement with any of the statements. Therefore, we conclude that there is no support for a risk-based explanation.

Conclusion

Across the three experiments, we find converging evidence for our hypothesis that in a mixed choice situation, failure to recall specific features affects choice in a systematic way. If participants fail to recall positive features, their evaluation deteriorates and there is a tendency to favor a stimulus alternative. Conversely if participants cannot recall negative features, their evaluation improves and the memory option is favored. We further established the memory-based mechanism and suggest the preference pattern is driven by imperfect information retrieval. Specifically, consumers with good memory are less likely to demonstrate the conservative bias when choosing from options with attractive features and less likely to

demonstrate the reversed bias when choosing from options with unattractive features. In other words, consumers with good memory are less likely to prefer the stimulus option than those with poor memory in the attractive set; they are also less likely to prefer the memory option than those with poor memory in the unattractive set.

As suggested by Feldman and Lynch (1988), information accessibility is determined by a range of different factors, such as the time delay, the level of interference, message elaboration, and motivation to process the information. Future research could consider how these factors influence the retrieval process and the preference pattern. For example, because information retrieval is largely determined by the cues in the environment in making a particular decision (Lynch and Srull 1982; Tulving and Psotka 1971), there is a possibility that providing cues may induce a different preference pattern. In the current study, memory quality was measured as a personal trait. Future research could employ retrieval cues as a manipulation of enhanced memory. It is likely that participants who were exposed to the pictures of the choice set may tend to retrieve more information from memory and exhibit less conservative bias comparing with those who were not exposed to the pictures. What’s more, Biehal and Chakravarti (1986) showed that information that was processed more was recalled more accurately in a subsequent cued recall test. In other words, brand-attribute information that receives more processing is remembered better. Future research could manipulate the memory accuracy by having participants engage in more or less information processing when they are exposed to the memory option.

APPENDIX

USED CARS (EXPERIMENT 1) ATTRACTIVE FEATURES SET

Option A

- It is quite fuel efficient for its category.
- It comes with very classy trim and interior design.
- It has a sleek and modern style.
- It comes with one year free subscription of satellite radio.
- It has a sliding glass sunroof.
-

Option B

- There is a lot of storage space in the trunk.
- The acceleration is short and smooth.
- It has a video monitor for reverse driving.
- The painting has a beautiful finish.
- It comes with a 100,000 mile warranty and road-side service.

USED CARS (EXPERIMENT 1) UNATTRACTIVE FEATURES SET

Option A

- The passenger's door only opens from the inside.
- The heater is very weak and helps very little in winter.
- The radio works, but it doesn't play CDs.
- The paint fell off on a few spots on the hood.
- The window does not close properly and you have to push it with your hand for it to fit in the frame.

Option B

- The engine is not very powerful.
- There is a crack in the windshield (but no leak).
- It is burning some oil, requiring you to add oil more frequently.
- It takes a long time for the air conditioning to take effect.
- The car trembles at high speed.

JOB OFFERS (EXPERIMENT 2) ATTRACTIVE FEATURES SET

Option A

- The company is located in a nice area where the weather is always sunny and pleasant.
- The working hours are very flexible. You can decide when you want to start and finish your work day as long as you accomplish the 8 hours.
- You will have 14 days of paid vacation every year and it is accumulative across years. It is up to you how you want to allocate it.
- The company frequently offers training and consulting programs in order to develop your long-term career.
- Employees are encouraged to think creatively.
- There are opportunities to work overseas for those interested in it.

Option B

- The company is located in a very safe neighborhood. Transportation to and from work is very convenient.
- Your office will be located in a central area of the city, close to bars, restaurants, and health clubs.
- Employees never do overtime or work on weekends.
- It is a growing company. Many of the recent hires are in your age group. You have the option of joining a mentoring program designed for the new comers.
- Most people in the upper management were promoted within the company.
- The job offer package also offers a very good retirement plan.

JOB OFFERS (EXPERIMENT 2) UNATTRACTIVE FEATURES SET

Option A

- The company is located in a small town, which is more than an hour away from any metropolitan area.
- The weather is quite rainy and cloudy.
- Due to the nature of the industry, your work hours are fixed from 5am-2pm and have little flexibility.
- You have 7 days of paid vacation every year and it is not accumulative across years.
- The decision making in this company seems to be very centralized.
- There is a strong and rigid hierarchy, so there wouldn't be much contact with upper management.

Option B

- The company is located in a not very safe neighborhood. Robberies are not uncommon in the area.
- Winters are long and very cold.
- Employees tend to do a lot of overtime are often expected to work on weekends.
- The company does not tend to provide much training or career development.
- The company has no policy regarding retirement plan.
- There doesn't seem to be many people in your age group.

APARTMENTS (EXPERIMENT 3) ATTRACTIVE FEATURES SET

Option A

- There is beautiful park nearby.
- There are plenty of good restaurants in the area.
- The apartment is in a new and modern building.
- Virtually no outside noise can be heard when the windows are shut.
- There is free high speed wireless Internet.
- The apartment receives plenty of natural light.
- The living room is spacious and well illuminated.

Option B

- The apartment has a nice view to a lake.
- All kitchen appliances are new.
- Public transportation to this area is very convenient.
- The bedroom is very spacious.
- Most neighbors are young professionals like you.
- The building has a well equipped gym.
- The apartment is in a beautiful and renovated building.

APARTMENTS (EXPERIMENT 3) UNATTRACTIVE FEATURES SET

Option A

- The apartment is in the 4th floor and there are no elevators in the building.
- The street has very poor lighting.
- It is a long commute from your work.
- There are no restaurants nearby.
- The street is very busy and noisy.
- The living room gets almost no sun light.
- There are no grocery stores nearby.

Option B

- The apartment only has a view to an internal patio.
- The heater is not strong enough to completely warm up the place.
- One of your neighbors plays trumpet during the day.
- The kitchen has very few cabinets.
- Traffic is intense in the area.
- The water pressure in the shower is somewhat low.
- It has two very small bedrooms, instead of a good sized one.

Introducing the WOM Transmitter in Generational Word of Mouth: Why Consumers Refuse to Transmit Positive or Negative Word of Mouth

Florian Dost, ESCP EUROPE Campus Berlin, Germany
Jens Sievert, ESCP EUROPE Campus Berlin, Germany
Martin Oetting, TRND.com, Germany

ABSTRACT

Taking a transmitter's perspective, this study identifies reasons to refuse word of mouth (WOM) transmission, creates a category system and analyzes the influence of either positive or negative WOM. We show that the transmission of negative WOM is refused more often, a result which is mainly driven by social constraints.

INTRODUCTION

Word of mouth (WOM) has become increasingly popular, both among marketing academics and marketing practitioners. While academics tend to focus on the generation of WOM (Oetting 2009), the excitement of practitioners more relates to the fact that WOM is spread by transmission. The rationale behind this is that network effects, also called contagion or viral effects, create powerful and potentially costless benefits, as WOM spreads across multiple generations of communicators (Carl, Libai and Ding 2008). However, knowledge on the individual processes of transmission is scarce. Moreover knowledge on why consumers might choose not to transmit and thus inhibit network effects is missing. Research on the WOM transmitter has been largely neglected on an individual level: Most previous studies on transmission focus on a network perspective (Bass 1969; Coleman, Katz and Menzel 1957). Additionally most past research is about successful WOM communication only. This is particularly surprising as it is already known that WOM transmission is a deliberative process (Banerjee & Fudenberg 2008), which implies that a transmitter will not only reason his decision to transmit but also might reason against it. Transmission refusal is therefore a key in understanding transmission process.

Moreover, despite extensive literature on positive and negative WOM, it is not known how WOM valence might influence whether WOM gets transmitted at all.

This study aims at exploring this gap by answering the following research questions:

1. What are reasons for a transmitter to refuse WOM transmission?
2. Do PWOM and NWOM have a different impact on transmission refusal?
3. If so, what are the reasons for this different impact of PWOM and NWOM?

Our study is mainly explorative in nature. Taking the perspective of the WOM transmitter, we aim at identifying and categorizing the

reasons for transmission refusal. In order to do so, precise definition and clarification of terms are mandatory, followed by a review of relevant literature, the study design and then the study results. Implications are presented at the end of the paper.

WORD OF MOUTH TRANSMISSION

Word of Mouth, Positive and Negative Word of Mouth

Word of mouth is "a process of personal influence, in which interpersonal communications between a sender and a receiver can change the receiver's behavior or attitudes" (Sweeney, Soutar and Mazzarol 2008, 345). We additionally introduce a third party to the sender and the receiver which we call "the transmitter". We will explain why we do so in the subsequent section.

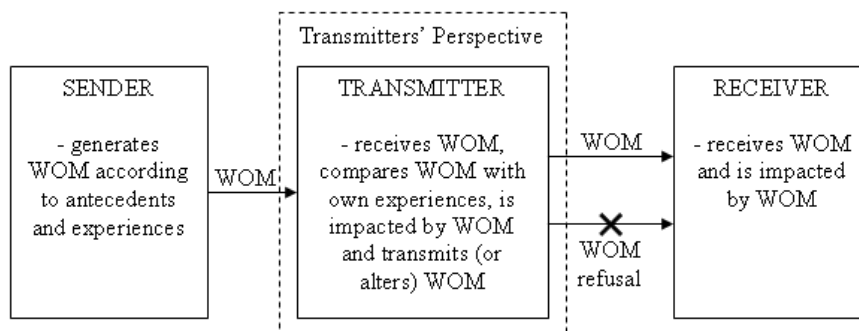

Throughout this paper we will use the term 'WOM impact' to describe any effect that is caused by WOM and the term WOM topic when referring to the actual content of the WOM message. When referring to the tone of the WOM message, we will restrict this to WOM valence. Most researchers divide WOM according to its valence into positive word of mouth (PWOM) and negative word of mouth (NWOM). We will also use this distinction.

WOM Transmission and Transmitter's Perspective

Unlike most prior WOM research we will take the perspective of the so-called WOM "transmitter", an intermediary of WOM. WOM transmission occurs when a WOM message generated by a sender is received by a transmitter and then passed on to another receiver. The transmitter himself acts on a dual role as he is first a receiver and then a sender. The WOM roles of sender, transmitter and receiver are shown in figure 1. We take the transmitters' perspective for two reasons. First, the unique feature of WOM is that WOM is frequently transmitted. This is known as contagion, viral, or cascade effect (Coleman et al. 1957). Secondly, prior research has focused on dyadic WOM between sender and receiver. While this approach is useful when describing the antecedents of original WOM generation (sender) or the impact of WOM (receiver), it implies that the mere transmission of the WOM would be actually a generation of new WOM by the former receiver.

Taking the transmitter's perspective incorporates existing knowledge on WOM generation, but also allows for a simple WOM transmission as in the case of viral campaigns.

FIGURE 1
The Roles of WOM Sender, Transmitter and Receiver

LITERATURE REVIEW

Reasons for WOM Transmission

A broad body of literature focuses on transmission processes, such as diffusion studies (Bass 1969) or studies on social contagion (Coleman et al. 1957). However the focus is on aggregate measures and network characteristics, neglecting the individual processes (Bansal and Voyer 2000). Only few works provided some insights into individual WOM transmission processes. Most important is that the transmitter's decision to engage in WOM transmission is deliberate (Banerjee and Fudenberg 2004; Stephen and Lehmann 2009). WOM is transmitted because it can lead to potential social benefits but it also involves risks if transmitted WOM is incorrect, not helpful, or not wanted. Therefore WOM transmission is selective (Stephen and Lehmann 2009). Transmission depends on the motivation or willingness of the transmitter to share WOM (Granovetter 1973; Frenzen and Nakamoto 1993). Moreover, it is particularly surprising that most research is about successful WOM communication only, implying that transmission refusal occurs in the absence of these antecedents. The fact that transmission refusal might be caused by particular reasons is neglected.

The Impact of WOM

WOM has an influence on the receiver's perceptions and therefore can lead to changes in judgment and likelihoods of choice (Arndt 1967; Fitzgerald Bone 1995). Regarding brand or product attitude, this is mainly due to an impact in reducing perceived risk (Roselius 1971). Consequently, WOM has a larger impact on consumers' attitudes in riskier categories

Regarding WOM valence, PWOM and NWOM are usually seen as closely similar behaviors (East, Hammond, and Lomax 2008). In contrast, Sweeney et al. (2008) argue that PWOM and NWOM are not homogenous in impact as people vary in their reaction to PWOM and NWOM

Marketers usually believe that NWOM is more common and has more impact than PWOM (East, Hammond, and Wright 2007). Still, there is an ongoing debate on the effect of WOM valence (East et al. 2008; Stephen and Lehmann 2009): Some works (e.g. Arndt 1967) support that NWOM might have a larger impact than PWOM. In contrast, East et al. (2008) state that the positive effect PWOM exerts on purchase probability is larger than the negative impact NWOM exerts on purchase probability. Other studies find that positive and negative information have much the same impact size on brand attitudes (Ahluwalia, Burnkrant, and Unnava 2000; Ahluwalia 2002). However, these works do not refer specifically to an impact on WOM transmission. We have to distinguish between the WOM impact on receiver's attitudes and the WOM impact on WOM transmission (Merton 1968). Therefore we will turn to the underlying explanations for different impacts of PWOM and NWOM. We should also note that any impact on a receiver is somehow intertwined with the impact on transmission. This transmitted impact is often referred to as „ripple effect“ (Gremler and Brown 1999; Sweeney et al. 2008; Oetting 2009), a multiplication effect of WOM that is not part of the current study.

Skowronski and Carlston (1989) find that negative information has a stronger impact on judgment than positive information and is therefore more persuasive. One reason for a greater diagnostic value of negative information is its rarity, compared to positive information (Anderson 1965; Chevalier and Mayzlin 2003; Mizerski 1982). Also, people prefer diagnostic information to more accessible ones (Lynch, Marmorstein, and Weigold 1988). With social desirability effects favoring recall of positive information (Fisher 1993), PWOM gets more accessible and is thus less preferred.

Given a higher diagnostic value of NWOM, we should expect that NWOM is more likely to be transmitted. However, social desirability may also let consumers avoid NWOM (Rosen and Tesser 1972), resulting in higher rates of NWOM transmission refusal.

Another explanation for the impact dominance of NWOM is the attribution effect (Mizerski 1982). Consumers attribute an adversary motive to positive information. They think for example that positive information might be arranged. Now one would expect PWOM to result in more transmission refusal. However, attribution is not by definition restricted to positive information. Our research questions refer to that overall ambiguity.

Antecedents of WOM Generation and Transmission

Research on WOM antecedents is restricted to WOM generation. While generated WOM starts with the sender as a reaction to any antecedent, transmitted WOM is passed on or altered after the event of received WOM. However, as the transmitter is also a sender, we argue that antecedents of original WOM generation may also influence WOM transmission.

Valence as Antecedent. Satisfaction and dissatisfaction are the main sources for PWOM and NWOM, respectively (Richins 1983). Dissatisfied consumers produce more WOM than satisfied consumers (Hanna and Wosniak 2001; Silverman 1997). A contradictory finding says that satisfied customers outnumber dissatisfied customers (Mittal and Lassar 1998). Still, East et al. (2007) show that in general, PWOM exceeds NWOM. We therefore also propose a higher occurrence of PWOM than WOM:

Proposition 1: PWOM occurrence exceeds NWOM occurrence.

Also Anderson (1998) states that WOM generation is higher for dissatisfied consumers and that extremely satisfied or dissatisfied consumers spread WOM most. Remarkably, about 80% consumers that were neither satisfied nor dissatisfied still engage in WOM generation of the more extreme cases. This is a general tendency for WOM generation or engagement that is not explained by satisfaction or dissatisfaction. According to Mangold, Miller, and Brockway (1999), satisfaction or dissatisfaction account for only 12% of all WOM generation, whereas over 50% relate to the need for WOM activity. In all, research fails to explain how valence direction relates to WOM generation while it is obvious that valence strength seems just to be one influence on WOM generation among many. Given this dominance of other reasons, such as a need for WOM activity, we expect and propose fewer transmission refusals than transmissions:

Proposition 2: There are fewer WOM transmission refusals than WOM transmissions.

Intrapersonal Antecedents. De Matos' and Rossi's (2008) meta-analysis on antecedents of WOM generation reveals that apart from satisfaction, key antecedents of WOM generation are brand or product loyalty, quality, commitment, perceived value, and trust. Most of these factors are intrapersonal to the transmitter. We would expect to see reasons for WOM transmission refusal that are related to such intrapersonal antecedents.

Interpersonal Antecedents. Other antecedents such as trust or source credibility lie in the transmitter's perception of the sender. These perceptions can be influential in a WOM context (Bansal and Voyer 2000; Fitzgerald Bone 1995). Therefore it is likely that perceptions such as the WOM need of the receiver assumed by the transmitter (Mangold et al. 1999) are influential. Another antecedent is the type of relationship between sender and transmitter. Numerous studies have shown an effect of tie strength. The stronger the tie strength the more likely it is that this relationship will be used for WOM communication (Brown and Reingen 1987), and more WOM occurs between close ties such as friends or relatives.

Literature also states an explicit influence of weak ties on WOM transmission (Granovetter 1973). However this explicit influence is not relevant for our study, as it refers to a network perspective, arguing that weak ties foster the wider spread of WOM by means of larger relationship distances. Still we expect to find reasons for transmission refusal that relate either to the transmitter's perceptions of the sender or the receiver's needs or to the closeness of the relationship. As close relationships incorporate intimacy and trust we additionally expect that matters of privacy play a role in transmission refusal.

Message related Antecedents: It is known that the style, power, and content of WOM can have an influence on the receiver (Dichter 1966; Herr, Kardes, and Kim 1991). Therefore these WOM message characteristics may be crucial for the decision whether to transmit or not.

Context related Antecedents: Time constraints were found to have an effect on WOM generation (Sweeney et al. 2008). But to our knowledge there are no studies on an effect of WOM place. However, we expect reasons that refer to context.

RESEARCH METHOD

Data Collection and Sample Structure

We collected data using an online questionnaire. Respondents were asked to remember an actual, recent WOM incident and to state details such as topic, category, WOM channel and type of relationship. Perceived WOM valence was measured as the average on three seven-point scale items (Cronbachs Alpha: .94). Respondents were then asked to state whether they would transmit this WOM. Any respondent to refuse WOM transmission was asked to state his top of mind reasons for doing so. The questionnaire was presented to about 200,000 members of a German panel in winter 2009. The panel is one of the biggest professional marketing communities in Europe and specialized in WOM marketing. A total of 31,173 respondents from Germany, Austria, and Switzerland returned the questionnaire resulting in a response rate of about 16% in two weeks.

Because the panel is especially aware of WOM related topics and has conducted several studies with professionally managed WOM, a careful but rigid data cleansing was mandatory with respect to the data validity and generalizability of our results. The elimination was done by an excessive search for all relevant brand or product names, including all spelling mistakes, in all open questions, to excluded any cases related to professional campaigns. Furthermore all cases with incorrect, or incomplete data (any missing values) were removed from the dataset. Regarding valence, the few respondents stating an average of exactly 4.0, and thus perfectly neutral WOM, were also excluded as we could not put them into one group or the other without risking bias.

The mean age of the remaining 19,648 respondents was 29 years (s.d. = 9.10), with a gender distribution of 74.9% female and 25.1% male. Therefore the sample structure was not representative for the German population but neither age nor gender had a main effect on transmission behavior, confirming the general suitability of the sample structure for our study.

Procedure of Data Analysis

The focus of our research is on the analysis of the open-ended question dealing with the reasons for transmission refusal. We aim at developing a categorization system inductively extracted from the 2,254 textbox answers in order to gain deeper insights into consumers' barriers for transmission of either positive or negative WOM as well as underlying mechanisms of WOM transmission behavior. We took the steps of Mayring's (2000) framework for

inductive category development. This procedure is in line with the reductive processes in psychological text processing (van Dijk 1980)

After having defined a scope of research derived from theoretical background and research question (step 1) the material was coded and paraphrased by two independent coders. Then, categories (for details see next section) were formulated (step 2). After having coded 30% of the material, we revised the category scheme (step 3), and in a feedback loop the new categories were applied to the whole material (step 4). Inter-coder differences were always solved by discussion. We then reduced our scheme to main categories (Miles and Huberman 1994; Strauss and Corbin 1990) and coded the material again (step 5). Intra-coder consistency in a final loop check was 97.8%, and simple inter-coder percentage of agreement (Bettman and Park 1980) was 91.2%. The results of the described process were the following main categories: intrapersonal reasons, interpersonal reasons, situation or context related reasons and message or topic related reason. Based on this category scheme, we analyzed relative frequencies of the different subcategories (step 6).

RESULTS

Intrapersonal Reasons

Missing Relevance of Product or WOM Topic to the Transmitter. Some respondents stated that they are generally not interested in this brand, product, or WOM topic. Exemplary respondent answers are: "Because I'm not interested." "Because I don't need that product."

Missing Judgment Ability. Some respondents said that they were not able to evaluate the product, brand, or WOM topic because of too little experience or because of lack of knowledge. Exemplary respondent answers are: "Because [...] I couldn't check the product myself." "Because I did not try it for myself and I do not recommend anything I do not know."

Product or WOM Topic Dislike. Some respondents disliked the product, brand, or WOM topic. Exemplary respondent answers are: "Because I disliked the taste of it." "The product failed to enthrall me after I tested it."

Alternative Product or WOM Topic Favorite. Some respondents expressed their preference or loyalty to another brand, product, or WOM topic as a reason to refuse WOM transmission. Exemplary respondent answers are: "Because I use very good products myself." "Because I am against constantly changing my provider."

Judgment Differences. Some respondents said that they hold opposite experiences or attitudes about the brand, product, or WOM topic. Exemplary respondent answers are: "Because my own experience is otherwise." "Because it was a one time event, bad luck."

Received Information was Forgotten. Some respondents stated that they were inattentive or had forgotten relevant information. Exemplary respondent answers are: "Because I did not listen well enough." "Because I have forgotten so much."

No WOM Motivation. Some respondents said that they did not have a reason to transmit or they expressed missing motivation. Exemplary respondent answers are: "Because I don't want to." "Because I don't have a reason for this." "I don't feel like it."

Interpersonal Reasons

Missing Perceived Relevance to Potential Receiver. Some respondents stated that they do not perceive an interest in the product, brand or WOM topic by anyone who could serve as a potential receiver. Exemplary respondent answers are: "I don't know anyone who would be interested in it." "Because no one I know would buy the product."

Interpersonal Barriers. Some respondents said that it was a conversation about private or personal topics, internal information, or private or business secrets and nobody else should or needs to

know. Exemplary respondent answers are: “It was about something very private.” “It was only intended for myself.” “Family matter.” “Because it should stay between us.”

Missing Credibility. Some respondents perceived the sender or the product, brand or WOM topic as not reliable or credible. Some even assumed hidden motives. Exemplary respondent answers are: “Because I don’t know if it’s true.” “He was too pushy.”

Solicitation Expected. Some respondents said that they are only willing to transmit WOM if a potential receiver requests the information. Exemplary respondent answers are: “As long as nobody asks me about it, I will not carry it further.” “Somebody has to ask me.”

Uncertainty about Receiver’s Benefit. Some respondents expressed their concerns that they cannot judge on the receiver’s taste or preferences. Exemplary respondent answers are: “Because everybody will rate this differently.” “I don’t like it, someone else might.”

Facilitate Own Experiences. Some respondents stated that everybody should make his own experiences. Exemplary respondent answers are: “Everybody should get his own view on it.” “Because everybody should make his own experiences.”

Reasons Attributed to Situation or Context

Missing Opportunity. Some respondents said that they had not found the time or opportunity to spread WOM. Some would only talk about the topic if it’s appropriate and of relevance to the conversation. Exemplary respondent answers are: “No time.” “I will only talk about it if a conversation touches the topic.”

Information Saturation. Some respondents said that all people they know already knew about the product, brand or WOM topic. Exemplary respondent answers are: “Because everyone I know owns one for himself.”

Reasons Attributed to the Message or Topic

Not Convinced by Received WOM. Some respondents stated, that they were not convinced. Usually it was not obvious whether this related to the topic, the sender, the message or anything else. Exemplary respondent answers are: “Because I was not convinced.” “Because the information was not convincing to me.”

Doubted Applicability to Receiver. Some respondents said that the product, brand or WOM topic is tailored to specific needs or is only applicable in specific contexts. Exemplary respondent answers are: “It is a very special product.” “Very specific information.” “Because it is a local offer.”

Missing Novelty. Some respondents stated that the brand, product, or WOM topic was either too old or not available any-

more. Exemplary respondent answers are: “Because the article is outdated.” “It was nothing new.”

Other Reasons

Categories that received only minor counts were summarized to “Other” and are as such presented here in shorter form. We deliberately set the threshold for this category at below 1% of all counts. Additionally this category includes all not interpretable answers. The categories were: *Negative WOM attitude* (some respondents had specific opinions about positive or negative WOM that let them to transmission refusal), *replace with own experience* (some respondents said that they had own experience and would transmit them instead)

relevant information was omitted (some respondents said that relevant information was missing when WOM was received or that it was to general) *missing self credibility* (some respondents stated the fear of not being a reliable source to spread the WOM), *self solicited* (few respondents said that they specifically asked for information themselves), and *don’t know/error* (this last category subsumes all respondents who stated that they don’t know as well as all cryptic or otherwise non interpretable answers).

Descriptive WOM Results

After having described and categorized the reasons for WOM transmission refusal in a qualitative way, the following results aim to draw a more quantitative picture.

As expected the total occurrence of NWOM was relatively low in respect to PWOM, thus confirming the findings of East et al. (2007) and our proposition 1. Also the total occurrence of not transmitted WOM was relatively low with 11.5% of all WOM transmitters not willing to transmit, thus confirming proposition 2. Still a first interesting finding to potential differences of PWOM and NWOM regarding transmission refusal is the relatively large share of NWOM incidents. A Pearson chi-square test revealed the difference as highly significant ($\chi^2(1, 19648) = 306.42, p < .001$) but according to Cramer’s V the association is not a very strong one (Cramer’s V = .125).

Frequencies of Transmission Refusal Results

All frequencies of categories are shown in table 2. The number of counts (2,254) is slightly different from the number of refusing respondents (2,261) because some respondents provided several answers and others provided none. The three most common reasons for refusal were: (1.) the transmitter has a low interest in the WOM topic (Missing Relevance of Product or WOM Topic, 16.0%), (2.)

Table 1
Counts of Transmitted and Not Transmitted WOM by WOM Valence

	PWOM	NWOM	Total WOM
Transmitted WOM			
Absolute Counts	16270	1117	17387
(Relative to Column)	(89.6%)	(74.6%)	(88.5%)
Not Transmitted WOM			
Absolute Counts	1881	380	2261
(Relative to Column)	(10.4%)	(25.4%)	(11.5%)
Total			
Absolute Counts	18151	1497	19648
(Relative to Column)	(100%)	(100%)	(100.0%)
(Relative to Row Total)	(92.4%)	(7.6%)	(100.0%)

the transmitter perceived the relevance or interest of potential receivers as low (Missing Perceived Relevance to Potential Receiver, 14.8%), and (3.) the transmitter felt not able to judge or evaluate the WOM topic (Missing Judgment Ability, 11.1%). Intrapersonal reasons were most common, followed by interpersonal reasons. Keeping in mind the little research on interpersonal reasons in a WOM context, this is of surprisingly high importance. Specifically, the transmitter’s perceptions of the receiver seem to be important while at the same time being neglected by previous research, thus potentially guiding future research. The same applies to situation and context factors which seem to be of importance (Missing Opportunity, 9.2%; Information Saturation, 5.8%), although prior research largely neglected them as antecedents, too.

Regarding the differences of PWOM and NWOM we find support for the notion that NWOM is perceived as being more relevant or diagnostic (Missing Perceived Relevance to Potential Receiver: PWOM, 15.8% vs. NWOM, 9.9%). NWOM therefore seem to be less susceptible to time constraints in conversation (Missing Opportunity: PWOM, 9.8% vs. NWOM, 6.0%), and is faster perceived as being saturated (Information Saturation: PWOM, 5.4% vs. NWOM, 7.8%).

In line with prior research, we also observe that NWOM is more easily recalled (Received Information was Forgotten: PWOM, 2.5% vs. NWOM, 0.8%). However, the differences of PWOM and NWOM within the important interpersonal category indicate that the spread of NWOM is socially more constrained, supported by the category ‘negative WOM attitude’ (not shown in table 2: PWOM, 0.6% vs. NWOM, 2.3%) and typical respondent statements in this

category (“You should not talk about bad memories.” “I just tell about positive things.”). Prior research supports the notion that people may avoid NWOM because of potential social undesirability (Rosen and Tesser 1972), or because NWOM is relatively scarce, implying the risk of social inconformity (Moscovici 1985; Burnkrant and Cousineau 1975). The latter is strongly supported by our data: For example, respondents are less willing to take the risk of transmitting a negative message they do not approve of than a positive message (Judgment Differences: PWOM, 1.7% vs. NWOM, 9.1%). In the case the transmitter already has a negative conviction, he will more likely transmit NWOM than without such a conviction (Product or WOM Topic Dislike: PWOM, 7.2% vs. NWOM, 2.6%). Furthermore missing credibility should then be more relevant for NWOM than for PWOM transmission (Missing Credibility: PWOM, 3.3% vs. NWOM, 7.3%).

To further verify that NWOM transmission is socially constrained, we should expect that tie strength moderates the importance of some reasons of transmission refusal. While the differences in relative frequencies are generally low, however the three criteria with the largest differences do all reflect the tie strength’ influence. As expected, transmission refusal due to missing relevance for the next receiver is higher for close ties (Relevance to Receiver Perceived as Missing: weak tie, 12.6% vs. strong tie, 16.1%) and nearly similar regarding WOM valence. Perceived sender credibility is also lower for weak ties (Missing Credibility: weak tie, 9.0% vs. strong tie, 1.1%) and not different in terms of WOM valence. However, the most interesting effect is seen on transmission refusal due to judgment differences. In support of the social conformity principle,

Table 2
Not Transmitted WOM by Category and WOM Valence

	PWOM		NWOM		Total WOM	
	Abs. Count	% of Col.	Abs. Count	% of Col.	Abs. Count	% of Col.
Missing Relevance of Product or WOM Topic	299	16.0%	62	16.1%	361	16.0%
Missing Perceived Relevance to Potential Receiver	296	15.8%	38	9.9%	334	14.8%
Missing Judgment Ability	213	11.4%	38	9.9%	251	11.1%
Missing Opportunity	184	9.8%	23	6.0%	207	9.2%
Product or WOM Topic Dislike	135	7.2%	10	2.6%	145	6.4%
Information Saturation	100	5.4%	30	7.8%	130	5.8%
Interpersonal Barriers	80	4.3%	30	7.8%	110	4.9%
Missing Credibility	62	3.3%	28	7.3%	90	4.0%
Judgment Differences	32	1.7%	35	9.1%	67	3.0%
Not Convinced by Received WOM	48	2.6%	10	2.6%	58	2.6%
Doubted Applicability to Receiver	44	2.4%	5	1.3%	49	2.2%
Received Information was Forgotten	46	2.5%	3	0.8%	49	2.2%
No WOM Motivation	43	2.3%	4	1.0%	47	2.1%
Alternative Product or WOM Topic Favorite	41	2.2%	1	0.3%	42	1.9%
Missing Novelty	36	1.9%	5	1.3%	41	1.8%
Solicitation Expected	30	1.6%	7	1.8%	37	1.6%
Uncertainty about Receiver’s Benefit	21	1.1%	14	3.6%	35	1.6%
Facilitate Own Experiences	14	0.7%	17	4.4%	31	1.4%
Other	145	7.8%	25	6.5%	170	7.5%
(Thereof Don’t know/Error)	(88)	(4.7%)	(11)	(2.9%)	(99)	(4.4%)
Total	1869	100%	385	100%	2254	100%

the higher risk by NWOM than by PWOM is more severe when the relationship is close (Judgment Differences weak tie 4.3% vs. strong tie 11.8%).

CONCLUSION

We developed a category system for reasons to refuse WOM transmission, comprising intrapersonal, interpersonal, context-related, and topic-related reasons as categories. We identified the most important reasons for transmission refusal, including the transmitter's perception of the receiver and context factors that have so far been neglected in WOM research. Further research should go into more detail with respect to these categories. We additionally replicated the larger occurrence of PWOM as previously found by East et al. (2007). Moreover, we confirmed that the refusal of WOM transmission is relatively scarce (transmission refusal rate below 10% of all WOM incidents). Still, there is a highly significant influence of WOM valence on WOM transmission. We then identified reasons for the different influence of WOM valence. This supported the notion that NWOM is perceived as being more relevant or diagnostic. Furthermore, we showed that social constraints are more related to the transmission of NWOM than of PWOM. We were able to argumentatively validate this finding using the moderating effect of tie strength on the social constraints proposition. This finding adds to the debate about differences of PWOM and NWOM in respect to their effects and may provide an additional explanation on the relative scarcity of NWOM occurrence. Social constraints are a topic with few related studies in WOM literature. But given the potential influence, this is another path for future research.

Marketing managers might be delighted to hear that NWOM is more susceptible to transmission refusal. But our key contribution is the categorized system of transmission refusal. The particular merit lies in a differentiated picture of the drivers for transmission refusal reasons for PWOM and NWOM which could be used to gain detailed insights into why PWOM campaigns might fail or to tailor specific marketing measures to fight NWOM.

For example, to minimize transmission refusal in a PWOM campaign, managers should engage in increasing the perceived topic relevance to the transmitter. This can be achieved by a variety of traditional communication measures that focus on generating awareness and need. In order to tackle missing judgment ability as a reason for transmission refusal, one should focus on informative communication as collateral measure.

Giving Advice to Others: The Role of Social Distance

Yu Hu, Salem State College, USA

ABSTRACT

This research examines the effects of social distance on interpersonal advising behavior. We propose that when an advice is based on a decision's desirability and feasibility attributes, the social distance between the advisor and the advisee would affect how the advisor evaluates the relative importance of those decision attributes, and consequently it would lead the advisor to offer different advice to different advisees. Specifically, this research demonstrated in two studies that although a decision's desirability attributes are judged by the advisor as more important than feasibility attributes, this difference is more evident when the advice is offered to a distant social relation (e.g., strangers) than a close social relation (i.e., best friends); a decision's feasibility attributes have more influence only when the advice is given to a close relation than to a distant one.

INTRODUCTION

We often seek advice from or give advice to other people—we trust others' advice on important life decisions; we also believe the advice we give to others is based on our best judgments. But ironically, empirical evidence has repeatedly shown that people who give advice to others often make different decisions for themselves (e.g., Jones, Schulz-Hard, and Frey 2005; Kray 2000). This self-other discrepancy has been demonstrated across many decision-making domains, including risk prediction (Hsee and Weber 1997), reward preference (Heath 1999), medical decision (Zikmund-Fisher 2006), and job selection (Kray and Gonzalez 1999). Despite the consistent finding, to date, researchers have primarily focused on the self-other comparison, and very few empirical studies have examined the conditions under which advisors would adapt their advice to suit different advice recipients. For example, would a physician recommend the same treatment regime to a new patient and to a close friend, if both of them display the same symptom? Would it be possible that he'd recommend an aggressive one for the new patient and a conservative one for his friend, or vice versa? If yes, then why? The goal of the present research is to investigate advice recipients' influence on interpersonal advising behavior.

From an advisor's perspective, there are many ways to characterize the advisee, such as gender, age, experience, attitude, etc. In this research we choose to focus on the *social distance* between the adviser and the advisee, a choice based on the reasoning and evidence that social distance or interpersonal relation is a dominating factor that guides human social interaction (Clark and Mill 1979; Heider 1958; Sahlins 1972). Psychologically and physically, people are closer to their spouses or friends than to their co-workers or casual acquaintances, and the influence of social distance (or relationship strength) on cognition and behavior has been shown in a variety of consumer domains (e.g., Frenzen and Nakamoto 1993; Kim, Zhang, and Li 2008). Adding to this literature, the present research proposes that social distance could affect how advisors evaluate other people's decision situations and consequently alters how they give decision advice to others. Specifically, we argue and found that the distinct effect of social distance in advising is that it could change the adviser's evaluation and judgment of a decision's feasibility concerns. In the next session, we first present literature examining the social distance effect on interpersonal perception and information processing, which will then be followed by our prediction of the social distance effect on the advisor's differential weighting of decision attributes.

SOCIAL DISTANCE EFFECT

To examine the influence of social distance on interpersonal advising behavior, we turn to the conceptual framework proposed by the Construal Level Theory (CLT, Trope and Liberman 2003). In simplicity, CLT articulates how psychological distances—time, space, social relation, or probability—influence individuals' mental representations of related objects, events or behavior (e.g., other people's actions or decisions): the greater the perceived psychological distance, the more likely are the perceivers to form high-level (e.g., abstract) rather than low-level (e.g., detailed) construal of the objects or the events. In other words, CLT predicts that people's mental representations of other people's actions can take different forms: for close social relations, people are more likely to use concrete, detailed, contextualized features (i.e., low-level construal) to construe the target person's action; for distant social relations, people are more likely to use abstract, simple, primary, generalized features (i.e., high-level construal).

Although CLT literature has mainly focused on the effects of temporal distance, there are studies that have examined the effects of social distance on construal levels (e.g., Kim, Zhang, and Li 2008; Liviatan, Trope, and Liberman 2008; Smith and Trope 2006). Most germane to the current research, Liviatan et al (2008) predicted and found that social distances induced by perceived interpersonal similarity changed people's construal of similar and dissimilar individuals, even when the same information about those individuals were presented. These different representations, in turn, had influenced people's judgments about similar and dissimilar others' decisions. In one of Liviatan et al (2008)'s study, the subjects gave more decision weight to lower-level, secondary decision attributes for similar (vs. dissimilar) target person's decision, and consequently, they also made different decisions for the target person because of the differential weighing of decision's secondary attributes. Additional evidence of the social distance effect can be found in the studies of interpersonal power relations. For example, Smith and Trope (2006) demonstrated that elevated power in social relations increases the perceived distance one feels from others. As a consequence, people with power consequently adopt a high level construal of their low power counterpart, which makes them process other's information in a more abstract fashion and base their judgments about other more on low-level, secondary information. Extending those existing CLT studies on social distance effect, this present research uses a different operationalization of the social distance—the interpersonal relationship strength exhibited between close and distant social relations—to examine how social distances between the advisor and the advisee would change the advisor's processing of the advisee's decision situation and would consequently affect the advisor's advice given to the advisee.

DECISION DESIRABILITY AND FEASIBILITY

When deciding on whether to take or advice other to take an action, the decision-maker or the adviser has two main concerns: the desirability concern, which focuses on the potential outcome of the action (i.e., reasons to commit to the action) and the feasibility concern, which focuses on the implementation process of the action (i.e., means to carry out the action), (Bandura 1982; Fischhoff 1999; Gollwitzer 1990). A job position, for example, might promise high salary and generous benefits (i.e., desirability); meanwhile, applying for the job might include a lengthy application process and multiple interview trips (i.e., feasibility). A job decision-maker

would assess the importance of these two concerns before reaching a decision. And, when it comes to advising on other's job decision, assessing these concerns becomes more challenging in that the adviser has to evaluate the implementation and consequences of the decision on behalf of the advisee. Will the adviser favor the job's desirability features more than the feasibility ones, or vice versa? As we elaborate later, we predict that the perceived social distance between the adviser and the advisee would influence whether the adviser assigns different evaluative weights to the desirability and feasibility concerns of the action.

According to the CLT research (e.g. Liberman and Trope 1998), desirability concerns are viewed as the high-level construals of a decision action; feasibility concerns the low-level construals of a decision action. CLT further predicts that the greater psychological distance from the decision-maker to the target action, the more influential is the desirability considerations than the feasibility considerations. For example, from a temporal distance perspective, Liberman and Trope (1998) demonstrated that purchase decisions for the near future (i.e., close psychological distance) was more likely to be affected by product feasibility concerns, whereas distance future purchase decision was more likely to be influenced by product desirability concerns. Hence, linking the evidence of temporal distance effects on information processing with the recent advances in the CLT research on the social distance dimension, it is reasonable to propose that, when evaluating decision situations and giving advice to social partners, advisors would assign disproportionate weights to either the desirability or feasibility considerations, under the influences of the perceived social distances between the advisor and the advisee.

What Liberman and Trope (1998) and Liviatan et al (2008) did not extricate in their studies was the comparative importance of a decision's desirability and feasibility attributes when those are considered together: in Liberman and Trope (1998; study 2 and 3), desirability and feasibility attributes were evaluated in isolation while temporal distances were manipulated. However, in many everyday situations, giving advice usually requires the advisor to simultaneously consider both types of attributes, so it is empirically important to examine how psychological distances would affect the advisor's joint evaluation of a decision's desirability and feasibility attributes. Building on the CLT's findings, we predict that when considered together for a decision or advice, desirability would have more influences than feasibility. More important, under the influence of social distance, the desirability's dominance is greater when the decision is related to a distance social relation, whereas feasibility should become more important when the decision is related to a close social relation. That is to say, for a casual acquaintance, the advisor would base his advice mostly on the high-level, desirability attributes; for a close friend, the advisor would be more likely to be influenced by the low-level, feasibility attributes. Formally:

Hypothesis 1: Decision advice offered to a distant social partner (e.g., casual acquaintances) would be influenced more by the decision's desirability concerns than its feasibility concerns,

Hypothesis 2: Decision's feasibility concerns would have greater influence when the advice is offered to a close social partner (e.g., best friends) than to a distance social partner.

State differently, we expect that when advising a distant advisee, the advisor tends to focus on the desirability considerations and is less likely to be concerned about the feasibility aspects of the

advice; comparatively, when advising a close advisee, the advisor tends to pay more attention to the feasibility aspects of the advice. But It is worth noting that we do not expect that the advisor would see a decision's feasibility features as more important than the desirability ones when the advice is offered to a close friend—Our prediction only specifies that the advisor would assign more weight to the decision's feasibility concerns when the advisee is a close social relationship partner, as compared to a socially distant advisee.

Two lab experiments were conducted to test the research propositions. Study 1 assessed the importance ratings participants attached to a job decision's desirability and feasibility information for distant and close social relationship partners. In Study 2, we directly examined the advice offered to those two different social relations. The research methods used in the studies benefited both from several aforementioned CLT studies (Liberman and Trope 1998; Liviatan et al 2008) and from the priming research of interpersonal relationship (e.g., Fitzsimons and Bargh 2003). As a whole, besides its focal proposition, this research introduces a new and effective experimental paradigm to the study of social distance and its effects on consumers' information processing and behavior.

STUDY 1

This study was designed to test the hypothesis that when giving decision advice to other people, advisors tend to attach different importance weights to a decision's feasibility and desirability considerations. Specifically, it's predicted that desirability considerations should play a greater role for a distance advisee, while feasibility considerations should play a greater role for a close advisee. In the study, participants were first randomly assigned to two relationship groups (best friend vs. stranger) by an imagination task modeled after a procedure used by Fitzsimons and Bargh (2003). Immediately after the priming, participants were asked to act on behalf of the target person to provide importance ratings on a job offer's desirability and feasibility attributes.

Procedure

Fifty five undergraduate students participated in this lab experiment in exchange for extra course credit. Upon arrival, they were given a survey booklet allegedly used to study how college students interact with their peers. Used as a priming task adopted from Fitzsimons and Bargh (2003), the survey consisted of a set of questions designed to activate a mental representation either of a best friend or a stranger. It first asked participants to take a moment to bring to mind either a stranger that they had met in class in the current semester or one of their best friends on campus. They were asked to provide the first name of the person they imagined, if they knew, and then to describe their latest conversation with the person. In order to strengthen the priming effect, in the best friend condition, the questionnaire asked two additional questions: (1) "Briefly describe two things this best friend has done for you that make you think it is worthwhile to have a friend like him/her;" (2) "Describe one situation in detail in which your best friend did something for you that made you think it is really worthwhile to have a friend like him/her?" In the stranger condition, the priming question simply asked the participants to describe one situation that they interacted with a stranger.

Decision Description, Dependent Measure, Manipulation Check

Immediately following the priming questions, participants were told that the person they had just imagined was deciding whether to accept a job offer. They were then instructed to evaluate the job offer on behalf of the target person. The job was briefly described

in the booklet in a random order of ten job related features: Five were related to the desirability considerations of a job decision (i.e., salary, promotion, interest, working hours, job security) and the other five were related to the feasibility considerations (i.e., application complexity, interview procedure, interview location, training period, job relocation requirement). A pilot study using the same subject pool confirmed the intended perception of desirability and feasibility concerns of the ten features. After reviewing the job information, participants were asked in the next page to indicate, in order for the target person to make a good decision, how important it is for him to have some additional information about each job feature. To highlight the advising role, it was reminded to the participants that they were making a judgment for the target person, not for themselves. The importance rating measure used an 11-point scale, ranging from *Not important at all* (0) to *Very Important* (10). To assess the success of social distance manipulation, at the end of the experiment, participants indicated how close they felt to the imagined person at a 9-point scale ranging from "Not at all" to "Very much". As expected, participants rated the imagined best friend closer to themselves ($M = 7.41$) than the stranger ($M = 2.82$, $p < .01$). Before they were debriefed and dismissed, participants were given an open-ended question to estimate the true research purpose of the study, and content analysis did not reveal any meaningful suspicion.

Results

A 2 (Target Person: best friend vs. stranger) X 2 (Job Feature Type: desirability vs. feasibility) mixed ANOVA with target person as between-subjects factor and job feature type as within-subjects factor was performed on participants' importance ratings. The main effect of feature type was significant, indicating both of the two groups were able to discriminate between desirability and feasibility concerns and they preferred the desirability attributes more than the feasibility ones ($M = 9.36$ and 6.75 , respectively; $p < .05$). More important, the results showed the expected interaction between job feature type and target person, $p < .01$, $\eta^2 = .17$, indicating that the perceived importance of desirability and feasibility considerations is a function of the relationship between the advisor and advisee. As expected, the perceived importance of feasibility considerations decreased when the advisor and advisee were close friends ($M_{\text{best friend}} = 7.39$ and $M_{\text{stranger}} = 6.11$); but somewhat unexpectedly, the best friend group also gave greater importance ratings to the desirability features ($M_{\text{stranger}} = 9.8$ and $M_{\text{best friend}} = 8.77$), which might be attributed to the lack of motivation for the participants in the stranger group. But, overall, this study confirmed the hypothesized role of social distance in advising behavior: although a decision's desirability attributes were perceived by the advisor as more important than its feasibility attributes, this difference was more apparent when the advising decision was related to strangers than to best friends. That is to say, when giving advice to others people, the advisor attaches greater importance to desirability concerns when the advisee is a distance social partner and feasibility concerns play a greater role in close relationship advising than in distant relationship advising.

Notwithstanding these confirming results, this study has two apparent drawbacks. First, the priming procedures could simply heightened the involvement or motivation of the participants in the best friend group, which might explain why those subjects rated the feasibility attributes more important than those in the stranger group did. Second, this study did not examine whether the importance rating was predictive of the advisor's actual advising behavior. A second study was conducted to address these issues.

STUDY 2

Study 1 has showed that social distance between the advisor and advisee can change how advisors perceive the relative importance of desirability and feasibility decision features. The present study was designed to test whether the different importance perception can in fact influence how advisors give advice. After the same priming procedure as in Study 1, participant was asked to act on behalf of the target person to evaluate a job position and express the likelihood that they would recommend the job to the target person. The job information was selected from the aforementioned ten job features in Study 1 and two versions of the job were created: Job 1 had two positive desirability features and one negative feasibility feature; Job 2 had two positive feasibility features and one negative desirability feature. We expect that Job 1 would be preferred across relationship groups and, more important, a job's feasibility features would have more influences on advice offered to a close friend than to a stranger.

Procedure

Eighty two undergraduate students participated in this lab experiment in exchange for extra course credit. Upon arrival, they were given the similar survey booklet used in Study 1, which, in its first part, contained the same relationship priming procedure and manipulation checks, which were successful and will not be discussed further. After the priming, participants were told that the target person was considering a job offer. What followed was the description of the target job position and choice likelihood measure. Participants were randomly assigned to the two job groups and were asked to express the likelihood (a 7-point scale, ranging from 1, *Not at all likely* to 7, *Very likely*) that they would recommend the target person to accept the job offer. Like in Study 1, before answering the likelihood measure, participants were reminded that they were making a judgment for the target person, not for themselves. In addition, participants in both experimental groups were asked to carefully evaluate the information and make a best judgment on behalf of the target person, a measure that was intended to remove the possible motivation differences between the two groups.

Results

A 2 (Target Person: best friend vs. stranger) X 2 (Job Type: most positive desirability [Job 1] vs. most positive feasibility [Job 2]) ANOVA was performed on participants' recommendation likelihood rating. As expected, job type main effect was found: participants preferred the job with most positive desirability features over the one with most positive feasibility features ($M = 5.47$ and 5.01 ; $p < .01$), replicating the finding of desirability superiority in Study 1. And there was a significant interaction between job type and target person type, $F(1, 80) = 12.87$, $p < .01$. Post hoc simple effect analysis of target person revealed that the job with all positive desirability features and one negative feasibility feature was disliked more by the best friend group than by the stranger group ($M_{\text{best friend}} = 5.1$ and $M_{\text{stranger}} = 5.84$; $p < .01$), confirming the hypothesized overweighing of feasibility concerns by the close relation advisors. There was no significant difference between these two groups on the job with all positive feasibility features ($M_{\text{best friend}} = 4.95$ and $M_{\text{stranger}} = 5.06$; NS). However, only participants in the stranger group liked the job with all positive desirability features significantly more than the other job, $M_{\text{job1}} = 5.84$ and $M_{\text{job2}} = 5.06$; $p < .05$. Together, these results clearly indicate that, when giving advice to others, decision's feasibility features exerted more influences on the advisor's preference of the job for best friends than for strangers; when advising strangers, desirability considerations are the ones that count.

GENERAL DISCUSSION

The goal of this research is to investigate the role of social distance on interpersonal advising behavior. We argue that when an advice is based on a decision's desirability and feasibility concerns, the social distance between the advisor and the advisee would affect how the advisor evaluates the relative importance of those concerns, and consequently it would lead the advisor to offer different advice to advisees of different social relations. Borrowing heavily from the seminal Construal Level Theory (Trope and Liberman 2003) and its empirical findings (e.g., Liberman and Trope 1998, Liviatan et al 2008), we reason that social distance changes the advisor's construal of the advisor's decision situation in the following way: a distant advisee's decision is construed with higher level abstraction, whereas a close advisee's decision is construed with higher level of concreteness. As a consequence of this information processing difference, the advisor assigns different evaluative weights to a decision's desirability and feasibility concerns in that a decision's desirability concerns are high-level construal and feasibility concerns are low-level construal. Put these propositions into an advising context, this current research predicts that decision advice offered to a distant social partner (e.g., casual acquaintances) would be influenced more by the decision's desirability concerns than its feasibility concerns; a decision's feasibility concerns would have greater influence when the advice is offered to a close social partner (e.g., best friends) than to a distance social partner.

Two studies tested the research hypothesis. Study 1 assessed the importance ratings advisors assign to a job decision's desirability and feasibility information for distant and close social relations. Participants were first randomly assigned to two relationship groups (best friend vs. stranger) by an imagination task. Immediately afterwards, they were asked to act on behalf of the target person to provide importance ratings on a job offer's desirability and feasibility attributes. The results indicated that while the job's desirability was deemed more important than its feasibility by both the experimental groups, advisors for their best friends gave more importance ratings to the job's feasibility attributes. In other words, when the advisee is a close social relation, advisors consider not only why the advisee should or should not take the action (i.e., desirability), they also take into consideration how the advisee could carry out the action (i.e., feasibility); when advising a distant social relation, the advisors only focus on the desirability concerns.

In Study 2, we directly compared the advice participants made to different social relations. Two versions of a job description were created: Job 1 had two positive desirability features and one negative feasibility feature; Job 2 had two positive feasibility features and one negative desirability feature. As expected, participants preferred the job with most positive desirability features (Job 1) over most positive feasibility features (Job2). More relevant, only the participants in the best friend group exhibited significant doubt about the job with one negative feasibility feature (Job 1), which echoed the finding from Study 1 that the importance of a decision's feasibility attributes is greater when the decision is related to a close social partner than to a distant one. Hence, taken together, two studies confirmed the dominant role of a decision's desirability considerations in distant relation advising and the stronger role of feasibility considerations in close relation advising.

The intended contribution of this research is to demonstrate the effects of advisees in the interpersonal advising behavior. Past research on this topic has focused exclusively on the decision

differences between advising others and deciding for oneself. Expanding this literature, two studies reported here show that the social distances between the advisor and the advisee would influence how the advisor evaluate decision attributes and consequently affect what advice the advisor offers to different advisees. For future research, we suggest to replicate the current findings by testing the advisee effects with other psychological dimensions. For instance, would the physical distance between the advisor and the advisee have the same effect as the social distance does? In other words, what are the differences between face-to-face advising and long distance advising? What about temporal distance? Would it be different if the decision happens tomorrow or next year? And how would this temporal distance interact with social distance? As we can see, many intriguing research projects await us. Bon voyage.

'No Longer, But Not Yet' – Tweens and the Mediating of Liminal Selves Through Metaconsumption

Kevina Cody, Dublin Institute of Technology, Ireland
Katrina Lawlor, Dublin Institute of Technology, Ireland
Pauline Maclaran, Royal Holloway, University of London, UK

ABSTRACT

Using the anthropological theory of liminality as a lens of analysis, the following paper outlines specific elements of a research project exploring the consumer culture of a liminal group – tweens. The lived experience of a tween is explored using a multi-method approach incorporating personal diaries, in-depth interviews and accompanied shopping trips. Outcomes of one aspect of this longitudinal research project – the theory of metaconsumption – are presented, suggesting an important divergent theoretical path from the 'effects' - dominated consumer socialization approach to researching young people and their relationships with consumption. We conclude that those in a shadowed reality, those social neophytes no longer children but not yet teens engage with consumption practices and spaces particular to those who must exist mid-way between two spheres of identity. Thus this shadowed reality, this socially indiscernible identity belies agentive consumption and active engagement with signifiers of a duality of mediated selves.

INTRODUCTION

Marketing theory and research, in particular the vibrant tendrils of consumer culture and consumer behavior research embodies a kaleidoscopic essence of cross-disciplinary infusion and hybridism. The origins of interpretive consumer research as outlined for example by Tadjewski, (2006), as well as contemporary theorizations (e.g. Arnold and Thompson, 2005) and empirical advancements (e.g. Kozinets, 2001) have been shown to embrace ontologies far beyond the scope of marketing's seminal mantras (e.g. Kotler et al, 2008). Rather than consequently exist as a diluted pseudo-discipline, consumer research has thrived in its plurality, with the work of those who seek to investigate and theorize upon the symbiosis between meaningful ways of life and the symbolic marketplace visibly nourished and revitalized by contributions from social sciences such as psychology, anthropology and sociology.

This paper attempts to harness one such untapped reservoir of potential empirical and theoretical advancement; the anthropological theory of liminality, attesting to the potential of this theoretical framework as a lens of analysis for consumption practices but also offering a divergent avenue of exploration and theorization in relation to consumer socialization. The interstices of socio-cultural organization have proved sources of fascination and powerful theory development in the fields of anthropology, sociology and psychology (e.g. Van Gennep, 1961; Turner, 1974; 1978; 1988; Freud, 1950; Foucault, 1977). Douglas (1966: 137) writes that within society, 'there is energy in its margins and unstructured areas'. Consumer culture research has hitherto acknowledged the fruitfulness of transitional phenomena, spaces and places, as well as the experiences of the individual or group in flux and evolution (e.g. Davies & Fitchett, 2004; Maldonado & Tansuhaj, 1999; Gentry, 1997; Schouten, 1991). But it is the heart of this transition that has evaded exploration, slipped beneath the radar of interest. The farthest realms of the threshold may inevitably beckon, but the interim must be experienced to enact the resolution so often the focus of researcher's attentions. For many, the threshold is their current reality, their centre of nowhere.

This research focuses on the premise that for those whose sense of self is ambiguous, vague or blurred by the experience

of standing mid-way between two symbolically-loaded social spheres of interaction, belonging to neither, but embedded in both, consumption practices and relationships with consumption take on a new meaning, a divergent core. Focusing specifically on the pre-adolescent or tween, who has come to represent the epitome of a categorical anomaly, a socio-cultural miasma (James, Jenks and Prout, 1998; Cook, 2004a), we set out to explore and theorize upon the dynamics of these liminars' relationships with and through goods and their associations. This paper presents one of the theoretical conclusions of this longitudinal research project – the theory of metaconsumption – which explores consumption within the tweens' liminal shadow of activity and regeneration which prepares these social neophytes for entry into a teenage world.

EVERYTHING AND NOTHING – THE THEORETICAL FRAMEWORK OF LIMINALITY

Defined by Turner & Turner (1978: p.249) as 'the state and process of mid-transition in a rite of passage', a 'moment in and out of time' (Turner, 1969: p.96), the liminal phase of a transition, represents an instance of incompleteness, when the liminars (the ritual subjects in this phase) 'elude or slip through the network of classifications that normally locate states and positions in cultural space' (Turner, 1969: p.95). Understanding the attributes of liminal entities also serves to illustrate the core ideologies of the theory. One such attribute is structural and social invisibility, seclusion from the spheres of everyday life (Turner, 1967). In addition, ideologies of liminal theory espouse characteristics such as *tabula rasa*, symbolization of concurrent degeneration and gestation or parturition (Turner, 1967), heteronomy, silence, equality and obscurity.

Turner's (1967, 110) 'invitation to investigators of culture to focus their attention on the phenomena and processes of mid-transition' has resulted in contrasting disciplines welcoming liminality and its constituent dimensions into their midst to enrich an understanding and analysis of many phases of cultural change. Several bodies of literature forming a hybridism of theoretical perspectives with liminality unite around a core trope of illness and loss (e.g. Little et al, 1998; Gough, 2005, Jones et al, 2007). In the context of these studies, the theoretical framework of liminality has added credence to instances where alliance with social categories and social structures is suspended and irrelevant. Anderson (2003), Campbell et al (2005), Landzelius (2001) and Waskul (2005) have engaged with contextual specificities such as implantable cardioverter defibrillators (ICDs), advertising, incubated pre-term babies and internet personas respectively in their integration of this anthropological theory of structural anomalies.

Contexts as disparate as place and space (Pritchard & Morgan, 2006; Matthews et al, 2000), performance (Dunne, 2002; Rill, 2006; Brown, 2007; Hooker, 2007), and Postmodernity (Bhabha, 2004; Zukin, 1991; Bettis, 1996) also highlight the infusion and contribution of many areas of socio-cultural research with ideologies of the liminal, adding vividness and analytical depth to contemporary lived experiences of socio-cultural evolution and disruption.

LIMINAL CONSUMPTION

But what of liminal consumption? Have the ideologies of interim states been used as a lens of analysis for consumption

practices and behaviours? Within interpretive consumer research's current brand of organization and theorization, CCT, liminal theory has been relatively underutilized as a theoretical lens through which to understand the consumption practices of those betwixt and between social categories or states of being. Schouten (1991) represents the inaugural integration of this anthropological perspective on mid-transition with individual consumption practices. Despite introducing a link between liminality and consumption, the overall emphasis of Schouten's (1991) research is divided between self-concept theories, role transitions, rites of passage and liminal ideologies. This multi-theoretical focus implies that less in-depth insights of specifically liminal consumption behaviours are garnished. Schouten (1991, 422) himself concludes that 'little is yet known about the consumption behaviours of liminal people'.

Despite focusing on a proposed relationship between liminal transitions, symbolic consumption and the extended self, the work of Noble & Walker (1997) gravitates around the notion of transitions as opposed to the state of liminality itself and additionally utilizes a positivist framework and quantitative methodology to align with its dissemination in predominantly psychologically oriented fields of inquiry.

Several other studies have approached the phenomenon of consumption in a liminal state (Hogg et al., 2004; Landzelius, 2001; Pavia & Mason, 2004). Although generating fascinating insights in their own right, these studies commonly relegate the liminal to a constituent dimension of a wider terrain of focus. It appeared that Schouten's (1991) cry to rally the troops towards explorations of this potential reservoir of symbolic meaning and consumer experiences had been relegated to the margins of interpretive consumer research. Thus this research aimed to explore the interweaving of consumption and identity amongst those whose sense of self is as much about past as future; selves that are embedded in what was, but concurrently gravitating towards what is to come.

METHODS

In order to explore the interaction of liminal lived experiences and tween consumption practices, there were several methodological considerations and implications. Firstly, cognizant of the inherent ideologies of liminality, an instance of time deemed fundamentally disruptive or ambiguous in the life of a pre-adolescent was selected so as to capture lived experience of 'betwixt and between' at its most lucid. Therefore, a longitudinal study of a year was undertaken spanning the participants' final months of primary school and early months of secondary education in two Irish cities¹. Three main sites of access were utilized; drama schools, personal contacts and primary schools.

Second, in line with Richardson's (1994) conceptualization of multiple methods within the interpretive domain as 'crystallization', this year-long exploratory research project was interjected at various points by a constellation of data collection techniques. A focal point of Richardson's (1994) theorization is the premise that 'what we see depends on the angle of our repose' (p.523). Five data collection methods were employed; namely in-depth interviews (which were conducted at two separate intervals), personal diaries, accompanied shopping trips, e-collages and researcher diaries. Each method was chosen so as to reflect a divergent angle of repose on the lived experience and consumption practices of a liminar. However, due to space constraints, only interview data will be integrated into this paper.

¹ These stages of education correspond to junior and senior high school in the United States

Analysis of such a myriad set of data collection techniques required a specific combination of rigor and creativity. In line with the work of Strauss and Corbin (1998), a grounded theory process of analysis was used which proved 'mechanistic and indeterminate in roughly equal portions' (McCracken, 1988: p.41). Following this process of analysis which inherently involves stages of memo writing, axial coding and selective coding, core categories were developed around which the other categories and constructs revolved and offered explanatory power (Spiggle, 1994). This process of data analysis culminated in a stage of data interpretation in the manner of 'a hermeneutic circle' (Arnold and Fischer, 1994: p.63).

RESEARCH FINDINGS AND ANALYSIS

The following section details one of the central findings of the first phase of data collection – during the last months of primary school – the theory of metaconsumption. Although the main focus of this paper is the metaconsumption theorized as reflective of the consumption practices engaged with by the liminal tweens, it is necessary to briefly ground this theory in the context in which it emerged. This contextual grounding lays the foundation for the emergence of the metaconsumption theory.

THE LIMINAL TWEEN

As discussed throughout the literature review, the theoretical framework of liminality (Turner, 1967; 1969; 1974) was utilized as a prism for interpreting the cultural and social categorization of these ambiguously located beings. Due to space constraints there will be a brief delineation of one of the component concepts of the notion of the liminal tween; clashing age perceptions. This and many other instances of liminality that emerged throughout the data add empirical credence to the social invisibility experienced by these 'betwixt and between' girls. This sense of being socially imperceptible would emerge as a focal point for the metaconsumption strategies engaged with by these interstitial consumers.

Clashing Age Perceptions

Established within the specific elements of Turner's (1967) theorization of liminality is acknowledgement of the ambiguity and indeterminacy that embodies the experience of one who exists as a miasma of socio-cultural categorization and perceptions. One of the most overtly liminal components of the tween identity was the tension experienced between their own conceptualization of how others in society should react to them versus the reality of their social positioning. Testament to the theorization that these girls are no longer, but not yet, their social and personal categorizations were often at odds with one another resulting in an acute sense of social invisibility and often darkness for the girls. Their sense of impending immersion into a teen sphere of social interaction was not matched with others' behaviors' towards them.

In the following interview excerpt, Elaine informs me that although she is given the responsibility of caring for her own brother and sister, many people outside of her family would consider her age far too young to be held responsible for their children. However she is quick to point out that she herself does not hold the same view.

E: *'but I am far more mature than a lot of 13 year olds I know...I think it is more to do with the fact that people hear 12 years old and they think oh that's too young to babysit children...*

K: *'and when do you think they would be okay with it... other people'*

E: *'I think at about 14 or 15 it is more acceptable, by other people, to be babysitting for children'*

Here Elaine finds herself grappling with her own sense of personal development and the views of those who ascribe to the wider

social implications of age-aligned development, socialization and consequent competencies. She exists awkwardly at the threshold of what is deemed acceptable socially and how she considers herself personally; blurring boundaries, confusing classification.

In this marketplace example, Rachel highlights the tension she experiences between her own sense of distance from a child-like persona but concurrently other peoples' conceptualization of her as far removed from the realms of teen consumer autonomy.

K: *'and how do you decide what to buy....when you're shopping'*

R: *'well probably like....when my mother's coming down town with me....and it's like oh this is lovely and she calls over the shop assistant...then I feel like such a child and I'm like oh no I hate that and she's like oh yea this is lovely, try this on....and I'm like oh no...I hate this outfit...like I hate the pants or something...and then you know the way you wouldn't want to say it in front of the shop assistant and then you're just like...oh okay I'll try it on'*

Rachel's experience with the sales assistant exemplifies her occupation of or location in a category lacking boundaries or clarification and as a result her developing sense of autonomy and independence resides uncomfortably beside society's attempts to classify her as a child. Although understanding herself as a competent, self-knowing consumer, this is not how others behave towards her. Thus Rachel's experience of shopping results in a clashing of subjectivities owing to her existence as a 'betwixt and between' (Cook, 2004), exemplifying an interim subjectivity, a liminal self.

THE EGOCENTRIC TWEEN

The incorporation of a theoretical perspective from the field of psychology was an emergent development following initial data analysis. Elkind's (1967) notion of egocentrism is considered by those specializing in the field of adolescent psychology, to be an under-researched idea, with constructive potential for anyone attempting to theorize on the lived experiences of young adolescents (Elliot & Feldman, 1990). In essence, Elkind's theory centres on the advanced cognitive capabilities of those approaching adolescence status in particular their increased ability to incorporate the perspectives of others into their own way of thinking and understanding themselves and the world around them. What differentiates adolescents however, and perhaps most pertinent to this research, is the tendency of this group to over-generalize and believe themselves to be the focus of most other people's attention all of the time akin to an 'imaginary audience' (Elkind, 1967).

Amanda's interview illustrates vividly her tendency to incorporate an imagined audience into her developing self-system. She explains that the impending move to secondary school has meant divesting herself of any stationary that would be considered young or child like, in the hope of avoiding what she imagines would be certain disdain and ridicule from her new class mates.

K: *'what else did you have to buy for secondary school?'*

A: *'yea like I used to have all these little parers² and little fancy girly parers but then I was like I'd probably get into trouble.... people would be like 'why do you have that'....so I went for a plain pencil parer'...*

K: *'what would people think if you have a plain pencil parer?'*

A: *'if you had a big girl sittin up on the table they might be like hmmmm...baby....'*

Here Amanda is using the imagined reactions of her peers to alter her consumption repertoire and future buying habits. It is almost like how she envisages her class-mates reacting to her display of consumption objects, is harnessed and utilized as a gauge for what will be suitable to bring along to secondary school. At this

point in time, Amanda has not yet experienced the social environs of secondary school at first hand. However her advancing cognitive abilities have allowed her to consider the perspective of those girls she has yet to meet, albeit to an exaggerated degree. Even something as seemingly unrelated to social judgments and ridicule as the theft of her MP3 player is reflective of the egocentric nature of Amanda's developing self.

A: *'I nearly made myself sick thinking about it....i dunno why I got so upset about it....'*

K: *'was it to do with losing your zen...or that it was robbed by someone....'*

A: *'I dunno...I guess it was a bit of both....i just dunno....i just cracked....i imagined everyone will think I can't look after stuff...'*

In this example it appears that what had unsettled Amanda so much following the theft of her MP3 player was less to do with the physical void of the item but more with what she imagined the incident conveyed to others about her ability to be responsible for her possessions. Egocentrically, she believes this mishap to be the sole focus of others' attentions.

METACONSUMPTION

As outlined above, the liminars' lived experiences are characterized by social ambiguity, categorical invisibility and an overt preoccupation with how they appear in the eyes of those around them. It emerged throughout the data analysis that despite their conveyed annoyance at their status as social non-descriptors, their shadowed realities were a vital resource. As evidenced in the data, various consumption strategies were being utilized by the tweens in order to paradoxically evade definite categorization via consumption owing to their egocentric tendencies and fear of social reprisal, prior to a more assured and competent entry into teenager-hood. But concurrently these strategies enable the tweens to tentatively participate in the consumer culture towards which they know their imperatives must be oriented if they are to be accepted by friends and envisaged onlookers.

Regardless of contextual application, the pre-fix 'meta' denotes 'something of a higher or second-order kind' (OED, 2009). A relatively recent consideration within the domain of cognitive analysis is that of second order thinking; or 'thinking about thinking' (Keating, 1990). Metacognition is frequently studied within the realm of psychology as 'the ability to monitor one's own cognitive abilities and activity for consistency, for gaps in information that need to be filled' (Keating, 1990: p75). This theory appeared to have potential for application within the domain of this instance of consumer research. When re-appropriated to analyze the emergent consumption practices of these liminal tweens, the theory of metaconsumption emerged as a viable theoretical process. Fundamentally metaconsumption was envisaged as involving a variety of second order consumption practices; or consumption about consumption. Specifically these metaconsumptive practices focused on consumption mastery, regulation & monitoring of consumption experiences & knowledge for gaps that need to be filled, as opposed to tangible marketplace experiences.

During this liminal existence, these metaconsumption strategies, as will be outlined, served to realize the main preoccupation of a tween; remaining covertly active. It appears to be one of the primary preoccupations of the liminal experience, the main product of this ambiguous, obscure interval. Eluding definite categorization as either child or teen, the tweens channel this cultural anonymity into preparing for one of the most socially pertinent roles of their lives thus far; becoming a teenager. These metaconsumption strategies, as will be delineated, allow the girls to paradoxically both evade definite categorization via consumption prior to a more assured

2 Parer is an Irish slang word referring to pencil sharpener

and competent entry into teenager-hood but also enables them to tentatively participate in the consumer culture towards which their imperatives must be oriented.

Prior to outlining a selection of metaconsumption strategies, it is necessary to theoretically position metaconsumption in relation to consumer behavior research extant in the area of young consumers and consumption practices.

CONSUMER SOCIALIZATION – A DIVERGENT PATH?

Despite the fact that 'a consumer culture of childhood stands as a ubiquitous fixture in public life' (Cook, 2004b: p1), there are few theoretical accounts of young people's specific negotiations and 'styles of agency' (James and Prout, 1996: p47) as they mediate the intricacies of their lived experiences and social contexts within contemporary consumer culture. Within the realm of children's consumer culture theorists, Martens et al (2004: p161) contend that 'relatively little is known about how children engage in practices of consumption or what the significance of this is to their everyday lives and broader issues of social organization.' The most widely accepted view amongst contemporary sociologists is that this subordinate theoretical positioning has its origins in the paradigm which has dominated the sociology of children and consequently consumer behavior studies with children, for decades; Developmentalism. Disseminated widely by the work of Piaget (e.g. 1955), the child is envisaged as an incomplete work in progress, evolving along a trajectory of cognitive capacity to a point of adult competence. Fundamentally this paradigm relegates the child's social world to inconsequentiality.

Within the sociology of childhood, these paradigmatic specificities became manifest in the form of socialization theory (e.g. Coley, 1998; Harris, 1995; Maccoby, 1992). In part due to its suggestion of the potential to influence or intervene at various stages of development (Gunter & Furnham, 1998; Mills, 2000) the theory of socialization has been applied to consumer research of children via a myriad of studies and theoretical advancements (John, 1999). The term consumer socialization was first introduced to the field of consumer behaviour by Ward (1974) and defined as: 'the processes by which young people acquire skills, knowledge, and attitudes relevant to their functioning as consumers in the marketplace' (p: 2). John (1999) presents the most comprehensive and thorough delineation of literature and theoretical developments in the consumer socialization of children, providing structure and summary to an increasingly expansive area of research. The recognition of brand names and advertising (e.g. Hogg et al, 1998; Achenreiner & John, 2003; Chaplin & John, 2005), and the influence of particular 'socialization agents' on children's growth as consumers (e.g. Dotson & Hyatt, 2005; Grant & Stephen, 2005; Ekstrom, 2007) represent the core focus of research in this area.

In other words, as represented in figure 1, children's evolving relationships with consumption have been predominantly conceptualized under the mantle of 'effects research'. However burgeoning research within children's consumer culture studies have begun an attempt to embrace an alternative perspective on young peoples' interactions and relationships with consumption practices.

For example Cook's (2008) concept of 'commercial enculturation' attempts to capture the 'variety of ways children come to know and participate in commercial life' (Cook, 2008: p9) by shifting the focus to 'how consumption and meaning, and thus culture, cannot be separated from each other but arise together through social contexts and processes of parenting and socializing with others.' (Cook, 2008: p9). Thus commercial enculturation espouses the notion that a more insightful perspective can be gained by view-

ing children as not so much socialized into becoming one kind of specific consumer as they are seen entering into social relationships with and through goods and their associations. There have been several key studies, as listed in figure 1, which align with such a perspective on children's interactions with consumption orienting from the premise that traditional theorizations via consumer socialization theory obscure fruitful ways of seeing consumer behaviour 'in expansive & nuanced ways' (Cook, 2008: p11). Thus from 'the effects' perspective consumption practices and the role of the consumer engage with fairly limited spheres of interaction, and are 'tied to market transactions, brand & products' (Cook, 2008: p11).

The metaconsumption practices outlined below highlight not a concrete socialization process of liminal tween to secure teenager, but rather an intricate interweaving of relationships between consumption and identities - past, present and future- as these social neophytes mediate the intricacies of their interstitial positioning.

Brand Apathy

The nexus of the metaconsumption strategy is thus the maintenance of an unobtrusive, yet concurrently burgeoning site of consumption, which the liminal period appears to represent for these girls. Several strategies had at their core the notion that any activity, which wrenched the girls from the comfort of their categorical ambiguity and assign them to either a child or teen status before they feel prepared, is detrimental. One concept reflective of the tweens' striving towards consumption practices that facilitate preservation of their social anonymity, for fear of premature emergence before their imagined audience, is brand apathy. Pervasive throughout the first interview data is a definite reluctance by the girls to express an alignment with or affinity to branded products for fear of making an error conducive to social exclusion and ridicule. Contrary to the abundant secondary research in this area (e.g. Siegal et al, 2004; Lindstrom, 2003b; McNeal, 1992), the girls displayed a noticeable reticence when a discussion of brands and their importance to them arose.

In this example Nicola dismisses the notion that brands are important to her, but acknowledges that 'some people' like to revolve their consumption patterns around them.

K: 'so do you think brands matter to people your age?'

N: 'well some people do...like they have to get all the brand.... it doesn't matter to me'

K: 'does it not...so what's important to you'

N: 'just kind of if I like the top or not.'

At this stage, she is still a novice when it comes to buying her way into the teen/consumption dialectic. By refusing to commit to an engagement with brand labels, she is not expected to know anything about them and thus cannot err in her discourse around brands and consumption. Her social status cannot be allocated and she can remain in the interstices of categorisation until such a time when she is equipped with enough social-kudos oriented information to emerge.

Another metaconsumption strategy seemingly utilized in order to convey a purposeful apathy about branded items is price preoccupation. There are numerous examples throughout the first interview data, which suggest that reverting to the reliable utilitarian justification of 'because non-branded things are cheaper', allays the possibility that their incompetence with consumer culture will be brought to notice.

Two excerpts from Rachel's interview add credence to the notion that apathy or resistance toward acknowledging the centrality of brands to their lived experiences is a strategic defense mechanism often couched in a fixation on value for money, designed to protect the shadow side of their being, their liminal regeneration.

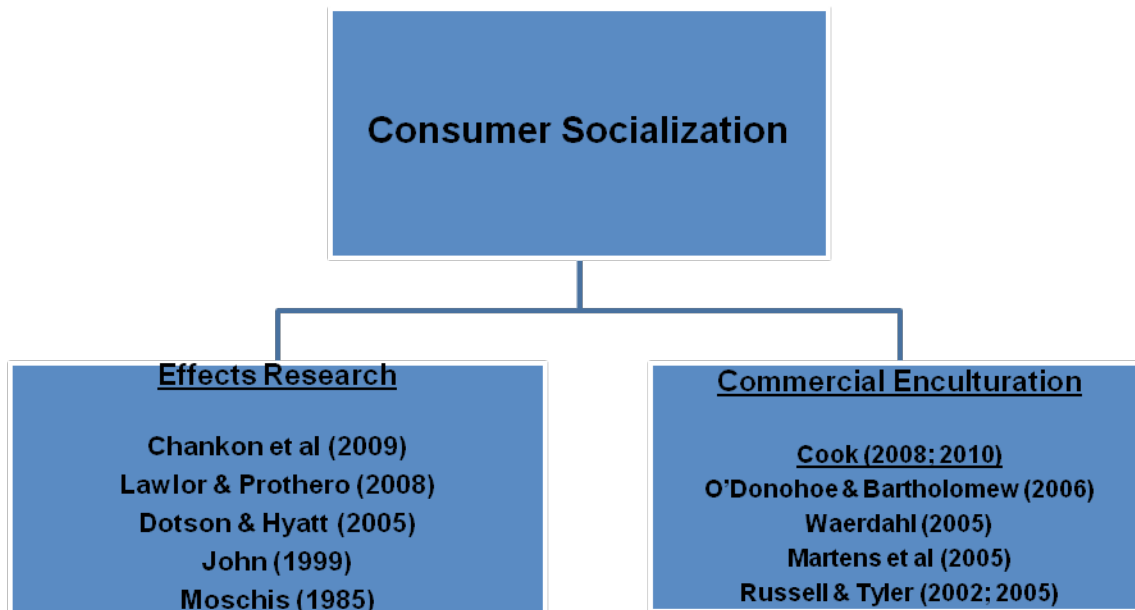

Figure 1

K: *'and do you think brands matter to people in your class.... well not just your class...but your friends....do ye talk about brands at all?'*

R: *'amm....not really....the main place that we go is penneys³.... coz it's so cheap and it actually does have some nice clothes and stuff...and they just have everything at a really cheap price... and say if you went into somewhere else...like where would you go... am...really expensive like Pauls or somewhere....and you'd see the same string top or the same jumper for like fifty euro and like the one you could get in penneys would be like fifteen or twenty...'*

In this first passage, Rachel's attitude is analogous to the other tweens, in that she justifies her supposed detachment from branded goods by referral to the value for money at non-branded stores. However just minutes later, Rachel recalls the experience of buying a new outfit for her confirmation a couple of months previously.

K: *'and what other shops would you go to....say if you went in with your mum?'*

R: *'well radical⁴ I bought my confirmation outfit in.*

K: *'what kind of outfit did you get?'*

R: *'well I got these grey bench combats....they're really nice and I got this tee-shirt and I love it I wear it all the time...and I got a bench hoody....and am its really cool you can put on the sleeve you can put your thumb through a little hole in it...its really cool... and I got my runners⁵ there as well....they're van.'*

It appears therefore that Rachel's earlier expressed indifference to brands is not consistent with her behaviour. In this instance, when her mother's financial agency enters the equation, and Rachel has had a tangible experience with a brand, Rachel's priorities change and the non-branded shop doesn't get a mention. Rather she manages to list two big brands in her purchases. Surely if the non-branded store is such good value, her mother's financial resources would have gone a long way further? Clearly Rachel's interview, visible

3 Penney's is a discount clothing and accessories store in Ireland

4 Radical is a store in Ireland which stocks branded clothing and footwear

5 Runners is Irish slang for trainers/sneakers

in part through this inconsistency, suggests that indifference is a defense mechanism. Expressing a detachment from the world of labels, logos and symbolism is less important a goal when resources not available to the neophyte materialize.

Parody

Cognizant of the fact that the core of the metaconsumption strategy is its focus on existing without exhibiting, I was made aware of yet another component of this strategy during the accompanied shopping trips. This strategy centred on the agentive dimension of this liminal shadow in which the tweens exist; consumption strategies that evinced monitoring and acquiring of information and competencies needed when the time came to lead their liminal cocoon and embrace young teen identity.

During these shopping trips, the ambiguity and ensuing tension that the girls experienced in many of the shops seemed to stem from their recurring misallocation as a group or social category. At times the shops we visited were so beyond the realm of possibility for these girls on every level, while concurrently other stores evinced notions of a former childhood self that they were eager to forsake. In other words, it was palpable throughout these trips, that expressing interest in particular items was a risky, value-laden endeavor. Signaling interest in an item deemed 'inappropriate' in any dimension appeared to represent social suicide. I soon realized that these weren't just shopping trips, but opportunities to manage, protect and accumulate the knowledge that was expected of them as young, female consumers.

The concept of parody emerged as a means through which the girls could openly experiment with possible signifiers and configurations of consumption, but maintain a distance from any personal reflections ensuing because of these experiments at the same time. It allowed them to exist without exhibiting. During the shopping trip with three tweens for example, I witnessed firsthand the use of this strategy. On entering one particular store, the girls picked up random tops and skirts claiming 'this is so you' or 'this is my dream outfit'. I only realized after chatting to the girls later on, that this was a statement of sarcasm meant to denote that something was not to their taste and they weren't at all genuine in their

sentiments. However although it was not genuine admiration they espoused, expressing opinions or preferences couched in parody or mockery, protects the girls' vulnerability at a time when their level of consumer experience is limited.

The Fake Facilitators

This concept refers to the conclusion that many of the girls chose to forsake a preoccupation with having the genuine brand and instead focused on manipulating and utilizing the sign value even associated with counterfeit versions to assert a provisional foot into the world of teen consumption. Therefore although many of the 'brands' they possess are in fact fakes, these products nonetheless facilitate a participation in a version of consumer culture, however diluted. This strategy allows for an engagement with the imperatives that dominate teen consumption but concurrently does not demand the resources only attributed to those of a more defined societal categorization such as finances, life experience or definite market place allocation. In this example, Katie is taking me through some of the possession in her room, including a fake Von-Dutch cap. Interestingly she herself points out that it is a fake.

K: *'What other brands do you use?'*

KL: *'von dutch...I got those in Majorca...they have lasted me two years now'*

K: *'wow...and do you have any other von dutch stuff...do you know much about the brand?'*

Katie roots underneath her bed

K: *'ooh a cap...do you wear that much'*

KL: *'yeah...its fake von dutch...but it's still von dutch'*

What Katie seems to mean here is that to others, it still appears to be Von Dutch, or at the very least she is appearing to others to be engaging with the brands that form the appropriate staple diet of any normative teen. The important thing for Katie then is appearances rather than authenticity. Appearances maintains the shadow side of their being so that they can incur as little anticipated social ridicule as possible while they experiment with the intricacies of the teen persona/consumption dialectic.

Rachel also displayed an affinity for the non-authentic version of some well-known brands.

K: *(reading diary)...Louis Vitton is one of my favourite designers. I love his bags....so which one is yours?'*

R: *'well I got the both of them off my next door neighbour (laughs), she got them...'*

K: *'what do you like about those bags?'*

R: *'I think they look really cool...and I don't mind of they're fake...because no-one really knows'*

Rachel here articulates the key element of the fake facilitator concept, as a metaconsumption strategy. Counterfeit products allow the liminal tweens, despite their lack of agency as a socially ambiguous category, to engage with a desirable facet of consumer culture; the repository of symbolic meaning and social implications behind the Louis Vitton logo. Although the use of fake brands is not a consumption practice limited to this age group, the role that these brands play in the lived experience of a liminal tween is significant towards understanding how consumption is enacted during a time of social invisibility.

DISCUSSION

This paper has described some of the constituent elements of metaconsumption; the proposed theorization of the liminars' consumption practices and a suggested diversion from 'the effects' perspective on young consumers' socialization. Being neither a child consumer nor a teen purchaser implies that there exists a gap between the self they were and the self they long to be and

the liminal status that ensues. In addition, advancing cognitive capacities instill the tweens with a flagrant sense of trepidation regarding their neophyte-like social standing and potential public transgressions. Consequently they long to reside in the shadowed side of being, attempting to learn, monitor and accumulate socially oriented consumer knowledge, but all the while protect and maintain the anonymity that shields them from social scrutiny and insinuations. This intense period of second order consumption practices, or 'consumption focused on consumption' aligning oneself with the nuances and mores of the social sphere which will help sculpt their entry into teenager-hood, provides examples of a myriad consumption strategies and practices which further a theorization of liminal beings and their consumption practices. In addition, metaconsumption advances the burgeoning area of children's consumer culture research which attempts to explore the mediation of socio-cultural hierarchies and boundaries by young people via their relationships with consumption.

Thus this desire to exist without exhibiting is the core characteristic of the liminal existence and subsequently the theory of metaconsumption has an integral role in its manifestation. For example, the visible propensity of the tweens to convey decided apathy and even resistance towards branded consumption with the variant but related strategy of price preoccupation, was reflective of an effort to preserve the unspecific nature of their social categorization. Not committing to a brand meant not committing to an (unfinished) teen identity. This theoretical conclusion stands in stark contrast to the prevalent literature on branded consumption, whether conceptually, theoretically or managerially oriented (Lindstrom, 2003; McDougall & Chantrey, 2004; Elliot & Leonard, 2004) that convey brand-oriented consumption as a transparently positive and desired facet of tween consumer culture.

However it is equally as intrinsic to the liminal existence that this period of time is not entirely static. As theorized by Douglas (1966, p.137) in relation to interstitial existences 'there is energy in the margins and unstructured areas'. A degree of agency must become part of the metaconsumptive practices of the tween if they are to progress towards the essence of their teen identity (Jenks, 2003). Thus the concepts of the fake facilitators and parody encapsulate the covert but fervent accumulation of consumer-oriented knowledge and experience that concurrently embodies the liminar's 'betwixt and between' existence. For example, parody, akin to the foundational premise of the other metaconsumption strategies is both an enabling and a protective mechanism in that it facilitates the tweens' engagement with the appearance of teen consumerism but yet safeguards the anonymity necessary to prevent premature alignment with a teen identity that they are ill prepared for.

Cognizant of the tweens' concurrent engagement with and detachment from consumption practices, the liminal period is proposed to represent a fruitful darkness (Turner, 1967, p110). Akin to understudies waiting in the wings anxiously ingesting as much information as possible in order to better prepare themselves for the biggest performative role of their lives to date – which as of yet is just out of sight – the fructile chaos of the fruitful darkness facilitates a private rehearsal for what will eventually be a very public performance. The metaphor of the fruitful darkness embodies the concurrent darkness and energy, the restorative obscurity that epitomizes the liminars' experiences with consumer culture within the interstices of socio-cultural categorization. Although at times the tweens appear passive or nonchalant about many of the signifiers of teen culture, this passivity appears to belie a fervent task. Turner (1967, p.102) similarly theorized when he claimed that during the liminal period 'his apparent passivity is revealed as

an absorption of powers which will become active after his social status has been redefined...'

CONCLUSION

Schouten's (1991: p422) assertion that 'little is yet known about the consumption behaviours of liminal people' was one which had been tentatively approached amongst those exploring the intricate and fascinating interweaving of self and consumption. Research had been instigated and conclusions drawn in relation to consumers and transitions without in-depth focus of that interim period when transition is midway and individuals exist on a threshold blurring past, present and future. As articulated by Turner (1974: p13) it is 'in this gap between ordered worlds that almost anything may happen'. In addition, studies of young consumers and their interactions with consumption have been stifled by a fixation on 'effects' approaches to the detriment of interpretive explorations of the social relationships which emerge between young people and various realms of consumer culture and practices, cognizant of the boundaries and hierarchies which constitute their social world. There are many other areas within consumer culture theory which would reap the rewards of considering the liminal; that threshold existence which embodies both light and dark, stillness and energy, ambiguity and focus. Those experiencing the mid-state of transition have received sparse attention in the field of consumer research. This paper has begun addressing this dearth and by doing so has attested to the potential of the liminality theory itself.

'The Liminal status is a fructile chaos, a storehouse of possibilities, not a random assemblage but a striving after new forms and structures, a gestation process'.

(Turner & Bruner, 1986: p42)

Personality and Sustainable Consumption: An Application of the 3M Model

Ricardo Teixeira Veiga, UFMG, Brazil
Juliane Almeida Ribeiro, UFMG, Brazil

ABSTRACT

The personality traits that predict sustainable consumption are investigated, adopting the 3M model as theoretical framework. Altruism seems to be a trait consistently useful to predict ecologically-correct purchase, resources saving, and recycling. Consumerism only seems to be useful to explain variance in resources saving.

INTRODUCTION

The increase of consumption in a global scale is a consequence of the extraordinary increase in the human population in the twentieth century, of the intensified urbanization and of the industrialization in most countries (Penna 1999). The obsession for economical growth and consumption is a reflection of the spreading of the development ideology, inherent to capitalism (Baudrillard 1998). The environmental problems resulting from that are acute and potentially catastrophically, for they tend to worsen. Deforestation, pollution, the destruction of ecosystems and biodiversity, global warming and others, are concrete activities that show the human influence on the planet.

It is necessary to raise people's awareness about their negative impact on the environment and about the importance of their assuming an active role regarding nature conservation and quality of life in the long run, through the engagement in an ecologically responsible lifestyle and way of consuming.

Authors like Fraj and Martinez (2007) and Straughan and Roberts (1999) show some optimism when remembering that the general concern about human consumption as a sustainable factor has increased. Nevertheless, the spreading of ecological consciousness has been occurring in a slow rhythm, especially in countries of late industrialization. In Brazil, for example, only one in three consumers is worried about separating garbage for recycling, buying organic products and/or products made with recycled material, avoiding water and energy waste or to perform other types of ecologically conscious behaviors (Akatu 2006).

So, it is important to deepen the researches about sustainable consumption, aiming at the elaboration of educational programs and social intervention that make consumers in general, more sensitive to ecological issues.

When investigating the relation between personality traits and ecologically conscious consumption, this research adopts the 3M Model of Motivation and Personality (Mowen 2000) as theoretical frame, in order to identify effective ways to persuade people to consume with ecological responsibility.

In the next section, we will present a brief literature review about ecologically conscious consumption. Based on this review and on the consumer behavior concept, we come up with a sustainable consumption concept that is integrated to the theoretical framework and to the research hypothesis.

THEORETICAL BACKGROUND

Consumers have been aware of the need to buy in a socially responsible way and to demand from the companies adequate ecological behaviors. There was an increase in ecological awareness during the twentieth century and the changing of the environmental issue into an strategic priority to citizens, countries and organizations (Straughan & Roberts 1999). According to the authors, many companies have been trying to act in a more relevant way, doing more than just implementing processes of clean production, but

engaging in ecological activities on behalf of sustainable development. In a more skeptical perspective, Peattie (2001) argues that the ecological engagement of the companies is a way of dealing with consumers that ask for a bigger responsibility towards nature conservation.

From the 1980's on, because of a greater worry about the consumption impact on the environment, the concept of "green consumer" has been consolidated. Together with the emergence of this consumer segment, a "green market" expanded to a considerable rate in the developed countries (Schlegelmilch, Bohlen and Diamantopoulos 1996; Follows and Jobber 2000; Peattie 2001), since a reasonable part of the consumers were willing to pay more for goods which were made regarding a greater care for nature. For example, a survey made by Mintel, concluded that 27% of English adults were willing to pay 25% more for green products (Prothero 1990 *apud* Schlegelmilch, Bohlen and Diamantopoulos 1996), whereas a research made by J. Walter Thompson suggested that 82% of North-American would pay 5% more for this kind of product (Peattie, *op. cit.*). Furthermore, as a group, the green products gained a market share of 20% and, in specific categories, of 30% (Kohl 1990 *apud* Follows and Jobber 2000).

Nowadays, although there are still many challenges in order to develop a sustainable market, there are indications that it is potentially big and profitable (Mintu-Wimsatt and Bradford 1995; Tucker 1980 *apud* Wergin 2009). According to the company of marketing research called Mintel International Group, in 2006 the green market had a turnover of 200 billion dollars, and it is supposed to grow more in the future. There are also evidences that the consumers are becoming more inclined to have ecologically conscious behaviors: according to Ottman (1993), 70% of the North-American consumers declared that the fact that the products they bought were in recyclable packages affected their buying decisions, whereas in Brazil, 74% of the consumers stated their intention of buying products that do not degrade the environment (Mansur, Arini and Ferreira 2008).

Some investigations done during the 1970's (Kassarjian 1971; Kinnear, Taylor, and Ahmed, 1974; Webster 1975) were already about identifying and analyzing the values, attitudes and behavior of ecologically conscious consumers, as well as explore means of reaching them more efficiently (Schaefer and Crane 2005).

Fraj and Martinez (2007) discuss three perspectives adopted along the years for the study of ecologically conscious consumers. Firstly, these researchers were interested in understanding these consumers behavior according to demographic and socio-economic measures (e.g., Vining and Ebreo, 1990, Bhate and Lawler, 1997, Daniere and Takahashi, 1999, Fraj et al., 1999, Fraj and Martinez, 2003). Later on, a new field of studies considered the amount of information and knowledge that people had regarding environmental problems and issues (e.g., Arnutnoth and Lingg, 1975, Ramsey and Rickson, 1976, Grunert and Kristnesen, 1992). A third approach used psychographic variables, that included values, lifestyle, personality traits and attitudes (e.g., Batson et al., Grazzini and Olsen, 1991, Ramanaiah et al., 2000), to trace the profile of ecologically conscious consumers.

Although the marketing focus of ecologically conscious consumption is related to the trading of ecologically right products, that is, those with a minimum or none negative environment impact (Ottman 1993; Roberts 1996; Peattie 2001; Fraj and Martinez 2007), this research assumes that sustainable consumption (SC) must be

widely understood. It must also include the search for a means of reducing the consumption of materials and energy, buying organic foods, buying goods that are produced in the local place, active participation in recycling, promoting the use of mass transportation and economy of resources (Halkier 1999 *apud* Connolly and Prothero 2008).

In fact, sustainable consumption must be also understood in the consumer behavior perspective, defined by Solomon (2002, p. 24) as “the study of the processes involved when individuals or groups select, buy, use or dispose products, services, ideas or experiences in order to satisfy necessities and desires”.

Based on this definition and on the review about ecologically conscious consumption, we propose to conceptualize sustainable consumption as: “the search for ecologically-correct products, the preference for corporations and organizations actively engaged in environment conservation, the using of materials and equipment up to the end of its service life, the saving of resources such as water and energy, the reusing, whenever possible, the right destination of materials to recycling and the propensity to a lifestyle with a smaller negative environment impact”.

The perspective adopted, aimed at complementing the previous studies, proposing a concept of sustainable consumption tied to the whole consumption cycle (acquisition, use and discharge) and coherent to the concern about saving the natural resources and support companies and institutions that are ecologically responsible. It is a way of consumption according to a less consumerist lifestyle, and, consequently, with a less negative environmental impact.

As in the long run, the objective of our research is to influence people so that they consume in a more sustainable way, we used the 3M model as framework, because identifying personality traits and associating them to sustainable consumption behavior, can set a base to elaborate messages that stimulate this behavior through the activation of these traits (Mowen and Harris 2003).

The 3M - a Meta-theoretical Model of Motivation and Personality

In this research, we employ the 3M Model that integrates control theory, evolutionary psychology principles, and elements of the hierarchical trait theories (Mowen 2000). This model provides a four-level structure to organize traits, based on an integrated account of how personality traits interact with situations to influence feelings, thoughts, and behaviors. The 3M Model has been employed as the theoretical model to investigate the trait antecedents of many types of behavior, including aggressive and distracted driving (Bone and Mowen 2006), credit card misuse among college students (Pirog III and Roberts 2007) and consumer competitiveness (Mowen 2004).

The 3M Model proposes that personality traits are arranged into a four-level hierarchy based upon their abstractness. Elemental traits are at the most abstract level and are enduring, cross-situational dispositions that arise from genetics and early learning history (Mowen 2000). The model proposes eight elemental traits, which should be included as control variables in the hierarchical model: openness to experience, conscientiousness, extroversion/introversion, agreeableness, emotional instability, need for body resources, need for material resources, and need for arousal. Based on works by Buss (1988) and Zuckerman (1979), Mowen suggested the addition of the last three elemental traits, extending the set of personality traits of the five-factor model (McCrae and Costa 1997). *Need for body resources* and *need for material resources* are traits strictly concerning self-preservation.

Compound traits are at the next level of the hierarchy. They are defined as cross-situational dispositions, that emerge from the interplay of elemental traits, culture, and the individual’s learning history (Mowen 2000). In the present study, we investigate two

compound traits: general self-efficacy (Mowen 2000) and altruism (Stern 2000).

Compound traits were based on literature. Empirical results show that a belief in one’s own capacity of succeeding in performing tasks, irrespective of chance, influence the engagement in ecologically-oriented behaviors (e.g. Bodur and Sarigöllu 2005). But self-efficacy is a compound trait linked to personal control and has a crucial role in the performance of tasks (Mowen, 200). Besides, self-efficacy influences the performance of types of behavior which demand commitment and persistence to overcome difficulties (Bandura 1977 *apud* Mowen 2000). So, we propose general self-efficacy as antecedent of sustainable consumption.

Altruism can be understood as value or personality trait. There are many studies which found relationship among altruism, concern with environment, and ecologically-oriented behavior (e.g., Granzin and Olsen 1991; Dietz *et al.* 1998; Karp 1996; Stern and Dietz 1994; *apud* Stern 2000), if we understand altruism as a personal orientation which surpasses selfishness, individualism, competitiveness, and the predominant interest in the immediate social circles. In the present research, we conceptualize altruism as a compound trait and propose that it is also antecedent of sustainable consumption.

At the third level of hierarchy are situational traits, which result from combinations of elemental traits, compound traits, as well as the effects of situational environment (Mowen 2000). The situational trait investigated in this study is consumerism.

At the most concrete level in the hierarchy are superficial traits, which represent enduring dispositions to act within category-specific contexts (Mowen 2000). Superficial traits have a strong behavioral component. They result from the combined effects of elemental, compound, situational traits, and the press of the specific situational context. Based on the concept of sustainable consumption, we propose ecologically-oriented purchase, resources saving and recycling as superficial traits in this research. Figure 1 shows the hierarchical model employed in the present research.

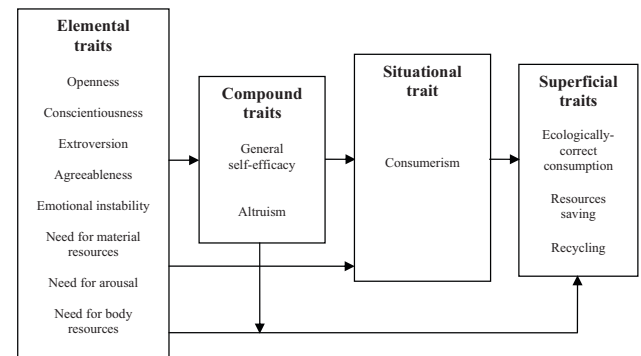

Figure 1. The research hierarchical model

Situational and superficial traits were defined at the exploratory stage of the research by factor analyzing a 24-item scale of sustainable consumption (SC) as defined in the present research. Source of items were other scales, literature (e.g., a scale of consumerism was provided by De Young 2000) and personal judgment. By using principal component analysis and orthogonal rotation (varimax), we retained only 13 items to operationalize consumerism, ecologically-correct purchase, resources saving and recycling. We selected the non-ambiguous items which loaded more strongly on the respective factors. As a result, factor unidimensionality was reached. See table 1 for more information.

Table 1
Situational and Superficial Traits Resulted of Exploratory Analysis

Factor	Variable	Item-total correlation	Item description
Consumerism (*)			
Cronbach's alpha = .62	i6	.42	I wear clothes that are in fashion.
All = .35	i8	.43	I have the most modern electronic gadgets and consumer goods.
	i17	.44	I have luxury items and conveniences available in our society.
Ecologically-correct purchase (**)			
Cronbach's alpha = .75	i4	.48	I vote for politicians who support the environmental causes.
All = .50	i12	.58	I stop buying from companies which doesn't show concern for the protection of the environment.
	i14	.66	I change my brand preferences to support companies that show more concern for the protection of environment.
Resources saving (**)			
Cronbach's alpha = .62	i16	.45	I let television and computer on even when not using them.
All = .35	i21	.29	I turn off the taps when soaping or washing dishes.
	i22	.51	I let lights on without need.
Recycling (**)			
Cronbach's alpha = .94	i2	.86	I separate metal objects (e.g. cans) for recycling.
All = .80	i11	.91	I separate glass (e.g. beer bottles) for recycling.
	i20	.80	I separate paper for recycling.
	i23	.89	I separate plastic packaging (e.g. plastic bottles, plastic bags etc.) for recycling.

Notes: AII – Average inter-item correlations; (*) situational trait; (**) superficial trait.

HYPOTHESES DEVELOPMENT

As recommend by Mowen (2000), all eight elemental traits were include in the research model as control variables. Proposed relationships among elemental traits and traits of other hierarchical levels are based on literature and logical analysis.

According to Borden and Francis (1978) people more concerned about environment tend to be more mature, responsible, sociable, and conscientious then the ones who are not concerned. Fraj and Martinez (2006) say that ecologically-correct consumers have higher scores in measures of extroversion (sociability), amiability and consciousness. Ramanaiah et al. (2000) found that the traits openness to experience and agreeability were more significant to distinguish consumer segments with high and low scores in environmental responsibility. Monteiro et al. (2008) observe that people who are more agreeable, creative and conscientious are more likely to strive for a balance between nature and modern life. As ecologically-correct purchase, resources saving and recycling are traits which show care for the environment, the following hypotheses were proposed:

Hypothesis_{1a}: Conscientiousness is positively related with ecologically-correct purchase.

Hypothesis_{1b}: Conscientiousness is positively related with resources saving.

Hypothesis_{1c}: Conscientiousness is positively related with recycling.

Hypothesis_{2a}: Openness to experience is positively related with ecologically-correct purchase.

Hypothesis_{2b}: Openness to experience is positively related with resources saving.

Hypothesis_{2c}: Openness to experience is positively related with recycling.

Hypothesis_{3a}: Agreeability is positively related with ecologically-correct purchase.

Hypothesis_{3b}: Agreeability is positively related with resources saving.

Hypothesis_{3c}: Agreeability is positively related with recycling.

Hypothesis_{4a}: Extroversion is positively related with ecologically-correct purchase.

Hypothesis_{4b}: Extroversion is positively related with resources saving.

Hypothesis_{4c}: Extroversion is positively related with recycling.

As in the long run sustainable consumption is oriented towards saving natural resources and protecting the environment in order to guarantee survival, we predicted the following relationships:

- Hypothesis_{5a}*: *The need for body resources is positively related with ecologically-correct purchase.*
- Hypothesis_{5b}*: *The need for body resources is positively related with resources saving.*
- Hypothesis_{5c}*: *The need for body resources is positively related with recycling.*

As Straughan and Roberts (1999) state that altruism and self-efficacy seem to be personality traits typical of ecologically-correct consumers, we proposed the following hypothesis about compound traits:

- Hypothesis_{6a}*: *Altruism is positively related with ecologically-correct purchase.*
- Hypothesis_{6b}*: *Altruism is positively related with resources saving.*
- Hypothesis_{6c}*: *Altruism is positively related with recycling.*
- Hypothesis_{7a}*: *General self-efficacy is positively related with ecologically-correct purchase.*
- Hypothesis_{7b}*: *General self-efficacy is positively related with resources saving.*
- Hypothesis_{7c}*: *General self-efficacy is positively related with recycling.*

Consumerism can be understood as the search for conveniences of modern society and continuous interest in new or innovative products (De Young 2000). We assume that four elemental traits are related with consumerism:

- Hypothesis_{8a}*: *Openness to experience is positively related with consumerism.*
- Hypothesis_{8b}*: *The need for arousal is positively related with consumerism.*
- Hypothesis_{8c}*: *The need for body resources is positively related with consumerism.*
- Hypothesis_{8d}*: *The need for material resources is positively related with consumerism.*

As consumerism is essentially self-oriented we assume that there must be a negative association between consumerism and altruism:

- Hypothesis_{6d}*: *Altruism is negatively related with consumerism.*

De Young (2000) did not find any correlation between consumerism and ecologically-correct consumption. Nevertheless, we assume that there is an association, so we proposed hypotheses of negative association among consumerism and the superficial traits concerning sustainable consumption.

- Hypothesis_{9a}*: *Consumerism is negatively related with ecologically-correct purchase.*
- Hypothesis_{9b}*: *Consumerism is negatively related with resources saving.*
- Hypothesis_{9c}*: *Consumerism is negatively related with recycling.*

Finally, some hypotheses concerned relationships among compound and elemental traits. According to meta-analysis, Mowen (2000) concluded that with the exception of the need for material resources trait, all elemental traits were significant predictors of general self-efficacy. In the case of altruism, we decided to test correlation with all eight elemental traits.

- Hypothesis₁₀*: *General self-efficacy is related with all the elemental traits, except with the need for material resources trait.*
- Hypothesis₁₁*: *Altruism is related with all the eight elemental traits.*

METHOD

College students of different undergraduate courses of the same university were surveyed. We obtained 512 valid questionnaires over a 2 week-time period. The mean age was 22.8 years, and 50.1 per cent were women. The four-page survey contained measures of the traits under investigation and also demographic measures. Consistent with prior research on the 3M Model, the survey was arranged such that respondents answered items in their order in the hierarchical model, starting by responding to the elemental traits items. Elemental traits items were taken from Monteiro et al. (2008). Compound traits (general self-efficacy and altruism) were respectively taken from Mowen (2000) and Schultz (2000). De Young (2000) provided items to measure consumerism, and the other sustainable consumption items were also taken from literature and personal judgment. Five-point scales were used for all variables.

Exploratory data analysis was carried out by employing SPSS version 17. The problem of missing data was almost negligible as only 0.2% of item data were missing. Their distribution was considered as completely at random (MCAR Litte's test: chi-square = 197.976, d.f. = 207, p = .662). So, multiple data imputation was adopted to get a complete data set. Variables did not exhibit univariate normality, according to Kolmogorov-Smirnov tests.

The sample was randomly split in two subsamples. The biggest one (n = 312) was used to operationalize the constructs associated to sustainable consumption (consumerism, ecologically-correct purchase, resources saving and recycling), and to select single items to represent the elemental traits and the best indicators of compound traits (altruism and general self-efficacy). The smallest subsample (n = 200) was used to estimate the research hierarchical model.

Table 2
Accounted Variances and Significant Effects in the Full Hierarchical Model

RESULTS

First of all, the measurement model was assessed. All traits were included. In the case of elemental traits, only a single item represented each trait. Although chi-square is significant, RMSEA and the incremental fit statistics were satisfactory in general ($\chi^2 = 304.3$, $df = 241$, $p < 0.01$, $\chi^2 / df = 1.3$, $CFI = 0.96$, $TLI = 0.94$, $NFI = 0.84$, $RMSEA = 0.036$). Composite reliabilities were all at least 0.65, except for altruism ($CR = 0.57$). Additionally, coefficient alphas for all constructs were all above 0.60, except for altruism ($\alpha = 0.59$). Bivariate correlations among constructs were not above 0.60, so discriminant validity was assumed.

A full mediation model was employed in order to assess the predicted hypotheses. The fit statistics of this model were satisfactory ($\chi^2 = 330.6$, $df = 259$, $p < 0.01$, $\chi^2 / df = 1.3$, $CFI = 0.96$, $TLI = 0.94$, $NFI = 0.83$, $RMSEA = 0.037$). Accounted variance and significant effects are shown on Table 2.

Altruism, whose accounted variance is 39%, is significantly predicted by six elemental traits (except for need for arousal and extroversion), whereas only three of the seven hypothesized elemental traits were significant predictors of general self-efficacy (accounted variance = 18%). As expected, altruism is a significant predictor of ecologically-correct purchase, resources saving, and recycling. Also, the hypothesis of a negative association effect of altruism on consumerism is supported. General self-efficacy predicts significantly resources saving. But, contrary to expected, neither ecologically-correct purchase nor recycling is significantly predicted by self-efficacy. Accounted variance in consumerism is 43%, and this construct has a negative effect on resources saving, and is significantly predicted by need for material resources, an elemental trait. But no significant effects were detected between consumerism and the other two superficial traits.

Accounted variance in ecologically-correct purchase is 38%, but only altruism is a significant predictor of this superficial trait. No elemental trait is a significant predictor of resources saving. But, as expected, altruism and general self-efficacy are significant predictors of resources saving. The model accounted for 26% of the variance in resources saving. Of the superficial traits, only recycling is significantly predicted by one of the elemental traits hypothesized (agreeability). Recycling, whose accounted variance is only 16%, is also predicted by altruism, as mentioned before.

DISCUSSION, IMPLICATIONS AND FUTURE RESEARCH

Our research aimed to investigate the traits antecedents of sustainable consumption, operationalized as three superficial traits: ecologically-correct purchase, resources saving, and recycling. Based on the literature review, we proposed that sustainable consumption is negatively related with consumerism, and positively related with general self-efficacy and altruism. We also predicted associations of these constructs with elemental traits.

Corroborating the point of view of Straughan and Roberts (1999), altruism, a compound trait, seems to be a trait consistently useful to predict sustainable consumption, because it is a significant predictor of ecologically-correct purchase, resources saving, and recycling. Consumerism only seems to be useful to explain variance in resources saving. Besides altruism, agreeability (an elemental trait) is a significant predictor of recycling. Resources saving has self-efficacy as a significant predictor, besides altruism and consumerism.

In the present research, taken into account the mediating effect of consumerism, self-efficacy and altruism, no elemental trait, with the exception of agreeability, seems to have a significant direct effect on constructs associated to sustainable consumption. (In fact,

no substantial increase in accounted variance of superficial traits was obtained in a partial mediation model in which paths were run from all the elemental traits to consumerism, ecologically-correct purchase, resources saving, and recycling.)

Nevertheless, six elemental traits are significant predictors of altruism: agreeability ($t = 3.75$, $p < 0.001$), openness to experience ($t = 1.77$, $p < 0.10$), conscientiousness ($t = 2.54$, $p < 0.05$), need for material resources ($t = -2.73$, $p < 0.05$), need for body resources ($t = 2.77$, $p < 0.05$), and emotional instability ($t = -2.24$, $p < 0.05$).

In order to enhance sustainable consumption, altruism should be encouraged. Surprisingly, altruism seems to be predicted not only by traits associated to agreeableness, but also by traits concerning self preservation. So, persuasive communication aimed to promote sustainable consumption could strengthen the importance of preserving the environment and natural resources as a means of collective survival. On the other hand, reduction of consumerism could be associated to a natural tendency to save natural resources if we succeed in discouraging materialism.

Future research should deepen the investigation of the relationship between personality and sustainable consumption. Scales of sustained consumption should be improved. Other traits, such as value consciousness, could be included in the research hierarchical model. A panel of consumers could be surveyed in order to get data from people more representative of the population in general. The inclusion of demographic variables would also be useful to assess their relevance as predictors of sustainable consumption.

ACKNOWLEDGMENTS

We thank very much FAPEMIG ("Fundação do Apoio à Pesquisa do Estado de Minas Gerais") for financial support for preparation and presentation of this work. We also thank two ACR's anonymous reviewers for helpful comments on an earlier draft of the article.

A Complex Account of Service Recovery: Subtle Efforts to Remedy Subtle Service Failure

Fang Wan, University of Manitoba, Canada

Pingping Qiu, Monash University, Australia

L. J. Shrum, University of Texas at San Antonio, USA

EXTENDED ABSTRACT

Service failure and recovery are complex and dynamic constructs (Bonifield and Cole 2007). However, most existing literature focused on blatant and outrageous service failure (Bonifield and Cole 2007; O'Donohoe and Turley 2007) and the role of strong and outward emotions such as anger in service failure and recovery (Bonifield and Cole 2007; O'Donohoe and Turley 2007). Our research explores an understudied area—the effectiveness of recovery strategies in a subtle service failure situation that involves a passive negative emotion embarrassment. Drawing on research on embarrassment (Grace 2007; Keltner and Buswell 1997) and goal automaticity (Bargh 2002; Leary 1995), we identify that even perfectly friendly and personalized service encounter can fail when it violates contextually activated social goals. More importantly, we propose that in such a situation with a subtle service failure, the effectiveness of various recovery efforts is impacted by subtle cues such as types of recovery strategy, awareness of the recovery efforts and time of service evaluation. Three experiments are reported to demonstrate the impact of these subtle cues in ameliorating the service experience.

In Study 1, we identified a service setting with a subtle failure. Specifically, we examined a personalized service scenario in which the server unintentionally discloses the customers' privacy (i.e., reminding the customer of their previous unhealthy food choice in a restaurant) and jeopardize their contextually activated social goals (i.e., impression management goal when dining with a date for the first time plus health goal if the date is a fitness instructor). By conducting a 2 (personalization: high vs. low) by 3 (social goal: dining with a friend, a date, a date as a fitness instructor) between-subjects experiment with restaurant dining scenarios, we identified that even high-personalized service may cause subtle service failure (evoke felt embarrassment and incur negative service evaluation) if this service unintentionally violates the customer's contextually driven social goals. The subtle service failure scenario (high personalization and dining with date as fitness instructor) identified in this study is utilized in the following experiments.

In Study 2 we examined whether the server or customer is the recovery initiator will make the service recovery more effective. As research on embarrassment suggests that either the person who feels embarrassed or the others who evokes the embarrassing situation can relieve the felt embarrassment (Miller and Leary 1992; Miller 1995)(Miller 1995). We designed strategies with the server (or self) initiating an attempt to mitigate the transgression: "Well, you (or I) may like trying something else today." We further argue that high awareness of server's recovery efforts can exacerbate the attention paid to the previous service failure and can incur more negative attributions about the server, making recovery efforts futile (Kelley 1972; Main et al. 2007). We tested the hypothesis with a 2 (remedy initiator: self vs. server) x 2 (awareness of the remedy effort: high vs. control) between-subjects design, plus a no-remedy control condition. We manipulated awareness of the recovery efforts by measuring responses to the self or the server's recovery attempts either before (high awareness condition) or after (control

condition) service experience related measures. ANOVA analyses yielded significant interaction effects, supporting our hypotheses.

Study 3 further explores the effectiveness of recovery efforts by examining the different recovery strategies a server can take, as well as the role of time lag. Based on service recovery (Hoffman, Kelley, and Rotalsky 1995) and embarrassment literature (Keltner and Buswell 1997), we designed two types of server's recovery strategies, explicit (directly correcting the transgression) versus implicit (offering a free coupon—distracting the attention). In addition, according to emotion regulation (Gross et al. 2007) and interpersonal relationship literature (Fletcher and Clark 2002), we argued that distraction (implicit recovery) may help reduce the felt embarrassment and enhance service evaluation in the short run. However, with a time lag, the explicit recovery (confronting the issue) can be more effective in helping reduce felt embarrassment, and therefore, ameliorate the service experience. In this study, a 2 (explicit vs. covert recovery) by 2 (immediate vs. delayed service evaluation) between-subject design was adopted to test the hypothesis. ANOVA findings supported our hypotheses.

Taken together, our research examines the subtle service failures and recoveries that involve a passive emotion such as embarrassment. Theoretically, service failure, recovery, and emotions are complex and dynamic processes that may vary dramatically from one situation to another (Bonifield and Cole 2007). We provide nuances of a complex interaction between subtle recovery efforts and consumers' perceptions and subsequent reactions. To service managers, the most important message is that service delivery can be personalized but can not be done at the cost of revealing sensitive information. When embarrassing service encounter is incurred, recovery strategies vary depending on whether a short-term or long-term oriented goal is adopted by service managers. In a short run, implicit strategies such as incentives can be effective. But in a long run, explicit strategies are more effective.

How Low Can I Go? The Comparative Effect of Low Status Users on Buying Intentions

Edith Shalev, Technion, Israel

Vicki Morwitz, New York University, USA

EXTENDED ABSTRACT

Imagine the following scenario: you are considering a subscription to a well established scientific journal. The journal is highly respectable and its readers are known to be intellectually curious and intelligent. On your way to the office, still undecided, you come across a maintenance worker who is sitting on a bench and avidly reading the latest issue of the scientific journal. How might such an observation effect your subscription decision? Will it increase or decrease your likelihood of subscribing to this journal?

The literature on social influence suggests that consumers from a low socio-economic class are not ideal influencers, at least not of premium brands. Empirical research profiles the “influential” as more educated than average (Boster, Serota, Andrews, & Carpenter, 2009; Row, 2004) and theoretical research (e.g. Berger & Heath, 2008; White & Dahl, 2006) suggests we are positively influenced by those who are similar to us or who are members of an aspirational reference group. Since consumers of premium brands typically do not aspire to be members of a low status group, it is unlikely that they will be positively influenced by actual members of that group. If anything, they would probably become less interested in products that low status users have chosen.

The current work questions this basic premise and reexamines the ways in which the observation of a low-status consumer using a particular product might influence the purchase intentions of an observer. We use the term “*observer*” to denote a consumer, who currently does not own the target product, and who observes another consumer using the product. While previous research that has investigated this question has taken a reference group perspective, we develop an alternative framework based on social comparison theory. In contrast to previous findings, we show that, under certain circumstances, observers are *more* likely to emulate the choices of *low status* than high status users—a phenomenon we call “*the low status user effect*”.

Our analysis begins with the notion that products serve a socially symbolic function (Belk, 1988; Grubb & Hupp, 1968; Levy, 1959). For example, using new technological products may signal high levels of innovativeness; eating organic foods may signal high levels of health consciousness; and subscribing to scientific journals may signal high levels of intellectual curiosity. We hereby define the “*focal trait*” of a product as a human trait, that users of that product would be expected to have at high levels. Given our earlier examples, the focal traits for new technological product, organic foods, and scientific journals would be innovativeness, health awareness and intellectual curiosity, respectively.

Intuitively, we would expect under most circumstances that low-status consumers would have low levels of the focal trait of a premium product. In fact, their mere usage of a premium product is likely to be surprising. An observer might be surprised by a low status consumer reading the scientific journal if he associates high levels of intellectual curiosity with high education and socio-economic status.

In this research, we posit that the observation of a low-status person using a premium brand elicits an attribution process whereby the observer attempts to reconcile the gap between his expectations and his observation of the low-status user’s product choice. The observer might reconcile his expectation and his observation by reasoning that the low status user, and therefore people in general, are, higher on the focal trait than he previously thought.

This account evokes a social comparison process (Festinger, 1954) whereby the observer re-evaluates his own relative standing on the focal trait and concludes that it is lower than previously estimated. In response to the ego-threat posed by this notion and in order to restore his expected relative standing on the focal trait, the observer purchases the target product (Gao, Wheeler, & Shiv, 2009). Ironically, this process leads consumers to emulate the purchase behavior of individuals they may under other circumstances not wish to be associated with. Our research establishes this low status user effect across different product categories, including apparel, MP3 players, and WiFi detectors.

We further show that, like other social comparison processes, this effect is sensitive to the importance of the focal trait to the observer (Tesser, 1988) and the confidence that the observer has about his standing on the focal trait (Kruglanski & Mayseless, 1990; Morse & Gergen, 1970).

Consumer Response to Spokesperson's Race: A Research Synthesis of Racial Similarity Effects in Advertising

Ioannis Kareklas, University of Connecticut, USA
Maxim Polonsky, University of Connecticut, USA

EXTENDED ABSTRACT

Following the civil rights movement, minorities were increasingly being portrayed in both television and print advertisements. Many researchers responded by investigating how White and African American consumers evaluate advertisements featuring models of different races. Some researchers examined how White consumers respond to advertisements featuring African American models (e.g., Bush, Gwinner, and Solomon 1974; Bush, Hair, Jr., and Solomon 1979; Hoon and Ramaprasad 2006; Whittler and DiMeo 1991). Others assessed the advertising evaluations of African American consumers in response to ads featuring either White or African American models (e.g., Choudhury and Schmid 1974; Green 1999; Simpson et al. 2000; Whittler 1989; Whittler and Spira 2002). A third set of studies examined the advertising evaluations of both majority and minority consumers in response to integrated advertisements, featuring both White and African American models in the same ad (e.g., Barban 1969; Cagley and Cardozo 1970; Guest 1970; Perkins, Thomas, and Taylor 2000; Schmid 2000; Stafford, Birdwell, and Van Tassel 1970; Szybillo and Jacoby 1974). The majority of extant findings suggest that consumers respond more favorably to ads that feature spokespersons of the same race as them (for a review, see Whittler 1991).

The Current Review

Using meta-analytic procedures we summarize extant advertising findings related to the effects of racial similarity (vs. dissimilarity) between source and participants. Furthermore, we investigate the conditions under which consumers may prefer racially similar (vs. dissimilar) endorsers, by examining various study characteristics (e.g., geographic region where data was collected), the demographic profile of participants, the methodological aspects of the studies (e.g., medium in which advertisements were presented), as well as additional variables of conceptual importance in this domain (e.g., the level of participants' ingroup identification). We focus on the evaluations of African American and White consumers exposed to advertisements featuring either racially similar or dissimilar endorsers. Our synthesis includes 84 statistically independent data sets, each of which was treated as the meta-analysis unit. Collectively, these studies span forty years of research work in this domain, ranging from 1969 to 2009, and include data from a total of 9,496 participants (3,232 African Americans and 6,264 Whites).

Computation of Effect Sizes

The effect size metric selected for the analysis was the standardized mean difference (g), defined as the difference between the advertising evaluation means for participants exposed to majority spokespersons (i.e., White models) and those exposed to minority spokespersons (i.e., African American models), divided by their pooled standard deviation (see Hedges and Olkin 1985). As defined, an effect size with a positive (negative) sign implies that participants exposed to majority spokespersons exhibited more positive (negative) advertising evaluations than participants exposed to minority spokespersons.

Major Findings

We found that participants of both races evaluated ads featuring same-race spokespersons more favorably than ads featuring different-race models. Specifically, using fixed-effects assumptions, the weighted mean effect size for studies with African American participants was: $d_+ = -.53$ (CI = -.60, -.45, $k=36$), and for studies with White participants the weighted mean effect size was: $d_+ = .15$ (CI = .10, .20, $k=48$).

Effect of Participant Characteristics. The gender composition of samples was significantly related to ds for African American studies ($\beta = .44, p < .001$), but not for studies with White participants ($\beta = .09, p = .24$). Specifically, the weighted mean effect size for studies with male African American participants, $d_+ = -1.31$ (CI = -1.53, -1.09, $k=36$) was almost seven times as large as that of studies with female African American participants, $d_+ = -.19$ (CI = -.31, -.08, $k=36$). The mean age of participants was also significantly related to ds for African American studies ($\beta = .17, p < .01$), but not for studies with White participants ($\beta = .03, p = .73$). Specifically, younger African American participants were much more in favor of their ingroup ($d_+ = -.68$, CI = -.81, -.55, $k=36$) than older African American participants ($d_+ = -.31$, CI = -.48, -.14, $k=36$).

Effect of ingroup identification. The level of participants' ingroup identification was significantly related to ds . This effect was larger for studies with White participants ($\beta = .57, p < .001$), than for studies with African American samples ($\beta = .40, p < .001$). Participants of both races reported a larger preference for ads featuring same race spokespersons when they identified highly with their ingroup, than when they had a low level of ingroup identification. Specifically, the weighted mean effect size, $d_+ = -.95$ (CI = -1.12, -.78, $k=8$), for studies with African American participants that were high in ingroup identification is more than twice as large as that observed for participants with low levels of ingroup identification, $d_+ = -.41$ (CI = -.58, -.24, $k=8$). Similarly, the weighted mean effect size, $d_+ = .64$ (CI = .48, .81, $k=8$), for studies with White participants who were high in ingroup identification is more than four times as large as that observed for participants with low levels of ingroup identification, $d_+ = .15$ (CI = -.01, .31, $k=8$).

Effect of Major African American Events. We tested the effect of the valence of major events in Black history during the year of data collection on effect sizes. Major African American events were significantly related to ds for studies with African American participants ($\beta = .20, p < .001$), but not for studies with White participants ($\beta = .05, p = .52$). Major historical events during the year of data collection which had favorable outcomes for African Americans (e.g., the Voting Rights Act of 1965) were associated with a greater preference for ads featuring Black models ($d_+ = -.61$, CI = -.69, -.52, $k=7$) than were negative events such as the assassination of Martin Luther King, Jr. in 1968, which were associated with a lower preference for ads featuring Black models ($d_+ = -.34$, CI = -.47, -.20, $k=29$) supporting our third hypothesis.

Measuring Associations Across Cultures: A Comparison of Best-Worst and Rating Methods

Julie Anne Lee, University of Western Australia, Australia
Geoffrey N. Soutar, University of Western Australia, Australia
Timothy M. Daly, University of Akron, USA

EXTENDED ABSTRACT

One of the major issues in cross-cultural research is that of response bias. Significant cross-cultural response biases have been attributed to extreme (i.e., using the end points of a scale) and acquiescent (i.e., yea-saying) response patterns. The current standard in cross-cultural research is to address potential response biases post data collection, using one of the several standardization methods recommended for such purposes (e.g., Hofstede, 1980; Schwartz, 1992; Van de Vijver and Leung, 1997). However, the danger of this strategy is that substantive cross-cultural differences may be removed (Van Hemert, Van de Vijver, Poortinga, and Georgas, 2002). Unfortunately, few studies have proposed or examined proactive solutions to avoid this, which has meant response bias continues to be a major unresolved problem (Campbell, 1996). This issue may be compounded in research involving East-Asian samples, as a large number of cross-cultural studies have reported fewer negative correlations in East-Asian than in Western samples. Although this has been attributed to East Asians' dialectical thinking, which recognizes a duality in all things, it is unclear whether any of the suggested duality might be attributable to response bias due to the reliance of ratings scales in cross-cultural research.

Best-worst scaling (BWS; Finn and Louviere, 1992) is a relatively new measurement method that has the potential to reduce response bias. It has been suggested BWS can reduce potential problems commonly produced by ratings scales in three major ways, including improving lexical equivalence of anchoring terms, eliminating the need to use numerical anchors and removing response style effects (Lee, Soutar and Louviere, 2007; 2008). In terms of response style effects, BWS does not allow respondents to consistently use the middle or extreme points, as they are asked to choose the most distinct pairs within each of a set of statements. To date, however, BWS's measurement ability has not been assessed against more traditional rating scales in cross-cultural contexts. Thus, the major aim of this study was to compare and contrast results obtained in a cross-cultural context using BWS with those obtained by traditional ratings scales.

As nomological validity is often lower in East Asian than in Western countries (e.g., Wong et al., 2003), the study also examined whether such problems can be reduced by the use of BWS, especially when there are expected negative relationships. In order to operationalize this, the current study examined a set of expected positive and negative correlations between Schwartz's (1992) personal values, which is the most widely used values measure in cross-cultural research, and tourism benefits in the United Kingdom (UK) and South Korea (SK) using the different response formats. The relationships between personal values and tourism benefits were chosen to reflect measures that should show less duality than personality and traits.

Data were collected from members of commercial online panels in the UK and SK. The samples were chosen from online panel members aged between 18 and 65 years, who were permanent residents of their country and resided in the Greater London area in the UK and the Greater Seoul area in SK. The samples were screened to include international travelers, who do not work in advertising, marketing research or the tourism industries. Schwartz's (1992) values were measured using either the traditional 57-item Schwartz Value Survey (SVS; see Schwartz and Littrell, 2005) in a rating scale

format, or the newer Schwartz Values Best-Worst Survey (SVBWS; Lee et al., 2008). The SVS was also standardized using the mean-centering approach suggested by Schwartz (1992), producing the SVSc. Each of these three values measures were used to compute the focal higher order dimensions of Openness-to-change and Conservation. Travel benefits (developed in conjunction with Tourism Western Australia) were also measured in both a ratings scale format and a BWS format. Sample sizes range from 201 to 242.

The results showed that, overall, each of the three method combinations (SVBWS-Benefits BWS; SVS-Benefits Rating; SVSc-Benefits Rating) produced the expected positive associations in both the UK and SK. The only exceptions being that the SVSc-ratings combination in SK did not produce a significant positive association between OC and *experience a different culture*, or CO and *safe and secure*.

However, the results were very different in terms of the predicted negative associations. Only the SVBWS-BWS combination produced all of the expected negative associations in both the UK and SK. The SVSc-rating combination produced the three expected negative associations in the UK, but only one in SK. The SVS-rating combination failed to produce a single predicted negative association in either the UK or SK. Indeed, this method resulted in counter-intuitive significant *positive* associations between CO and *step into the unknown* and CO and *experience a different culture*. Further, the average expected negative correlations were significantly ($p < 0.05$) higher for the SVBWS-BWS combination than for the SVS-rating combination in both the UK and SK, but only marginally ($p < 0.10$) higher than for the SVSc-rating combination in SK.

In summary, the BWS combination was the only method that produced all of the expected positive and negative correlations in both the UK and SK. Further, the BWS combination was the only combination not to have a significant difference between the expected correlations in the UK and SK. Finally, the BWS combination worked significantly better than the SVS combination for SK, and marginally better than the SVSc combination, but importantly, *without* the post hoc standardization of scores that may remove both substantive and response bias. As such, cross-cultural researchers should consider using the BWS approach when collecting data, especially in East Asian cultures. The BWS approach has several advantages for cross-cultural researchers, as the BWS task produces metric scores that are equivalent across cultures and do not need to be standardized, issues with lexical equivalence are reduced, the BWS does not use numbers, which can often have different meanings in certain cultures and the BWS task is simple for respondents, and takes much less time to complete than do equivalent rating scale tasks.

A Prognosis on Consumerism

Can Usley, Chapman University, USA
Gokeen Coskuner-Balli, Chapman University, USA

EXTENDED ABSTRACT

Despite its obvious importance for marketers, policy-makers, and consumers, there is a dearth of research on the *future* of the consumerism movement in the post-modern society. It has been well established in consumer behavior and sociology literature that minorities and sub-cultures are influential in driving mainstream culture in future generations (Clark 2003; Etzioni 1987; Giesler 2008). In order to anticipate the future of consumerism, we conduct an exploratory analysis of the emerging consumer movements and trends. The effort results in a startling discovery: regarding all four basic consumer rights that were granted back in the sixties, a growing minority of consumers have expectations that are in figurative contrast with what the regulators and in some cases marketers had intended. These consumers do not necessarily want to be safe, heard, informed, or be forced to choose.

In this article, we identify, discuss, and exemplify the reasons why these consumers are resenting, and at times opposing current regulation and/or marketing practices regarding their rights. We posit that consumerism will be transformed dramatically in the coming few decades as first individual consumers, next marketers, and ultimately the government adapts to this post-modern societal transformation.

The End of Consumerism (The Way We Know It)

The Right to be NOT Safe. There have been impressive developments to enhance the safety of consumer goods, yet there are an increasing number of consumers that do not want to be safe. Their motivations can vary drastically, but the resulting action is the same: these consumers would rather take risk than be safe about their consumption. In the past couple of decades the number of consumers who participate in extreme sports have exploded in growth (Celsi et al. 1993; Tomlinson 2004). There are consumer demanding they be allowed to take medication without having to wait for the completion of lengthy experimental trials and the FDA approval process (Conko 2008). Some consumers want a unique experience minimizing, and at times undermining western medicine and treatments. For example, natural childbirth with midwives at home instead of with doctors and hospitalization (and frequently C-section (Declercq, Menacker, and MacDorman 2005) has been gaining ground.

The Right to be NOT Informed. There have been advancements with regard to regulation to provide consumers with more and accurate information regarding their options, yet there are an increasing number of consumers that would rather be disturbed less, and in some cases not be informed at all. Consumers are being bombarded by an excessive array of marketing messages every day. Many of these marketing activities simply represent wasteful or dumb marketing (Sheth and Sisodia 2006). The promotion bombardment continues to intensify, and the opt-out procedure to avoid marketing remains confusing and cumbersome. Nevertheless, the FTC initiated Do Not Call list apparently struck a chord with the consuming public (more than 157 million phone numbers have been enrolled in the program (FTC 2008)). Currently, consumer groups across the US are working to pass municipal/state resolutions in support of a Do Not Mail registry to stop junk mail but Federal action is not expected anytime soon (Sullivan 2009).

The Right to be NOT Heard. There are an increasing number of consumers that would rather be not heard. These consumers and their advocates believe that their privacy is being trampled upon

by the marketers that collect information and then share these with third parties for profit or for access to other databases (Zwick and Knott 2009). The Center for Digital Democracy and the U.S. Public Interest Research Group recently filed a complaint against several behavioral online advertising networks that track and record the surfing patterns of unaware consumers (Tynan 2007). Internet advertising through behavioral tracking is a cause for controversy since consumer information can be collected, compiled, and sold secretly, all done without reasonable safeguards.

The Right to NOT Choose. The service and product providers have been putting their efforts enhance the variety of goods available to consumers. Yet there are at least two groups of growing number of consumers that would rather simplify the process, and in many cases not be faced with a choice at all. The first group feels that there are just too many choices out there. They do not think that 285 varieties of cookies, and 275 types of cereal in an ordinary supermarket are necessary (Botti and Iyengar 2006). Even from the marketer perspective, this clutter represents wasteful product development and less effective sales outcomes (Iyengar and Lepper 2000) in addition to less satisfied consumers (Carmon et al. 2003; Schwartz et al. 2002). The second group would like to ignore choices altogether (or making a choice to circumvent hyperchoice), favoring subscription based business models where the cost is not directly tied to a specific purchase allowing experimentation and sampling. For example, these consumers would like to subscribe to music databases to sample a variety of music of different genre without the limitations of paying per album or song.

Conclusion

Freud (1930) argued that the modern consumer traded her *personal freedom* for *economic security*. In contrast, Bauman (1998, 1999) argued that the *post-modern consumer* was ready to reclaim and enjoy her personal freedom to consume at the expense of her economic security (also see Tester 2004). In retrospect, we think both theses were partially supported. Our attempt provides interesting insights into how consumers deal with this alleged paradox between security and freedom in the post-modern society. Interestingly, we suggest and our analysis alludes that the post-modern consumer may opt for *economic and personal freedom* at the expense of economic security, and at times personal safety. To facilitate this, it has been argued that “[m]arketing doesn’t need reform; it needs restraint” (Brown 1995; 2006, 63). It remains to be seen if this will be primarily in the form of self-restraint, imposed upon, or both.

Iconoclasm, Autotelicity, Narcissism, and COOL Beyond Distinction

Soonkwan Hong, Michigan Technological University, USA

EXTENDED ABSTRACT

Distinction as an imperative of consumer culture and a prerequisite for postmodern self-identity has been widely recognized and discussed by theorists ever since the homogenization of consumers in modernity provoked individuals to seek a distinct identity (e.g., Bourdieu 1984; Holt 1998; Jameson 1991). This subsumption of distinction under consumer identity project, which also manifests as an unprecedentedly important part of consumer culture, necessitates consumers' proactive devotion to distinction-making (Firat and Venkatesh 1995) and thus interests consumer researchers. Nevertheless, the extant literature on distinction tends to stay within the normative boundary of distinction that all can conceive, perceive, simulate, and emulate, with a slight exception as to gender and sexual-orientation issues (e.g., Kates 2002, 2004).

In order to contribute to the advance of the theories relevant to distinction as a recursive topic of consumer culture, this study employs a context that facilitates the understanding of novel styles of making distinction. The X Games event is selected as the context for the theorization of "hyper-distinction," which seems quite evident in the extreme locale. As extreme sports participants display self-fulfilling characteristics of socio-cultural "distancing" from others in the context, newly emerged "freestyle" and "no string attached" distinctions become palpable. It is also frequently quoted that the followers of extreme sports are defying not only gravity but also social standards. This constant distinction-making that is to contrast with mainstream culture, establishment, social structure, and hegemonic brands ultimately brings much attention and value to the extreme sports event, as a culturally and theoretically rich context for this study of distinction and the dynamics in consumer culture.

Following grounded theory approach, this study employs a multi-sited and multi-layered approach, often used in consumer culture theory literature (e.g., Giesler 2006; Kjeldgaard and Askegaard 2006; Kozinets 2001, 2002; Kozinets and Handelman 2004; Schau and Gilly 2003). The multi-layered approach for this study involves ethnographic in-depth interview (primary data source), fieldnotes, participant observation, videotaping, and photographs.

Among many possible forms that autotelic and/or narcissistic consumption praxes can take, extreme sports participants employ iconoclastic, self-complacent, and intrinsic (cool hunting) methods to make distinction. Extreme sports participants appear to pursue autotelic self-identity that is less negotiated and more asserted than what theories have by far codified (cf., Giesler 2008; Kates 2002; Kjeldgaard and Askegaard 2006; Sandikci and Ger 2010; Thompson and Haytko 1997). Distinction in extreme sports context, in which "mild and naïve" distinctions become worse than "no distinction," may be seen as the extreme case of "the cult of the self." In order to turn the blurred line between self and others to a bolder one, consumers perform narcissistic practices with less concern about reflexivity of the self (cf., Finkelstein 1991; Giddens 1991). The narcissism consumers in the context take for granted is their ultimatum to others that prevents unwanted overlaps of self-identity. Narcissism for those consumers is the mode of being that is not a pathological anomaly, but a purely cultural choice for cultivating the self as Giddens (1991, 81) states, "we have no choice but to choose." The extracted themes of distinction indicate possibilities of presenting distinctiveness to the outside of the self without staying within the normative boundary.

Consumers who freely improvise and still display nuanced hipness are distinct in the context. Socio-cultural background is neither questioned nor relevant. Unlike some macro (national) and

global(ized) contexts in which the logic and practice of distinction-making have been studied (e.g., Holt 1998; Ustuner and Holt 2010), in the relatively micro and more culturally defined context, consumers appear to unleash themselves from the rigid cultural propositions and schemata. Because Bourdieu (1984, 1990) is not a determinist, there is always a room for consumer agency, not subjectivity, even though the habitus is all-pervasive. In practice, perhaps consumers have to be a subject with minimal consumer agency in certain contexts wherein habitus is less malleable, but they can be rule-breakers in some contexts (i.e., X Games) that encourage agentic contribution to cultural progress (cf. Bourdieu 1990). Thus, some research has to follow in order to better understand how consumers perceive the boundary between the two possibly distinct types of context. Research on how consumers maneuver within the field of distinction that connotes different levels of plasticity of the habitus will also provide a theoretical insight for consumer researchers.

"Trickling-up" cultural penetration and proliferation are of particular interest. The hipness and cool invented and spread by a group of people (i.e., extreme sports athletes and participants), who socio-politically represents almost the opposite of "high-cultural-capital" consumers, are now the dominant form of distinction in many contexts. The encroachment of the culture from the "bottom of the pyramid" upon the historical role of cultural capital, which has been operating as the most important currency for distinction, is widely observed and rapidly developing. The Winter Olympic Games' acceptance of some events (i.e., ski cross and half pipe) created by rebellious and yet cool people, who originally ridiculed the elitism in the sports, clearly shows how the logic can be upside down.

The consumers who portray a cool persona and practice natural hipness are comparable to the consumers in the past who enjoyed their high cultural capital. Although cool may not be something to be explained, analyzed, and theorized, it will be thought-provoking if research explores different facades of cool in different context to see if a similar manifestation of cool in a context can be transferred to the other. Cool as distinction in the context of X Games seems well-received in many other contexts as marketers strived to transplant the cool to brands and trends. However, the grass-roots types of distinction (cool), found in this study, is very far from what is usually targeted by marketers and consumers because they present extremity and essentialism. The distinction inflation promoted in such a context may hinder the co-optation as business culture, and therefore it protects the distinction from commercialization. In that case, what would be hyper-co-optation of hyper-distinction like?

Conceptions of Consumption in Consumer Culture Theory: A Dynamic Framework

Ahir Gopaldas, York University, Canada

EXTENDED ABSTRACT

Presidential addresses to the *Association of Consumer Research*, from the first published (Pratt 1974) to the most recent (Janiszewski *forthcoming*), and editorial statements in the *Journal of Consumer Research*, from the first (Frank 1974) to the most recent (Deighton 2005), regularly assert that what anchors the field of consumer research is not a theoretical perspective but a substantive domain called consumption. Thus, unsurprisingly, the field houses several conceptions of consumption. Consumption is conceived of as utility maximization in an economic perspective, as information-processing in a cognitive-psychological perspective, as decision-making in a behavioral-economic perspective, as structuration in a sociological perspective, as meaning-making in a cultural-anthropological perspective, and as goal seeking, identity management, need fulfillment, and want negotiation among numerous other conceptions. There is nothing intrinsically wrong with any of these conceptions so long as one does not reify these conceptions. Conceptions are images, models, or ways of perceiving. Conceptions are neither true nor false; rather, conceptions are more or less useful. It is futile to seek a universal best conception; instead, one must determine which conceptions of a phenomenon are valuable across different sets of circumstances, or inversely, which sets of circumstances substantiate the value of different conceptions (Lewis and Grimes 1999; Morgan 1980; Weick 1989).

Scope. In a historical period when the consumer research community is home to over a thousand researchers and over a dozen annual conferences and dedicated journals, the field is simply too vast and varied to fit all of its working conceptions of consumption into a single essay. One functional way to manage the issue of scope is to choose one sub-field of consumer research as a boundary condition. There are three established sub-fields of consumer research, consumer culture theory (CCT), consumer decision making (CDM), and consumer information processing (CIP), and one growing field of transformative consumer research (TCR) (Arnould and Thompson 2005; Hudson and Ozanne 1988; Johar, Maheswaran, and Peracchio 2006; Loken 2005; MacInnis and Folkes *forthcoming*; Mick 2008; Simonson et al. 2001). The decision making and information processing conceptions of consumption lie at the foundations of CDM and CIP respectively, though each of those sub-fields also host variations of those conceptions (Newell and Broder 2008). By contrast, conceptions of consumption lie at the frontiers of CCT research. A tacit assumption among CCT researchers is that because there can be no universal conception of consumption across contexts, perspectives, or times, there should be no ruling conception in CCT either. Rather, CCT researchers often try out multiple conceptions during the course of a single study and debate the merits of various conceptions across a stream of literature (Arnold and Fischer 1994; Holt 1995; Spiggle 1994). It is precisely because conceptions of consumption are contested and evolving in CCT that it is theoretically valuable to focus our attention on this sub-field.

Conceptions. This essay could have been framed as *analogies*, *images*, *interpretations*, *models*, *metaphors*, or *theories* of consumption, or even *concepts* or *conceptualizations* of consumption. Our preference for *conceptions* of consumption is based on a few heuristics and on early reviews. *Conception* is not as superficial as *image* but not as deep as *theory*. Though all conceptions discussed in this essay have generated substantial insight for marketing theory or practice, not all conceptions have produced full-fledged theories as of yet. *Conception* does not carry as much disciplinary

baggage as some of the other terms do. For example, while some cultural anthropologists and cognitive scientists have documented the function and power of *metaphor* in human culture and cognition (Lakoff and Johnson 1980), many theorists and practitioners overlook *metaphor* as a mere rhetoric matter owing to the term's association with literature. Unlike *concept*, the terms *conception* and *conceptualization* clearly evoke not only the cognitive product but also the cognitive process that produces it. Furthermore, reviewers of an early draft of this essay misconstrued *concepts of consumption* to be concepts within consumption theory rather than conceptualizations of the consumption phenomenon, as we intended. Finally, the hexa-syllabic *conceptualization* proved too cacophonous for many readers. In sum, we prefer *conception* because it communicates both cognitive process and product, at an appropriate level of theoretical maturity, without associative or aural excess.

Organization. Our ongoing objective is to map conceptions of consumption along informative dimensions of differentiation. Owing to the space constraints in this forum, it is not possible to discuss each of the dimensions and each of the conceptions in the detail that each deserves. However, it is possible to identify and partially illuminate some of the major dimensions and major conceptions in a condensed tabular form. The first section delineates the dimensions of differentiation that are useful in sorting through alternative conceptions of consumption. The second section itemizes major conceptions of consumption and explicates them along relevant dimensions. Thereafter, distinguishing characteristics of our framework are discussed and recommendations for future research and theory building are proffered.

Same Destination, Different Paths: The Effect of Observing Others' Divergent Reasoning on Choice Confidence

Cait Poynor, University of Pittsburgh, USA
Rebecca Walker Naylor, The Ohio State University, USA
Kelly L. Haws, Texas A&M University, USA

EXTENDED ABSTRACT

After Barack Obama's victory in the 2008 presidential election, strategists convened to analyze John McCain's loss. Pundits generally grouped McCain's supporters into two camps: Moderates, who appreciated McCain's centrist libertarianism, and Conservatives, who valued his social and fiscal conservatism. Both groups together made up the American center (Kass 2008). The fact that these groups supported McCain could have bolstered the confidence of individuals in either group that they had chosen the correct candidate, thus enhancing McCain's chances of victory. Interestingly, however, this failed to occur. Rather, divergence in perceptions of the importance of various issues among Conservatives may have led to fragmentation within the Republican party (Rodgers 2008), increasing McCain's vulnerability among what should have been his base. Could observing others' *divergent perceptions of importance of reasons* for a *convergent choice* have undermined the confidence of McCain's supporters in their choice of candidate? More generally, can the observation of divergent assessments of the relative importance of potential reasons for making a convergent choice have such a strong influence on individuals' choice confidence? Certainly, social influence research shows that observing others' behavior can have a strong influence on our own (Burnkrant and Cousineau 1975; Escalas and Bettman 2003; Park and Lessig 1977). We contend, however, that convergence or divergence of choice does not fully explain the influence that observing others can have on one's own choice confidence.

Rather, our results suggest that when an observed other's justification for making the same choice as our own does not correspond with our justification, choice confidence can be undermined. In other words, when individuals disagree on how important different reasons should be in justifying a choice, their reasoning is divergent even if their choice is convergent. We argue that in such cases the importance prescribed by observed others to possible reasons for making a given decision is seen as highly diagnostic in determining the validity of our own choice. When others rely on reasons we consider relatively trivial, it throws into question the validity of our decision process and decreases confidence in our choice. By contrast, reasoning related to divergent choices is not perceived to be as directly diagnostic in evaluating our own choice. In these cases, we propose that the applicability of others' behaviors will be discounted and our choice confidence will not be adversely affected.

We therefore propose a framework which recognizes that both observed choice and reasoning may either converge or diverge with an observer's own. Reasoning is a key element in evaluating the validity of a thought process (Simonson and Nowlis 2000). As such, models of reason-based choice assume that individuals choose by considering the reasons for choosing one alternative versus the other (Shafir, Simonson, and Tversky 1993). That is, consumers believe that good choices are based on good reasons and that good reasons will lead to good choices (Barber, Heath, and Odean 2003). Seeing someone choose what we do based on the same reasoning that drove us to choose it (i.e., perfect choice and reasoning convergence) should be doubly affirming—we have convergent support for our choice and know that we made it well. However, we propose that knowing that someone else has differ-

ent justifications for a choice can be quite damaging to our choice confidence, particularly if the choices are convergent. We propose that an individual consumer who observes another making the same choice s/he does will see the underlying reasoning of the observed other as highly diagnostic in determining the validity of his/her own choice. Therefore, the consumer will question his/her choice if the reasoning of the observed other for making the same choice diverges from his/her own.

We also predict that observing divergent reasoning for the same choice may shake confidence more so than does observing another consumer making a completely different choice. Unexpected reasoning attracts more attention and elaboration than does expected reasoning (Greenwald and Sakumura 1967; Simonson and Nowlis 2000). Divergent reasoning for a shared choice is likely to be less expected than is any reasoning related to divergent choice—while shared choices promote tendencies to anchor on one's own thought processes as the norm, divergent choices may cue consumers to recognize heterogeneity among those around them (Gilovich, Savitsky, and Mevec 2000) and, therefore, to be less surprised if they report divergent reasoning. The direct applicability of divergent reasoning to convergent choice behavior will also make it more persuasive than reasoning related to a different option (Goldstein, Cialdini, and Griskevicius 2008). Thus, we anticipate that individuals will question the validity of their decision processes more when faced with reasoning relevant to their own choice versus reasoning irrelevant to that choice.

Results from two studies demonstrate the circumstances under which an observed other's choice and reasoning for choice will impact one's own choice confidence. Specifically, in study 1, we use the context of political decision making to demonstrate that while observing convergent choice and reason ranking evokes the greatest confidence in our own choice, observing someone make a convergent choice based on divergent reason ranking actually undermines confidence such that confidence in choice is decreased compared to when the observed other chooses a different alternative. This effect, however, only exists when choices are framed in terms of selection rather than rejection, highlighting the difference in the diagnosticity of reasons for liking versus disliking an alternative (Gershoff, Mukherjee, and Mukhopadhyay, 2007). Study 2 suggests that the effects we predict and demonstrate on choice confidence are most likely to emerge when individuals anticipate having to defend the validity of their decisions (e.g., in a public setting), and that these effects are attenuated when no public revelation or discussion is anticipated.

Perceptual Prominence Effects in Consumer Choice

Sehoon Park, Sogang University, Republic of China

Moon-Yong Kim, Dongguk University, Republic of Korea

Se-Hyuk Park, The College of William and Mary, USA

EXTENDED ABSTRACT

One of the most important and robust context effects is the attraction, or asymmetric dominance, effect that was first described by Huber, Payne, and Puto (1982). Although most research on context effects, including that on the attraction effect, has explored how context can influence relatively deliberate analytic processes, recent research by Hamilton, Hong, and Chernev (2007) has examined how context can affect intuitive choice processes. Hamilton and colleagues found that in the context of the attraction effect, adding fully dominated options that change the perceptual characteristics of the decision set can make one option (i.e., the non-dominating option) perceptually focal, increasing its likelihood of being chosen due to the perceptual focus effect and decreasing the strength of the attraction effect. That is, contrasting the perceptual focus effect and the attraction effect, they found that the preference for asymmetrically dominating options decreased in the presence of a perceptually focal option.

In the current research, however, we examine consumer choice as a function of the perceptual similarity of options at the attribute level in a two-attribute decision set. In particular, adding to the findings of the attraction effect by Hamilton et al. (2007), we examine a scenario in which a binary decision set is extended by adding asymmetrically dominated frequency or range decoys that change its perceptual characteristics, thus increasing the prominence of one of the attributes in the decision set and generating a perceptual prominence effect at the attribute level. In this context, we propose that perceptual prominence at the attribute level may either decrease or increase the choice share of the target depending on the added decoys' location in the set (frequency vs. range), which will, in turn, moderate the strength of the attraction effect; the attraction effect is attenuated in the frequency decoy condition, whereas the attraction effect occurs in the range decoy condition. Further, we propose that the perceptual prominence effect at the attribute level and its subsequent impact on the attraction effect in frequency and range decoy conditions will be a function of the type of processing (by attribute vs. by group) affecting consumers' decision procedures, such as lexicographic or dominance procedures; the proposed effects are more pronounced in the by-attribute condition, whereas the effects are mitigated in the by-group processing condition.

In experiment 1, participants consisted of 250 students from a large university in a metropolitan area, and they were randomly assigned to one of five experimental conditions. Participants in the first condition were presented with a binary set of options described on two attributes (set AB), such that option A was superior on attribute 2 and option B was superior on attribute 1. Asymmetrically dominated decoys were positioned according to the different decoy placement strategies (i.e., frequency or range). Participants in the second condition chose from a three-option set in which a third, asymmetrically dominated frequency option (C) had been added to the core set (set ABC), while participants in the third condition chose from a three-option set where a third, asymmetrically dominated range option (C') had been added to the core set (set ABC'). Participants in the fourth condition chose from a five-option set where two additional asymmetrically dominated frequency options (D and E) were included along with the three-option set, ABC (set ABCDE). Participants in the fifth condition chose from

a five-option set where two additional asymmetrically dominated range options (D' and E') were added to the three-option set, ABC' (set ABC'D'E'). All attributes were rated on a 100-point scale, with 100 as the best. The choice sets were designed so that options C, D, and E (C', D' and E') all shared a common attribute value on attribute 2 (attribute 1) with option B. Thus, option A was the only option with a dissimilar attribute value on one attribute, and it was a perceptually focal option in the choice set. Following the methodology established by Hamilton et al. (2007), once assigned to an experimental condition, participants were asked to select one option from each of two choice sets (cell phones and MP3 players). The experimental findings showed that (1) the attraction effect occurs when an asymmetrically dominated decoy is added to a binary (core) set, irrespective of the decoy location; and that (2) when three additional asymmetrically dominated options (one asymmetrically dominated option and two newly-introduced asymmetrically dominated options) are added to the binary set, the attraction effect can be attenuated in the frequency decoy condition, while the attraction effect can still occur in the range decoy condition.

In experiment 2, participants consisted of 200 students from a large university in a metropolitan area. They were given a choice task involving five-option decision sets that consisted of a digital camera and vitamin water. As in experiment 1, the attribute values of digital cameras and vitamin water were rated on a 100-point scale. Participants were randomly assigned to the conditions of a 2 (processing type: by attribute vs. by group) x 2 (location of decoy: frequency vs. range) factorial design. In the by-attribute processing condition, the choice sets included horizontal lines separating attribute values in each row, as in Hamilton et al.'s (2007) experiment. In the by-group processing condition, the choice sets included vertical lines separating a group of options and a lone option, which encourages by-group processing. The experimental findings supported the prediction that the observed perceptual prominence effect is indeed contingent on the type of processing; that is, the perceptual prominence effect at the attribute level and its subsequent impact on the attraction effect in frequency and range decoy conditions are more pronounced in the by-attribute processing condition, whereas the effects are mitigated in the by-group processing condition.

Taken together, we extended the research done by Hamilton et al. (2007) by positing that perceptual prominence at the attribute level that has been induced by changing the perceptual characteristics of a choice set can either decrease or increase the choice share of the target depending on the location of the added decoys (frequency vs. range) in the set, which will moderate the strength of the attraction effect. Moreover, we provided additional support for the perceptual prominence effect at the attribute level in choice by showing that effects are moderated by the type of processing (by attribute vs. by group) facilitating consumers' decision procedures, such as lexicographic or dominance procedures.

Coloring Decisions: The Effect of Red and Blue Colors on Consumer Behavior

Rajesh Bagchi, Virginia Tech, USA
Amar Cheema, University of Virginia, USA

EXTENDED ABSTRACT

Colors play an important role in affecting our perceptions. They form an integral part of our daily lives, influencing our interactions with other individuals and with inanimate objects. Colors are ubiquitous in consumer contexts. Identical products are often sold in different colors or with different colors of packaging. Shopping mall walls, aisles, and displays use multiple colors. Web site backgrounds and product displays use varied colors. Colors are integral in advertisements and in company logos. In spite of its importance, however, little is known about how color affects consumer behavior (Elliot et al. 2007).

The literature on animal behavior suggests that red signals vigor and dominance among animals and induces aggression (Andersson et al. 2002; Cuthill et al. 1997). Similarly, physiological studies of human responses to color reveal that exposure to red versus blue colors increases irritability and decreases patience (Bellizzi, Crowley, and Hasty 1983). In laboratory studies using retail scenarios, Bellizzi and colleagues (Bellizzi et al. 1983; Bellizzi and Hite 1992) find that although warm colors (red, yellow) attract more attention, these colors are less likely to lead to purchases relative to cool colors (green, blue). However, prior studies are inconclusive about whether these color differences affect individual-level aggression in social contexts, and whether colors influence consumers' willingness-to-pay.

The present research investigates the influence of red versus blue colors on aggression in social settings and on consumers' willingness-to-pay in auctions and negotiations. In doing so, we seek to make two important contributions. First, we explicitly test the proposition that red enhances aggression relative to blue in social situations (study 1). Second, and more importantly, we investigate how color influences consumers' monetary transactions (studies 2-4). In study 2 we show that red induces more aggressive bidding relative to blue in laboratory auctions with real money. In study 3 we analyze data from eBay auctions and demonstrate that these effects also manifest in real-world settings. Finally, in study 4 we investigate the role that color plays in negotiations and demonstrate that red induces more aggressive negotiation relative to blue.

Summary of Findings

We find that red induces greater aggression relative to blue, while blue increases patience relative to red in social settings (study 1). We also demonstrate the effect of color on aggression in auctions (studies 2-3) and negotiations (study 4). In auctions, buyers attempt to "win" the auctioned product by outbidding other potential competitors. In such instances, aggression induces bidders to offer higher bid jumps (Sinha and Greenleaf 2000). Correspondingly, we find that buyers offer higher bid jumps when a product is sold using a red background relative to when it is sold using a blue background. We demonstrate these effects in auctions conducted in the lab with real money (study 2) as well as in eBay auctions (study 3).

In contrast, in negotiations, where a buyer negotiates one-on-one with a seller, aggression typically entails eliciting unilateral concessions from the opponent (Ganesan 1993). In price negotiations, a more aggressive buyer would try to reduce the buying price. As expected, we find that red color reduces buyers' willingness-to-pay relative to blue colors. We also find that buyers negotiating the purchase of the red product report a lower likelihood of being persuaded to increase their willingness-to-pay than do people who see the blue product (study 4). This likelihood of persuasion

measures mediates the effect of color on willingness-to-pay. These results are consistent with those of Bellizzi and Hite (1992) who find lower purchase incidences with red colors relative to blue in a scenario study conducted in a lab.

Implications

We find that red induces greater aggression in consumer purchase contexts, such as in auctions and negotiation settings, relative to blue. In auction settings, aggression leads to higher bids, and bidders who see red (vs. blue) pay more. Thus, bidders are worse off (but sellers are better off) in auctions with red (vs. blue) listings. In contrast, in negotiation settings, red reduces buyers' willingness-to-pay. Thus, buyers are better off (but sellers are worse off) in negotiations where buyers see red (vs. blue). These results are consistent with the findings of Bellizzi and Hite (1992), who find that red colors reduce purchase incidences relative to blue.

Our findings provide a possible explanation, demonstrating that red reduces buyers' willingness-to-pay as well as buyers' willingness to be persuaded to consider higher prices relative to blue. Thus, our results document conditions where red may be beneficial as well as detrimental from the seller's perspective.

Brands and Impulsive Desire: Implicit Brand Processing Biases Incidental Decision-Making

Philip Harris, The University of Melbourne, Australia
Carsten Murawski, The University of Melbourne, Australia

EXTENDED ABSTRACT

This study examined whether implicit brand processing can impact on decision-making for incidental rewards. Findings indicated a bias towards impulsive choices of incidental rewards following subconscious brand logo exposure. Findings of the study were linked with the effect of a generalized affective-motivation mechanism cued by favored brand exposure.

Introduction

Recent research has indicated that subliminal brand presentation may influence goal-directed behaviour, even without conscious awareness of the stimulus (Chartrand, Huber, Shiv, & Tanner, 2008; Fitzsimons, Chartrand, & Fitzsimons, 2008). In addition, recent neuroimaging insights support the proposal that favored brands act as reward cues that moderate decision-making (e.g. Plassmann, Kenning, Deppe, Kugel, & Schwindt, 2008; Schaefer & Rotte, 2007). Additionally, recent theory discussing motivated goal pursuit distinguishes two separate reward-related components of goal-related behaviour: a status linked with specific goal-pursuit states, and also a non-specific status which motivates behaviour towards or away from a reward cue (Kent. C. Berridge, Robinson, & Aldridge, 2009; Martin Veltkamp, Aarts, & Custers, 2009). Together, these insights may have important consequences for brand theory. Brand responses may impact on behaviour via reward-related processing in parallel with activation of brand-related schema in the absence of conscious processing. Furthermore, the impact of brand processing on decision-making may occur not only by moderating the salience of goal-linked attitudes, but also by activating non-specific valence-linked motivational states. In this research we sought to examine these processes. We examined whether: 1). implicit brand processing can impact on incidental decision-making, and 2). whether implicit processing primed by brands provides an impulsive bias on decision-making processes.

Conceptual Development

Insights from neurobiological research provide the basis for the intriguing possibility that implicit brand processing may impact on decision-making not only via implicit goal-linked processes, but also by influencing the contribution of the affective-motivational system towards decision-making. Following subliminal priming with favored brands, we anticipated that reward-based decision-making subserved by a non-specific motivational process would show greater influence of impulsivity than decisions that are less exposed to the influence of the affective-motivational system. Furthermore, as motivational states primed by reward cues may bias incidental decisions (Li, 2008; Van den Bergh, Dewitte, & Warlop, 2008; Wilson & Daly, 2004), an initial experimental hypothesis (H1) proposed that subconscious priming by brands linked with reward value would motivate impulsive choices for incidental rewards. In view of evidence linking impulsivity with faster task responses (Ramanathan & Menon, 2006), a second experimental hypothesis (H2) proposed that response times for choices of incidental rewards would be reduced when subconsciously primed by brands linked with reward value.

Method

One hundred and eighty-three undergraduate college students participated in a computer-based temporal discounting task which offered a series of choices between an immediate reward of \$20

and a reward of higher value to be paid at one of six possible delays (1, 10, 21, 55, 90 180 days). Each choice was preceded by the subliminal presentation (16 ms, pre- and post-masked) of one of four priming image types: brand logos (Apple or Windows); smiling faces, or household objects which served as a baseline condition. Participants completed the discounting task four times, once for each of the priming image types. The principal dependent variable was the subjective value assigned to delayed rewards when subliminally primed by each of the four image types. Following the discounting task, participants completed a five-item brand affect scale which incorporated seven-point ratings of brand salience, brand affective value, brand ownership, desire to own brand products, and intention to purchase branded products within the next six months. A post-hoc recognition task assessed participants' recognition of stimuli used in the main experimental task.

Results

Brand affect scale ratings for Apple were significantly higher than for Windows overall, $t(183)=3.83, p=.0001$. A logistic model was fitted to participants' choices in order to investigate the relationship between decision parameters (reward amount, reward delay, and priming condition) and response time on the one hand, and choice on the other. Compared to decisions made following a neutral prime, 'Now' decisions were significantly more likely following brand primes ($b_{\text{Apple}}=-.0703, p<0.05$; $b_{\text{Windows}}=-.0566, p<0.10$). These data provide support H1. In a second model, the probability of choice of a 'Now' reward decision was higher when response times were lower ($b_{\text{ResponseTime}}=-.0648, p<0.01$) and when decisions were primed with the Apple or Windows logos. ($b_{\text{Apple}}=-.0667, p<0.05$; $b_{\text{Windows}}=-.0666, p<0.05$). This data demonstrates that impulsive choices are significantly associated with faster responses and support H2. Panel regression models fitted to response times indicated that incidental reward choices following brand and smile primes were associated with faster response times than when following a neutral prime ($b_{\text{Apple}}=-.0582, p<0.01$; $b_{\text{Windows}}=-.0636, p<0.01$), and that the reduction in responses time following a brand prime was directionally strongest when choosing immediate rewards ($b_{\text{Apple}}=-.1021, p<0.01$; $b_{\text{Windows}}=-.0613, p<0.10$). These data provide further support for H2. Finally, logistic models of choice revealed that that incorporation of response times in a choice model increased the predictive power of the model, and thus revealed participants' preferences.

Discussion

Our results indicate that the affective value associated with a brand may impact on unrelated decision-making processes. Following presentation of brand logos, participants were more likely to choose an immediate reward, and to do so more quickly than when primed by a neutral stimulus. Further, participants did not explicitly recognize presentation of brand logos in the discounting task, indicating that the effects of brand presentation on decision-making occurred without conscious awareness of the priming episode.

Questionnaire responses indicated significantly stronger brand affect ratings linked with Apple than with Windows brands. Linking these explicit questionnaire responses with decision data, we note that stimuli with affective value have been demonstrated to impact on the extent that delayed rewards are discounted (Van den Bergh, et al., 2008; Wilson & Daly, 2004). Further, neuroimaging research indicates that immediate reward choices reflect greater relative contributions of neural systems associated with affective

processing (McClure, Ericson, Laibson, Loewenstein, & Cohen, 2007; McClure, Laibson, & Cohen, 2004). In view of these findings, we propose that in the current research, a favored brand may have primed generalized affective processes underlying decision-making mechanisms.

Response time data support this proposal. When primed by a favored brand, preference for immediate rewards was strongly associated with faster response-times for immediate reward choices but less so for delayed choices. Furthermore, a prediction model incorporating both choice and response times demonstrated that response time data improve the predictive power of a model that links brand priming with subsequent reward choices.

In parallel with research demonstrated that affective primes may provide an incidental impulsive bias on reward-linked decision-making, the current study provides initial evidence that brand logos may also provide a subconscious motivational bias on incidental decisions. We tentatively propose that a bias towards impulsive incidental reward choices reflects the effect of a generalized affective-motivation mechanism cued by favored brand exposure.

Opportunity Costs Neglect in the Tradeoff between Time and Money

EXTENDED ABSTRACT

Recent research suggests that when consumers tradeoff between price and quality, they may not spontaneously consider the opportunity cost of money in their decision-making. For example, Frederick, Novemsky, Wang, Dhar, and Nowlis (2009) show that in a choice between a 32 gigabyte iPod for \$399 and a 16 gigabyte iPod for 299, the choice of the cheaper iPod increased from 37% to 71% when its price was reframed from “spend \$299” to “spend \$299 and save \$100” (Page 555). The authors suggest that consumers tend to confine their thoughts to the information that marketers provide to them, and seldom bother to “fill in the logical consequences of their choice” (Frederick et al. 2009, Page 554) unless marketers explicitly remind them to do so. The purpose of our paper is to extend Frederick et al.’s (2009) research to investigate if consumers spontaneously account for opportunity costs of time along with money when they have to tradeoff between these two fungible currencies.

Although both time and money are fungible currencies, research suggests that figuring out the next best use of time may be more difficult than figuring out the next best use of money. For example, Okada and Hoch (2004) observe that the opportunity cost of time is more ambiguous than the opportunity cost of money. LeClerc, Schmitt, and Dube (1995) point out that time, unlike money, is less transferrable since time cannot be stored, and planning how to make the best use of time is perhaps even more important than planning how to make the best use of money. Consequently, frames that sensitize consumers to the opportunity cost of time could be more powerful than frames that sensitize consumers to the opportunity cost of money.

In one experiment, we asked ninety-five undergraduate students (58 females) to imagine that they were on vacation and waiting in line to purchase a train ticket that would take them to a ski resort. They had a choice between a slower train (Train A; 3 hours, \$10 ticket price) and an express train (Train B: 45 minutes, \$26 ticket price). After reading the scenario, the participants reported their likelihood of selecting each train (9-point scale, 9.0=Very Likely, 1.0=Very Unlikely), and the train that they would select (A, or B). We randomly assigned the participants to one of three experimental conditions. In the “money” condition, we reminded participants that taking the slower train would save money (“select Train A, and save \$16”). In the “time” condition, we reminded participants that taking the express train would save time (“select Train B, and save 2 hours and 15 minutes of travel time”). In the “control” conditions, we did not sensitize them to either saving time or saving money (“select Train A or Train B”).

Sensitizing the participants to the opportunity cost of time significantly increased the choice of the express train, from 59% in

the control condition to 81% in the “time” condition ($\chi^2 = 3.74, p=.05$). The significant increase in the likelihood of selecting the express train (M 's of 5.97 and 7.77; $F(1,55)=7.30, p<.01$) was coupled with a significant decrease in the likelihood of selecting the slower train (M 's of 5.07 and 3.19; $F(1,55)=8.32, p<.01$). Sensitizing the participants to the opportunity cost of money, however, decreased the choice of the slower (and cheaper) train, instead of increasing it (from 41% in the control condition to 21% in the “money” condition;

$\chi^2 = 3.21, p=.07$). While there was no change in the likelihood of selecting the express train (M 's of 5.97 and 6.76; $F(1,58)<1$), there was a significant reduction in the likelihood of selecting the slower train (M 's of 5.07 and 3.53; $F(1,58)=4.61, p=.04$).

We speculate that, in the context of vacation travel time, consumers may be more inclined to save time than money, and generally prefer the faster train. Therefore, a “time” frame “fits” with the consumers’ natural inclination, and gives them a “just right” feeling about their choice (see Aaker and Lee, 2006). However, the “money” frame tries to enhance the appeal of the disliked option, locking consumers in a prevention mindset and making them avoid that option (Malkoc, Hoeffler, and Hedgcock, 2008). We tested this prediction in a follow-up experiment, with an iPod Touch as the focal product. Our pretests indicated that consumers generally consider saving money more important than saving time in the context of an iPod purchase.

In the second experiment, we asked eighty-seven undergraduate students (57 females) to imagine that they could buy an iPod Touch either from Store A (\$199.99; 5-minute drive) or from Store B (\$129.99 with a student discount; 80-minutes drive). We randomly assigned the participants to one of three experimental conditions. In the “money” condition, we reminded participants that choosing Store B saved them money (“select Store B and save \$70”). In the “time” condition, we reminded participants that choosing Store A saved them driving time (“select Store A and save an hour and fifteen minutes of driving time”). In the “control” conditions, we did not sensitize them to either saving time or saving money (“select Store A or Store B”). Sensitizing the participants to the opportunity cost of money significantly increased the choice of the cheaper (but more distant) store from 56% in the control condition to 82% in

the “money” condition ($\chi^2 = 4.58, p=.03$). However, sensitizing the participants to the opportunity cost of time did not affect the choice of the nearer (but more expensive) store. The store choice decreased from 44% in the control condition to 34% in the “money” condition ($\chi^2 < 1$).

Our research extends that of Frederick et al. (2009) and suggests that when consumers tradeoff between time and money, they do not spontaneously consider the opportunity costs of either of these currencies. However, they come into the decision with some sense of what matters more to them, saving time or saving money. For example, saving money may matter more than saving driving time in the context of an iPod Touch purchase. Therefore, sensitizing consumers to the opportunity cost of money favors the selection of the cheaper iPod (entailing a longer drive time), but sensitizing them to the opportunity cost of time does not bias them towards the more expensive iPod (even though the drive time is less). Conversely, saving time may matter more than saving money in the context of a vacation. Consequently, sensitizing consumers to the opportunity cost of time favors the selection of the faster (but more expensive) train, but sensitizing them to the opportunity cost of money does not bias them towards the slower (but cheaper) train.

Strategy Compatibility: The Time versus Money Effect on Consumer Decision Making

Lei Su, The Chinese University of Hong Kong, China
Leilei Gao, The Chinese University of Hong Kong, China

EXTENDED ABSTRACT

Consider a consumer who wants to buy a piece of furniture at IKEA. She needs to spend money on the purchase and delivery. She also spends time visiting the store, searching for the product, waiting for delivery, and assembling the furniture at home. Despite the well-known adage that “time is money”, recent research suggests that time and money are fundamentally distinct resources and that people evaluate and allocate them in different manners (Leclerc, Schmitt, and Dube 1995; Soman 2001; Zauberman and Lynch 2005). In this study, we focus on the influence of activating time versus money on consumers’ evaluation strategies. We show that priming time versus money during a purchase leads to the greater use of alternative-based evaluation strategies, whereas priming money leads to the greater use of attribute-based evaluation strategies. As a result, consumers display systematic preference reversals across several choice contexts.

Research Hypotheses

Time and money are two fundamentally distinct resources, and the distinction is enhanced through the different roles they play in our daily lives. On the one hand, time is independent of human effort, cannot be inventoried, and cannot be measured but not compared because its value depends on how people use it, and its opportunity cost is difficult to judge (Frederick 2009; Okada, Mina, and Hoch 2004). The evaluation of time is discretionary, and people tend to focus on the intrinsic value of spending time doing something. This ambiguity and context dependency prevents extensive comparisons across different scenarios of using time, and induced people to evaluate time according to the alternatives for which it could be used. As a consequence, time is associated with holistic information processing. On the other hand, money is created specifically for exchange and is thus fungible—its units can be substituted for each other. Consumers are also trained to compare value and utility in monetary transactions and emphasize the relative value of spending money. And consumers even tend to automatically adopt these market norms for activities that involve money (Ariely, Gneezy, and Haruvy 2008). The value of money is then judged by more explicitly measurable standards, and consumers can easily compare the value of money across transactions. We propose that the concept of money is associated with comparative information processing.

Consistent with the notion that a given concept can not only activate semantic features but also dynamic properties such as forms of behavior and goals related to that concept (Bargh, Chen, and Burrows 1996; Dijksterhuis et al. 2000), we propose that when time is activated, consumers are more likely to adopt alternative-based strategies with greater emphasis on attributes compatible with holistic evaluation. Conversely, priming money activates the greater use of attribute-based strategies whereby consumers focus more on those attributes that are compatible with comparative evaluation. We tested this general proposition in a series of four experiments.

Method and Results

Experiment 1 was conducted to test the time versus money preference reversal between options superior in verbal and numerical attributes. Time or money was activated by asking participants to note whether time or money expenditure was involved in acquiring an electronic product. The results across three scenarios reveal that verbal (vs. numerical) attributes tend to weigh more in activation of time (vs. money).

In experiment 2, we examined preference shifting between options superior in alignable and nonalignable attributes. We extended our test to experiential products. In addition, the manipulation of time or money priming was achieved by asking participants to list thoughts related to time or monetary expenditure. The results across different product categories consistently demonstrate that nonalignable (vs. alignable) attributes weigh more in activation of time (vs. money).

In experiment 3, we showed that the well-known prominence effect is enhanced after the activation of money but alleviated after the activation of time. Furthermore, a more rigorous test of the time versus money effect was achieved by only activating the concepts of time and money in general.

To further demonstrate the decision process after the activation of different concepts, Mouselab was used in experiment 4. The results show that time (vs. money) induces consumers to employ alternative-based (vs. attribute-based) strategies in subsequent decision tasks. The aforementioned preference reversals are mediated by the different decision strategies.

To summarize, in four studies involving binary choices in various categories, we show that the activation of time (vs. money) leads to a greater likelihood of choosing options that feature more verbal (vs. numerical) attributes, nonalignable (vs. alignable) attributes, and relatively less (more) important attributes. In addition, mediation analyses and a process-tracing procedure provided further evidence that the time vs. money preference reversal was due to the different decision strategies employed. Simply making people think about time versus money (in general) can shift their decision criteria and lead to systematic preference reversals.

The Impact of Price on Preference Consistency over Time

Ki Yeon Lee, University of Toronto, Canada

Min Zhao, University of Toronto, Canada

EXTENDED ABSTRACT

Past research has shown that consumers have inconsistent preference over time in interdisciplinary areas such as behavioral decision making (e.g., Thaler 1981), self-control (e.g. Rachlin 1995), and delay of gratification (e.g., Mischel, Shoda, and Rodriguez 1989). Construal-level theory (CLT, Liberman and Trope 1998; Trope and Liberman 2000, 2003) proposes that people's preference is time-dependent due to their tendency to focus on different aspects of future events depending on the time frame. People put more weight on the desirability-related aspect of a distant future event and like options with high desirability, whereas they focus more on the feasibility-related aspect of a near future event and prefer options with high feasibility (Trope and Liberman 2003). As a result of this inconsistent preference over time, consumers might regret their choice, have lower satisfaction and not redeem their committed choice (Soman 2003). Thus, knowing how to overcome this preference inconsistency is crucial for both consumers and marketers.

How can consumers overcome their preference inconsistency? Prior research has demonstrated some moderators which help people overcome their inconsistency such as practicing or planning distant-future tasks in full detail (Gollwitzer 1999; Trope and Liberman 2003), switching their attention away from the concrete qualities of the immediate temptation and focus on its abstract qualities in the long term (Baumeister and Heatherton 1996; Hoch and Loewenstein 1991; Mischel, Shoda and Rodriguez 1989), and using two different mental simulations—process vs. outcome simulations (Zhao, Hoeffler, and Zauberman 2007). Our research extends research on preference consistency over time and proposes that introducing price information or simply increasing people's price sensitivity leads to preference consistency over time due to the increased importance perception of product quality. We report findings from four experiments to support our predictions.

To test our proposed predictions, experiment 1 used two software packages from Zhao et al. (2007). We manipulated the prices of software packages as free of charge, \$10, or \$200. We replicated prior literature, illustrating that people have inconsistent preference over time for a free product (i.e., a higher preference for higher-desirability (feasibility) option in the distant (near) future). However, having price information (e.g., \$10 and \$200) increased preference towards the higher-desirability option in the near future which led to preference consistency over time.

Experiment 2 aimed to generalize our findings to a different consumption situation (i.e., the choice of a desk) and test the mediating role of perceived quality importance. Again, we found that preference inconsistency obtained from no price conditions was overcome in the price conditions. Furthermore, our mediation analyses revealed that the perceived quality importance mediated the interactive effect of time and price on relative preference between two options.

The objective of experiment 3 was to address an alternative process for the intertemporal preference consistency with price. One possible account is the pain of paying (Prelec and Loewenstein 1998; Rick, Cryder, and Loewenstein 2008). One may argue that when people see the price information of a product, they might feel painful by realizing how much they have to pay to obtain the product. And it is this pain of paying that led to a desire to get the best features to make up for the cost. If this were true, the effect of price information on preference consistency over time should

vanish if we remove the pain of paying. To test this idea, we used a scenario of winning a prize (e.g., a digital camera) from a lottery rather than paying for it themselves. Even for the prize product, we still found the intertemporal choice and preference consistency in price conditions as opposed to no price conditions. As long as people know the price of product, whether they purchase the product or obtain it as a prize does not matter. This finding suggests that the driver of the intertemporal preference consistency is not the pain of paying.

Although we replicated the effect of price on intertemporal preference in different product domains throughout experiments 1 to 3, one may still claim that giving the same price information for two different products is problematic. Experiment 4 intended to address this issue by having participants to be sensitized to price, instead of providing a specific price. To manipulate price sensitivity, we used two surveys—purchase history (e.g., listing their purchase items and prices) and price surveys (e.g., indicating their WTPs for three products). We expect that this manipulation would make participants more sensitive to price and cause them to process the descriptions of products in a similar way as they have price information. Thus, even though they do not have the price information of the target products (i.e., restaurants), we believe, the price sensitivity manipulation will give rise to intertemporal preference consistency. The results of experiment 4 showed that participants who were sensitized to price were more likely to be consistent in their choice and preference over time than those who were not.

Taken together, our findings showed that including price information leads to preference consistency across near future and distant future. Across four experiments, we obtained the same results in different product domains (e.g., software, desk, digital camera, and restaurant), and showed increased perception of quality importance as the underlying mechanism. Further, we demonstrated that this effect held for an extremely low or high price (experiment 1), just a regular price (experiment 2), a price that people actually didn't need to pay out of their own pocket and thus did not incur personal pain of paying (experiment 3), or when no specific price information was even given other than the fact that people's price sensitivity was increased (experiment 4).

We believe that this research make several important contributions. First, it contributes to extend our understanding of the underlying mechanism for inducing preference or choice consistency over time by demonstrating that price information itself or price sensitivity helps people make consistent decision, which may reduce their regret from their choice and increase their satisfaction. Second, contrary to previous literature on framing effects in pricing which has shown preference reversals, this research illustrates a positive role of price by making people consider desirability information (e.g., the quality of a product) even if the decision is for near future. Thus, price information can be a useful cue which induces decision consistency over time.

Bending Arms, Bending Discounting Functions. How Motor Actions Affect Intertemporal Decision-Making

Bram Van den Bergh, Erasmus University Rotterdam, The Netherlands
Julien Schmitt, Loughborough University, UK
Siegfried Dewitte, K. U. Leuven, Belgium
Luk Warlop, Catholic University Leuven, Belgium

EXTENDED ABSTRACT

Many consumer decisions involve trading off costs and benefits over time. For example, a consumer may think about replacing a two-year-old car with a shiny new model, rather than driving his old car and saving for retirement. A dieter may find that a fattening chocolate cake is irresistible in the short run, although a fruit salad is more beneficial in the long run. In making such decisions, consumers trade off long run and short run benefits. The factors that influence intertemporal choice receive increasing attention from marketing scholars (e.g., Malkoc and Zauberma 2006; Zauberma et al. 2009) because a better understanding of intertemporal preferences is critical to gain a better understanding of numerous consumption decisions.

Our research examines the effect of bodily feedback from motor actions on intertemporal tradeoffs. We test whether the enactment of basic motor actions, such as extending or flexing one's arm, affects intertemporal decision-making. More specifically, we conjecture that somatic motor actions associated with "approach" lead to present-biased preferences. That is, flexing your elbow may cause you to spend now rather than to save for later or may lead you to prefer chocolate cake over fruit for dessert. Prior research suggests that bodily positions are able to influence attitudes: Simply by pairing stimuli with arm flexion (where the motor action is directed toward the self) or arm extension (where the motor action is directed away from the self), rudimentary attitudes can be established (Cacioppo, Priester, and Berntson 1993). We conjecture that the effects of arm positions extend beyond attitude formation. In this research, we propose that the effects of somatic activity, such as flexing or extending your arm, generalizes beyond attitude formation and affects intertemporal choices between smaller, sooner and larger, delayed monetary rewards (hypothesis 1).

In the *pilot study*, we found that consumers using a shopping basket (i.e., arm flexion) are more likely to purchase vice products (i.e., products providing immediate benefits) at the cash register of a retailer than consumers using a shopping cart (i.e., arm extension). Because of the correlational nature of the pilot study, we designed 4 follow-up experiments to demonstrate the causal path that leads from arm flexion to present-biased preferences. In the experimental studies, participants pressed one of their hands against the table: In the arm flexion (extension) condition, participants put the palm of one of their hands under (on) the table and press upward (downward). In *study 1A*, participants showed a greater preference for vice options relative to virtues (e.g., camping versus studying over the weekend) in the arm flexion condition than in the arm extension condition. In *study 1B*, participants had a greater preference for smaller, earlier rewards (e.g., ?67 tomorrow vs. ?85 in 70 days) in the arm flexion condition than in the arm extension condition. These studies demonstrate that somatic activity associated with approach leads to a preference for immediate over delayed benefits (i.e., present-biased preferences)

Prior research suggests that increasing desire in one domain (e.g., sex, cookies, heroin, cigarettes,...) can affect intertemporal choices in an unrelated domain (e.g., money) (Field et al. 2006; Giordano et al. 2002; Van den Bergh, Dewitte, and Warlop 2008). That is, upon an increase in desire, consumers might want anything

rewarding (Wadhwa, Shiv, and Nowlis 2008). This is consistent with recent neuroscientific evidence demonstrating that many rewards are processed similarly in the brain (Breiter et al. 2001; Montague, King-Casas, and Cohen 2006): Indeed, the same dopaminergic reward circuitry of the brain is activated for a wide variety of different reinforcers (Camerer, Loewenstein, and Prelec 2005). That is, a similar set of brain reward regions responds in common to very distinct categories of reward—for example, beautiful female faces and erotic stimuli activate the classical reward circuitry associated with drug and monetary rewards (Aharon et al. 2001). We propose that somatic activity, through arm flexion contraction, activates this general neurological system processing rewards and affects intertemporal choice as a consequence (hypothesis 2). We demonstrate in *study 2* that the effect of arm flexor contraction on present-biased preferences is moderated by the sensitivity of the brain circuitry processing rewards: Only when the Behavioral Approach System is sensitive enough to be activated by somatic actions, impatience is observed.

In addition, we test whether the effect of arm flexion on present-biased preferences relies on the learned association between arm flexor contraction and the activation of the neurological reward system. A lifetime of experience of motor actions paired with differential evaluative outcomes has established an association between arm flexion and approach orientation (Cacioppo et al. 1993). In the absence of a learning process, the association between arm flexion and approach is most likely not established (hypothesis 3). We hypothesize that actions of the nondominant arm have established fewer higher-order associations between motor actions and evaluative outcomes than actions of the dominant arm. In *study 3*, we are able to confirm that the effect of arm flexion on preference for immediate gratification is restricted to reward system activation by means of the dominant arm.

These studies demonstrate that task-irrelevant somatic activity is able to influence intertemporal decision making: Simply flexing one's arm leads to present-biased preferences. To our knowledge, this is the first research (1) demonstrating effects of somatic activity on economic decision making, (2) that demonstrates that the effect of arm flexor contraction is dependent on the sensitivity of the general reward system, and (3) investigating the role of conditioning as the causal mechanism fostering higher order associations between motor actions of the arm and evaluative outcomes. A limitation of the present research is that we have only focused on the role of arm flexion and the reward system. A complementary set of studies might well be carried out to investigate the consequences of arm extension and the potential role of the punishment system (Carver and White 1994; Gray 1987, 1990; Torrubia et al. 2001). Future research could investigate whether arm extension makes individuals more likely to buy insurances (i.e., avoiding negative outcomes) or affects the choice between a smaller, immediate fine and a larger, delayed fine.

What to *Acquire* and What to *Forfeit*: The Effect of Decision Task and Product Type on Consumers' Choice between Promotion and Prevention Appeals

Tilo Chowdhury, Quinnipiac University, USA
Camelia Micu, Fairfield University, USA

EXTENDED ABSTRACT

Motivation

Consider Nina and Kaitlin, who need to replace their current DVD players. The two girls face different decision choices: Nina got a gift card from her relatives that she decided to use towards the purchase of a new DVD player (acquisition task), whereas Kaitlin got two DVD players from her relatives as a gift and she needs to decide which she will return (forfeiture task). In this decision task, they are both seriously considering two brands whose advertisements emphasize different strengths. One brand claims to “enhance one’s entertainment needs in life,” whereas the other claims to “prevent any boredom in life.” The former claim reflects a promotion-based message (Higgins 1997), involving a strategy that maximizes presence of a positive outcome, whereas the latter claim reflects a prevention-based message, involving a strategy that maximizes avoidance of a negative outcome. Considering the hedonic nature of DVD players and the different nature of their decision tasks, which brand would each prefer?

In the current research, we bring together multiple theoretical perspectives to investigate how individual consumers’ relative brand preferences for promotion (vs. prevention) messages change based on the decision task (acquisition vs. forfeiture) and product type (hedonic vs. functional) via two experimental studies. Our work is distinguished from previous research on decision task effects and regulatory focus in several ways. First, to our knowledge, this is the first research ever indicating which type of regulatory focus message individuals prefer in different purchase situations (acquisition versus forfeiture), depending on the type of product (hedonic versus utilitarian), within the same product category. Second, despite the recent work done by Dhar and Wertenbroch (2000), there has not been much follow up research done in the acquisition and forfeiture area. Our work extends acquisition and forfeiture decision situations in a new context, giving rise to a variety of interesting questions for researchers to investigate with regards to brand preferences. Finally, although a significant body of work has contributed to understanding post-ad exposure effects of message’s regulatory focus, it is noteworthy that research to-date has not examined how consumers’ evaluations are affected by direct experience with the product. Our work is designed to assess the impact of product trial on choice (Study 1), as well as to examine the role of individuals’ need for touch (Peck and Childers 2003; Study 2) on these assessments.

Conceptualization

Regulatory focus theory (Higgins 1997), proceeding from the fundamental principle that people approach pleasure and avoid pain, distinguishes between two modes of motivation and self-regulation termed as promotion and prevention goals or foci (Higgins, 1997; 1998). Building on regulatory focus theory, researchers have proposed that advertising persuasion might also depend on a message characteristic called “message’s regulatory focus,” which could also be promotion-oriented or prevention-oriented. According to Aaker and Lee (2001), when individuals’ regulatory goals match the message frames in terms of regulatory orientation (i.e., when there is goal compatibility), more positive persuasive effects result. Research extended the notion of compatibility to the context of

purchasing hedonic versus utilitarian products. Chernev (2004) suggests that hedonic products may help individuals attain promotion goals, whereas utilitarian products help them attain prevention goals. Building on these findings, Micu and Chowdhury (2010) show that prevention (vs. promotion) focus messages are more preferred for utilitarian products, whereas for hedonic products, the reversed effect is true. We expect these findings to be differentially affected by the *decision task* and provide our rationale below.

Our focus on differences between acquisition and forfeiture choices is motivated by research on loss aversion that demonstrates an asymmetry in evaluations depending on the direction of the proposed trade, that is, whether a good is acquired or forfeited relative to the consumer’s current state (Kahneman, Knetsch, and Thaler 1990); indicating consumers are more likely to experience more risk aversion in the forfeiture than in the acquisition condition. Further, according to Sanna (1996), consumers are more likely to engage in prefactual thinking when they have to forfeit an item (i.e., upward prefactual; comparison with more preferred alternatives) than when they have to acquire an item (i.e., downward prefactual; comparison with less preferred alternatives). Also, upward prefactual thinking induces negative emotions because one is about to be worse off than before (Roese 1997; Sanna 1999). To the extent that forfeiture situations spontaneously trigger upward comparisons that highlight negative affective consequences, consumers are motivated to minimize the anticipated negative emotions.

For hedonic products, the negative emotions experienced in forfeiture conditions are amplified by the feelings of guilt associated with the purchase of hedonic products, which is perceived as being decadent and involving self-gratification (Khan, Dhar, and Wertenbroch 2005). Further, research on regulatory focus indicates that a promotion focus prompts the use of relatively risky strategies, whereas a prevention focus is associated with the use of more conservative strategies. Thus, to minimize the perception of risk, as well as the negative emotions spontaneously triggered in a forfeiture (vs. acquisition) condition, consumers will choose a prevention focused message. Examined from the other direction, the acquisition (vs. forfeiture) condition should make the promotion focused appeal more valued. Although previous research indicating that promotion (vs. prevention) appeals are preferred for hedonic products has not manipulated decision task, the scenarios in those studies resemble an acquisition situation (see Micu and Chowdhury 2010).

Further, we assume that utilitarian products relative to hedonic products do not evoke much hedonic thoughts irrespective of whether the consumer is acquiring or forfeiting; instead it should primarily evoke more utilitarian thoughts focused towards the product quality/value etc. Unlike hedonic products, utilitarian products are not perceived as being decadent and involving self-gratification (Khan, Dhar, and Wertenbroch 2005) and are not associated with guilt and consequently individuals buying utilitarian products should be relatively less risk averse, irrespective of whether they are forfeiting or acquiring the product; hence they should not differ significantly in their preferences for promotion vs. prevention-oriented messages.

Furthermore, when consumers experience the products, we expect the post-ad exposure effects hypothesized above to disappear. Indeed, previous research indicates that pre-trial advertising does not impact consumers’ evaluations of highly diagnostic products (as

those used in our study) if advertising and trial provide consistent (e.g., positive) information (Hoch and Ha 1986; Kempf and Smith 1998). However, an individual's need for touch is a key variable that explains the way individuals respond to product experience (Peck and Childers 2003). Thus, we expect the effects hypothesized above to be moderated by individuals' need for touch, specifically, for hedonic products, when given the opportunity to explore the product, for forfeiture conditions, low (vs. high) NFT individuals will prefer more prevention focus messages. However, for acquisition conditions, there will be no significant differences in message preference for varying levels of need for touch. Further, in case of functional products, individual need for touch will not interact with decision task.

Methodology and Findings

In study 1, 121 undergraduate student participants were randomly assigned to one of the four experimental conditions: 2 (decision task: acquisition versus forfeiture) X 2 (product type: hedonic versus utilitarian). Participants took part individually in a brand decision task on a PC equipped with a high-speed Internet connection. After reading the given decision task scenario for a specific product type, participants were exposed to two different brand advertisements (one promotion oriented and one prevention oriented; order randomized) in the same product category. After examining the ads, they indicated their relative brand preferences and then they answered some questions regarding their task motivation, thought measures, manipulation checks, and demographics. Study 2 procedure was very similar to study 1 (112 undergraduate students). Thus, the main differences in study 2 were: individual need for touch measures and actual thought protocols were collected and individuals made their brand choice after having the opportunity to touch and visually see the two brands.

Results from study 1 confirm that individuals faced with an acquisition (vs. forfeiture) decision task engage in more hedonic thoughts and do prefer a more promotion vs. prevention oriented brand message and this is mainly true for buying hedonic products. Also, results from study 2 provide support that an individual's need for touch attenuate the effects of decision task on relative brand message preferences, only in case of hedonic (not, functional) products.

Mixing It Up: The Effects of Cognitive Contrasting on Cognitive Resource Availability and Advertisement Recall

Ryan S. Elder, University of Michigan, USA
James A. Mourey, University of Michigan, USA

EXTENDED ABSTRACT

Resource depletion theory is predicated on the idea that cognitive resources are finite and limited. Thus, tasks involving cognitive effort tap into this finite pool of resources and, in doing so, leave fewer resources available for subsequent tasks requiring cognitive effort (Engle et al. 1995, Baumeister et al. 1998). These effects have been shown with self-regulation and self control in the domains of dieting and emotion regulation (Vohs and Heatherton 2000), avoiding impulse purchases (Vohs and Faber 2007), and resisting persuasive messages (Wheeler, Briñol, and Hermann 2008). Additionally, recent research has extended these findings in to the domain of choice (Poceptsova et al. 2008).

The prior literature, therefore, displays the robust findings that a task that utilizes cognitive resources will lead to fewer cognitive resources in a subsequent task. However, the malleability and replenishing of these resources has received less attention. In their self-control strength model, Muraven and Baumeister (2000) show that even self-control failure could lead to stronger self-control in the long-term suggesting that the resource pool could, in fact, increase over time. Furthermore, findings in cognitive neuroscience exhibit the brain's flexibility in addressing the need for cognitive resources through a feedback loop involving the dorsolateral prefrontal cortex and the anterior cingulate cortex (MacDonald et al. 2000).

We propose that the malleability of cognitive resources will be greatest when a series of tasks oscillate between levels of difficulty, therefore disrupting the feedback loop and causing the brain to plan for this uncertainty in resource need by increasing resource availability. Therefore, individuals presented with tasks placing inconsistent (vs. consistent) demands on cognitive resources will have greater (fewer) cognitive resources available for subsequent tasks. Following the oscillation in task difficulty, we anticipate that the resulting increase in cognitive resources will lead to heightened recall of advertising information contained within the series of tasks. Finally, we anticipate that an explicit measure of cognitive resource availability will mediate the relationship between task consistency and advertising recall.

Study 1

The purpose of the initial study is to show the fundamental idea that a series of tasks placing either consistent or inconsistent demands on cognitive resources will produce differences in the availability of cognitive resources available for a subsequent task.

Our study design is a 2 (first task: easy or hard) x 2 (second task: easy or hard) between subjects design. One hundred and twenty-one participants were told they would be solving a series of math questions for the GMAT®. Each participant answered six questions that were either all hard, all easy, alternating beginning with hard or alternating beginning with easy. Following the six math questions, participants were given an anagram task, which is our measure of cognitive resources. Specifically, we focus on the time they spent solving the anagrams (Muraven, Tice, and Baumeister 1998).

Our primary dependent variable of interest is the time participants spent solving the anagrams. Neither the main effect of first task difficulty nor the effect of second task difficulty is significant; however, we do get a significant interaction between first and second task difficulty ($p < .05$). Examining the means we see that on average,

participants in the alternating conditions spent significantly more time on the anagram tasks than those in the consistent conditions ($M_{\text{alternating}} = 266.82, M_{\text{consistent}} = 194.96$). Thus, as predicted, alternating task difficulty leads to a higher availability of cognitive resources than does maintaining consistency.

Study 2

With study 2, we seek to replicate the effects of study 1 in an advertising context. Additionally, although the phenomenon found in study 1 was theorized to be due to cognitive resource availability, this underlying process was not explored in the initial study.

The design for study 2 closely mirrored that of study 1, except that the second, fourth, and sixth task was to view an advertisement. The first, third, and fifth task in the sequence was a math question from study 1. We manipulated advertisement difficulty by varying the typeface used to convey product relevant information (Sung and Schwarz 2008). In sum, we used a 2 (math question: easy, difficult) x 2 (advertisement: easy, difficult) between subjects design.

One hundred participants completed the study, moving between the math questions and the advertisements. In addition to the questions from study 1 (and the anagram task), following the task sequence participants reported their current enjoyment of performing difficult tasks. This was captured as a more explicit measure of cognitive resource availability. They then proceeded to answer questions regarding the advertisements they had seen earlier, including any specific information they recalled.

An analysis on time spent on the anagram task reveals only a significant interaction of the two factors, replicating our findings from study 1. More importantly, we also get the hypothesized two-way interaction on advertising recall. The means exhibit the hypothesized relationship as participants in the contrasting conditions recalled significantly more information than those in the consistent conditions ($p < .01$; $M_{\text{contrasting}} = 4.96, M_{\text{consistent}} = 3.41$).

Our explicit measure of cognitive resources (current enjoyment from performing difficult cognitive tasks) also revealed only the significant interaction with participants in the contrasting conditions, reporting significantly more enjoyment than in the consistent conditions. Indeed, this measure partially mediates the relationship between cognitive contrasting and recall. (Sobel $z = 1.77, p < .08$).

Study 3

Study 3 was designed to replicate the findings from study 1 and study 2 with a direct manipulation of cognitive resources (cognitive load). Participants memorized either a 10 or 2 digit number and then proceeded to view the advertisements, and complete the anagram task, as well as report their current enjoyment of difficult tasks.

As in studies 1 and 2, an analysis on our implicit measure of cognitive resources (time spent on anagrams) reveals the hypothesized interaction as participants in the contrasting conditions spent significantly more time on the anagram tasks than those in the consistent conditions. Similar significant interactions were present for our explicit measure of cognitive resources ($p < .05$), and advertisement recall ($p < .05$). As in study 2, the explicit measure of cognitive resources mediates the relationship between cognitive contrasting and recall (Sobel $z = 1.97, p < .05$).

Devaluation and Fluency Effects of the Depth Position of a Non-focal Image on Image Evaluation

Sangdo Oh, University of Illinois, USA
Sukki Yoon, Bryant University, USA
Patrick Vargas, University of Illinois, USA

EXTENDED ABSTRACT

People live and consume in the three-dimensional (3D) world. Yet most prior research into consumers' perception of advertising has been limited to just two physical dimensions: horizontal and vertical. Presently we examine an under-studied topic—how the position of an image on a third dimension—depth—influences consumers' evaluation of an image. Consumers encounter numerous images appearing in various points on the depth dimension: billboards are erected near and far alongside the highway; cereal boxes on promotion are displayed near and far in the aisles of a grocery store.

Consumers often encounter marketing messages that are placed outside their focal point (Ferraro, Bettman, & Chartrand, 2009). For example, suppose that a consumer is reading the news online and notices an image that is transparently superimposed on the headline and appears to be nearer than the headline (the depth dimension operating in a 2D environment).¹ Or consider someone playing a 3D Tetris game when an image suddenly appears either nearer or farther than the target. Given that the reader or gamer has focused attention on the task-relevant target—a headline to read or a shape to match—would they evaluate the image differently depending on whether the image appears nearer or farther than the target? Would this depth position effect vary for consumers who are trying to read or trying to play a game when the encounter occurs? Does the image, itself, matter (e.g., meaningless abstract or brand logo)?

Marketers enjoy one potential advantage when they place an image in front of, rather than behind, a focal target: the image has direct, upfront exposure. But this advantage also has a potentially threatening flip side: viewers might be irritated by an ad's invasiveness. A practical dilemma, then, is whether the advertiser should go with the foreground position for better exposure, or the background position for less intrusiveness (Edwards, Li, & Lee, 2002). Although marketers recognize that question is important, the literature has been silent on this point. In the virtual world, particularly, this question is even more pressing because technology enhances advertisers' abilities to introduce images in the foreground and background of web pages. Unfortunately, the psychological consequences of the depth position of visual stimuli are largely unknown. The present research is the first, to the best of our knowledge, to explore this question.

Although no direct evidence has indicated whether the position of stimuli on the depth dimension produces different evaluations of an image, two contrasting predictions may be deduced from the extant literature: devaluation and fluency effects (e.g., Raymond et al. 03 vs. Janiszewski and Chandon 2007). We test these rival hypotheses in Experiment 1 in a 2D setting and in Experiment 2 in a 3D setting.

H1.1. *The Devaluation Hypothesis:* A foreground image relative to the attentional focus will be evaluated more negatively than a background image.

H1.2. *The Fluency Hypothesis:* A foreground image relative to the attentional focus will be evaluated more positively than a background image.

Furthermore, we question whether the depth position effect (H1) would be contingent on (1) whether a consumer is in the

conceptual or perceptual information processing (H2), and (2) whether the distracting image is a meaningless abstract or a brand logo (H3).

H2. When the focal and non-focal stimuli elicit different processing modes, foreground stimuli should be evaluated more favorably than background stimuli.

H3. When focal and non-focal stimuli elicit similar processing modes, foreground stimuli should be evaluated more negatively than background stimuli.

EXPERIMENT 1

Participants in the foreground image condition were exposed to a set of abstract patterns that were transparently superimposed in front of the target words; participants in the background image condition were exposed to the same set of abstract patterns that were transparently superimposed behind the target words.

Participants in the foreground image condition ($M_{front} = 4.66$) exhibited a higher degree of favorability toward all abstract figures than did participants in the background image condition ($M_{behind} = 3.75$). This results support the fluency hypothesis (H1.2) but not the devaluation hypothesis (H1.1) in a simulated 2D setting.

EXPERIMENT 2

We tested H2 and H3 in a 2 (Image Position: Front vs. Back) x 2 (Task Nature: Word Recognizing vs. Arrow Matching) x 2 (Distracter Type: Abstract vs. Logo) factorial design.

The results from Experiment 2 showed that when perceptual distractors (abstract figures) and target objects appeared together in different positions on the depth dimension, the fluency effect (i.e., higher favorability for the nearer-than-target image over the farther-than-target image) emerged among participants in the conceptual processing mode (i.e., the task-distractor mismatch), but the devaluation effect (i.e., lower favorability for the nearer-than-target image over the farther-than-target image) emerged among participants in the perceptual processing mode (i.e., the task-distractor match). However, when participants saw conceptual distractor (brand logos) instead of perceptual distractors (abstract figures), the devaluation effect emerged in the conceptual processing mode, but no such effect, if not a reversal, emerged in the perceptual processing mode.

The findings are theoretically and practically important in several ways. First, they shed light on how the conceptual or perceptual natures of a task determine the depth position effects of an image in a 3D setting. Second, the findings show that the relationship between the depth position of an image and the nature of a primary task is contingent on the type of image that appears. Third, the findings offer marketers principles to adopt and ways to improve their understanding of what they should show and where they should show it on the depth dimensions of reading- and gaming-oriented websites.

Although the depth dimension is a 3D-relevant concept, it could still play a role, as we see in this example, in influencing one's perception in a 2D setting.

When White Space Is More than Burning Money: Economic Signaling Meets Visual Commercial Rhetoric

John Pracejus, University of Alberta, Canada
Thomas O'Guinn, University of Wisconsin-Madison, USA
Douglas Olsen, Arizona State University, USA

EXTENDED ABSTRACT:

When White Space Is More than Burning Money: Economic Signaling Meets Visual Commercial Rhetoric

The pioneering work of Nelson (1970, 1974, & 1978) brought forth the idea that under certain conditions high advertising expenditures can inform consumers about particularly high product quality, even if consumers never actually see any of the advertising. While this mechanism of action for the economic analysis of advertising is widely accepted, there are few demonstrations of consumers inferring quality from advertising elements which suggest "burning money". One set of studies show that ad repetition can lead to inferences of quality (Kirmani, 1997; Moorthy & Hawkins, 2005) or ad size (Kirmani, 1990; Homer 1995). As Moorthy and Hawkins (2005) pointed out, ad frequency effects are thoroughly confounded with mere exposure effects leaving the role of signaling in doubt for those studies that manipulated frequency. This limitation effectively leaves ad size as the only advertising variable purported to indicate product quality to consumers through a burning money signal.

Both Kirmani (1990) and Homer (1995) manipulated ad size in their studies. Surprisingly, however, both studies also manipulated the amount of white space in the ads. Given this, it is possible that large ads did not signal quality to consumers via inferences about market power. An alternative explanation for the behavioral effects of white space proposed by Pracejus, et al. (2006) holds that in North America, white space is a well-known and widely understood trope in the lexicon of modern visual commercial rhetoric, which developed from specific historical moments during the late 1950's and Early 1960's when advertising and commercial design were strongly influenced by the minimalist movements taking place in art.

Given these two potential ways white space can influence consumers, two studies were conducted. Study one contrasts white space against ad size. If the economic signaling explanation is correct, there should be little difference between these two expensive and extravagant advertising techniques. Study two compares the effect of white space across cultures. If the economic signaling explanation is correct, there should be little difference in the impact of white space across cultures.

Study 1

Participants. One hundred and eighty-four undergraduate students at a North American university.

Design and Stimuli. Three ad conditions (full-page, low white space; full-page, high white space; and, 1/5th page low white space) were used, with 2 product category replicates for each ad (furniture and mutual funds). Participants were told they would view an ad for Hastings (furniture/clothing) that would run in, a British newspaper.

Dependent Variables. After viewing the ad for 30 seconds, participants responded to 10 statements about Hastings along a seven-point, 1= "Strongly Disagree" and 7="Strongly Agree" scale. Eight of these statements were from Pracejus, et al. (2006). Attitudes and purchase intentions were also taken.

Results

For cases where the type of the advertisement differed, contrasts were conducted to examine the source of the difference. The impact of ad size alone can be assessed through contrasting the 1/5th page

ad with the full page, low white space ad. Here, the only significant impact of ad size is on the item *Hastings has considerable market share* ($F=14.71, p<.001$). This is in keeping with the expectations of the burning money signaling theory.

When the 1/5th page ad was compared with the full page, high white space ad, however, we observed significant increases in beliefs about Hastings in 6 out of 8 of the specific meanings expected to be conveyed by white space, as well as significant increases in attitudes and purchase intentions.

Study 2

The second way the rhetorical account can be distinguished from the burning money account is cross culturally. If the socio-historical account is accurate, we should expect a different—weaker, narrower—impact of white space on consumers outside of the North American context. To explore the role of culture and social history on the meanings conveyed to consumers through the use of white space in advertising we compared responses to white space across groups with different social histories.

Participants. 260 undergraduate students 130, at a university in North America, and 130 at a university in Hong Kong.

Design and Stimuli. A 2 (product category) x 2 (high/low white space) x 2 (country of residence) between-subjects design. All advertisements contained a picture of a clock, accompanied by a logo for a fictitious brand (Hastings), along with ambiguous copy like that used in Study 1. Exposure and cover story and dependent variables were similar to study 1.

Results

The impact of white space on brand perceptions varied significantly by country. After mean centering by country and product class, an ANOVA revealed a significant interaction of white space and country of residence on quality, risk, prestige, trust, and overall brand attitude. The interaction was also marginally significant on expensive ($F=3.7, p>.055$) and leadership ($F=3.4, p>.06$). So, for nearly every meaning associated with the social history of white space, its impact was principally dependent on culture.

For North American participants, white space significantly increased perceptions of quality, low risk, prestige, trust, and leadership. It also significantly increased overall brand attitude and purchase intention. For the Hong Kong participants, however, white space only significantly influenced perceived market share ($F=5.29, p<.023$). It also marginally impacted expense ($F=3.57, p<.061$) and trust ($F=3.25, p>.074$). However, for both of these measures, the impact of white space was in the opposite direction to the North American participants. That is, low white space was marginally predictive of the brand being expensive and trustworthy.

General Discussion

Whereas white space in an ad can imply that the advertiser is a large company much like a large ad does, it does not only mean the company has money to burn. In North America, it turns out that white space in ads implies much more about the brand.: quality, prestige, trust, etc. In Hong Kong, white space only implied a large market share. This is convincing evidence that the rhetorical account

adds substantially to our understanding compared to economic signaling alone.

The Confluence of Ideologies in Consumption Activities

Lindsay McShane, Queen's University, Canada

EXTENDED ABSTRACT

Globalization has facilitated the transfer of cultural activities across borders such that consumers in Western societies increasingly engage in activities and use products that have roots in other cultures. As consumers adopt these products and participate in these activities, they draw on elements from their own culture rather than fully embracing the product/activity in its traditional form, along with its existing cultural underpinnings. For example, while yoga has philosophical roots in India (Eliade 1973), Western consumers only selectively draw on elements of this ancient practice and instead engage in a revised form of yoga that also reflects local cultures (Marowetz 2007). This adaptation is particularly interesting given these activities/products often embody ideological values that lie in stark contrast to the capitalist ideology of Western societies. For instance, given the centrality of transcendence in yoga, consider the divergent views across Eastern and Western philosophies of the relationship between technology and transcendence. Western consumers are quite adept at uniting their "infatuation with technological advance" with their "spiritual quest for transcendence" (Sherry 2000, p. 276). In fact, Western consumers rely heavily on technology to advance several capitalist ideals (e.g., freedom, efficiency, control) and are accustomed to drawing on technological resources to enhance consumption experiences and achieve goals (Kozinets 2008; Simpson 2003). In contrast, Eastern philosophy adopts an experiential and internally-driven worldview of transcendence (Gould 1991a). Eastern philosophy demands the rejection of the external world (i.e. material possessions), stating that this is necessary to becoming attuned with your inner self and achieving connectedness with the universe (Eliade 1973). Yet, Western consumers seamlessly integrate ancient practices into the capitalist marketplace such that the fusion of Eastern philosophies with Western ideology has become ubiquitous in culture. This paper seeks to enrich our understanding of the lived experience of consumers who negotiate these ideological conflicts and to examine why they may choose to immerse themselves in these conflicts.

To develop a rich understanding of the consumers' lived experience as they engage in activities and use products that blend disparate ideologies, I conducted six phenomenological interviews with yoga practitioners in Western cultures. The interviews, which ranged from 60 to 90 minutes, were initiated with a grand-tour question yet remained largely unstructured so that participants could steer the interview. Probing questions, adapted to the language of the participant, were asked as needed to facilitate a fulsome discussion. While the confluence of ideologies is relevant across numerous consumer activities, yoga is a particularly rich context in which to examine the phenomenon. *With historical roots in India, yoga refers to "any ascetic technique or any meditation method"* (Eliade and Trask 1970, p.3). *The focus is on achieving nirvana, a state of nothingness that contrasts with the materialist orientation of Western societies (Ojha 1999). Yet, despite these philosophical roots that seem antithetical to capitalism, yoga has been incorporated into Western society. American consumers buy technical yoga clothing and mats, engage in yoga forums and retreats, purchase yoga videos, join yoga studios and subscribe to yoga magazines (Morawetz 2007; Moran 2006).*

The interviews suggest that consumers are aware of the disparate worldviews that they are uniting in constructing their Westernized yoga practice. The participants actually held strong normative views of yoga and wrestled with the notion that their yoga practice diverged from these normative views. Interestingly, the gap between their yoga practice

and normative yoga appeared to stem from the use of technology and its underlying values. In fact, a dominant theme across interviews was the conflicting presence of technology as both a liberator and constraint. Consumers used technological resources extensively to enhance their yoga experience (e.g., to engineer an ideal environment), yet were so dependent on these technological resources that they felt constrained by these same liberating resources. For example, because the interviewees depended on certain external resources (e.g., music, temperature, DVDs) to achieve instrumental goals, they were no longer self-sufficient and instead dependent on these resources. Thus, central to understanding the consumers' lived experience is the contradictory relationship with technology. Technology at once liberates them from constraints (e.g., time) and yet constrains them from achieving their normative views of yoga.

The interviews also shed light on why consumers may choose to immerse themselves in these ideological conflicts. It appears that one reason consumers may do so is to authenticate their hedonistic pursuits. For instance, participants framed traditional Western forms of exercise (e.g., aerobics), which focus solely on physical benefits with little meaning behind the movements, as more shallow and superficial. Thus, unable to authenticate their hedonic needs through exercise routines that align with capitalist ideology, consumers may endeavour to do so by engaging in activities that have socio-historic roots in non-capitalist systems of philosophy. In a sense, consumers seem to use the inherent conflict associated with these activities to their advantage, reworking the Eastern ideology of individual transcendence to authenticate their practice while also satisfying hedonic needs. By co-opting cultural elements from Eastern philosophy, consumers can lend authenticity to their consumption experience without sacrificing hedonic pursuits such as comfort, efficiency and enjoyment.

This paper extends the literature in two important ways. First, whereas previous work notes that certain people turn to Eastern health solutions in rejection of Western scientific practices (Thompson 2004), this study notes that one reason consumers may instead engage in activities from Eastern cultures to authenticate their individual hedonistic pursuits. Second, this study suggests that consumers draw on ideological discourses not only to craft their identities (Denzin 2001; Hebdige 1979; Holt 2002; Holt and Thompson 2004) but also to construct meaningful consumption experiences. Broadly speaking, this paper enriches our understanding of the consumer's lived experience as they participate in activities that embody ideological conflicts. Despite the inherent contradictions in the activities, which seems to stem, in part, from a conflicted relationship with technology (i.e., technology as liberator and constraint), consumers are able to draw on Eastern ideologies to authenticate their hedonic pursuits and craft an authentic consumption experiences. In doing so, consumers demonstrate how they can fluidly bring together seemingly disparate ideological elements into their daily consumption activities.

Beyond Consumer Boundaries: A Conceptual Model for Understanding the Consumer Role and its Impact on Behavior

Jodie Whelan, Richard Ivey School of Business, Canada

EXTENDED ABSTRACT

Despite the prevalence of the consumer role and the existence of a discipline devoted to studying the consumer, little is known about the consequences of being a consumer. The relevant empirical findings, though indirect and scattered, seem centered on the effects of living in hyperchoice and on making choices (Mick, Broniarczyk, and Haidt 2004; Schwartz et al. 2002; Vohs et al. 2008a). As a field, we have yet to explore whether the consequences of being a consumer extend further, “perhaps degrading key aspects of human psychology, including moral character” (Mick et al. 2004, 207) and penetrating non-consumer domains. Furthermore, little is known about the consumer role in general. The actual norms, expectations, values, and behaviors that define the consumer role have yet to be specified. Until we understand everything this role entails, we cannot begin to fathom its consequences on the individual. Thus, the purpose of this article is to provide a conceptual framework for exploring the consumer role and its potential spillover into non-consumer domains. Using nine theoretical propositions, I outline how individuals transition into the consumer role; how behavior may be altered by the consumer role; and when and why the consumer role may spillover into non-consumer domains.

Role theory began as a theatrical metaphor. Like actors playing specific roles, human beings behave in ways that are different and predictable depending on the context and the role they occupy (Biddle 1986). Role theory is not new to marketing; however, it has yet to be applied to the *consumer* level (see Wilson and Bozinoff 1980 for a comprehensive overview of role theory and marketing). The study of role-related problems is most frequent in management studies and gender/family studies, where the primary focus seems to be how individuals transition between work roles and home roles (Ashforth, Kreiner, and Fugate 2000; Burr 1972).

Like any other role, the consumer role begins with a role-relevant cue (proposition 1). Cues specific to the consumer role could include such things as a salesperson, a store, an ad on TV, and even money. Whether cues are successful at triggering consumer role entry will depend on the degree of role integration (i.e., the existence of role boundaries; Ashforth et al. 2000) and the strength of the situation. I propose that, for most North Americans, the consumer role is highly integrated with other daily roles (propositions 2 and 3); thus, consumer role entry is likely to be mindless and automatic—all that is required is a role-relevant cue. Furthermore, even if individuals have created idiosyncratic boundaries around the consumer role (i.e., voluntary simplifiers), consumer role entry will still be automatic if the situation is strong enough (i.e., context-appropriate; proposition 4).

The next three propositions concern consumer role definition. They are all based on the assumption that, because these expectations or behaviors are so common to consumer experiences, they have become ingrained in the consumer role and detached from their original sources. Subsequently, being in the consumer role is all that is required to experience their effects—the usual antecedents are no longer necessary. Specifically, I propose that the consumer role triggers materialistic values (proposition 5), engenders a sense of entitlement (proposition 6), and provides feelings of empowerment (proposition 7). While the propositions concerning materialism and entitlement have direct behavioral implications, empowerment is viewed more as a benefit of the consumer role. This distinction is important when considering why and how the consumer role is likely to spillover into non-consumer domains.

While these consequences may be acceptable in a consumer context, they could be extremely inappropriate and even harmful in other situations. Consider materialism. We know that high materialism leads to increased possessiveness and nongenerosity (Belk 1985). Though this may be advantageous while shopping, how could it impact behavior in non-consumer contexts? Will a mom in the consumer role be less responsive to her children’s needs and more focused on her own desires? Consider entitlement. Will a student in the consumer role feel entitled to above-average marks—after all, he is *paying* for his education?

Given the frequency and mindlessness with which individuals can enter the consumer role and the unique benefits it can provide, I believe spillover is highly probable. Spillover occurs when the consumer role is active in an inappropriate context, and it can happen for two different reasons. As we become more practiced at enacting a role, transition is likely to become more automatic and more mindless (Ashforth and Fried 1988); thus, encountering a role-relevant cue could lead individuals to enter the consumer role without any regard for whether or not such behavior is appropriate (proposition 8). This will be most likely to occur when the consumer role is highly integrated; if the role is highly segmented, boundaries should prevent mindless entry when in an inappropriate context.

Proposition 8 details how spillover can occur due to dysfunctional role entry. Proposition 9 focuses on role exit. Though highly integrated roles should be easy to transition in and out of, individuals may be reluctant to exit a role when they are good at performing it and/or the role is extrinsically rewarding and intrinsically satisfying (Kohn and Schooler 1983). For some, the consumer role may be the only role in their lives that provides respect, courtesy, and attendance to their needs (Wänke 2009); thus, even though a different role may be more suitable, individuals may be unwilling to exit the role. The consumer role and its role-relevant behaviors persist even though they may no longer be appropriate.

Fully understanding the consumer role and its impact on both consumer and non-consumer domains will provide new and valuable insight into both individual- and societal-level behavior. We have long acknowledged that we are a society of consumers—it’s about time we move beyond consumer boundaries and begin to explore everything else this entails.

Where to from Here? A Comparison of the Meanings Designed Into Three Public Spaces.

Jan Brace-Govan, Monash University of New South Wales, Australia

EXTENDED ABSTRACT

This paper challenges the commonly presented view in marketing that space is open to negotiation and that meanings emerge from individual experiences within spaces. Instead the role of space in conveying specifically created or designed meanings is explored and suggested as a research area with potential.

Drawing from anthropology, Sherry (1998) noted that the spaces people shopped in had an effect on the shopping experience. Thus open air markets were different to the enclosed shopping mall and others examined meanings for shoppers (Sandicki and Holt 1998) and the immersed experience of bridal salons (Otnes 1998). Kozinets and colleagues uncovered the spectacular consumption space provided by ESPN Zone t (Kozinets et al 2002, 2004), while Maclaran and Brown (2005) considered the literary metaphor of utopia to discuss a reconstruction of a shopping space. Other consumer culture research explored the joint production of space through events like the rodeo (Penaloza 2001) and the fantasy world of Rocky Mountain men (Belk and Costa 1998) and Star Trek (Kozinets 2001). In this research the self-expression and self-transformation that were part of the immersed imaginings of consumers was key. Overall though, in these studies the co-creative and dialogic elements of consumer experiences within these spaces was the focus of the research. That spatial elements had a joint part to play is not the issue here. Instead the focus is shifted to space as a means to convey specific meanings that were selected by the designer.

Specifically this project explored whether the intended design of physical open space, such as public gardens, was understood and experienced as intended by consumers. A great deal of marketing relies on the visuality of consumption to comprehend advertisements, web sites, and other means of communication (Schroeder 2002). And the marketing discipline has expended quite some effort on understanding this feature of human consumption. However, little attention has been paid to the vista, or the visual display that is a designed open space. If the agenda of environmental sustainability is to gain any ground then the visual aspects of our landscape will become increasingly important both as a means of gauging the extent of the sustainability agenda, and also as a way in which to represent in public the values of "being green". This initial, exploratory study is a first step on this journey into a research sphere that is expected to be substantial. As such the paper is not intended to offer closure but instead begin to open up questions that need to be examined in much greater depth.

Method

A modified grounded theory method was adopted and was appropriate given the exploratory nature of this investigation. In this process a preliminary literature was used to direct the initial engagement of the project and devise research questions. The ensuing stages were selected through analysis of the findings from the previous steps. This generated further research questions, established criteria for the selection of suitable sites and created related and relevant interview questions (Goulding 2005). After developing an understanding of each site through literature and other secondary information, interviews were taken with 15 informants relevant to each public space. Interviews were transcribed verbatim and the text was analysed for themes through open and axial coding (Goulding 2005). As each example space builds from the analysis of the previous space, the findings for each section of the project will be presented separately at first. A comparison across all three will draw the threads of the argument together. A short closing

discussion identifies the ensuing research question(s) that informed the selection of the next space and its relevant informants. [Images included in the presentation.]

Recreational Space provided within a real estate development. In all six interviewees confirmed the symbolism presented in marketing materials that suggested the recreational site encouraged feeling of escaping the hustle and bustle of the city and created the sensation of an oasis. Although these consumers had all chosen to engage with this space so their agreement was unsurprising, the point for this first example was that the intention of the designers was indeed upheld.

Cultural Space provided by a migrated group to celebrate their culture. This example asked, what is the consumer experience when there is a distinct difference between the symbolism from which the space is designed and the symbolism in which the consumer is living? A public garden created by the Chinese community as a gift was the next example. Five informants were quizzed about their understanding of the Chinese garden's symbolism. Three were first generation Chinese and two were second generation Chinese. There were no differences in their views about Chinese gardens and their experience of them. All five enjoyed the gardens as a place of recovery and respite reflecting the intention of the garden design. However, there were differences in their understandings of the symbolism. This raised the question about the extent to which visual information can convey ideological density

Communal Space Provided as a Community Garden

Community gardens have existed for several decades and there are well known examples in New York, Boston (Barlett 2005) and around the UK. Interestingly this space presented a visual mayhem of the individualized plots and the overall impression of disaggregation in terms of vista was a strong contrast to the consistency of the singular design of the previous examples. Nonetheless, the space as a whole presented quite a clear picture as the encompassing and welcoming community that it claimed to be and thus achieved a collective symbolic representation above and beyond the individualized plots. Four interviewees discuss how their activism engages with politicians and corporations, thus opening up the co-optation of this space to the politicians and corporations to utilize in their branding.

The final discussion is formed around the function, structure and aesthetic of the space (Schroeder 2002) to suggest that the disjunctions in understanding here need further research in particular around sustainability, politics (Mansvelt 2009) and brand image.

Thank you to Michelle Dichmann, Peta McIver, Jun Yao, and Ringo Teng for their assistance and enthusiasm. However, they are not responsible for the current interpretation; this is all my own.

Learning to be Cosmopolitan

Bernardo Figueiredo, University New South Wales, Australia
Julien Cayla, University of New South Wales, Australia

EXTENDED ABSTRACT

Cosmopolitanism refers to a perspective that considers that all individuals are citizens of the world. In recent years, it has received considerable research attention from consumer researchers (Cannon and Yaprak 2002; Cleveland, Laroche, and Papadopoulos 2009; Holt 1998; Thompson and Tambyah 1999). These studies recognize the overarching influence of cosmopolitanism as an important shaper of consumption in the global arena, which moderates and mediates many consumer attitudes and values. Despite the fact that consumer researchers agree that cosmopolitanism has a profound impact on consumer behavior, they have not explained how consumers acquire such dispositions.

There is a dearth of studies in the literature which investigate the process of becoming cosmopolitan. Current literature focuses on the relationship between cosmopolitanism and other consumer dimensions such as ethnocentrism and materialism (Cleveland et al. 2009), and fails to the dynamic nature of the construct itself. Thompson and Tambyah (1999), in one of the few studies that view cosmopolitanism as a dynamic process, point out that the expatriate informants of their study are neither completely cosmopolitan nor completely local, but rather aspiring to cosmopolitanism. The authors offer extensive ideographic data on masculine and feminine narratives present in expatriate discourses and relate them to the postcolonial economy. However, they cannot explain why some expatriates can adopt cosmopolitan ideals while others cannot. The literature lacks explanations on how consumers learn to be cosmopolitan. Therefore, this article aims to fill that gap by answering the following questions: *How do consumers learn to be cosmopolitan and what are the implications of that for consumer research?*

In our first section we differentiate among four types of cosmopolitanism in the literature: a) *philosophical cosmopolitanism*, a moral and political standpoint that seeks universal rights and global justice; b) *analytical cosmopolitanism*, an investigative tool and solution for problems created by the second modernity (Beck); c) *banal cosmopolitanism*, concrete processes of diversification and complexification of the world; and d) *ideological cosmopolitanism*, a set of neoliberal ideas historically linked to the growth of capitalism and therefore promoting values of mobility, fluidity, individuality, and flexibility. This research addresses the last two types of cosmopolitanism. In other words, we want to know how the cosmopolitan ideology is learned and how it integrates with diversification of the world.

We chose transnational mobile professionals (Bardhi 2004) as our research context, as the literature and travelling patterns indicate a high possibility of finding cosmopolitans among this group. The research took place in Sydney, Australia, a multicultural city that attracts expatriates from all over the world. We conducted 17 in-depth interviews with 11 transnational mobile professionals. Informants were asked to describe their life trajectories and explain their motivations for living in different countries. The identification of major life themes and life projects (Mick and Buhl 1992) together with processes of comparison, dimensionalization, and integration in categories relevant to the processes related to transnational mobility and the reproduction of cosmopolitanism.

Our findings show that cosmopolitanism, as an ideology of dominant classes, reinforces ideals attached to flexibility, adaptability, mobility, and diversity that provide transnational professionals with extra motivation for moving and seeking new and different

places. Cosmopolitans process these novel experiences as opportunities for self-development and for exercising mobility skills valued by dominant classes. For cosmopolitans, mobility becomes a means of building up competencies, which are necessary in the competitive capitalist arena. These competencies involve the ability to orchestrate knowledge, experiences, and stories from different places and transform them in resources that are reprocessed as social, cultural or economic capital.

Cosmopolitan ideology, as a set of practices and skills, must be learned. As demonstrated here, it is by experiencing cosmopolitanism in a prolonged manner, through social institutions (e.g.: family, schools, workplaces) that especially convey cosmopolitan ideals, that mobile professionals acquire it in an embodied form. However, institutionalized cosmopolitanism is not accessible to everyone. These competencies are class based and represent a form of global-cultural capital that is not accessible to all. Transnational mobile consumers who have little contact with institutionalized forms of cosmopolitanism cannot incorporate embodied forms of cosmopolitanism. As a result, they do not learn how to be cosmopolitan. Moreover, they tend to interpret their mobile experiences in very different ways from those who are more cosmopolitan; rather, they see it as difficult and painful, which only reinforces their class position.

The performance of cosmopolitan practices allows individuals to highlight the benefits of their mobility and underplay the problems caused by it in a way that creates opportunities for capital accumulation and reproduction of the status quo. They actively consume cultural differences and display these differences as assets, which sets them apart from the less travelled. Their cosmopolitan identities are not linked to the objects themselves but to the way they organize consumption practices and objects. These creative uses of consumption products and experiences function as authenticating acts (Arnould and Price 2003) that transform personal agency into cosmopolitan self-narrative. These acts however are only meaningful to the extent they can be used to differentiate the performer from the others.

Explaining cosmopolitanism as an ideology which moves through global dimensions of cultural capital has many implications for consumer research. First, it becomes clear that cosmopolitanism is not accessible to everyone, which implies that underlying the debate around cosmopolitanism in the marketplace, there should be an awareness of how the society is stratified. Second, we use caution when inferring democratization of the marketplace, as different objects and experiences will be filtered differently, depending on the level of embodied cosmopolitanism one has. Third, according to the data, cosmopolitanism as an ideology seems to be adopted by people from different parts of the world, which suggests some isomorphism of structures present in different countries. In analytical terms, this is good because it creates a platform of comparison between marketplaces, in the so-called global structures of common differences (Wilk 1995) Fourth, pointing out the modes in which cosmopolitanism exists (institutionalized, embodied, and objectified) creates constructs that can be further used to explain relationships between consumption and cosmopolitan ideology in the marketplace.

Evidence for Two Faces of Pride in Consumption: Findings From Luxury Brands

Brent McFerran, University of British Columbia, Canada

Karl Aquino, University of British Columbia, Canada

Jessica Tracy, University of British Columbia, Canada

EXTENDED ABSTRACT

What is it that consumers feel when they adorn themselves with products that speak in the silent language of luxury, exclusiveness, and extravagance? Undoubtedly, one of the emotions experienced in such situations is pride. The *Oxford English Dictionary* defines pride as “a high or overweening opinion of one’s own qualities, attainments, or estate, which gives rise to a feeling and attitude of superiority over and contempt for others.” This definition is consistent with ancient Greek and Biblical thought condemning “excessive pride,” or “hubris”. However, recent research in psychology (e.g., Tracy and Robins 2007) has identified two distinct facets of pride.

The first cluster (authentic pride) includes words such as “accomplished” and “confident,” and fits with the pro-social, achievement-oriented conceptualization of pride. The second cluster (hubristic pride) includes words such as “arrogant” and “conceited,” and fits with a more self-aggrandizing, egotistical conceptualization. If people prone to experiencing hubristic pride are motivated to self-aggrandize and inflate an artificially positive sense of self, then they may be particularly motivated to consume luxury brands. Luxury brands convey a sense of status, wealth, and achievement (Chadha and Husband 2006; Mandel, Petrova, and Cialdini 2006), and thus may be a shorthand way of informing others (and the self) of one’s high status, accomplishments, and even perfection. For such persons, luxury brand purchases can bolster their self-image in the absence of authentic achievement. They may use the purchase and display luxury brands as one way of maintaining these artificially inflated self-representations. In contrast, individuals prone to experiencing authentic pride should have less need for luxury brands, given that it is tied to actual hard work and achievements.

Study 1 employed a one factor design where 214 participants were randomly instructed to write a story about themselves in an episodic recall task (e.g., Galinsky, Gruenfeld, and Magee 2003) where they felt either snobbish (hubristic pride condition), accomplished (authentic pride condition), or a typical day (control condition). Results revealed that those primed with hubristic pride exhibited a significantly greater willingness to pay extra for luxury brands ($M=3.47$) than those primed with authentic pride ($M=2.91$, $p=.03$), or those in the control group ($M=2.88$, $p=.02$). The latter two conditions did not differ statistically. However, this study does not rule out the possibility that hubristic pride results in a generalized heightened desire to purchase *all* products, and treats each of the pride facets as only induced feelings, when research shows they are also chronic, dispositional states as well (Tracy and Robins 2007).

Study 2 utilized a survey design with 149 participants. All completed the Tracy and Robins (2007) Authentic and Hubristic pride scales, followed by unrelated items, and then their desire to purchase 3 luxury brands (Rolex, Lexus, Armani) as well as 3 non-luxury brands from the same category (Timex, Hyundai, Old Navy). Results showed that while hubristic pride was positively related to a desire to purchase luxury brands ($\beta =.42$, $p=.02$), the relationship between trait authentic pride and a desire to acquire luxury brands was not significant ($\beta =.30$, $p>.20$). When the brands were non-luxury, however, the relationship between hubristic pride and a desire to consume disappeared ($\beta =.11$, ns), and again there was no relationship between authentic pride and a desire to consume ($\beta =-.09$, ns).

Study 3 examined each facet of pride as a consequence, rather than an antecedent, of consumption. We tested the possibility that consumers will be more likely to experience a heightened feeling of hubristic pride from consuming a luxury rather than a non-luxury equivalent of the same product. However, their feelings of authentic pride should not be as strongly influenced by the brands they consume. 120 participants completed a survey that utilized a 2 (brand: luxury vs. non-luxury) x 2 (pride: authentic vs. hubristic) mixed experimental design, with the first factor manipulated between subjects and the second a repeated measures factor. The first factor was manipulated using an episodic recall task, where participants wrote a brief story about themselves involving a luxury (or non-luxury) brand. Results revealed the predicted brand x pride interaction ($p=.01$). Consistent with our hypothesis, while authentic pride was not affected by whether the product was a luxury ($M=4.99$) or non-luxury brand ($M=4.69$), people felt significantly more hubristic pride when they wrote about themselves consuming a luxury ($M=3.24$) than a non-luxury ($M=2.22$) brand ($p<.001$).

Finally, Study 4 investigates the possibility that observers infer authentic and hubristic pride in others as a result of the product choices they make. We also propose that when people infer that a consumer experiences heightened hubristic pride, they may consequently assume that the consumer is also less prosocial. This prediction is based on the link between hubristic pride and various anti-social qualities (Tracy et al. 2009). 52 females participated in a study where they read a story actually completed by a former undergraduate student about her life in 5 years time, which was manipulated to contain a number of luxury or non-luxury brands. A mixed design ANOVA revealed the predicted brand x pride interaction ($p<.001$). Inferences of authentic pride were not affected by whether the products owned by the story’s author were luxury ($M=5.69$) or non-luxury brands (5.73), but participants inferred that the author felt significantly more hubristic pride when she consumed luxury ($M=4.10$) rather than non-luxury ($M=2.65$) brands ($p<.001$). Results also showed that participants in the luxury condition judged the author to possess fewer pro-social personal qualities (concern for others/generous/ a good person/ cares for the environment) ($M=3.79$) than those in the non-luxury condition ($M=4.46$) ($p<.01$), and that hubristic (but not authentic) pride mediated the relationship between the other’s brand choices and their social attractiveness.

This research provides the first evidence of the two-faced nature of pride in consumption settings. Further, we show that pride can serve as both an antecedent and consequence to consumption, provide the first evidence of which we are aware that people’s inferences of others’ pride experiences are shaped by their consumption preferences. Furthermore, these inferences are associated with decreased attribution of prosocial personal qualities in the consumer.

Affective Sensory Regulation: A Framework for Understanding Affect Regulation via Sensory Regulation

Dan King, University of Florida, USA

EXTENDED ABSTRACT

The author integrates emerging findings in the affective neurobiology and physical regulation literatures to propose *Affective Sensory Regulation*, a parsimonious framework to account for how consumers use physical sensations as visceral indicators in the process of affect regulation, causing them to prefer different kinds of products under different states. Using neural theories on how physical sensory perception is linked to affective circuits, it is proposed that different affective states induce different temperature tones, weight tones, speed tones, and brightness tones. First, affective states can have different temperature tones. Loneliness feels cold whereas frustration and anger feel hot; hence consumers under these states unconsciously prefer different products with different thermoregulatory tones. Second, affective states can have different weight tones. Anxiety and guilt feel heavy and relief feels light, hence consumers under these states prefer perceptually light soups when anxious, whereas consumers prefer rich soups when relieved. Third, affective states have different speed tones. Fear and anger have fast sensory-motor tones, whereas loneliness and despair have slow sensory-motor tones, hence consumers prefer advertising materials with different speed tones under different states. Fourth, affective states have different brightness tones. Interest has a bright tone, whereas pessimism has a dark tone, hence consumers prefer bright advertising materials when they are experiencing interest, whereas consumers prefer dark advertising materials when they are experiencing pessimism. The article also explores under what conditions consumers wish to maintain their affective temperature, weight, or brightness tones (even when they are aversive), and under what conditions consumers wish to change their affective temperature, weight, or brightness tones (even when they are pleasant).

Dissociating Positive Emotions of Hope and Hopefulness and their Differential Impact on Consumer Financial Risk-Taking: A Functional Magnetic Resonance Imaging Study

Martin Reimann, University of Southern California, USA

Gergana Y. Nenkov, Boston College, USA

Deborah MacInnis, University of Southern California, USA

Maureen Morrin, Rutgers University, USA

Antoine Bechara, University of Southern California, USA

EXTENDED ABSTRACT

The construct of hope has captured the interest of researchers in numerous fields, including psychology (Snyder 1994), sociology (Desroche 1979), medicine (Taylor 2000), theology (Moltmann 1983) as well as consumer and marketing research (e.g., Agrawal and Menon 2009; MacInnis and De Mello 2005; Passyn and Sujun 2006). As an emotion experienced in relation to future outcomes, hope has considerable relevance to understanding motivation and decision-making. This is so because choices are often guided by future outcomes individuals hope will happen. Without a doubt, the incorporation of future goals and outcomes is central to appraisal theories of emotion, which regard hope as an emotion emanating from appraisals of goal-congruent and desired outcomes whose future occurrence is appraised as uncertain but possible. Moreover, like other future-oriented emotions, such as fear, hope may be associated with distinct areas of brain activation, adding to our knowledge of emotion-brain-behavior linkages. Despite the potential value of the hope construct, however, hope is a relatively understudied emotion (Lazarus 1991).

Prior research on hope reveals subtle but important differences in the definition of hope. Appraisal theories of emotion (Frijda, Kuipers, and Ter Schure 1989; Roseman 1991; Smith and Ellsworth 1985) characterize hope as an emotion that arises from assessments of outcomes viewed as compatible with one's goals (i.e., goal-congruent), yearned for (i.e., desirable), and uncertain but possible. Characterizing hope along these appraisal dimensions is useful as it helps to distinguish hope from other emotions such as fear, disgust, pride, and happiness, as well as from potentially related constructs like expectation, involvement, wishing, and faith (MacInnis and Chun 2007). Although the aforementioned appraisals characterize the emotion of hope, hope has not been consistently defined in the literature (MacInnis and Chun 2007; MacInnis and De Mello 2005). Specifically, although various definitions entail the above-noted appraisal dimensions, definitional variants have emphasized different appraisal dimensions.

The current research addresses this issue and contributes to the literature in several important ways. First, we contribute to the emerging *literature on hope* by conceptually and empirically differentiating two positive emotions, "hope" and "hopefulness," which are oftentimes used interchangeably. This differentiation clarifies definitional inconsistencies in the literature on hope. These constructs entail the same underlying appraisals described above, but they involve *variation* on different appraisal dimensions. *Hope* varies with the degree of yearning for (or desirability of) a future outcome. *Hopefulness*, in contrast, varies with the degree to which the future outcome is seen as more (vs. less) likely (hence is seen as less (vs. more) uncertain), and is defined as the extent to which one appraises a goal-congruent and yearned possible outcome as more or less likely (or less vs. more uncertain). With this construct, what varies is not how much the goal-congruent outcome is yearned for, but rather how certain or uncertain the goal-congruent outcome is appraised to be. People become more (or less) hopeful about a yearned for and possible goal-congruent outcome as *likelihood estimates* of the outcome rise (or decline).

Second, we show that distinguishing hope and hopefulness is important because these constructs have distinct effects on consumer financial decision-making. We demonstrate this distinctiveness here by showing their unique effects on *decision-making under risk*.

Third, we contribute to the literature on the *neural underpinnings of emotions* (Damasio 1994, 1999), showing that hope and hopefulness activate distinct areas of the brain when consumers make financial decisions involving risk. We find that hope is linked to activation of the insula, the prefrontal cortex, and anterior cingulate, areas of the brain previously linked to yearning and risk aversion. Hopefulness, in contrast, is linked to activation of the nucleus accumbens, globus pallidus, and caudate, brain regions previously linked to appraisals of likelihood and risk taking behavior.

In the present study, we found that hope and hopefulness recruit different neural processes when anticipating financial choice. We observed distinct neural patterns of activation for the two emotions; patterns which are consistent with our framework and past literature. These results further establish the notion that hope and hopefulness are discrete constructs that are differentially related to risk-taking.

We add to past research on the neural underpinnings of discrete emotions. Our results suggest that two emotions—hope and hopefulness—indeed have distinct neural patterns. While increased activation in the insula, the prefrontal cortex (particularly, the medial frontal gyrus), and the anterior cingulate was identified when participants were hoping, in states of hopefulness increased activations were found in the nucleus accumbens, the globus pallidus, and the caudate as well as decreased activation was identified in the prefrontal cortex (in particular, the gyrus rectus). These findings extend prior research by shedding more light on discrete emotions, their neural mechanisms, and behavioral effects on consumer financial decision making.

Neural Structures of Emotional Responses to Television Commercials: A Functional Magnetic Resonance Imaging Study

Feng Shen, Saint Joseph's University, USA

Jon Morris, University of Florida, USA

EXTENDED ABSTRACT

No study to date has directly compared the discrete and dimensional approaches of emotional responses to advertising from a neurobiological perspective. We took the initiative to address this issue, and discovered a prefrontal-temporal cortical circuitry that corresponded to a pleasure-arousal response system in modeling emotions in television commercials.

INTRODUCTION

A rich consumer behavior literature indicates that emotion in advertising can be classified into a spectrum of discrete categories or identified in a multidimensional space, and preference is given to the dimensional approach, more specifically the pleasure-arousal-dominance (PAD) model (Mehrabian and Russell 1974). The most important support for the dimensional approach comes from Havlena and Holbrook's (1986) consumption experience study. Havlena and Holbrook (1986) found that the PAD dimensions exhibited higher reliability and validity in explaining consumption-related emotions than did the emotion categories from Plutchik's (1980) Emotion Profile Index. Nevertheless, this evidence turned out to be quite tenuous when Richins (1997) noted that emotional experiences with consumption were significantly different from emotional responses to advertising.

The advent of cognitive neuroscience brings consumer behavior researchers an unprecedented opportunity to reassess many of the important topics in marketing (Yoon, Gonzalez, and Bettman 2009). This article is the beginning of a process to reinvestigate the relative advantages between the discrete and dimensional emotion models in advertising with neuroimaging technology, particularly functional magnetic resonance imaging (fMRI).

LITERATURE REVIEW AND HYPOTHESES

In essence, the concept of discrete emotions reflects a Darwinian approach to emotions, which seeks evolutionarily fundamental emotions to define all emotional experiences (Darwin 1872/1965). According to this approach, there is a finite set of basic emotions that are innate to all human beings across various cultures and development stages, and certain pattern or combination of these basic emotions results in the experience of emotion (Plutchik 1980). Nevertheless, the status of an emotion as basic is often proposed on grounds, such as frequency-related salience in Western culture and levels in an emotional hierarchy, that are irrelevant to whether the emotion is biologically or psychologically primitive (Ortony and Turner 1990).

Despite all these concerns over the validity of this approach, a majority of the current neuroimaging studies still focuses on identifying distinctive brain activations for each basic emotion (Posner, Russell, and Peterson 2005). It turned out that one basic emotion can activate multiple brain regions and one brain region can be activated by multiple basic emotions, so it could be largely futile to seek an exact link between one brain region and one basic emotion (Barrett and Wager 2006). Furthermore, studies of the discrete approach essentially require respondents to recognize stimuli as belonging to certain emotion categories (Mackay 1980). This requirement itself produces neural activities that contaminate natural brain responses to emotions.

A better framework of emotional response in the brain should be a system perspective that endeavors to identify hardwired neural

circuitry for emotional response systems rather than individual emotions (Ortony and Turner 1990). This neural circuitry should be composed of a set of brain regions activated by both sensory experience and information processing of emotional stimuli, and the exact structure of the circuitry varies by the characteristics of a stimulus (Barrett and Wager 2006).

The dimensional approach to emotions or the PAD model conceptually fits this alternative system perspective. Compared to the discrete approach, the PAD model essentially posits an emotional response system composed of three dimensions, and all individual emotions can be quantitatively identified with their positions along the three dimensions (Mehrabian and Russell 1974). Previous research suggests that three brain regions, the amygdala, prefrontal cortex and temporal cortex, are likely to be associated with emotional responses to television commercials. Together with findings at the gyrus level of these regions (Decety and Chaminade 2003; Morris et al. 1998; Morris et al. 1996; Morris, Scott, and Dolan 1999), it was hypothesized:

- H1:** Emotional responses to television commercials activate the amygdala, prefrontal cortex, and temporal cortex.
- H2:** The inferior frontal gyrus and middle temporal gyrus are activated by the pleasure dimension of the emotional responses.
- H3:** The superior frontal gyrus and superior temporal gyrus are activated by the arousal dimension of the emotional responses.

EMPIRICAL EVIDENCE

Our arguments above led to a recent neuroimaging study with our colleagues in neuroscience (Morris et al. 2009). Respondents watched television commercials inside of a scanner, and their emotional responses included both BOLD signals recorded through fMRI and self-reported feelings on the pleasure, arousal and dominance dimensions.

Our analysis indicated activation of the prefrontal and temporal cortices by both pleasure and arousal. But we were unable to find activation in the amygdala. Hypothesis 1 was partially supported. Further investigation of the activations in the prefrontal and temporal cortices led to the selection of the bilateral inferior frontal gyri and bilateral middle temporal gyri for the pleasure dimension. Hypothesis 2 was supported. We were also able to identify the bilateral middle frontal gyrus and right superior temporal gyrus for the arousal dimension, but the activation of the superior frontal gyrus was insignificant. Hypothesis 3 was partially supported.

DISCUSSION AND CONCLUSION

No study to date has directly compared the discrete and dimensional approaches to emotions in advertising from a neurobiological perspective. We took the initiative to address this issue, and discovered a prefrontal-temporal cortical circuitry that corresponded to a pleasure-arousal response system in modeling emotions in television commercials.

Neuroscientists traditionally use sensory stimuli without or with limited social cues in imaging studies on emotion. Our selection of television commercials substantially enriches this line of research. Brain systems are known to function differently depending on the characteristics of social stimuli (Hietanen et al. 2006), and these

differences can be further explained at the behavioral level by social contextual research from advertising scholars (Forehand, Deshpandé, and Reed 2002). Our research can also lead to a paradigm shift in neuroscience. Although an increasing number of researchers are questioning the concept of basic emotions and the existence of distinct brain regions of these emotions, these researchers did not provide enough empirical evidence to support an alternative model and the discrete approach still dominates the neuroimaging research of emotion. We advocate the use of the dimensional PAD model, and our preference is supported by the successful identification of the prefrontal-temporal cortical circuitry of the pleasure-arousal response system.

How the Order of Information About an Experiential Product Impacts Affective Evaluation

Keith Wilcox, Babson College, USA
Anne Roggeveen, Babson College, USA
Dhruv Grewal, Babson College, USA

EXTENDED ABSTRACT

In three experiments, this research demonstrates that when favorable product information is presented before sampling an experiential product it leads to an assimilation effect and more positive affective evaluations. However, when favorable information is presented after sampling it results in a contrast effect and more negative affective evaluations.

Numerous studies have demonstrated that product information, such as its price or brand name, learned prior to experiencing a product can affect consumers' expectations, which can, in turn, influence their product evaluations (Klaaren, Hodges and Wilson 1994). Less is known, however, how learning such information after the initial product experience affects consumers' evaluations. This current research examines whether product information learned before or after sampling an experiential product will lead to differences in consumers' evaluation of the experience.

Experiential products have affective, sensory and informational components (Nowlis and Shiv 2005). Importantly, when consumers sample experiential products, the affective component carries more weight than the informational component (Biswas, Grewal and Roggeveen 2010). One of the key differences between these components is that the affective and sensory components are based on reactions that arise from the experience and occur automatically; whereas the informational component is based on controlled processes (Nowlis and Shiv 2005). Based on assimilation and contrast theory (e.g., Stapel and Winkielman 1998), we expect the automatic formation of affective evaluations to result in differences in affective evaluations when information is received before or after a product is experienced.

One of factor that decides whether contextual information results in assimilation or contrast is how distinct the information is from the target being judged (Stapel and Winkielman 1998). Distinctness is often determined by the extent to which the information is evaluated with the target being judged or presented separate from the evaluation. For example, Martin and Seta (1983) showed that if descriptions of two persons were given and participants were asked to read about both before forming their evaluations, the impression of the target person was assimilated towards the contextual person. In contrast, when participants were asked to form separate evaluations of the target person and the contextual person, the impression of the target was contrasted with the context. This is because the separate evaluations lead the context to serve as a comparison standard when judging the target.

For somatosensory experiences if information is received prior to experiencing the product, then we expect assimilation of the experience towards the product information. This is because, knowing that they will be experiencing the product immediately, people are not expected to judge the product on the product information alone. Instead, judgments are expected to occur after both the product information and the experience have occurred resulting in judgments being assimilated towards the contextual information. However, if product information is received after the experience, then we expect contrast to occur for affective judgments. This is based on the fact that affective judgments occur automatically (Nowlis and Shiv 2005). After experiencing the good, the consumer is expected to automatically think about how much they liked the taste. This will lead subsequent contextual information to be distinct from the experience and serve as a comparison standard.

More formally, we hypothesize that when product information is presented before sampling an experiential product, it will result in an assimilation effect such that consumers' affective evaluations of the experience will be more (less) favorable when the information signals a good (poor) experience. However, when the same information is presented after sampling, it will result in a contrast effect for affective evaluations such that consumers' affective evaluation of the experience will be less (more) favorable when the information signals a good (poor) experience.

We test this prediction in three studies. In study 1, participants were asked to sample a piece of chocolate before or after being told the chocolate was from either Switzerland (favorable experience) or China (unfavorable experience). Even though the sampled chocolate was the same in all conditions, consistent with an assimilation effect, participants' affective evaluation was higher when they thought the chocolate was from Switzerland (vs. China) prior to sampling. Interestingly, and in line with our prediction, when the country-of-origin was presented after sampling, but before the formal evaluation, participants' affective evaluation was higher when they thought the chocolate was from China (vs. Switzerland).

The second study replicated the findings using price as the product information. Specifically, we found that when price was presented prior to sampling, participants' affective evaluation was higher when they thought the chocolate was expensive (vs. inexpensive). However, when the price was presented after sampling participants' affective evaluation was higher when they thought the chocolate was inexpensive (vs. expensive). Interestingly, when participants were given a price discrediting cue, price had no effect on participants' evaluations.

In the third study, we only focused on the after sampling conditions. However, instead of presenting participants with information about the chocolate, we made an enjoyable chocolate experience salient. The results, replicated those in the previous studies. Specifically, we found that when an enjoyable experience was made salient after sampling, participants rated the chocolate more negatively, compared to when a less enjoyable product experience was made salient.

These results have important implications for both retailers and market researchers who are actively engage in sampling programs in a host of sensory categories ranging from food, beverages, videos, music and perfumes. More specifically, for high-end products, our results suggest that it is important to convey that information (e.g., price, brand, country-of-origin) prior to the participant sampling the merchandise. The reverse order would be preferable for products that have less favorable cues (e.g., a wonderful tasting chocolate that is made in China).

Your Life or Your Money: Threat Revision in Response to Taboo Trade-offs

Adriana Samper, Duke University, USA

Janet Schwartz, Duke University, USA

EXTENDED ABSTRACT:

Consumer-driven healthcare is increasingly relied upon as a strategy to curb rising healthcare costs. A key assumption is that by making consumers both more aware of cost, the healthcare market will become more efficient. However, this rationale fails to consider that consumers often reject trade-offs that treat “sacred values,” such as health and life, as fungible entities that can be traded for money (Fiske and Tetlock 1997). In reality, such taboo trade-offs often lead to moral outrage (Tetlock et al. 2000) and evoke negative emotion (e.g., Haidt and Algoe 2004). In fact, given the opportunity, people are motivated to avoid taboo trade-offs altogether (Tetlock, 2003). In this research, we show price transparency has the unintended consequence of influencing consumers’ risk perceptions, and does so in a manner distinct from other contexts that involve risk but not taboo trade-offs. Consistent with consumers’ desire to avoid negative emotion (Luce 1998), we propose that, when facing high prices for health goods, consumers avoid making complete trade-offs between health and money by downplaying the perceived threat of disease.

To first test this hypothesis we presented a web-based sample of adults with a short passage about a new vaccine for the H1N1 pandemic. Participants were told that the vaccine would cost them either \$10 or \$250 and were then asked to rate the seriousness of the H1N1 threat (perceived threat). Participants in the \$250 condition rated the perceived threat significantly lower than those in the \$10 condition, demonstrating that price influences the perceived threat of a negative health event.

In Study 2, we examined whether this pattern was driven by a reluctance to confront taboo trade-offs by asking people about perceived threats at different price points across “taboo” (health) and “non-taboo” (electronics) domains. We also examined the extent to which threat perceptions were influenced by whether or not consumers were responsible for the cost. A web-based sample of adults participated in this 2 (price: low (\$10) vs. high (\$250)) vs. x 2 (payer: self vs. insurance) x 2 (domain: sacred (health) vs. secular (electronics)) experiment. Participants read either a similar passage about the threat of H1N1 flu from Study 1 or a passage about the threat of electronics damage due to strong summer thunderstorms. They were told that the vaccine (high powered surge protector) was available for either \$10 or \$250 and that this preventive product was either covered or not covered by insurance. Participants then rated how serious they perceived the threat of H1N1 flu (storm-induced electronics damage) to be and the extent to which they felt that the price for the vaccine (surge protector) was fair.

The results revealed a 3-way interaction on both perceived threat and price fairness. While those in the H1N1 flu condition downgraded the perceived threat from \$10 to \$250 (regardless of payer), those in the electronics damage condition only downgraded the threat when they bore the cost themselves. In fact, individuals in the electronics damage condition directionally increased the perceived threat when insurance took on the cost. Perceived price fairness revealed a similar pattern of results whereby individuals in the H1N1 condition found the \$250 cost marginally more fair if insurance was paying, while individuals in the electronics condition found the \$250 to be significantly more fair if insurance was paying. Further analyses examining the impact of price on perceived threat in the insurance conditions (isolating responses to those of the mere comparison between the health (consumer) good and money) revealed a significant moderated mediation, whereby the perceived fairness of the trade-off mediated the effect of price on

perceived threat in the health insurance condition, but not in the electronics insurance condition. These results suggest that the perceived unfairness of making a trade-off between health and money leads to a reduction in perceived threat. Thus, in the sacred health domain, any price information leads to risk revision, while in the secular consumer goods domain, risk revision only occurs when individuals are paying out of pocket.

Finally, in Study 3, we extended this work to disease screening and examined how high price may move beyond threat to impact health care consumption. A web-based sample of female participants participated in this 2 (payer: self vs. insurance) x 2 (price: \$800 vs. \$15) experiment. Participants were informed that due to recent evidence questioning the effectiveness of mammograms for women under 50, to imagine that insurance coverage for the test had changed. As a result, an upcoming mammogram would cost \$800 (\$15) and would (not) be covered by insurance. Participants then rated the perceived seriousness of the threat of breast cancer, as well as the likelihood of getting a mammogram. As in Study 2, results revealed only a main effect of high price reducing perceived threat relative to low price, regardless of payer. For perceived likelihood of getting a mammogram, however, the results revealed a significant payer by price interaction. Reflecting the current reality, individuals were more likely to get a mammogram when the cost was covered by insurance than when it was paid out of pocket. However, within the insurance conditions, individuals were less likely to get a mammogram if the cost was \$800 covered by insurance than if it were \$15 covered by insurance. These results suggest that high price of screening reduces both the perceived threat of illness and the likelihood of getting screened. This takes place regardless of payer, such that high prices, regardless of who pays, affect perceptions of risk and the willingness to consume healthcare.

Taken together, these findings have important implications for communications and price transparency in consumer health decisions. We see that high price may actually lead to falsely deflated threat of illness as well as reduced consumption of care, independent of who is paying for the care. Given upcoming changes that may take place in the health care space involving increased price transparency as well as increased health care coverage, it is important to understand the potential influences of these changes on risk perceptions and behavior to improve consumer health decisions and outcomes.

Promoting the Effective Use of Counterfactual Generation to Tackle Negative Consumption

Candy K. Y. Ho, Hong Kong Baptist University, Hong Kong, China

Jessica Y. Y. Kwong, The Chinese University of Hong Kong, China

EXTENDED ABSTRACT

Negative consumption (e.g., having a car accident or missing a flight), like negative life events, are inevitable to consumers. To help consumers to tackle negative consumption is therefore imperative to consumer research. This research explores how the generation of counterfactual thoughts may help consumers to tackle negative consumption.

Counterfactual thoughts are imaginations of how the negative consumption might have turned out differently. Extant literature suggests that certain types of counterfactual thoughts appear more helpful to tackle negative consumption than the others. Specifically, recent research (Ho and Kwong 2009) has made a distinction between counterfactuals that are process-focused (i.e., thoughts that focus on the process or actions that might have led to a better consumption outcome) or outcome-focused (i.e., thoughts that elaborate on the benefits that might have brought by the better consumption outcome). It is demonstrated that while process-focused counterfactuals better help consumers to tackle problems with the consumption, outcome-focused counterfactuals induce stronger negative feelings. These findings establish that, by generating process- but not outcome-focused counterfactuals, consumers can learn how to tackle negative consumption without hurting their feelings. Importantly, however, research to date has not addressed how we may promote generating process- but not outcome-focused counterfactuals.

In this research, we aim to identify the factors that promote the generation of process- and outcome-focused counterfactuals. First, we propose that consumption repeatability, or how likely consumers expect they will be in similar consumption situations again, will promote the generation of process- but not outcome-focused counterfactuals. Consumers who perceive the consumption situation to be more repeatable are more motivated to find out the ways of getting better outcomes (Markman et al. 1993). This increased motivation is likely to promote the generation of process-focused counterfactuals, which provide information on what corrective actions might have led to a better outcome. This corrective information will help consumers to pursue better outcomes next time they are in similar consumption situations. Outcome-focused counterfactuals, however, focus on how much better off consumers would have been had they had a better outcome. These elaborations do not provide corrective information and therefore do not serve the motivation to excel. Therefore consumption repeatability is expected to increase the amount of process- relative to outcome-focused counterfactuals generated by consumers.

Second, we argue that outcome closeness will promote the generation of outcome- but not process-focused counterfactuals. Outcome closeness relates to how close consumers perceive they have missed a better consumption outcome. Compared with those who missed by a great deal, consumers who missed closely a better outcome are likely to have a stronger belief that they should have got that outcome (Kahneman and Varey 1990). Thus they are more likely to elaborate on how better off their consumption outcome would have been. Elaborations of this kind amount to outcome-focused counterfactuals. These consumers, however, who assume that they have got a better outcome, should pay less attention to the means to getting that outcome. Therefore, outcome closeness is proposed to increase the amount of outcome- relative to process-focused counterfactuals generated by consumers.

In addition, this research also examine whether consumption repeatability and outcome closeness would influence consumers' ability to tackle negative consumption and the role the amount of process- and outcome-focused counterfactuals played in it. It is predicted that consumption repeatability will increase consumers' ability to solve consumption problems and that such effect will be driven by the relative amount of process-focused counterfactuals it induces. Similarly, we predict that outcome closeness will intensify negative feelings and that such effect will be driven by the relative amount of outcome-focused counterfactuals it induces.

We conducted an experiment to test these predictions. The experiment used a 2 (consumption repeatability) x 2 (outcome closeness) between-subjects design. The participants, who were undergraduate students, were asked to participate in a game to win prizes. The study manipulated consumption repeatability (no-repeat vs. repeat) by telling the participants that they would play the game three times (the repeaters) or one time (the non-repeaters). Winners would receive real prizes. However, the game was set such that all participants lost in the first time they played. Outcome closeness (far-miss vs. close-miss) was manipulated by varying how close the participants might have won the game in the first round, such that the close-missers missed the chance to win more closely than did the far-missers. After playing the game once, the participants generated counterfactuals related to their losing in the game and reported their feelings about losing in the game.

In addition, be unknown to the non-repeaters, they were also invited to play the game one more time at the end of the study. The study compared the second round performances of the repeaters and that of the non-repeaters.

Supporting our predictions related to consumption repeatability, results indicated that: (1) the repeaters (vs. the non-repeaters) reported a higher proportion of process- to outcome-focused counterfactuals; (2) the repeaters outperformed the non-repeaters in the second round of game, and this differential performance was explained by the relative amount of process-focused counterfactuals they generated. Similarly, consistent with our predictions related to outcome closeness, we found that: (1) the close-missers (vs. the far-missers) reported a higher proportion of outcome- to process-focused counterfactuals; (2) the close-missers (vs. the far-missers) felt more negative about losing in the game, and such difference was mediated by the relative amount of outcome-focused counterfactuals they generated.

To conclude, this research show that (1) consumption repeatability increases the amount of process- relative to outcome-focused counterfactuals consumers generated, which in turn increases consumers' ability to tackle problems in a subsequent consumption, and that (2) outcome closeness increases the amount of outcome- relative to process-focused counterfactuals consumers generated, which in turn intensifies consumers' negative feelings about the current outcome. These findings implies we can promote the generation of process-focused counterfactuals, those that help tackle problems, while suppressing the generation of outcome-focused counterfactuals, those that are painful to consumers. We believe this knowledge is important to consumer well-being because this helps consumers to draw useful lessons from imaginations that are not painful and saves them from repeatedly experiencing negative consumption outcomes.

Angels and Demons: The Differential Effects of Less Threatening Food Temptations on Consumption

Nina Belei, Maastricht University, The Netherlands
Kelly Geyskens, Maastricht University, The Netherlands
Caroline Goukens, Maastricht University, The Netherlands
Jos Lemmink, Maastricht University, The Netherlands

EXTENDED ABSTRACT

This research examines whether and under which conditions less threatening food temptations (e.g., heart-healthy chips and low-fat chips) are effective in promoting food intake control. We demonstrate the differential effects of temptations with health references and temptations with low-fat references.

Conceptualization

Literature provides conflicting findings regarding the effects of food temptations on consumers' abilities to control their food intake. While it was generally accepted that tempting food cues trigger self-control failure, recent research suggests that temptations may have the potential to enhance self-control if the temptations exceed a critical level of threat (Fishbach, Friedman, and Kruglanski 2003; Geyskens, Dewitte, Pandelaere, and Warlop 2008). Yet, instead of increasing the perceived level of threat of food temptations (e.g., by making food enticements even more alluring), health organizations continue to encourage the dissemination of less threatening food alternatives.

Our research examines whether and under which conditions food temptations for which the perceived level of threat is reduced are effective in promoting food intake control. In a series of experiments we compare the effects of hedonic food with low-fat references to hedonic food with health references. In contrast to low-fat hedonic food alternatives stressing the reduced amount of something 'bad' (e.g. less fat), healthier versions of hedonic food often directly refer to a long-term health goal, thereby emphasizing the 'good' aspects of the food. In line with prior research, we expect that low-fat references on highly tempting, yet unhealthy food lead to self-control failure expressed in overconsumption of that food. Contrarily, when an unhealthy yet tempting food is made less threatening by making an explicit link to consumers' long-term health goals, we expect self-control to be enhanced, as a result of the activation of a health goal. This, in turn, should induce health-goal relevant behavior, which is reflected in decreased consumption of the food in question, as well as of other unhealthy food. Moreover, this activated health goal should result in an increased consumption if it results from health references for an inherently healthy food.

Studies

In a first study (N=109) we examine whether healthier (versus low-fat) versions of hedonic food decrease (versus increase) actual food consumption. The results reveal that only temptations with a direct link to consumers' long-term health goals lead to a significant decrease in actual food consumption, thereby effectively enhancing self-control. We observe the same increase in actual consumption as was found by Wansink and Chandon (2006) for hedonic food with low-fat references. In a second study (N=130), we show that the decreased consumption of healthier hedonic food appears to be driven by an increased activation of one's health goals triggered by the health reference on the food. Seeing healthier versions of hedonic food through the lens of the activated health goal leads to less consumption of this food because it remains unhealthy in nature and thus does not contribute to attaining the activated health goal. Contrarily, no such health goal activation was found for hedonic

food with low-fat references implying that the increased consumption of low-fat hedonic food alternatives seems to be attributable to an implicit license to eat often associated with low-fat food. We continue with focusing on the dynamics of health references on hedonic food and demonstrate in a third study (N=62) that we find the same effects of healthier temptations when consumers subsequently consume another food item of the unhealthy product category. We replicate this effect in study 4a (N=55) and 4b (N=52) in which we switch from hedonic food to hedonic beverages. To finally challenge the robustness of the underlying mechanism, we conducted a fifth and final study (N=84), in which we show that health references on healthy food are able to increase the consumption of that healthier food.

Summary and Contribution

Together, the results illustrate the differential effects of low-fat references and health references on hedonic food. Both low-fat references and health references aim at making the respective food appear less threatening to consumers' long-term goals. Yet, we demonstrate the counter effect of health references in that instead of reducing the level of threat of the healthier hedonic food, the activation of a health goal lets consumers reassess the food as being helpful to attain the activated health goal or not. As the healthier hedonic food still remains unhealthy in nature, it is considered as inappropriate for attaining the activated health goal. Consequently, consumers eat less of it than they would of a regular version of a hedonic food. Thereby, our study provides clarity on the question to what extent the recent hedonic food alternatives promoted by health organizations are successful in stimulating more healthy eating patterns. Our study contributes to existing literature in that we provide evidence that also a less threatening food temptation can increase self-control if the food is directly linked to a long-term health goal. As such, we complement the research by Fishbach et al. (2003) by demonstrating that the combination of a less threatening food temptation with a health reference enhances self-control as well. Our findings have strong implications for food manufacturers in that we show that the strategy to offer healthier alternatives of inherently unhealthy food might end up having a counter effect as consumers will be careful in not eating too much of such food. In contrast, we demonstrate that adding health references on inherently healthy food can increase consumption up to 50 %, implying that food manufacturers would reap benefits if they remind consumers on the healthiness of inherently healthy food. For public policy makers our findings imply that not all marketing efforts aimed at decreasing the level of threat of unhealthy, yet tempting food have negative consequences for consumers' eating patterns. While we again show the detrimental effects of low-fat references on food intake, we demonstrate the positive outcomes of health references in terms of consumption regardless of whether they are put on unhealthy or healthy food. As such, stressing the positive, healthy aspects of food appears to be an effective strategy for promoting more healthy eating patterns.

The Obesity Superhighway: An I³ Theory Analysis of Unhealthy Food Consumption

Eli Finkel, Northwestern University, USA
Kenneth Herbst, Wake Forest University, USA
Gráinne Fitzsimons, Duke University, USA

EXTENDED ABSTRACT

This paper approaches obesity from a psychological perspective, exploring the circumstances under which people eat moderately versus excessively when they confront an unexpected opportunity to consume fattening, unhealthy food. In this paper, we introduce a novel meta-theory designed to provide a process-oriented, integrative framework for organizing these risk factors.

According to I³ Theory (pronounced “I-Cubed Theory”), individuals will overeat unhealthy food when *Instigating* triggers are strong, *Impelling* forces are strong, and *Inhibiting* forces are weak. (The underlined vowels represent the three *I*s in I³ Theory.) *Instigating triggers* are situational events or circumstances that induce a behavioral inclination toward unhealthy consumption (e.g., the degree to which the consumer is focused on the viscerally enticing aspects of the food or whether the presence of other people triggers moderate versus excessive consumption). *Impelling forces* consist of factors that strengthen the consummatory craving individuals experience in response to an instigating trigger (e.g., hunger or liking for the food). *Inhibiting forces* consist of factors that increase the likelihood that consumers will override the craving to eat the food rather than to act upon this craving (e.g., plentiful self-control resources or an imminent life event for which the consumer wishes to look relatively thin). According to I³ Theory, risk factors predict unhealthy consumption not only on their own, but also in interaction with risk factors from the other I³ Theory categories. Unhealthy consumption is most extreme when instigating triggers and impelling forces are strong and inhibiting forces are weak.

In this paper, we examined the effects of two different instigating triggers, one impelling factor, and one inhibiting factor. The instigating trigger in Study 1 (conducted in a supermarket) was whether consumers were assigned to think about the food (cinnamon rolls) in terms of its appealing gustatory (visceral) properties or in terms of its nongustatory (non-visceral) basic ingredients (Mischel, Shoda, and Rodriguez 1989). The viscosity manipulation was effective. Shoppers in the visceral condition ate significantly more grams of cinnamon roll than did shoppers in the focused nonvisceral condition and the no-instructions condition.

To test I³ Theory, we predicted grams of cinnamon roll eaten from the viscosity manipulation, self-reported hunger and depletion, all two-way interactions, and the three-way interaction. Consistent with predictions, the Viscerality x Hunger x Depletion interaction effect was significant. Simple effects tests revealed that the Hunger x Depletion interaction effect was not significant in the nonvisceral condition, but it was significant in the visceral condition. Follow-up simple effects tests revealed that, within the visceral condition, the association of hunger with grams eaten was not significant for shoppers who were not feeling depleted, but it was significant and positive for shoppers who were. It seems that shoppers in the visceral condition remained capable of resisting the craving to eat excessively as they became hungrier—unless their self-control resources were depleted.

The instigating trigger in Study 2 (conducted in the lab) was whether consumers witnessed other people (confederates) consume Peanut m&m’s with or without exuberance (Nisbett and Storms 1974). We also manipulated the impellor (hunger) and the inhibitor (depletion) (Schmeichel 2007; Vohs and Faber 2007) using a new unhealthy food (Peanut m&m’s).

All three manipulations were effective and powerful. Participants in the strong modeled exuberance condition ate significantly more than did participants in the weak modeled exuberance condition. Participants assigned to the hungry condition ate significantly more than did participants assigned to the nonhungry condition. In addition, participants assigned to the depletion condition ate significantly more than did participants assigned to the nondepletion condition.

To test I³ Theory, we predicted grams of Peanut m&m’s eaten from the three experimental manipulations, all two-way interactions, and the three-way interaction. Consistent with the Study 1 results, the Modeled Exuberance x Hunger x Depletion interaction effect was significant. Simple effects tests revealed that the Hunger x Depletion interaction effect was not significant in the weak modeled exuberance condition, but it was significant in the strong modeled exuberance condition. Follow-up simple effects tests revealed that, within the strong modeled exuberance condition, the effect of hunger on grams eaten was not significant for participants in the nondepleted condition, but it was significant and positive for participants in the depleted condition. Consumers in the strong modeled exuberance condition remained capable of resisting the craving to eat excessively as they became hungrier—unless their self-control resources were depleted.

Taken together, the results of Studies 1 and 2 speak to the power of I³ Theory to generate novel approaches to the study of unhealthy food consumption. These two studies demonstrate that hungry people are likely to indulge in unhealthy consumption when faced with an instigating trigger, but only when their self-control resources are depleted.

The Influence of Front-of-Pack Nutrition Labels on Consumers' Food Choices at the Point of Purchase and the Point of Consumption

Joerg Koenigstorfer, Saarland University, Germany
Andrea Groeppel-Klein, Saarland University, Germany
Friederike Kamm, Saarland University, Germany

EXTENDED ABSTRACT

Front-of-pack labels on food products commonly feature on major food manufacturers' products. Grunert and Wills (2007, 385) state that they are an attempt to provide consumers "with information about the nutrition content of individual food products, in order to enable consumers to choose nutritionally appropriate food." The goal of this article is to assess whether front-of-pack nutrition labeling is effective in stimulating healthy food choices. This is highly relevant for two reasons: First, most buying decisions with respect to food items are conducted habitually or impulsively and take just a few seconds, with little or no cognitive control (Hoyer 1984; Moorman 1996; Rook 1987). Thus labels have to be designed to attract consumers' attention and provide them with clear information. Second, past attempts to trigger healthier choices by providing additional information on the packages—such as back-of-pack labeling, nutrition or health claims—were either unsuccessful or even counterproductive in stimulating healthier food selection and consumption (Balasubramanian and Cole 2002; Roe, Levy, and Derby 1999; Wansink and Chandon 2006).

As part of our investigation, we carried out an initial qualitative study aimed at analyzing both conscious and unconscious, habitualized aspects of consumers' food choices with respect to different front-of-pack nutrition labeling schemes. In the study we employed a projective photo-elicitation technique. This method was chosen for three reasons: to assess differences in the use of nutrition labels at the point of purchase and the point of consumption; to reduce the social desirability bias (Rook 2006); and to investigate unconscious aspects of human behavior (Kassarjian 1974; McClelland, Koestner, and Weinberger 1989). We took photographs of ten families at different stages of the family lifecycle at both the point of purchase (during a shopping trip made by the main person responsible for meal planning) and the point of consumption (during a family meal at home). We used selected photos as stimuli for photo elicitation and conducted autodiving interviews, which we recorded and analyzed using a holistic approach. Four themes emerged from the data: perceived time pressure at the point of purchase; the relevance of nutrition information for making inferences with regard to the healthiness and tastiness of products; consumers' trust in nutrition information; and their use of this information at the point of purchase or point of consumption. The results show that nutrition labels influence consumers' food choices only at the point of purchase, if at all; people generally disregard them when preparing and eating a family meal at home. At the point of purchase, people appreciate labels, particularly those that provide precise information about the main nutrients without overly limiting their freedom of choice. Examples of such systems are Guideline Daily Amount systems (GDA systems).

In a second study, we investigated the effectiveness of two different labeling schemes in stimulating healthy food choices at the point of purchase: the traffic light color-coded (TL) GDA and the monochrome (MC) GDA systems—both of which were characterized as particularly helpful systems by consumers in study 1. We proposed six hypotheses about consumer decision-making processes, relating to the awareness and automatic processing of labels, the degree to which labels permit accurate information processing, the direct effect of labels on actual choices, and de-

terminants of future choices. A laboratory experiment examining actual product choices for ready meals with 209 participants shows that TL-GDA systems generate higher awareness and tend to more positively impact healthy product choices than MC-GDA systems, but only if consumers are aware of the label. Although nutrition labels are not the main reason for choosing a product, consumers refer to labels employing the TL-GDA system more often than to those using the MC-GDA system. Consumers also find it somewhat easier to interpret labels that use the TL-GDA system, especially in forced exposure conditions. Study 2 extends previous attempts to compare different nutrition labeling systems (Feunekes et al. 2008; FSA 2009a; Jones and Richardson 2007; Kelly et al. 2009; Kumpel Nørgaard and Brunsø 2009; van Kleef et al. 2007) by analyzing actual product choices in close-to-real-life environments and minimizing the tendency to evoke socially desired responses.

In the two studies we focus on nutrition labels and showed that two types of GDA systems impact on consumers' food choices, making them more likely to choose a lower-calorie diet. In reality, however, we need to consider a range of other marketing factors when evaluating the potential of front-of-pack nutrition labeling for supporting healthy diets. These factors include the store environment, product prices, package and portion sizes, shapes and other front-of-pack stimuli such as images of slim models and athletes. We also need to consider consumers' emotions and cognitions relating to food, such as their tendency to regulate their affect, self-control and conscious or subconscious goal conflicts. Nevertheless, the results of our study provide both insights into the relevance of front-of-pack nutrition labeling and important directions for future research.

To Think or Not to Think: The Effect of Cognitive Deliberation on Social Norm Influence

Vladmir Melnyk, Wageningen University, The Netherlands
Erica van Herpen, Wageningen University, The Netherlands
Arnout Fischer, Wageningen University, The Netherlands
Hans C. M. van Trijp, Wageningen University, The Netherlands

EXTENDED ABSTRACT

Marketers have realized the potential of social norms to influence consumers' attitudes and preferences, and use norms frequently in marketing campaigns (Berkowitz 2005). Consumers can process norm information at different levels of cognitive deliberation. Sometimes their thinking is inhibited by, for example, time pressure or fatigue, whereas at other times consumers may freely and actively think about social norms. As the depth of deliberation is often seen as key to attitude change (Petty, Haugtvedt, and Smith 1995), it is likely that this will also affect the influence of social norms.

Despite a large body of research on social norms and on the role of cognitive deliberation in persuasion little is known about the effect of cognitive deliberation on social norms messages, and whether this influence differs between injunctive and descriptive norms. The effect of cognitive deliberation on different norm formulations is particularly interesting because it can explain a fundamental difference between injunctive and descriptive norms. This study thus provides an understanding about how and why social norms influence decision making, and focuses on the role of cognitive deliberation.

Social norms can be formulated in two distinct ways: (1) through giving information about the behavior of other people—descriptive norms (what most people do), and (2) through highlighting social rules—injunctive norms (what ought to be done). Descriptive norms are generally supported by the belief of consumers that others act in an effective way (Cialdini 2006), and therefore in a process of deliberation consumers are likely to come up with arguments in favor of the behavioral patterns observed in others. In contrast, injunctive norms contain an explicit request of what one should do. These norms do not convey information about behavioral effectiveness, and therefore can stimulate both thoughts in favor and against the behavior. For example, consumers may perceive an injunctive norm as a limitation of their freedom to choose and while deliberating on this injunctive social norm, they are more likely to come up with reasons which would help to overcome this request (Mann and Hill 1984). Thus the effect of cognitive deliberation would be different, and even opposite for the two norm formulations.

The experimental study ($N=1010$) had a 2 (norm formulation: injunctive vs. descriptive) \times 3 (cognitive deliberation level: cognitive load vs. control vs. cognitive deliberation) between subject design and a two level measured factor (belief in the content of the message: non-believers vs. believers). Formulation of the social norm was manipulated in a fictitious short newspaper article entitled "Study among Dutch consumer", which promoted either a descriptive norm ("Yes, I always buy environmentally-friendly processed potatoes"), or an injunctive norm ("Everybody should buy environmentally-friendly processed potatoes"). Participants in the cognitive load condition were instructed to count how many times the whole-word "the" was used in the newspaper article, thus preventing deliberation on the message and social norm content. Participants in the control condition were provided with the newspaper text without any instructions that might influence their cognitive deliberation level. In the cognitive deliberation condition participants were asked to carefully read the text of the newspaper article and think about its content.

To test the types of thoughts that the different social norms activate, an open question was added, asking participants to list

all the thoughts that they had in separate boxes. Subsequently, participants were asked to answer a number of questions about their attitudes and purchase intentions towards environmentally-friendly processed potatoes.

Results showed that when consumers have limited cognitive capacity to process a normative message their attitudes and intentions are less in favor of the advocated behavior, compared to when they can process the message without cognitive limitations. Furthermore, and interestingly, the effect of cognitive deliberation depends on norm formulation. Cognitive deliberation on a descriptive norm makes attitudes and intentions more congruent with the normative message, whereas deliberation on injunctive norms has a negative effect on attitudes and intentions in favor of the advocated behavior. Cognitive deliberation appears to suppress either negative or positive thoughts depending on norm formulation. In particular, deliberation suppresses negative thought for descriptive norms and suppresses positive thought for injunctive norms.

Our study has several implications. First, it reveals a fundamental difference between descriptive and injunctive norms and explains the different effect of cognitive deliberation between these. This effect is not due to the *number* of thoughts, but is fully mediated by the difference in *valence* of the thoughts that each norm formulation triggers. Second, norm formulation can influence the thought generation process, which is in line with the reasoning that, depending on information characteristics, cognitive deliberation can produce thinking that is biased either in favor or against (e.g., when reactance is instilled) an advocated position (Petty and Briñol 2008). By switching the formulation of a persuasive message from injunctive to descriptive it is possible to partially compensate for or even reverse the effect of cognitive deliberation. Therefore when using descriptive norms one should make sure that it is used in situations where consumers are stimulated to deliberate upon this norm message. In contrast, messages using injunctive norms should be simple and straightforward to avoid cognitive deliberation upon this message. Third, consumers who are cognitively loaded in the process of reading a social norm message are less susceptible to social norm influence. Future research may shed light on how and to what extent this can be generalized to situations in which consumers are cognitively depleted prior to reading the message (compared to cognitively loaded while reading the message).

This study increases our understanding of the influence of social norms on decision making by showing how the level of cognitive deliberation with which norms are being processed in combination with norm formulation affects the influence of social norms on both attitudes and purchase intentions.

Out of Sight, Out of Mind: On the Irrational Side of Egocentrism in Social Comparisons

Steven Chan, New York University, USA
John Chambers, University of Florida, USA
Justin Kruger, New York University, USA

EXTENDED ABSTRACTS

Social comparisons are common in everyday life. Whether comparing their intelligence with other students, their chances of winning a round of Texas Hold'em against other gamblers, their likelihood to contract a virus versus peers, or their ability to succeed with a startup venture relative to other entrepreneurs, people are interested in knowing their standing relative to others (Festinger 1954). Fearing they may not be as academically gifted as their peers, students expend less effort studying and ultimately do worse in school (Marsh and Parker 1984). Expecting that their business is more likely to survive in a competitive marketplace than other new businesses, entrepreneurs invest more and are more confident of their chances of success (Camerer and Lovallo 1999; Moore and Cain 2007). And convinced that they are less vulnerable to sexually transmitted diseases, people may take fewer precautions than advised (Menon, Block, and Ramanathan 2002).

Yet, as often as people compare themselves with others, a wealth of research suggests that those comparisons are systematically biased. Most people believe that they are more happy, conscientious, socially skilled, and generous than the average person, and less neurotic, impatient, and immoral (see Alicke 1985; Campbell 1986). They do so in defiance of simple laws of probability that state that not everyone can be better than average. They are overconfident in competitions, believing that they have a greater chance of winning than their competitor(s) (Windschitl, Kruger, and Simms 2003; Moore and Kim 2003).

Initially, researchers suggested that these tendencies reflected a fundamental motivation to see oneself in the most favorable light possible (Taylor and Brown 1988; Alicke 1985). However, more recent work suggests that people occasionally see themselves in a less positive light (Chambers and Windschitl 2004). Although people believe that they are above-average in their ability to perform easy tasks such as riding a bicycle and operating a computer mouse, for instance, they believe they are below-average in their ability to perform difficult tasks such as riding a unicycle or programming a computer (Kruger 1999). Similarly, although they see themselves as having above-average chances of experiencing common desirable outcomes like finding a quarter lying on the ground, they believe they have below-average chances of experiencing rare desirable outcomes like finding a \$50 bill lying on the ground (Chambers, Windschitl, and Suls 2003; Kruger and Burrus 2004).

Evidence now suggests that when people compare themselves with others, they myopically focus on their own strengths and abilities and pay less attention to the (equally relevant) strengths and abilities of the comparison group (Chambers et al. 2003; Klar and Giladi 1999; Kruger 1999). We suspect, however, that all is not equal. We suggest that the self receives the lion's share of the attention because it is the self. Specifically, we propose that social comparisons are not merely myopic, but egocentric. After all, representations of the self are some of the most accessible representations that people possess. Conceptual representations become more accessible the more they are activated (Higgins and Bargh 1987; Srull and Wyer 1979), and we spend considerably more time thinking about ourselves than we do about others. This leads to the fairly straightforward prediction that people are likely to egocentrically focus on their own strengths and achievements more than the strengths and achievements of others when they compare

the two. And yet, despite nearly a decade of research on the topic (including many with "egocentrism" in the title), there are no data that explicitly rule in egocentrism.

The present research was designed to provide the first unequivocal evidence of egocentrism in social comparisons. We present three studies. In Study 1, we show that information about the self is brought to mind more quickly than information about others, and that difference mediates the magnitude of bias in social comparisons. In Study 2, we manipulated participants' accessibility of the comparison group by changing the salience of the competitor while holding information about that competitor constant. Participants predicted their chances of beating a competitor on a trivia game comprised of easy and difficult categories. Path analyses revealed that participants based their predictions on their own knowledge of the trivia category more than on their competitors' knowledge of the category. However, that effect was attenuated when participants had a constant reminder of their competitor with a simple photograph. Finally in Study 3, we demonstrate that the mode of competition matters in highlighting the salience of competitors. Participants who played a game directly against their opponent (head-to-head) exhibited less egocentric bias than those who played through an intermediary (the computer).

Whether comparing their event chances, abilities, or entrepreneurial success, people tend to overweight self-assessments and underweight assessments of the comparison group, giving rise to both above- and below-average effects. Although much prior work has identified egocentrism as the cause of this myopia, very little work explicitly rules in egocentrism. In the present work, we show that comparisons are indeed egocentric. We demonstrated not only that self-information comes to mind more rapidly than information about a comparison group, but that those for whom self-information is especially accessible tend to be most myopic in their comparisons (and as a result, see themselves as most above- and below-average). Furthermore, we showed that increasing the salience of the comparison group led to corresponding decreases in egocentrism and above- and below-average comparisons. As a key implication from this research, we emphasize that changing the context of social comparison or competition, by simply highlighting the presence of the other or competitor (without changes in amount or quality of information) can alone diminish the degree of comparison bias. As for the theoretical take away, these results suggest that a major reason why comparisons are myopic is that others are simply "out of sight" and "out of mind."

Revisiting Contexts of Socialization: Friendship Group as the Consumer Socialization Context

Cagri Yalkin, King's College, London, UK

Richard Elliott, Bath School of Management, UK

Ekant Veer, University of Canterbury, New Zealand

EXTENDED ABSTRACT

The aim of this study is to explore the role of friendship groups as the context of socialization and to provide an account of the actual use of fashion goods in the consumer socialization process. It draws on recent reviews in socialization (Harris 1999), which suggests a re-examination of the role of the environment in consumer socialization. This work suggests studying what consumer knowledge, skills, and competence means for consumers in different contexts (Cook 2004) and that the actual use and consumption of goods need to be featured in consumer socialization studies (Ekström 2006). It also suggests that talking and emotional sharing is a significant part of women's friendships and that these friendships take place against the backdrop of an activity (Sheehy 2000). In light of this recent work, this thesis studies consumer socialization in the female friendship groups' by qualitatively inquiring about their consumption and use of fashion.

As Wooten (2006) pointed out, consumer culture theory (CCT) (Arnould and Thompson 2005) approaches to consumer socialization have the potential to "advance knowledge of consumer socialization by illuminating aspects of social life that influence the acquisition of consumption motives and values" (p.196). As CCT is proposed as a framework to help study socio-cultural, experiential, symbolic, and ideological aspects of consumption, this approach could prove useful in the study of consumer socialization, whose symbolic, experiential, and ideological aspects have more or less been understudied.

Furthermore, Ekström (2006) points out the insufficient coverage of the use and consumption of goods in consumer socialization studies. John's (1999) review of 25 years of consumer socialization research provides insight into the categories of findings in the bulk of these studies. The findings are generally about children's advertising knowledge, transaction knowledge (products, brands, shopping, and pricing), decision-making skills and strategies, purchase requests and negotiation strategies, and consumption motives and values. One of the more insightful studies is Peracchio's (1992) study which examines learning abilities and concludes that young children are able to gain knowledge equivalent to that of older children when the experiment materials and response formats are congruent with their encoding and retrieval abilities. Others include John and Whitney's (1986) study which suggests that older children use more sophisticated processing skills and strategies than younger children as they get more information and experience in the marketplace, and Belk et al.'s (1982) study which dealt with the development of consumption symbolism in children. These three studies have adopted experimental methods. Hence, with the exception of Banister and Booth's (2003) study on the formation of children's likes and dislikes, the consumer socialization literature has mainly adopted quantitative studies. Especially thick descriptions of how young consumers gain symbolic skills, knowledge, and competencies are missing from the children's and adolescents' accounts of consumer socialization (see John 1999).

Cook's (2004) discussion of commodification of childhood and the transformation of the child into the individualized consumer is noteworthy in that it reflects a summary of the accumulated research in consumer socialization: "Consumer socialization studies need to consider what competence means for consumers in different contexts and should not be limited to focusing on utilitarian outcomes and effectiveness. There is a need to feature social as well as market

relationships in consumer socialization research. In other words, to show how people use products and services in negotiating relationships with others as well as how the market is incorporating these relationships" (p.149).

Finally, Webley and Lea (1993, p.461) note that researchers should not focus on "how do children come to understand the economic world of grown-ups" but that rather they should ask "how do children solve the economic problems they are faced with" (Webley and Lea 1993, p.461). Together, Cook's (2004) suggestion that researchers need to explore what competence means for young consumers in different contexts, and that there is a need to take into account social relationships when studying consumption and Webley and Lea's (1993) suggestion that researchers should ask how do children solve the consumption-related problems they are faced with constitute the gaps that warrant attention in order to advance the consumer socialization studies. Hence, non-family environment or the outside-of-home context needs to be taken into account and the research question is: *What is the role played by the non-family environment, particularly in the form of a friendship group, in consumer socialization?*

Analysis and interpretation of the data collected through focus groups and interviews with 12 to 16 year-old adolescents revealed that the information flow in friendship groups leads to communication, which serves as the key catalyst of consumer socialization. The friendship group, furthermore, emerged as the site where the socialization process took place, as suggested by Harris (1995; 1999). Adolescents are able to strengthen both rational and symbolic skills within their friendship groups by participating in the background act of 'going shopping' and by talking about consumption related issues, hence enabling them to operate as successful consumers in the marketplace. The gendered consumer identity is also negotiated within the context of shopping, consuming fashion, and marking individuality versus belonging in one's friendship group. Finally, the data analysis revealed that the adolescents surrealize the images in fashion communications as a way to resist such advertisements.

Variety For Nothing

Mauricio Mittelman, Universidad Torcuato Di Tella, Argentina & COPPEAD Graduate School of Business, Brazil
Amitava Chattopadhyay, INSEAD, Singapore
C. Miguel Brendl, Northwestern University, USA

EXTENDED ABSTRACT

When choosing multiple items from a product category, people often seek variety in order to achieve a goal (e.g., to get stimulation). But not always. In this work we propose that sometimes people seek variety for no reason other than to merely satisfy an urge to make different choices. In other words, when choosing multiple items from a product category, not only do people seek variety in the choice outcome, but they also do in the choice process—defined here as the series of individual choices needed to carry out the overall choice. Our argument builds on Drolet's (2002) results. She has shown that consumers tend to vary their use of decision rules because of a favorable valuation of the decision change itself. That is, sometimes consumer choices are not based on the valuation of the choice options, but instead reflect an urge to adopt a different decision rule (e.g., to choose an intermediate option rather than to choose the cheapest option). Likewise, we propose that consumers tend to choose different items because of a favorable valuation of making a different choice itself. That is, consumers' variety-seeking is not necessarily driven by any benefit associated with a set of varied items, but instead may reflect an urge to make different choices. Making a different choice, like applying a different decision rule, is intrinsically satisfying.

The hypothesis above suggests an important corollary. Suppose that when choosing multiple items from a product category, people do not make a series of choices but instead make a single choice. It follows from our hypothesis that people who choose items one-by-one (i.e., a series of choices) will seek more variety than people who choose items all-at-once (i.e., a single choice). When choosing items one-by-one, people may seek variety in the choice process by making subsequent choices different from previous ones. Not so when choosing items all-at-once, because in that case there is only a single choice. As a consequence, in all-at-once choices people may seek variety in the choice outcome only, whereas in one-by-one choices people may seek variety both in the choice outcome and in the choice process. We report two studies supporting these two hypotheses.

In study 1, participants whose first choice was of a high-variety set of candies sought less variety by choosing low-variety sets more often than those whose first choice was of a low-variety set of candies (63% and 17%, respectively; $\chi^2(1)=13.61, p<.001$). They did so because they sought variety in the choice process by making a second choice different from the first choice. As a consequence, they got *less* varied candies than they could get otherwise—had they made the second choice identical to the first choice, they would have chosen a set of more varied items. Beyond supporting the main hypothesis, this result showed that people could in fact be much eager to seek variety in the choice process than in the choice outcome. In study 2, participants who composed their bouquet of roses choosing their roses one-by-one selected mixed-color bouquets more often than those who picked up a pre-arranged bouquet choosing their roses all-at-once (70% and 48%, respectively; $\chi^2(1)=4.80, p<.05$), a result that supports the corollary.

This work has two important implications. Theoretically, it offers a novel explanation for why people often seek too much variety (Kahn and Ratner 2005). We propose that people's choice of varied items can be driven by an urge to seek variety in the choice process (i.e., to make different choices) rather than by an urge to

seek variety in the choice outcome (i.e., to choose different items). Differently from what has been proposed so far, our results thus suggest it is not that people may miscalculate how much variety they want. Rather, people may not make any calculation at all. For example, Read and Loewenstein (1995) reported that students who chose snacks to be received in the future later regretted choosing too many different snacks. Our explanation suggests that these students did not miscalculate their snack preferences in the future. Instead, they may not have thought much about their preferences, chose too many different candy snacks because they sought variety in the choice process, and later found out they would have been better off if they had chosen their most-preferred option.

Practically, this work suggests that consumers may behave differently depending on how sellers make their products available. Specifically, it suggests that people are more likely to choose varied items when selecting individual units than when selecting whole assortments. When selecting individual units, people may seek variety in the choice process by making subsequent choices different from previous ones. Not so when selecting whole assortments, because in that case there is only a single choice. As a consequence, people may seek variety in the choice outcome when selecting whole assortments, whereas people may seek variety both in the choice outcome and in the choice process when selecting individual units. This idea explains the common market practice of offering packs of identical items, which is otherwise difficult to explain given the plenty of evidence that people are avid variety-seekers.

In conclusion, this research shows that people need no reason to seek variety. Sometimes preference for variety stem from a desire to make different choices, not from a desire to choose different items.

Social Networks and the Value of Collaborative User-Generated Content

Sam Ransbotham, Boston College, USA

Gerald Kane, Boston College, USA

Nicholas Lurie, Georgia Institute of Technology, USA

EXTENDED ABSTRACT

User-generated content is a valuable resource for many firms. Examples include product reviews that affect product search, choice, and sales (Chevalier and Mayzlin 2006; Dellarocas, Zhang, and Awad 2007; Mayzlin and Moe 2009), consumer-created ads that generate brand excitement (Kozinets, Hemetsberger, and Schau 2008), and user-developed information that drives traffic to websites that depend on advertising. Although much user-generated content is created by individuals, an increasing amount is developed by groups of people working collectively. This includes the wiki websites Wikia and Wikipedia, where contributors work together on articles; virtual worlds such as Second Life and World of Warcraft, where participants create shared objects and spaces and perform shared tasks (Hemp 2006); and citizen journalism websites like CNN's iReport, where amateur reporters create content that drives advertising viewership. All of these involve collaborative user-generated content, which may be distinguished from individually created content through characteristics such as concurrent editing of the same content, the need to reach consensus given constraints about what to include and what not to include, and final output that is often substantially different from the original contributions made by individuals.

We propose that the social networks that result when individuals work with others to generate multiple sources of user-generated content are important determinants of the market value of that content. We assess market value through viewership since viewership is a primary determinant of the revenue that advertisers obtain from user-generated content. We focus on three dimensions of the social networks involved in the creation of collaborative user-generated content: (1) the size of the network (i.e., the number of distinct contributors to the user-generated content), (2) the strength of the network (i.e., the intensity with which collaborators work on multiple other sources of user-generated content), and (3) the richness of the network (i.e., the relative importance of other user-generated content on which collaborators work). We further argue that the effects of these network characteristics in increasing the market value of collaborative user-generated content should be greater for newer relative to older content, since collaborative content is likely to stabilize over time.

We test our hypotheses by applying social network analysis (SNA) to Wikipedia's Medicine Wikiproject, examining how social network characteristics affect the market value of user-generated content. Medical information is an increasingly important and valuable type of user-generated content (Fox and Jones 2009). We downloaded the full text history of 2,026,992 revisions of 14,088 articles by 40,479 unique contributors within the Medicine Wikiproject as of March 2009 to construct a 174,800 observation monthly panel. Controlling for article topic, links to other content, and other factors that may affect the market value of user-generated content, our data provide unique insights into the role of social networks in the creation of user-generated content. Results demonstrate a curvilinear relationship between the number of distinct contributors to content and its market value. We also find that content created by stronger and richer social networks of contributors generate more valuable content. These social network effects are stronger for newer user-generated content with the exception of network strength, which has a stronger impact on increasing market value as content ages.

Tell the Truth: The Effects of Disclosure in Word-of-Mouth Marketing

Lisa Abendroth, University of St. Thomas, USA

James Heyman, University of St. Thomas, USA

EXTENDED ABSTRACT

During the past two decades, marketers have implemented a variety of stealth marketing tactics that deliver product messages surreptitiously (Kaikati & Kaikati, 2004). Word-of-mouth (WOM), which previously existed as an organic product discussion between friends, was hijacked along the way as marketers began incenting everyday people to talk about brands with other consumers. The technique's usage grew (PQ Media, 2009) as it proved effective at generating sales (Godes and Mayzlin, 2009; Ryu and Feick, 2007). However, it simultaneously gathered scrutiny for being deceptive and unethical (Kennett and Matthews, 2008) as agents often failed to disclose their material connection to the marketer, even when instructed to do so (Ahuja, Michels, Walker, and Weissbuch, 2007; Carl, 2008). In response, the WOMMA, and more recently the FTC (2009), developed guidelines that WOM agents must disclose material connections with the brand, but it is still too soon to tell how much compliance they will obtain (Baar, 2009). The goal of this research is to gain a better understanding of how disclosure of the agent-brand relationship affects WOM recipients' thoughts, feelings, and purchase intentions as compared to seemingly organic WOM. Is honesty really the best policy?

There is a general sense among marketers and agents that disclosure undermines the effectiveness of the recommendation (Ahuja et al., 2007; Carl, 2008; Creamer, 2005; Kaikati and Kaikati, 2004; Kennett and Matthews, 2008). Disclosure is believed to turn turn everyday conversations into commercial messages, causing consumers to engage their persuasion defenses, doubt that the agent is sincere, and therefore discount his or her recommendation (Campbell and Kirmani, 2000; Friestad and Wright, 1994; Verlegh, Verkerk, Tuk, and Smidts, 2004). While we agree with this logic, we argue that the consumers' reactions also depend on how and when they learn about the agent-brand relationship. We argue that if the agent discloses the relationship during the conversation, consumers' reactions are likely to be less negative, and perhaps even positive, compared to a situation where disclosure occurs incidentally after the WOM incident. While there have been two papers on the timing of disclosure, during vs. after the WOM incident (Carl, 2008; Tuk, Verlegh, Smidts, and Wigboldus, 2009), neither paper compares this known, incited WOM to seemingly organic WOM. To truly gauge the effect of disclosure that marketers are worried about, we extend the disclosure research by comparing disclosure during and after the WOM incident to seemingly organic WOM where the consumer has no information that such a relationship exists. At the same time, we examine whether the effect of disclosure is moderated by the strength of the tie between the consumer and agent, strong or weak.

Experiment 1 (N=86) used a latin-square design with agent (friend, stranger) manipulated between subjects, disclosure (none, later, during) manipulated within subjects, and product (cell phone, energy drink, and movie) manipulated within-subject and counter-balanced such that each group saw a different disclosure-by-product combination. The products and brands used as stimuli were selected based on a pre-test (N=23). As expected, later disclosure reduced attitudes towards the agent and product, but surprisingly had no effect on purchase intentions. Meanwhile, the ethical and legal approach of disclosure during the conversation increased purchase intent while simultaneously reducing attitude toward the agent and having no effect on attitude toward the product. Participants viewed friends as more sincere and were more likely to act on their recommendations,

which is consistent with Godes and Mayzlin (2009) and Tuk et al. (2009). However, the consumers' relationship with the agent did not interact with disclosure, suggesting that tie strength does not moderate the effect of disclosure on effectiveness.

Experiment 2 (N=64) had only friends as agents and manipulated disclosure (none, later, during) and product (cell phone, energy drink) between-subjects to eliminate possible contrast effects from seeing multiple disclosure conditions. We also added measures on feelings (deceived or informed) and perceptions of the conversation (unethical, clever, and typical). Compared to seemingly organic WOM, we replicated the finding that disclosure during helped purchase intent, while disclosure after had no effect on behavioral intentions, though intermediate attitudinal measures were affected. We also identified three attitudinal measures that appeared to mediate the effect of disclosure on purchase intentions. While it was not surprising that attitude toward the product had a strong influence on purchase intent, the more interesting finding was that feeling informed as a result of the conversation also positively influenced purchase intent, while finding the agent to be sincere and credible had a negative effect on purchase intent.

In summary, the big picture finding is that ethical and legal disclosure of the agent-brand relationship can be beneficial for both marketers and agents, while a failure to disclose that gets uncovered later can have a backlash effect. These results support recent FTC guideline changes that mandate disclosure, which will ultimately protect consumers from stealth marketing approaches.

The Impact of Shopping the Right Way: The Influence of Fit between Mindsets and Shopping Orientations on Product Evaluations and Willingness to Pay

Oliver B. Büttner, Zeppelin University, Germany

Arnd Florack, Zeppelin University, Germany

Anja S. Göritz, University of Würzburg, Germany

EXTENDED ABSTRACT

In retailing, value for consumers is created not only by the offered products, but also by the shopping experience. Kaltcheva and Weitz (2006), for instance, found that music played in a store that fits the shopping orientation of the consumers affects the pleasantness of the shopping experience and the intentions to visit a store and to make purchases. In this article, we argue that it is not only a fit between the store environment and shopping orientations that has value for consumers, but also the fit between mindsets of cognitive procedures applied during shopping and shopping orientations. In line with research on regulatory fit theory (Higgins et al. 2003), we assume that consumers “feel right” when mindsets that are active during shopping match the way consumers prefer to shop. We suppose that this feeling right spreads to the evaluations of products and strengthens the willingness to purchase an appealing product, and to pay a higher price for such a product.

Research on regulatory fit has found that when people are able to pursue a goal in a way that sustains their regulatory orientation, they “feel right” and enjoy the action more (Freitas and Higgins 2002). Moreover, the value from feeling right may spill over to the outcome of the process, resulting in a more positive evaluation of products and persuasive appeals, as well as in a higher willingness to pay (Avnet and Higgins 2003, 2006; Cesario, Grant, and Higgins 2004; Higgins et al. 2003). Regulatory fit effects, however, have not been examined for a regulatory orientation that is especially important at the point of purchase: consumers’ shopping orientation. Two fundamental shopping orientations can be distinguished: a utilitarian shopping orientation and a hedonic shopping orientation (cf. Babin et al. 1994; Kaltcheva and Weitz 2006). Under a utilitarian shopping orientation, consumers consider shopping a task to be done and they are satisfied when they accomplish their mission as efficiently as possible. In contrast, hedonic shoppers focus on experiencing pleasure from the process of shopping itself.

We assume that these two shopping orientations entail different mindsets (Gollwitzer and Bayer 1999). We argue that shopping under a hedonic orientation draws on cognitive procedures that constitute a deliberative mindset, and that shopping under a utilitarian orientation draws on the cognitive procedures of an implemental mindset. This assumption is supported by a study using verbal protocols on shoppers’ in-store experience (Büttner 2008).

In line with regulatory fit theory (Higgins et al. 2003), we assume that consumers experience regulatory fit when the active mindset provides cognitive procedures that support how consumers usually shop. Hedonic shoppers will experience regulatory fit when in a deliberative mindset; utilitarian shoppers will experience regulatory fit when in an implemental mindset. When consumers are confronted with attractive products, regulatory fit (non-fit) increases (decreases) the value they attribute to the product. As a consequence, consumers are more tempted by the offer and are willing to pay higher prices. Hence, hedonic shoppers are more tempted by the offer and are willing to pay higher prices when in a deliberative mindset than when in an implemental mindset. Utilitarian shoppers are more tempted and willing to pay higher prices when in an implemental mindset than when in a deliberative mindset. We examined these assumptions in three experiments.

In Study 1, we examined the assumption that a fit between consumers’ chronic shopping orientation and activated mindset increases their susceptibility to persuasive communication in a point-of-purchase setting. We applied a 2 (chronic shopping orientation: utilitarian vs. hedonic) X 2 (deliberative vs. implemental mindset) between-subjects design ($N=66$). We measured chronic shopping motivation using a seven-item scale and manipulated active mindset by the personal problem versus project paradigm (e.g., Gollwitzer, Heckhausen, & Steller, 1990). Results from moderated regression support the fit hypothesis. Utilitarian shoppers were more willing to taste the product in an implemental mindset; hedonic shoppers were more willing to taste the product in a deliberative mindset.

Study 2 and 3 used the same design and the same measure for chronic shopping motivation, but different scenarios and mindset manipulations. In Study 2 ($N=140$), we manipulated participants’ mindset by either writing down the pros and cons of buying a new car (deliberative mindset), or by listing five important steps when planning to buy a new car (implemental mindset) (Dhar, et al., 2007). A product-sampling scenario followed the mindset manipulation. As expected, we found that a fit between chronic shopping orientation and active mindset increased consumers’ desire to consume the offered product and increases the price that consumers were willing to pay for the product.

In Study 3 ($N=62$), mindsets were evoked by either writing down the pros and cons of preparing an Italian dinner (deliberative mindset), or by naming the five most important steps when preparing an Italian dinner (implemental mindset). In a subsequent impulse-purchasing scenario, we found support for the fit hypothesis: utilitarian shoppers were more willing to pay a premium in an implemental mindset; hedonic shoppers were more willing to pay a premium in a deliberative mindset.

Overall, we established the fit effect between activated mindset and chronic shopping orientation across three studies. Utilitarian shoppers were more tempted by products encountered at the point of purchases and were willing to pay higher prices when in an implemental mindset. Hedonic shoppers, on the other hand, were more tempted and were willing to pay a higher price when in a deliberative mindset. These findings extend research on regulatory fit: while Higgins et al (2003) speculated about fit effects concerning mindsets, this link had not yet been empirically demonstrated. Moreover, the studies contribute to research on mindset effects on consumer behavior. Our findings suggest that these effects, such as the shopping momentum effect (Dhar et al. 2007), are moderated by consumers’ shopping orientation. Concerning practical implications, our results suggest that retailers’ persuasive attempts at the point of purchase as well as consumers’ strategies to shield themselves against unwanted purchases are more effective when they are tailored to consumers’ chronic shopping orientation.

The Effect of Construal Matching on Consumers' Evaluative Judgments

Susanna Y. N. Wong, The Chinese University of Hong Kong, China

Jessica Y. Y. Kwong, The Chinese University of Hong Kong, China

EXTENDED ABSTRACT

Construal level theory (CLT) posits that psychological distance, defined as the distance of an event from the perceiver's direct experience, can be specified in four dimensions: temporal distance, spatial distance, social distance and hypotheticality (or probability) (Liberman, Trope, and Stephan 2007). Research to date has focused on the premise that as the psychological distance of a product increases, its evaluations are more influenced by its primary, essential, high-level features, as compared with its secondary, peripheral, low-level features (Liviatan, Trope, and Liberman 2008; Todorov, Goren, and Trope 2007; Trope and Liberman 2000). As an extension of CLT, we propose a construal matching effect in which psychological distance influences evaluations of a product independent of its features.

Specifically, we propose that there is a greater degree of match when the product is psychologically distant, or close, in various dimensions. For example, a gift to be purchased in a few months' time for a causal acquaintance involves a temporally distant future as well as a socially distant person, and is said to have a good match in its psychological distances (i.e., the gift is psychologically distant in both dimensions). Similarly, a gift to be purchased in a few days' time for a good friend involves a temporally close future and a socially close person, and hence is also said to have a good match in its psychological distances. Conversely, there will be a poor match when the product is psychologically distant in one dimension, but close in another dimension. Thus, a gift to be purchased in a few months' (few days') time for a good friend (causal acquaintance) is said to have a poor match in its psychological distances, as it involves a temporally distant (close) future yet a socially close (distant) person.

We further hypothesize that a product with a greater match in psychological distances will be evaluated more favorably. Since the more psychologically remote an object is, the higher the level it is construed (Liberman et al. 2007), a match in the psychological distances implies a consistency in the construal level of the object along each dimension. For instance, a temporally remote purchase for a casual acquaintance will be construed primarily with high-level features along the temporal and social dimensions. This requires activating a relatively small set of features and thus is cognitively less demanding. Conversely, a poor match implies that different dimensions call for different levels of construal. For instance, a temporally remote purchase for a good friend will necessitate representations of both high- and low-level features simultaneously. This involves activating a relatively large set of features and thus requires greater mental efforts.

In prior investigations on the phenomenal feelings of meta-cognitive experiences, ease in processing product information leads to a sense of feeling right (or feeling appropriate) about the product (Lee and Aaker 2004; Reber, Schwarz, and Winkielman 2004). This feeling right yields enhanced evaluations of the product, as people misattribute such experience to a higher quality of the product. Because of the lower cognitive demand in comprehending its information, this research suggests that people are more likely to feel right about a product when it has a greater match in psychological distances. This will stimulate a more favorable evaluation of the product. In other words, a product would be evaluated more favorably when it has a greater match in psychological distances. Further, the feeling right experienced in processing its information would mediate such effect.

We assessed our ideas using scenario experiments that undergraduate students participated for cash reimbursement. Study 1 tested the effect of the match in psychological distances on product evaluations. In the scenario, participants would depart for a trip five days later (near future condition) or nine months later (distant future condition) and considered a hotel for their trip from a choice set of three hotels (high base probability condition) or 15 hotels (low base probability condition). Here the base probability pertained to the chance for a particular hotel being chosen, which was much higher in the 3-hotel choice set (i.e., 1/3) than in the 15-hotel choice set (i.e., 1/15), given that the participants had no idea about any of the hotels. Then, participants were given information of a hotel from their choice set and asked to evaluate the hotel. Consistent with our proposed construal matching effect, participants who would depart five days later evaluated the hotel more favorably when the hotel was from a 3-hotel versus 15-hotel choice set. Yet, participants who would depart nine months later evaluated the hotel more favorably when the hotel was from a 15-hotel versus 3-hotel choice set. These results support our idea that a greater match in psychological distances could enhance product evaluations.

Study 2 was conducted to explore the mechanism underlying the proposed construal matching effect. In the scenario, participants considered a CD as a gift for their good friend (socially close gift recipient) or a casual acquaintance (socially distant gift recipient). They were asked to read a review of the CD. The author of the review acted as the influencer in participants' decision to purchase the CD and was described as a student from participants' university (socially close influencer) or a working adult (socially distant influencer). Results showed that participants who read a review written by a socially close (distant) influencer evaluated the CD more favorably when their gift recipient was socially close (distant) versus distant (close). More importantly, the feeling right participants experienced in processing the review mediated the interactive effect of the social distances of gift recipient and influencer on evaluation of the CD. These findings support our idea that the feeling right aroused in the process of evaluation drives the enhanced evaluations under construal matching.

In sum, we proposed and demonstrated a construal matching effect that a product is evaluated more favorably when it has a greater match in psychological distances. While previous research on psychological distances focuses on how product features shape consumers' evaluations, our proposed construal matching effect is driven by the feelings generated from the processing of product information.

Message Framing of Health Communications: Effects on Pap Exam Attitude and Intention

Laurie Balbo, Grenoble University, France

Elizabeth Pomery, Yale University, USA

Marie-Laure Gavard-Perret, Université Pierre mendes France, CERAG, France

Peter Salovey, Yale University, USA

EXTENDED ABSTRACT

Introduction

From a marketing point of view, authors recognize the potential consumer research has for the study of health (Moorman, 2002). To date, articles related to health marketing exist (Maheswaran and Meyers-Levy, 1990; Block and Keller, 1995; Ragubir and Menon, 1998; Cox and Cox, 2001; Chandran and Menon, 2004; Keller 2006) but the needs for researchers and practitioners to better understand health related behaviors draws our attention and interest to the study of health communications.

Health communication has been defined as “the study and use of communication strategies to inform and influence individual and community decisions that enhance health [...] Another area is the dissemination of health messages through public education campaigns that seek to change the social climate to encourage healthy behaviors, create awareness, change attitudes, and motivate individuals to adopt recommended behaviors.” (Healthy People, 2010). The costs of health care and the consequences of some diseases (cancer, obesity, AIDS) has risen the question of individuals education regarding prevention, detection and treatment (Latimer *et al.*, 2008). Because of their impact on peoples’ decision to engage health behaviors (Gerend and Shepherd, 2007), health communications are of the interest of researchers.

Conceptual Background

In their meta-analysis, Latimer *et al.* (2008) highlighted different message tactics that showed evidences in motivating people to engage in health-protective behaviors. One is the framing of health messages. The literature on the framing effect concept (Tversky and Kahneman, 1981; 1986) within health communications (Meyerowitz and Chaiken, 1987; Rothman *et al.*, 1993) suggests that the wording of a health message associated with a recommendation can be a reason for a communication’s effectiveness (Meyerowitz and Chaiken 1987; Rothman *et al.*, 1993). The fundamental aspect of this theory is that people respond differently to the same problem if it is positively or negatively framed. Health messages can be framed to highlight potential benefits associated with engaging in a particular behavior (gain-framed messages), or to highlight potential costs resulting with failing to engage in the behavior (loss-framed messages). Early research on health message framing compared the relative influence of gain- and loss-framed messages in leading to different attitudes, intentions and behaviors. While some authors underline the effectiveness of gain-framed messages (Rothman *et al.*, 1993; Detweiler *et al.*, 1999; Apanovitch *et al.*, 2003; Keller *et al.*, 2003) others (Meyerowitz and Chaiken, 1987, Banks *et al.*, 1995, Block and Keller, 1995, Schneider *et al.*, 2001) report similar findings for loss-framed messages. These mixed results inspired researchers to further explore the conditions under which gain- and loss-framed messages are more efficient.

One approach gives attention to the function of the behavior promoted to understand the frame that will be more efficient. Detection behaviors (which represent the efforts to screen and stop the development of a specific illness, *e.g.* mammography can reveal the presence of breast cancer), are viewed as more risky than prevention behaviors (that enable people to increase their control over and

improve their health, *e.g.* eating fruits and vegetables every day to stay healthy). On the postulate of prospect theory (Tversky and Kahneman, 1981; 1986), authors (Rothman *et al.*, 1993; Rothman and Salovey, 1997) proposed that “the function served by a health behavior can be a reliable heuristic for whether people construe a behavior as a relatively risky or safe course of action” (Rothman *et al.*, 2006, p.205): gain-framed messages are more efficient in promoting prevention behaviors, whereas loss-framed messages are more efficient in promoting detection behaviors.

Even if this rule has received some supports in the literature (Detweiler *et al.*, 1999; Kiene *et al.*, 2005; Gerend and Shepherd, 2007), a new stream of research seeks to explore “the optimal conditions for using gain- and loss-framed messages, looking beyond categories such as prevention versus detection” (Latimer *et al.*, 2007). Some researchers postulate that the *perception* an individual has about a behavior is more predictive than the category to which this behavior belongs. This recent hypothesis has received little attention and partial support in the literature (Rothman *et al.*, 1999; Rivers *et al.*, 2005).

We were interested in testing this hypothesis; so we predicted that fitting message framing with perceived behavior function will result in more favorable attitude (H1) and greater intention to follow recommendation (H2).

The literature on health related behaviors posits individuals’ perception of vulnerability as one of the most important construct (*e.g.* Health Beliefs Model, Rosentsock, 1974; Protection Motivation Theory, Rogers, 1975). We were also interested in exploring how perceived vulnerability (*i.e.* the perceived likelihood to experience the undesirable consequences embedded in the message by not taking action) could moderate the effects of message framing and perceived behavior function on attitude (H3) and intention (H4).

Method

To test our hypotheses, we run an experimentation as a full-factorial between-subjects design with two levels of message framing (gain *vs* loss) and two levels of perceived behavior function (prevention *vs* detection). Four pamphlets were designed to recommend women to get an annual Pap exam in order to examine cervical changes that can result in cervical cancer. Two hundred and nine females of at least 18 years of age ($M_{age}=35,76$; $SD_{age}=11,82$) were recruited to participate in this online experiment.

Results

Analyses revealed that the message framing by perceived behavior function interaction had an effect on attitude and intention toward the recommendation. While perceived behavior function had no effect in the gain conditions, it had the predicted effect in the loss conditions with participants having more favorable attitude and higher intention when exposed to a message that described a Pap exam as a detection behavior.

Regarding the moderation of perceived vulnerability, as predicted we found that under non-fit conditions (gain-detection and loss-prevention), that is to say, when the frame used in the message is not the most relevant according to the level of risk induced by the targeted behavior, participants that thought that they could contract cervical cancer in their lifetime had higher intention to get an an-

nual Pap exam. However, the present data suggests that perceived vulnerability does not moderate the interaction between message framing and perceived behavior function on attitude toward the recommendation.

Consumer Victimization: A Psychological Contracts Perspective

Hyokjin Kwak, Drexel University, USA
Anupam Jaju, George Mason University, USA
Marina Puzakova, Drexel University, USA

EXTENDED ABSTRACT

According to the Oxford English Dictionary (2009), victimization entails cheating, swindling, or defrauding an individual, making them a victim and causing them to suffer inconvenience, discomfort, and annoyance either deliberately or through misdirected attentions. Consumer victimization occurs when firms exploit their consumers. Much of the consumer affairs literature focuses on the economic and physical consequences victimization has on consumers. In this paper, a psychological contract model is introduced to explain how victimization develops and its implications for consumers' reactions.

Psychological contracts represent the perceived reciprocal obligations that consumers believe that they have with a given company. It consists of the beliefs the parties hold regarding the terms of the informal exchange agreement. While expectations and psychological contracts are related concepts, researchers suggest that the two constructs are not equivalent with one another (Rousseau 1990). Expectations can take a number of forms ranging from an individual's probabilistic beliefs regarding the likelihood that a given behavior will have a given outcome, to their normative beliefs regarding the appropriate behaviors required in a given situation (Oliver 1980; Rousseau and Parks 1993). These expectations, however, may not be contractual in nature if promises are absent. As such, psychological contracts differ from the general notion of expectations in part because psychological contracts are promissory and reciprocal (Rousseau 1990).

When the ratio of benefits provided by the organization in relation to the benefits promised matches the ratio of contributions provided by the consumer in relation to the contributions promised by him or her, the contract is perceived as being fulfilled (Morrison and Robinson 1997). If, on the other hand, this relationship becomes unbalanced, the contract is breached. That is, psychological breach refers to consumers' cognitions that a company failed to fulfill its obligations in a manner commensurate with consumers' contributions. The psychological contract model differs from the expectations-dissatisfaction model, in part due to the inclusion of the concept of violation. This model incorporates a sense of relationship and trust, not seen in other models, and can be used to understand the existence of continued future relationships (Turnley and Feldman 1999). Violation involves not only the experiences of unmet expectations, but also something deeper and more emotional (Rousseau 1989, 1995). As per Rousseau (1989), violation is a feeling or perception of betrayal and strong emotional distress, where the individual experiences anger, bitterness and wrongful harm. In essence, violation involves anger, disappointment, and frustration stemming from the perceived betrayal and mistreatment by the firm. Elaborating on Rousseau's definition, we suggest that psychological contract violation can be interpreted as a measure of victimization. Victimization by definition suggests that an individual is being misled, defrauded, or taken advantage of (Oxford English Dictionary 2009). Thus, following Rousseau's definition, when a seller is perceived as intentionally not fulfilling their obligations to a buyer, the buyer will feel misled or taken advantage of, manifesting itself in perceptions of violation.

We explore consumers' possible behavioral reactions when the company fails to (intentionally/unintentionally) live up to its obligations (i.e., breach, violation) as perceived by the consumer. We expect that the violation of psychological contract will lead to consumers' retaliatory behavior (i.e., switching, direct and third-party

complaining). Using SEM, we test our model across three different threats to consumers' well-being (i.e., economic, physical, social). Our experimental data show that consumers' perceptions of breach lead to higher perceptions of psychological contract violation, and violation in turn leads to higher incidences of consumer retaliatory behavior (i.e., switching, complaining). Our results also showed that not all breaches are created equal. When examining the results across the three threat conditions, we found that the associations between breach and violation were typically stronger for social threats and weaker for economic threats. In support of hypothesis two, the perceived intentionality of the unmet obligations also moderated the associations between breach and violation in the physical and social threat conditions, but not the economic condition. While perceptions of breach are lower in the social threat conditions, when social threats do occur and are perceived as intentional they would be more surprising and unsettling, producing greater negative reactions and, consequently, stronger retaliatory behaviors than was seen with economic threats. Finally, the current research outlines theoretical implications and future directions of scientific inquiry. For instance, we suggest that outcome assessments (e.g. magnitude of the breach, nature of the breach), social and formal contracts (e.g. legal obligations, written contracts, type of exchange) may influence consumers' perceptions of victimization. When examining the effects of violation on participants' retaliatory behavior it will be informative to take into account the influence of investment and perceptions of alternatives. Overall, we show how consumers' interpretation process can influence their reactions to firms' breach, and how the magnitude of their retaliation may vary with the type of threat they experienced.

Can Biases About the Future Push Consumers to Act? Effects of Affective Forecasting on Consumer Procrastination

Lily Lin, University of British Columbia, Canada
Timothy Silk, University of British Columbia, Canada

EXTENDED ABSTRACT

Behavioral economics classifies procrastination as present-biased preference. This perspective implies that people are insufficiently forward-looking and that procrastination occurs as a consequence of failing to appreciate that repeated decisions to postpone today's tasks will result in a lack of progress in the long term (Akerlof 1991). A logical extension of this perspective suggests that manipulations that encourage forward-looking behavior may de-bias present-bias preference. The proposed research introduces affective forecasting as a means of manipulating forward-looking behavior in an attempt to mitigate procrastination.

Procrastination applies to a wide range of consumer contexts with important consequences, such as completing tasks on time to obtain financial rewards or avoid penalties (e.g., tax returns, financial investments, etc.), and meeting purchasing deadlines for gift-giving occasions (e.g., birthdays, Christmas, Valentine's day, etc.). Research on procrastination suggests that people are likely to procrastinate due to factors such as task aversiveness and perceived effort required for a given task (Anderson 2003). Numerous individual difference variables can also contribute to procrastination (Steel 2007). Research in this domain, however, is largely silent on mediating variables that may motivate action. For example, research has yet to examine whether limitations in people's self-knowledge (e.g., inability to accurately predict one's future emotional states) can influence procrastination.

Affective forecasting refers to predictions people make about their future emotional states. Research in this domain has consistently demonstrated an effect termed the "impact bias" whereby "forecasters" tend to overestimate the intensity and duration of their reactions to future events compared to "experiencers" who experience the same events but do not engage in affective forecasts. (Gilbert et al. 1998). Importantly, the impact bias has been shown to be stronger for negative emotions (e.g. regret) than for positive emotions (e.g. happiness) (Wilson and Gilbert 2003). While the majority of research in affective forecasting has focused on the identification of these biases, little empirical work has looked at how these biases might influence people's actions. That is, most work has focused on the forecasts themselves and research has yet to examine whether the motivation to avoid such negative states in the future might encourage individuals to take action to change their environment. Therefore, the main motivation behind this research is to examine the behavioral consequences of affective forecasting by looking at its influences on procrastination.

The current research examines the effects of affective forecasts on people's progress in three consumer contexts. Three studies track changes in consumers' progress, stress, and other emotional responses over time to identify underlying mechanisms that influence procrastination. We observe that consumers who make affective forecasts overestimate the negative emotions associated with procrastination. This impact bias motivates consumers to avoid forecasted negative states by initiating and completing tasks earlier than non-forecasters. Further, we find that issuing implicit and explicit warnings about the negative consequences of procrastination are largely ineffective at motivating action. Findings suggest that the underlying process that takes place during affective forecasts is unique and does more than serve a mere warning function.

Experiment 1 examined the relationship between affective forecasting and consumers' progress on holiday shopping. Longitudinal data was collected over a one-month period to assess changes in participants' affective forecasts and progress on their holiday shopping lists. One month prior to the holiday gift exchange season, 44 undergraduates were randomly assigned to either the "forecaster" or "experiencer" condition. Following the lab session, participants were contacted periodically and asked to complete six additional online diaries. As predicted, forecasters were found to significantly overestimate the intensity of negative emotions (stress, unhappiness, and perceived difficulty) they would feel in the future. Results also showed that forecasters initiated and completed tasks earlier than experiencers and made greater progress over time.

Experiment 2 examined the relationship between affective forecasting and consumers' progress toward Valentine's Day shopping. The complexity of the task was decreased in this study because participants only needed to shop for one individual. Additionally, a shorter two-week time frame was examined in order to test if similar effects would be observed over a shorter period of time. In essence, we were curious to know whether the effects observed in Experiment 1 would manifest themselves in a less complex task with potentially higher consequences over a shorter period of time. The overall design and basic methodology were similar to Experiment 1. Fifty-six undergraduates in romantic relationships were randomly assigned to either the "forecasters" or "experiencers" condition. Following the lab session, participants were contacted asked to complete 3 additional online diaries. As in Experiment 1, the forecasters overestimated intensity of their future negative emotions, initiated and completed tasks earlier than experiencers, and made greater progress over time.

The purpose of Experiment 3 was to examine whether affective forecasting essentially operates as a mere warning function. Specifically, we aimed to investigate whether the process that occurs when making affective forecasts differs from being warned about how one will feel in the future if they procrastinate. To test this, 169 undergraduates participated in a consumer-themed scavenger hunt modeled after the TV reality show *The Amazing Race*. Participants were given two weeks to complete a series of five tasks which required them to take a photograph of various retail stores in the local area and upload the photographs to a website that tracked each participant's progress over time. Participants were randomly assigned to the "forecasters", "experiencers", "implicit warning", or "explicit warning" condition. The manipulations for the forecasters and experiencers conditions were similar to the first two studies. Those in the implicit warning condition were warned that they would feel negative emotions if they were to procrastinate, and were told to act accordingly. Those in the explicit warning condition received the same warning and were explicitly told that such negative emotions could be avoided by not procrastinating and starting the task right away. Forecasters again exhibited an impact bias and a higher proportion of forecasters completed the race by the deadline. Issuing implicit and explicit warnings about the negative consequences of procrastination were largely ineffective at motivating action, suggesting that the underlying process that takes place during affective forecasting does more than serve a mere warning function.

The Effects of Circular and Linear Time Orientations on Personal Savings Estimates and Savings Behavior

Leona Tam, Old Dominion University, USA

Hanie Lee, Rice University, USA

Utpal Dholakia, Rice University USA

EXTENDED ABSTRACT

A low personal savings rate has been an important concern from economic, social and policy standpoints, especially as the U.S. savings rate dipped into negative territory in 2005 (Guidolin and Jeunesse 2007) and remained there until unease from the recent economic down turn brought it back up to positive levels in the fourth quarter of 2009 (BEA 2010). Nevertheless, there is still a wide range in personal savings rates across consumers. Some consumers are able to save a significant amount of their incomes, whereas others can barely make it from paycheck to paycheck. Moreover, such differences cannot be explained solely by differences in income (e.g., Masson, Bayoumi and Samiei 1998). It is therefore important to examine factors affecting personal savings of consumers. Prior research has shown that the temporal frame such as length of duration and delay used in decision making is crucial to personal finance tasks (e.g., Ulkumen, Thomas, and Morwitz 2008; Tam and Dholakia 2010).

We examined effects of circular and linear time orientation on personal savings estimates and savings behavior. The distinction between circular and linear time orientation originates from people's view of life. Under a linear time orientation, there is a past, present, and future, and time is separable into discrete compartments and moves toward the future in a linear fashion. Under the circular time orientation, in contrast, time is not perceived as a straight line stretching from the distant past to the far future, but rather, it is seen as a circular system in which the same events are repeated according to some cyclical pattern (Graham 1981). The "discrete compartment of time" view in the linear time orientation results in a difference in how much people focus on the future versus the present. Individuals under a linear time orientation are more future oriented and less present oriented than those under circular time orientation (Bergadaa 1990). Linear and circular time orientations also differ in how goals are approached.

Based on the three different characteristics between linear and circular time orientation, (1) the overall progression in life, (2) a future versus present orientation, and (3) a planning mind set, one would expect to see higher savings rate from people with a linear time orientation than a circular time orientation because linear time orientation is expected to put a stronger emphasis on future retirement needs and enable formulation of more concrete plans to accumulate personal savings. Future goals should determine present actions and people with linear time orientation should plan for the future and thus behavior in the present should be based on making forward progress towards achieving long-term goals. Yet, in reality, many empirical surveys show that people that tend to adopt a linear time orientation save much less than those who tend to adopt a circular time orientation (Horioka and Wan 2008; Caillois and McKeon, 1963).

We draw on Resource Slack Theory (Zauberman and Lynch 2005) and Construal Level Theory (Liberman and Trope 1998) to explain this anomaly and to better understand the effects of circular and linear time orientations on savings estimates and personal savings. Theoretically, resource slack as operationalized by future optimism and level of construal of the savings task are likely to be affected by time frames for which savings estimates are given. In the context of saving behavior, Resource Slack Theory suggests that

people think they will be able to save more in the distant future than the near future because of the notion of future optimism. Future optimism is expected to result in a higher estimate of saving for distant future time periods than near future time periods. Linear time orientation is more future oriented and circular time orientation is more present oriented. When future optimism affects personal savings estimates, we expect higher savings estimates to result from linear time orientation than circular time orientation. However, once specific savings plan (e.g., saving 10% of paycheck) is set, a circular time orientation that has lower level of future optimism and focuses on tasks on hand could save actually more than linear time orientation.

Construal Level Theory posits that temporal distance changes decision makers' responses to future events by changing the way they mentally represent those events (Trope and Liberman 2003) and provides useful insights into the role of savings task construal under linear and circular time orientation. This theory suggests that in the case of circular time orientation, decision makers think of saving activities and estimation tasks more concretely using lower level construal, in comparison to linear time orientation where personal savings is considered in more long term progress with higher level construal. Consequently, under circular time orientation, people would be thinking of more specific ways in which they will be able to save money and sticking to the more mundane savings activities set for each paycheck. Construal of the savings task in detailed, concrete (vs. abstract) terms for circular time orientation is expected to lead to a greater personal savings when compared to linear time orientation.

For these reasons, we expected circular time orientation would result in higher level of savings estimates and actual personal savings. Two longitudinal experimental studies were conducted. Study 1 found that people who applied circular time savings method provided higher personal savings estimates and indeed saved more in reality, compared to people who applied linear time savings method. Study 2 tested future optimism and construal level as mediators in the effects of circular and linear time orientation on personal savings estimates and savings behavior. Study 3, using a longitudinal method, is currently underway.

Hate the Wait? Why Customers Who Wait Longer Buy More

Alan D. Cooke, University of Florida, USA

Nira Munichor, The Hebrew University of Jerusalem, Israel

EXTENDED ABSTRACT

Delays are an abhorred but inescapable element of shopping. Scholars have sought to understand the effects of waiting on consumer reactions, and to find ways to manage waiting with the goal of mitigating negative reactions usually elicited by a wait (e.g., Carmon, Shanthikerumar, and Carmon 1995; Maister 1985; Zhou and Soman 2003). Surprisingly, however, little research examines how waiting might influence subsequent purchase behavior. Researchers have examined intentions to revisit the store or to spread word-of-mouth about the retailer (e.g., Gorn et al. 2004; Hui, Dube, and Chebat 1997), but have not addressed the effects that waiting may have for purchases during the trip. Our research is aimed at bridging this gap; it reveals the counterintuitive impact of waiting time on subsequent purchase behavior.

While waiting duration is assumed to have considerable influences on consumer behavior, the exact nature of those influences is still a puzzle. Available literature portrays contradicting findings with regard to the impact of wait time on consumers (e.g., Hornik 1984; Hui and Tse 1996; Munichor and Rafaeli 2007; Taylor 1994), which may hint at the complex nature of the effects of wait-time on consumers. On the one hand, consumers typically regard prolonged waits as distasteful, which may result in lower purchase levels. On the other hand, the process of waiting and cognitions about the nature and reasons for the prolonged wait may affect both beliefs about the goods and/or the process by which consumers determine purchase quantities, potentially resulting in a counterintuitive increase in purchases that are made following the wait (such as those made in counter-service restaurants).

Experiment 1 tested the effect of waiting time on the number of items chosen to be consumed subsequently, using a computer-based consumption task. Participants were asked to evaluate the presentation skills of some speakers based on a series of videos. We asked them to choose which of two types of videos to watch (lectures or stand-up comedy), and then manipulated the amount of time they had to wait before choosing the specific videos to watch. The number of videos chosen served as our primary dependent variable.

We found that, although participants perceived a longer wait as more annoying than a shorter wait, they also chose to watch more videos. Thus, when made to wait before a choice, people choose more if made to wait longer. This result occurs despite, or possibly because of, the additional frustration resulting from the wait.

Experiment 2 further tested whether the positive relationship between wait time and purchase amount results from people who waited longer believing the goods to be more attractive, a social signaling account. Participants went through a procedure similar to that used in experiment 1. Social signaling was manipulated through instructions; participants in the signaling condition were told that their wait time was dependent on other people's choices, whereas participants in the no-signaling condition were told that their wait time was dependent only on the speed of the network.

Again, participants perceived a longer wait as more annoying than a shorter wait. Further, a significant effect of the interaction between time and signaling on the number of chosen videos was found. When participants were told that their wait time was dependent on other people's choices, they chose more videos following a longer wait than following a shorter wait. When participants were told that their wait time was dependent on network connectivity, however, the opposite pattern emerged. These results support the hypothesis that social signaling underlies the positive effect of

wait time on purchase amount. When wait time is perceived to be the product of others' preferences, such that a longer wait signals greater product's popularity, people choose more items following a longer, rather than a shorter wait. When wait-time is perceived to be independent of other people's choices, however, longer waits lead to fewer items chosen.

In summary, the current work shows that longer waits produce subsequent *increased* purchase when waiting time serves as a social signal about the value of the items. This study contributes to the investigation of the effects of waiting on subsequent actual behaviors, and sheds light on the psychological mechanisms that underlie these effects. Our results undermine the commonly held view that waiting can only damage firms' bottom lines, and shows that some effects of waiting time may take a counterintuitive form. Our findings therefore may carry important implications for the management of queues and waiting, and may also make customers more aware of the non-trivial influences that a wait may exert on their behavior. Our research also contributes to the development of behavioral theory by revealing the direct and indirect relationships between the process of waiting and other common consumer behaviors. We also discuss the role that cognitive dissonance and self-control depletion may play in causing people who have waited longer to consume more.

Effect of Temporal Units on Duration Sensitivity

Ashwani Monga, University of South Carolina, USA

Rajesh Bahchi, Virginia Tech, USA

EXTENDED ABSTRACT

Because individuals usually prefer to receive rewards sooner rather than later, they want to be compensated for delays. For example, while holding a certificate of deposit (CD) that is about to mature and yield cash, an investor may be willing to delay the CD's maturity date, but only in return for an additional amount at the end. Moreover, the acceptable amount is likely to be higher if the maturity date is delayed by, say, 6 months rather than 3 months. The amount is likely to depend on individuals' duration sensitivity—the extent to which they are sensitive to a prospective change in the time of CD maturation. The current research demonstrates that duration sensitivity depends on the units employed to express durations. We show that sensitivity to delays expressed in larger units such as months (3 vs. 6) might be different from delays expressed in smaller units such as days (90 vs. 180).

Our arguments are based on a confluence of two different streams of research: numerosity (Pelham, Sumatra and Myaskovsky 1994), which offers insights into how people respond to numbers of differing magnitudes; and construal-level theory (Vallacher and Wegner 1987; 1989), which provides guidance on how events and actions can be construed at concrete or abstract levels. The starting point of our thesis is that a duration has two components: a number and a unit. For instance, a duration of 6 months is composed of the number "6" and the unit "months." If the units of a duration are changed, the numbers need to be changed as well in order to keep the duration objectively equivalent. That is, as units become smaller (e.g., from month to day), the associated numbers become larger (from 6 to 180). This inverse relationship between units and numbers is central to our arguments. We conduct a series of studies, primarily in the context of Certificates of Deposit, because such financial products do not have complex characteristics and provide a relatively simple template to cleanly test our predictions. This approach is consistent with prior research (e.g., LeBoeuf 2006) that has relied on Certificates of Deposit to study issues related to time discounting. In our studies, we explore conditions that facilitate a focus on units versus numbers, with consequent implications for duration sensitivity. We show that duration sensitivity is sometimes higher for larger units (months, rather than days), but, at other times, it is higher for smaller units (days, rather than months).

Our results have practical implications. For instance, when banks decide on the amount of money that they would need to offer in return for extending a CD, they need to consider how individuals would react to duration differences expressed in different units. Similarly, if online bookstores observe insensitivity between, say, a 2-day versus a 4-day delivery, they might be better off using the latter, which is likely to save costs.

Our results are also important from a theoretical standpoint. The idea that objective and subjective time durations are different has been long known to researchers in different disciplines, including consumer research (Hornik 1984). However, the notion that subjectivity of time might be determined by the units used to express durations has not been considered earlier. If duration sensitivity changes with units, as we propose in this article, it would have implications for a variety of areas, but particularly the area of time discounting, which refers to individuals having a strong bias toward the present rather than the future. It has recently been shown that this phenomenon can be attributed to individuals' sensitivity to duration (Kim and Zauberaman 2009; Zauberaman et al. 2009).

Our results on duration sensitivity imply that time discounting might also depend on temporal units. Our results also contribute to research on numerosity, which shows that people use the magnitude of numbers as a heuristic to make various judgments (Pelham et al. 1994). While people do indeed rely on the magnitude of numbers on some occasions, we show that they might ignore numbers at other times, and instead rely on the magnitude of the associated units. Finally, our results contribute to research on construal-level theory (Trope and Liberman 2000). We decompose a duration into different elements that have different levels of construal, and demonstrate consequent implications for duration sensitivity.

When Biasing Cues Improve vs Bias Quality Judgments

Wouter Vanhouche, Lessius University College, Belgium

Stijn van Osselaer, Erasmus University Rotterdam, The Netherlands

EXTENDED ABSTRACT

Recent research demonstrates that quality judgments made at the time of repeat purchase can be more accurate, as opposed to less, when those quality judgments had been biased at the time of trial (e.g. when the price is high but quality low), compared to when quality judgments had never been biased (Vanhouche and van Osselaer 2009). This phenomenon was dubbed “the accuracy-enhancing effect of biasing cues” and could easily be taken as evidence for consumers’ updating of pre-existing price-quality beliefs. Such an interpretation might seem reasonable given some specific task characteristics in the paradigm used by Vanhouche and van Osselaer—e.g. the easiness of the rules to be learned and the non-ambiguous quality feedback—but would be at odds with most of the literature which documents scant rule updating (Pechmann and Ratneshwar 1992; Broniarczyk and Alba 1994; Lichtenstein and Burton 1989).

The current research replicates the accuracy-enhancing effect of biasing cues (Study 1) and uncovers the mechanism behind it (Study 2). Even though rule updating seemed to have been possible or even likely, the results indicate that consumers use the initially biasing cue as an extra powerful memory cue to retrieve the quality level of individual previously experienced price-quality points. In other words, the accuracy-enhancing effect of biasing cues is driven by an exemplar based process rather than a rule based process. In addition, the pre-existing price-quality belief had remained unchanged. It was not updated.

As a result, quality judgments of not previously experienced products remained biased (Study 3) even though participants could have learned that, “at least in this particular context”, price did *not* positively predict quality. In other words, the accuracy-enhancing effect does not generalize easily to situations in which the prices and brands at time of repeat purchase are different than during trial, indicating that pre-existing price-quality beliefs remain powerful and influential.

The broader implication may be that consumers use different processes to judge the quality of products they have versus have not tried before. The exemplar-based process helps them to quickly learn to avoid specific products they had a bad experience with. The rule-based process is updated much more conservatively and seems hardly affected by a few rule-inconsistent experiences. This conservativeness may be highly functional by providing stability in quality judgment (McClelland, McNaughton, and O’Reilly 1995), but may also represent a dysfunctional failure to learn from experience, as if rule-inconsistent experiences are picked up by the exemplar-based system (and used to correctly evaluate the specific, previously-experienced, rule-inconsistent products in the future) but are totally ignored by the rule-based process. In that case, Brehmer’s (1980) conclusion about learning, “in one word: not from experience,” may indeed apply. But it only applies to rules and judgments about products we have not tried before. Luckily, consumers also have an exemplar-based process that very effectively helps them to avoid the berries that made them sick when they tasted them, or that high-priced orange juice that tasted like vinegar.

Catching More Flies with Vinegar: The Ironic Effect of Product-Specific Search Cost on Consumer Choice

Xin Ge, University of Northern British Columbia, Canada

Gerald Häubl, University of Alberta, Canada

Neil Brigden, University of Alberta, Canada

EXTENDED ABSTRACT

This paper introduces the hypothesis that making it harder for consumers to find out about a product can actually result in greater preference for it. The results of three experiments demonstrate this phenomenon and illuminate the mental mechanisms that underlie the ironic effect of product-specific search cost on consumer choice.

In purchase decisions, search costs often vary across alternatives even for a single consumer. For example, a consumer might be in a convenience store and observe that the store only carries a few brands of chips. The consumer might know that a grocery store nearby carries several additional brands. For this consumer, at this moment, the brands that are only available at the grocery store have a relatively higher search cost associated with them. The consumer would have to expend additional resources in order to acquire more information about these brands and to have an opportunity to purchase them. The question of how such differential search costs might influence consumer choice is the focus of the present research.

Economic theory suggests that the cost of search is a key determinant of the extent of consumer search activity such that one should stop searching when the expected marginal benefit no longer exceeds the marginal cost of search (Ratchford 1982; Rothschild 1974; Weitzman 1979). There is no economically rational reason for search costs to influence the decision making process once search is complete. This combined with the fact that adding a differentially higher search cost to an alternative will decrease the number of consumers who are exposed to that alternative, leads to the conclusion that a higher search cost can only reduce market share.

We propose that higher search costs can ironically increase market share because these costs do influence decision making after the search phase. Bastardi and Shafir demonstrated that a piece of information favoring an alternative became more influential once searched for (1998). Similarly, having incurred an additional cost to see and potentially purchase an alternative, a consumer might be more inclined to purchase that alternative. We propose two mechanisms that jointly contribute to this effect: (1) the acquisition of information about a product for which search cost is comparatively high might increase a consumer's commitment to that product in line with a sunk cost fallacy and (2) choices might be influenced by a self-perception process whereby consumers use their own search behavior, and in particular the effort they have expended to acquire information about a product of high search cost, as a basis for making inferences about their preference for that alternative.

Search costs, once incurred become "sunk" or irretrievable and should therefore not affect choice. The final product choice should be based only on whatever information about the alternatives themselves is available to the consumer when making the choice. However, behavioral research has revealed a greater tendency to continue an endeavor once an investment in money, time, or effort has been made in connection with it, and this phenomenon has been termed the "sunk cost fallacy" (Arkes and Blumer 1985). We hypothesize that "sunk" search costs influence choices in the same way increasing a consumer's tendency to choose options for which additional search costs have been incurred.

Self perception theory argues that an individual uses observations of her own behavior to make inferences about her own

attitudes (Bem 1967, 1972). Therefore, consumers who observe themselves choosing to pay additional search costs to view an alternative might infer that they have a relative preference for the higher search cost alternative over the alternative that was available without additional cost.

To test these hypotheses we conducted three experiments. In each experiment participants saw one alternative (the Competitor), and had the option of incurring an additional search cost to see and potentially purchase a second alternative (the Target). Search cost was operationalized as distance (Experiment 1), keystrokes (Experiment 2) and money (Experiment 3). Experiments 1 and 3 involved consequential choices while experiments 2 used hypothetical choices. Across all experiments the alternatives that served as the Target and the Competitor were counterbalanced.

Across all three experiments the Target alternative, which had a higher search cost, earned a significantly greater share of participant choices than the Competitor. Experiment 1 demonstrates the basic effect in a consequential choice for granola bars. Participants were initially presented with one flavor of granola bar. They could either take that bar or they could walk across the room to see a second flavor (the first flavor was also present across the room). Participants preferred the second flavor. Experiment 2 used an online shopping task involving six product categories. Participants were assigned to either an equal search cost or differential search cost condition. Participants in the differential search cost condition preferred the alternative with the higher search cost while no preference existed for the same alternatives when search costs were equal. Experiment 3 involved consequential choices for gambles. This experiment demonstrated that even when search cost was recoverable, participants preferred the alternative with the larger search cost. This result suggests that sunk costs are not sufficient to explain the effect and that self-perception also contributes.

The Effect of Scarcity on Product Evaluation

Seung Yun Lee, McGill University, Canada
Ashesh Mukherjee, McGill University, Canada

EXTENDED ABSTRACT

Marketers often use scarcity to influence consumers, with announcements such as “hurry, limited quantities”, “until stocks last,” or “few tickets left for this event.” Past research indicates that scarcity generally has a positive effect on product evaluation, because consumers infer that scarcity is a consequence of high demand for the product, which in turn arises from superior value offered by the product^{1,2}. In the present research, we argue that consumers can also make a second type of inference about scarcity—namely that scarcity is perceived as a signal of manipulative intent on the part of marketers to increase demand for the product. For example, it is possible for marketers to artificially restrict the quantity of product being offered in a given retail outlet or sales territory, and thus send a false signal of popularity among consumers. In summary, therefore, we argue that two kinds of inferences are possible when consumers are faced with scarcity: value inference and manipulative intent inference. Greater the value inference, the more positive would be the effect of scarcity on product evaluation; the greater manipulative intent inference, the less positive would be the effect of scarcity on product evaluation. Based on this framework, we specify four moderators, namely persuasion knowledge, frequency of exposure to scarcity claims, decision reversibility, and cognitive load that influence the interpretation of scarcity as value or manipulative intent, and hence the effect of scarcity on product evaluation.

Study 1 focused on persuasion knowledge, defined as individuals’ knowledge about persuasion tactics^{3,4}. We argued that when salience of persuasion knowledge is high, consumers are likely to think about why the marketer is using scarcity claims. This questioning of marketers’ motives, in turn, is likely to prompt inferences that the scarcity is a manipulative intent designed to boost demand. And greater these inferences about manipulative intent on the part of marketers, the less positive will be the effect of scarcity on product evaluation. In contrast, when salience of persuasion knowledge is low, consumers are likely to fall back on the inference that scarcity implies value. Consequently, scarcity will have a stronger positive effect on product evaluation when salience of persuasion knowledge is low. Participants in this study were told that they were participating in two independent experiments. The first experiment manipulated salience of persuasion knowledge using a priming procedure validated in previous research⁴. The second experiment presented participants with a hypothetical retail scenario, which included an ad for a wristwatch. The ad manipulated scarcity, in terms of limited quantities. The dependent variable of product evaluation was measured by a single item, nine-point scale for purchase intent and an item assessing willingness to pay (WTP). Inferences about scarcity were measured by coding thought listings from study participants after they evaluated the target product. We predicted and found that scarcity increased purchase intent and WTP when salience of persuasion knowledge was low, but not high. Consistent with our hypothesis, 61% of participants under the high salience of persuasion knowledge condition perceived scarcity as a manipulative intent to increase sales, as compared to only 29% of participants under the low salience of persuasion knowledge condition.

Study 2 focused on frequency of exposure to scarcity claims. We argued that the individuals who are exposed to many (compared to few) scarcity claims, i.e., high frequency of exposure, are more likely to interpret scarcity claims as a signal of manipulative intent. For example, consider an individual who is reading a

magazine where several ads contain statements such as “Hurry, few items left in stock” and “Only a limited number of products released”. Seeing repeated use of scarcity claims, individuals may wonder if these claims are really manipulative techniques used by marketers to increase sales. To the extent individuals see scarcity as a signal of manipulative intent, the positive effect of scarcity on product evaluation will be weakened. In contrast, when frequency of exposure to scarcity claims is low, consumers are less likely to infer manipulative intent, and hence scarcity would have a stronger positive effect on product evaluation. Participants in this study were told that they were participating in two independent experiments. In the first experiment, frequency of exposure was manipulated in the magazine by inserting scarcity claims into either one ad (low frequency) or four ads (high frequency). In the second experiment, the participants were asked to rate a new line of sunglasses available through an online shopping website. A printout of the online shopping webpage manipulated scarcity using limited quantities of the product. We developed a two-item scale to measure the inference of scarcity claims as a manipulative intent: “The ad was being honest about the number of sunglasses available for sale” and “The ad tried to artificially increase sales by mentioning the number of sunglasses available for sale.” This two-item scale was adapted from the six-item scale measuring inferences of manipulative intent validated in past research⁵. We predicted and found that scarcity increased purchase intent and WTP when frequency of exposure to scarcity claims was low, but not high. Consistent with our hypothesis, respondents were more likely to perceive scarcity as a manipulative intent when frequency of exposure was high, compared to low.

Study 3 focused on decision reversibility, defined as the ability to undo a purchase decision⁶. We argued that when a scarce product is unconditionally refundable (“30-day unconditional money-back guarantee”), individuals are likely to interpret scarcity as a signal of product value. This is because a money back guarantee indicates that the seller is confident about product quality⁷. As a result, the “scarcity=value” inference should be highlighted, and scarcity should have a positive effect on product evaluation. In contrast, if a scarce product cannot be refunded once purchased (e.g., “All sales are final”), such low reversibility protects sellers from the consequences of selling defective items. Consequently, scarcity with low reversibility should highlight manipulative intent on the part of marketers, which is likely to reduce the effect of scarcity on product evaluation. As in Study 2, participants were asked to rate a new line of sunglasses available through an online shopping website. A printout of the online shopping webpage manipulated scarcity using limited quantities of the product validated in past research⁸; reversibility was manipulated by a sign saying either “All sales are final” or “30 day unconditional money-back guarantee.” We predicted and found that scarcity increased purchase intent and WTP when decision reversibility was high, but not low. Consistent with our hypothesis, respondents were more likely to perceive scarcity as a manipulative intent when decision reversibility was low, compared to high.

Study 4 focused on cognitive load. Drawing inferences about hidden marketing tactics behind a persuasive message are likely to require cognitive capacity. Thus we argued that when cognitive load is low, consumers possess sufficient mental capacity to draw inferences about hidden marketing tactics behind a persuasive

message. In this case, consumers are likely to think about why the advertiser has created the ad with scarcity claims. This questioning of marketers' motives, in turn, is likely to prompt inferences that marketers are using scarcity to manipulate consumers into buying the product. Such inference of manipulative intent can dilute value inference, and hence reduce the positive effect of scarcity on product evaluation. In contrast, when cognitive load is high, consumers do not have the cognitive capacity to engage in inferential processing. In this case, consumers are likely to fall back on the simpler and less effortful inference, namely value inference, and hence scarcity would have a positive effect on product evaluation. Participants in this study were told that they were participating in two independent experiments. In the first experiment, cognitive load was manipulated by asking participants to memorize either a seven-digit number (high cognitive load condition) or a two-digit number (low cognitive load condition)⁹. In the second experiment, participants were asked to rate wines available through an online shopping website. A printout of the online shopping webpage manipulated scarcity using limited quantities of the wine products. We predicted and found that scarcity increased purchase intent and product choice when cognitive load was high, but not low. In addition, respondents were more likely to perceive scarcity as a manipulative intent when cognitive load was low, compared to high.

In summary, the four studies reported herein make a theoretical contribution by identifying a new psychological mechanism (i.e., *why*) and corresponding boundary conditions (i.e., *when*) of scarcity, a tool that is widely used in marketing communications.

Until the Dust Settles: Why an Economic Downturn Promotes Consumer Spending Strikes and How to Overcome This

Jaione Yabar, Tilburg University, The Netherlands

Rik Pieters, Tilburg University, The Netherlands

Diederik A. Stapel, Tilburg University, The Netherlands

EXTENDED ABSTRACT

This research examines the “dust settling effect,” that consumers’ feelings of uncertainty about the future state of the economy activate an automatic inaction tendency which leads to a tendency to stop and postpone spending, even if the uncertain future does not have direct personal financial consequences, and even if the uncertain future may actually hold positive financial implications. The dust settling effect has been speculated upon by economic psychologists at least since the Great Depression of the 1930s, but not yet studied empirically among consumers. The dust settling effect may lead to self-fulfilling prophecies and thus have grave implications for the economy at large. Then, uncertainty about the future economy leads to spending strikes by consumers that actually create or worsen the feared crisis. Thus, the present research investigates consumers’ apparent tendency to wait until the economic dust settles, even when the dust does not block the own eyes. In addition, it examines a potential strategy to overcome uncertainty-invoked spending strikes, namely stimulating feelings of anticipated regret of inaction.

Economic downturns can have severe negative effects for large groups of consumers due to income loss or reduced investments. However, they can also have positive side effects and generate advantageous purchase opportunities in particular for those consumers who do not face direct income drops by the crisis, for instance, because retail prices drop and deep promotions are used by firms to stimulate sales. Still, recent industry studies suggest that even consumers with sufficient resources and without direct economic threats reduce their spending when a crisis hits (BCG, 2009, TNS 2009). This seems to reflect an automatic tendency to stop spending in times of general uncertainty. Then, consumers may miss opportunities to take advantage of changed market conditions. Besides, widespread consumption cutbacks by consumers may aggravate the economic crisis in depth and duration

Research on consumer coping during economic hardships (e.g., Kelley & Scheewe, 1975; Shama, 1981) has focused on the behavior of consumers who were actually directly affected through reduced financial resources (unemployment, lost investments and savings). As a result, we know surprisingly little about the influence of an economic crisis on those consumers who are not directly negatively affected by it, and this group may be the largest even under the severest downturns. The economic psychologist Katona (1975) offered the postponement hypothesis that “during a recession, as well as during inflation, most people, irrespective of whether or not they are directly affected, have a sense of reduced certainty and reduced security and hence spend less”. Although there is indirect and macro evidence for the hypothesis, direct evidence obtained from consumers is not available. The present research tests the hypothesis. However, we extend and build on the idea in two important ways. First, we will argue and show that dust settling effects occur even when the uncertainty feelings concern potential gains, such as winning a lottery. Second, we examine one specific strategy to overcome the dust settling effect, namely activating consumers’ anticipated regret of inaction

Uncertainty is an aversive state that motivates behaviors aimed at reducing it. Theories on decision-making under uncertainty have suggested that a dominant mechanism to cope with uncertainty is

to actively gain full information and understanding. Thus, these theories imply that uncertainty leads to action. But individuals may not always try to actively reduce uncertainty by searching information and taking action. Uncertainty can be attributed to the external world or to the individual’s state of knowledge (Kahneman and Tversky 1982). When uncertainty feelings are about the external world and beyond personal control, collecting additional information may not be possible or may not help to reduce uncertainty, as those feelings do not refer to individual knowledge. Research on the omission bias in emotion research, for instance, has found that people tend to remain inactive under uncertainty. Organizational decision theories have also shown the role of postponement in managing of uncertainty. This and other research suggests that inaction rather than action is at the core of the uncertainty.

Building on this, we propose that with uncertainty in the economic environment, consumers’ spending decisions are driven by an inaction tendency, regardless of the consequences of the economic uncertainty for their personal situation (hypothesis 1). Moreover, given the influence that emotions exert on behavior and the importance of uncertainty resolution for human behavior (Loewenstein, Weber, Hsee, and Welch 2001), we hypothesize that even when the uncertainty implies potential gains and not losses, perceived uncertainty leads to focus on not-spending. (hypothesis 2). Finally, since consumers attempt to minimize regret rather than risk (Bell 1982; Zeelenberg and Pieters 2004), we propose that evoking future regret of something consumers’ failed to do will help reduce this inaction focus of uncertain consumers (hypothesis 3).

Four studies tested these predictions. Study 1 documented the natural tendency to stop spending during times of economic uncertainty even when the uncertainty does not have direct personal financial implications (hypothesis 1). Study 2 found that uncertainty, even when it concerns potential gains (and not losses)—such as winning a lottery prize—, also invokes a not-spending focus (hypothesis 2). Study 3 ruled out that the sheer valence of the emotions, positive-negative, rather than uncertainty, and that active-saving rather than not-spending, account for the findings. The study revealed that uncertainty feelings, and not specific emotions (happiness, hope, anger or fear), lead consumers to not-spend rather than to actively save money. Finally, Study 4 tested one mechanism to overcome the inaction effects of uncertainty and encourage consumers to spend, namely evoking future regrets of inaction. After showing participants a news item about consumers’ future regrets of action [inaction] during an economic downturn, those participants told about future inaction regrets spent more money and overcame their inaction tendency. Jointly the findings reveal that uncertainty about future economic situations, even if consumers are not directly affected, and even if they may entail gains, promote spending strikes. These can be routed by activating anticipated inaction regret. In this way, the present research identifies how consumers’ self-fulfilling prophecies about economic downturns arise and can be broken.

Effect of Attribute Change on Preference Modification

Ataollah Tafaghodi Jami, University of Utah, USA

Himanshu Mishra, University of Utah, USA

EXTENDED ABSTRACT

This paper uses dual-systems of processing to explain why people, who detect an attribute change in their choice set, choose the option with the highest (lowest) absolute change when the change is positive (negative). Three studies provide support for the proposed account and reject other alternative explanations.

Imagine that a grocery store sells Kellogg's Special-K in two package sizes: 10 oz. for \$2.50 and 15 oz. for \$3.75. John buys Special-K, and since the unit price for each pack is the same, he is indifferent between either of the packs. Recently, he noticed that Kellogg's is offering bonus packs with the purchase of Special-K—a 10 oz. pack plus 4 oz. for \$2.50, and a 15 oz. pack plus 6 oz. for \$3.75. Which package would John prefer now? Based on his past preference, one might predict that he would be indifferent between both packages as unit price is still the same across both of them. Contrary to this prediction, we find that he would no longer be indifferent and would prefer the bigger package over the small package. We call this phenomenon the Detection of Change Effect (DCE), where people, who were indifferent between two options before the change, later prefer the option with a higher magnitude of change when the change is positive (desirable), and the option with a lower magnitude of change when the change is negative (undesirable).

The preliminary evidence of the DCE was found through a study in which participants were randomly assigned to a two cell between-participant experimental design, and presented with a choice between two breakfast cereals. In the control condition, participants were asked to choose between two packages of cereal (i.e., package A: 12 oz. for \$4; and package B: 18 oz. for \$6). Note that the unit price for both packages was 33 cents/oz. In the "positive change" condition, participants were first given information akin to the information given to the control condition participants. Then, they were told that the company had introduced some changes by adding smaller bonus packages to the original ones (Package A: 12 oz. plus 4 oz. for \$4; and package B: 18 oz. plus 6 oz. for \$6). Note that the unit price for the new packages was 25 cents/oz. Then, the participants were asked to choose the option that they preferred to buy.

In the control condition, participants chose the smaller package slightly more than the bigger package (package A: 59.5%, package B: 40.5%). However, in the positive change condition, participants preferred the bigger package more than the smaller one (package A: 35.7%, package B: 64.3%) which was significantly different from the control condition ($\chi^2(1)=4.77, p<.03$).

Why do people prefer the option with a higher absolute change? Research has shown that people use two modes of processing (known as System 1 and System 2) for making a decision (Kahneman 2003). System 1 is known for its automatic judgments and heuristic-based decision making whereas System 2 produces more deliberative responses toward a stimulus (Kahneman 2003). While System 1 and 2 are often working simultaneously and independently, research has shown that the outcome of one system can interact with the other system which results in a biased mental representation (Mishra et al. 2007). Following this literature, we propose that people, who perceive an attribute change, use System 2 to compare the original and changed options and to find out how much the original options have changed. Then, when they want to evaluate the changed options, System 1 uses the outcome of System 2 (i.e., the difference between the original and the changed options)

and the bigger-is-better heuristic to form the preference toward the option with the highest absolute amount of change. Since the bigger-is-better heuristic was mainly observed on the gain side (i.e., when people receiving something), it is expected that people use the bigger-is-worse heuristic when they are comparing losses. Therefore, we expect that when there is a negative attribute change (i.e., when quantity is reduced or price is increased), people choose the smaller box over the larger one since they want to avoid the bigger loss.

There are three alternate accounts that can also explain the results of the preliminary study. These three accounts are the value-of-free products (Shampanier, Mazar, and Ariely 2007), Increasing Proportional Sensitivity (IPS) (Prelec and Lowenstein 1991), and the general law of demand (Marshall 1895). According to these accounts, participants in the preliminary study chose the bigger cereal box because either they assigned higher value to the bonus box as a free product (the value-of-free product), or changing the weights of boxes, regardless of knowing about the original options, improved the importance of the weight attribute in decision making (IPS), or increasing the weight of boxes reduced the unit price (price per weight) and consequently increased the demand for the product (the general law of demand).

The aim of study 1 and 2 was to provide more evidence for the main account and to assess the efficacy of the three alternate accounts. Study 1 supported our proposition for the negative attribute change as it showed that participants chose the option with lowest amount of change when the change was negative. This pattern was not predicted by the value-of-free-product account since no additional product was offered in this case. Moreover, study 1 ruled out the IPS account as it showed that the preference for the bigger option depended on knowing about the original options and detecting the change.

Study 2 supported our proposed account as it showed that directing participants' attention toward the differences between the original and changed options increased the DCE. Also, the second study ruled out the general law of demand as an alternate account since the results showed that directing participants' attention toward the unit price eliminated the DCE. Finally, in the third study, with the help of Process Dissociation Procedure (PDP), we provided empirical evidence that showed and contrasted the role of System 1 and System 2 in the DCE.

In sum, these findings suggest that people's response to an attribute change is not their mere reaction to the new magnitude of the changed attribute. In other words, they do not evaluate a weight of 12 oz. plus 4 oz. similar to a weight of 16 oz. But, they use the additional information that they have (i.e., the magnitude of the attribute before the change) to evaluate the changed product.

Evaluating Ratio Data and the Role of Consumer Processing Mode: Can Analytical Processing Bias Judgments?

Dipayan Biswas, Bentley University, USA
Patricia Norberg, Quinnipiac University, USA
Donald Lehmann, Columbia University, USA

EXTENDED ABSTRACT

Consumers often encounter information presented in the form of ratios (Peters et al. 2007; Silverblatt 2009), and they are sometimes required to compute the averages of multiple pieces of data in ratio formats. Commonly encountered ratios in daily activities include laundry detergent information given as loads per container (LPC), fitness equipment information regarding calories burned per minute (CPM) of exercise, and vehicle speed information in miles per hour (MPH). In this research, we examine how computing averages for multiple pieces of data in such ratio formats might bias consumer judgments. Equally importantly, we also examine how processing mode might moderate the effects of ratio formats on consumer averaging judgments.

There has been limited research on how consumers process ratio information (with Denes-Raj and Epstein 1994, Hsee et al. 2003, Larrick and Soll 2008, and Raghubir and Greenleaf 2006, being notable exceptions), and no study has examined how consumer judgments might be biased when they are computing averages of multiple pieces of data in different ratio formats. Further, no study has examined the moderating effects of consumer processing modes in this context. Thus, the present research examines the potential for bias when computing averages, and examines the moderating effects of consumer processing mode (Studies 1 and 3) and cognitive capacity (Study 2). We find an interesting paradoxical result—analytical (vs. heuristic) processing accentuates the bias when processing certain ratio data, and likewise higher cognitive capacity reduces the judgment accuracy for certain ratio data. Finally, we identify alternative data formats that can potentially reduce consumer judgment biases.

People tend to process numerical information in a linear fashion (Brousseau, Brousseau, and Warfield 2002). Such linear arithmetic processing is likely to lead to erroneous judgments when evaluating inverse ratio data (i.e., where the focal variable is in the denominator). Specifically, for inverse ratios (like LPC, CPM, or MPH), the appropriate mathematical computation to use would be a harmonic mean. However, consumers are instead likely to employ the linear arithmetic mean, leading to biased judgments.

Study 1 examined how consumers compute the average rate of calories burned across multiple exercise routines (or fitness machines) with information given in a commonly used format of calories burned per minute, or CPM (see Zeni, Hoffman and Clifford 1996), versus an alternative format of minutes taken per calorie (MPC). Study 1 also examined the moderating effects of consumer processing mode (analytical versus heuristic) (e.g., Alter et al. 2007; Kahneman and Frederick 2002). Under analytical processing, a consumer is more likely to rely on mathematical calculations, and therefore more likely to compute the linear arithmetic mean across the multiple pieces of ratio data. In contrast, under heuristic processing, an equivalent of a random choice between the options would be more likely. Hence, analytical (versus heuristic) processing of the data would magnify the proportion of erroneous judgments. Therefore, we propose that when consumers are computing averages across multiple pieces of data in CPM format, analytical (vs. heuristic) processing will paradoxically increase judgment inaccuracy. However, when consumers are computing averages across

multiple pieces of data in MPC format, analytical (vs. heuristic) processing will increase judgment accuracy.

Study 1 was a 2 (type of data format for calorie burning rate: calories per minute vs. minute per calorie) X 2 (processing mode: analytical vs. heuristic) between-subjects experiment (N=114). The results of study 1 supported our hypothesis that when computing averages across multiple pieces of data in inverse ratio formats (such as CPM), consumers are prone to make erroneous judgments. Study 1 also showed that such erroneous judgments for ratio data are likely to get enhanced when consumers are making judgments under analytical (than heuristic) processing mode.

Study 2 extended the findings of study 1 by examining a different context using the scenario of a decision-maker choosing between two route options with speed data in miles per hour (MPH), and the moderating effects of cognitive capacity. Study 2 showed that different levels of cognitive capacity lead to a similar pattern of results as processing mode. That is, paradoxically, when consumers exert greater effort in analyzing the given options and employ mathematical computations to a greater extent under high (vs. low) cognitive capacity, their judgments become more inaccurate/biased.

Study 3 had three objectives. First, it replicated the potential bias in computing of averages of ratios in the context of laundry detergent usage. Second, it examined how presenting ratio information through a medium (e.g. Hsee et al. 2003) such as price per load might reduce consumer judgment bias. Third, while in Study 1 processing mode was manipulated, Study 3 measured processing mode as an inherent personality trait (Pacini and Epstein 1999). Study 3 was a 2 (type of data format for laundry detergent: loads per container vs. Dollar per load) X 2 (processing mode: analytical vs. heuristic) between-subjects experiment (N=144). The results of Study 3 again highlighted how an inverse ratio format like LPC, which is commonly used, can bias consumer judgments when computing averages of multiple pieces of data; the judgment bias can be reduced by presenting the data with the help of a medium, such as price per load. Study 3 also demonstrated that analytical (vs. heuristic) processing tendency increases consumer judgment biases with the LPC format, but lead to more accurate judgments with DPL format.

In sum, the results of three experiments highlight how some commonly used ratio formats might bias consumer judgments when they are computing averages. Equally interestingly, analytical processing or higher cognitive capacity can reduce judgment accuracy when consumers attempt to compute the mean of multiple data pieces in certain ratio formats such as CPM, MPH, or LPC. The bias can be corrected if the data are presented in alternative formats of MPC or DPL, which are conducive to linear mathematical processing.

Covariation Learning, Quality Expectation and Product Valuation Under Homoscedastic and Heteroscedastic Uncertainty

Bart de Langhe, Erasmus University Rotterdam, The Netherlands

Stefano Puntoni, Erasmus University Rotterdam, The Netherlands

Ann L. McGill, University of Chicago, USA

Stijn van Osselaer, Erasmus University Rotterdam, The Netherlands

EXTENDED ABSTRACT

Over the past four decades, a substantial amount of research has been conducted to study how people acquire cue-outcome relations, including literature on contingency learning (Allan 1993; van Osselaer et al. 2004), covariation judgments (Baumgartner 1995; Pechmann and Ratneshwar 1992), category representations (Erickson and Kruschke 1998), and function learning (DeLosh et al. 1997; Juslin et al. 2008). Despite the important insights gained into how humans detect systematic cue-outcome associations against a background of uncertainty, no research has investigated if cue-outcome learning depends on whether the degree of uncertainty is the same (i.e., homoscedastic) or varies (i.e., heteroscedastic) across different ranges of the cue. To illustrate this distinction in the nature of randomness, consider consumers' price-quality beliefs for restaurants. Prior research on cue-outcome learning assumes no differences between a *homoscedastic* world where high-end restaurants display the same medium level of variance in quality as do inexpensive restaurants and a *heteroscedastic* world where quality can vary wildly among inexpensive restaurants but instead tends to be consistently high among high-end restaurants.

According to linear statistical theory, the correlation coefficient is a function of overall error variance and it is not affected by where, in the range of the cue, the uncertainty is located (Cohen et al. 2003). Therefore, if the overall cue-outcome association strength (i.e., the correlation coefficient) is the critical input for covariation inferences (e.g., Brehmer 1973), then the nature of the error (homoscedastic vs. heteroscedastic) may not matter, as long as the overall level of uncertainty remains the same. However, the distinction between homoscedastic and heteroscedastic uncertainty may be crucial if covariation judgments are in fact influenced by local variations in cue-outcome association strength (i.e., local correlations).

The current research proposes that (a) local correlations are taken into account when expressing overall judgments of covariation and (b) that local correlations are influenced by the nature of outcome uncertainty (heteroscedastic vs. homoscedastic). We theorize that homo- versus heteroscedasticity determines the perception of local correlations according to a two-step process. The first step entails a statistical nonlinear decreasing effect of error variance on local correlations (Doksum et al. 1994), whereas the second entails a psychophysical nonlinear increasing effect of objective correlation on perceived correlation (Jennings et al. 1982). The result of this process is that, all else being equal, the reduction in error variance in the low uncertainty range of heteroscedastic environments has a disproportionately large impact (relative to the impact of the increase in error variance in the high uncertainty range) on perceived local cue-outcome association strengths.

The first two experiments in this paper establish that heteroscedastic error variance, relative to homoscedastic error variance, results in more extreme judgments of cue-outcome association strength. In Study 1, we presented participants with cue-outcome pairs in tabular format and asked them to judge the overall cue-outcome association strength. We manipulated homo- versus heteroscedasticity within-participants via an elaborate procedure that varies across tables the nature of the error while holding constant other factors that may influence judgments of covariation (overall cor-

relation, regression slope, intercept of the regression, mean, etc.). To avoid that any effect of homo- versus heteroscedasticity could be attributed to the existence of prior theories about the association between cue and outcome, we used X and Y as cue-outcome labels in this first study (e.g., Baumgartner 1995). The results show that overall judgments of cue-outcome association strength are more extreme when error variance is heteroscedastic.

In Study 2, participants learned first about the prices and quality scores of several brands in a fictive product category. Homo- versus heteroscedastic uncertainty about quality was manipulated between-participants. Subsequently, we asked participants to indicate to what extent they thought it was difficult to predict quality at different price levels (to measure the perceived local correlations). The results show that participants found it less difficult to predict quality in the low uncertainty range of the heteroscedastic condition than in the homoscedastic condition, while there was no difference between the high uncertainty range of the heteroscedastic condition and the homoscedastic condition. This study shows that error variance has a nonlinear decreasing impact on the perceived local correlations.

Two additional experiments attest to the managerial importance of these findings by establishing systematic differences in product quality expectations and product valuation between homoscedastic and heteroscedastic environments. Study 3 shows that quality expectations are more sensitive to price under heteroscedastic outcome uncertainty than under homoscedastic outcome uncertainty. When heteroscedasticity is manipulated by increasing uncertainty at higher price levels, participants in the homo- and heteroscedastic condition expect similar quality for low-priced brands. However, for higher-priced brands, participants in the heteroscedastic condition expect higher quality than participants in the homoscedastic condition.

Finally, Study 4 investigates consumers' product ratings (value for money) when they are provided with objective information about product price and quality. If, compared to participants in a homoscedastic condition, participants in a heteroscedastic condition with increasing variance over the price range expect higher quality for higher-priced products, they should also rate a high-priced product with a specific quality to be of less value for money. The findings confirm this prediction.

Affective Evaluations Are More Ordinal

Michel Tuan Pham, Columbia University, USA

Olivier Toubia, Columbia University, USA

Claire Lin, Columbia University, USA

EXTENDED ABSTRACT

There is growing evidence that affective responses provide an alternative means of assessing value. We advance the hypothesis that, compared to the cognitive system, the affective system assesses value in a relatively more ordinal (less cardinal) fashion. We base this hypothesis on the rationale that our ancestral affective system was originally meant to support behavioral choices, which requires primarily ordinal (rather than cardinal) assessments. The relatively greater “ordinality” of the affective system helps explain various apparent biases in affective judgments of value, such as their greater reference-dependence and scope-insensitivity (see Pham, 2007).

Support the ordinality-of-affect hypothesis was obtained across three studies involving both outcome and process-level data. First, affective assessments of value have more ordinal distributions than more cognitive assessments of the same targets. Second,

process-level data indicate that, when asked to assess evaluative targets based either on feelings or on cognitive assessments, affect-oriented participants tend to evaluate targets jointly as if ordinally ranking them, whereas cognition-oriented participants tend to evaluate each target separately. Finally, affect-oriented participants appear to have stronger memory for rank-order information than cognition-oriented participants.

The purpose of the first study was to provide process-level evidence that the affective system assesses values in a more ordinal fashion. Participants were shown the pictures of target individuals of the opposite sex and asked to rate them either as potential dates (a more affective assessment) or as potential teammates for a project (a more cognitive assessment). (Previous studies and pretests had shown that these instructions indeed varied the reliance on affective vs. cognitive information.) As predicted, participants assessing the targets as potential dates tended to generate their own order to rate these targets, suggesting that relative ordering of the targets was an important consideration to these affect-oriented participants. In contrast, participants assessing the targets as potential teammates tended to simply follow the order in which the targets were presented, suggesting that the relative ordering of the targets was less important to these cognition-oriented participants. In addition, compared to participants in the potential teammates (cognition) condition, participants in the potential dates (affect) condition had more accurate memory for the relative location of the pictured target individuals, suggesting that comparisons across targets were more likely in the potential date (affect) condition. Finally, compared to participants in the potential teammates (cognition) condition, participants in the potential dates (affect) condition re-ranked the targets more consistently, suggesting that relative ranking was a more important determinant of their assessments. These process results suggest that affect-oriented participants tended to evaluate the targets jointly as if ordinally ranking them, whereas cognition-oriented participants tended to evaluate these targets separately.

The purpose of studies 2a and 2b was to document a previously unrecognized property of affective evaluations that logically follows from the proposition that affective evaluations are more ordinal. Specifically, if affective evaluations are indeed generated by an ordinal, rank-ordering process, people making affective evaluations should tend to distribute targets more uniformly along the full evaluative scale. We call this phenomenon *distributive scale use*, which we demonstrate both in a field study and in a lab study.

In the field study, men and women participants took part in a “speed-dating” event in which they had a series of “mini-dates” with opposite-sex participants. After each date, each participant rated the other person in terms of physical attractiveness, a presumably more affective judgment, and intelligence, a presumably more reason-based judgment. Individual-level analyses of these ratings revealed that ratings of attractiveness indeed exhibited more distributive scale use—that is, had more ordinal distributions across potential dates—than ratings of intelligence, which had more interval-scale-like distributions.

Another lab study replicated and generalized these in the context of responses to magazine pictures. Compared to the field study, more direct measures of affective versus cognitive evaluative responses were obtained by instructing respondents to record either the pleasantness of the feelings elicited by each picture or the judged quality of each picture using previously validated instructions (Pham, Cohen, Pracejus, and Hughes, 2001). More refined distributions of the two types of responses were additionally obtained by increasing both the number of target stimuli (pictures) and the number of levels of responses on which they could be assessed (a 1-100 real-time electronic dial-turning scale). Again, individual-level analyses of these responses revealed that feelings elicited by the pictures had more ordinal distributions than the judged quality of these pictures, which had more interval-scale-like distributions.

Overall, the results of these three studies are consistent with the hypothesis that the affective system of valuation is more ordinal and more attuned to rank-order information than the cognitive system of evaluation.

When one culture meets another: The impact of culturally (mis)matched thinking styles on self-regulation

Minkyung Koo, University of Illinois, USA

Sharon Shavitt, University of Illinois, USA

Ashok K. Lalwani, University of Texas at San Antonio, USA

Sydney Chinchanchokchai, University of Illinois, USA

EXTENDED ABSTRACT

It is well documented that Westerners tend to engage in analytic thinking whereas Asians tend to engage in holistic thinking (Nisbett, Peng, Choi, & Norenzayan, 2001). Although a great deal of research has revealed various antecedents and consequences of cultural differences in thinking styles, little attention has been paid to the consequences of engaging in culturally mismatched thinking styles. We hypothesized that culturally mismatched thinking styles impact the self, particularly one's regulatory resources. Self-regulation refers to "the self's capacity to alter its own states and responses" or limited resources similar to strength or energy (Baumeister, 2002). In three studies, we provide evidence that culturally mismatched thinking styles can be an important source of self-regulatory depletion and thus can impair subsequent evaluation and further actual consumption behaviors. Our findings indicate the effects are generalizable to real-life settings and therefore have significant implications for creating advertisements and forecasting their effects on audiences of differing ethnicities and cultural backgrounds.

Study 1 tested the hypothesis that a mismatch between one's culturally dominant thinking style and a situationally induced thinking style can impair self-control. Participants from both individualistic (e.g., Caucasian) and collectivistic (e.g., Asian, Hispanic) cultural backgrounds were recruited. Half of the participants in each cultural background were assigned to an analytic task condition: they were shown a picture in which 11 embedded objects were to be found (Monga & John, 2007). The rest of the participants were assigned to the holistic task condition, in which they were shown the same picture but with an instruction to focus on the background. Subsequently, participants' self-regulation was measured using a self-control scale (Tangney, Baumeister, & Boone, 2004).

As hypothesized, a significant interaction emerged between the participants' cultural background (individualists vs. collectivists) and their primed thinking styles (analytic vs. holistic). In the analytic condition, individualists scored significantly higher on self-control than did collectivists. In contrast, in the holistic condition, collectivists scored higher on the self-control scale than individualists.

These findings suggest that a culturally mismatched thinking style can deplete self-regulatory resources. However, it can be argued that those participants in the matched condition may have experienced a greater degree of fluency while doing the task and that this led to more favorable judgments about themselves compared to those in the mismatched condition. In other words, the disfluency experiences associated with culturally mismatched thinking styles may have affected participants' perceived ability to engage in self-control.

Study 2 was designed to pit these two explanations (depletion vs. disfluency) against each other. Participants were induced to think either analytically or holistically using the same procedures as in Study 1. They were then given a description of one of two cereal bars (a delicious but unhealthy chocolate cereal bar vs. a healthy but less delicious multi-grain bar) and were asked to rate their evaluation and likelihood of buying the described food item. Finally, participants' chronic thinking styles were measured using the Analysis-Holism Scale (Choi, Koo, & Choi, 2007).

Processing fluency is known to increase the perceived familiarity with and fondness for a stimulus (e.g., Reber, Winkielman, and Schwarz, 1998). Therefore, if a mismatched task creates a sense of disfluency, participants' evaluation of the tempting food and evaluation of the less tempting one should not differ. Instead, those in the matched (vs. mismatched) condition should evaluate whichever food they were shown more positively. In contrast, if a culturally mismatched task leads to depletion, participants in the mismatched condition should evaluate the tempting option more positively than the less tempting option.

Supporting the depletion explanation, a significant interaction was found between the type of experience (matched vs. mismatched with one's chronic thinking style) and the type of food (chocolate bar vs. multi-grain bar) both in evaluation and purchase likelihood. Participants in the mismatched condition evaluated the chocolate bar more positively than the multi-grain bar and also reported a greater purchase likelihood for the chocolate bar than for the multi-grain bar. Those in the matched condition did not differ in their evaluation or purchase likelihood as a function of the type of food.

Study 3 examined the managerial implications of the effect of culturally mismatched experiences using a real-world situation and measuring participants' actual consumption behavior. In a field study, which was introduced to the participants as a consumer study, participants were given a set of mock ads and asked to evaluate them. Each ad included a picture of individual chocolates or candies of different colors and shapes arranged in the shape of different objects such as a house and a tree. Participants in the analytic condition were asked to describe what made each piece distinct, and those in the holistic condition were asked to describe what shape the individual pieces make as a whole. Analytic thinkers were expected to have a harder time finding the figure than holistic thinkers because analytic thinkers in general tend to focus on details whereas holistic thinkers tend to focus on the big picture (Nisbett et al., 2001). Subsequently, participants were guided to a popcorn tasting study in which they were given an opportunity to sample as much popcorn as they wanted. The amount of popcorn they served themselves was our measure of self-regulation.

Consistent with the previous two studies, a significant interaction between culture (individualistic vs. collectivistic) and the type of task (analytic vs. holistic) emerged. Individualists took more popcorn when they had to find an overall figure than when they had to focus on individual chocolates in the ads. The opposite was the case for collectivists.

Overall, the three studies showed converging evidence that engaging a culturally mismatched thinking style is depleting and can impair a person's self-regulatory performance. This was evidenced on a self-control scale, on food evaluation, and on actual snack consumption. The findings suggest that (mis)matches to one's cultural thinking styles are an important set of experiences impacting one's self-regulatory resources. Indeed, people of certain ethnicities, nationalities, and backgrounds can experience self-regulatory depletion (and increased temptation) merely through exposure to ads or activities that require them to think in an unfamiliar way.

Just This Once: Perceptual Distortion Entitles Consumers to Indulge

Bert Weemaes, K. U. Leuven, Belgium
Siegfried Dewitte, K. U. Leuven, Belgium
Luk Warlop, Catholic University Leuven, Belgium

EXTENDED ABSTRACT

Three experimental studies show that perceived differences between current and future choice situations reduce food intake self-regulation in the current choice. We demonstrate that the effect occurs because, in response to a currently available food temptation, consumers perceptually differentiate the current choice situation from future choice situations allowing them to indulge without threatening their long-term goal.

This work examines how relating a current food temptation to future food temptations influences the current decision to indulge. Specifically, it looks at the impact of perceived dissimilarity between current and future choice situations on the current decision.

In itself, the long-term consequences of consuming a few potato chips, a single burger, or a frappuccino may not sufficiently motivate consumers to abstain from the immediate pleasure of consuming them (Gilbert et al. 2004; Read, Loewenstein, and Rabin 1999). Still, consumers do not always follow the logic that marginal amounts of vice consumption will only have marginal effects on their weight or health. Instead, they translate higher-order goals into guidelines for behavior by implicitly forming overgeneralized decision rules (Amir and Ariely 2007; Amir, Lobel, and Ariely 2005). For instance, a consumer who holds a weight goal may implicitly form the rule “not to eat fattening food.”

Indulging in a frappuccino right now causes a negligible weight gain but, more importantly, the mere act of choosing against one’s implicit rule causes people to make inferences about themselves (Khan, Dhar, and Wertenbroch 2005). Thus, the decision whether to indulge in the current choice situation is influenced by what this choice tells consumers about their future choices (Huffman, Ratneshwar, and Mick 2000).

This framework implies that consumers may be able to justify current indulgence if they can perceive the current situation as different from future choice situations. Combining the findings that temptations motivate consumers to construct justifications to indulge without harming goals or rules (Cheema and Soman 2006; Poynor and Haws 2009) and that ambiguous stimuli are assimilated to consumers’ current motive (Balcetis and Dunning 2006), we suggest that a currently available food temptation (e.g. the opportunity to have a burger now) may distort consumers’ perception such that consumption appears justifiable.

We predict that consumers differentiate current from future food temptations by depicting the current and future choice situations as dissimilar. We hypothesize that doing so can even be triggered by trivial (i.e. non-diagnostic) differentiation cues. Establishing the current choice situation as dissimilar from future choice situations in turn leads to increased current indulgence. Two studies tested these predictions.

Study 1 demonstrates the effect by manipulating a non-diagnostic differentiation cue. Participants were given the opportunity to indulge in a small, presently available food temptation (M&Ms®). Before they decided whether or not to indulge in this temptation, they were explicitly provided with a future reference point in the form of a second temptation that was to follow later on in the experimental session. In the Classic-Classic (CC) condition participants were given the opportunity to eat from a small amount of Classic M&Ms currently in front of them while they expected to get a large bowl of Classic M&Ms later. The Halloween-Classic

(HC) condition offered the opportunity to consume a small amount of “Halloween M&Ms” (colored black and orange) while expecting to receive a large bowl of Classic M&Ms later. A mirrored Classic-Halloween (CH) condition was also added. Relative to the CC condition, we found that tempted participants were likely to eat if a subtle, non-diagnostic differentiating cue was present (HC and CH conditions). Presumably, the differentiation cues allowed participants to more easily construe the current choice as different from future decisions, increasing the likelihood that tempted individuals chose to indulge.

Study 2 exposes the proposed process using an experimental-causal-chain design (Spencer, Zanna & Fong, 2005). Study 2A aims to show that currently available food temptations cause consumers to perceptually differentiate the current choice situation from future choice situations. Study 2B provides the causal chain’s second part: perceiving current and future choice situations as dissimilar increases indulgence in the current choice.

Participants in the large-amount-later condition of 2A received a small serving of sweet pepper flavored potato chips. They were told that would receive a second temptation later that consisted of a large amount of salt flavored potato chips. As a comparison point, we included a second, baseline condition with neither a currently available food temptation nor the expectation of a second temptation. We also included a control condition: the small-amount-later condition was identical to the large-amount-later condition, but participants were told that the second temptation consisted of a small amount of salt chips. We used a multidimensional scaling (MDS) approach to observe participants’ perceptions of a two-dimensional product space (Kruskal and Wish 1978). Aggregate consumption would be threatening to the long-term goal by exceeding a critical limit only in the large-amount later condition (do Vale, Pieters, and Zeelenberg 2008; Gilbert et al. 2004). We expected and found that, relative to the baseline condition, the large-amount-later (but not the small-amount-later) condition would start to perceive products that differ among the flavor dimension (the dimension in which the sweet pepper and salt potato chips differ) as more dissimilar. Large-amount-later participants perceptually set the current and future choice situations apart.

Study 2B manipulated dissimilarity while keeping products identical across conditions, ruling out a variety seeking explanation. We selected sweet pepper chips (current temptation) and sweet pepper encrusted peanuts (future temptation) as stimuli. We examined whether participants decided to eat from a small amount of sweet pepper chips, while they expected to receive a large bowl of sweet pepper encrusted peanuts later in the experimental session. Before participants had the opportunity to consume the sweet pepper chips, the latter were suggested to be more dissimilar from (vs. similar to) the encrusted peanuts through a task that repeatedly depicted products of the two consumption phases as belonging to a different (vs. the same) product-group. Indulgence increased when a cue, allowing participants to more easily perceive the current and future choice situations as different, was emphasized (vs. suppressed).

People often sincerely intend to avoid having too many tasty frappuccinos or delicious burgers. Still, they stray from their long-term goals more frequently than they would like (Hoch and Loewenstein 1991). Our findings imply that one of the reasons for this phenomenon may be that consumers unwittingly undermine

their good intentions by spontaneously and repeatedly distorting their perception of the current choice situation.

Healthy Satiation: The Role of Satiation in Having Effective Self Control

Joseph Redden, University of Minnesota, USA

Kelly Haws, Texas A&M University, USA

EXTENDED ABSTRACT

The present research merges perspectives from past research on satiation and self-control. We study how satiation may serve to enhance self-control in the domain of food consumption. Past research has shown that people tend to satiate on a variety of products and experiences. Interestingly, satiation is most typically viewed negatively, as something that needs to be overcome through a variety of mechanisms such as variety seeking (Ratner, Kahn, and Kahneman 1999), use of more detailed levels of categorizations (Redden 2008), among other things. In the present research, we examine the potential positive effects of satiation. Specifically, we examine circumstances under which various levels of satiation beneficially impact self-control related behaviors.

We define satiation as the decline in pleasure with repeated consumption (Coombs and Avrunin 1977; Redden 2008). Research regarding the “hedonic treadmill” (Brickman and Campbell 1971) suggests that we continually seek to have new experiences in order to simply keep our current level of happiness from declining. Such perspectives suggest that reducing satiation will provide benefits to the consumer. However, hedonic treadmill aside, could it be that the human tendency to satiate actually serves a very useful purpose in goal-driven behavior?

Consider for example, the abundance of cookies, candies, and other tempting desserts readily available during the holiday season. Might some people simply get their fill of such indulgences more quickly than others, and therefore have fewer holiday pounds to shed in the aftermath? Presumably, they enjoy such indulgences as much as the next guy, but perhaps they more quickly feel satisfied with the experience? In the present research, we examine how self-control and decreases in the enjoyment of a consumption opportunity may interact to contribute to “healthy” satiation. After establishing the basic effect, we examine differences in product type and a potential process explanation for our results in a series of three studies.

In study 1, we establish a link between inherent self-control and predicted satiation on an ambiguous stimulus. The 73 adult participants were provided with a description of pretzels, and were then asked to indicate how much they would enjoy the first, fifth, and tenth handful of these pretzels. Separately, their inherent self-control was assessed using the 13-item version of the general self-control scale (Tangney et al. 2004). Results indicated that the decreases in enjoyment from the first bite to both the fifth and tenth bites were more dramatic for consumers higher in self-control. In other words, they predicted that they would satiate more quickly on the pretzels. We note that initial levels of enjoyment did not differ based on self-control.

In study 2, we test the role that product type might play in influencing rates of satiation. We theorize that the consumption of virtuous products should not be perceived to negatively influence long-term goals because such products do not elicit the same level of temptation for immediate gratification or threat to achievement of long-term outcomes (Werthenbroch 1998). As such, differences in rates of satiation based on one’s level of self-control will be enhanced for products viewed as more vice in nature. To test this prediction, 175 adult consumers were asked to consider either a set of three relatively healthy desserts or three relatively unhealthy desserts. Our results indicate that high self-control consumers tend to enjoy healthier desserts more initially, but satiate at the same rate as low self-control consumers with repeated consumption. In

contrast, high self-control people find unhealthy desserts to be just as enjoyable the first time they have it, but they get satiated much faster. This overall interaction illustrates that the type of product matters, and that high self-control individuals appear to satiate more quickly when it is healthy to do so, but not when it is less beneficial to do so.

Finally, in study 3 we examine actual consumption as well as the underlying process for our effects. Specifically, we propose that the reduction in liking or desire that high self-control individuals exhibit for ambiguous or unhealthy alternatives can be explained by the enhanced monitoring or attention that they pay to their consumption experiences. This leads to an enhanced recognition that their enjoyment of the stimulus has decreased. We used a natural between subjects manipulation of healthiness (based on pretesting) and presented 215 students with either a set of three candy bars or a set of three granola bars. Three options were given in order to ensure that participants would have a reasonable level of liking for the selected product (thereby providing “room” for decreased enjoyment). Our primary measures of satiation in this study included anticipated recovery time (i.e., how soon they would want the snack again) and desire to have the snack again the next day. In addition, after a filler task, we presented them with another serving of their chosen snack and we measured their actual consumption. Self-control was once again assessed separately from the main study. As in study 2, a significant interaction emerged. For healthy snacks, the recovery time had a negative relationship with self-control, indicating that high self-control individuals expected to recover from satiation on healthy snacks faster than those low in self-control. For unhealthy snacks, the data showed the opposite pattern as high self-control individuals tended to expect longer recovery times. Similar patterns were found for the desire to eat tomorrow and actual consumption of a second serving of the snack. Additional analysis demonstrates that the attention paid to consumption mediates the relationship between the self-control X snack type interaction and all three of our dependent measures.

In conclusion, we suggest that differences in satiation rates may help explain why some people find it easier to exhibit self-control than others. In particular, people high in self-control will get satiated faster with unhealthy foods and less so with relatively healthy foods. We suggest that this is explain in part by the attention that high in self-control pay to their consumption quantity when consuming an unhealthy food that helps them recognize their reduction in desire.

Saying No to Tattoos and Yes to Safe Sex: Ego-Depletion May Help Boost Self-Regulation

Monika Lisjak, Northwestern University, USA

Angela Y. Lee, Northwestern University, USA

EXTENDED ABSTRACT

A large body of research shows that exercising control over one's impulses and other inner processes in one domain leads to subsequent impairments in self-regulation in other domains, a phenomenon that has been referred to as ego-depletion (Baumeister et al. 1998; Muraven, Tice and Baumeister 1998). Existing literature finds that ego-depletion has negative consequences for the individual and the society, such as overeating, overspending and violence. In this research we suggest that ego-depletion may also lead to some beneficial outcomes. More specifically, we suggest that ego-depletion leads to a strategic reallocation of the diminished regulatory resource to increase vigilance. That is, depleted people pay more attention to negative information and are less likely to engage in risky behaviors.

A resource model has been proposed to explain the ego-depletion effect (Baumeister et al. 1998; Muraven et al. 1998). According to this model, all acts of self-regulation draw on a common pool of resource that is limited. After exerting self-control in one domain, people have less resource available to engage in subsequent self-regulation. Recent findings suggest that effects of ego-depletion do not reflect a complete loss of the capacity to self-regulate; rather the effects are due to attempts to conserve the diminished resource—a highly adaptive strategy to prevent a complete loss of self-regulatory ability. The objective of this paper is to more systematically explore the adaptive nature of the ego-depletion effect.

It is commonly accepted that people engage in vigilant processes, which are highly functional for survival. Research shows that negative stimuli are detected faster than positive stimuli (Dijksterhuis and Aarts 2003), and that people pay more attention to negative as opposed to positive information (Pratto and John 1991). And adaptive vigilant processes are thought to underlie people's general tendency to assign more value to negative than positive information (Kahneman and Tversky 1984).

Drawing from this functional perspective, we suggest that ego-depletion leads to a strategic reallocation of the diminished regulatory resource to increase vigilance. We posit that depleted individuals pay more attention to negative information and are less likely to engage in risky behaviors compared to their non-depleted counterparts. We tested our hypothesis in four experiments.

Experiment 1 was designed to examine the effect of ego-depletion on the recognition of concepts associated with vigilance. We first manipulated ego-depletion by using the Stroop task. Following established procedures (Pocheptsova et al. 2009) we presented participants with color words displayed in a font that mismatched the word (e.g., the word "green" written in yellow). Participants assigned to the control condition were instructed to indicate the semantic meaning of the color word (green), while participants assigned to the depletion condition were asked to indicate the font color of the word (yellow). Next, participants completed a lexical decision task. Participants were randomly presented with words and non-words and were asked to identify whether the letter string represented a word or a non-word. Some of the words were neutral (e.g., blouse) while other were vigilance-related words (e.g., safety), negative other-focused words (e.g., brutal), negative self-focused words (e.g., lonely), positive words (e.g., happy), and self-related words (e.g., mine). The results showed that depleted participants were slower at recognizing neutral words than non-depleted participants. However, depleted participants were faster than non-depleted

participants at recognizing vigilance-related words and negative other-focused words after controlling for baseline responses. No difference in response time was observed for the other target words.

In experiment 2 we investigated the effect of ego-depletion on the persuasiveness of messages that promote risky behavior. We first manipulated ego-depletion by using the "cross-off-the-letter" task (Wan and Sternthal 2007). Control participants were asked to cross-off all instances of the letter "e" that appeared in a text. Depleted participants were asked to cross-off all instances of the letters "a" and "e" when several criteria were met. Then, participants read a persuasive message about tattooing and reported their interest in learning more about tattooing. As predicted, we found that depleted participants reported lower interest in learning more about tattooing than their non-depleted counterparts.

The objective of experiment 3 was to investigate the effect of ego-depletion on the intentions to engage in risky behaviors. We first manipulated depletion by using the "cross-off-the-letter" task. Then, we presented participants with a scenario in which they had to decide whether to engage in unprotected sex with an attractive acquaintance. We found that depleted participants reported lower intention to engage in a sexual intercourse than non-depleted participants.

Our final experiment was designed to rule out the potential rival explanation that depleted people are less likely to act; that is, they prefer inaction rather than action. Another objective was to examine whether perceived risk may moderate the effect. We first manipulated ego-depletion using the same cross-off-the-letter task as in study 2 and 3. Then, we asked participants to read a message about hepatitis testing (Hong and Lee 2009). Half of the participants read a high perceived risk message, while the other half read a low perceived risk message. Next, participants reported their intention to get tested for hepatitis. As expected, among participants in the low perceived risk condition those who were depleted indicated greater intentions to get tested than those in the control condition. Depletion had no effect on participants in the high perceived risk condition.

Taken together, these findings suggest that the ego-depletion may strengthen self-regulation through greater vigilance. More broadly, this research provides novel insights in the nature and the adaptive value of the ego-depletion effect.

You Save, I Save, You Spend, I Spend: The Moderating Role of Deliberative Mindsets on Mental Budgeting by Social Comparison

Karen Stilley, University of Pittsburgh, USA
Karen Page Winterich, Pennsylvania State University, USA
Gergana Y. Nenkov, Boston College, USA

EXTENDED ABSTRACT

How much should you be saving? How much is too much to spend? Though many consumers may not know how much to save or spend, we know that American consumers tend to save too little and spend too much (Kostigen 2007). Perhaps attempts to change these behaviors have been futile due to the extent to which social comparisons influence consumers' evaluations of their own behaviors, thereby altering subsequent behaviors (Festinger 1954). In two studies, we examine the moderating impact of deliberative mindsets on consumers' reactions to social comparison saving and spending information.

Though consumers use mental budgets, the exact amount that should be allocated to each budget category is somewhat ambiguous (Thaler 1999). In situations where the correct behavior is unclear, individuals tend to conform to the behavior of referent others (i.e., Asch 1956; Bernheim 1994). Festinger's (1954) theory of social comparison states that individuals compare themselves and their behaviors to those of others to better understand themselves. An upward comparison (a comparison to someone or something which is better than the current self or object) tends to result in a negative self-evaluation, often resulting in changes in behavior (Argo et al. 2006; Suls et al. 2002), or increasing savings. In contrast, a downward comparison (a comparison to someone or something which is worse than the current self or object, respectively) tends to result in a positive self-evaluation (Wills 1981) such that individuals tend to maintain their behavior, or maintain savings.

Inferring "correct" behavior from social comparisons can have detrimental consequences for savings. Thus, we seek to understand when the positive impact of upward social comparison information could be increased. To do so, we utilize Gollwitzer's (1990) deliberative mindsets which results in consumers being more open-minded to peripheral information such as social comparison information (Fujita et al. 2007). When consumers are more open-minded to this information, the threat associated with an upward comparison increases, thereby resulting in increased savings. While these individuals will also be more open-minded to the downward comparison information, deliberative mindsets also tend to increase generation of counterfactuals which leads to a decreased susceptibility to information framing effects (Nenkov et al. 2009) such that they should not decrease savings allocation. Two studies test this theorizing.

The first study was a 2 (Social Comparison Information: Upward vs. Downward) X 2 (Mindset: Control vs. Deliberative) X 2 (Consumer Susceptibility to Interpersonal Influence (CSII): High vs. Low) between-subjects design with the informational dimension CSII from Bearden et al. (1989) measured as a continuous variable ($\alpha=.68$). We examine the moderating role of CSII in this study to provide greater support for our theorizing such that the moderating role of deliberative mindsets should only exist for those with low CSII, or those who do not tend to pay attention to social comparison information.

Participants first read a scenario and indicated what amount of their monthly internship income to they would allocate to savings. Then they completed either a deliberative or control mindset prime (Gollwitzer 1990), received social comparison information for the average college student savings in a hypothetical newspaper article

(\$450/high vs. \$50/low), and reported their savings allocation again before completing a variety of measures including the CSII scale.

Supporting our theorizing, we find a significant three-way interaction between social comparison information, mindset prime, and CSII on final savings allocation while controlling for initial savings allocation. For those low in CSII, the effect of the social comparison information is qualified by the mindset prime such that those in the upward social comparison condition with a deliberative mindset reported greater savings allocations than those in the control group. A reverse pattern emerged for the downward social comparison condition, with the mindset prime leading to marginally lower final savings than the control condition. For those with high CSII, the social comparison information and mindset prime interaction was not significant such that there were no differences in savings allocation between mindset conditions. Additionally, social comparison-related thoughts mediate the moderating effect of CSII, deliberative mindset, and social comparison information on final savings allocation.

These results indicate that among those with low CSII, the deliberative mindset prime led to a larger *increase* in savings following an upward comparison, which is consistent with our theorizing. These results are particularly important given America's current economic crises and the American consumer's tendency to engage in detrimentally low amounts of savings (Nannie 2005). What if, however, individuals are provided with an upward social comparison for spending? In a spending frame (instead of a savings frame), individuals will focus on the positive aspects of spending such as enjoyment and status (Tversky and Kahneman 1981). Therefore, individuals are likely to be threatened by an upward spending comparison, thereby displaying an increased tendency to spend.

Study 2 tested the effect of deliberative mindset and social comparison information on spending as theorized above. Deliberative mindset was primed similar to Study 1. Then participants read an article for a "memory study" that contained social comparison information regarding average college student spending in a particular product category (\$400 high, upward/\$100 low, downward condition). Last, participants evaluated an advertisement for designer handbags (females; designer watches, males) and reported their likelihood of buying one of these designer goods priced at \$278.

As hypothesized, we found a significant interaction of social comparison information and mindset prime on likelihood to purchase (i.e., spending intentions). Those with an upward comparison in the deliberative mindset (vs. control) condition indicated significantly greater spending intentions. In contrast, deliberative mindset did not have a significant impact on spending for those in the downward social comparison condition. These results indicate that the deliberative mindset prime can result in *increased spending* (i.e., *likelihood to purchase a designer handbag or watch*) for an upward comparison. Self-importance of savings mediates the effect of deliberative mindset and social comparison information on spending.

Taken together, we find that a deliberative mindset increases the reliance on upward social comparison information. While beneficial for enhancing consumer savings, such comparisons could be detrimental in the realm of consumer spending. Clearly, marketers, public policy officials, and consumers alike need to consider the pervasive impact of social comparison information on consumers' behaviors, particularly when one may be elaborating on potential consequences.

Flocks, Herds, and Families: The Influence of Victim-Unitization on Charitable Giving

Katherine Burson, University of Michigan, USA

Robert Smith, University of Michigan, USA

David Faro, London Business School, UK

EXTENDED ABSTRACT

Charitable donations are often insensitive to the number of victims. Six studies show that people donate more to multiple victims if those victims are perceived as a single coherent unit. Because this occurs due to an increased emotional response, unitizing negative victims actually decreases donations.

People react strongly to images, names, and personal stories of individual victims. However, when it comes to helping large numbers of victims, charitable and emotional reactions are typically muted. Two patterns of findings have been documented. First people are “scope insensitive.” When asked how much money they would donate to save 2,000, 20,000, or 200,000 migrating birds from drowning in oil ponds, people indicated they would give only slightly more to save 200,000 birds than to save 2,000 birds (Desvousges et al. 1993). Second, people show a “singularity effect”: They donate more to help a single child identified with a photo and a name than to help several children (Kogut & Ritov, 2005a, b). Thus, though tragedy often occurs on a large scale and requires action that takes the quantity of victims into account, both the scope insensitivity and singularity effect literatures suggest that it is in these cases that reactions are often most muted.

The singularity effect is driven by an increase in sympathy and concern for a single individual. Previous research has suggested that people react more strongly to individual victims than multiple victims because single units are perceived as more internally consistent than multiples (Kogut & Ritov, 2005b). Individuals are perceived as more coherent entities, or “entitative,” than disaggregated groups, which causes their salient attributes to be perceived as psychologically coherent. This in turn makes trait judgments more extreme for individuals than for groups. However, groups can also be entitative; those that are presented with higher coherence and unity receive more extreme judgments than those that are not (Hamilton & Sherman, 1996; Mishra, 2009; Geier, Rozin, & Doros, 2006).

We hypothesize that perceiving multiple victims as a single unit increases the coherence of their defining attributes. When those victims are defined by positive attributes, perceived favorability, sympathy, and concern should increase when these multiple victims are unitized. This will then lead to an increase in donations. However, by the same logic, unitizing will not always lead to a more favorable response than disaggregated victims. Any victims with unfavorable defining attributes should be judged as more unfavorable when presented as a unit (see Mishra, 2009 for a product-related example of this). Thus, sympathy and concern should be diminished when unfavorable victims are unitized and donations should suffer in turn.

In this article we show that people can react more strongly to a large number of victims if they are perceived as a single, coherent unit. In 3 studies, we manipulate the quantity of victims and their perceived unity. In Study 1, participants made hypothetical donations to save 2,000, 200,000, or a flock of 200,000 birds. Though participants' donations were not different for 2,000 and 200,000 birds, donations were significantly higher for a *flock* of 200,000 birds than the disaggregated 200,000 birds. This effect was replicated when perceived unity was affected through priming of global processing instead of semantically describing the birds as a flock. In Study 2, hypothetical donations were made to save 1, 200 or a herd of 200 gazelles. Similar results were observed, and could be explained by participants' emotional reaction to the manipulation. As in study 1, the effect was replicated with a unitization prime.

Study 3 involved actual donations. Though donations were lower for 6 disaggregated children than for a single child, donations were significantly higher when the same six children were said to belong to one unit. As entitativity research would predict, this effect held only for children with positive traits. In fact, the pattern reversed for unfavorable children: Donations were lower for the family of 6 child prisoners than the disaggregated 6 child prisoners. Participants' feelings of sympathy and concern explain these effects. Additionally, unitizing multiple favorable victims increases their perceived favorability, while unitizing multiple unfavorable victims decreases their perceived favorability.

These results show that the singularity effect is much more general than originally thought. Single victims are just one example of a unit. The process of increased sympathy and concern that underlies the assessment of a single victim also extends to unitized multiple victims. Therefore, these results suggest a simple way to increase prosocial behavior toward multiple victims. However, there is also an unfortunate effect to unitizing some victims. We show that unitization reduces perceived favorability and prosocial behavior toward some less favorable victims. In these cases, sympathy and donations are higher if the multiple victims are presented as disaggregated.

The Drunken Idiot Bias: Consuming Alcohol Can Reduce Perceived Intelligence

Scott Rick, University of Michigan, USA

Maurice Schweitzer, University of Pennsylvania, USA

EXTENDED ABSTRACT

What we consume often conveys information about who we are. Consumers often select products to signal favorable aspects of their identity (Belk 1988; Berger and Heath 2007). Additionally, observers often infer aspects of a target's personality based on what the target chooses to consume (Calder and Burnkrant 1977). These inferences are not totally unfounded: observers can often draw reasonably accurate personality inferences based on possessions (Gosling 2008).

Intelligence, in particular, can often be accurately estimated based on minimal cues (Borkenau and Liebler 1993). However, irrelevant cues, such as warmth (Cuddy 2009; Fiske et al. 2002), can bias perceptions of intelligence and competence. We examine whether a different cue—alcohol consumption—is treated as diagnostic of intelligence even when it is not.

Specifically, we experimentally examine whether consuming alcohol can reduce the perceived intelligence of the person consuming it, in the absence of any actual reduction in cognitive performance, a mistake we term the 'drunken idiot' bias. In order to detect a drunken idiot bias, we experimentally unconfound alcohol consumption and cognitive performance. That is, we manipulate whether confederates appear to be consuming alcohol, but hold their cognitive performance constant across conditions. Any difference in perceived intelligence across conditions is a mistake attributable to the observation of alcohol consumption.

We hypothesize that the drunken idiot bias is a misapplication (or more specifically, an over-application) of a heuristic or 'lay theory' that is grounded in reality and often correct. At sufficiently large doses, alcohol impairs attention, general cognitive functioning, and short-term memory, particularly on the ascending limb of the blood alcohol curve (e.g., Jones and Vega 1972; Steele and Josephs 1990).

Because alcohol consumption and diminished cognitive performance frequently co-occur, we anticipate that observing alcohol consumption will increase the accessibility of the concept of diminished intelligence, which will in turn color perceptions of people of ambiguous intellect. The prediction is based largely on semantic network models of memory, which posit that concepts that co-occur frequently (e.g., *tiger* and *stripes*) are stored close to one another in memory. When one concept is activated, closely related concepts tend to become more accessible via a spreading activation process (Collins and Loftus 1975). Concepts or categories that are particularly accessible tend to act as lenses through which ambiguous stimuli are subsequently perceived (e.g., Higgins, Rholes, and Jones 1977).

Thus, we predict that observing alcohol consumption will bring to mind the concept of diminished intelligence, which will in turn color perceptions of people of ambiguous intellect. We utilized four experiments to examine whether the drunken idiot bias exists, to explore its implications, and to rule out alternative explanations. In Experiment 1A, participants evaluated photographs of confederates either holding a beer or holding no drink. Confederates were perceived as significantly less intelligent when holding a beer, but no less likeable, suggesting alcohol selectively reduces perceived intelligence.

To control for the act of consumption, and to examine whether the bias generalizes across different types of alcohol, Experiment 1B elicited perceptions of a confederate drinking wine, Coke, or nothing. Consistent with Experiment 1A, confederates were per-

ceived as significantly less intelligent when consuming wine than when consuming soda or when consuming nothing.

Because the judgments in Experiment 1 were made in the absence of context, it is difficult to definitively determine whether observers were actually making a "mistake." Additionally, it is difficult to determine whether people believe that consuming alcohol leads to diminished intelligence or whether people believe diminished intelligence leads to the selection of alcohol (or perhaps both). Experiment 2 addressed these limitations by utilizing confederates who were actually attempting to make intelligent, persuasive arguments, and by manipulating whether confederates chose their own beverage or had it selected for them. Specifically, a confederate made videotaped arguments in favor of comprehensive exams for undergraduates while drinking either Coke or a beer. We also varied whether participants believed that the confederate chose their own drink, or whether the experimenter selected the drink. Confederates were perceived as significantly less intelligent and persuasive when they were consuming alcohol, regardless of whether they chose to consume it. The results suggest that the bias results from the over-application of a heuristic suggesting that consuming alcohol diminishes cognitive performance.

We next explored whether the drunken idiot bias could have important professional consequences. In Experiment 3, real-world managers viewed a hypothetical job interview held over dinner and evaluated the hireability and intelligence of the candidate. We manipulated the drinks ordered by the candidate (wine or soda) and the manager (wine or soda). The real-world managers viewed candidates as significantly less intelligent and hireable when consuming alcohol than when consuming soda, even when the manager was also drinking alcohol.

Participants in Experiments 1-3 were sober, but typically evaluations of people drinking alcohol will be made by evaluators who are themselves drinking alcohol. Because people who are not currently drinking alcohol may fail to understand how they would view the world when they are drinking (cf. Loewenstein 1996), in Experiment 4 mildly intoxicated MBA students, playing the role of bosses, interviewed job candidates (confederates) who were either drinking alcohol or soda. Consistent with Experiments 1-3, candidates were viewed as significantly less intelligent and hireable when consuming alcohol, suggesting that the drunken idiot bias is not an artifact of a cold-to-hot empathy gap.

Experiment 5 examined whether people in a position to be evaluated anticipate the drunken idiot bias. Specifically, we presented MBA students about to go on the job market with a hypothetical job interview that manipulated the boss's drink choice (alcohol, soda, or unknown). Participants were then asked what they would order if they were the job candidate. If prospective candidates anticipate the drunken idiot bias, we should observe minimal selection of alcohol across conditions. Instead, one-quarter of participants ordered alcohol when the boss's drink choice was unknown, and this figure nearly tripled when the boss ordered alcohol first. Thus, candidates generally do not appear to anticipate the drunken idiot bias.

The Effect of Schadenfreude on Choice of Conventional versus Unconventional Options

Thomas Kramer, Baruch College, CUNY, USA
Ozge Yucel-Aybat, Baruch College, CUNY, USA
Loraine Lau-Gesk, University of California, Irvine, USA

EXTENDED ABSTRACT

“Mr. Borovina is indulging in what seems to be the summer’s favorite guilty pleasure – delighting in others’ misfortune, or schadenfreude. Between Martha Stewart, Michael Ovitz, L. Dennis Kozlowski, Kenneth Lay and Jeffrey Skilling, and Samuel D. Waksal, there is plenty of misfortune going around, and, as it turns out, plenty of delight.”
St. John (2002)

Although others’ fortunes often make us feel happy, and their misfortunes sad, as the above quote from the *New York Times* illustrates, sometimes it is others’ hardships and troubles rather than their good luck that delight us and give us joy. Another recent instance of such malicious joy, or schadenfreude, includes coffee drinkers rejoicing at Starbucks’ financial woes and its subsequent decision to close down 600 of its stores: “I’m so happy; I’m so not a Starbucks person,” says one aficionado of small independent cafes (Wulforth 2008). Persuasive messages may also often seek to elicit schadenfreude. For example, the recent “more bars in more places” AT&T advertising campaign featured comical situations in which misfortunes (such as a house destroyed by an exploding deep-fried frozen turkey) befall cell phone owners because they had made the wrong choice of cell phone service and could hence not be reached in time to avert the calamity.

Yet, even though schadenfreude is often discussed in the popular press and may indeed arise in many situations, it has received surprisingly little attention in the psychological and marketing literatures. Schadenfreude, or pleasure in others’ misfortunes (Heider 1958), is a socially reprehensible emotion that is elicited through social comparison in response to others’ failure (Feather and Sherman 2002; Foster 1972). Research has started to examine empirically the antecedents of schadenfreude, including envy (Smith et al. 1996; Sundie et al. 2009), liking (Hareli and Weiner 2002), resentment (Feather and Nairn 2005; Feather and Sherman 2002), and deservingness (Brigham et al. 1997; van Dijk et al. 2005). Importantly, findings have confirmed the role of deservingness in the relationship between misfortune and schadenfreude (Feather 1994, 1999). Van Dijk et al. (2005), for instance, showed that the more others were responsible for their misfortune, the more the misfortune was perceived to be deserved, which in turn increased the level of schadenfreude experienced.

Overall, although extant research has thus demonstrated the ubiquity of schadenfreude and some of the conditions under which schadenfreude is elicited, if, how, and under which conditions schadenfreude can impact everyday choices has not been explored. For example, does the experience of schadenfreude have a systematic impact on the choice likelihood of safe over risky options? Clearly, others’ unfortunate decisions will not elicit the same level of schadenfreude for all choices alike. Based on our proposition that others’ choices that go against the norm are perceived as more deserving of misfortune, we expect not only that greater levels of schadenfreude are experienced when others’ choices of unconventional (vs. conventional) options turn out badly, but also more crucially, that the experience of schadenfreude systematically increases the choice likelihood of conventional options, such as compromise or safe options.

Study 1 establishes that others’ unfortunate choices of unconventional, hedonic (vs. utilitarian) and risky (vs. safe) options elicit greater feelings of schadenfreude. In a follow-up study we then rule out social acceptance to expressing schadenfreude for unfortunate unconventional choices as a possible alternative explanation. In study 2, we demonstrate that incidental schadenfreude, as opposed to happiness, results in greater choice likelihood of a conventional, compromise option. A conceptually similar preference pattern emerges when comparing schadenfreude with sadness: decision-makers feeling schadenfreude, as opposed to sadness, are more likely to choose a conventional, safe option than an unconventional, risky option. Finally, Study 3 offers process insights. Specifically, the relatively greater choice share of conventional options following the experience of schadenfreude appears to be driven by decision-makers’ interpretation of schadenfreude as information regarding the options they should choose. That is, if schadenfreude serves an informational function regarding the options individuals should choose, then its experience should no longer be informative if its informational value is discredited (Schwarz and Clore 1983; Pham 1998). Following Raghunathan et al. (2006), we discredit the informational value of schadenfreude for half the subjects in study 3 by making its source salient, and find that schadenfreude increases the choice share of the conventional option only when subjects were not aware of the source of their affect.

Sadness and Consumption: The Attenuating Role of Choice

Nitika Garg, University of Mississippi, USA

Jennifer Lerner, Harvard University, USA

EXTENDED ABSTRACT

Research on incidental emotion has discovered the pervasive tendency of emotions to carry over from one situation to another, coloring behavior in unrelated tasks (for reviews, see Forgas, 1995; Isen, 1993; Keltner and Lerner, 2009). For some time now, researchers have been paying closer attention to the influence of emotion on consumption and have hinted at a possible relationship between the two. One of the most curious carry-over examples involves sadness and consumption. First, its effects depart from what one would predict based on emotional valence. The standard prediction of a valence-based model would be that any negative emotion, including sadness, should trigger generalized negative valuation of, say, a new product. The idea is that a negative state leads one to perceive the world in negative ways. While disgust, another negative emotion, fits that predicted pattern, sadness does not. Sadness triggers positive valuation of new products, as measured by willingness to pay (Lerner et al., 2004). A second curious aspect of sadness and consumption is that the carry-over effect drives consumption behavior across diverse domains. In the domain of eating, for example, sadness (relative to happiness) leads to increased consumption of tasty, fattening food products, such as buttered popcorn and M&M candies (Garg et al., 2007). In the domain of monetary transactions, sadness (relative to a neutral state) leads to increased amount spent to purchase items (Lerner et al., 2004). Importantly, these undesirable consumption effects of sadness typically occur without awareness by those in the sad state; they also typically occur even when the sadness-eliciting events have no rationally-justifiable relation to the consumption choices at hand (Cryder et al., 2008). Thus, the increased consumption represents more than typical, conscious attempts at “consumer therapy.” Rather, it represents unbidden and undesirable behavior.

Understanding how to attenuate the undesirable effects of sadness on consumption is an important issue. Individuals do not want to pay more or over-consume when they are sad; yet they do so. In the present research, we seek to examine whether increasing decision makers’ sense of individual control and decreasing their sense of helplessness would moderate the carry-over effects. Although a few studies have now documented carry-over effects of sadness on consumption (i.e., spending and eating), we do not know of any study that has discovered ways to significantly attenuate its effect on consumption. More generally, we examine both the robustness of the effect of sadness on consumption and its moderating and mediating factors.

As discussed earlier, sadness has been associated with conscious or unconscious attempts at mood repair (e.g., Raghunathan and Pham, 1999; Schwarz and Clore, 1983). Given the underlying themes of loss and helplessness associated with sadness (Frijda, Kuipers, and ter Schure, 1989; Keltner and Lerner, 2009; Lazarus, 1991) as well as the pattern of compensatory consumption, could sadness’ effect on consumption be attenuated by providing individuals greater individual control and diminished helplessness?

An opportunity to choose a hedonic (i.e., rewarding) gift, rather than merely being given one, may attenuate the otherwise robust carry-over effect. A long line of research on perceived control and choice suggests that individuals prefer choice (vs. no-choice) because of its link to self-determination and sense of control (Averill, 1973; Langer, 1975). Thus, because choice might give individuals some semblance of control and therefore alleviate the helplessness that is typically concomitant with sadness, we expect that choice will

attenuate sadness’ effect. We test this idea across two studies with different dependent variables of interest. Study 1 focuses on the more established relationship between sadness and food consumption (e.g., Garg et al., 2007; Tice et al., 2001), and Study 2 examines the lesser-known effect of sadness on monetary transactions, such as willingness to pay for a new product (e.g., Lerner et al., 2004).

Study 1 established three key points: (1) that sadness elevates self-reports of helplessness in response to the emotion-inducing situation; (2) that this increased helplessness mediates the sadness-consumption effect; and (3) that inducing a sense of control (via the provision of choice) attenuates sadness’ effect. Study 2 also established three key points: (1) that sadness’ effect replicates not only in food consumption but also in purchasing consumption; (2) that different kinds of sadness inductions (writing versus video watching) both produce sadness’ carry-over effect; and (3) that the timing of receiving the good (pre- or post- emotion induction) is not responsible for the effect of choice (control) on attenuation of sadness’ effect.

Overall, the studies provide critical insight into the underlying mechanism relating sadness and consumption, and extend prior work by discovering a key moderator and a key mediator. Specifically, giving sad individuals a choice about what they can receive, rather than simply giving them a good, determined whether sadness’ effect was attenuated. Our data suggest that this occurs because having a choice confers a sense of individual control, which counteracts the sense of helplessness associated with sadness. Now that we better understand the sadness-consumption relationship, such undesirable effects as spending or eating too much when one is sad can hopefully be reduced with strategic interventions. As part of the larger discussion about emotions and their effects on decision making, our research suggests that the underlying ‘appraisal theme’ of an emotion might be the key to understanding and managing its effects.

Ambiguity of Direct Experience and Product Specification Effects on Consumer Choice

Sehoon Park, Sogang University, Republic of Korea
Moon-Yong Kim, Dongguk University, Republic of Korea
Se-Hyuk Park, The College of William and Mary, USA

EXTENDED ABSTRACT

Consumers often resort to indirect experiences with products, such as reading product specifications, to make purchasing decisions. In particular, quantitative specifications such as megapixels for digital cameras, wattage ratings for stereos, cotton counts for sheets, calorie counts for cookies, and sun protection factors for sunscreens, among others, can provide useful information for potential buyers to predict their consumption experience with the products that they may purchase (Hsee, Yang, Gu, and Chen 2009). With respect to the effects of quantitative specifications on consumer behavior, recent research by Hsee et al. (2009) showed that even when consumers can assess the quality of a product through direct experience, their purchasing decisions are susceptible to the influence of superfluous quantitative specifications, even meaningless ones.

In the current research, we extend the findings of Hsee et al. (2009) by identifying the conditions under which the effects of quantitative specifications on consumer choice would be strong or weak when direct experiences are either available or not available. We propose that the effects of specifications on choice are not constant under all circumstances; that is, under certain conditions, specifications fail to have a significant effect on choice, whereas under other circumstances, specifications may have a significant effect on choice. This proposition implies the moderating influence of the ambiguity of direct experience on the specification effects. It is doubtful that the observed specification effect in experiments by Hsee et al. (2009) would also be found when the direct product experience is unambiguous because prior research (e.g., Ha and Hoch 1989; Hoch and Ha 1986; Wooten and Reed 1998) has suggested that other information about a product is of limited use to a consumer who has an unambiguous experience with that product. Hoch and Ha (1986, experiment 1) found that advertising did not affect evaluations for participants who had an unambiguous product experience following message exposure. Similarly, specifications may not influence consumers' own evaluations of a product if they have an unambiguous experience with it.

Study 1 examined whether the effects of quantitative specifications on consumer choice vary depending on the format of specifications when direct experiences are unavailable. The participants consisted of 200 students from a large university in a metropolitan area. In the absence of direct product experience, two factors--the specification format (total-dot specification vs. diagonal-dot specification) and the level of the ambiguity of direct product experience (unambiguous vs. ambiguous)--were manipulated between subjects, and they were randomly assigned to one of four cell conditions. The participants were asked to imagine that they were shopping for a TV and had narrowed their choice to two models (A and B). The participants could not directly view and experience the sharpness of the images from the TV screens. Instead, only the specification information (i.e., price and sharpness (resolution)) on the two TV models was offered to the participants. The participants were presented only with the specifications for image quality indexed by dot counting (total or diagonal) reflecting the high- or low-ambiguity of direct experience. Finally, based on the specification information alone, the participants under the high-ambiguity and low-ambiguity conditions were asked to choose between the two models with different levels of sharpness (resolution). The experimental results indicated that the format of specifications (i.e., total-dot specification vs. diagonal-dot

specification) could influence choice outcomes, irrespective of the level of the ambiguity of direct experience.

Study 2 examined how the ambiguity of direct product experience moderates the effects of specifications on consumer choice when direct experiences are available. The participants consisted of 300 students from a large university in a metropolitan area. As in study 1, the participants were asked to imagine that they were shopping for a TV in the market and had narrowed their option to two models, A and B. In study 2, however, the participants could directly view and experience the sharpness of the images from the two TV models. That is, in the presence of direct product experience, two factors--the ambiguity of direct product experience (unambiguous vs. ambiguous) and the specification format (no specification/total-dot specification/diagonal-dot specification)--were manipulated between subjects, and they were randomly assigned to one of six cell conditions. The image quality (sharpness) of each TV model was represented as photos of TV screens. We made certain adjustments to make the differences in image quality relatively clear or ambiguous; that is, we made the image of Model A (vs. Model B) in the unambiguous condition look much better, whereas we made the image of Model A (vs. Model B) in the ambiguous condition look comparable. As in Hsee et al.'s (2009) study, sharpness was either unspecified or specified in terms of the total number of dots or in terms of the number of diagonal dots. Finally, the participants were asked to choose between Model A and Model B. The experimental results suggested that neither the availability of specifications nor the method by which specifications are presented affects consumer choice when direct experience is unambiguous (vs. ambiguous). That is, specification effects were found to be moderated by the ambiguity of one's experience with a product.

Taken together, we extend the work of Hsee et al. (2009) by positing that the ambiguity of direct experience moderates the effects of specifications on choice when direct experiences are available. Furthermore, the results of our study with respect to the interaction between direct product experience and indirect experience (i.e., specifications) are consistent with those of previous studies (e.g., Ha and Hoch 1989; Hoch and Ha 1986; Wooten and Reed 1998), and the current study contributes to the literature by investigating how multiple factors interact to influence product preference and evaluations. From a managerial perspective, the present results imply that marketers can emphasize the difference between options by presenting the same underlying attribute information in a different specification format. In addition, when consumers can directly experience the consequences of using the products under consideration, marketers need to know how ambiguous the direct product experience is to better understand the effects of specification on consumer choice.

To Do, to Have, or to Share: The Value of Experiences Over Material Possessions Depends on the Involvement of Others

Pater Caprariello, University of Rochester, USA

Harry Reis, University of Rochester, USA

EXTENDED ABSTRACT

Recent evidence suggests that spending money on experiences makes people happier than spending money on material goods. We propose and test the hypotheses that experiences take place with others more often than not, and that it is the social aspect of experiences that provides value relative to material goods.

Scholars have long questioned how having money affects happiness (Diener, Suh, Lucas, & Smith, 1999; Howell & Howell, 2008). However, little research has examined how *spending* money on different kinds of purchases affects happiness. Those who have distinguished between types of purchases have focused their distinctions on varieties of tangible, material goods (e.g., Dhar & Wertenbroch, 2000), at the exclusion of intangible, experiential purchases, which may have comparable but distinct benefits (Sears, Le Bel, & Dube, 2004).

Van Boven and Gilovich (2003) provided the first empirical test of the effects of buying “life experiences” versus tangible, material goods on happiness. Their data (and those from Nicolao et al.’s, 2009, replication) consistently supported the hypothesis that experiences make people happier than material objects. However, we propose that there may be a key hidden variable in this research: More often than not, experiences involve others, an influential source of happiness (Baumeister & Leary, 1995; Reis & Gable, 2003). Furthermore, Dunn, Aknin, and Norton (2008) showed that spending money on others better promotes happiness than spending money on oneself. Therefore, spending money to do things with others should make people happier than material objects or to do things alone. Conversely, spending money to do things alone should make people *less* happy than material objects.

In Study 1, 33 participants viewed a list of 12 hypothetical experiences and were asked to imagine they “chose to do the following activities,” to “picture yourself doing each of them,” and to “describe each experience in about three sentences.” No other instructions were given. Two coders, blind to hypotheses, viewed the list of spontaneous descriptions and rated each for a social reference (0=“other people were not clearly part of the person’s experience;” 1=“other people were clearly part of the person’s experience;” $\alpha=.88$). Across all descriptions, 179 (49%) were spontaneously described as involving other people. Overall, these results support our assumption that experiences tend to be social insofar as that without any prompting by us, participants spontaneously described many of the experiences in terms of doing things with others nearly half the time. Although there was variability in the degree to which experiences were depicted socially, it seems that including others is a naturally accessible component of most experiences.

In Study 2, 327 participants were randomly assigned to pick between 1 of 2 kinds of purchases—between material objects and social experiences, material objects and solitary experiences, solitary and social experiences, and material objects and experiences in which the presence of others was not explicitly stated. When comparing material purchases to social experiences, participants were significantly more likely to pick the social experience, $M=.64$, $\chi^2(1)=73.61$, $p<.001$, and to indicate it would make them happier, $M=.70$, $\chi^2(1)=151.36$, $p<.001$. When comparing material purchases to solitary experiences, participants were significantly *less* likely to pick the solitary experience, $M=.37$, $\chi^2(1)=65.97$, $p<.001$, and to indicate it would make them happier, $M=.38$, $\chi^2(1)=54.22$, $p<.001$.

When comparing material purchases to ambiguous experiences, participants were equally like to pick both, $M=.51$, $\chi^2(1)=.68$, $p=.41$, but were significantly more likely to indicate that experiences would make them happier, $M=.60$, $\chi^2(1)=35.74$, $p<.001$. Finally, when comparing solitary to social experiences, participants were significantly more likely to pick the social experience, $M=.82$, $\chi^2(1)=411.00$, $p<.001$, and to indicate it would make them happier, $M=.85$, $\chi^2(1)=465.08$, $p<.001$. These results make clear that sharing experiences with others is necessary for deriving happiness from the experience.

In Study 3, as part of a representative panel study, 1,424 German respondents were given definitions of material, solitary, and social purchases, asked to think of a time that they spent money on each kind, reported how happy each of the purchases made them on a scale from 1 (*Neutral*) to 5 (*Exceptionally Happy*), and ranked the 3 purchases in terms of happiness. Consistent with hypotheses, social experiences were rated as making people the happiest ($M=3.55$), material purchases the next happiest ($M=3.33$), and solitary experiences the least happiest ($M=3.24$), $F(2, 2286)=32.59$, $p<.001$, $\chi^2=.03$. On average, social experiential purchases were ranked higher ($M=1.71$) than material purchases ($M=2.12$) and solitary experiences ($M=2.17$), $\chi_r^2(2)=187.80$, $p<.001$. No interactions between happiness ratings and demographic variables were statistically significant, indicating that these effects were not moderated by demographic niche. Thus in Study 3 we again reversed Van Boven and Gilovich’s (2003) effect, by showing that solitary experiences made people *less* happy than material possessions, whereas social experiences made people more happy. Furthermore, participants described the effects on happiness of spending their own money on actual purchases, rather than hypothetical purchases. The results suggest that when you remove others from the experience, its value and potential for providing happiness drops relative to material possessions and social experiences.

These results are consistent with recent data showing that spending money on others makes people happier than spending money on oneself (Dunn et al., 2008). Although evidence suggests that merely reminding people of money distances the self from others (Vohs, Mead, & Goode, 2006), overcoming a self-reliant mindset to spend money to do things with others, rather than to have things, may be an important outlet for promoting sustainable happiness (Lyubomirsky, Sheldon, & Schkade, 2005). Theoretically, these findings hint that social interaction itself may be a “conceptual commodity” that people are motivated to purchase to increase happiness, above and beyond the motivation to acquire life experiences per se (Ariely & Norton, 2009).

When Rewards Backfire: Customer Resistance to Loyalty Programs

Dominique Roax, Université paris-Sud 11, France

Mariem El Euch Maalej, IRG-Université Paris-Est, France

EXTENDED ABSTRACT

Customer loyalty represents a critical issue for firms that try to create enduring relationships with their customers, which helps explain the multiplicity and diversity of loyalty programs (Palmatier et al. 2006). However, most existing research indicates that the success of these programs is questionable and that their effects have only limited scope (Dowling and Uncles 1997; O'Brien and Jones 1995; Sharp and Sharp 1997). Prior studies note the relative ineffectiveness of loyalty programs but, owing to behavioural methods they use, they leave in the dark the possible reasons for negative assessments. Besides, staying at a general level, very few qualitative approaches consider the causes of potential negative perceptions of loyalty programs and the marketing practices on which they are based (Fournier, Dobscha, and Mick 1998; O'Malley and Prothero 2004).

In the light of scarce information about perceptions of loyalty programs, which represent main tools of relationship marketing, this study explores the negative elements perceived by customers that may lead them to reject membership in such programs. Using an exploratory study of 15 customers who resisted joining a loyalty program, this research attempts to answer three questions: What reasons do they give to explain their refusal? What is their aim exactly? What individual and situational characteristics might influence these justifications?

Entry into loyalty programs primarily is motivated by a gain or use that the consumer expects to attain. However, research provides widespread evidence of the effect of autoselection, which poses the crucial question of how retailers can attract occasional and not only regular customers who are naturally loyal to a particular point of sale. Besides, questions about privacy and discrimination raise concerns about loyalty programs (Wendlandt and Schrader 2007). In addition, other factors are likely to provoke customer resistance to loyalty programs, such as perceived attempts by the seller to influence them, the level of engagement required, and subsequent appeals to which members are subjected (O'Malley and Prothero 2004). As Friestad and Wright (1994) suggest, consumers' "metacognition" about persuasion mechanisms may increase their perception of influence attempts thus hampering their will to participate in relationship marketing. This article thus explores how practically consumers negotiate their refusal to join loyalty programs and what reasons they put forward to support their decision. We seek to understand whether this resistance follows from previous bad experiences and what situational and/or psychological antecedents play a part in customers' refusal. In this respect, we investigate individual characteristics that are likely to influence consumer resistance and have not been addressed in previous studies.

Because of the extent, novelty, and lack of prior investigation into this issue, this study adopts a qualitative, in-depth approach, based on the analysis of discourses by 15 informants who have refused loyalty cards, including free ones offered by retailers. Five informants had never possessed a card, and the other 10 owned one or two that they had never used. Because age appears to influence the informants' cognitions, this study adopts a homogeneous split, based on the average age of the sample, 47 years, which matches the median that falls between 22 and 70 years. It seemed equally important to vary the size of the households and the family structure, which both influence the amount and nature of purchases. The approximately two-hour respondent interviews were recorded, transcribed, and analyzed sequentially, which allowed for control

of the progressive development of themes and provided a guideline for choosing subsequent profiles. Four resistance themes emerge from the discourses: the unacceptable invasion of privacy that programs impose; shifts of interpersonal frames of reference and domestic values being unduly appropriated by the marketing sphere; suspected dishonesty of companies; and perceptions of the poor value of the programs, such that the rewards do not compensate for the overall inconvenience.

The results suggest reasons that consumers might refuse loyalty cards, which, except the perceived unbalance between rewards and nuisances, have less to do with the content of the scheme itself than to what such programs represent in relation to the marketplace. The informants are recalcitrant about such forms of loyalty because customer-company relationship appears as a commercial strategy, whose hidden profit objective is masked by rhetorical discourse and fallacious methods. This resonates with O'Malley and Prothero's (2004) contribution but extends it two ways: firstly, it shows that informants' alleged resistance do not solely derive from previous bad experiences and feelings about the program, but from an extended sympathy for more vulnerable customers who may be victims of companies' interests; secondly, it accounts, other than plain rejection of loyalty card, for various resistant behaviours that are less discernible but possibly more detrimental to firms, such as opportunist and disloyal behaviours. Our findings also show that informants have developed a "marketplace metacognition" (Friestad and Wright 1994) that influences their perceptions of the consumer society and the loyalty devices that companies use to capture them. This knowledge makes them circumspect in their responses to every attempt used by companies to create a relationship. The perception of a mismatch between the "Market World" and the "Domestic World" or "Civil World" (Boltanski and Thévenot 2006), as well as the psychological reactance, need for cognition and cynicism that characterize this group of consumers, play key roles in their refusal. As a consequence for practitioners, relational approaches are inappropriate for these consumers and a better strategy would be to maintain a transactional orientation toward them. In addition, the informants' inferences about corporate dishonesty and unethical practices suggest the need for more transparency, respect, and ethics, as well as the more moderated and timely use of marketing techniques. The possible consequences of consumer resistance also suggest many avenues for further exploration. Because of their metacognition about market function, customers who resist loyalty programs may develop other negative perceptions of companies' practices. Their more general tendency to doubt the allegations of the firms and disloyalty toward ads, offers and labels represent additional areas that could benefit from further development of this research.

Consumption as Contaminating Innocence: A Study of Children's Birthday Parties

Laura Jennings, Monash University, Australia
Jan Brace-Govan, Monash University, Australia

EXTENDED ABSTRACT

Are children's birthday parties occasions for material abundance and the embrace of commercialism? A study of Australian mothers finds it not to be so. Consumption is to be managed to ensure it does not contaminate the innocence of childhood—especially in such a special context as a birthday party.

BACKGROUND

Birthday parties represent the most personal celebration of all annual celebrations (McKendrick, Bradford, and Fielder 2000) and serve to both individuate children and socialise them into larger groups (Shamgar-Handelman and Handelman 1991; Weil 1986). Despite the apparent simplicity and fun of children's birthday parties, they are multi-textured, multi-layered events (Schoonmaker 2006) that have offered researchers opportunities to study family ritual and socialisation (Otnes, Nelson, and McGrath 1995), gender socialisation (Otnes and McGrath 1994), rites of passage (Weil 1986), income-constrained celebration consumption (Lee, Katras, and Bauer 2009), and the consensual processes surrounding motherhood (Clarke 2007). In addition, the Australian children's birthday party industry is conservatively valued at AU\$200 million and is part of the US\$20 trillion that women spend globally per year (Silverstein and Sayre 2009). Given that younger children's parties are family celebrations which concentrate on children and build broader social ties, their organisation and orchestration is usually completed by mothers (Clarke 2000). Thus, the context of birthday parties offers marketing researchers the opportunity to study how a mother's consumption intersects and frames her own and her family's identity (Thomsen and Sorensen 2006) and her enactment of this identity. In understanding birthday parties as enactments of ideology or public performances by mothers (Goffman 1959), a broader understanding of their significance can be gained.

METHOD

To understand the cultural, family and individual influences on women as they planned and navigated their child's birthday party, this research was designed to develop a deeper understanding of the forces at play for women in the public performance of their role as mother. In-depth, face-to-face interviews were conducted with eight mothers of children who were between five and seven years at their most recent birthday party. Variation across the sample was sought in relation to child's age, school attended, birth order, and child's gender. Semi-structured interviews were used to discuss cultural, family, and individual influences on mothers as they recollected how they planned and navigated their children's birthday parties. Goffman's (1959) performance theory was used as the analytical lens to understand the actions of the mothers and directly addresses Fisk and Grove's (1996) call to apply the drama metaphor more broadly in marketing. It also moves marketing literature about children's birthday parties beyond the ritual frame.

FINDINGS

The children's birthday parties were all complex social and personal events where mothers celebrated and demonstrated an intimate understanding of their children and also maintained her and her child's social networks. Through this, the birthday parties provided a significant social space in which the women performed

their identities as a mother to herself, her child, her family, friends, and the broader community. They represented a celebration of the individual child and a time of reflection for the mothers.

Media, children's schools, memories from childhood, and reference groups did not merely present different options or provide recommendations for children's parties, they also provided a normative framework and created a social discourse of good mothering (Banister and Hogg 2007). To be a good mother, the mothers enacted three ideologies—the mother's love was shown through the personalisation of the party to her child, the children were made to feel special with a focus on non-material means, and childhood was protected by the mothers so it could be fun, innocent and simple. For the mothers in this research, birthday parties were also occasions where commercial consumption activities, consumer socialisation of children, and teaching children the importance of relationships over and above materialism (Miller 1997) intersected.

In orchestrating their children's birthday parties, the mothers were hostesses, directors, protectors, event planners, friends, family members, and mothers of the birthday child. The complexity and number of roles each mother assumed made this an involved and consuming performance for the mothers and caused them all a level of anxiety which had to be managed. The two key roles played by the mothers were director and teacher at their children's birthday parties. As directors they used consumption to assist in staging the best party possible, and as educators they sought to educate their children as consumers and thus protect their children from being exploited through commercialism (Cook 2008).

DISCUSSION

The mothers all purchased goods or services in the course of organising and orchestrating their children's birthday parties, and they did so with both themselves and their child in mind (Cook 2008). Importantly, consumption was representative of interpersonal care (Thompson 1996) and was used and viewed by these mothers more as an "expression of relationships (rather) than some mindless materialism" (Miller 1997, 75) as it was used to socialise children (Otnes and McGrath 1994) and to demonstrate love through intimate knowledge of their needs and likes. By personalising their children's birthday parties, the mothers also used consumption to define their and their family's identity (Clarke 2000) and demonstrate their position in consumer culture (Schoonmaker 2006). Importantly, this personalisation of the birthday party through consumption and other acts was viewed as the opposite to the commodified birthday parties that were offered by venues such as commercial play centres. Whilst consumption was a tool in enacting the mothers' ideologies, its use and type was constrained by each mother's individual commodity frontier (Hochschild 2003). Each mother defined this frontier individually and uniquely. It was the responsibility of the mothers to set limits on the level of "commercial violation" (Hochschild and Machung 1989, 284) into the home and party and determine the commodity frontier.

Excess commercialism is generally felt to intrude upon the sanctity of childhood through either exploiting children or forcing them to mature early as consumers in order to be able to successfully navigate the efforts of marketers (Cook 2008). The mothers in this study educated their children as consumers through gift exchange processes and demonstrated that birthday parties are a celebration

of 'togetherness', rather than material consumption. Mothers are re-affirming the importance of birthday parties as family rituals (Otnes et al. 1995) and events to forge community togetherness (Schoonmaker 2006).

Changes in Relationship Closeness: A Turning Point Analysis

Gary Daniel Futrell, Florida State University, USA

EXTENDED ABSTRACT

Spending on relationship marketing programs has grown exponentially since the early 1980's as managers have adopted the premise that investments in relationship marketing build stronger relationships and improve financial performance by creating loyal customers that spread positive word-of-mouth, make repeat purchases, and are willing to pay price premiums (Pine, Peppers, and Rogers 1995). Researchers and managers alike have made relationship marketing a top priority. Yet research in this field has often yielded mixed results, and managers readily admit that they have experienced only limited success and often question the ability to translate relationship marketing theory into practice (Band 2009). Numerous calls have been made for greater understanding about relationship building. Price and Arnould (1999, p. 38) caution that, "charging ahead with relational programs without an understanding of what marketing relationships can and cannot be puts the cart before the horse."

By utilizing a novel research technique, this research investigates marketplace relationships between customers and service providers. Turning point analysis (borrowed from the communications literature) is used here to investigate how *relationship closeness*, a key factor in relationship building, changes over the course of a marketplace relationship.

Closeness is often the characteristic referred to when differentiating strangers, acquaintances, friends and intimates. Collins and Feeney (2004, p. 164) define closeness as "the degree to which relationship partners are cognitively, emotionally, and behaviorally interdependent with one another." That is, the degree to which individuals influence one another's outcomes and depend on one another to meet social, emotional, and physical needs. It is the process that underlies many relationship phenomena and is proposed as the primary construct by which a relationship should be assessed (Berscheid, Snyder, and Omoto 1989). Several relational constructs have been proposed in the marketing literature as key elements for relationship assessment. Among the most commonly cited are: attachment, commitment, bond, relationship strength, relationship satisfaction, and relationship quality. A study by Jones, Ranaweera, and Bansal (2009) suggests that there is significant overlap in meaning among these constructs and that both researchers and consumers see little difference among them. These constructs directly or indirectly use closeness as a key dimension. For example, relationship quality has been conceptualized as relationship commitment (Jones et al. 2009). Commitment, in turn, has been conceptualized as attachment and closeness (Garbarino and Johnson 1999).

A qualitative study was undertaken in an effort to gain greater understanding about what events trigger a change in relationship closeness between consumers and service providers. The research question of interest for this study is "what events characterize changes in closeness throughout the history of a consumer's relationship with a service provider?" The method of investigation, turning point analysis, is a new technique in the marketing research. This research method has proven to provide insight into critical events that affect closeness, as well as how relationships change over time. The following section provides an overview of the use of turning point analysis in relationship research. This is followed by a discussion of the methods used for this study, results and conclusions.

Fourteen participants were interviewed separately using the retrospective interview technique (Baxter and Bullis 1986). They were asked to think of a specific service professional that they are currently using, have used at least three times, and have patronized

for at least 12 months. The concept of relationship closeness was defined for the participant and they were asked to rate on a scale from 0 to 10 (with 0 being the lowest possible score and 10 being the highest), how "close" they felt to the service provider currently and when they first used the service provider. In accordance with Collins and Feeney (2004) closeness was defined as "the degree to which individuals influence one another's outcomes and depend on one another to meet social, emotional, and physical needs." Using a preprinted graph with 0 to 10 marked on the Y-axis to indicate closeness, the author then completed the graph by plotting the months on the X-axis. The participant was oriented to the graph, and asked to plot their level of closeness when they first used the service provider and currently. Participants were then asked to recall and plot "all of the times when there were changes in the closeness you felt toward the service provider." Participants were asked to describe the nature of the event that affected the relationship, how they felt about the event and how they altered their behavior. After discussion of each plotted turning point, the participant was asked to connect the prior point to the most recently drawn point and explain how the line represents the change in relationship. This procedure was repeated as the participant moved from left to right across the x-axis. After completing the graph, the participant was asked to review the graph and consider the initial instruction and discussion about the relationship. The participant was allowed to make any changes and provide any additional information that they felt relevant. The participant was debriefed and thanked.

Turning points were coded by the researcher and similar turning points were grouped together. Several themes emerged based on the data analyzed in this study: economic salience, community connection, and insider knowledge. The first category, economic salience occurs when, through the actions of the service provider, the customer is reminded that the relationship is an economic arrangement. Results from the study suggest that customers feel less close when they are reminded that the relationship is a marketplace arrangement. The second category, community connection, occurs when the customer discovers that the service provider has ties to the community. Closeness increases when, for example, the customer learns that the service provider is a member of a local civic organization, school or church.

The final category, insider knowledge, refers to when the customer learns personal information about the service provider's family or business. Customer's feeling of closeness increases upon meeting or learning personal information about the service provider's family members.

In addition to the findings of this qualitative study, this research provides evidence that turning point analysis and RIT are viable methods of investigation and data analysis in consumer behavior research.

Revisiting The Subculture: Fragmentation of The Social and The Venue for Contemporary Consumption

Emre Ulusoy, University of Texas-Pan American, USA

A. Furat Firat, University of Texas-Pan American, USA

EXTENDED ABSTRACT

Although, subcultures have traditionally been defined mostly on the bases of nationality, ethnicity, religion, and class distinctions and thus people have been categorized and compressed into given, stable and clearly demarcated categories based on traditional and modern lineages, with the cultural turn from the modern to the postmodern, it is observed that people have the potential and vision for generating their own categories and, therefore, do not need to obey or try to fit in these predetermined, static categories with boundaries. People have begun to construct and structure cultural identities more often on the basis of their personal choices. The very idea of stable, coherent subcultures as distinct entities with recognizable boundaries has thus been challenged. Instead the focus is on the fluid, heterogeneous, taste-based, fragmented, and transitory nature of so-called postmodern subcultures.

Thus, subcultures have come to provide a venue for people to find anchors and feel empowered to generate more dynamic, fluid and organic identities and modes of life. Subcultures have also grown to be venues for consumers to not only perform their personal lifestyle choices, but to also respond to an alienating and objectifying individualism by constructing collective identities using activities, including music, style, and ideology. On the one hand, subculture is perceived as a meaningful alternative to a dominant culture, therefore, not a direct challenge to the dominant institutions in our lives. On the other hand, alternative lifestyle practices and creating venues for expression for alternative ways of being can also be considered to be a resistance to the dominant system of meanings and values.

When humanity lost faith in the emancipation potential of science and the progress of modernity, the grand narratives of modernity have waned and the social is fragmented. No longer the grand narratives of modernity but multiple, fragmented narratives that we observe in subcultures tend to be employed to practice fragmentation and dispersion. Postmodern subculture identities are multiple and fluid. They are constituted through consumption and are the new sources of identity, as well as the new signifiers of difference. Consumers do not have to worry about contradictions among their selected subcultural identities for there are only ephemeral attachments to a variety of styles.

In the fragmentation process, one form or style does not dominate over or eliminate all others. Instead, different styles work as a catalyst for fragmentation, in which consumers are willing to experience and sample the different styles and cultural artifacts. A postmodernist sensibility recognizes the fact that various subculture groups will have preferences for different and multiple ways of being and living rather than cling to or claim the superiority of just one. Therefore, fragmentation gains strength in postmodernism by having tolerance for differences and multiplicity; without any judgmental assessment in terms of superiority and inferiority. However, in order for these fragmented life modes to work, community is required since consumers can only achieve meaning and existence through participation in or construction of communities, thus enabling experiences of varied (sub)cultures, styles, and modes of being. In sum, contemporary subcultures are the consequence of the fragmentation of society and the means for producing the meaningful experiences that are sought in life, as well as for producing selves or self images within these experiences. Human beings

transform from relatively passive consumers into active producers in the venues of subcultures whereby they are empowered.

Music is a core element or artifact of subcultural phenomena that is set apart from other arts and activities due to its transcendent popularity over the others and its highly permeated position in everyday life. Music is proposed as a producer of people and experiences rather than simply a reflection. Subcultural identities are created and developed through active participation in the production and consumption of music. Music works as a means of facilitating the entry of a subculture as well as diffusing it. Music provides this resource for subcultures because not only can members utilize it easily but also because it has a culturally integrative potential to integrate individuals with the group. Music and live performances, as a form of cultural expression and cultural artifact, play a key role in generating subcultural identity and collective experience.

The forms of resistance have transformed in step with the epochal changes in human history. Rebellion was the dominant form of resistance in traditional culture where forces beyond humanity were believed to control human destiny. With modernity, confrontation became the dominant form of resistance in which discontent could be confronted with the goal of changing the world. However, with the waning of modernity, presentation is substituting confrontation as the dominant form of resistance. There are no claims of fundamentals, but the universe we encounter is seen as what has been culturally constructed, providing people greater license to present possible and potential modes of living and being in the world. In sum, subcultures present core meanings of resistance, but then offer venue for individuals to customize their subcultural identity. Subcultures are consumers' own sites of being by resisting imposed meanings while producing their own. Self-creativity through resistance, mixing styles, music, and ideologies, which offer aesthetic avenues and thereby greater texture for immersing into and experiencing life becomes the preferred presentational mode.

We have attempted to explain the reasons for the growth and multiplication, through fragmentation, of subcultures as the sites of much future consumption. We identified two key forces in the development and growth of subcultures: The cultural impulse for fragmentation and the change to presentational forms of resistance; two forces that impel each other. We have also identified the means most conducive to helping the trend toward fragmentation and presentation: Music. Consequently, what we find is a continual multiplication of subcultures, as different members of an initial subculture find purpose in presenting a different, even if in nuance, mode of organizing and experiencing life to produce meaningful and substantive moments.

In Pursuit of Balanced Perspective on Consumer Agency and the Power of the Social: Discourse Theory of Laclau and Mouffé for Consumer Research

Hyun Jeong Min, University of Utah, USA

Debra Scammon, University of Utah, USA

EXTENDED ABSTRACT

The debate of consumers as agents versus dupes has been widely discussed in the literature of social sciences and consumer research (Arnould 2007; Schor 2007). Consumer images of single minded, status seeking (Veblen 1979) individual or the helpless, manipulated consumers in the Frankfurt School's theorization gave way to a view of "consumers as motivated, discerning, even demanding in their relationship to the producers of cultural texts, products, and advertising" (Schor 2007, 23). However, if zooming out to the more macro level of actions, we can see that the structuring power of the social is still working strong. To accommodate the need to balance between consumer agency and structuring power of the social, we draw on the discourse theory of Laclau and Mouffe.

Laclau and Mouffe's discourse theory sees all reality as discursively constituted and in principle it is legitimate to use discourse analytical tools to analyze all aspects of the world including physical reality such as the body and the material world (Jørgensen and Phillips 2002). Their analysis rejects the distinction between discursive and non-discursive practices. Instead it affirms that every object is constituted as an object of discourse and that any distinction between what are usually called linguistic and behavioral aspects of social practice is an incorrect distinction (Laclau & Mouffe 1985) because the boundary between the linguistic and the non-linguistic in a certain social practice is not clear (Laclau and Mouffe 1987). They propose that discourses fix meanings in certain ways and therefore exclude all other possible meanings through hegemonic closures and that the discursive constructions appear as natural through myths about society and identity. According to Laclau and Mouffe (1985), no discourse is a closed entity but it is constantly being transformed through contact with other discourses. Different discourses, each of which represents particular ways of talking about and understanding the social world, are emerged in a constant struggle with one other to achieve hegemony, fixing the meanings in their own way (Jørgensen and Phillips 2002; Laclau and Mouffe 1985).

Although Laclau and Mouffe are mostly interested in more abstract discourses, the idea that these discourses are created, maintained and changed in diverse everyday practices is implied in their theory (Jorgensen and Philips 2002). Especially their concepts including nodal points, articulation, and the logic of equivalence and difference have potentials to be used effectively in detailed empirical analysis to answer the questions such as how each discourse constitutes knowledge and reality, identities and social relations.

By drawing on the discourse theory of Laclau and Mouffe, consumer researchers can have a means to balance between consumer agency and socio-political forces structuring consumption. In consumer research, the term discourse has been examined in relation to the construction of consumption narratives (Thompson & Haytko 1997; Murray 2002; Kozinets 2008) and mainly focused on the linguistic performances of consumers. By concentrating on consumer narratives, consumer's agency in consumer culture was emphasized while the influence of structural forces was under-investigated. Another problem of looking at discourse in the context of consumer narrative construction is that concrete practices of consumption are missed in the discussion of consumer behaviors. Concrete practices of buying clothes, putting things together to make an ensemble, and accessorizing only exist in the narratives

of consumers. Considering that a consumer's narrative is also an act of representation (Hall 1997), consumer researchers need to understand how certain consumption practices and the narratives about them are produced in the socio-political context beyond the relationship of specific consumption behaviors to consumer's life project and life theme.

As another benefit of utilizing discourse analysis consumer researcher can overcome the limitation of thematic analysis. Consumers' narratives have usually been analyzed according to hermeneutic or phenomenological approaches and these approaches are mainly interested in the text-content relationship and therefore overlook the discursive conditions of production, diffusion, and reception of complex discursive configurations (Sitz 2008). However, the hermeneutic circle approaches used for discourse analysis may raise a problem by treating quotes from transcribed interviews as thematic evidence of discourse although the quotes should be analyzed as the evidence of local production of discourse (Cloyes 2007). In fact, Foucault was deeply critical of the conventional notion of the subject as the independent, authentic source of action and meaning. He challenges the privileged position of the subject in relation to meaning. Subjects may produce particular texts, but they are operating within the limits of the discursive formation of a particular period and culture (Hall 1997). Another problem in using thematic analysis for discourse analytic studies arises from the loss of the detail and discursive subtlety of the original (Antaki et al. 2002). Discourse analysis is more concerned with 'parole,' which pertains to the particular acts of utterance, rather than 'langue,' which refers to underlying rule-governed structure of language. Therefore summarizing data into several themes may lose sight of the subtle ways that the 'I' as author construct stories with the character 'I' to produce certain effects, which can be the justification of his or her consumption choice or impression management in the interaction with researchers.

In this vein, discourse theory of Laclau and Mouffe (1985) suggests specific strategies to overcome the drawbacks of using thematic analysis in researching discursive aspects of consumption behaviors. Their work is not strictly methodological texts (Cloyes 2004), the concepts in their theorization provide useful guidelines to study discursive formation in consumer culture.

Forget Negotiation: The Non-Dialectical Model of Identity Project By Extreme Sports Participants

Soonkwan Hong, Michigan Technological University, USA

EXTENDED ABSTRACT

Consumer culture theory views identity project as a process and a practice through and by which consumers' cultural bricolage of the self is embodied and enacted in negotiation with the hegemonic market influences, such as globalization, brands, and gendered consumption environment (Arnould and Thompson 2005; Askegaard et al. 2005; Epp and Price 2008; Holt 2002; Kates 2002; Kjeldgaard and Askegaard 2006; Oswald 1999; Üstüner and Holt 2010). Accordingly, negotiation, compromise, reconciliation, cooperation, and rapprochement have thus far been the preferred (in fact, almost required) methods to present idiosyncratic identities (Giesler 2008; Holt 2002; Kozinets et al 2004; Thompson and Coskuner-Balli 2007; Thompson and Tian 2008).

The received view of identity negotiation, however, has overlooked other possibilities (forms) of consumer-market power relations (see Foucault 1980 for power relation) that are palpable and facilitate non-negotiated and thus dialectic-absent identity projects. Hence, this study first seeks to illuminate a context wherein consumers perform purely self-fulfilling identity projects with less concern about social consequences of such existential endeavor (cf., Marino 2004). Second, it is of importance to re-examine the current view of authentic self-identity *vis-a-vis* the continuously inculcated notion of fragmentation of self (cf. Ahuvia 2005), as identity negotiation becomes less germane to a certain context.

The annual X Games event is selected as the research context. The counter-mainstream ethos of extreme sports represents the sub-cultural or countercultural values that underpin the events (Quester, Beverland, and Farrelly 2006). The deliberate "distancing" from mainstream culture, establishment, social structure, and hegemonic brands brings much attention and value to the extreme sports event, as a culturally and theoretically rich context for this study of non-negotiated identity project. The event is still a carnivalesque-like paradoxical consumption festival through which authenticity becomes commercialized; resistance to the market is intermingled with or even acclimatized to the profit-driven practices; and consumers act multiple roles as they face subcultures/mainstream cultures, conformists/rebels, and co-optation/countervailing forces.

Thirty phenomenological interviews, as the primary data source, were conducted (Thompson 1990). Observations were recorded using fieldnotes, videotapes, and photographs in order to easily utilize them for the following analyses and interpretations. Overall, 581 photographs were taken, and approximately 172 minutes of video recording was conducted. Following Thompson (1997), a creative, playful, subjective, and yet substantially translative hermeneutics is expected to yield meaningfully interpreted and theoretically contributing themes of non-negotiated identity project, based on consumers' transformative ideologies and performances.

Consumers' signification process for non-negotiated identity is represented mostly by creativity, reminiscence (memory or nostalgia), personalization, unusual experience, relationship-orientation, experimentation, and, especially, being outdoors as the first priority for extreme sports participants. It is an observation that "being outdoors" is not only the inception, but also the quintessence of the signification process.

There were six convergent themes identified from the semiotic clustering. Each of the themes represents a distinct (non-negotiated) way in which consumers engage in the sense-making of their lives in relation to (at times in opposition to) social norms, enticing

marketing influence, pseudo-authentic cultural materials, and conformity-ridden socio-cultural environment.

It is noteworthy that a new context can promote a theoretical divergence. In contrast to the Burning Man project that only guarantees temporary and geographically-bounded sanctions to such an anti-market endeavor, X Games unleash the consumers from cultural and normative dogma, which have constrained consumers to discontinue pursuing non-negotiated identities in other spaces (i.e., home and work) after the duration of such events. Evidently, some extreme sports participants continuously work on their authentic non-negotiated identity. Thus, research that specifically discusses some contexts in which consumers opt to be a true agent with no or little concern about inter-agential conflict will move the current theoretical outlook of consumer agency forward. Moreover, when more of such contexts are found to exist and become more common than before, the boundary conditions should be identified. In other words, it is of importance to study when the supposedly incessant pursuit of non-negotiated identity fostered in the context is ceased.

The "dialectical model of branding" (Holt 2002) can be revisited as well. When consumers practice non-negotiated identity project, the dialectics in the domain of branding become less explanatory. That is, consumers do not necessarily need to symbolically rely on or respond to the brands they constantly face in the market. Authenticity of the brands does not concern them as they can totally "dis-necessitate" brands for their identity narratives, which may be more coherent without any brand. There are some exemplary grass-roots brands widespread in snowboards and outdoor equipment industry. A group of handful individual fanatics and supporters of snowboarding have launched their own brand in order not to negotiate with the brands identities and personalities developed by marketers and other consumers. Research should address this type of "no logo" praxes that are not as direct or perceptible as boycott, anti-consumption, consumer terrorism or "culture-jamming" (Lasn 2000) but still transforming the current consumer culture.

Perhaps all the simulations and emulations in the identity narratives by signifying consumers are not to contest or escape the market system but to revitalize the inertia in the market. The context of X Games and the participants appear to propose a new way to enjoy symbiosis between consumers and the market as the context promotes "hyper-authenticity" and individuals take advantage of it to survive, as contemporary consumers, without dialectics. It will be, however, of more interest to observe and theorize how marketers respond to the extreme presentations of self-identity without any trace of negotiation. Can (will) they still co-opt them?

Construal and Categorization: Impacts of Psychological Distance on Brand Extensions

Fang-Chi Lu, University of Iowa, USA

Dhananjay Nayakankuppam, University of Iowa, USA

EXTENDED ABSTRACT

The topic of brand extension has been pervasively studied in the fields of marketing and consumer psychology. Previous research suggested that brands and their affiliated products are represented in memory as different categorical representations, and consumers use those mental representations to assign a new product or service to a certain category, and draw inferences about it (Loken et al., 2002). Categorical representations are flexible and malleable, and the likelihood of category inferences depends on the similarity or match between the representation of the existing brand category and the representation of a new category member (i.e. Meyvis & Janiszewski, 2004; Cowley & Mitchell, 2003). The higher the match between the extension product and its parent brand category, the more likely beliefs and attitudes typical to the parent brand will be ascribed to the extension.

Recently, Ahluwalia's research (2008) showed a consumer's self-construal influences the perceived fit of an extension and thus, a brand's stretchability. Interdependent self-construal leads to a superior ability to uncover relationships between an extension and its parent brand, and thus is likely to enhance the perceived fit and acceptance of an extension.

The construal level theory (CLT) proposed by Liberman and Trope (1998) suggested that the chronically-built association between psychological distance and abstraction in cognition results in the tendency to construe objects/events with more high (low)-level, abstract (concrete) features when they are psychologically distant (near). Categorization itself is hierarchical and with different levels of abstractness; one could construe less or more inclusive categories of objects, depending on the level of construal being used to represent the objects. Greater psychological distance leads to a more inclusive categorization (Liberman et al., 2002).

On the basis of this literature, we propose that psychological distance also enhance the stretchability of a brand extension. Psychological distance will influence the levels of construal people use to represent an extension, its categorization, and the likelihood of category inferences from existing brand category to the extension. Specifically, when a brand extension is represented at a higher, more abstract, and superordinate construal level, it is more likely to be included in the existing brand category, leading to greater category inferences. We report the results of four experiments that examined our propositions.

In Study 1, construal level was manipulated by temporal distance of brand extensions. Participants were presented with a series of brand extensions (four brands and each had eight proposed extensions) which were suggested to be introduced in either near or distant future, and then reported their attitude toward the extensions. A control group was asked to evaluate the consistency of those extensions to their affiliated parent brands. A median-split was performed on these consistency measures to categorize the extension into low and high consistency group. Fifty-eight undergraduate students participated in this study. Results showed extensions represented in distant future were evaluated more favorably than the ones in the near future. Furthermore, the interaction between temporal distance and consistency suggested that the psychological distance effect was greater for low consistency extensions than high consistency ones.

To increase generalizability, different brand extensions were used in Study 2. Furthermore, another psychological distance dimension was included to manipulate construal level. Study 2 is a

2(psychological distance: near vs. far) X 2 (distance type: temporal vs. spatial) mixed design with construal level as between-subjects factor and distance type as within-subjects factor. Forty-seven undergraduate students participated in this study. They were presented with eighteen hypothetical extensions (three brands, each with six extensions), suggested to be introduced either in the near (distant) future or in the US (a foreign country). For each brand, half of the extensions were manipulated by temporal distance and the other half was by spatial distance. Participants then reported their attitude toward each extension. Results of study 2 again supported our hypothesis. When extensions were introduced in either distant future or spatially distant, participants evaluated the brand extensions more favorably. And the effect of psychological distance remained regardless of brands, extensions, and distance type.

Study 3 is to examine the mediation effect of perceived similarity (fit). The design of study 3 is similar to study 2, except that one more brand and six more extensions were included, and measures of brand attitude as well as perceived similarity (fit) were included because previous research suggested that brand attitude effect on brand extension evaluation is also mediated by fit. One hundred undergraduate students participated. Results replicated the findings of study 1 and 2, and extended previous studies by demonstrating that the influence of psychological distance on brand extension evaluation was mediated by the perceived similarity (fit) (Sobel's test: $p_{1-tailed} = 0.01$).

Study 4 adopted a 2 (temporal distance: far vs. near) x 2 (social distance: far vs. near) between-subject design to examine the potential interplay between different dimensions of psychological distance. Participants were presented with ten domestic (US-based) vs. foreign (foreign country of origin) brand extensions to be introduced in temporally near vs. distant future. We matched the brands in terms of their product class and brand strength. It's assumed that although all the brands are available in the US markets, foreign brands should be perceived more socially distant than domestic brands. Results showed a significant social distance main effect on liking and purchase intention toward brand extension, and a marginal significant two-way interaction effect on purchase intention.

Taken together, the findings across four studies shed light on the linkage between construal level theory and categorization theory, and their application on brand extension. The categorization and evaluation of a new product extension is influenced by its psychological distance, especially when the extensions are inconsistent with the parent brands. The present study contributes to the brand extension literature by providing construal level as another route to understand the potential of brand stretchability, and how a brand extension is perceived, and its likelihood of acceptance by consumers. This study also extends previous research by examining the effect of other psychological distance dimensions (spatial and social) and their interplay on brand extension evaluation.

Top 10 or #10?: How Positional Inferences Influence the Effectiveness of Category Membership Claims

Mathew S. Isaac, Northwestern University, USA
Kent Grayson, Northwestern University, USA

EXTENDED ABSTRACT

When making advertising claims, marketers routinely highlight their product's membership in a ranked list (e.g., a top 10 list) in an attempt to enhance perceptions of the product. The present research shows that touting a product's membership in an elite list can sometimes backfire on marketers and lead to *less* favorable consumer evaluations of their product. Specifically, I claim that when consumers make positional inferences by attempting to estimate a product's specific rank in a list, product evaluations will be negatively affected. In this research, I explain when positional inferences occur and why they adversely influence evaluations of a target.

My research focuses on lists in which all members are arranged ordinally, such that each member has a specific rank or position in the set. Marketers often highlight their product's inclusion in such lists at the broad category level (e.g., "top 10," "25 best") without disclosing their product's exact rank. As a result, consumers may often be aware of a product's presence in a ranked list without knowing its *specific* position in the list. If consumers receive category membership information about a target, they often integrate this new information into their evaluation of the target at the category level. For example, learning that a specific item has been ranked among the top 10 products of its type is likely to bolster evaluations of the item since its inclusion in an elite set presumably carries positive associations. Rather than relying solely on broad category-level information to inform their evaluations, consumers may also attempt to *infer* a target's precise position within the list. In the above example, learning that a product has been ranked in the top 10 may motivate some consumers to make a positional inference regarding the exact rank of the product within the set.

When consumers estimate a target's rank based on category membership information, I propose that they tend to infer a rank relatively close to the lower bound (i.e., the least desirable value) of the category. This phenomenon, which I label the Category Floor Tendency (CFT), can be explained by consumer reliance on communication norms. As a result of the CFT, I predict that evaluations of a target will generally be *less* favorable when consumers estimate the target's specific rank within the category rather than relying on category-level information. Across three experiments, I provide evidence of a systematic CFT and show how this particular positional inference diminishes evaluations of a target. I also demonstrate two ways in which cognitive elaboration influences whether consumers make positional inferences altogether.

Participants in experiment 1 learned that a target product had been included in an elite numerically bounded category (e.g., a top 10 list). I then manipulated the presence or absence of positional inferences by explicitly instructing (or not instructing) participants to consider the specific rank of the target prior to making their evaluation. Consistent with my predictions, I found that reflecting on a target's specific position within a ranked list has an adverse effect on subsequent evaluations. I also produced direct evidence that the CFT is responsible for the negative impact of positional inferences on target evaluations. Participants who estimated a rank closer to the category floor evaluated the target less favorably than those who estimated a rank that is farther from the floor (i.e., more favorable).

In experiment 2, I showed that increasing the likelihood of elaboration by using unconventional category floors (e.g., top 19, 21) fosters positional inference-making. Consumers who were explic-

itly prompted (versus who were not prompted) to make positional inferences evaluated a target *less* favorably when they encountered conventional category claims (top 20). However, unprompted and prompted evaluations of a target did not differ if the target was a member of an unconventional category (top 19, 21). This difference suggests that consumers are more likely to make unprompted positional inferences when they encounter unconventional category claims than when they encounter conventional category claims.

In experiment 3, I demonstrated that engaging in qualitatively different forms of elaboration also impacts whether positional inference-making occurs. Specifically, level of construal (i.e., how abstractly or concretely stimuli in the environment are represented) determined whether a consumer processed a category membership claim at the broad category level or embarked on a search for ordinality. I found that consumers who had been explicitly prompted (versus who had not been prompted) to make positional inferences evaluated a target *less* favorably if they were at high levels of construal. However, unprompted and prompted evaluations of a target did not differ if consumers were at low levels of construal. This difference suggests that consumers are more likely to make unprompted positional inferences at low levels of construal than at high levels of construal.

This research broadens our understanding of numerical cognition, which has examined the information processing of numerical values but has largely ignored numerically bounded categories. I contribute to this literature by showing how consumers evaluate products that are defined by their membership in a numerically bounded category. In addition to documenting a systematic positional inference that consumers make (i.e., the CFT) when encountering a claim of membership within a ranked list, I identify two moderators of this effect. I demonstrate that quantitative and qualitative dimensions of cognitive elaboration determine if consumers engage in unprompted positional inference-making altogether. As another contribution to the numerical cognition literature, I provide evidence that the numerical conventionality of category floors determines whether positional inference-making occurs. Additionally, this research also enriches our understanding of categorization by exploring a structurally distinct type of category (i.e., a ranked list) that has been understudied. Despite the ubiquity of ranked lists, very little academic research has previously explored how consumers process information about categories in which members are organized ordinally.

Although I have focused exclusively on ranked lists in this paper, the applications of my research are considerably broader. When evaluating a target, consumers may base their evaluation of the target on category-level information or they may attempt to seek out individuating information about the target. Using ranked lists, my research seeks to understand when consumers seek out individuating information rather than relying more generally on category-level information. This objective is shared by researchers studying impression formation, person perception, and stereotyping, who are all interested in the antecedents of categorical thinking (and the stereotypical judgments which follow). Given our common objective, my findings may be highly relevant to these other domains. For example, based on the results of my third experiment, one could extrapolate that high levels of construal result in greater reliance on stereotypes. Future research might investigate whether the insights derived from numerically bounded categories transfer

to social judgments, which may be somewhat more motivational and less cognitive in nature.

When Seeing Many Types of Wine Makes You More Sensitive to Technological Threats: Unrelated, Prior Categorizations and Reactions to Change

Amitav Chakravarti, New York University, USA

Christina Fang, New York University, USA

Zur Shapira, New York University, USA

EXTENDED ABSTRACT

Detecting change is a fundamental, all-pervasive cognitive activity. It forms the core of many cognitive activities, such as visual, auditory, olfactory, and tactile discrimination tasks, similarity judgments, and categorization. Naturally then, the ability to detect a change, to accurately assess the magnitude of the change, and to react to the change in a commensurate fashion, is of critical importance in many substantive domains (Massey and Wu 2005, Rensink 2002), ranging from medical decisions, business investment decisions, and face recognition, to air traffic control. Thus, it is important to understand factors that systematically affect people's ability to detect change. To that end, we document a simple, yet novel effect: people's reactions to a change (e.g., visual change, or technology change), are systematically affected by the categorizations they encounter in an unrelated, prior task (e.g., how a wine store categorizes its wines).

Before surmising about reactions to change, it is important to consider, more generally, how exposure to many, narrow (vs. few, broad) categorizations might affect an individual's information processing. First, an individual who is exposed to a detailed environment with many, narrow (vs. few, broad) categories, should be cued to the notion that objects differ from each other in many different ways, and will fine tune her cognitive apparatus accordingly, using more (vs. less) dimensions to perceive and evaluate objects (e.g., see Barsalou 1993, Linville 1982). Further, as long as the subsequent context does not cue the need for cognitive reorganization, the recently tuned cognitive apparatus will likely be used, as is, for the next task at hand (e.g., see Bargh and Chartrand 2000, Smith and Branscombe 1987, Mullen, Pizzuto, and Foels 2002, Ülkümen, Chakravarti, and Morwitz (forthcoming)). Therefore, in a subsequent, unrelated task, an individual previously exposed to narrow (broad) categorizations is likely to continue to employ and discern relatively many (fewer) dimensions.

This brings us to the more specific question: how would such an individual react to a change that she subsequently encounters? Theoretically, there are two distinct possibilities. If the *perceptual* system alone is affected, then people previously exposed to many, narrow (few, broad) categorizations should have a more (less) sensitive perceptual encoding system, one that is attuned to processing incoming perceptual stimuli on relatively many (fewer) dimensions. Such people, therefore, should detect and *perceive* more (less) change, subjectively, when they encounter a subsequent change. In this case, then, prior exposure to unrelated, narrow (broad) categorizations will lead to stronger (weaker) reactions to a given change.

In contrast, if the *evaluative* system is affected, then prior exposure to many, narrow (few, broad) categorizations should encourage decision makers to *evaluate* the subsequent change more (less) carefully, using many (few) dimensions. The use of many (few) dimensions to evaluate the presented change should lead to perceptions of a relatively small (large) change, since the presented change would have to satisfy multiple (fewer) criterion in order to be deemed a significant enough change. Thus, in this case, prior exposure to narrow (broad) categorizations will lead to weaker (stronger) reactions to a given change. The question of which of these two conjectures is likely to prevail, is an empirical one, one which we leave our studies to answer.

Across four different studies, we find that unrelated, prior exposure to narrow (vs. broad) categorizations improves decision makers' ability to detect a visual change (study 1) and leads to stronger reactions to a given change (studies 2-4). These differential reactions occur because the prior categorizations, albeit unrelated, alter the extent to which the subsequently presented change is perceived as either a relatively large change or a relatively small one.

Each experiment comprised two, ostensibly unrelated studies. The first task was used to administer the prior categorization manipulation and the second task was used to record reactions to a presented change (Figure 1). We began by looking at how these prior categorizations affect a person's ability to detect a presented visual change, using well-established stimuli from the "change-blindness" paradigm (study 1). We then went on to looking at judgments that are contingent on people's subjective reactions to a presented change (studies 2-4). Specifically, we assessed their reactions to an innovative new technology that loomed in the horizon. A pretest was used to verify that the new technologies were perceived to be relatively innovative.

We operationalized the fine grained nature of the decision context in multiple ways. In some instances participants answered preference questions presented either on relatively simple 3-point semantic differential scales, or on more differentiated 7-point ones. In other instances, participants are incidentally exposed to the same set of products that have been grouped either in a coarse-grained manner (e.g., movies classified as comedy or drama movies), or in a fine-grained manner (e.g., movies classified as comic action, dark comedy, romantic comedy, courtroom drama, historical drama, or melodrama movies). Irrespective of the nature of the manipulation, we find a very similar pattern of carryover effects.

The manipulations used show that even incidental exposure to narrow-broad categorizations can have a systematic effect on change detection, and reactions to change. Interestingly, the effects are not attributable to differential involvement, confidence, familiarity, knowledge, mood, and task completion times. Taken together, these findings suggest the interesting possibility that decision makers can become more discerning, even in the absence of having exerted any extra effort. Given that category structure is a ubiquitous feature of many decision environments, our work constitutes an important first step in documenting how seemingly innocuous categorizations might affect a decision maker's reactions to change.

Does Exposure to Concept Products Affect Judgment of Marketed New Products?

Irene Scopelliti, Bocconi University, Italy

Paola Cillo, Bocconi University, Italy

David Mazursky, The Hebrew University of Jerusalem, Israel

EXTENDED ABSTRACT

In some industries, it is a common practice to develop prototypes that are very innovative and that are loosely coupled with the actual product that is subsequently marketed. These prototypes are referred to as *concept products*, and are usually exhibited at trade shows and at industry events. They typically feature technical functionalities that are very innovative, sometimes too advanced to be implemented on large scale production, and are typically characterized by an extreme design, often too futuristic to be featured by marketable versions without substantial adaptations and moderations.

By means of theories on the effects of exaggeration and on structural alignment, we argue that exposure to the design and functionalities of concept products may affect consumer evaluation of marketed products. Specifically, we predict a positive effect of exposure to a visually exaggerated concept product on the judgment of the marketed product (H1): when a novel design is preceded by exposure to its exaggerated form, i.e., the concept product, exaggeration may attract subjects' attention to the distinctive features of the design more than in the case of exposure to a non-exaggerated exemplar (Rhodes, Brennan and Carey 1987; Mauro and Kubovy 1992; Rhodes and Tremewan 1996). Moreover, the emphasis on the distinctive features of the design provided by exaggeration is feasible to leave a stronger trace in subjects' implicit memory. This trace may eventually enhance the ease in elaborating those features when subjects encounter other exemplars, more moderate, of the same design, thus enhancing their evaluation. We expect, however, that functional exaggeration of the concept product moderate such effect (H2): On the one hand, we expect that exposure to an exemplar featuring very high (extreme) levels of performance on a given functional feature may set a new standard for the judgment of other exemplars on that same feature, causing a contrast effect that hurts the judgment of the other exemplars (Herr, Sherman and Fazio 1983; Herr 1986). On the other hand, however, the occurrence of such contrast effect is contingent upon the degree of context-target similarity, i.e., occurs only both the priming (concept product) and target (marketed product) are judged as belonging to the same category (Stapel and Winkielman 1998). An exaggerated design (high visual exaggeration) may favor the perception of the concept product as less thematically or temporally related, thus reducing the contrast effect due to the concept product exaggerated functionalities on the judgment of the moderate target product.

Concept products may feature different degrees of visual and functional alignment with their respective marketed versions. For instance, firms may invest in developing and promoting a very advanced technological feature within a concept project, but then implement and promote different features in the moderate marketed version. Similarly, they can develop very innovative and futuristic designs for their concept products, but then base the actually marketed products on different and less disruptive designs. We argue that the visual alignment between the concept product and the marketed product influences negatively the judgment of the marketed product (H3), since it activates a 'thematic link' between the two objects in consumers' mind. The more the two products are visually aligned, the higher likelihood that they are judged as belonging to the same category and thus compared in terms of functionalities. Once this link is activated, it leads to an implicit comparison between the technical features of the concept product and those of the marketable product. In the case in which the concept product features high

functional alignment with the marketable product, then the very high (extreme) levels of performance on the technical functionalities are likely to influence negatively the evaluation of the marketable product, since the latter typically features more moderate levels of performance on those same technical functionalities than the former. However, it may be that the concept product features different technical functionalities (low functional alignment) than the marketable car. Therefore, it is less easy for consumers to compare the features of the concept product with those of the marketable products, since non-alignable differences are harder to compare than alignable differences (Markman and Gentner 1996; Gentner and Markman 1993). In such case, consumers would be less likely to be influenced by the extreme performance of the concept product when they evaluate the marketable product (H4).

Results of two experimental studies using concept cars and cars as stimuli support our hypotheses and show that i) exposure to a visually exaggerated concept product positively affect the judgment of a moderate product featuring a similar design, and moderates the negative effects of the concept product functional exaggeration; ii) the degree of functional alignment between a concept product and a marketed product negatively affects the judgment of the marketed product upon exposure to the concept product, with this effect being moderated by the degree of visual alignment between the concept product and the marketed product. Our results contribute to shed light on the role of concept products on the evaluation of marketed products, thus emphasizing a different way in which the use of design in the initial stages of new product development may enhance new product performance.

Choosing versus Rejecting: How Power Shapes our Decision Strategies

Mehdi Murali, University of Calgary, Canada
Anish Nagpal, University of Melbourne, Australia

EXTENDED ABSTRACT

When deciding among several alternatives, consumers may proceed by choosing (selecting, including) the most attractive option. Alternatively, they may adopt a decision strategy of rejecting (eliminating, excluding) the unattractive options. The literature on task framing investigates whether choosing and rejecting are two sides of the same coin. The principle of task invariance requires that decision makers should arrive at the same conclusion about product choice regardless of whether they reject or choose from the same finite set. However, past research has shown that the principle of task invariance does not always hold, and that decision outcomes are sensitive to which decision strategy consumers adopt (e.g., Park, Jun, and MacInnis 2000; Shafir 1993). Prior research has focused primarily on the consequences of framing a decision as either a choosing task or a rejecting task. However, much less is known about the circumstances under which consumers are more inclined to choose versus reject. Initially, Shafir (1993) noted that choosing might be the more preferred strategy relative to rejecting. Conversely, Ordóñez, Benson, and Beach (1999) concluded that the norm during screening tasks seems to be to reject the bad options rather than to screen in the good ones. Later investigations, however, revealed that the natural process for screening choice options is dependent on the characteristics of the decision task. Levin et al. (2001), for instance, found that people are more likely to favor an inclusion strategy when the task is positive (e.g., hiring employees), while preferring a rejection strategy when the task is negative (e.g., firing employees).

The present research goes beyond the influence of task characteristics, and examines the role of power—a consumer characteristic—in determining the preferred decision strategy. It also investigates the interactive effect of power and task frame on consumer satisfaction with the chosen option. Building on the approach/inhibition theory of power (Keltner et al. 2003), we hypothesize that activation of the behavioral approach system would make choosing a more natural strategy than rejecting for powerful consumers, whereas activation of the behavioral inhibition system would make rejecting a more natural strategy than choosing for powerless consumers. Indeed, activation of the behavioral approach system results in greater attention to potential rewards and positive outcomes. This should lead powerful consumers to favor a decision strategy that accentuates the choice options' positive features, which is more typical of a choosing strategy (Shafir 1993). In contrast, activation of the behavioral inhibition system heightens the perception of threat in the environment. Further, a focus on threats and negative outcomes is likely to emphasize the choice options' negative features. Since negative features tend to be weighted more heavily under rejection instructions than under choosing instructions (Shafir 1993), we predict that powerless consumers are likely to prefer rejecting over choosing decision strategies.

Consistent with our predictions, study 1 found that a heightened sense of power increases preference for choosing versus rejecting. Further, high power consumers were more satisfied with their choices when they adopted a choose strategy than when they adopted a reject strategy. Conversely, low power consumers were more satisfied with their choices when they adopted a reject strategy than when they adopted a choose strategy.

In study 2, we investigated the moderating role of responsibility. We argued that a heightened sense of responsibility would raise the perceived constraints that a powerful individual feels which,

in turn, would lead to reduced approach-related tendencies and reduced preference for choosing versus rejecting. Our data showed that the effect of power on decision strategy indeed disappeared when consumers' sense of responsibility was made salient. We also found that a high sense of responsibility makes both high and low power consumers more satisfied with their choices after adopting a reject strategy than after adopting a choose strategy.

How Objective and Subjective Mental Resources Influence Task Performance: Testing the “I Worked Hard, I Must Be Depleted” Hypothesis

Anick Bosmans, Tilburg University, The Netherlands

Rik Pieters, Tilburg University, The Netherlands

Hans Baumgartner, Pennsylvania State University, USA

EXTENDED ABSTRACT

At the end of an extensive shopping trip or after a complicated decision task, we should be depleted. We worked hard, so we must be tired, not? How will this influence how much resources we will allocate to a subsequent task?

We test the hypothesis that resource allocation to a task depends not only on the actual amount of resources available for a task, but also on consumers' inferences about the amount of resources available. More specifically, we propose and test the idea that inferences about the resource demands of preceding tasks (regardless of that task's actual demands) affect the amount of resources that will be allocated to a subsequent task. When people believe that a preceding task was difficult, they will allocate fewer resources to a subsequent (unrelated) task and task performance on this task will thus deteriorate, compared to when people believe that the preceding task was easy.

Of course, resource allocation to a task depends on the demands set by that task (Locke and Latham 1990), and on the amount of resources the consumer has available for that task. When a demanding preceding task has depleted one's pool of mental resources, insufficient resources will be available for subsequent tasks and task performance will decrease (Ackerman and Kanfer 2009; Baumeister et al. 2008; Vohs et al. 2008).

Research on the effects of resource scarcity has mainly focused on the objective amount of mental resources available (i.e., how many resources one actually has available), but little is known about whether and how beliefs about resource availability (i.e. how many resources one assumes to have available for a task) affect resource allocation to a current task. This is surprising, because most people find it difficult to determine how much mental resources were consumed in the past (Ackerman and Kanfer 2009) or will be required for a future task (Fennema and Kleinmuntz 1995; Garbarino and Edell 1997). Because people find it difficult to assess their objective resources, they may instead rely on their ideas about subjective resources when allocating resources to a task.

The results of three studies in which we manipulate perceived task demands but keep the actual task demands constant support our “I worked hard, I must be depleted” hypothesis. In a first study we asked participants to write a short essay about a task they had executed in the recent past that was either easy and simple or complex and difficult, thereby manipulating the salience of preceding task demands. In a control condition, we simply asked participants to write an essay about the physical environment they were currently in. Consistent with the “I worked hard, I must be depleted” hypothesis, we observed that participants consulted less information about a new product in a subsequent task when they were first asked to write about a difficult task performed in the near past, compared to when they were asked to write about an easy task or about the physical environment.

In a second study we tested our proposed hypothesis under different conditions of actual and perceived depletion. We asked participants to work on an anagram task for either one or ten minutes (thereby manipulating actual depletion levels). In both conditions, participants were led to believe that the anagram task was either easy or difficult (thereby manipulating perceived depletion levels). Afterwards, task performance on a subsequent (unrelated) task was

measured. We observed that, as long as actual depletion levels were low, people inferred the amount of resources available for a task from the perceived difficulty level of the preceding (anagram) task. That is, when people believed that the preceding task was difficult, they felt more depleted and allocated fewer resources to a subsequent task compared to when they believed that the preceding task was easy.

In study 3, we tested the hypothesis that people would be less likely to infer available resources from the perceived demands of a preceding task when both tasks appear dissimilar. Indeed, when we explicitly instructed participants that both tasks drew on different psychological processes and resources, the amount of resources consumed in the past was no longer informative when assessing the amount of resources available for a subsequent task and the “I worked hard, I must be depleted” effect disappeared.

In sum, we observed that resource allocation to a current task does not only depend on the actual amount of resources available for that task, but is also a function of the inferences that people make about the amount of resources they assume to have available. Characteristics of the context, such as the perceived ease or difficulty of a preceding task, can inform people about how many resources they can allocate to subsequent tasks. These findings reveal the great flexibility in resource allocation that consumers have and show that resource depletion is not necessarily an objective phenomenon. Our studies show that not only the actual level of resource depletion, but also consumers' naïve theories about when they should or should not be depleted determine subsequent task performance.

Inhibition Spill-Over: Sensations of Peeing Urgency Lead to Increased Impulse Control in Unrelated Domains

Mirjam Tuk, University of Twente, The Netherlands
Debra Trampe, University of Groningen, The Netherlands
Luk Warlop, Catholic University Leuven, Belgium

EXTENDED ABSTRACT

People often encounter decision situations in which they have to choose between an option that is on the short term more rewarding and attractive, and another option that is on the long term the more beneficial one, like choosing between going out for dinner tonight versus saving money for retirement. When people follow their impulses (prefer the more immediate option) and when people resist impulsive input (and opt for the more long-term beneficial option), has been an important topic of previous research (e.g., Vohs 2006). Recent research adds to this domain by providing evidence for the existence of a general reward system (Briers et al. 2006; Van den Bergh, Dewitte, and Warlop 2008). When people's desire for a reward is triggered (e.g., by the sight, smell or taste of rewarding stimuli), their desire for any kind of reward increases, rather than only their desire for stimuli that are directly linked to the aroused state. For example, exposing people to a consumption sample of a tasty food does not only increase their desire for food, but also their desire for other rewarding goods (like beverages and a holiday).

In the current research, we argue that inhibitory signals are domain unspecific. Recent neurological research (Berkman, Burklund, and Lieberman 2009) suggests that inhibitory signals in the motor, cognitive and affective domain share the same neurological network. Berkman and colleagues argue for the relative efficiency of such a network from a neurological point of view. However, a side-effect of such a shared network is the possibility that inhibitory signals are not completely domain specific, but can spill-over to other domains and result in an unintentional increase in inhibitory signals in unrelated domains as well. Berkman et al. provide neurological evidence for inhibition spill-over effects. We aim to provide evidence for inhibition spill-over from a behavioral point of view. We argue that inhibitory signals from one domain can spill-over and result in more impulse inhibition in unrelated domains. One important physiological condition that largely relies on inhibitory signals is bladder control. As the bladder becomes increasingly full, the impulse (immediate voiding) has to be inhibited until an appropriate place and time. This inhibition occurs during most parts of the day, and is relatively automatized since an early age. Griffiths and Tadic (2008) show that the inhibitory signal stems from the Anterior Cingulate Cortex (ACC), which is also one of the brain areas identified as an important part of the general inhibition network. In the current research, we argue that increased inhibitory signals due to increased bladder control will spill-over to unrelated domains and result in increased impulse control.

In the first study, we manipulate peeing urgency by means of a water drink test approximately one hour upfront. After one hour passed, respondents engaged in an intertemporal choice task (adapted from Li 2008). They were asked to choose eight times between either a smaller but sooner reward, or a later but larger reward. Foregoing a smaller but more immediate reward in order to obtain a later, but larger reward requires impulse control. Manipulation checks showed significant differences in reported peeing urgency. In line with our expectations, respondents more often chose for the later larger reward when they had to pee more urgently.

In the second study, we show that sensitivity of the Behavioral Inhibition System (BIS) moderates this effect. BIS is known to be involved in response inhibition and punishment avoidance (e.g.,

Carver and White 1994). In line with our expectations, peeing urgency had a stronger effect on intertemporal patience for people with a relatively sensitive BIS compared to people with a relatively insensitive BIS.

In study 3, we examined whether the inhibition system can also be triggered by exogenous cues. We primed half of the respondents with the concept of peeing, which we expected to induce an increase in peeing urgency. In line with this reasoning, we found that the peeing prime induced an increase in reported peeing urgency, which subsequently significantly influenced intertemporal patience. Mediation analysis was significant.

Finally, in study 4 we show that increased peeing urgency also impacts performance on a task that strongly relies on inhibition, namely switching abilities in a stroop task (Stroop 1935). When people had to pee relatively more urgently, they could more easily switch between two tasks (word naming versus color naming), indicating that they were relatively better in inhibiting the previously learned behavior (which interferes with the currently required behavior after switching between two tasks).

The results of these four studies provide support for inhibition spill-over effects. With this research, we contribute to recent neurological research suggesting that people possess a general inhibition system (Berkman et al. 2009), by providing behavioral data that suggests in the same direction. This suggests that inhibition spill-over effects are not only of neurological nature, but also show itself in human behavior. Furthermore, this research contributes to the current knowledge about impulse control. We show that increased impulse control can be the unintentional side-effect of increased inhibition in an unrelated domain (e.g., bladder control). We provide evidence for inhibition spill-over effects on an intertemporal choice task which is quite deliberative in nature, but also on a task relying more on automatic responses, namely response times on a stroop task. This suggests that inhibition spill-over is a relatively automatic process. The current research suggests that impulse control does not necessarily rely on an energy consuming resource that can become depleted after previous acts of self-control, but can also be a by-product of inhibitory signals in a completely unrelated domain.

Body Beliefs Shape the Perceived Accuracy of Virtual Models

Ellen Garbarino, University of Sydney, Australia
Jose Antonio Rosa, University of Wyoming, USA

EXTENDED ABSTRACT

Apparel is one of the big success stories of online retailing, with double digit sales growth in recent years (Mui 2007). As competition has intensified, online retailers have begun to rely on product visualization technologies, such as virtual models. While product visualization tools have been shown to enhance the retail experience (Daugherty, Li, and Biocca 2008; Kim and Forsythe 2008), most research ignores the potential for individual differences to influence their effectiveness. In high body-involvement categories, such as apparel, the effectiveness of product visualization may depend on consumers' perceptions and beliefs about their physical body in ways that potentially limit its accuracy and effectiveness.

To explore the influence of body beliefs, we surveyed women consumers to examine how two different body belief systems affect their perception of virtual model accuracy and willingness to use them. We focus on how two distinct types of body beliefs—body image discrepancy (Cash 1994; Cash and Szymanski 1995) and body boundary aberration (Fisher 1986). Body image discrepancy (BID) is a cognitive evaluation of how well the appearance of various aspects of our body (e.g., hair, muscle tone, body proportions, and weight) aligns with our ideals for those body parts (Cash 1994; Cash and Szymanski 1995), weighted for the importance of that aspect. Body boundary aberration (BBA) addresses the individual's sense of the location and stability of the edges of his or her body (Fisher 1970, 1973). The alignment of the body boundary with the skin surface differs between persons. BBA occurs when an individual's sense of the location of that edge does not align with their skin surface (Fisher 1970, 1986). It is possible for our sense of body containment to either move inward from the skin surface or extend beyond it to incorporate immediately adjacent objects. One example of mild BBA is the sense of nakedness and vulnerability when a habitually worn accessory (e.g., hat, bra, watch, or ring) is absent. Another example is the enhanced sense of power when wearing bold colors or tightly-woven dense fabrics (Fisher 1986).

Body image discrepancy should negatively influence perceived virtual model accuracy. High body image discrepancy exists when consumers believe that aspects of their looks do not meet important standards, suggesting a more critical view of the self in the mirror. This same critical eye should be used to assess the accuracy of any representation that purports to serve the same function as a mirror.

Body Boundary Aberration is expected to have a positive influence on the perceived accuracy of virtual models by virtue of the reassurance that comes from seeing a stand-alone representation of the self with unambiguous boundaries. High BBA consumers glean reassurance from seeing their boundaries well-defined, and we expect that a representation of self with well defined edges against a neutral and uniform background will be reassuring to consumers with high BBA.

Perceived model quality captures how effectively the model can represent how the clothing looks and fits. It is expected to positively influence both their perception of how accurately the model can represent them and how likely they would be to use it. Both perceived accuracy and quality are expected to positively influence usage intentions.

Using an online panel, a sample of 978 women consumers was collected. The demographics closely match the U.S. Internet consumer population (ClickZ 2003). The respondents answered questions about their web usage, interest in apparel, online apparel purchase habits and demographics, including height and weight.

Respondents were then shown a virtual model based on their body dimensions. After viewing the model, respondents assessed the quality (3 item $\alpha = .93$) and accuracy (2 items $r = .88$) of the model, and their interest in using such a model in the future (2 items $r = .91$). Finally, they responded to BID and BBA items.

Body image discrepancy (BID) was assessed using the scale developed by Cash and Szymanski (Cash and Szymanski 1995); respondents rate how well they match their ideals on eleven physical characteristics and indicate the importance of each aspect. The 11 items form a single factor ($\alpha = .81$) with higher score indicating higher BID.

Body boundary aberration was assessed using a scale developed by Chapman et al. (Chapman, Chapman, and Raulin 1978), subjects responded to 49 statements with 10 BBA items interspersed. The 10 items form a single factor ($\alpha = .87$), with higher scores signifying higher BBA. The BBA scores are widely distributed; 1-1.99 (highest BBA) = 4%, 2-2.99 = 14%, 3-3.99 = 45%, 4-5 (lowest BBA) = 37%. As expected, the two body beliefs are not highly correlated ($r = .11$).

The structural equation model shows an acceptable level of fit (SRMR of .05, TLI of 0.95, NFI of 0.94, and RMSEA of 0.04) with all of the hypothesized relationships as expected and statistically significant. Virtual model accuracy ($\gamma = .315$, $p < .00$) has a positive influence on consumer intentions to use virtual models. Body Boundary Aberration has a positive influence on virtual model accuracy ($\gamma = .117$, $p < .00$), consistent with the idea that consumers high in BBA consider renditions that highlight the body's edges more accurate. In contrast, Body Image Discrepancy ($\gamma = -.120$, $p = .00$) has a negative influence on assessed virtual model accuracy, suggesting that consumer whose body image differs substantially from their held ideals are less likely to consider virtual models accurate. As expected, quality perceptions have a positive influence on assessed virtual model accuracy ($\gamma = .507$, $p = .00$) and intentions to use models ($\gamma = .486$, $p = .00$). The SEM results affirm our expectations that body beliefs influence consumer assessments of the accuracy of virtual models even after accounting for quality perceptions.

Additional SEM analyses show that the effects of body beliefs on model usage intentions are fully mediated by their influence on perceived accuracy. All alternative models lead to substantial reductions in model fit, supporting that the influence of body beliefs on intentions to use virtual model is mediated by perceived accuracy.

Satisfaction in the Context of Customer Co-Production: A Behavioral Involvement Perspective

David Hunt, University of Wyoming, USA
Stephanie Geiger Oneto, University of Wyoming, USA
Philip Varca, University of Wyoming, USA

EXTENDED ABSTRACT

Customer satisfaction has a decades-long history of research in marketing. Scholarly interest has been sustained by evidence that satisfaction leads to loyalty (Suh and Yi 2006), efficiency of promotional programs (Luo and Homburg 2008), and financial performance (Anderson, Fornell, and Mazvancheryl 2004; Fornell, Mithas, Morgeson, and Krishnan 2006).

Against this backdrop of the established importance of satisfaction, marketing appears to be undergoing a paradigm shift from goods dominant logic to services-dominant logic (S-D Logic: Vargo and Lusch 2008; Vargo and Lusch 2004). That is, marketing scholars and practitioners have shifted their focus from tangible resources, to intangible resources, the co-creation of value, and relationships (Vargo and Lusch 2004). A cornerstone of S-D Logic is the assumption that consumers are integrated in value creation from the initial stages of design through the entire usage life of a product (Lusch, Vargo, and O'Brien 2007).

This development reflects a dramatic shift in researchers' interest in consumer behaviors that occur after a market transaction to consumer behaviors that are wholly integrated throughout production and consumption. This wholly integrated role of consumers likely is not devoid of implications for consumers' evaluations of their experiences with goods. The influence of behaviors on a broad range of experiences is well established (Fishbein and Ajzen 1975). However, despite evidence that behaviors influence attitudes and despite the increasing emphasis on customer value creation, research has not addressed the degree to which behavioral engagement in value creation activities relates to customer satisfaction.

The present study aims to address this gap by examining the extent to which behavioral commitment to value creation is associated with satisfaction with the product. Our study differs from past studies in that we examine how behavioral variables, as opposed to attitudinal variables, relate to customer satisfaction outcomes. Satisfaction studies grounded in an attitudinal perspective are limited in the degree to which they can explain how the behavioral demands of customer value creation relate to satisfaction.

The produce product category reflects a market landscape where some consumers are presented with choices between traditional market channels or less traditional channels that require greater customer co-production. Understanding why consumers pursue and remain within alternative market channels has obvious implications for marketing practice. However, a conceptual framework for understanding these consumer decisions is a necessary prerequisite for developing generalizable practices. We argue here that dissonance theory is an apt framework for examining the co-production effects that occur in non-traditional market channels.

The purpose of this paper is to add to the current research on consumer satisfaction by 1) using CSAs as a context to test Vargo and Lusch's (2004) service dominant logic, 2) offering an initial conceptual frame for understanding consumer satisfaction in this CSA context; 3) developing a framework for further research and practical steps for increasing the market for alternative food channels such as CSAs.

In order to test our theoretical framework, data were collected in three urban areas using a stratified random sample design. Respondents were randomly recruited from zip codes found to have

a high concentration of CSA locations. One-hundred ninety-eight individuals, serving on a panel at a large marketing research firm, completed an online survey. Results showed several significant differences between CSA and non-CSA members. First, CSA users were found to have greater levels of satisfaction with their vegetables than traditional grocery shoppers. Second, CSA members reported more behavioral involvement in food-related activities than traditional supermarket shoppers. Third, the relationship between CSA membership and product satisfaction was found to be mediated by behavioral involvement in food-related activities. Finally, this mediated effect is more robust with time. In other words, continued behavioral involvement increases the likelihood of continued CSA membership and increases in product satisfaction.

Our findings suggest that the relationship between greater customer co-production and greater satisfaction can be explained by a dissonance-reduction framework. The effort demanded from co-production produces dissonance that is reduced by strong feelings of satisfaction with the product. These findings are consistent with the inherent value from co-production suggested by Vargo and Lusch (2004). Lusch, Vargo, and O'Brien (2007) argue that consumers add value to product experiences through both pre-purchase co-production and post-purchase consumption activities. That is, consumers collectively create value through both co-production and value-in-use activities (Merz, He, and Vargo 2009). By demonstrating significant relationships between satisfaction and both commitment to co-production and behavioral involvement in the product category, our study provides empirical support for both types of value-adding activities proposed by service-dominant logic theorists.

The Impact of Emotions on Customers' Perception of Website Atmospheric Cues: An Empirical Cross-Cultural Investigation

Ebrahim Mazaheri, Concordia University, Canada
Marie-Odile Richard, University of Montreal, Canada
Michel Laroche, Concordia University, Canada

EXTENDED ABSTRACT

Eroglu, Machleit and David (2001) categorized the environmental cues into two groups: high- and low-task relevant cues. They defined high-task relevant cues as all the site descriptors on the screen which facilitate the consumer's shopping goal attainment and low-task relevant cues as the ones that are "relatively inconsequential to the completion of the shopping task" (p. 180).

Previous research has studied the importance of site atmospheric cues such as site informativeness and entertainment (e.g. Davis, Wang, Lingridge, 2008; Hausman and Siekpe, 2009; Richard, 2005). It has been suggested that these site atmospheric cues influence customers variables such as website attitudes, involvement, flow, and purchase intentions (Hausman and Siekpe, 2009; Richard and Chandra, 2005). Surprisingly, the impact of emotions is often ignored in customers' evaluation of site atmospheric cues. The purpose of this research is twofold: First, consistent with Zajonc's (1980) theory of emotions we propose that the customers' emotions arise upon the initial Internet experience, which influence other affective and cognitive variables. As a result, we investigated the impacts of emotions on customers' perception of site high-task and low-task relevant atmospheric cues. Then, following the Stimulus-Organism-Response (SOR) framework developed by Mehrabian and Russell (1972) and previous literature, we hypothesize the impacts of customers' perception of site atmospheric cues on other consumer variables such as site attitudes and site involvement, and purchase intention.

Second, the attempt was made to compare the proposed model between two cultures: Chinese and Canadian. Given the wide reach of Internet and the fact that culture does impact the customers' responses to store atmospherics (Davice, Wang, and Lindridge, 2008); it is crucial to explore the role of culture in customers' reactions to the online store atmospherics. Based on Hofstede's (1991) cultural value dimensions, we hypothesized that the impact of high- and low- task relevant cues on customer variables vary across the two cultures.

For testing the hypotheses, 8 service industries were chosen: hotels, online bookstores, dental services, banks, vacation destination, restaurants, financial investments and plastic surgery. We selected four websites four dental services, two sites for online bookstores, four sites for restaurants, two sites for financial investments, four sites for hotels, four sites for plastic surgery, three sites for vacation destinations and two sites for banks. The subjects were randomly assigned to one of the twenty five websites. They were exposed to a real website of a service company and were asked to surf the site and collect information

Data were collected online using a computer lab in a large Northeastern university. After elimination, the data consist of 234 Chinese (54% female and 46% male) and 350 Canadian (58% female and 42% male). The majority of the respondents were undergraduate students (98.3% of Chinese and 98.9% of Canadian) between the age of 18 to 24 (75% of Chinese and 80% of Canadian).

The results of multi-group analyses in EQS strongly supported the overall model. Emotions strongly impacted the customers' perception of high- and low-task relevant cues in both cultures. Customers' perceptions of site atmospheric cues influenced customers' attitudes toward the site and site involvement; which in

turn impacted purchase intentions. Moreover, the result suggested that the impacts of low-task relevant cues on site attitudes and site involvement are stronger for Chinese customers compared to their Canadian counterparts. On the other hand, customers' perceptions of high-task relevant cues on site attitudes and involvement was found to be stronger for Canadian customers compared to their Chinese counterparts.

A Meta-analysis on the Effectiveness of Publicity versus Advertising

Martin Eisend, European University Viadrina, Germany
Franziska Küster-Rohde, Free University Berlin, Germany

EXTENDED ABSTRACT

This study tries to provide an answer to the question whether and when publicity (versus advertising) is more or less effective. For this purpose, we investigate the trade-off between enhanced credibility effects (due to third-party endorsement) and negative effects of recipients' exposure to negative information (due to lack of control over media content by the advertiser) by means of a meta-analysis.

Three models are applied in the literature to explain the effects of publicity versus advertising. The source credibility model shows that highly credible sources are viewed as more trustworthy and generate more attitude change than low-credibility sources. The information processing model assumes that intentional exposure to news and publicity enhances the number of cognitive responses. Publicity, compared to advertising, also lends greater salience to information. Enhanced information processability can produce positive responses towards the message and the product being evaluated. The information evaluation model assumes that publicity in comparison to advertising will not only lead to enhanced processing, it is also likely that the increase is higher for negative than for positive information. Negative information is also more salient. That leads to more thorough processing of negative information than positive information, which directly impacts object evaluation.

The literature search for the meta-analysis covered the period from 1971 (the publication year of a study that is considered the first empirical study on the topic) up to and including 2009. Only studies that investigated the impact of marketing-oriented publicity versus advertising on recipients concerning the following dependent variables were considered: attitude towards message, attitude towards brand, cognitive responses (total, positive, and negative), message processing, purchase/behavioral intention, source credibility, recall, and recognition. This search resulted in 30 independent samples with 257 effect sizes that could be included in the meta-analysis. The effect size metric selected for the analysis is the correlation coefficient; higher values of the coefficient indicate a stronger effect of marketing-oriented publicity over advertising on outcome variables. The meta-analytic integration procedures were performed taking a random-effects perspective. The integration of the correlations uses variance weights in order to consider the varying sample sizes of the studies. Furthermore, measurement errors were corrected by considering reliability coefficients of the dependent and independent variables. Weights for multiple measures were considered as well. Study moderator variables are used as predictors in a regression model in order to explain the heterogeneity of the effect sizes of dependent variables that are based on a sample of at least twenty effect sizes. Furthermore, a structural model analysis was performed. The suggested models include seven variables in total. That is, 28 off-diagonal cells have to be filled in order to produce the input of the correlation matrix for structural equation modeling. Hence, in addition to the results of the effect size integration, the studies were searched for further statistical measures reporting the relationship between the dependent variables.

The meta-analytic results show that marketing-oriented publicity (compared to advertising) has a positive effect on all dependent variables. The structural models show an acceptable fit. All coefficients are significant and indicate the assumed direction in the models. That is, marketing-oriented publicity versus advertising enhances source credibility, total, positive, and negative cognitive responses. Both source credibility and total cognitive responses

enhance attitude towards message, which enhances attitude towards brand. Positive cognitive responses enhance and negative cognitive responses reduce attitude towards brand. Attitude towards brand enhances purchase/behavioral intention. The total effects show that the source credibility path explains most of the variance in the dependent variables brand attitudes and purchase/behavioral intention; the effect is about twice as strong as the effect of the information evaluation model, and about five times as strong as the total effect of the information processing model. The moderator model showed that the effect of publicity versus advertising on positive cognitions and on source credibility decreases significantly for known versus unknown products. If we replace the coefficients in the model with the coefficients for the subgroups of known versus unknown products the results indicate a moderator effect. For unknown products, the total effects become stronger. For known products, however, the total effects become negative with the negativity effect increasing and the source credibility effect even reversing due to a superior effect of advertising over marketing-oriented publicity.

The results of the meta-analysis support the effect of publicity over advertising that is due to a source credibility effect, an information processing effect, and an information evaluation effect. While the last effect is an overall negative effect, both other paths show a positive effect, with the source credibility effect being about twice as strong as the negative effect due to evaluation of negative information. The results show that the trade-off between credibility and control is in favor of the credibility of the source. This effect is moderated by prior product knowledge, though. The described relationship holds and even becomes stronger for unknown products. However, the effect changes for known products where the total effect of the source on dependent variables becomes even negative. These results show that marketing-oriented publicity versus advertising is superior for products where consumers lack prior knowledge. Indeed, most studies that have investigated and supported the positive effects of media coverage refer to product innovations, product pre-announcements, or products with which most consumers are not yet familiar. The meta-analytic results further contribute to the research on the negativity effect as triggered by publicity, because they support this effect but also show that an overall evaluation of publicity effects needs to take different effect paths into account in order to produce an overall effect on consumers. By introducing prior knowledge as an important moderator for the negativity effect, the findings show that the negativity effect can be outweighed by a positive source credibility effect in case consumers do not yet know a product.

Bounded Defensive: Advertising Deception, Deception Knowledge, and Meta-cognitive Expectancies

Guang-Xin Xie, University of Massachusetts Boston, U.S.A.

David M. Boush, University of Oregon, U.S.A.

Courtney N. Boerstler, University of Oregon, U.S.A.

EXTENDED ABSTRACT

Advertisers often emphasize positive product attributes and promise superior value. When consumers' experience falls short of expectations, the perceived discrepancies are often ascribed to advertising deception (Russo et al. 1981). Using the framework of the Persuasion Knowledge Model (Friestad and Wright 1994), we propose that consumers' deception knowledge and meta-cognitive expectancies influence their attitudes toward ads and brands in two ways: while the expected seriousness of the consequences of being misled aggravates the negative effect of deception, the optimistic tendency to trust the claims attenuates this effect.

Experiment 1

Experiment 1 employed a 2 (deception knowledge: more salient vs. less salient, between) x 2 (high- vs. low-stake, between) x 2 (high- vs. low-deceptiveness ads, within) mixed design. Participants (N=133) were asked to carefully evaluate six print advertisements (pre-tested) presented on PC screens. For each ad, they were asked to identify the brand name first, and then answered attitudinal questions on 9-point scales. Deception knowledge salience was manipulated by the priming instructions at the beginning of the questionnaire. The one-page instructions described the nature of deception knowledge, common deceptive tactics, and cues to detect advertising deception. Participants in the control condition were not primed. The seriousness of expected consequences and deceptiveness were manipulated by having the participants view different types of print ads. In the high-stake condition (more serious consequences), the participants rated six ads: three were high in deceptiveness and three were low in deceptiveness (within-group). This was repeated in the low-stake condition (less serious consequences).

Participants in the primed condition ($M=5.17$) rated the ads as more deceptive than those in the unprimed condition ($M=4.61$), $F(1, 130)=4.23, p=.032$. The interaction between manipulated deceptiveness and deception knowledge salience was not significant, $F(1, 130)=.38, p=.35$. But the deceptiveness had a significant negative impact on attitude toward the ads: the attitude ($M=3.35$) was more negative toward high-deceptiveness ads than low-deceptiveness ads ($M=4.62$), $F(1, 128)=75.22, p<.001$. The interaction between deceptiveness and high- vs. low-stake situation was significant: the negative attitude ($M=2.84$) was significantly stronger toward the deceptive than non-deceptive ads ($M=4.83$) in the high-stake condition, $F(1, 130)=38.93, p<.001$. In the low-stake condition, however, attitude toward deceptive ads ($M=4.60$) was not significantly different from non-deceptive ads ($M=4.64$), $F(1, 130)=.02, p=.89$.

Experiment 2

The purpose of Experiment 2 (N=176) is to examine the effect of optimistic expectancy and need for cognition in relation to the outcome expectancy of deception. We followed the same procedure as that in Experiment 1. In addition, the optimistic expectancy scale was asked for each advertisement, and participants also completed the Need for Cognition (NFC) scale (Cacioppo et al. 1984) at the end. Structural equation modeling was used to test mediation/moderation effects following the methods suggested by Judd et al. (2001). In the best-fit model, the expected seriousness of consequences moderated the effect of advertising deceptiveness

on attitude toward ads. The moderation effects of all other exogenous variables were not significant at $p < .05$. In comparison, the attitude differences toward brands differed significantly across the average, the difference of optimistic expectancy in high- and low-deceptiveness ads conditions, as well as the individual difference in NFC. The proposed moderation effect was found in the attitude towards the brands, but not in the attitude toward advertisements.

The results suggest that optimistic expectancy can function as both a moderator and mediator of the attitude difference toward brands between high- and low-deceptiveness ads. The advertised claims (deceptive or not) may have caused more optimistic expectancy, which in turn, leads to less negative attitude toward the advertised brands.

Discussion

In two experiments, we demonstrate that consumer deception knowledge and expectancies may not only undermine advertising effectiveness as widely acknowledged, but also regulate the effect of deceptiveness in favor of the advertised brands. The salience of deception tactics schema can significantly increase the perceived deceptiveness of ads but the salience does not necessarily lead to more negative attitude toward the ads. More interestingly, the optimistic expectancy can be both a moderator and mediator for the negative effect of advertising deception on attitude toward the brands. A possible explanation is that the optimistic expectancy serves two functions. The mediation effect occurs because expectancy is a significant motivating factor in favor of the brands (but not the ads). In comparison, the moderation effect occurs as a result of individual difference in the extent to which consumers would like to think positively about the brands. Even when the advertised claims are perceived more deceptive, those with more optimistic expectancy would have less negative attitude toward the brands.

Match-Up Effects Happen for a Reason: The Impact of Activating Persuasion Knowledge on Endorser Effectiveness

Leen Adams, Hogeschool-Universiteit Brussel, Belgium
Maggie Geuens, Ghent University, Belgium
Tina Tessitore, Ghent University, Belgium

EXTENDED ABSTRACT

An experiment was set up to clarify the when and why of endorser effectiveness. We found that match-up effects are more likely in case of high than low activation of persuasion knowledge (advertising vs. product placement) due to differences in perceptions of fit. The depth of processing did not contribute...

The use of endorsers is a common ad tactic. Research on endorser effectiveness has put forward the match-up hypothesis which states that the message conveyed by the image of the endorser and of the product should converge (Kahle and Homer 1985). However, the results of empirical studies testing this hypothesis are inconclusive. Therefore, researchers started to investigate moderators.

For example, Kang and Herr (2006) recently showed that the depth of processing and/or the sensitivity to source biases moderate the impact of endorsers on persuasion. More specifically, in case of heuristic processing and/or in case of low sensitivity to source biases, endorsers merely serve as cues, whereas in case of in-depth processing and/or in case of high sensitivity to source biases, the link between the source and the product becomes important and match-up effects on persuasion arise.

Although prior studies already tested moderators related to the depth and the type of processing, they did not examine the relative weight of each antecedent in the formation of match-up effects yet. The contribution the current research would like to make is to integrate the different prior perspectives and further clarify the conditions in which match-up effects can be expected and why in particular.

Therefore, we turn to the Persuasion Knowledge Model (PKM) of Friestad and Wright (1994). Research built on the PKM shows that the depth of processing only explains skeptical responses to persuasion to the extent that it also leads to a more intense activation of PK (Campbell and Kirmani 2000). Based hereupon, we predict that the activation of PK, rather than the mere depth of processing, drives the perception of the level of product-endorser fit, and as such, determines the persuasiveness of product-endorser combinations used in marketing campaigns.

Additionally, we also look into the role of specific perceptions of tactic appropriateness next to the more general perceptions of persuasive intent (i.e., activation of PK), as the results of Kang and Herr (2006) also indicate that a product-endorser match generally leads to highly favorable attitudes, even after an endorser bias is primed. This is counter-intuitive given the assumption that the activation of PK leads to resistance to persuasion and thus, to unfavorable responses (Campbell and Kirmani 2000). However, concerning the latter, Wei, Fischer, and Main (2008) showed that the activation of PK only had a strong negative impact on evaluations when respondents perceived the stimulus to be inappropriate. So, perceptions of tactic appropriateness also seem to determine consumer responses to persuasion attempts.

Therefore, we set up an experiment with a 2 (level of product-endorser fit: non-fit vs. fit) x 2 (level of PK activation: high vs. low) x 2 (depth of processing: high vs. low) between-subjects design in the context of promoting foods as healthy by means of healthy-looking endorsers. We also measured perceived product-endorser fit and perceived appropriateness of the persuasion attempt to test whether they mediate match-up effects on persuasion.

To investigate the impact of depth of processing, we implemented a distraction task (Williams, Fitzsimons, and Block 2004). To manipulate the level of PK activation, we used TV ads versus product placements (Balasubramanian, Karrh, and Patwardhan 2006). Within these formats, real-life stimuli showing either congruent (i.e., healthy model and healthy food) or incongruent product-endorser (i.e., healthy model and unhealthy food) combinations were sought. To prevent confounds, we set out standards for content and execution style and selected several (i.e., four) stimuli per condition (Jackson, O'Keefe, and Jacobs 1988). An online pretest with our target group (i.e., female respondents between 18 and 26 years old) showed that the selected stimuli contained the intended level of product-endorser fit.

In the main experiment, run in a lab, 252 young females participated. In two seemingly independent studies, we first randomly exposed them to one of the 16 stimuli, whether or not accompanied by the distraction task, and then asked stimulus related questions (attitudes and attention). A second study with filler and target questions concerning product considerations and purchase intentions followed. Finally, we incorporated questions about mediators, manipulation checks and covariates.

As predicted, we found that in a clear persuasive context, the difference between a product-endorser fit and a non-fit was clearly perceived, which led to a significantly more favorable attitude towards the congruent versus the incongruent stimulus and towards the accompanying endorser. Moreover, the congruent combinations were perceived to be more appropriate than the incongruent ones, also partially explaining the match-up effects. In a context in which the persuasive intent was less obvious, there was no significant difference in perception of product-endorser fit. As a result, no match-up effects were found.

As such, we demonstrated the usefulness of the PKM for the endorsement domain (Friestad and Wright 1994). Based on this model, we were able to clarify the type of processing that leads to the perception of a match versus a mismatch between products and endorsers, and as such, extend prior research (Kang and Herr 2006). Further research could study whether the perception of product-endorser fit and the perceived appropriateness of a product-endorser combination are independent concepts and examine their relative contribution.

Despite the contributions of this study, we did not find the same results on product related responses as on ad related responses. However, prior research has encountered the same issue (Till and Busler 2000). Explanations could be found in the differences between these dependent measures, as, for example, they tend to result from a different type of processing (i.e., rational vs. emotional, conscious vs. unconscious).

The current study also suffers from the limitation that we used ads versus product placements to manipulate PK activation. We controlled for several potential confounds (e.g., type of creative strategy: transformational and positive), but from a theoretical point of view, this was not the cleanest manipulation. Further research could, therefore, manipulate PK activation in a more conservative way. However, using several real-life stimuli has the advantage that they enhance the external validity of the results.

Mere Proactivity Effects of Sales-related Service Offerings: A Field Experiment

Walter Herzog, WHU-Otto Beisheim School of Management, Germany
Mike Hammerschmidt, University of Mannheim, Germany

EXTENDED ABSTRACT

Excellent post-sales services are considered to be an effective strategy for stimulating customer loyalty. However, as relationships evolve, customers' repurchase intentions become increasingly salient making so-called pre-sales services for existing customers an important feature of relationship marketing. For example, a car dealer might offer the opportunity to test drive a new car in temporal proximity to a prospective repurchase decision (Bhattacharya and Bolton 2000). To the best of our knowledge, pre-sales services have been the subject of scientific inquiry only in the context of customer acquisition but not in the context of relationship marketing. Pre-sales services like product trials can either be provided reactively, i.e. in response to customer requests, or they can be provided proactively, i.e., the firm takes the initiative to contact customers and offer the product trial (Challagalla, Venkatesh, and Kohli 2009). Despite the enormous relevance of pre-sales services in the repurchase phase of a customer's buying process, it is not clear if suppliers should really offer these services proactively or remain with their traditional reactive strategy. In the present paper, we answer this question for product trials by existing customers.

At first glance, a positive effect of a proactive strategy could be fully attributed to the fact that some customers (so-called "compliers") are encouraged to test the product, which in turn enhances their loyalty. This argument implies that the effect of proactively offering a product trial on customer loyalty is completely mediated by the customer's increased probability to experience the product (Jo 2008). However, we propose that this argument neglects that "the mere act of a supplier proactively reaching out to customers" (Challagalla et al. 2009, 73) produces psychological and behavioral effects above and beyond the effects of using the service (product trial). More specifically, we argue that there are two mere proactivity effects: First, a proactive strategy results in a significant proportion of customers rejecting the offer as they do not have interest in a product trial (so-called "never-takers"). We argue that never-takers, who do not test the product independent of any company activities, are likely to perceive the offer as an intrusive tactic which undermines their loyalty (Deci, Koestner, and Ryan 1999). Second, there are customers trying the product independent of the company's strategy ("always-takers"). We assume that always-takers, due to their intrinsic interest in the product, are likely to perceive a firm proactively and voluntarily offering product trials as likeable and empathic (Palmatier et al. 2009), which should increase their loyalty.

Our hypotheses are tested by means of a large-scale field experiment with more than 3000 customers of a car manufacturer. The experiment consisted in proactively offering a test drive to a randomized set of customers by means of a personalized invitation by their respective car dealers (proactive condition) and withholding the offer from the remaining customers (reactive condition), i.e. the latter group could conduct a self-initiated test drive under the very same conditions. Our analysis combines experimental, psychometric, and behavioral data. We used the principal stratification approach (based on Rubin's Causal Model) to estimate the effect of proactive strategy on repurchase behavior via relationship satisfaction with the car dealer and brand loyalty for the three latent customer classes or "principal strata": compliers, always-takers, and never takers (Jo and Muthén 2001; Frangakis and Rubin 2002). The identification of principal stratification models requires the inclusion of covariates predicting class membership (Mealli and Rubin 2002). In this study, we consider perceived value of test-driving, perceived importance

of the brand, age, gender, price of the current car, and number of purchased cars of the brand.

For compliers we find that a proactive product trial strategy initiated by the dealer directly boosts brand loyalty-creating a direct upstream spillover to the aggregated manufacturer level-and indirectly enhances brand loyalty via increasing dealer satisfaction, i.e. creating an indirect upstream spillover. The increased brand loyalty in turn enhances repurchase probability. Therefore, at a first glance, the predominant goal of dealers' proactive strategies could be to encourage customers to use a service (product trial) that they would otherwise not use. However, this focus neglects the fact that compliers only account for a very small proportion of the customer base and hence exclusively targeting this group hinders the deployment of economies of scale. Moreover, it neglects that-against intuition-significant effects can also occur for customers whose service usage decision is independent from dealers' actions (always-takers and never takers).

In support of our hypotheses, we not only find significant proactivity effects for compliers but also for always-takers and never takers, i.e. we find *mere* proactivity effects. Specifically, we find that for never-takers and always-takers satisfaction with the dealer fully mediates the proactivity-brand loyalty link, i.e. we only observe indirect upstream spillovers. With respect to always-takers, by providing proactive offers the dealer can not only enhance customer evaluations for the own business but indirectly facilitates the generation of favourable manufacturer-related evaluations although the manufacturer does neither provide nor control the proactive offerings. For the never-takers, we find that the frustration following a proactive (i.e. intrusive) action is not only targeted to the dealer but subsequently also to the brand.

It has to be noted that the observed positive dealer- and brand-related effects for the always-takers are exclusively caused by proactively offering a service that is used anyway by the consumer, i.e. it is the incremental effect of mere proactivity beyond and above the effect of using the offered test drive. At the other hand, the negative response of never takers to a proactive strategy (negative mere proactivity effect) is exclusively caused by the unsolicited offer of a service that they would never use.

Conflicting Selves and the Role of Possessions: Exploring Transgenders' Self-Identity Conflict

Ayalla Ruvio, Temple University, USA
Russell Belk, York University, Canada

EXTENDED ABSTRACT

While the notion of possessions as an extension of the self has received extensive research attention (e.g. Belk 1988; Hirschman and Labarbera 1990), most of the literature has focused on possessions as reflecting a holistic self or specific aspects of the self (e.g., uniqueness). However, according to Erikson (1956), conflicts between different aspects of their self-identity are experienced by all individuals throughout their lifetime. Though some argue that possessions play an important role in cases of self-conflict (Csikszentmihalyi and Rochberg-Halton 1981), there have been very few studies on this subject. Taking a qualitative approach, this study seeks to understand the role possessions play in the formation, development, coping and resolution of the conflict between different selves using an extreme example of gender identity conflict--transgendersim.

Since gender is one of the most defining characteristics of the self (Gagne, Tewksbury and McGaughey 1997; Rudacille 2006), incongruency between gender identity and one's genital configuration leads to a gender identity conflict. The establishment of gender identity occurs during early childhood, becomes an internalized aspect of one's self and is virtually immutable. Transgender people experience a gender identity conflict which compels them to develop an alternative gender identity and enact a gender presentation that does not coincide with their sex (Gagne et al. 1997). In this study, using grounded theory analysis and interpretation of five in-depth, unstructured interviews with male-to-female transgenders, we explore the way transgenders utilize material possessions in negotiating their gender conflict. We assert that insights gathered from these extreme cases of self-conflict can educate us about more common or usual behaviors (Katz 1998).

The formation of an alternative gender identity requires transgenders to cross over either temporarily or permanently from one sex/gender category to another (Gagne et al. 1997; Lev 2004). In Western society, dominated by the binary perceptions of gender, the act of crossing over challenges the cultural and structural social order, exposing the person to social sanctions. Several multiple stage developmental models have been used to describe this process, building on Erikson's (1956) social development theory.

Our findings are consistent with Gagne et al.'s (1997) integrative model. In its first stage, *conflict emergence*, our informants experienced transgendered feelings, but have not labeled them as such. This stage occurs during childhood, and our informants reported feeling that something was wrong with them (Bocking and Coleman 2007; Katz 1998). The gendered meaning of possessions (such as clothing and toys) raised their feelings to the level of conscious awareness. Possessions also defined the boundaries of socially accepted behaviors. While using possessions the "wrong way" (e.g., a boy wearing a skirt) resulted in acts of correction or punishment from others in an attempt to address the "problem", at the same time they allowed the informants to engage in initial cross-gender socialization.

Identity exploration, the second stage, involved an extensive information search in an effort to label the source of the conflict as well as reach out to similar others. Our informants reported building a parallel world that enabled them to practice the performance of their new identity. Possessions (e.g., a secret cosmetics box) helped them segregate their conflicting identities, and thus, minimize and control their conflict.

In the third stage, *coming out to one's self*, our informants coped with and internalized the meaning of their new transgender

identity ("this is who I am"). Possessions played different roles in the variety of coping strategies utilized (Lazarus and Folkman 1984) such as denial (dressing like their original sex), acceptance (dressing according to their alternative gender identity), and self-control (keeping their alternative gendered possessions private). However, in order to resolve the conflict, transgenders had to accept and build their alternative gender identity and develop its public presentation ("to pass").

In the fourth stage, *coming out to others*, the participants disclosed their transgender identity to significant others (spouses, family, friends), and often experienced rejection as a result (Lev 2004). Passing in this stage was not enough for them as they felt the need to present a convincing public image of cross-gender identity. As part of the new self, possessions were presented as embedded in the new gender identity.

Striving to find their "true" identity, most of our informants reached the final stage of *conflict resolution*. They explored various identities in an attempt to achieve a coherent identity in which transgenderism was only a part. Decisions regarding to what extent to cross over (e.g., have full surgery, just take hormones, etc.) were made in order to finalize their private and public identity. Possessions were no longer perceived as a means to project gender identity but as a means to express a new congruent self-identity.

Our study can be viewed in the context of the over arching theory of the extended self. The findings indicate that a person's process of dealing with self-conflict is reflected in the use of possessions. As the conflict evolves, the role of possessions changes. They surface the conflict to the level of consciousness, are part of the coping process, and reflect the conflict's resolution and the eventual formation of a new self-identity. We posit that our findings can be generalized to many other self-conflicts such as those involving athleticism, overt sexiness, and class affiliation, thereby contributing to the literatures on transgenders and the extended self.

Conflicting Imperatives of Modesty and Vanity Among Young Women In The Arabian Gulf

Rana Sobh, Qatar University, Qatar

Russell Belk, York University, Canada

Justin Gressel, University of Texas-Pan American, USA

EXTENDED ABSTRACT

Muslim women's clothing is a visible form of public consumption, and has been the subject of much debate within social science literatures. A large body of work has looked at the diverse meanings and connotations of the Muslim veil and the practice of *hijab* (observing Muslim women's dress code) in many Muslim countries including Egypt (e.g., El-Guindi, 1999b), Turkey (Sandikci and Ger, 2007; Secor, 2002; Gole, 2002), Mali (Shultz, 2007), Cote D'Ivoire (leBlanc, 2000), Indonesia (Jones 2003), South India (Oseall and Osealla, 2007), and London (Tarlo, 2007b). However, the black abaya within oil-rich Gulf countries is embedded in a different contemporary local context and is increasingly associated with status and wealth (Abaza, 2007). Young Muslim women's dress in the Gulf States of Qatar and United Arab Emirates (UAE) is both emotionally and politically charged.

The Gulf States are unique for several reasons: 1) There is a distinct and strong ethos of traditional dress for both men and women, 2) There is an omnipresent awareness of Islam and religious values in shaping identities and informing behavior, 3) There has been a rapid increase in wealth due to petrodollars, and 4) There is a dramatic presence of foreigners from both Western and Non-Western cultures, such only around 17% of Qatar residents are Qataris and 16% of Emirates residents are Emirati. The latter conditions create a situation unique in the immigration literature in which there is pressure for the locals to acculturate to the immigrant rather than the more normal reverse situation. Locals increasingly fear the dissolution of their ethnic identity and therefore strive to emphasize their authenticity and ethnic affiliation distinction through wearing ethnic dress but also through other consumption styles such as extravagant conspicuous and luxurious consumption that foreigners in general cannot afford. Furthermore, the main acculturative agent in our context is not the dominant host culture as opposed to the minority or immigrant culture, but rather the forces of globalization and more specifically transnational Western consumer culture and its underpinning ideology that fundamentally conflicts with the local religious and patriarchal principles. Hence, new clothing styles and adornment practices are increasingly adopted by young women in the region and reflect the conflicting forces of Western values that emphasize display of women's beauty and sexuality in the public sphere and traditional values requiring modesty and promoting a virtuous public domain. The abaya itself has been gradually reinvented and has evolved from being a concealing garment that hides women's sexuality and beauty in public to an embellished fashionable, trendy haute couture garment that enhances beauty and reveals sexuality, all supposedly without undermining the local look. We propose to understand the dynamics underlying conflicting imperatives of modesty and vanity and to probe the ambivalence inherent in such performative constructions of identity and conceptions of the self as well as explore how young women negotiate and reconcile resulting tensions.

In-depth interviews were conducted with twenty four middle class university students in business from Qatar University (12) and American University of Sharjah (12). The informants ranged in age from 17 to 22. In addition to interviews, all researchers used observations of clothing and adornment practices in public places by young women (e.g., university, malls, restaurants) and the female

researcher observed clothing and adornment practices in private spaces as well (homes, social gatherings, fashion shows, weddings and other women's parties). Projective techniques were used and consisted of showing participants a set of stimulus pictures of girls wearing different types of abayas and using adornment practices across the spectrum from vain to modest.

Our findings reveal that young women resolve conflicting tensions between the conflicting imperatives of the transnational consumer ideology and traditional local values through a number of appropriation and adaptation processes. Informants construct idiographic meanings of prevalent religious, cultural and fashion discourses informed by the two conflicting ideologies. They negotiate dominant values in the Western ideology, adopting and adapting some while resisting and rejecting others. They appropriate global fashion trends to create local glamorous fashion trends and symbolically charged clothing practices that give them a sense of uniqueness and superiority over expatriates and foreigners. In effect they out-global the global consumer culture representatives, at least in some respects. Young women also enact Western style identities in uncontrolled spaces and settings such as in women-only gatherings and gender segregated spaces where tensions between the traditional and modern and the modest and vain are alleviated.

While accepting and acknowledging the local value systems, they manipulate and reinterpret some of the meanings to justify their clothing practices and condemn those of others. Regardless of their degree of religiosity, Islam was used by all informants to justify their clothing practices whether vain, modest or somewhere between the two extremes. Informants negotiate their need for beauty display in public within the Islamic discourses of beauty and the legitimacy of good self-presentation and enjoyment of life.

Besides, young women seem to reconcile opposing pressures by injecting Western symbols such as designer names and fashion trends and patterns into traditional garments in order to rejuvenate and bestow modernity on them. This reinvention of tradition gives them a feeling of connection with the youth consumer culture and engagement in the world of fashion while still maintaining connections to local traditions that they are proud of. The purpose of wearing the abaya is also manipulated to be more aligned with Western ideologies and beauty discourses. Ironically, the abaya is interpreted by locals as a camouflage garment that makes them look taller and thinner, hence enhancing their beauty and hiding their body imperfections, tendencies which are in accordance with Western fashion discourses. Playing with meanings and altering the original uses and meanings of the abaya can be interpreted as unintentional resistance (Ger and Belk 1996) of the local hegemony emphasizing social conformity and as an affirmation of young women's power in managing their appearances and enacting their identities in public. Following Blumer (1969), the abaya fashion seems to help young women mediate cultural contradictions they are subject to in some Arab Gulf countries and to adjust in a disciplined and orderly way to their fast moving society to help cope with the major social changes their countries have been undergoing as a result of globalization.

Mixed Origins, Diverse Preferences: Consumption Compromises in Contemporary Homes

Samantha N. N. Cross, Iowa State University, USA

Mary C. Gilly, University of California, Irvine, USA

EXTENDED ABSTRACT

This research examines everyday food consumption relationships and compromises in contemporary bi-national and mono-national homes. In this study, a bi-national household consists of spouses from differing countries of origin (e.g., China and the U.S.), whereas a mono-national household has partners from the same country of origin. Building on the studies and methodological approaches of Fournier (1998) and Coupland (2005), this study seeks to further our understanding, as researchers and consumers, of the significance of food purchases and food consumption patterns in bi-national homes. To better understand food consumption practices in the home, this research uses a combination of interviews, observation and photographic documentation to take a deeper look at the contents of consumers' food storage areas. The following research questions are asked: 1) How are consumption compromises manifested in bi-national and mono-national families in the context of everyday food consumption? 2) What symbolic role does food play in the formation and maintenance of the individual and collective identities within the bi-national family unit?

The findings suggest that everyday food purchases and consumption behavior in participant families can be indicators of relative influence and negotiation in the household. Food is a key cultural expression (Alba 1990, Mintz and Du Bois 2002, Peñaloza 1994) and offers an opportunity to examine household consumption in a new context: bi-national families. Aspects of Miller's (1998) theory of shopping as essentially about sacrifice, and ultimately about relationships, are seen to be applicable when examining the trade-offs that take place between spouses in the participating households, with differing implications for consumption compromises, depending on the type of household.

We find that compromise happens not at the individual purchase level as the family decision making literature assumes, but over time and in response to other decisions. When cultures interact within the confines of the family, consumption decisions take on meaning beyond simply what is purchased and why. There is a blending process taking place in bi-national families, as well as an alternative type of juggling—juggling of consumption preferences based on cultural differences. The usual compromises spouses face are amplified when one spouse is an immigrant to the native spouse's homeland. Household member preferences are seen to be very specific, yet there are a host of constraints to satisfying those preferences, both internal and external to the household. The specificity of the preferences and the impact of the constraints vary depending on the type of household. In bi-national families, there seem to be greater constraints on preferred consumption, but there is also considerable effort expended to mitigate those constraints. The limited accessibility to immigrants' food choices results in greater shopping effort and stockpiling, with the native spouse also seeking out opportunities for the immigrant spouse to connect to their country of origin through food.

For members of bi-national homes, especially for immigrant household members, preferred food items were more than just sustenance or even desired treats, but links to home, identity and a vital aspect of maintaining access to both cultures within the family unit. Substitutability of preferred products was not a desired option or even a considered option at all. Stockpiling in these homes is based not just on price and bulk (Mela et al. 1998, Wansink and Deshpande 1994), but also on availability of the preferred items for the immigrant spouse. Food consumption is shown to be a

manifestation of negotiated influence and compromise between the immigrant and native spouses, with the bi-national family unit providing a unique setting for harmony, resourcefulness, ingenuity and ultimately enhanced food consumption experiences.

Implications are drawn for the family decision making literature and consumer/brand relationships. Conflict and negotiated compromise are seen to be manifested not through major purchase decisions, but through everyday food consumption decisions. The analysis demonstrates that while there are clear similarities between mono-national and bi-national households, there are also key differences in everyday consumption experiences. This research highlights the importance of considering household characteristics and cultural diversity within the home as key factors in better understanding family decision making and consumption.

This study also augments the findings of researchers such as Fournier (1998) and Coupland (2005), by showing that partners who were born and raised in different countries, and even in different regions within the U.S., expend maximum effort to satisfy their specific consumption preferences. Participants expressed aversion to substitution, an aversion often intensified after a less than positive substitution experience. In several cases brand preferences seemed to be strengthened after substitution and then substitution at the same brand or preference level was no longer an option. These findings have implications for brand relationships when there's limited accessibility and advocate future research on the effect of accessibility and substitution on brand preference and loyalty.

The findings also emphasize the paradox within the home to build the collective unit versus the effort to retain the individual identities of the spouses. Compromise in food consumption choices and offerings is both a means of achieving harmony and a manifestation of respect for what each culture has to offer. The bi-national family is an aggregate entity, but an entity with a role and requirements that transcend those of the family members of which it is composed. Individual preferences are both encouraged and contained, as the bi-national household as a unit accommodates, unifies and eventually develops into a distinct entity that is greater than the sum of its founding partners.

Globalization Tug-of-War: Consumption as a Site of Conflict

Aliakbar Jafari, University of Strathclyde, UK

Christina Goulding, Wolverhampton Business School, UK

EXTENDED ABSTRACT

Over the past two decades, consumer researchers have taken timely steps in uncovering the complexities associated with globalization and their findings have delicately supported some of the key debates on the globalization of consumption culture; that is, 'consumptionscapes' (Ger and Belk 1996) and the proliferation of identities via the commodification of consumer goods (Friedman 1994). Based on their key contributions, the existing seminal studies could fall within at least three thematic categories: 1) addressing Wilk's (1995) notion of 'global structures of common difference' (Askegaard and Kjeldgaard 2002; Kjeldgaard and Askegaard 2006) 2) addressing Robertson's (1992) proposed concept of 'glocalization' (Kjeldgaard and Ostberg 2007) 3) addressing consumers' 'identity salience' (Kjeldgaard 2009; Sandikci and Ger 2002; Thompson and Arsel 2004; Russell and Russell 2006).

These studies have genuinely enriched the consumption culture literature on globalization; yet, they focus mainly on Western or, at least, secular contexts in which consumers are viewed as emancipated individuals whose 'liberatory consumption' choices (Firat and Venkatesh 1995) provide them with a broad array of opportunities to exploit a choice of lifestyles. None of these studies has investigated consumers' interactions with globalization in a non-secular society, widely disciplined according to a set of non-secular socio-cultural and political ideologies. Moreover, these investigations have generally examined the *contents* and *consequences* of globalization. That is, they have analyzed either the ways by which consumers use the global *contents* (market resources) to create meanings (i.e., identities) or the ways these people react to the *manifestations* of globalization (e.g., brandscapes and global styles). Therefore, the processes in which "tensions between local and global meanings systems and institutions" (Arnould and Thompson 2007, 12) occur have been considerably overlooked in consumer research. It is these traits that underpin our study as we analyze the *mechanisms* of the global-local interactions.

We present an analysis of 'cultural globalization' (Appadurai 1990; Ger and Belk 1996) in order to examine consumption practices and lifestyle choices of young adult individuals in Iran, a society in which globalization is highly contested and problematic. In so doing, we analyze the *processes* in which the consolidating forces of the local socio-cultural and political context clash with the dynamics of cultural globalization and tackle individuals' 'self-actualization' projects (Giddens 1991). Iran offers an interesting context to study such issues because reposed on theories of cultural imperialism (Mattelart 1994), globalization is populistically demonized as an invasive project of neo-colonialism (Czinkota and Ronkainen 2001).

Given the paucity of research in Iran, the complexities associated with the sensitivity of the topic and political situation of the country, we embarked on an inductive theory building process using in-depth interviews, participatory observation and memo writing. Following Glaser and Strauss (1967), we analyzed our data (collected from Tehran and Karaj over a period of six months) through a systematic process of constant comparison.

Our findings indicate that through its influx, cultural globalization has produced a strong basis of 'knowledge' (Kim 2005) for Iranian youth. It has generated an excess of 'signs', 'images', 'meanings', 'lifestyles', and 'identities' (Nijman 1999; Friedman 1994) whereby reflexivity, as a way of 'self-analysis' and 'self-confrontation' (Beck 1994) is fostered. We theorize this reflexivity as

a 'virtual intercultural learning' process and present two conceptual models to demonstrate how in 'confrontation with other cultures' (Ger 1998), young Iranians compare and contrast themselves with other people around the world. Reading consumer practices against the socio-cultural and political background of Iran, we discuss that this kind of reflexivity becomes extremely problematic in society. Reflexivity, as Archer (2007) states, depends on a 'subject-object' relationship. That is, whilst the subjects (agents) aspire to shape their lives based on their own tastes and needs, their life-design projects depend on the "objectivity of their social circumstances which, through their own descriptions, will encourage them to follow one course of action rather than another" (Archer 2007, 34). The examination of such interplay between social structure and agency (Giddens 1994) suggests that these individuals' critical vision is rejected in Iran. Whilst these young people seek to subjectively define their own intended lives based on a large number of sources (offered to them by cultural globalization), the objectivity of their socio-cultural context acts as a deterring force. Although such restraints are also rooted in the society's mindset (concatenated with history and tradition), they are strongly related to the grand narratives of the state that forces them to believe that their culture is unrivalled. We acknowledge the fact that such ideology (exaggeration of identity) is not an exclusive characteristic of Iranian society as it is indicative of an 'imagined community' (Anderson 1983). Yet, what becomes paradoxical in this case is the obvious opposition of this mentality with the solid teachings of Islam explicitly stated in the Holy Koran.

Scrutinizing our informants' consumption practices in the context of a political/ideological Islam, we argue that quite contrary to common belief (i.e., globalization threatens Islamic values), Islam itself fuels globalization as it essentially deems 'self-reflexivity' a progressive human practice. Also, reflecting on Islam as a 'discursive tradition' (Wong 2007), we discuss that unlike other Islamic societies (e.g., Turkey and Malaysia) where political secularity has provided a relatively tolerant state-citizen relationship, the state's political ideology of Islam in Iran has resulted in discrepancies between the state's objective structure and the citizens' subjective agencies. Consequently, consumption has become a problematic site of socio-cultural conflict; one in which consumers' very personal life practices are extensively affected by the state's omnipresent social policies. Therefore, the real clash happens to be not merely between the local and global institutions, but between the local and local systems of meanings because globalization only acts as a catalyst. Based on our findings, we propose our conceptual models as useful analytical tools to systematically investigate consumers' multiple interactions with global and local dynamics in other societies as well.

Negotiating the Boundary between the Self and the Other: Individuation and Association through Socially-visible Brand Use

Heather Schulz, University of Texas at Austin, USA

Patricia Stout, University of Texas at Austin, USA

EXTENDED ABSTRACT

Recent research in consumer culture theory has focused on the role of the brand as an instrument in the interpretation of social interactions. In this paper, we expand this stream of research by examining how consumers use socially-visible brands to create and communicate their identity. Here we define a socially-visible brand as a brand located on or near an individual's body that is visible to another individual in the public atmosphere. Socially-visible brand use is centered on the everyday and even mundane brands all consumers use during their daily routines. It is argued that socially-visible brands are a strategic tool consumers can use for impression management. Socially-visible brands offer identity cues to others about one's self-concept, but they also assist in the bonding relationships one has with others. Overall, socially-visible brands serve in the identity negotiation process between an individual and society.

We briefly explain how three social psychology theories, namely social identity theory, self-verification theory, and impression management theory, juxtapose with consumer culture theory in general and self-extension theory in particular. The goal is to impart a framework for understanding the interaction of people, their possessions, and society. Every individual faces the conflicting task of connecting with other individuals in pro-social interactions (i.e., association), while at the same time maintaining a comfortable boundary so the individual self remains intact (i.e., individuation). The individuation side of this self-other boundary negotiation has been discussed in previous consumer research literature topics such as a "consumer's need for uniqueness," "counter-conformity" (Tian, Bearden, and Hunter 2001), and "identity signaling" (Berger and Heath 2007). The association side of this self-other boundary negotiation has also been discussed in several ways, but can best be described as communal consumption. This can occur at the dyadic level (Argo and Main 2008; Ramanathan and McGill 2007; Tanner, Ferraro, Chartrand, Bettman, and Van Baaren 2008) and at the reference group level (Epp and Price 2008; Escalas and Bettman 2005; Luna, Ringberg, and Peracchio 2008; White and Dahl 2007).

Social identity theory argues that one's personal identity (the individual self) and one's social identities (the collective selves) combine to form one's total identity (Hogg 2003). Through the process of identity negotiation, people maintain social group membership and distinctiveness. Swann (1987) argued that people engage in identity negotiations in order to obtain "existential security" (p. 1039). Individual self-concepts are the lens people use to understand their world and their place in the world. They desire stable self-concepts, and engage in activities that will provide them with feedback from others confirming their self-concept. He called this process "self-verification." One technique utilized by individuals during times of incongruence is impression management (Goffman 1959). During this process, individuals attempt to exert control over the perceptions others may have of them. Using a theatrical metaphor, Goffman explained how people put on shows for one another by managing their impression through the use of social cues.

Self-extension theory describes the items used during impression management, which can include setting, clothing, appearance, words, and nonverbal actions. In terms of mass communication, self-extension theory looks at how consumers use the possession of specific brands in order to express their identity (Belk 1988).

The symbolic meanings attached to brands are cultural markers. Therefore, if one is able to possess that brand, one can indirectly possess that cultural meaning. Therefore, during impression management, socially-visible brands are a tool utilized to create one's identity for the self and to communicate one's identity to others.

Forty-one informal face-to-face interviews were conducted with graduate and undergraduate students at a university in the southwestern U.S. Most of the interviews lasted about 30 minutes. The structure for the interview protocol consisted of asking respondents about the individual and social aspects of their identity, top-of-mind brand awareness, the specific brands they own for socially-visible items such as clothes, shoes, sunglasses, etc., and the socially-visible brands the respondent was currently wearing.

From these interviews, a Boundary Negotiation Framework is presented that can be used as a guide to gain a better understanding of how individuals use socially-visible brands in order to develop their self-concept and various levels of social identity. The results show how people use socially-visible brands in order to associate with other individuals, reference groups, and society as a whole during interpersonal interactions. Using this Boundary Negotiation Framework, individuation and associations interactions can be analyzed at the dyadic, reference group, and societal level. This Boundary Negotiation Framework can be utilized in the future to analyze post-purchase behavior of consumers with their socially-visible brands. In addition, advertisers can use this framework while crafting their branding and communication strategies.

Copycats as Uncertainty Reducing Devices

Femke van Horen, University of Cologne, Germany
Rik Pieters, Tilburg University, The Netherlands
Diederik A. Stapel, Tilburg University, The Netherlands

EXTENDED ABSTRACT

Purchase decisions are often made under conditions of varying uncertainty regarding product quality. When the context induces such uncertainty, consumers tend to seek additional information to reduce these feelings. Copycat brands may benefit under these circumstances.

Copycats imitate the trade-dress of a leading brand in order to leverage the positive associations that the latter has in the mind of the consumer (Loken, Ross, and Hinkle 1986; Zaichkowsky 2006). Research has demonstrated that consumers generally dislike blatant copycats, especially when these are blatant and awareness of the imitation strategy is high (Van Horen, Pieters and Stapel 2009; Warlop and Alba 2004, study 4). Surprisingly little is however known about the circumstances under which consumers actually *like* blatant copycats even when fully aware that the copycat is imitating. The extant research has focused on how package similarity influences copycat evaluation and purchase, but has not yet tested the potential influence of contextual factors on evaluation and choice of copycats. In the current research, we posit and show that copycat evaluation is critically dependent on contextually induced uncertainty.

Consumers are often faced with uncertainty about product quality when choosing between competing brands. Uncertainty refers to situations in which consumers do not know which choice to make (Lipshitz and Strauss 1997, Muthukrishnan and Kardes 2001). When feeling uncertain, consumers are likely to search for signals to assess quality in order to reduce these feelings of uncertainty. Information about the price, packaging, and brand image can then serve as such signals (Dawar & Parker, 1994; Kirmani & Rao, 2000). As copycats imitate the trade-dress of leading national brands and packaging is an important component of stored product knowledge, imitation can activate knowledge associated with the leader brand and serve as a signal. Thus, when consumers are uncertain about the quality of products and are looking for familiar cues to guide them in decision-making, copycats may be able to profit most. However, when consumers feel certain about the quality of products and do not need to rely on familiar cues, copycats may be interpreted negatively. When consumers are aware that a copycatting strategy is being used, similarity may be perceived as a intentional ploy to mislead consumers about product quality (Campbell and Kirmani 2000; Warlop and Alba 2004).

Three studies demonstrate that consumers systematically prefer copycats to visually differentiated products when the situation induces feelings of uncertainty about the quality of products, whereas the reverse is true when the situation induces feelings of certainty. In addition, we show that the positive evaluation of copycats in uncertainty inducing situations is due to consumers' reliance on familiar cues that signal quality. Two situations are explored that are likely to induce different levels of uncertainty. The first, more explicit, situation is when people are abroad as compared to being at home. When consumers are visiting another country and are unacquainted with the available brands, they are likely to feel uncertain about product quality. A second, more subtle situation is store-type. As compared to high-end stores, the quality of products at discounters is more variable and perhaps lower, which should activate consumers' feelings of uncertainty.

Study 1 tested the influence of being abroad or at home on copycat evaluation and choice. Participants were either instructed

to imagine being in Beijing, China, or in their home country, looking for a coffee shop. Next, they evaluated a copycat logo, which was a clear imitation of the "Starbucks" logo and a visually differentiated logo that did not share any similarities with the Starbucks logo. Further, they were asked to indicate whether their evaluation of the coffee shops was guided by familiar cues. In support of the hypothesis, copycat evaluation was dependent on country-induced uncertainty: when people imagined to be in a foreign country, the copycat was evaluated more positively and chosen more often than the visually differentiated product, whereas the opposite pattern emerged when people imagined to be in their home country. These results were mediated by reliance on familiar cues and were not due to source confusion. Study 2 tested whether the same effects appeared when uncertainty was manipulated through store-type. Half of the participants were asked to imagine doing shopping in a typical discount store, whereas the other half in a typical high-end store. Then, they were asked to evaluate a copycat chocolate bar ("Milka" look-alike) as compared to a visually differentiated brand. The results reveal that—compared to a visually differentiated product—a copycat was evaluated more positively in a discounter, than in a high-end store. These effects were shown not to be due to source confusion. In study 3 uncertainty was directly manipulated, instead of indirectly through specific situations, to provide further support for the idea that uncertainty is the key factor. Two packages (a copycat and a visually differentiated product) were created within the product category "Energy drinks". In the uncertainty (certainty) condition participants were asked to imagine doing shopping in an unknown (well known) supermarket, in which they were uncertain (certain) about the quality of the products. Again, participants were asked to evaluate both energy drinks and to make a choice. As predicted the copycat energy drink was evaluated more positively and chosen more often when uncertainty was induced than when certainty was induced. These results provide direct support for the underlying "uncertainty reduction" mechanism.

These results contribute to the literature on trademark infringement in several ways. First, the present research is, to our knowledge, the first to demonstrate that, besides package similarities, the specific shopping situation critically determines copycat evaluation and choice. This underlines the importance of moving beyond the similarities between copycat and leader brand in package design to understand copycat effects. Furthermore, it shows that even when fully aware and thus "not tricked", consumers may still prefer and choose copycats to reduce feelings of uncertainty. Hence, whereas consumers generally prefer differentiated brands to copycats, the reverse holds under conditions of uncertainty.

Reputable Brand Names can Improve Product Efficacy

Moty Amar, Ono Academic College & Duke University, USA

Dan Ariely, Duke University, USA

Maya Bar-Hillel, The Hebrew University, Israel

Ziv Carmon, INSEAD, France

Chezy Ofir, The Hebrew University, Israel

EXTENDED ABSTRACT

Common sense suggests that the efficacy of products should be a function of how they are designed and produced. Brand names, on the other hand, can presumably only influence expectations and subjective assessments of efficacy. However, we illustrate that the brand name that products carry can also influence rather than merely reflect objective efficacy. We thereby extend Shiv, Carmon, and Ariely's (2005) pioneering work on placebo effects of marketing actions, to a different type of marketing action (branding), study it with several new types of tasks, less likely to be influenced by voluntary control. In particular, across four experiments, each conducted in carefully controlled conditions, we show that attaching a prestigious brand name to a product can boost the performance of those who consume the product.

In experiment 1, participants repeatedly held the same titanium framed eyeglasses bearing either a prestigious or the less prestigious brand name in one hand, then held one of several paperweights each weighing slightly less or slightly more than the eyeglasses with no cue to its weight in the other hand, then judged which was heavier—the eyeglasses or the paperweight. Several aspects of the experimental design made it difficult to be insincere, thus reducing the likelihood of demand effects. As predicted, results showed that participants underestimated the true weight of the frame bearing the prestigious brand name more frequently and overestimated its weight less frequently, suggesting that the glasses seemed lighter when they bore the more prestigious brand.

In experiment 2, all participants first drank a cup of the same chamomile tea that was described as soothing to body and mind, which carried either a prestigious brand name or a less prestigious one. After a few minutes they were asked to complete as many puzzles as they could during a limited timeframe. As predicted, results showed that participants whose tea bore the more prestigious brand name gave more correct answers and fewer incorrect answers than those whose tea bore the less prestigious brand name.

In experiment 3, all participants faced a glaring light and were asked to read printed words as accurately and as quickly as they could, receiving compensation proportional to their performance. As predicted, those wearing sunglasses bearing a reputable brand name were able to read more quickly and with fewer errors than those wearing sunglasses bearing a less reputable brand name but were otherwise identical. Note that there are two ways that a participant who believes he or she is wearing quality sunglasses might perform better, to fulfill the expectation caused by the prestigious brand name. One is to try harder. That could account for the smaller number of errors, but not for the faster rate. Since both were recorded, willful effort seems to be ruled out. The other is to contract the pupil more, thus cutting out more glare. But our experimenters were instructed to make sure that participants did not do this. More importantly, inasmuch as the pupil is under voluntary control, it seems that putting one's faith in one's sunglasses would lead to the opposite inclination: One need not contract one's pupil as much when one has effective sunglasses as when one does not. Whatever happens in this task, then, is not trivial.

In experiment 4, all participants wore the same pair of earmuffs said to reduce noise while assisting in hearing conversations,

bearing either the prestigious brand name or a less prestigious one. They listened to a recording of an announcer reading a list of 62 unrelated words, read on the background of a very loud and noisy construction site and were asked to identify the words as they heard them. As predicted, participants whose earmuffs bore the more prestigious brand name identified more words correctly and fewer words incorrectly than those whose earmuffs carried the less prestigious brand name. Note that in this task it is not clear what a motivated participant could do in order to improve performance over a less motivated participant.

Altogether, this paper illustrates that in addition to coloring preferences and expectations the commercial reputation that is embodied in brand names can also influence objective efficacy in a manner that is difficult to attribute to volitional effort. The results can have significant managerial and public policy implications. As one example, firms may be able to boost the efficacy of their products by attaching more reputable names to them. Analogously, the findings suggest that generic medications may in fact not be as effective as branded ones, putting into question the common practice of substituting one for the other.

Guilt Appeals in Green Advertising: Influences of Issue Proximity and Environmental Involvement

Chun-Tuan Chang, National Sun Yat-sen University, Taiwan
Yu-Kang Lee, National Sun Yat-sen University, Taiwan
Ting-Ting Chen, National Sun Yat-sen University, Taiwan

EXTENDED ABSTRACT

With increasing public concern about the environment and corporate social responsibility on environmental sustainable development, the 1990s was declared the decade of environmentalism (Drumwright, 1994; Kangun, Carlson, and Grove, 1991). Consequently, recent studies have begun to examine potential factors that might affect the effectiveness of green marketing campaigns and how consumers respond to green marketing initiatives (e.g., Chan, 2000; Obermiller, 1995; Schuhwerk and Lefkof-Hagius, 1995). One influential variable that has been identified to determine the success of green marketing is its advertising (e.g., Karna et al., 2001). Emotional appeals are widely used to “cut through the clutter” and arouse persuasive communication. Among them, guilt appeals are identified as popular, especially in the contexts related to public service announcement.

This article contributes to this evolving stream of research by applying guilt appeals in green marketing campaigns to demonstrate that guilt appeals are not equally persuasive in all conditions, and can be influenced by the impacts of issue proximity and environmental involvement. A fictitious product, leftover-grounds printer, was developed as the test product. An experiment with 2 (advertising appeal: guilt appeal vs. positive appeal) X 2 (issue proximity: low vs. high) X 2 (environmental involvement: low vs. high) factorial design was conducted. The first two factors were manipulated and the final one was measured. Therefore, four experimental versions were produced. Participants were randomly assigned to one of the conditions above. After successful manipulation checks, a series of analysis of variance were conducted to examine proposed hypotheses.

The results indicate that focusing on the comparison between guilt and positive appeals may be overly simplistic. Indeed, the findings presented here establish that the influence of guilt appeals on consumer response is relatively complex and contingent on issue proximity and environmental involvement. Three observations are noteworthy.

First, in terms of the relative effects of issue proximity, this study shows systematic effects on consumer responses by comparing low and high issue proximity. High proximity made a difference in advertising effectiveness; a local issue, as opposed to a foreign issue in a less familiar region, yielded more favorable evaluation and higher behavioral intention. This perspective is conceptually consistent with social impact theory and signaling theory. The reason could lie in the notion that the local community is more salient to consumers—regardless of the advertising appeal. No differences are found between a guilt and positive appeal in advertising effectiveness of high-proximity issue. This idea does not suggest, however, firms only address local issues and neglect global or foreign issues because advertising appeal may not be a concern in their advertising campaign when presenting a local issue. When an issue is perceived as less proximal, the tactic of guilt appeal allows a firm to enhance consumers’ attitudes toward the product and purchase intention.

Second, that effects of advertising appeal are contingent on environmental involvement is noteworthy. This construct delineates the boundary conditions for the guilt appeals on persuasion. A guilt appeal works for those with low environmental involvement.

Compared with individuals with low environmental involvement, those with high environmental involvement are less likely to be influenced by the advertising appeals. The results are consistent with the observation by Schuhwerk and Lefkof-Hagius (1995). The study here also echoes that guilt can generate negative responses and disrupt the advertiser’s intended objectives as well (Cotte et al., 2005; Shrum et al., 1995).

Third, the effectiveness of guilt and positive appeals depends on issue proximity and environmental involvement simultaneously. Instead of blindly applying any type of advertising appeal, advertisers should pay particular attention to perceived proximity of the environmental issue and consumers’ individual differences in environmental involvement. When facing individuals with low environmental involvement, the guilt appeal performed better than the positive appeal in promoting an issue with high proximity. Thus, when dealing with a problem people regard as relatively important or about which they are self-relevant, the impact of guilt appeal may offer advantages. As Schuhwerk and Lefkof-Hagius (1995) note that consumers pay attention to external cues such as how an ad is framed when they do not possess strong beliefs about the environment. Alternatively, when concern for the issue is low (low issue proximity), no differences of advertising effectiveness between a guilt and positive appeal can be found. Because of weak impetus to process the message and less well-developed green product schema, the less involved consumers may not be able to identify the differences between the two appeals. When facing highly involved consumers, the guilt appeal was more persuasive than the positive appeal in promoting a less proximal issue. However, this observation appears to be reversed when the ad was presented to less involved consumers. The guilt appeal may offer a redundant warning, or worse, cause a boomerang effect. Consistent with prior work on involvement and skepticism about advertisers’ environmental claims, environmentally involved individuals may engage in more effortful and elaborative processing and discount the received information. In such cases, the positive appeal is preferable. The implication is that advertisers must be careful not to arouse guilt feelings through the ads. If such care is not taken, a backlash may occur whereby the consumers develop negative attitudes toward the promoted product. In any event, advertisers are advised to adopt a situational perspective by taking the possible interaction effect among advertising appeal, issue proximity, and environmental involvement.

Findings from this investigation are informative both theoretically and pragmatically. This study contributes to the academic literature and industry by increasing our understanding of guilt appeals in a green marketing context by proposing issue proximity and environmental involvement as factors that moderate the relationships between guilt appeal and consumer responses toward the promoted product. The findings underscore the importance for green marketers to learn more about whether guilt appeals work, and in turn describe how practitioners can avoid negatively toward guilt appeals. The present research should serve a starting point for entry into this under-researched area.

Metaphors in Advertising: Cognitive Flexibility Matching Perspective

Kyung-Jin Kim, The University of Suwon, Korea
Jongwon Park, Korea University Business School, Korea

EXTENDED ABSTRACT

Prior research suggests that a metaphor in advertising can have a positive effect on evaluations of the target product (McQuarrie and Phillips 2005; Moreau, Markman, and Lehmann 2001). However, the effect tends to be restricted to the metaphors which are easy to interpret (Gregan-Paxton and John 1997; Roehm and Sternthal 2001). Yet, it is common that companies employ complicated, idiosyncratic, and difficult metaphors in their advertising. This discrepancy can be resolved, however, if we consider both the level of cognitive flexibility required to process the metaphor and the level of individuals' actual cognitive flexibility at the time of metaphor processing as determinants of the effectiveness of a metaphor.

The present research proposes a cognitive flexibility matching hypothesis that the match between the required and actual level of cognitive flexibility is a key determinant of the metaphor's effectiveness. That is, when the level of cognitive flexibility necessary to comprehend a metaphor matches the level of individuals' actual cognitive flexibility at the time of metaphor processing, using the metaphor in an ad could be beneficial for evaluations of the target product. When the individuals' actual cognitive flexibility is either below or above the required level to process a metaphor, however, using the metaphor could be detrimental.

To test this proposition, we borrow from research based on temporal construal theory that a distant-future perspective (vs. a near-future perspective) increases individuals' cognitive flexibility momentarily (Forster et al. 2004; Trope and Liberman 2003). Based on this, we hypothesize that a difficult metaphor, compared to its easier version or a literal message counterpart, can lead to more favorable product evaluations when people consider the target product for a distant-future purchase, but would produce less favorable evaluations when they consider it for a near-future purchase. To put it differently, an increase in temporal distance is expected to increase the effectiveness of a difficult metaphor, but to decrease the effectiveness of an easy metaphor.

These hypothesized (diametrically opposite) effects were confirmed in five experiments in which participants evaluated a target product described by either a difficult metaphor, an easier version of the metaphor, or its literal message counterpart, while considering the message for a possible purchase of an advertised product either next day (near-future condition) or next year (distant-future condition). Moreover, the effects generalized over different products and metaphors and were evident regardless of whether the level of difficulty of a metaphor was manipulated by employing different versions of a metaphor, by varying individuals' knowledge to process a metaphor, or by varying their mood state.

Experiment 1 demonstrated that a difficult metaphor, compared to a literal message that has a same implication of the metaphor, led to a more favorable evaluation of the target product in the distant future condition, whereas this difference was reversed in the near future condition. Experiment 2 replicated these results and in addition showed that a difficult metaphor was more effective than an easy metaphor as well in the distant future condition, whereas this difference was reversed in the near future condition. Experiments 3a, 3b, and 3c investigated the role of individuals' knowledge to process the metaphor and found that a (difficult) metaphor was more effective for low-knowledge individuals than for high-knowledge individuals when the product decision was made for a distant future, whereas the difference was reversed when the decision was made for a near-future. Similarly, Experiment 4a and 4b demonstrated

that a (difficult) metaphor was more effective for individuals in the positive mood condition than for those in the negative mood condition when the product was evaluated for purchase in the distant future, whereas the difference was reversed when the product was considered for a near-future purchase. Finally, experiment 5 assessed the level of comprehension about the metaphor based on participants' thought protocols. A mediation test confirmed that the effect of temporal distance on the effectiveness of a difficult metaphor was mediated by its influence on the extent to which participant actually comprehended the meaning of the metaphor.

Thus, collectively, results from five experiments provide consistent evidence for our cognitive flexibility matching hypothesis. At the same time, the research identifies moderators (product knowledge and mood state) for the diametrically opposite effects observed in the experiments. Theoretical and managerial implications of these findings are discussed.

Testing Phonetic Symbolism Effects on Brand Name Preference for Bilinguals Across Multiple Languages

L. J. Shrum, University of Texas at San Antonio, USA
Tina M. Lowrey, University of Texas at San Antonio, USA
Dawn Lerman, Fordham University, USA
David Luna, Baruch College, USA
Min Liu, University of Texas at San Antonio, USA

EXTENDED ABSTRACT

Good brand names can enhance memorability, create favorable images, and increase preference for the products, and are an important component in building brand equity (Aaker 1996; Keller 1993). When investigating the construction of the brand names, researchers found that not only the semantic meaning, but also phonetic symbolism, which refers to a non-arbitrary relation between sound and meaning, may influence brand preference (Klink 2000). In its simplest form, phonetic symbolism suggests that phonemes (the smallest unit of sound) can convey meaning apart from their configuration in words or syllables. Research on the relation between phonetic symbolism and brand name preference has shown that brand name preference and brand attitudes are more positive when the fit between phonetic symbolism and the product attributes is maximized. Although previous research has been successful at documenting phonetic symbolism effects in brand names, the processes underlying these effects have remained elusive. First, as some critics have pointed out, phonetic symbolism effects do not necessarily occur spontaneously, but only when specific dimensional judgments (e.g., size, shape, brightness) are elicited (Bentley and Varon 1933), suggesting that the effect may be a methodological artifact. Second, the effects that have been obtained with determining the meaning of foreign words (e.g., matching pairs of antonyms in a foreign language with comparable English antonyms; Brown, Black, and Horowitz 1955) are eliminated if both sets of stimulus words are in languages foreign to the participants (Maltzman, Morrisett, and Brooks 1956). Besides, there are in fact some reasons to think that phonetic symbolism effects would not hold for some forms of language. For example, in the Chinese written language, there are important differences in how alphabetic and logographic word representations are processed (Schmitt, Pan, and Tavassoli 1994; Tavassoli 2001), and there is considerable debate as to whether phonetic information in logographic characters can even be activated prior to some semantic activation (Chua 1999; Zhou 1978).

The goal of this paper is to extend previous research on the existence of phonetic symbolism and its application to brand naming by testing the generalization of these findings across languages, and testing the extent to which fluency may moderate the phonetic symbolism effects. On the one hand, if the phonetic symbolism effects are indeed universal (Ultan 1978), fluency may have little effect. On the other hand, research shows that form and meaning in a second language, even for fluent bilinguals, are not as tightly connected as for a first language (Luna and Peracchio 2001). If so, then we would expect to see weaker effects for less fluent second-language learners.

Three experiments were conducted to determine the extent to which phonetic symbolism effects are spontaneous and generalizable to other languages, and the extent to which non-native speakers are influenced by second-language fluency. In experiments 1–3, Spanish-, French- and Chinese-speaking participants who were fluent in English expressed preferences between brand name pairs that differed only in their primary vowel sound (front vs. back), and did so as a function of product category (2-seater convertible, knife, 4 X 4 vehicle, hammer). In addition, Chinese-speaking participants

received brand name stimuli that were constructed using either alphabetic letters or logographic symbols in order to test possible differences in the two presentations. Our focal hypothesis was that preference for front versus back vowel sound words as brand names would vary as a function of product category: front vowel sound words should be preferred over back for 2-seater convertible and knife, and back vowel sound words should be preferred over front for 4 X 4 vehicle and hammer. Note that the elicitation of a brand name preference for each product category does not directly elicit a judgment regarding concepts such as size, speed, or sharpness (cf. Bentley and Varon 1933). Rather, the predicted effects should be noted only if participants form perceptions of these concepts spontaneously and then apply them to their preference judgments. The results of the ANOVA indicated that there was a significant interaction between vowel sound and product category as we predicted, whereas the effect of experiment was not significant. These findings indicate that phonetic symbolism effects are robust across the different languages and cultures we tested, including logographic representations in Chinese. The results also show that these general relations were for the most part unaffected by whether participants completed the experiment in their native language or a foreign language, and were also unaffected by their proficiency in that language.

The studies we have presented make a number of contributions to the consumer behavior literature, but they also contribute to the more general fields of cognitive psychology and psycholinguistics. We replicate the phonetic symbolism effects noted in previous studies (Lowrey and Shrum 2007; Yorkston and Menon 2004), but also show that a) these effects generalize to languages other than English, b) generalize to languages in which presentation is non-alphabetic (logographic), c) hold for second-language as well as first-language participants, d) these latter effects are observed regardless of level of proficiency of participants, and e) the effects are spontaneous rather than a function of being elicited by the research method.

What Makes Things Cool? How Autonomy Influences Perceptions of Coolness

Caleb Warren, University of Colorado, USA

Margaret C. Campbell, University of Colorado, USA

EXTENDED ABSTRACT

Coolness is a socially desirable trait often pursued by consumers and marketers (Belk, Tian, and Paavola 2008; Dar Nimrod et al. 2008; Kerner and Pressman 2007). Both people and brands can become cool, although it is not well understood how this occurs. Leading theories suggest that coolness comes from conforming to behaviors desired within a particular subculture (Danesi 1994; O'Donnell and Wardlow 2000; Thornton 1996) or by quickly mimicking the behaviors of other cool people (Gladwell 1997; Lupiono-Misdorn and de Luca 1998). These theories, however, provide an incomplete explanation because they do not account for the origins of coolness nor do they explain how coolness diffuses across subcultures.

Building on prior work in cultural studies, sociology, and psychology (Frank 1997; Heath and Potter 2004; Pountain and Robins 2000), we hypothesize an alternative way people and brands can become cool: display bounded autonomy from mainstream society. In other words, we suspect that people and brands can become cool by going their own way, rather than following society's conventions. We test this hypothesis in three experiments.

Autonomy cannot be directly observed. Rather, it must be inferred by observing the extent to which a person or brand adheres to society's norms. People and brands that resist or ignore these norms will likely be seen as more autonomous than people and brands that conform. Consequently, we hypothesize that rebellion and uniqueness will influence perceptions of autonomy, which will influence perceptions of coolness.

Our first study tests whether people who are more rebellious and unique are perceived to be cooler than people who are less rebellious and unique. Furthermore, we test whether these effects are mediated by perceived autonomy. Participants read descriptions of target people who either described themselves as fairly rebellious or not rebellious and fairly unique or not unique. Rebellion and uniqueness were fully crossed and manipulated between-subjects. For example, one target person was either described as "not afraid to go against the grain" or "careful not to go against the grain," depending on whether the participant was in the high or low rebellion condition, respectively. After reading the descriptions, participants rated their perceptions of the target person's autonomy and coolness. As expected, target people who seemed more rebellious were considered cooler than target people who seemed less rebellious ($M = 6.9$ vs. 4.6). Uniqueness had a similar effect ($M = 6.8$ vs. 4.8). Importantly, both main effects were mediated by perceptions of autonomy.

Next we investigate whether the relationship between autonomy and perceptions of coolness is strictly increasing or curvilinear. Social norms exist in part to prevent destructive, anti-social behavior (Rousseau 1994). Consequently, we suspect that showing extreme levels of autonomy by completely disregarding these norms will not be seen as cool. Thus, the relationship between autonomy and perceived coolness will likely be curvilinear: perceived coolness will initially increase with displays of autonomy, but will begin to decrease as displays of autonomy become too extreme.

Individuals differ in terms of the extent to which they value autonomy and, consequently, the amount of autonomy they will consider acceptable. Individuals higher in counterculturalism, an ideology centered on the belief that societal institutions promote widespread conformity while repressing individuality, will likely value autonomy more than individuals lower in countercultural-

ism. Consequently, we hypothesize that the level of autonomy considered cool—i.e., the point at which the curvilinear function between autonomy and perceived coolness peaks—will be higher for consumers higher in counterculturalism.

Our second study tests whether the relationship between autonomy and perceived coolness is curvilinear, and whether the amount of autonomy considered cool varies depending on counterculturalism. Participants read about a target person who was described as displaying either a low (e.g., "she rarely would assert her independence"), moderate (e.g., "she occasionally would assert her independence"), high (e.g., "she often would assert her independence"), or extreme (e.g., "she always would assert her independence") level of autonomy. Participants rated perceived coolness of the target person and completed a scale measuring their level of counterculturalism. As hypothesized, perceived coolness initially increased as autonomy increased from a low to moderate level, but decreased as autonomy moved from a high to extreme level. Additionally, however, participants higher in counterculturalism considered higher levels of autonomy cooler than participants lower in counterculturalism.

Our third study explores when consumers will desire cool brands. Because displays of autonomy lead to perceptions of coolness, we suspect that consumers can use cool brands to signal an autonomous identity. Individualistic consumers will want to signal their autonomy, and hence will be most likely to prefer cool brands, when their identity as an autonomous individual has been threatened (Brewer 1991; Gao, Wheeler, and Shiv 2009).

In this study we test whether American consumers whose autonomous identity has been threatened are more likely to prefer cool brands. We threatened the autonomous identity of some participants by making them feel undifferentiated from others by priming their interdependent self (e.g., Aaker and Lee 2001). Subsequently, participants indicated whether they preferred a cool winter hat brand (i.e., one displaying bounded autonomy) or an uncool winter hat brand (i.e., one displaying low autonomy). Participants primed with an interdependent self were more likely to select the cool hat brand (68%) than participants primed with an independent self (44%). Desire to express autonomy was higher for participants primed with an interdependent self, and this measure mediated the effect of the self-construal prime on brand preference.

Following subcultural norms and mimicking cool people are not the only ways to become cool. People and brands can also become cool through displays of bounded autonomy. Identifying autonomy as an additional antecedent of perceived coolness suggests where coolness originates and how cool trends diffuse across subcultures. Things first become cool when they are seen as autonomous from mainstream society and cool trends typically diffuse from outsider subcultures and consumers higher in counterculturalism to more mainstream subcultures and consumers lower in counterculturalism. Our research suggests that consumers and brands that want to be cool should be rebellious and unique, but be careful not to go too far.

How Asking “Who Am I?” Affects What You Buy: The Influence of Self-Discovery on Consumption

Eugenia Wu, Cornell University, USA
Keisha Cutright, Duke University, USA
Gavan Fitzsimons, Duke University, USA

EXTENDED ABSTRACT

Are you an introvert or an extravert? A dreamer or a realist? Tools that ask and answer such questions are becoming a ubiquitous part of our lives, seeking to serve a universal thirst for self-discovery. Stores like Nordstrom and Bloomingdale's offer color consultations to shoppers so they can learn whether “summer” or “winter” colors are better for them. Gyms offer fitness assessments to help consumers understand what type of exerciser they are and which activities they should be doing to reach their fitness goals. Self-help books abound which profess to help consumers learn about the self.

Consumers' drive towards self-discovery makes sense—the better we understand ourselves, the better decisions we can make. Interestingly, the process of discovering and defining the self can also be seen as a way of placing constraints on the self. If you are Type A, you cannot also be Type B. For individuals who are sensitive to the prospect of limitations, the findings from self-discovery may be particularly likely to be viewed as a constraint on who they can be. Thus, these individuals may reject such findings. We hypothesize that individuals characterized by an independent self-construal (for whom the act of defining the self is inconsistent with their conception of the self as an indefinable whole), as well as individuals who are highly reactant, will reject the findings of self-discovery and make consumption choices inconsistent with them, even as they actively seek to learn about themselves. Conversely, individuals who are characterized by interdependent self-construals and are low in reactance should accept the findings of self-discovery and incorporate such into their consumption decisions.

In study 1, participants completed a “personality quiz” consisting of personality items, IQ questions, and Singelis' (1994) Self-Construal Scale. Participants were either told that they were better than 70% of students in competence and better than 95% in excitement, or that they were better than 95% of students in competence and better than 70% in excitement. As the dependent measure, participants chose between *Business 2.0* (low competence/high excitement) or *Consumer Reports* (high competence/low excitement) magazines. As expected, interdependents were more likely to choose *Business 2.0* (low competence) when they received low competence feedback. They were more likely to choose *Consumer Reports* (high competence) when they received high competence feedback. In contrast, independents were more likely to choose *Consumer Reports* (high competence) when they received low competence feedback and *Business 2.0* (low competence) when they received high competence feedback. Thus, interdependents made choices that were consistent with the self-information they received while independents made decisions that were inconsistent.

In study 2, we further explore the idea that self-knowledge can be constraining by demonstrating that individuals who are known to react against constraints (i.e., highly reactant individuals) also react against the limiting nature of self-knowledge. Participants first made a series of selections between pairs of products. Product pairs could consist of two branded products, two generic products or one branded and one generic product. Participants were then assigned to one of two feedback conditions. In the ‘brand conscious’ condition, participants read that they were more brand conscious than the average consumer. In the ‘not brand conscious’ condition, they read that they were less brand conscious than the average

consumer. Participants then made a second series of choices between branded and generic products. As expected, highly reactant individuals chose fewer brands when told that they were more brand conscious than others, and more brands when told that they were less brand conscious than others. Individuals low in reactance, however, chose more brands when told that they were more brand conscious than others, and fewer brands when told that they were less brand conscious.

While the results of studies 1 and 2 reveal that in response to self-discovery findings, independents conduct themselves like high reactants and that interdependents behave like low reactants, we aimed to show a more direct link between self-construal and reactance in study 3. We expected independents to report increased levels of state reactance in response to the limitations inherent in self-discovery findings relative to interdependents. We further expected feelings of state reactance to mediate the relationship between self-construal and subsequent choice. Participants first completed the same product choice quiz described in study 2. Before being primed to be independent or interdependent (Brewer and Gardner, 1996). Next, participants read that they were more brand conscious than average, less brand conscious than average, or received no information at all. Participants who received feedback then answered four questions about their feelings of reactance toward the information (Lindsey 2005). Finally, all participants made choices between a second series of brands and generics. As expected, independents made product choices that were inconsistent with the self-knowledge they received while interdependents made choices consistent with their self-information. Importantly, reactance mediated the relationship between self-construal and brand choice as independents reported stronger feelings of reactance, regardless of the type of feedback.

Overall, studies 1-3 suggest that certain individuals may view self-knowledge as constraining, and that this may lead to some unexpected consequences for consumer behavior. Specifically, we find that independents and high reactants reject self-discovery findings and make consumption choices inconsistent with them even as they actively seek to learn about themselves. Thus, this research provides a key theoretical refinement in terms of when individuals will seek and yet reject self-discovery findings and establishes how this has significant consequences for consumption. We also contribute to research suggesting that individuals use consumption to enhance and express the self, especially when threatened (Gao, Wheeler, and Shiv 2009). We show that individuals' conceptualization of the self will determine how they use consumption to express the self in the face of feedback. This research also brings together the reactance and self-construal literatures in a novel way, offering new insights regarding when and why they exert similar effects on consumers' choices. Moreover, our results have important practical implications: Consumers' innate desire for self-discovery may be one need that marketers should be wary of fulfilling, as it may lead to surprising and unintended consequences.

Distracted by the Man in the Mirror: Focusing Attention on the Outside Body Reduces Responsiveness to Internal Signals in Food Intake

Evelien van de Veer, Wageningen University, The Netherlands

Erica van Herpen, Wageningen University, The Netherlands

Hans C. M. van Trijp, Wageningen University, The Netherlands

EXTENDED ABSTRACT

In Western societies, an increasing number of people is overweight or obese (WHO 2004). At the same time, media increasingly emphasize thinness ideals and outward appearance (Wiseman et al. 1992). In the current study, we test the relation between focusing on outside appearance and food consumption. More specifically, we hypothesize that focusing on the outside of the body impedes internal body cues to have an effect on food consumption.

A wealth of literature shows how internal cues, external cues and psychological states separately influence food intake (Wansink 2004), yet little is known on whether and how these cues and psychological states interact. Our study extends this work by examining consumers' responsiveness to internal satiety cues in different psychological states. To do so we assess how capable consumers are of compensating for previous food intake rather than looking at an absolute amount of food intake at a single point in time. One of the psychological states that has been found to stimulate food intake is distraction. Whereas it has been repeatedly demonstrated that distraction increases food intake within the consumption episode (e.g. Bellisle, Dalix and Slama 2004), there is some recent evidence that the effects of distraction may go beyond the consumption episode in affecting subsequent consumption (Higgs and Woodward 2009). We build on this work and, drawing on self-objectification theory, propose that focusing on outward appearance is a distractor that hinders individuals in compensating for previous food intake.

Self-objectification has been defined as the process whereby individuals observe themselves from a third-person perspective and regard their body as an object instead of as a subject (Fredrickson and Roberts 1997). Appearance focus is a manifestation of self-objectification. Fredrickson et al. (1998) found that a state of self-objectification, had detrimental effects on task performance due to a limited availability of cognitive resources. Based on the same reasoning, self-objectification theory predicts that focusing on outward appearance reduces responsiveness to bodily cues. Initial evidence indeed shows that self-reported measures of self-objectification and responsiveness to bodily cues are negatively related (Daubemier 2005). However, using self-report measures of these constructs seems problematic. In the current study we have therefore tested this prediction assessing actual consumption.

In a pilot study we tested and showed that exposure to a mirror induces in participants a focus on public observable parts of the body, but not on private parts of the body. Thus, the use of a mirror appears to be a good manipulation of an outward appearance focus. In an experiment we subsequently tested the effects of an outward appearance focus on consumers' ability to compensate for the caloric content of previous food intake. Participants were served either a high caloric milkshake or a low caloric milkshake and were either seated in front of a mirror or not. In a second part of the experiment, participants evaluated neutral video fragments with a bowl of M&M's placed next to their screens. At the end of the experiment, participants' M&M consumption was assessed.

The effects of appearance focus and caloric content of the milkshake were assessed for the likelihood of M&M consumption and for the amount of M&M consumption. The results showed that the likelihood of starting to eat M&M's was influenced by the caloric content of the milkshake: When participants had previ-

ously been served a high caloric milkshake, they were less likely to start consuming M&M's. Interestingly, the effect that the caloric content of the milkshake had on the amount of consumption, was qualified by whether an appearance focus was induced in participants. Under control conditions, participants compensated for the caloric content of the milkshake by consuming fewer M&M's when previously served a milkshake of high caloric content than when served a low caloric milkshake. However, when participants were induced to focus on their outward appearance, the effect of caloric content on M&M consumption was (marginally) significant in the opposite direction. That is, participants consumed more M&M's when they had previously consumed a high caloric milkshake than a low caloric milkshake, indicating counterregulation rather than compensation of previous food intake.

The current study makes a number of contributions to the literature on cues affecting eating behavior. As our findings demonstrate that an appearance focus reduces the extent to which individuals are able to compensate for their previous intake, this indicates that the psychological state a consumer is in affects the influence of internal cues on consumption. This extends previous work that has looked mostly at how internal cues, external cues and psychological states separately affect food intake. The current findings provide insight into how a psychological state and internal physiological cues can jointly affect consumption. We have done so by looking at compensation for previous intake, rather than at absolute amounts of food intake. How well individuals are able to compensate for previous food intake under different psychological states, may also provide an understanding of when individuals are able to counteract the negative influences that a range of external cues and psychological states have on consumption levels (Wansink 2004). Finally, our findings suggest that future research may benefit from assessing both initiation of consumption and the amount of consumption, as our findings indicate that they may be affected by different processes.

This study has implications for consumers who regularly focus on their looks to monitor and regulate the potential harmful consequences of food consumption on body appearance. Our findings show that the effect may be counterproductive: Focusing on the outer body diminishes the power of internal satiety cues to regulate food consumption. This could result in a pattern where consumers overeat, gain weight and subsequently focus even more on their looks. On a broader level, the thinness and beauty ideals that are conveyed through commercials and other media may also foster an attentional focus on outward body appearance. These have the potential of negatively affecting healthy eating patterns as they may exert their effects within consumption contexts such as TV commercials, shopping malls or cinema's.

Bandwagon, Snob and Veblen Effects in Luxury Consumption

Minas Kastanakis, ESCP Europe, UK

George Balabanis, Cass Business School, UK

EXTENDED ABSTRACT

Conceptualization

Many years ago Leibenstein (1950) highlighted the importance of “signaling effects” on consumption, which means that the utility derived from a product is enhanced or decreased due to the fact that “others” are purchasing and consuming it or due to the fact that the product bears a higher or lower price tag. In marketing it was taken for granted that “people buy luxuries to impress”: most of consumer research has implicitly assumed that luxuries are consumed for social signaling purposes (Kapferer, 2006; Dubois, Laurent, and Czellar, 2001). However, there is a scarcity of empirical support to this claim. This study tries to plug this gap by providing empirical support to the possible antecedents of three luxury consumption effects. It aims to improve the existing theoretical understanding of the psychological antecedents and signaling behavior of luxury consumption.

Specifically, a veblen effect arises when consumer preference for a good increases as a direct function of its price; a snob effect when preference for a good increases as its quantity in the market is decreased; and a bandwagon effect is observed where consumer preference for a good increases as the number of people buying it is increased. As Vigneron and Johnson (1999) have pointed out, these effects are particularly observed in luxury product markets.

Research on luxuries’ consumption has led to recent evidence (Tsai, 2005) that calls for a distinction between socially and personally-oriented luxury consumers (Wiedmann, Hennigs, and Siebels, 2007). The origins of these two orientations can be traced in an individual’s self-concept. Some individuals focus more on the “internal domain” and their self-related goals or needs (independent self-concept); while others are more concerned about the interpersonal domain, the reaction of others and their external “persona” (inter-dependent self-concept). This literature (Wong and Ahuvia, 1998) advocates that consumers with an independent self show a more personal orientation in the way that they consume luxuries (focusing on their hedonic, utilitarian and self-communication goals) whereas consumers with inter-dependent self care more for the social impact of such consumption (the three investigated effects).

The existing work has not paid sufficient attention to the social effects (i.e., the bandwagon, snob, and veblen effects). It is not clear how exactly the self orientations impact on the consumption of luxuries. Against the previous background, this study proposes that these effects are driven by both an independent and an inter-dependent self-concept (they are both personally and socially-driven behaviors) and that a number of relevant traits act as mediators between the self-concept(s) and the signaling behavior.

With the help of the literature and qualitative exploratory research (interviews with managers of luxury products) the following four traits emerge to be related to the bandwagon, snob and veblen effects: need-for-uniqueness, vanity, status-seeking, and susceptibility to interpersonal influence.

Need-for-uniqueness (NFU) is “the trait of pursuing differentness relative to others through the acquisition, utilization and disposition of consumer goods” (Tepper, Bearden and Hunter, 2001). NFU is positively related to both independent and inter-dependent self concepts and is hypothesized to be an antecedent of both snob and veblen effects, while negatively related to a bandwagon effect.

Vanity (Netemeyer, Burton, and Lichtenstein, 1995) has a physical and an achievement dimension. Vanity is hypothesized to

be positively related to both independent and inter-dependent self concepts. In addition vanity is an antecedent of a veblen effect (i.e., expensive luxuries), a snob effect (i.e., rare luxuries) and a bandwagon effect (i.e., through consumption of popular luxuries) as well.

Status-seeking is defined as the “process by which individuals strive to improve their social standing through the conspicuous consumption of products that confer and symbolize status” (Eastman, Goldsmith, and Flynn, 1999). It reflects a social orientation and it is hypothesized to be positively related to the inter-dependent self (and negatively to the independent self). In addition, using the same argumentation line, status-seeking is hypothesized to be an antecedent of the veblen, snob and bandwagon effects.

Consumer susceptibility to interpersonal influence, refers to the need to “identify with or enhance one’s image in the opinion of significant others” through relevant consumption (Bearden, Netemeyer, and Teel, 1989). This trait reflects a social orientation and, as such, is hypothesized to be positively related to the inter-dependent self (and negatively to the independent self). It is an antecedent of the bandwagon effect and it is negatively related to snob effect.

Method

Data were collected by the “drop and collect” survey method in a probability sample of 431 consumers of luxuries in London. Three mediated structural models with the following variables were estimated: (independent and inter-dependent) self-concepts as antecedents (exogenous variables), need-for-uniqueness, status-seeking, vanity and susceptibility to interpersonal influence as mediators, and bandwagon, snob and veblen behavior(s) as outcome variables.

Major Findings

Bandwagon behavior is mostly influenced by inter-dependence. Managers who want to position their products as popular luxuries should focus-with this order-on enhancing their products’ projected status (status from popularity/conformity), normative (fit-in) messages, and (physical) vanity/attractiveness appeal; while avoiding “stand-out” (avoidance of similarity) messages.

Snob behavior is mostly influenced by independence. Managers who want to position their products as exclusive luxuries should focus-with this order-on status derived from exclusivity, creating an aura of scarcity and uniqueness, and (physical) vanity/attractiveness appeal; while avoiding conformity (fit-in) messages.

Veblenian behavior is marginally influenced by inter-dependence. Managers who want to boost consumption of their luxury products using (very expensive) price-signaling should focus-with this order-on communicating messages coherent with the traits of these target consumers: status messages (status from prestige-pricing since, for the purely conspicuous consumer, the satisfaction comes from audience reaction to the wealth displayed), (physical) vanity/attractiveness appeals, as well as on scarcity and uniqueness messages based on creative counter-conformity.

These results contribute to understanding in depth the antecedents behind the signaling behavior of consumers of luxury goods. This behavior is both personally meaningful and socially driven. These findings provide practical help to managers in a) segmenting their markets, and b) evaluating and predicting the reaction of consumers to changes in their offerings and communication campaigns.

The Power of Positive Thinking: Asymmetrical Affective Perseverance in Consumer Brand Judgments

Brent Coker, University of Melbourne, Australia

EXTENDED ABSTRACT

Consumers update their attitudes towards brands as new information is encoded. For example, when reading online reviews about hotels or restaurants when booking a holiday, consumers will adjust their attitude in line with the positivity or negativity of the reviews being read. In many situations, the valence of information encoded about a product or service is mixed. It is rare for instance for online hotel reviews to be consistently positive or negative; there are always some patrons who appear to have had a more positive or more negative experience with the hotel than the majority. From a big picture standpoint, the issue of how consumers form attitudes towards products and services from reading online reviews raises the more general issue of how consumers adjust their attitudes when information describing the quality of product or service is mixed. The goal of this research therefore is to explore how consumers update their attitudes towards products and services when information encountered during decision making is of opposite valence.

Conventional wisdom would suggest that if a consumer has a favorable attitude towards a brand, which is then contested by negative information, the consumer will have control over their judgments and adjust their evaluation accordingly. For example, a consumer may hear a rumor about a brand, which they later find to be untrue. Similarly, when a consumer encodes positive information contesting previously encoded negative information, they will also have control over their judgments and adjust their evaluations accordingly. The present research argues however that consumers are less successful at adjusting their attitudes in a positive to negative direction than they are at adjusting their attitudes in a negative to positive direction. Specifically, this research proposes a theory of asymmetric affective perseverance, whereby positive attitudes continue to contaminate judgments towards a brand when replaced by negative attitudes, but negative attitudes do not. This leads to the paradoxical finding that consumers' attitudes towards a brand are positively skewed if they encode positive information before negative information, than if they encode the same information in the opposite order.

This research further finds that this asymmetrical perseverance of affect is contingent on trend of information over time, and that it only occurs when information is deeply encoded. When trend information is available, such as when positive reviews are old, and negative reviews are recent, the pattern of results is reversed, and the nature of asymmetric affective perseverance is muted.

The phenomenon of asymmetric affective perseverance is attributed to people's relative difficulty in shifting their attitude in a positive to negative direction, than in a negative to positive direction. Anecdotally, the concept of denial in psychiatric literature describes a similar cognitive process. A person given bad news will often experience the protection mechanism of disbelief, deferral, and dismissal before a relatively negative affective state sinks in (Lubinsky 1994). In contrast, the shift from relative despair to happiness is often instantaneous, and has a stronger effect on imagined outcomes than negative factors. In general, human beings prefer to remain optimistic and are more willing and hopeful towards adopting a positive outlook than remaining in a relative state of negativity. The asymmetry in attitude adjustment pertaining to brands is demonstrated in two studies comprised of four experiments.

The first study demonstrates asymmetric perseverance of positive affect in two hypothetical brand evaluation exercises.

Experiment one documents the existence of positive contamination when a positive attitude is replaced by a negative attitude, with an absence of negative contamination when the attitude replacement is from negative to positive. Experiment two further documents asymmetrical attitude replacement, finding the same effect when attempts by participants to adjust attitudes to a relative state of ambivalence are unsuccessful after participants are told the positive information that shaped their attitude was false.

The second study investigates the mechanisms underlying asymmetric affective perseverance. Specifically, experiment 3 further tests the theory by demonstrating how asymmetric perseverance of affect is contingent on time trend information. In a simulated task of evaluation based on online reviews, it is assumed that a consumer should be more forgiving of a brand if negative reviews are relatively old, and have been replaced by more recent positive reviews. This pattern should suggest improvement, and therefore less likelihood of regret. The results suggest attenuation of positive contamination when trend information is available. Finally, experiment four lends support to the theory by showing that asymmetrical affective perseverance appears to be a function of cognitive elaboration.

From a big picture standpoint, our theory is interesting because it sheds light on how consumers form attitudes towards brands, when influenced by oppositely valenced information. Our theory is also interesting because it explains inconsistent findings in psychology literature about attitude replacement, which is also relevant to how consumers form brand judgments. Although some research has found that people are successful at discounting previously formed judgments (Golding et al. 1990), other research has found that invalidated information may continue to contaminate future judgments, without the subject being aware (Bekerian and Bowers 1983; Greenwald and Banaji 1995; Lindsay and Johnson 1989).

Mood Matching: The Importance of Fit between Moods Elicited by TV Programs and Commercials

Joseph Lajos, HEC Paris, France

Nailya Ordabayeva, Erasmus University Rotterdam, The Netherlands

Amitava Chattopadhyay, INSEAD, Singapore

EXTENDED ABSTRACT

Previous consumer research suggests that TV viewers have more favorable attitudes toward commercials when they are in a happy mood than when they are in a sad mood. Research has demonstrated this effect with moods induced by commercials themselves (Batra and Stayman 1990; Derbaix 1995; Edell and Burke 1987; Holbrook and Batra 1987) and with moods induced by TV programs in which the commercials are embedded (Goldberg and Gorn 1987; Mathur and Chattopadhyay 1991). This research has revealed two main effects. All else equal, TV viewers like commercials more when (1) they induce happy moods rather than sad moods, and (2) they are embedded in programs that induce happy moods rather than sad moods. These effects are important since attitude toward the ad (A_{Ad}) reliably influences brand attitudes and purchase intentions (MacKenzie, Lutz, and Belch 1986; Madden, Allen, and Twible 1988; Miniard, Bhatla, and Rose 1990; Mitchell and Olson 1981; see Brown and Stayman 1992 for a review), and is the single best predictor of an ad's ability to influence sales (Haley and Baldinger 1991). However, previous research has not examined whether commercials that induce a happy mood elicit more favorable responses compared to those that induce a sad mood, irrespective of whether the mood induced by the program is positive or negative. This is the focus of our research.

In this paper, we propose that when TV viewers watch a program that establishes a mood, they expect to continue experiencing that mood throughout the duration of the TV viewing experience. We draw on research on mood as input to role fulfillment evaluation processes (Martin et al. 1997) to hypothesize that TV viewers have more favorable attitudes toward commercials that support moods established by programs than toward those that break established moods. Our hypothesis leads to the novel prediction that, during a sad program, TV viewers will like sad commercials more than happy commercials.

The results of experiment 1 support our hypothesis. In the experiment, we find that participants liked two sad commercials significantly more when they followed sad program clips than when they followed happy program clips, and liked two happy commercials more when they followed happy program clips than when they followed sad program clips, albeit not significantly so.

A key finding of experiment 1 is that, under some conditions, viewers may actually have more favorable attitudes toward commercials when they are aired during sad programs than when they are aired during happy programs. This finding may initially seem to be at odds with mood as information theory (Schwarz and Clore 1983, 1988), which proposes that people use their momentary affective states as information when making judgments and evaluations, for example by asking "how do I feel about it?" Mood as information theory thus predicts that people will evaluate stimuli more favorably when they are in a positive mood than when they are in a negative mood. However, we assert that the apparent contradiction between our predictions and those of mood as information theory can be reconciled by noting that role fulfillment evaluations are based on an expectation comparison process. Specifically, we hypothesize that role fulfillment evaluation theory makes accurate predictions when people are likely to have mood expectations, whereas mood

as information theory makes accurate predictions when people are unlikely to have mood expectations.

The results of experiment 2 support this hypothesis. In the experiment, we find that, following a sad program clip, viewers who focused on their mood during the TV watching experience liked sad commercials more than happy commercials, whereas viewers who were distracted from their mood during the experience liked happy commercials more than sad commercials. Furthermore, we find that a second focus manipulation administered after, rather than during, the TV viewing experience, did not affect viewers' evaluations, thus providing further evidence that a difference in expectations underlies the aforementioned results.

Our research contributes to theory and practice in three ways. First, we use role fulfillment evaluation theory to identify an effect that is at odds with the recommendations of previous research on the attitudinal effects of moods induced by TV programs and commercials. Second, we identify mood expectations during the experience as a moderating variable, allowing us to reconcile our main result with those of extant research. Third, our results provide guidance to advertising managers who seek either to select a program during which to air existing commercials, or to produce commercials that will be aired during a particular program. Our suggestion that sad commercials can be more effective when aired during sad programs than during happy programs seems to go against common advertising practice. According to Mathur and Chattopadhyay (1991), several major organizations have policies that prohibit advertising during sad programs. Consistent with this, news articles report that many groups have pulled their commercials from sad programs. Based on our findings, we believe that advertising managers should reassess the usefulness of scheduling some commercials during sad programs.

How Mood Moderates the Effect of Context on Product Judgments

Davy Lerouge, Tilburg University, The Netherlands
Yana Avramova, Tilburg University, The Netherlands
Diederik A. Stapel, Tilburg University, The Netherlands

EXTENDED ABSTRACT

Does a restaurant serve meals that are sufficiently large? Is a 640M 2.5GH laptop at \$1300 attractive? How one perceives, evaluates, and judges a product is not only driven by characteristics of the product itself, but also by the context the product is presented in. The size of a gastronomic nouvelle cuisine meal may look ridiculously small on an oversized plate, but sufficiently large when served on a normal sized plate (Wansink and van Ittersum 2006; Wansink, van Ittersum, and Painter 2006). And the same notebook is typically perceived as more attractive when it is the middle option in a choice set than when it is an extreme option (Simonson 1989; Simonson and Tversky 1992). As pervasive and robust as context effects are, however, we predict that mood critically determines the extent to which consumers take the context into consideration when making product judgments.

Our prediction is mainly based on the assumption that mood alters attentional scope as such that positive mood broadens attentional scope to both the target product and context and negative mood narrows attentional scope to the target product only. First support for this assumption is provided by studies using perceptual tasks that contain both broad and narrow visual features. These studies consistently found that happy individuals focused more on the broad feature and sad individuals focused more on the narrow features (Basso et al. 1996; Frederickson and Branigan 2005; Gasper and Clore 2002). In addition, other studies in which participants are asked to focus on a central target and ignore flanking distracters showed that sad participants were less affected by the distracting context stimuli and therefore performed better compared to happy participants (Fenske and Eastwood 2003; Rowe, Hirsh, and Anderson 2007). Finally, Schmitz, Rosa, and Anderson (2009) provided neuroscientific evidence illustrating that mood alters visual cortical responses, such that negative affect decreases and positive affect increases the scope of early perceptual encoding in a visuospatial task.

So, previous research suggests that attentional scope is fundamentally influenced by mood. Therefore, it seems reasonable to predict that happy consumers will rely more and sad consumers will rely less on the context when making product judgments compared to consumers who are in a neutral mood state. We provided support for this prediction with three studies testing the effect of different mood manipulations on a variety of context effects that have been previously observed in consumer behavior.

In the first study, we employed the perceptual contrast effect (based on the Ebbinghaus Illusion task) to find initial evidence for the notion that mood moderates the extent to which product judgments are affected by the context. After we induced mood, we asked participants to estimate the size of a target product (apples, coke cans, bottles of liquid laundry detergent, peanut butter jars) that was surrounded by either larger or smaller versions of the target product. Consistent with our predictions, size estimations of positive mood participants were significantly more and those of negative mood participants were significantly less affected by the surrounding stimuli than those of neutral mood participants. In other words, happy participants were more and sad participants were less susceptible to the Ebbinghaus illusion than neutral mood participants.

In study 2 and 3 we further tested the effect of mood on two well-known and robust context effects in consumer behavior: the

attraction (or asymmetric dominance) effect and the compromise effect. Consistent with our assumption that positive (negative) mood results in more (less) attention to the other products in the choice set, we found that positive (negative) mood resulted in stronger (weaker) attraction and compromise effects compared to the neutral control condition.

Together the current studies provide strong evidence that positive mood strengthens and negative mood eliminates the effect of context on product judgments and refute a depth of processing account as alternative explanation. Instead, we argue that our effects are driven by a shift in attentional scope with positive mood promoting broader attention to both the target and the context and negative mood focusing attention on the target. Study 3 indeed illustrated that the effect of mood on context dependence was fully mediated by attentional scope.

We believe that the effect of mood on context dependence may have ample implications for consumers and decision makers. As long as there is a target product to be judged and a context in which it is presented, the pattern we proposed should hold strong. We would speculate that a sales assistant who is trying to trick us into buying a product by comparing it to a ridiculously overpriced alternative, or a product's television ad featuring poignant music and heart-warming scenes will be more successful if we are in a good, than in a bad mood. Our findings suggest that being happy can make us more susceptible to persuasive communication that relies on the power of context. However, being happy can also be pretty useful. Looking at the top and bottom (and left and right) shelves in the supermarket can save you money, and make you discover new and potentially better product alternatives.

Responses to Animal Anthropomorphism in Advertising Based on Character Similarity to Humans

Paul M. Connell, Stony Brook University, USA

EXTENDED ABSTRACT

Throughout civilization, people have imbued creatures from the natural world with human traits and motivations. Marketers have capitalized on this tendency by creating a plentitude of anthropomorphic animal mascots for a variety of products and services. Yet, research examining anthropomorphism on consumer behavior is sparse. The purpose of this research is to understand which types of animals are portrayed anthropomorphically most often in marketing communications (based upon their perceived similarity to humans) and how consumers' attitudes are affected by such anthropomorphism.

Anthropomorphism is the process of assigning real or imagined human characteristics, intentions, motivations, or emotions to nonhuman objects, often motivated by explaining and understanding the behavior of those nonhuman agents (Epley, Waytz, and Cacioppo 2008). People do this with a seemingly unending array of things, including brands and television characters, to the extent that they sometimes form parasocial relationships with them (Fournier 1998; Russell, Norman, and Heckler 2004). Instead of leaving it up to individuals to anthropomorphize objects of consumption, marketers often create advertising mascots with the express intent of imbuing them with personality characteristics, in a sense anthropomorphizing the brand for the consumer (Aaker 1997).

Individuals help to make sense out of their world by organizing things in categories. Each category and subcategory has mental prototypes. Objects are stored in memory around these prototypes by both their similarity to the prototype and their similarity to other items in the category (Tversky 1977). People seem to be particularly adept at categorizing animals. Henley (1969; see also Tversky 1977) devised a study asking participants to rate the similarity of 30 familiar animals to each other. The results were plotted on a cognitive map where the animals that were perceived to be most similar to each other were closer to one another (i.e., closer in psychological distance) on the cognitive map. While Henley (1969) interpreted this cognitive map as having two axes of size and ferocity, one could also interpret this cognitive map as indicating each animal's similarity to human beings. I characterize these animals as highly similar to humans (e.g., non-human primates such as monkeys and gorillas), moderately similar to humans (e.g., carnivorous animals such as lions and wolves as well as rodents and rodent-like animals such as rabbits), and relatively dissimilar to humans (e.g., hooved mammals such as horses, goats, and deer). Results from a pilot study support this categorization.

A large body of research has converged on the finding that people like similar others, possibly due to an increased motivation to process information about close others (Aron, Aron, Tudor, and Nelson 1991). The foundational work in this literature stream was built on attitude similarity (Byrne 1971; Byrne, Clore, and Smeaton 1986; Heider 1958). This research has been subsequently extended to domains such as similarity in personality traits (Tesser and Campbell 1980; Tesser and Paulhus 1983) and biological characteristics (Chen and Kenrick 2002). Miller and colleagues (1998) found that even trivial similarities, such as a shared birthday, cause people to view others more favorably. In extending this similarity-attraction principle to animal images, the most obvious prediction would be that high-similarity animals would be viewed more positively than moderate-similarity animals, which would in turn be viewed more positively than low-similarity animals. Furthermore, all types of

animals should be viewed more positively when presented in anthropomorphic form due to heightened levels of similarity to humans.

However, researchers have found that construal level can moderate the relationship between similarity and attraction. Less similar objects, because they are psychologically more distant, are construed at higher, more abstract levels (Liviatan, Trope, and Liberman 2008). Likewise, higher similarity leads to lower-level, more concrete construals. Thus, it is possible that nonanthropomorphic images of all animals would be assigned more abstract representations, such as "animal." Therefore, due to lower similarity to humans among all animal types in nonanthropomorphic portrayals, there may be little or no preference for highly similar animals over less similar animals. However, because greater similarity leads to more concrete construals with more focus on secondary features, it is possible that anthropomorphizing animal images increases salience to the differences between the high, moderate, and low similarity animals, thus leading to differences in preference for anthropomorphic images but no preference among nonanthropomorphic images.

Additionally, Chen and Kenrick (2002) found that increasing similarity for outgroup members can have a more powerful effect on liking than increasing similarity for ingroup members. The authors argue that these effects are driven by lower levels of baseline similarity, and thus liking, in outgroups. Thus, enhancing similarity leads to a positive violation of expectations and increased attraction that does not occur for ingroups, whose baseline similarity is already high. In the context of this research, relatively dissimilar animals would have lower baseline similarity to humans, whereas moderately similar animals would have higher baseline similarity to humans, and highly similar animals would have the highest baseline similarity to humans. Therefore, it is possible that relatively dissimilar animals would benefit more from anthropomorphism than moderately similar animals, which would in turn benefit more from anthropomorphism than highly similar animals.

The purpose of this research is to explore how anthropomorphized animal images are used in marketing communications and how consumers respond to them based on their similarity to humans. Findings of content analyses indicate that animals that are perceived to be moderately similar to humans are more frequently used as anthropomorphic mascots than animals that are either highly similar or relatively dissimilar to humans. However, results from an experimental study indicate that, while participants are indifferent between animal types when they are presented non-anthropomorphically, relatively dissimilar animals gain the most in terms of attitude favorability when presented anthropomorphically. I argue that these results are driven by a lower level of baseline similarity to humans in the nonanthropomorphic form. Thus, enhancing similarity to humans via anthropomorphism leads to positive violation of expectations and enhanced attraction toward relatively dissimilar animal images. Consequently, animals that are relatively dissimilar to humans might be underutilized as anthropomorphic spokescharacters.

Brand Anthropomorphization: A Homocentric Knowledge Activation Perspective

Marina Puzakova, Drexel University, USA
Hyokjin Kwak, Drexel University, USA
Trina Larsen Andreas, Drexel University, USA

EXTENDED ABSTRACT

We describe a four-stage process of brand anthropomorphization, which begins with primary cognition and proceeds through secondary cognition stages. Two types of anthropomorphized brands perceptions are formed—one that is transient and one that lasts longer. Stronger forms of brand anthropomorphization, going beyond brand personality attribution (e.g., weaker forms), exist.

Consumers' perceptions of brands as human may have important implications in the area of branding. At present, we do not know much about the process that influences the degree to which consumers perceive brands as complete human beings. Social science researchers have considered anthropomorphization an automatic psychological process that does not vary among individuals, and marketing researchers who have explored the notion of humanized brands (e.g., brand personality), have also considered the process as a chronically occurring consumer judgment (Fournier 1998). However, the anthropomorphization theory introduced by Epley et al. (2007) posits that the tendency to anthropomorphize objects is a phenomenon varying in strength depending on different domains, contexts, and individual differences.

This research contributes to the literature in the following three manners. First, we fill a gap in the marketing literature by extending consumers' perceptions of brands as fully human, instead of as merely possessing personality traits. We show that consumers consciously report their anthropomorphic perceptions of brands and behave toward them as if they, in fact, possess human traits. Second, we go beyond the idea that anthropomorphism is explained by the qualities of the target (i.e., morphological features of a product (Aggarwal and McGill 2007)) and show that the characteristics and motivations of perceivers are an important component of the process of anthropomorphization. Third, we introduce a process of brand anthropomorphization. Finally, we delineate the outcomes of the brand anthropomorphization process for consumer behavior.

Deriving our argument from related research in social and neuropsychology, and from the results of in-depth interviews (8 focus-group interviews (n = 21) and three one-to-one in-depth interviews), we posit that the process consists of two phases: a) primary cognition and b) second-order cognition. In the first phase, we argue that the concurrent activation of human knowledge (i.e., highly accessible and salient brand personality attributions) and a strong emotional arousal triggered at a specific moment of consumer-brand interaction make individuals anthropomorphize brands. Amygdala, the neural structure in the brain, participates in both emotional processing and complex social judgments, including anthropomorphism (Heberlein and Adolphs 2004). Thus, the processing of social information and emotionally arousing stimuli are causally related. In fact, we observed that respondents experienced strong emotional arousal at their first encounters with brands, and, concurrently, they possessed accessible social (e.g., brand personality) knowledge about the brands that they perceived in human terms. A less stable initial perception of anthropomorphized brand (AB) is formed at the end of the primary cognition stage.

In the secondary-order cognition (metacognition) stage, a more enduring perception of AB is formed. At the metacognition phase, individuals evaluate their initial judgment and identify their thoughts as favorable or unfavorable (Petty et al. 2007). When consumers find that their AB perceptions are favorable or desirable, they will be motivated to refine their existing thoughts of afferent AB. We define

the refinement process of afferent AB as the process through which consumers engage in more complex attribution of human capabilities to the initial afferent AB judgment. The relevant literature and the results of in-depth interviews have shown that AB refinement agents such as sociality motivation, effectance motivation, and brand love-dependency operate as drive states which facilitate the perception of brands as human. In turn, high cognitive capacity leads to the correction of the initial perception of brand as a transient human to the perception of brand as a commercial entity.

In the refinement stage, we find that consumers project mind, intentions, emotions, and spirit to brands. Consumers also show signs of parental solicitude by viewing their brands as little brother or son. That is, individuals feel the desire to treat a brand with the same social conventions that they would give to another human. The fourth stage ends with the formation of stable, long-lasting perception of brand as a human. Finally, AB perceptions have important theoretical and practical implications. Specifically, consumers who anthropomorphize their brands trust the brands more, expect higher performance, forgive the brands' transgressions as they would forgive a friend, care for them with parental solicitude, and are willing to spend extra for brands' accessories. Brands also consciously affect consumers' manner to behave. Deeper understanding of the nature of anthropomorphic brand judgment presents rich material for more effective marketing communications.

This is an exploratory, qualitative study, and future research should further empirically test the process presented across a wider variety of respondents. We believe that the theory of anthropomorphism may be extended by incorporating the activation of not only human knowledge structures but also self-knowledge representations. We also believe that there are additional avenues for future examination regarding how specific marketing communication efforts may impact consumers' perceptions of brands as empathic or moral and, subsequently, influence further inferences regarding brands in human terms.

Emotional Anthropomorphism: What Kind of Face Sits Well on a Car's Frontal Appearance?

Jan R. Landwehr, University of St. Gallen, Switzerland

Bernd Weber, University of Bonn, Germany

Andreas Hermann, University of St. Gallen, Switzerland

EXTENDED ABSTRACT

While there is an increasing body of research on the effects product design and its aesthetics unfold on consumers' behavior (e.g., Bloch 1995; Chitturi et al. 2007, 2008) the specific aspect of anthropomorphism as a guideline for designers has only attracted scattered attention in the scientific study of product design (Aggarwal and McGill 2007). This is astonishing since it is well known that the human face poses an evolutionary highly relevant stimulus configuration that is processed faster and with more attention than most other stimuli in the environment (Mondloch et al. 1999). Both these characteristics constitute basic marketing aims (Pieters and Wedel 2004).

Although scientific insights into the specific mechanisms underlying anthropomorphism are only scattered, this concept seems nevertheless to enjoy at least in the domain of car design a high popularity among practitioners. In a detailed exploration of several car designs and based on interviews with car designers Welsh (2006) for example reaches the conclusion that in practice the analogy between human faces and car fronts is a widespread source for inspiration and used by almost all car makers as an orientation for their designs. While it is appealing to rely on this simplified heuristic and go ahead with designing anthropomorphized cars, it nevertheless leaves open some questions that are both from a theoretical as well as from a practical point of view critical. The present research is aimed at providing insights into detailed aspects of anthropomorphizing on a process level and employs the neuroscientific method of fMRI to shed light on the involved mental processes. Answers to three major questions regarding the specifics of anthropomorphism are intended to be answered by the present research endeavor.

First, whether the reference to human faces is suited to guide a company's design strategy or whether it is just a scientific construct that is pulled on the shapes that actually unfolds its effect independently of any emotional interpretation. We found evidence in the neuronal activation pattern that the perception of car and human faces leads to a considerable correspondence in neuronal activity which suggests more of an effect for anthropomorphism than a simple descriptive metaphor that conveys placement and shape of the car's features. Our findings suggest that people do indeed see cars as having facial expressions in a way that goes beyond simple descriptive metaphor.

Second, the question whether different kinds of faces (male vs. female) are equally suited to serve as an inspiration to design a product with the aim of increasing its liking. We found that liking of car faces and female faces can be traced back to similar patterns of activation in the reward circuit while male faces are (at least by male participants) judged on a different basis. In addition to the insight that there are many different kinds of faces and one is well advised to think about anthropomorphism in a more detailed way, this finding also offers some initial hints for the clarification of the underlying motives for a peoples' preference for certain car designs. In particular, one can clarify whether people are searching for a design that allows them to express themselves in a desired way; thus, literally using the car front as a kind of mask for themselves or whether they simply strive for the most attractive or aesthetically appealing design, respectively. Because car fronts activate the reward circuit in a similar way as female faces do, it is unlikely that

our exclusively male participants are willed to use a car as a way to express themselves. In contrast, as men like female faces better than male faces, are longer looking to them and appreciate them according to their attractiveness (Levy et al. 2008), the similarity in processing indicates that car fronts cause a feeling of reward directly due to attractiveness and not mediated by semantic associations.

Finally, the third question asks for the best liked combination of friendliness and aggressiveness in a car's front. Our findings allow the recommendation to give the grille a friendly expression whereas the headlights should rather look aggressive. From a theoretical perspective it is very interesting to notice that this preference pattern was found both in the reward circuit as well as in the observed behavioral pattern. This points to the conclusion that this specific combination of emotions unfolds a rather direct impact on preference without complex or sophisticated mental processes mediating this relationship. That is, people seem to have an initial preference for this combination of emotions rather than having to think intensively about the potential meaning of these emotions. Further research is however needed to clarify the exact nature of the underlying mental mechanism to better understand this result.

Cars do have a face—this is the answer to the central question posed at the outset of this research project. The remarkable similarity in processing human faces and car fronts indicates that the anecdotal evidence gathered by Welsh (2006) has a substantial basis and is suited to serve as a valuable source for inspiration when it comes to design a new car front. This result enables a more intense application of insights gathered in the domain of human facial attractiveness and, thus, to tap so far unused potentials. Especially proportions that constitute an attractive female face seem to be suited to optimize a car's front to please the eyes of the beholder.

Product Involvement vs. Product Motives as Moderators of the Effects of Ad-evoked Feelings: An Analysis of Consumer Responses to 1,100 TV Commercials

Maggie Geuens, Ghent University and Vlerick Leuven Gent Management School, Belgium

Michel Tuan Pham, Columbia University, USA

Patrick De Pelsmacker, University of Antwerp, Belgium

EXTENDED ABSTRACT

Many studies have shown that ad-evoked feelings have a positive influence on consumers' brand attitudes (e.g., Brown, Homer and Inman 1998; Burke and Edell 1989, Holbrook and Batra 1987). While these effects of ad-evoked feelings thus seem well established, three things are striking: (1) the limited pool of ads in each study, raising issues of selection bias (e.g., Aaker, Stayman and Hagerty 1986, Burke and Edell 1989, Stayman and Aaker 1988), (2) the fact that unknown brands are often used (e.g., Burke and Edell 1989, Derbaix 1995, Miniard et al. 1991), and more importantly, (3) the fact that product category effects are not considered, even though academics and advertising practitioners generally assume that the effectiveness of emotional advertising appeals depends on the product category (e.g., Adaval 2001, Batra and Stephens 1994, Johar and Sirgy 1991, Malhotra 2005, Morris et al. 2002, Rossiter, Percy and Donovan 1991). The purpose of this research is to revisit the role of feelings on brand evaluations using a much more comprehensive and representative set of existing commercials (addressing the issue of potential selection bias, fictitious ads and unfamiliar brands) and testing whether these effects depend—as previous experimental lab research would suggest—on the level of involvement and the type of motives, hedonic versus utilitarian, associated with the product category.

Although a dual role of affect has been theorized by several researchers in the sense that ad-evoked feelings automatically transfer to brand attitude under low involvement, whereas under high involvement feelings are assumed to impact brand attitudes by biasing brand cognitions (e.g., MacInnis and Park 1991, Miniard et al. 1991, Petty et al. 1993, Olsen and Pracejus 2004), other researchers suggest that emotional advertising works better for low than for high involvement products (e.g., Lautman and Percy 1984, Morris et al. 2002, Rossiter et al. 1991). Indeed, it is a classic prediction of dual-route models of persuasion such as the ELM (Petty and Cacioppo 1986) that feelings should have lower influence on persuasion under conditions of high elaboration likelihood than under conditions of low elaboration likelihood. Our studies will test whether this theoretical prediction holds when the source of involvement comes from the product category being advertised rather than from an external manipulation, as in typical persuasion research.

Another stream of research on the effects of affective states in consumer judgments and decisions suggests that affect is more likely to be relied upon when consumers have hedonic motives than when they have utilitarian motives (Pham 1998)—a finding that has been replicated in multiple subsequent studies (e.g., Adaval 2001, Yeung and Wyer 2004). According to a feeling-as-information explanation (Schwarz and Clore 1983, 2007; Pham 1998), this is because feelings are perceived to be more relevant in light of hedonic/experiential motives than in light of instrumental motives. This finding raises the question of whether similar moderating effects would occur in typical advertising exposure settings when the type of motives comes not from an external manipulation (as in previous studies) but simply from the product category being advertised.

Therefore, previous experimental laboratory research makes very clear predictions about the moderating effects of involvement and types of motives on the effects of feelings on attitudes and evaluations. However, it is not clear whether these predictions would

hold in typical ad exposure settings where the primary source of involvement or type of motives is not an experimental manipulation, but merely the product category being advertised. The purpose of this research is thus to submit these two lab-derived theoretical predictions to a large-scale “external reality check.”

Study 1 examines how the emotions evoked by 413 TV commercials (featuring 294 different brands across 93 different product categories) influence the brand evaluations of a representative set of 907 adult consumers. Each respondent evaluated a set of about 20 commercials and each commercial was evaluated by 40 to 60 respondents. After seeing each commercial, respondents rated their (1) attitude toward the ad (Aad) (3 items, $\alpha=.96$), (2) their cognitive assessments of the ad's content (2 items, $\alpha=.90$), and (3) their attitudes toward the advertised brand (Ab) (2 items, $\alpha=.86$). These Aad, cognitive assessments (CogAss), and Ab responses were averaged across respondents for each ad to form 413 aggregate ad-level dependent-variable observations. The emotional content of each ad was assessed on a 15-item emotional scale by an independent group of 12 judges who were blind to the study's hypotheses ($\alpha=.97$). To control for the possibility that ratings of emotional responses to the ads may reflect some other aspects of the ads, such as their originality or creativity, the same 12 judges also rated all the ads in terms of their originality (5 items, $\alpha=.99$). Finally, the 93 product categories represented in the ads were coded by another set of six judges. This second set of judges were given the names of the product categories and asked to rate them on 5 ‘product category involvement’ items ($\alpha=.94$) and 5 ‘utilitarian/hedonic product motive items’ ($\alpha=.95$). Inter-judge reliabilities were high for all items and for all judges.

The results of a series of regressions show that, even after controlling for respondents' Aad and cognitive assessments of the ad and for the ads' originality, the emotional content of the ads had a significant positive influence on consumers' brand attitudes ($\beta=.236, t=4.93, p<.001$). Further, the results suggest that, contrary to what one would predict based on a peripheral-route explanation of affective influences, the effects of emotions on brand attitudes did not depend on the level of involvement associated with the product category ($\beta_{\text{Emotion} \times \text{Involvement}}=.014, t<1$). However, the effects of emotions on brand attitudes were significantly moderated by the type of motivation associated with the product categories ($\beta_{\text{Emotion} \times \text{Hedonic}}=.112, t=3.03, p<.01$).

A second study was carried out (1) to assess the robustness and generalizability of the first study's findings, and (2) to address a limitation of the first study by controlling for brand familiarity effects. To this end a different set of 687 TV commercials were evaluated by a different sample of 427 consumers, keeping the design and methodology largely identical to Study 1. This time the impact of the emotional content of the ad on consumers' brand attitudes was fully mediated by Aad. However, the results concerning the product category motivational factors remained identical as in Study 1. Again product involvement did not and utilitarian/hedonic product motive did moderate the impact of emotional ad content on brand evaluations. The latter finding is consistent with recent theoretical suggestions that the selective reliance on feelings as a function of their relevance is quite flexible (Pham 2004).

The Variety Paradox. Why LESS Evokes MORE

Anne Klesse, Maastricht University, The Netherlands

Kelly Geyskens, Maastricht University, The Netherlands
Ko de Ruyter, Maastricht University, The Netherlands

EXTENDED ABSTRACT

Conceptualization

Nowadays, consumers are used to being spoiled with choice: Most retailers offer an abundance of product variants since they acknowledge that consumers prefer stores that provide large assortments. Some stores, however, (strategically) form an exception. For instance, convenience stores trade fulfilling consumers' need for convenience against their wish for variety. Accordingly, choice is limited to one or two kinds per product category. In this research we examine whether consumers behave differently when facing low-variety assortments compared to high-variety assortments. In particular, we intend to find out whether they will include more variety in their subsequent choices to make up for the perception of limited choice triggered through low-variety assortments.

Although consumer researchers have extensively studied the effects of assortment breadth on choice making (Chernev 2003; Gourville and Soman, 2005; Iyengar and Lepper, 2000; Kahn and Wansink, 2004; Sela et al., 2009), they have focused on choice-specific effects within the assortment. They neglected general motivational effects that are triggered through looking at the assortment, linger on, and influence subsequent decisions from different choice sets. We know from psychological research that providing choices determines consumers' feelings of autonomy (Deci and Ryan, 2000). Being able to choose from various options enables consumers to express themselves as individuals (Kim and Drolet, 2003) and boosts happiness (Patall, 2008). On the contrary, situations perceived as restricting one's option to choose freely arouse reactance (Brehm, 1966), a motivational state that triggers behavior aimed at reasserting one's personal freedom (Wicklund, 1974).

Accordingly, we propose that low-variety assortments trigger the perception of limited choice and evoke reactance. Once the motivational state of reactance is aroused consumers are increasingly interested in behavior that functions as a means to regain their freedom. Levav and Zhu (2009) showed that spatially confined consumers engage in more variety seeking in order to reassure their personal freedom. Thereby, they demonstrated that variety seeking behavior constitutes a means to deal with reactance. Hence, we predict that low-variety assortments trigger subsequently more variety seeking than high-variety assortments since they evoke the need to offset the perception of limited choice.

Studies

The validity of this prediction is tested in five studies. In the first study (N=94) we manipulated the variety that participants saw before making a subsequent, seemingly unrelated choice. They saw either three (low variety) or eight (high variety) different chips flavors. Afterwards, they chose five snacks out of a five item choice set as a reward for their participation. We measured variety seeking behavior through the number of different snacks that participants chose. Consistent with our hypothesis participants sought significantly more variety after seeing the low-variety assortment than after seeing the high-variety assortment.

The objective of study 2 (N=68) was to test the robustness of the effect by varying the nature of the stimuli. We used a print advertising depicting chocolate. Second, we kept the overall number of items equal across conditions: both advertisings showed

twelve chocolate bars and differed only in the variety of different flavors they showed (3 vs. 12). The results confirmed our previous finding: Participants who saw the low-variety advertising sought significantly more variety.

We use reactance theory to explain the underlying process of our finding. The objective of study 3 (N=67) was to test the effect of reactance directly by measuring participants' chronic reactance tendencies. As predicted participants' chronic reactance tendency interacts with the variety manipulation. This suggests that reactance is the underlying psychological factor driving the effect. The effect of the variety manipulation was accentuated for highly reactive individuals and attenuated for weakly reactive individuals.

We claim the perception of limited choice to be responsible for evoking more variety seeking. The objective of study 4 was to test this by deliberately manipulating the perception of limited choice. Hence, this study made use of three conditions: one low-variety condition and two high-variety conditions. One of the high-variety conditions (high-confined) showed some items crossed out indicating that they are no longer available. This evokes the perception of limited choice. The results showed that participants in the low-variety and high-confined condition did not significantly differ from each other in their variety seeking behavior. However, both sought significantly more variety than the high-variety condition. This implies that the perception of limited choice is responsible for evoking a heightened need for variety.

While the previous studies demonstrate the effect in laboratory conditions, study 5 intended to replicate our findings in a real purchase context, i.e. the coffee shop at the university. One day we put up advertisings showing a low-variety of pastries in the while on another day we used advertisings showing a high-variety of pastries. We compared students' variety seeking behavior on the two days. Thereby, we defined variety seeking not as taking several different products but as trying out something special. Students tried out significantly more special coffees when they saw the low-variety advertising while they chose more normal coffee kinds when they saw the high-variety advertising.

General Discussion

Across five studies we show that facing low-variety assortments compared to high-variety assortments evokes subsequently more variety seeking. This is grounded in reactance theory: Low-variety evokes the perception of limited choice and triggers reactance. Accordingly, consumers experience the heightened need to reassure their threatened freedom and engage in variety seeking behavior.

Our findings hint at a 'variety paradox'. Although retailers offer high-variety to cater consumers' needs for variety, less variety is more effective in triggering subsequent variety seeking. Our findings provide some interesting guidelines for retailers and convenience stores: It is important to acknowledge that assortment variety triggers motivational states which prevail and affect consumers' subsequent behavior. For instance, in stores where the assortment is limited facing the first shelves evokes the perception of limited choice and triggers consumers to seek more variety. These stores could cater this need by providing more variety in the following shelves or offering specialities, new or lesser known brands. Consumers' desire to express themselves through their

choice will increase the likelihood of choosing several different items or trying out new products.

The Impact of Assortment Variety on Inferences and Purchase Intentions

Chrissy Mitakakis, Baruch College, USA

Thomas Kramer, Baruch College, USA

EXTENDED ABSTRACT

Consumer inferences play an important role in marketing (see Kardes, Posavac, and Cronley 2004 for a review). For example, consumers often use observable product attributes to judge unobservable ones, such as inferring product quality based on its price (e.g., Huber and McCann 1982), warranty period (Srivastava and Mitra 1998), or country of origin (Teas and Agarwal 2000). However, although research has shown that consumers may indeed often rely on observable attributes or the overall product evaluation (e.g., Broniarczyk and Alba 1994) when evaluating products, we currently do not know if, or more specifically, under which conditions, consumer inferences of product quality are based on retailers' assortment variety. This lack in the literature is even more surprising given that assortment variety differs greatly across stores.

Based on our proposition of the existence of a lay theory suggesting that retailers with larger product assortment variety cannot know much about the quality of any one product and hence offer lower quality product selections overall, we identify a "jack-of-all-trades-master-of-none" inference strategy as a tool employed by consumers when evaluating a product. That is, although normatively quality perception of a product should not differ according to the variety of other noncomparable products sold in the store, we propose that consumers are likely to rely on the degree of variety of a retailer's assortment for quality inferences, which in turn will drive purchase likelihood. Furthermore, because we expect that the "jack-of-all-trades-master-of-none" inference requires cognitive resources, purchase likelihood and quality perceptions based on this lay theory should be limited to those consumers with available cognitive resources.

To examine the proposed lay theory consumers have regarding the presence of noncomparable products, we investigated the effects of the size of the assortment of noncomparable products in the purchase environment on consumers' evaluations of a target product. For our first study, we told participants that they were shopping for a toothbrush that was found in an assortment with either three or twenty noncomparable products (such as household cleaners, food items, etc.). Since we expect the proposed inference strategy to be employed only when consumers have the cognitive resources to do so, we also varied some participants' cognitive resources with a cognitive load task. After the presentation of the hypothetical shopping scenario, we assessed participants' likelihood of purchasing that product. Our results support the hypotheses that consumers use a "jack-of-all-trades-master-of-none" inference strategy, and thus are more likely to purchase a product when it is found in a small (vs. large) assortment variety. However, as hypothesized, this effect occurs only with participants who have the cognitive resources available.

We extend our findings with our second study, and also demonstrate that use of the "jack-of-all-trades-master-of-none" inference is moderated by the level of comparability of other products in the assortment. More specifically, participants were told that they were shopping for a notebook that was found in an assortment of either three or twenty comparable or noncomparable products. Similar to study 1, we also varied participants' cognitive resources. Consistent with our hypothesis, we found that the extent of comparability of the other products in the assortment moderated consumers' use of the "jack-of-all-trades-master-of-none" inference.

In our third study, we sought to find process evidence for our proposed inference strategy, and to demonstrate that differences in

quality perceptions drive the effect of assortment variety on purchase likelihood. We told participants that they were shopping for a digital camera that was found in an assortment variety of either three or twenty noncomparable products. In addition to purchase intentions, we also examined participants' quality perceptions of the digital camera. Analyses show that quality perceptions drive the effect of assortment variety on purchase intentions. In particular, participants were more likely to purchase the digital camera and had higher quality perceptions of the digital camera that was part of a small (vs. large) assortment variety. Quality perceptions fully mediated the effect of assortment variety on purchase likelihood.

In sum, we were able to provide evidence for a "jack-of-all-trades-master-of-none" inference strategy that consumers use. We found that consumers use this inference when evaluating products that are found in assortments of noncomparable products, suggesting that it is variety, and not size, of the assortment that drives this lay theory. We showed that consumers were more likely to purchase an item when it was found in a small (vs. large) assortment variety. Since we argued that use of this inference would require cognitive resources, we did not expect to find this inference to be utilized when consumers were under cognitive restraint. Furthermore, we provide evidence that it is the level of comparability of the other items in the assortment, and not merely the size of the assortment variety itself that drives consumers to use the "jack-of-all-trades-master-of-none" inference. Lastly, we provide support that shows how the relationship between assortment variety and purchase intent is mediated by consumers' quality perceptions.

Improving the Power of Switching Intent to Predict Actual Switching Behavior-A Construal Level Theory Perspective

Yu-chen Hung, National University of Singapore, Singapore
Catherine Yeung, National University of Singapore, Singapore
Jochen Wirtz, National University of Singapore, Singapore

EXTENDED ABSTRACT

Recent research has shown that repurchase intent is often not a good predictor of actual repurchase. A number of reasons for this discrepancy have been suggested in the literature, but have not been examined empirically. We propose that one critical distinction between switching intention and actual switching is that the former is a response to a hypothetical situation, whereas the latter is an action that is actually carried out. Recent behavioral research on construal level theory (CLT, see Trope and Liberman 2007 for a review) shows that when an event feels psychologically far away (e.g., when the event is going to happen in the distant future, is socially distant, or is hypothetical), people tend to focus on “central” aspects of the event—i.e., aspects that give direct implications to the desirability of the event. According to CLT, these aspects constitute the “higher level construal” of the event. On the other hand, when an event feels psychologically near (e.g., when it is going to happen in the near future, is socially near, or when is not hypothetical), people tend to focus on aspects that are associated with the procedures involved in carrying out the action (e.g., practicality, feasibility considerations). These aspects constitute the “lower level construal” of an event.

We first conducted a longitudinal study surveying cell phone service subscribers of all three providers in a city state. This approach allowed us to measure satisfaction and other attitudinal variables and switching intent in one period, and subsequently observe actual switching behavior in the next period. The survey was conducted in six waves over a 24 months period.

Monetary switching costs (e.g., penalties for switching during a contractual period) and non-monetary switching costs (e.g., the hassle of going to the service provider to cancel the contract, signing up for a new contract, potentially changing cell phone number) feature highly in switching cell phone service switching. Based on CLT, we expect that monetary switching costs, which are closely related to the desirability of switching, constitute a higher level construal, whereas non-monetary costs constitute a relatively lower level construal of switching. According to CLT, consumers are likely to focus on desirability-related aspects and underestimate the importance of other feasibility-related considerations when they respond to hypothetical situations—to this extent, monetary costs, but not non-monetary costs, are likely to serve as a basis for their response to intention questions. Moreover, non-monetary costs will be taken into account only when consumers consider carrying out actual switching.

The findings of our longitudinal study confirm this hypothesis, to the extent that the non-monetary switching cost main effect and its interaction effect with satisfaction are insignificant in predicting switching intent. However, for actual switching behavior, the non-monetary switching costs effects explain more variance than the equivalent effects of monetary switching costs. This finding suggests that while non-monetary switching costs are important determinants of actual switching behavior, they may not be taken into consideration when consumers report their switching intention.

We then conducted a series of experiments to directly test the CLT and demonstrate how the consideration of non-monetary costs can be facilitated when consumers respond to intention questions. Specifically, recent research has shown that process simulation (i.e., asking respondents to visualize the step-by-step process of carry-

ing out a certain action) highlights the feasibility-related aspects of an event and encourages a lower-level construal of the event (Zhao, Hoeffler and Zauberan 2007). We therefore predicted and found that when process simulation is employed in surveys, it can potentially reduce the inconsistency between responses to intention measures and actual switching behaviors. Our findings suggest the possibility of an unobtrusive administration of this procedure in surveys that will improve the predictive power of intention measures of actual switching behavior. These findings have potential applications beyond the immediate switching behavior application to any intent-actual behavior measurement context.

Can Thinking Abstractly Help Choosing From Large Assortments?

Jing Xu, Peking University, China

Zixi Jiang, Peking University, China

Ravi Dhar, Yale University, USA

EXTENDED ABSTRACT

A visit to the supermarket attests to the large assortment or variety in almost any product category. Recent research shows findings for the negative effects of assortment size and relies on the assumption that choosing from large assortments involves making more trade-offs among the competing advantages and disadvantages and thus making decision makers generally worse off. Prior research has shown that an increase in the assortment size is accompanied with an increase in choice difficulty, and consequently a decrease in choice satisfaction (Chernev 2006; Iyengar and Lepper 2000).

Besides number of options in the assortment, choice conflict depends on whether the attribute differences among assortment options are seen as linked to competing goals or seen as servicing the same goal. Specifically, a consumer may experience greater conflict when the options in an assortment are seen as more dissimilar and being linked to different goals. This is because the more dissimilar are the alternatives to each other, the more distinct dimensions are considered and compared and require more difficult trade-offs to be made (Shugan 1980). On the contrary, a consumer may find choice less difficult to make when the attributes of the assortment options are seen as servicing the same objective and options appear to be more similar to one another. Thus, holding constant the assortment options, changes in similarity perception could affect levels of difficulty and satisfaction experienced in the choice process. This paper examines how changes in mental representation of choice options in large assortments affect similarity perceptions, and subsequently influence choice difficulty and outcome satisfaction. We propose that when choosing from large assortments, consumers who represent the options at a higher level are likely to engage in higher-level, alternative-based evaluations and perceive alternatives in a single category as serving the same higher order goal and thus more similar and substitutable to one another. In contrast, consumers who represent options at a lower level will focus on lower-level, feature-based trade-offs and perceive alternatives as attaining different competing sub-goals and thus more dissimilar and unsubstitutable to one another. This reliance on feature level comparisons heightens the level of conflict and choice difficulty experienced when choosing from large assortments. Here, we stress that similarity perceptions of options in a large assortment made by different levels of representations are construed at different levels. Specifically, whereas a higher level of representation finds options in a single category more similar in terms of serving the same consumption goal and providing similar benefits, a lower level of representation perceives options as more dissimilar to one another with respect to the attribute level difference.

Therefore, we hypothesize that when choosing from a large assortment, individuals who represent assortment options at a higher level experience less choice difficulty and more satisfaction with the chosen option than those who represent options at a lower level. Consistent with our proposition, three experiments demonstrated that, when facing large assortments, participants activated with a higher level of representation found options in an assortment more similar to one another, experienced less difficulty while choosing, and reported greater satisfaction with the chosen option than those activated with a lower level of representation.

Experiment 1 tests the effect of mental representations of the choice set on choice difficulty and satisfaction in a real choice scenario involving small versus large assortments. Experiment 1

found that, when facing a large assortment, consumers who represent options at a lower level find options more dissimilar to one another and competing for different sub-goals. As a result, they considered more distinct dimensions, made more comparisons, and consequently experienced more difficult trade-offs. On the other hand, representing options at a higher level makes the options in large assortment seen as more similar, less diversified, more substitutable in satisfying the same consumption goal, and consequently experiences less conflict and less difficult trade-offs. Indeed, our mediated moderation analysis show that perceived similarity among options mediated the moderating effect of mental representation of options on assortment size and choice difficulty.

To provide a stronger test of our argument, we next explicitly manipulate the perceived similarity among options in Experiment 2 and Experiment 3. Experiment 2 manipulates perceived similarity with same-colored plates vs. different-colored plates for candy options. Since different-colored plates highlights the differences among options, consumers with lower level of representation in such condition perceive greater dissimilarities among choice options and engage in more trade-off comparisons than when candies displayed in same-colored plates. Consequently, consumers with lower level of representation experience greater degree of difficulty and less satisfaction with the chosen outcome when candies displayed in different-colored plates than in same-colored plates.

Experiment 3 manipulates perceived similarity with assortment structure. Whereas choosing from feature-based categories highlights the differences among options and would lead to more trade-off difficulty and less satisfaction, choosing from benefit-based assortments focuses on the similarities among options and would lead to less choice difficult and greater satisfaction with choice outcome. The results show that choice difficulty experienced by consumers with a lower level of representation is mitigated when perceived similarity among items increases in benefit-based assortment structure. As options are perceived as more similar to one another in a large assortment, they are seen as more substitutable and servicing the same consumption goal.

The present paper contributes to the existing literature in two important ways. First, our research provides new insights into the ways in which levels of mental representations affect choice making process and choice consequences in large assortments. Second, we provide new perspective of the role of similarity perceptions in comparisons and choice process. Particularly, we show that different levels of representation construe similarity perceptions differently. Our results also provide important implications for marketers. Although recent research on assortment size has generally concluded that large assortments lead to increased choice difficulty and decreased satisfaction, marketers can improve choosers' experience and satisfaction with large assortments by altering the level at which assortment options are represented.

Price-Based Expectations

Ayelet Gneezy, University of California at San Diego, USA
Uri Gneezy, University of California at San Diego, USA

EXTENDED ABSTRACT

Consumers often lack the time, training, or inclination to judge the quality of a product. Consequently, to infer quality, they seek simpler alternative signals (cf. Aaker 1991), such as the product's country of origin, how heavily it is promoted (Raghubir 1998), or, most relevant to the current paper, its price.

Considerable evidence demonstrates that consumers judge higher-priced products to be of higher quality (Riesz 1979; Huber and McCann 1982; Gerstner 1985; Rao and Monroe 1989). It appears that our pleasure from consuming products like wine does not depend only on our sensors (e.g., smell, taste), but also on extrinsic attributes such as price or brand name.

One way in which prices can affect quality judgment is through expectations. For example, prices have been shown to produce placebo effects such that discounted products are less effective than regular-priced products (e.g., Shiv, Carmon, and Ariely 2005; Waber, Shiv, Carmon, and Ariely 2008). Participants in these experiments assigned higher efficacy to the fully priced product, hence the placebo effect. In line with these findings, we can reasonably assume individuals tasting wines are following the same reasoning: having relatively high expectations when tasting highly priced wines.

In a between-participants design, we asked three groups of participants in Experiment 1 to indicate how much they expected to like our 2004 Cabernet Sauvignon before asking them to taste it, based only on price (\$10, \$20, or \$40) and appearance. We find that expectations were positively correlated with price.

What will the effect of high expectations be after tasting the wine? Expectations Confirmation Theory (ECT, Oliver 1977, 1980) conjectures that the interaction between expectations and perceived or actual performance leads to post-purchase satisfaction. If a product meets one's expectations, satisfaction will follow. However, if a product falls short of expectations, the consumer is likely to be dissatisfied (Oliver 1980; Spreng et al. 1996).

One way to consider expectations here is as a reference level in which people are loss averse and the environment determines endogenously the reference point they use (Kőszegi and Rabin, 2006). By this account, a person's reference point is the rational expectations she held in the recent past about outcomes that are consistent with optimal behavior given expectations. In the language of our Experiment 1, the model predicts that higher prices will increase peoples' expectations that will be subsequently used as a reference point.

Moving to a dynamic set up (Kőszegi and Rabin, 2009), higher prices should create higher expectations, and consumers would judge the realization (taste of the wine) relative to this reference point. If the wine meets or exceeds the high expectation, an individual will evaluate a wine using the price-quality heuristic, assigning higher ratings for higher-priced wines. In contrast, if the wine quality falls short of the expectations, we expect tasters to be disappointed and give the wine a lower rating. Since higher prices result in higher expectations, the likelihood of disappointment increases with price.

To test this prediction, in Experiment 2, we gave six different groups of participants the opportunity to taste and rate the wine. Three groups tasted the lower-quality Cabernet Sauvignon, whereas the other three groups tasted the higher-quality Cabernet Sauvignon (a pretest confirmed the wines' quality). Participants were informed that the wines were available for purchase in the winery, for \$10, \$20, or \$40. Consistent with past research, the higher the price of

the high quality wine (2005), the higher the participants rated it. In line with the above predictions, the responses of participants tasting the lower quality wine produced a negative correlation between price and quality.

The results of Experiment 1 and Experiment 2 suggest that high prices create high expectations, and that these expectations serve as a reference point in subsequent quality judgments. When a product meets (or exceeds) expectations, quality judgments are high, but when a product falls short of expectations, quality judgments drop.

Experiment 3 provides a direct test of the degree to which participants' expectations are met under each price-quality combination. We asked participants in this experiment to first taste the wine under the same six conditions as in Experiment 2. Then each participant indicated what they thought about the wine: "disappointing," "meets expectation," or "exceeds expectations." The results support our predictions: the good wine met expectation, and disappointment in the low quality wine increased with price.

Even if consumers' appreciation of a product is positively correlated with its price, demand will not necessarily increase. Often consumers approach the winery with a budget constraint, so even if a higher price makes the wine tastier, actual sales may not increase. Recently, Heffetz and Shayo (2009) investigated the relationship between price, inferred quality and demand by disentangling the price-quality effect from the budget-constraint effect. Their findings show that prices do affect the stated willingness to pay. When they considered actual demand, however, quality-judgment elasticities were smaller than budget-constraint elasticities, and hence, in line with standard assumptions, the demand function was downward sloping.

How should wine sellers use our empirical findings when pricing their products? The most appropriate way to test the effect of expectation confirmation on demand is by conducting a field study in a real business. To the best of our knowledge, ours is the first demonstration of the effect the price-quality heuristic has on demand in an actual market setting. In the winery we study, despite the noticeable difference in quality between the 2004 and 2005 wines, the owner of the winery was planning to price the new wine at \$10 also, primarily because sales were slow and he did not want to scare customers away (the experiment was conducted during the summer of 2009). Before introducing the higher-quality wine, the owner agreed to experiment with different prices.

We offered winery visitors one of the Cabernet Sauvignon as part of the six wines they tasted (we never had the 2004 and 2005 present at the same time). On different days, the wines' prices varied: \$10, \$20, or \$40. The dependent variables were the number of bottles of Cabernet Sauvignon sold in each of the six treatments, and the profits to the winery. We find downward-sloping demand for the lower-quality wine. For the higher-quality wine, however, more people bought the wine at \$20 than at \$10.

Deep Discount or Free? The Effects of Price Promotion on Willingness to Pay

Mauricio Palmeira, Monash University, Australia
Joydeep Srivastava, University of Maryland, USA

EXTENDED ABSTRACT

Research on price promotions has shown that when a free product is bundled together with another product, consumers reduce their willingness to pay for the free product when it is not being offered for free (Kamins, Folkes and Fedorikhin 2009; Raghurir 2004). For example, when a pizzeria offers free bread sticks with the purchase of a pizza, consumers expect to pay less for bread sticks on a subsequent visit when the promotion is no longer in effect. Raghurir (2004) reasoned that when a product is offered as a free gift, consumers infer that the cost of the product is low and lower their willingness to pay for it when it is not in promotion.

In the current research, we examine promotions in which a product is offered for a low price—but not free—with the purchase of another product. If a free offer reduces consumers' reservation price through inferences regarding the cost of the product, it follows that the impact of a promotion that allows a purchase for a reduced price should be a function of the magnitude of the promoted price. In this sense, free, or zero price, would be an extreme example of the application of this inference. In other words, compared to a situation in which a product is promoted for free, when a product is promoted for a price greater than zero, consumers should infer a higher cost. In turn, we should expect that this type of promotion would have a smaller impact on consumers' willingness to pay on subsequent purchases.

Research on several aspects of human psychology has shown that zero is used in a qualitatively different manner than other numbers, often causing discontinuity in the transition from small numbers to zero (Heyman and Ariely 2004; Kahneman and Tversky 1979; Shampanier, Mazar and Ariely 2007). This literature suggests that zero is a special number and the effect of price promotions on subsequent purchase occasions may not be a direct function of magnitude of the discount. We propose that the value of the required purchase is used as an anchor when consumers estimate their reservation prices. In addition, when a product is not offered for free, but for a low price, consumers will also use this low price as an anchor. While a product can't possibly cost zero, it can conceivably have a low price. Thus, we argue that zero will not be used as an anchor to estimate the price of a product, but a low price will. In this case, the reservation price of a free product will have only one anchor (value of the required purchase), while the reservation price of a product promoted for a value greater than zero will have both the required purchase and the promoted price as anchors.

Our reasoning leads to an interesting effect: a low price can lower reservation prices further than a zero price. Referring back to our opening example, we expect that a promotion that offers bread sticks for free with the purchase of a pizza will have a smaller impact on reducing consumers' willingness to pay for bread sticks on subsequent visits, than one that offers bread sticks for a low price, like one dollar with the purchase of a pizza. Consistent with an anchoring mechanism, as the promoted price increases, reservation prices also increase and eventually are superior to those of the free condition. Therefore, we predict a discontinuity in the relationship between promoted product price and reservation price at zero, such that a zero price will lead to higher reservation prices than a low price.

Our hypothesis was tested in two studies. In our first study, 164 participants answered a series of questions about two promotional advertisements. Participants were randomly assigned to one of four

conditions: control, free, 50 cents and 2 dollars. Thus, the between-subject manipulation was the type of promotion (if any) that was offered with the purchase of a product. In the control condition, participants were informed about the price of a product (pizza and tomato sauce), but no mention was made to the price of the promoted product (bread sticks and spaghetti). For both products, we found that participants in the free condition were willing to pay more for the promoted products when they were not in promotion than participants in the 50 cents condition. For bread sticks, even a two-dollar price lead to lower WTP than a free price. For both products, expected quality was not affected by the price manipulation.

In study 2, we manipulated two factors: type of promotion (free vs. low price) and price of the required purchase (medium vs. high). Participants were randomly assigned to four conditions and asked to consider that they were looking for a gift for a friend who loved wine and to state how much they would be willing to pay for a wine thermometer. Participants also answered a few questions related to their expectations of quality. We found main effects for required purchase price and promotion type. More importantly, we found a significant interaction, as the WTP of a free product was significantly affected by the price of the main purchase, whereas the WTP of a low price product was not. Together, these studies offer support for our hypothesis.

EXTENDED ABSTRACT

In January 1999, 12 countries decided to adopt the Euro at a given exchange rate: Belgium, Germany, Greece, Spain, France, Ireland, Italy, Luxembourg, the Netherlands, Austria, Portugal and Finland. In all of these countries, except Ireland, the nominal prices of goods were lower in Euros than they were in the prior local currency. From January 1999 onwards, the 12 participating countries included prices in Euros along with the prices in their local currencies. The legal tender of Euro was introduced on January 1, 2002, and countries gradually ended the circulation of their existing national currencies. There was a dual circulation period until the changeover was complete, during which time both the new Euro and the old national currency remained in circulation. By the end of February 2002, all 12 countries had discontinued the use of their local currency. However, to help people translate prices from one currency into the other, in many countries, a reverse pricing communication system was adopted: Prices were displayed in Euro terms, with the local national currency conversion shown just below. It was expected that, over time, consumers would become accustomed to thinking in Euro terms, and would no longer require the local currency reference as an aid. This paper examines whether that assumption was well founded.

We investigate how framing a price in two nominally different (but economically identical) currencies affects consumer-spending decisions based on the predictions of the "money illusion," a tendency to over-weight nominal values relative to real values (cf. Shafir, Diamond, & Tversky, 1997). Prior research has shown that the money illusion influences spending in foreign currencies: People under spend when one unit of their home currency buys multiple units of the foreign currency and overspend in the reverse situation (Raghubir & Srivastava, 2002). We extend this line of research by examining how sequential and simultaneous exposure to multiple currencies, that is exposure to a price in French Francs and in Euros, affects consumers' price magnitude perceptions and spending. The primary theoretical contribution of this paper is to show that when multiple nominal values are available, then the manner in which people integrate them can lead to "money illusion" biases, and that these individual level effects have economic consequences with implications for consumer welfare, public policy, and the prices that companies can charge.

We first examine the impact of sequential exposure to foreign currencies on price perception and intended spending. We propose that people will perceive prices in Euros to be cheaper if they are first exposed to a currency whose face value is larger than the Euro (DM 2 \cong €1) than if they are first exposed to a currency whose face value is smaller than the Euro (£0.5 \cong €1). A one-way ANOVA on the total cost of a hypothetical shopping basket using three levels of prior currency exposure (DM, £ or Irish Punt 1=€1) was significant ($F(2, 48)=9.96, p<.01$). As predicted, those in the UK £ condition overestimated the cost of their shopping basket ($M=€89.78$ vs. Actual=€46.96, Control Irish Punt=€52.13), whereas those in the German DM condition underestimated it ($M=€33.47$).

The second experiment examines the impact of simultaneous exposure to two foreign currencies. We propose that people anchor on the nominal value of the currency that is more salient and display the "money-illusion" effect, even when the original currency is available to them in the context. We provided people prices in two currencies: Euro and French Franc highlighting one and providing

the second as a reference: €_{FF} or FF€. Study participants rated their likelihood of purchasing 13 different products including toiletries and clothing, using the cover story that they had to shop due to their baggage being misplaced by an airline. A repeated measures ANOVA on the purchase intentions for the thirteen items showed that people are likely to spend more when the frame is €_{FF} versus FF€ ($M_{€_{FF}}=2.24$ vs. $M_{FF€}=1.87, F(1, 22)=3.55, p<.05$), and are also likely to consider a larger set of items ($M_{€_{FF}}=5.60$ vs. $M_{FF€}=3.62, F(1, 22)=4.49, p<.05$). Study 3 examines the external validity of these effects. We analyzed tourist receipts data from 1993–2008 for 10 of the 12 countries that adopted the Euro (excluding Ireland as the exchange rate is in the opposite direction, and Luxembourg due to data unavailability) compared to a set of six comparable countries that did not: UK, Denmark, Iceland, Norway, Sweden, and Switzerland. To control for country differences and overall trend in tourism expenditures, we included GDP, CPI, population, and unemployment numbers for the year as predictor variables along with whether or not the country had adopted the Euro (0=not, 1=yes), the number of years prior to or subsequent to the introduction of the Euro (e.g., 1993=-9, 2002=0, 2008=6), as well as the interaction between these two variables. The regression was significant ($R^2_a=.73, F(8, 196)=66.24, p<.01$), with the interaction term positive and significant ($\beta=4433.93, t_{196}=2.64, p<.05$). The positive and significant interaction implies that tourism receipts were higher after the Euro introduction in 2002 for those countries that adopted the Euro as compared to those who did not, controlling for overall trend and other differences across Euro and non-Euro countries.

To summarize, we show that while presenting prices in multiple currency frames could lead to a gradual adaptation to the new Euro currency standard as demonstrated by Marques and Dehaene (2004), it may not be sufficient. Results of our laboratory experiments determined that there was a systematic error in the price magnitude perceptions of the same unfamiliar currency due to differences in prior exposure to another currency (experiment 1), and when prices were presented in more than one currency (experiment 2), suggesting that providing both currencies simultaneously is not adequate at attenuating money-illusion effects.

Framing and Sales Promotions: Understanding the Characteristics of Present and Prospective Consumers

Fei Lee Weisstein, University of Texas-Pan American, USA

Kent Monroe, University of Illinois, USA

EXTENDED ABSTRACT

Economic-based literature suggests that charging loyal customers a higher price than prospective customers would lead to greater profits if loyal customers are comparatively more price insensitive than prospective customers (Chen 1997; Chen, Narasimhan, and Zhang 2001; Taylor 2003). Behavioral research, however, shows that when targeted promotions occur, loyal customers perceive higher unfairness and betrayal when they know that they paid higher prices than non-loyal customers (Feinberg et al. 2002). Targeted promotions may generate a side effect by making the targeted segment salient as potential comparison others to those consumers who are not offered the promotions. Other consumers (e.g., loyal customers) will necessarily be at a price disadvantage in relation to the targeted segment (e.g., prospective customers). In particular, loyal customers, knowing that they paid higher prices, exhibit higher perceived unfairness than prospective customers (Tsai and Lee 2007). Loyal customers often perceive that they are entitled to an equal or even a lower price since they invest comparatively more than prospective customers in the firms (Cox 2001). These different conclusions from marketing research raise an interesting and important question: what is the effect of sales promotion framing on consumers' perception of price fairness across different customer segments (regular vs. prospective)? Recently, a study showed that price framing, presenting the same price offer or price change in various formats, may reduce consumers' negative reactions even when consumers know that they paid higher prices than other people (Lee and Monroe 2008). However, the study did not examine whether using price framing to minimize consumers' negative perceptions can be implemented across different customer segments. This research contributes to consumer research by showing that using different price promotion framing tactics can induce price-disadvantaged consumers to have different transaction perceptions and subsequently increase their perceived price fairness across different customer segments and promotion deal comparisons of different magnitudes.

The prediction that consumers generally would prefer segregated gains more than reduced losses in their buying decisions was first proposed by Thaler (1985). Diamond and Sanyal (1990) later confirm that sales promotions framed as gains are chosen more often than promotions framed as reduced losses. Their study finds that consumers perceive promotions of equivalent financial magnitude framed as gains as better value than those framed as reduced losses. We propose that for assumed less price sensitive and more emotionally attached regular customers, they would be more attracted to a reward promotion (e.g., free gift) framed as a separate extra gain than discount promotion framed as a reduced monetary loss. The additional reward may generate an exclusiveness effect that loyal customers may feel more special than other customers who do not receive any rewards. On the other hand, if prospective customers are more price sensitive and less emotionally attached to the firm, they would be more attracted to a discount promotion (e.g., pure price reduction) framed as a reduced monetary loss.

Using two experiments, we examined whether the effect of sales promotion framing can successfully reduce consumers' negative perceptions of targeted pricing across different customer segments and deal comparison situations. Participants first read a short scenario asking them to consider buying a notebook computer from their all-time favorite and frequently visited online store or an

online store that they had never patronized before. All participants were presented the same notebook computer web page with the same product but with a different sales promotion framing format. Participants were randomly assigned to either the control or various framing conditions. After all participants indicated their willingness to buy the notebook computer, they were told that a friend recently bought the same notebook computer from the same online store for a much lower price. Finally, participants were asked to evaluate the dependent measures on nine-point scales.

In both two studies, price discount and reward framing, compared to an equivalent financial offer without any framing tactics, successfully increased consumers' perceived transaction dissimilarity, which subsequently increased their perceived price fairness. The results confirmed that the degree of perceived transaction similarity is highly related to perception. In addition, price promotion framing tactics work differently across different customer segments. Our findings suggest that regular customers perceived significantly higher price fairness when they received a price promotion that was framed as a reward than as a discount. On the other hand, prospective customers perceived significantly higher price fairness when they received a promotion that was framed as a discount than as a reward. Previous studies suggest that retailers should treat regular customers better since they would be more upset when they learn that prospective customers received a better deal than they did. We propose an alternative explanation that price-disadvantaged regular customers' negative price unfairness perception might also be influenced by the easiness of comparing their own transaction to other individuals' transactions. Our research findings suggest that price-disadvantaged customers' negative perceptions toward targeted pricing can be mitigated by not only using different price promotion presentation formats but also giving different levels of promotion to different customer segments so that the offers will be less comparable.

Consumer's Motivation of Counterfeit Consumption in China

Purchase Intention Toward Counterfeits—Antecedents And Consequences From Culturally Diverse Countries

EXTENDED ABSTRACT

Introduction

The sale of counterfeit products accounted for up to 9% of the world trade volume, amounting to an increase of 10,000% in the past two decades (IACC 2009). Since firms manage their brands internationally across many markets, marketers should understand how the antecedents' impacts on consumer behavior vary across countries. Even counterfeiting is a cross-national phenomenon; its antecedents have rarely been investigated cross-nationally.

Brand manufacturers of illegally copied brands sustain damage: the brand's equity is jeopardized and the consumer's demand is diverted into gray markets (Green and Smith 2002). Nevertheless, Nia and Zaichkowsky (2000) note that the majority of consumers "did not believe that counterfeits decrease the demand for original, luxury brand name products" (Nia and Zaichkowsky 2000, 494). Commuri (2009) states that the impact of counterfeiting on consumers of genuine goods (originals) is little-noticed. Thus, a further investigation is needed on counterfeits' impact on originals.

In their literature review, Eisend and Schuchert-Güler (2006) note antecedents related to the person, such as demographics, antecedents related to the product, such as price, social as well as cultural context, and also purchase situation, which all stimulate the purchase of counterfeits. They emphasize a more solid theoretical grounding for further studies and call for cross-cultural investigations to illuminate potential differences between the antecedents (Eisend and Schuchert-Güler 2006).

The purpose of the following study is to examine antecedents of purchase intention toward counterfeits (PItC) and its influence on consumers' willingness to pay for the original (WtPO).

Conceptual Framework

To develop the conceptual model, we draw firstly upon the theory of planned behavior (Ajzen 1991), secondly on the adaptation-level theory (Helson 1964), and thirdly focus on the moderating effect of country specifics.

Armitage and Conner (2001) achieved a higher explained variance for intention using the theory of planned behavior instead of the theory of reasoned action. Following the theory of planned behavior, we first hypothesize the impact of subjective norm of socially legitimate (counterfeit) behavior, and secondly hypothesize the impact of perceived behavior control, defined as the ease of access to counterfeits, on purchase intention toward counterfeits (PItC). Additionally we hypothesize the impact of novelty seeking, perceived risk, integrity, and fairness toward the original on purchase intention toward counterfeits (PItC).

We refer to Helson's (1964) adaptation-level theory linking PItC to willingness to pay for the original (WtPO). According to this theory, exposure to formerly perceived stimuli serves as a reference by which stimuli perceived later are judged. As noted by Cordell, Wongtada, and Kieschnick (1996), counterfeits are sold at a lower price, thus we hypothesize a negative impact of PItC on WtPO.

We suggest that culture (i.e. collectivism, uncertainty avoidance, Confucian values, and holistic thinking), economic development (GDP per capita) and trademark legislation serve as context

factors. Thus, consumer behavior in the counterfeit context and its antecedents' impacts are proposed as varying across countries.

Method

Our sample included 700 face-to-face consumer interviews in each country of investigation. Enhancing the generalizability of the study (Alden, Steenkamp, and Batra 1999), we chose China, Romania and Germany as countries of investigation in view of their differences in economic development, culture, and trademark legislation, where we note a considerable variation, to make our hypothesis more suitable for generalization (van de Vijver and Leung 1997). In addition to validity and reliability confirmation, we also confirmed partial scalar invariance of the measurement in comparing country samples (Steenkamp and Baumgartner 1998). Since we operationalized PItC as a formative measurement to include the main product categories that are counterfeited, we applied the partial least squares approach for its handling of formative and reflective measurement models and its less stringent assumptions concerning the distribution of variables and error terms (Hensler, Ringle, and Sinkovics 2009). The structural model was estimated for each country, and differences in path coefficients were tested for significance (Keil et al. 2000).

Findings and Discussion

Our study pursues the call of Eisend and Schuchert-Güler (2006) for a better theoretical grounding and a cross-cultural investigation in further studies on the counterfeit context, and the call of Commuri (2009) for an examination as to how counterfeits impact genuine brands.

Applying the theory of planned behavior (Ajzen 1991), we examine the antecedents' impact on PItC and reveal that country specifics, such as culture, economic development and Confucianism, matter when investigating consumers' illicit behavior. Such a cross-country investigation amplifies the understanding of consumer behavior and thus provides insights for internationally implemented actions that are aimed at tackling companies' losses caused by counterfeits.

In China, where Confucian values are a strong cultural trait, Fairness to the genuine brand does not lower PItC, whereas in Western countries it does. Thus Fairness, which has not been discussed previously in the counterfeit context, matters as an antecedent of PItC when investigating societies where Confucian values are not common. The Asian understanding of copying and of honoring one's master differs from Western beliefs and has its roots in the Confucian set of values and ethical norms

Integrity has no significant/negative impact for developing countries, such as China and Romania, where trademark law was only established quite recently and its implementation is somewhat sporadic. Recently, China has aligned its legal framework within the international intellectual property rights treaty and is still revising its trademark legislation. Since laws and norms are related, a cross-national legal alignment is of increasing importance.

Subjective Norms do legitimate counterfeiting behavior and have a higher impact on PItC for collectivistic countries, such as China and Romania, than for individualistic countries. Popular

endorsers and opinion leaders are a means of increasing consumers' awareness of negative outcomes affecting brand manufacturers, as well as society at large. Once counterfeiting is socially disregarded, especially in collectivistic societies, counterfeits will not be used any more to display status and prestige.

Following the adaptation-level theory (Helson 1964), we show that the availability of typically low-priced counterfeits lower the reference price for genuine brands in the consumer's mind. Especially in Romania, brand manufacturers seem to be jeopardized by the visibility level of counterfeits.

Opinion Seeking In Consumer Networks

Seung Hwan (Mark) Lee, University of Western Ontario, Canada
June Cotte, University of Western Ontario, Canada

EXTENDED ABSTRACT

The importance of social communication in explaining consumer behaviour has been highlighted across a wide variety of research streams (e.g., Childers 1986). What is known from prior research is that consumers tend to rely on their social networks (e.g., like a network of friends) as resources for product information, evaluations, and recommendations to make better purchase decisions (Brown and Reingen 1987; Gershoff, Broniarczyk, and West 2001). Given the importance of social networks in the consumer's search process, it is surprising that research has largely ignored the effect of consumer's position in a social network on opinion seeking behavior. Studies in this domain have generally ignored the possibility that *where* a consumer is located within a social network may influence the degree to which that consumer seeks opinions from others. For instance, will the opinion seeking behavior of a consumer be any different if he is strategically connected to others in the network versus if he is not strategically connected? Will a consumer increase her propensity to seek out opinions knowing she is in a better network position to reach those who could help her with her information search? These research questions suggest that as a discipline we do not have a thorough understanding of how network positions influences the opinion seeking behavior of consumers. Therefore, our research focuses on both the structural properties of the social network (network centrality), and the outcomes of those relational characteristics (e.g., how the social links affect opinion seeking behavior).

Opinion seeking is the act of searching out advice from other consumers (Flynn et al. 1996). Our research investigates how occupying a certain network position affects the extent to which consumers seek the opinions of others, as well as the extent to which consumers are approached by others for their opinions. One of the ways in which individuals can occupy such an advantageous position is to become *central* in a network (Lee, Cotte, and Noseworthy 2010). Network centrality is measured by examining the number of direct relationships an individual has with others, or by assessing the extent to which an individual links otherwise unconnected cliques or individuals (Freeman 1979). Thus, centrality can be defined by the number (quantity) of ties or the configuration (strategic location) of ties. In this paper, we focus on two common measures of network centrality: degree centrality and betweenness centrality.

Occupying a central position, through either degree or betweenness centrality, reflects greater social capital (Burt 2000). Individuals located in central positions have unique social advantages; they can take advantage of their network structure for information and resources (Coleman 1990). We propose that those who are centrally located in a network will exhibit a greater tendency to seek opinions than those who are on the periphery of the network. By tendency, we mean the frequency with which central people approach others for their opinions. In addition, we propose that central individuals are more likely to be approached for opinions than those residing in the periphery.

To test our theory, we conducted two network studies using social network analysis. One of the main strengths of social network analysis is that it enables researchers to locate the structural position of individuals in a network (Lee et al. 2010). In study 1, we examine a brand community made of primarily young adults. We measure an individual's opinion seeking behavior for a *product* associated with the brand community. In study 2, we extend our theory to a differ-

ent type of a social network (a seniors' social club), and measure opinion seeking behaviors for a *service* associated with this club.

The results of two field studies provide strong support the positive association between network centrality and opinion seeking, as well as, network centrality and opinions sought. With regards to degree centrality, out-degree centrality was positively related to both opinion seeking measures. However, this was not the case for in-degree centrality. The results support the notion that people who rated themselves as central (social perception) were associated with having higher opinion seeking tendencies, while people who were central (as rated by others) did not have higher opinion seeking tendencies. In contrast, for the opinions sought measure, a positive relationship was found for in-degree centrality, but not for out-degree centrality.

With regards to betweenness centrality, the data reveals positive relationship with both opinion seeking and opinions sought. Results from the two field studies reveal that those occupying a high betweenness position are most likely to take advantage of their brokering opportunities to seek opinions from others; but it also opens up opportunities for others to seek opinions from them. This is an important finding because it emphasizes the social benefit (i.e. increased opportunity to seek out diverse information) from occupying a betweenness central position. However, it is possible that they may also face social costs or burdens as others may come to depend on them for information.

Concluding, this research contributes to the literature by recognizing that there are unique opportunities and advantages of occupying a central position in a social network. Overall, the findings suggest that centrality is positively related to both opinion seeking and opinion approachability. We have firmly demonstrated the importance of both the number of social ties and the position of those ties in the flow of opinions through a social network. Future researchers can continue to advance on this understanding in both face-to-face and online social networks and communities. The growth in peer-to-peer technologies is fuelling growth in virtual social networks, and the opinion-seeking and opinion-sharing that attend those communities.

The Flow of Cosmetic Routines in Iran

Aliakbar Jafari, University of Strathclyde, UK
Pauline Maclaran, Royal Holloway, University of London, UK
Babak Taheri, University of Strathclyde, UK

EXTENDED ABSTRACT

Conceptualizing consumption as an experiential process rather than solely a cognitive purchasing behavior (Holbrook and Hirschman 1982; Bloch 1982; Hawkins et al. 1983; Bloch and Bruce 1984), in the past three decades, researchers have addressed “consumers’ subjective and emotional reactions to consumption objects” (Holt 1995, 2). Among a variety of dimensions of consumption as experience (e.g., emotional, experiential, hedonic, aesthetic) (Holbrook and Hirschman 1982; Belk et al. 1989; Celsi et al. 1993), autotelic consumption has gained momentum in studying recreational activities in which consumption becomes ‘an end in itself’ (Csikszentmihalyi 1975). That is, consumers’ deep involvement with the object of consumption results in their self-defined form of recreation, pleasure, and flow experience (Csikszentmihalyi 1975, 1992; Bloch and Bruce 1984).

Within consumer research, Csikszentmihalyi’s concept of ‘flow’ has been acknowledged as an important part of autotelic consumption, usually associated with various leisure activities such as games (Holbrook et al. 1984), aesthetic appreciation (Joy and Sherry 2003), sports (Holt 1995; Sherry et al. 2005), extraordinary experiences such as skydiving (Celsi et al. 1993; Celsi 1992) or white water rafting (Arnould et al. 1999), gambling (Cotte 1997), and even online search experience behaviors (Mathwick and Rigdon 2004). Noticeably, although Csikszentmihalyi (1975, 1992) highlights opportunities for finding flow in non-leisure activities, and perhaps due to the cultural turn’s emphasis on identity issues, the more mundane aspects of everyday life have been overlooked in the literature on autotelic consumption. Neither has his point about flow’s context-dependency triggered any cross-cultural research, particularly in non-Western societies. Our present study addresses these gaps in the literature and scrutinizes consumption of cosmetics as an everyday life practice among young adult women in Iran.

In our study, first, we were inspired by the fact that with a population of only 70 million (25 million women under the age of 35), Iran achieved the seventh rank in global markets for consumption of cosmetics and toiletries in 2007 (Euromonitor, 2008). Also, given the recent political interpretations of Iranian women’s excessive consumption of make-up (as either a silent rebellion against the political ideology of the Islamic Republic or a sign of Western decadence), we were motivated to explore the potential symbolic meanings (McCracken 1988; Schouten 1991) embedded in these individuals’ consumption of cosmetics. Although our non-participatory observations and memos provided us with a pool of ideas, through our in-depth interviews with 15 young adult women (aged between 21 and 32) in Tehran and Karaj, we gained a deep understanding of our informants’ consumption practices. Our data analysis followed a systematic process of constant comparison in terms of searching for similarities and differences (Glaser and Strauss 1967).

Quite contrary to our expectations, our emergent findings revealed that our informants’ make-up practices were less to do with identity construction (Schouten 1991; Merskin 2007; Thompson and Haytko 1997; Askegaard et al. 2002; Reynolds et al. 1977; Bloch and Richins 1992; Brownmiller 1984; Ragas and Kozlowski 1998; Peiss 1990) and more to do with a total immersion in the experiential and creative aspects of make-up use and as a way to uplift their tired spirits in a monotonous environment. Despite facing various challenges, including frequent stigmatization on account of their

often excessive use of make-up, our informants derived high levels of satisfaction from their make-up routines.

The consumption of cosmetics, as our study reveals, is a way of sustaining wellbeing for those women who have less exciting lives. They use their body as an immediate natural environment (Tuan 1997) and a great potential source of joy (Csikszentmihalyi 1992; Stebbins 1977, 2009). Their ‘escapist’ (Hirschman 1983) engagement with make-up as a source of ‘flow’ provides them with a sense of solace, pleasure, and creativity (Holbrook and Hirschman 1982; Bloch and Bruce 1984). In the absence of extrinsic satisfaction and appreciation from their society (Csikszentmihalyi 1992; Bloch and Bruce 1984), they continue to engage in their make-up rituals on a daily basis. Although they do not necessarily believe that make-up makes them more beautiful or relate its use to their self-esteem, they still experience ‘significant mood changes’ (Celsi 1992). For them, flow (i.e., application of make-up) becomes its own reward and offers intrinsic satisfaction (Bloch and Bruce 1984) and brings feelings of serenity and ecstasy. Yet, for these women, the real challenge of flow experience lies not in the task itself (i.e., consumption of cosmetics) (Csikszentmihalyi 1975) but in the *consequences* of accomplishing the task, which are related to the dominant cultural order of their society (Jafari and Goulding 2008). Generally speaking, excessive use of make-up is frowned upon in Iran. The state views it as an un-Islamic behavior and a sign of Western decadence. Therefore, women with heavy make-up are labeled as ‘street women’ and are usually stopped and advised by the morality police. Likewise, conservative families do not approve of their female members’ excessive use of make-up as it signals lack of dignity. Such women are also more susceptible to sexual harassment.

Despite all these problems, these individuals accomplish the task of wearing make-up with determination. They feel more “alert, concentrated, happy, satisfied and creative” (Csikszentmihalyi and LeFevre 1989, 816). The ‘activation energy’ embedded in their autotelic experience (Csikszentmihalyi 1975) focuses them in total absorption on the task in hand to the exclusion of all else around them. Although they know that make-up will do little to change their situation in real life, they can escape into a fantasy world for some part of the day. They give themselves up to the processes of its application, losing themselves in the creative play and artistry that these processes facilitate without giving much thought to final outcomes.

Based on our findings from this context, we stress that changing socio-cultural dynamics in contemporary societies give rise to new forms of autotelic consumption which need to be investigated. By extending the application of autotelic consumption to very mundane life practices, we also emphasize that flow is context-bound and what may lead to flow for one person in a particular socio-cultural context may not necessarily hold true across different socio-cultural environments.

Caught Between a Rock and a Hard Place: Adult Children's Consumption of Care Services for Their Elderly Parents

Aimee Huff, University of Western Ontario, Canada

June Cotte, University of Western Ontario, Canada

EXTENDED ABSTRACT:

There is no shortage of anecdotal or scholarly evidence that adult children experience stress as they engage in care decisions for their elderly parents. However, adult children are often conflicted when faced with the task of translating their respect and love for their parents into actual decisions about care. That is, the tasks of choosing and using elder care services are not straightforward or unproblematic for adult children.

The purpose of this paper is to theoretically account for the stress experienced by adult children by attending to the underlying cultural influences on elder care consumption. We take the position that adult children are consumers of elder care services because they are (typically) caregivers for their parents; adult children can choose to provide the requisite care themselves, or to consume commercial services that provide care. The marketplace for elder care services has responded to the care-giving needs of adult children by offering a variety of care options, ranging from in-home visits to assisted living facilities to long-term nursing care. However, although the need for elder care services is often inevitable and the marketplace offers a number of solutions, many children find the experience of making care decisions traumatic and stressful.

It is critical that we acknowledge that we are examining only a sub-set of elder care decisions—those made by the adult children—and, in doing so, we implicitly strip agency from the elderly parents. Certainly, many seniors make their own decisions about care, and others make decisions in conjunction with their children. In this paper, we choose to focus on the experiences of adult children who play the lead roles in decisions about their parents care. We use the context of making care decisions for an elderly parent to reveal how consumers experience stress in the marketplace, and, therefore, do not seek to imply that elder care decisions are the sole responsibility of adult children.

The context of elder care is particularly revealing of consumption-related stress because it often does not involve one specific decision. Rather, elder care consumption involves a cycle of major and minor decisions as various care services are chosen, used, and then deemed inappropriate. Further, adult children typically want to do what is best for their parents, yet are torn between a desire to keep parents safe (from physical harm, etc.) and a desire to respect their parents' wishes to live as independently as possible. However, being physically and cognitively self-sufficient can become problematic as we age, and many children find themselves worried about their parents on a host of issues including mobility and physical safety, diet and medication, hygiene, finances, and social interaction. Further, many children experience significant lifestyle changes as their parents become more dependent on them to provide and manage their care. This can result in children feeling torn between their responsibilities to their parents and to their own spouses and children.

In this paper, we use data gathered from depth interviews with adult children to examine these tensions and to reveal how they are experienced. We find evidence of two dominant tensions in our informants' narratives. The first is a general awareness that it is not possible to respect a parent's wishes to live independently *and* to ensure that s/he is receiving the "proper" level of care. The second tension revolves around an awareness that it is not possible to fulfill the obligations of actively managing a parent's care needs

and to maintain independence from the parent. We suggest that adult children experience stress as an outcome of these tensions, and we find that stress is characterized by guilt, exhaustion, and anxiety.

We also discuss the cultural ideologies of autonomy and active care management, and suggest how they are related to the context of elder care. Autonomy encompasses the strong cultural value placed on being independent individuals. In the context of elder care, the independence of both parties (i.e., the adult and the child) becomes compromised as the parent's need for care becomes apparent. Active care management encompasses the broad, pervasive expectation that adult children will employ an active, managerial approach to their parents' care by taking all steps necessary to ensure health and safety.

In our interpretation, we propose that the tensions arise as adult children encounter these two distinct cultural ideologies, which can have opposing implications for elder care consumption. That is, in the context of elder care, consumers experience tensions across their individual interpretations of the cultural ideologies because these interpretations push them in different directions in terms of consumption. The outcome of these tensions is stress, as adult children feel torn between the different levels of care that would satisfy them and that would satisfy their parents.

The theoretical contribution of this research is that it demonstrates that consumers are not always able to satisfactorily resolve tensions between their interpretations of cultural ideologies. Prior research has demonstrated that consumers can appropriate discrepant ideological positions and discourses to effectively negotiate personalized consumption meanings and shape their individual consumption behavior. In this paper, we build on this extant work, and we suggest that a particular consumption context can link seemingly unrelated cultural ideologies such that consumers are unable to negotiate an acceptable outcome, and that inability to negotiate the discrepancy can result in stress. Further, we demonstrate that marketplace solutions to consumer needs can, in fact, problematize and complicate consumption; in the context of choosing and using elder care services, many adult children are unable to negotiate disparate ideologies and are therefore unable to reach a satisfactory consumption outcome.

Inalienable Wealth and Trauma Resolution: An Explanation of Genealogy Consumption

Andrew Lindridge, Open University, UK

EXTENDED ABSTRACT

Inalienable wealth has been defined as possessions that are intentionally kept within a close group, with previous research focussing on certain possessions taking on behavioural dynamics of guardianship or temporal orientation (Curasi, Price and Arnould, 2004; Price, Arnould and Curasi, 2000). These perspectives, however, have focussed on possessions becoming a contested area arising from issues of ownership and wanting to maintain and perpetuate cherished meanings associated with products. However, this perspective is from a living individual wanting and willingly seeking out ways to engage with later generations by perpetuating these memories. This paper aims to understand how the living create inalienable wealth by seeking out possessions and information from previous ancestral generations (including photographs, sharing ancestral data, visiting places and historical documents), even though there may be no living, emotional, linkage between the generations concerned. We will argue that peoples motivations to undertake genealogical consumption reflects not only cultural and societal changes but a fundamental need by individuals to use genealogy consumption for, conscious and unconscious, resolution of personal and inter-generational traumas.

The antecedents of genealogical consumption were explored using a Consumer Culture Theory perspective that focussed on the individual's self-identity and their cultural context. Western culture has been identified to varying levels with individualism, referring to a cultural system that emphasises the rights of the individual over the community and attributed to declining levels of family orientation and, from a British context, declining levels of religiousness (Halman, 1996; **, 2005). Previously individualism has been attributed to materialism, reflecting wider dissatisfaction within an individual's life (Burroughs and Rindfleisch, 2002; La Barbera and Gurhan, 1997). However, the failure of possessions, and hence materialism, to lead to personal happiness may be reflective of a deeper, personal, crisis, within the individual. This crisis, we argue, motivates the consumer to seek resolution through alternative possession meanings, i.e. obtaining inalienable wealth through genealogy. The motivation for these behaviours we argue can be identified with personal and inter-generational trauma, i.e. inherited from previous generations.

Inter-generational trauma can be identified from two perspectives. First, the psycho-analytical perspective argues that trauma is inherited by the child from the parent preventing the child from developing their own, unique, personality, consequently, resulting in inter-generational trauma (Abraham and Torok, 1994; Praeger, 2003). The second distinct research field draws upon sociological studies, which argues that each generation occupies a particular social location, allowing for social experiences to be refracted and made meaningful. However, failure by the individual to identify with and belong to that period of time ensures that they remain traumatized and instead focused on historical experiences and events (Dilthey, 1924; Mannheim, 1928/1972).

The methodology involved a four year immersion into the genealogical consumption arena, covering the period January 2006 to January 2010, including access to a variety of genealogical data and consumption arenas. The sampling procedure employed was theoretical, relational and discriminative. To achieve this, only participants who were related to the researcher were interviewed, regardless of whether this connection was within his wider extended family or from several generations back. This was assessed by participants having a *.* surname appear within their respective genealogical

lineage. All the participants were approached via a genealogy website producing a sample group consisting of eight people, aged from 48 to 67, living in Australia or Britain. Participants were interviewed with open-ended, grand tour style questions exploring various inter-related themes including: the participants' reasons for their genealogy research, how they engaged with historical records (including their personal meaning for the participant) and their immediate family histories. During the interview process the author probed participants to explore in greater depth personal experiences, family myths, stories and traumas, opinions and thoughts and how this was reflected in their genealogy research.

The interviews were then transcribed, analyzed to identify emergent themes. Finally to ensure reliability and validity the findings were reviewed and discussed with the help of two academic reviewers—one a consumer behaviorist, the other a qualified psychotherapist.

The findings supported the notion that participants were using genealogy as a means of creating a sense of identity in response to their irreligious, lack of materialistic traits and need to seek out a community and wider sense of family. Genealogy offered then an opportunity to substantiate and maintain a sense of identity through creating inalienable wealth through genealogical consumption. Participants discussed how they collected, shared and exchanged ancestral documents, photographs, and stories, often leading to meetings and trips to shared ancestral locations. These engagements offered an opportunity for a reconstruction of a sense of family and inter-connectedness. The need to seek information from the past is reflective of the sociological perspective of inter-generational trauma.

From a psycho-analytical perspective, only one participant did not discuss a personal and /or inter-generational trauma that had motivated them to undertake genealogical research. Personal traumas ranged from loss of a father, unwanted divorce or a wider need to understand their world, whilst inter-generational trauma included stories of slavery, death in child birth and loss of aristocratic titles and lands. Participants by seeking out ancestral documents, stories and myths provided an opportunity to explore, understand and resolve the cultural, economic and social aspects of their inherited trauma.

Genealogy then presented opportunities for participants to seek out and develop the cues, materials and prompts for the individual to recall particular events to the extent of creating memories that they may never have experienced. These memories were then actively shared and sought out amongst participants and genealogical communities providing a needed and sought affirmation of their self-identity. Commemorative and other related memory symbols (such as documents and photographs) become then symbolic to the participants because of their ability to elicit a reaction from individuals; a reaction identifiable with and developing further previous work into inalienable wealth by Curasi, Price and Arnould's (2004) and Price, Arnould and Curasi's (2000). The genealogical community based upon a shared ancestor offered opportunities for intimacy, creating social networks and resolution of personal and inherited traumas but also a means to achieve autonomy and independence.

The Defensive Trust Effect: Consumers' Defensive Use of Belief in a Just World to Cope with Decision-Generated Threat

Andrew Wilson, St. Mary's College of California, USA
Peter Darke, York University, Canada

EXTENDED ABSTRACT

The Defensive Trust Effect: Consumers' Defensive Use of Beliefs in a Just World to Cope with Decision-Generated Threat

Consumers cope with many threats in the course of buying, consuming, and interacting with marketers. Previous research has examined how consumers cope with the threat of negative emotions (Yi and Baumgartner 2004), potentially misleading persuasion attempts (Campbell and Kirmani 2000; Darke and Ritchie 2007), and difficult decisions (Luce 2005; Luce, Payne, and Bettman 1999). Decision-making is inherently threatening to consumers; both in terms of their goal to make accurate decisions (Luce, Bettman, and Payne 1997), and also their goals of maintaining self-esteem and self-presenting as competent deciders (Janis and Mann 1977; Luce 2005). This research introduces a previously unexamined coping strategy consumers engage—termed *defensive trust coping*—in which consumers fall back on positive world beliefs to re-construct the situation as one in which they can and should trust marketing agents.

Drawing on just world theory (Hafer and Begue 2005; Lerner 1980), positive illusions research (Taylor and Brown 1988, 1994) and cognitive experiential self theory (CEST; Epstein and Pacini 1999), we develop theory that specifies psychological mechanism and situational moderators. Just world theory specifies that individuals are motivated to perceive the world as a place where they get what they deserve (Lerner 1980; Lerner and Simmons 1966). This belief is more strongly held by some individuals than others (Rubin and Peplau 1975). BJW functions as a healthy coping mechanism that helps individuals adapt to their own potential misfortunes (i.e. I am a good person, I deserve good outcomes, so I will get good outcomes; Furnham 2003; Hafer and Begue 2005). Our research views BJW as a type of positive illusion (Taylor and Brown 1988, 1994), which operates through consumers' trust judgments of marketing agents. Past research suggests that consumers typically respond negatively to threat by becoming less trusting of marketers (Campbell and Kirmani 2000; Darke and Ritchie 2007) (Slovic, Flynn, and Layman 1991). In contrast, our model predicts that high-BJW consumers respond to decision-generated threats by falling back on their BJW as a coping resource, leading to buffering—or even positive—effects on trust judgments. The result of four experiments support our conception and predictions.

Exp 1 used choice as a manipulation of threat, with post-choice serving as the high threat condition. Pre (post) choice participants responded to an adapted seven-point trust scale (Delgado-Ballester 2004) before (after) choosing between the two cameras. BJW was measured as a continuous variable using seven items from an established scale (Dalbert 1999). Participants imagined an interaction with a retail salesperson culminating in the salesperson recommending one digital camera over another. Moderated multiple regression analysis (Aiken and West 1996) revealed a significant choice-stage x BJW interaction ($\beta .259, t=2.422, p<.05$), such that high-BJW participants (+1 SD) trusted the salesperson more [Predicted Value (PV)=4.46] than low-BJW (-1SD; PV=3.58), but only in the post-choice stage, when decision-generated threat was high. A mediation test (Baron and Kenny 1986), using coded thought listings of valenced thoughts as a mediator, supported the assumption that defensive trust coping operates through a relatively pre-conscious process, in that it did not require cognitive elaboration.

Exp 2 examined conditions wherein consumers experience threat both pre- and post-choice. Consumers experience conflict in the pre-decision phase when choice alternative are not differentiable, because they cannot find a reason on which to base their choice (Shafir et al. 1993). A non-differentiable choice set was inserted into the scenario described for Exp 1. Under this form of decision conflict, high-BJW consumers again trusted a retail salesperson more (PV=5.01) than low-BJW (PV=3.73; $\beta=.429, t=4.428, p<.001$), across both decision phases.

Exp 3 further extended the findings in three important ways: 1) an experimental priming manipulation of BJW provided causal evidence for the effects, 2) a cognitive load manipulation provided further evidence that defensive trust coping operates through a pre-conscious process, and 3) a manipulation of ulterior motive established a boundary condition of the effects, such that they were extinguished under ulterior motive.

Exp 4 provided clearer evidence of the defensive nature of the effect by manipulating the level of decision-generated orthogonally along two dimensions, material consequence and psycho-social threat. Material consequence threat was manipulated by instructions to half the participants that a draw would award some participants the actual digital camera chosen. Psycho-social threat was manipulated by assigning half the participants to role of buyer (high-threat), and the other half to observer (low-threat). Exp 4's protocol differed from the earlier studies in that participants shopped for a digital camera on an actual electronic retailer website. The salesperson interaction occurred through an instant messaging (IM) software protocol that ensured a plausible, but controlled, salesperson interaction. The main result was a marginal BJW x consequence x role interaction ($\beta=.113, t=1.904, p=.058$), such that high-BJW participants in the buyer role/real consequence condition trusted more (PV=5.13) than all other conditions (PV's from 4.46 to 4.60).

This research makes a number of contributions to our understanding of the ways in which consumers cope with decision threat. For instance, whereas extant research on consumer coping has focused on conscious coping strategies (Duhachek 2005; Duhachek and Iacobucci 2005; Duhachek and Oakley 2007), we extend this pursuit by examining a new coping strategy that focuses on a just world belief, which seems to defend consumers against threat without the need for conscious awareness. Moreover, in contrast to extant research (Campbell and Kirmani 2000; Darke and Ritchie 2007; Slovic et al. 1991) which shows threat generally has negative effects on trust, we identify conditions under which threat can actually lead to positive effects on consumer trust of marketers. Although this pattern is somewhat counterintuitive, it is nonetheless predicted by the proposed model of defensive consumer coping.

When Does an Attack to the Brand Call for Action? The Role of Self-Brand Connection and Implicit Self-Esteem

Monika Lisjak, Northwestern University, USA
Angela Y. Lee, Northwestern University, USA
Wendi L. Gardner, Northwestern University, USA

EXTENDED ABSTRACT

In the modern marketplace consumers are often exposed to negative brand information. Existing research shows that brand commitment, which reflects consumers' desire to have a particular brand, influences how people respond to negative brand information. After reviewing negative brand information, low commitment consumers revisit their attitude toward the brand downward, whereas high commitment consumers tend to counterargue the negative information and resist attitude change (Ahluwalia, Burnkrant and Unnava 2000). More recent research shows that brand commitment is influenced by the extent consumers identify and connect with the brand (Escalas and Bettman 2003). In this paper, we suggest that to understand how consumers respond to negative brand information, it is important to examine the interplay between their connection with the brand and their implicit self-esteem.

Research suggests that consumers who are connected with a brand include the brand in their self-concept (e.g., Belk 1988; Escalas and Bettman 2003). Seminal work by W. James (1890) suggests that when objects are incorporated in the self, they elicit the same emotional responses and behaviors as the self. Therefore, an attack to the brand is analogous to an attack to the self. When people are attacked, they use an arsenal of defensive strategies to maintain a positive self-evaluation. Research shows that when participants cope with threats by affirming important aspects of the self, they are no longer defensive (Steele and Liu 1983; Tesser and Cornell 1991), suggesting that different defensive strategies are substitutable for one another. People also defend more when the self is activated (Steele, Spencer and Lynch 1993).

People's defensive responses are influenced by their self-esteem. Research suggests that implicit self-esteem, which is an automatic evaluation of the self, buffers people against threats (e.g., Spalding and Hardin 1999; Greenwald and Farnham 2000). Following a threat to the self, people with low implicit self-esteem become defensive, whereas those with high self-esteem are not.

By building on these findings, we suggest that consumers who are connected with a brand will defend the brand when it is under attack. More importantly, we predict that consumers' defensive responses will be accentuated among those with low implicit self-esteem when their self-concept is activated. Finally, we predict that their defensive response will dissipate if they have the opportunity to self-affirm. We tested these predictions in three experiments.

In experiment 1, we first measured participants' implicit self-esteem by using the name-liking measure (Gebauer et al. 2008). Then, we assessed the connection participants had with Starbucks by using the self-brand connection scale (Escalas and Bettman 2003). Next, participants were randomly assigned to write an essay that either activated or not the self. Finally, participants were presented with an unfavorable editorial about the Starbucks and asked to report how their attitude toward the brand might have changed. Consistent with past research we found a main effect of self-brand connection, whereby participants who felt connected with Starbucks were less likely to devalue the brand after reading the negative editorial. This effect, however, was qualified by the three-way interaction between self activation, self-brand connection and implicit self-esteem. When the self was not activated, participants' self-brand connection negatively predicted attitude

change; whereas implicit self-esteem had no effect. However, when the self was activated, participants' self-brand connection and their implicit self-esteem jointly influenced attitude change. In particular, participants with low implicit self-esteem who felt connected with Starbucks reported more favorable attitudes toward the brand. We replicated these findings in a follow-up experiment using the implicit association test (IAT; Karpinski and Steinman 2006) as a measure of implicit self-esteem.

The objective of experiment 2 was to provide converging evidence for our predictions by using a different brand (Facebook) and to investigate the underlying process. We first assessed participants' implicit self-esteem and their connection with Facebook by using the same measures as in experiment 1. Participants then wrote an essay that activated (or not) the self. Next, participants read a negative editorial about Facebook. Finally, participants were asked to report their attitude change and respond to some process measures. Similar to experiment 1, the results revealed a significant effect of self-brand connection, which was qualified by the three-way interaction. When the self was not activated, no effect was significant. However, when the self was activated, participants with low implicit self-esteem had a more favorable attitude toward Facebook compare to their high implicit self-esteem counterparts. Participants' net positive brand thoughts partially mediated the effect.

In our final experiment, we examined whether affirming the self might dissipate the defensive response of low implicit self-esteem individuals. As in experiment 1, participants first filled in a measure of implicit self-esteem and reported their self-brand connection with Starbucks. To activate the self, participants were asked to write a brief essay. Next they were asked to read a negative editorial about Starbucks. After reviewing the editorial, half of the participants were affirmed while the other half were not. Finally, participants were asked to report their attitude change toward Starbucks. We found a main effect of self-brand connection, which was further qualified by the three-way interaction. When participants were not affirmed, we replicated the results from previous experiment. That is, participants with low implicit self-esteem who were connected with Starbucks boosted their brand attitude. However, when participants were affirmed, low implicit self-esteem participants who felt connected with Starbucks did not defend the brand. It seems that it is possible to buffer low-implicit self-esteem participants against self-threats by making them feel good about themselves.

This research demonstrates the importance of examining the interplay between consumers' connection with the brand and their implicit self-esteem when trying to gain a better understanding of how people respond to negative brand information. After receiving negative brand information, low implicit self-esteem consumers who are connected with the brand defend the brand as they would defend the self.

“Keeping It Real”: Marketing Implications of Brand Authenticity

Melissa Minor, University of Florida, USA
Robyn LeBoeuf, University of Florida, USA

EXTENDED ABSTRACT

Although there is evidence in the literature that being authentic provides benefits to the firm, most, if not all, of these conclusions have been drawn from depth interviews or other qualitative work. What is missing is experimental evidence that perceptions of brand or product authenticity provide other benefits to the firm. Using an experimental approach, this paper demonstrates that authenticity is a malleable facet of the brand, and provides evidence that consumers' perceptions of a brand's authenticity affect other brand-related cognitions such as quality perceptions and willingness to pay. This paper also shows the potentially ironic consequences of fostering authenticity.

Although many definitions of authenticity have been offered in the literature, this paper will focus on two main sources of authenticity: inherent qualities of the object and consumers' subjective judgments about the brand. In general, offerings that are natural, handmade, simple and/or based in fact are generally considered by consumers to be more authentic (Groves 2001; Boyle 2003; Munoz, Wood and Solomon 2006; Beverland 2005; Potter 2008). Consumers also make subjective judgments about the authenticity of a product using contextual information such as information about the brand's image and its marketing. Summarized in Gilmore and Pine's (2007) *Polonius Test*, brands are considered to be authentic if they are “true to self” and/or “are what they say they are”. Being “true to self” means that a brand is perceived as existing because of the passion of its founder—not simply for monetary gain. On the other hand, “being what you say you are” means that to be authentic, a company or offering must live up to its own promises—there must be truth in advertising.

While much attention has been given to the importance of authenticity to the consumer, limited attention has been paid to the benefit (or detriment) being authentic has for the firm. The extant literature provides some evidence that judgments of authenticity have the potential to have a direct and indirect impact on consumers' search for information, consideration set formation and, ultimately, choice (Chalmers 2007; Groves 2001). While existing work suggests that consumers' perceptions of authenticity may affect inferences consumers make about the brand, it does not address the types of inferences that consumers make. We hypothesize that consumers will infer that more authentic brands are also higher in quality, and that they will be willing to pay more for these products. Additionally, to the extent that consumers believe that authentic products are more “real” than inauthentic products, we hypothesize that consumers will be more confident in the inferences they make about authentic products than inauthentic products.

In studies 1a and 1b, authenticity was manipulated by informing participants that authentic and inauthentic brands were owned by large corporations. Revealing this information should cause consumers to doubt the authenticity of the authentic brands, because the discrepancy between the images and motives of the authentic brands and their parent corporations should bring into doubt whether the authentic brands truly are who they say are, a key component in perceptions of authenticity. Measures of authenticity perceptions, product quality, willingness to pay and attitude confidence were taken both before (Time 1) and after (Time 2) the corporate ownership information was revealed. Study 1a and 1b revealed that perceptions of authenticity do affect other brand-related cognitions. At Time 2, after reading of the authentic brands' corporate parents, participants' reported lower perceptions of authenticity of quality,

decreased willingness to pay, and less confidence in their attitudes. The drops in quality perceptions, willingness to pay, and attitude confidence were fully mediated by participants' lower perceptions of brand authenticity. However these results were unique to the authentic focal brands. The inauthentic brands actually benefited from their connection to a large parent corporation. At Time 2, perceptions of authenticity, product quality, and willingness to pay increased among the inauthentic brands.

While studies 1a and 1b, and previous work on brand authenticity, seem to suggest that increased authenticity is uniformly positive for the brand, might there be situations where a brand's authenticity could be detrimental? In study 2, we are interested in determining how authentic brands weather brand transgressions, and if perceptions of the brand following the transgression are affected by the type of transgression committed. Although all transgressions should be detrimental to any brand, we hypothesize that some transgressions will be especially harmful for authentic brands. Specifically, we hypothesize that a transgression directly related to the basis of an authentic brand's authenticity will be more damaging for the authentic brand than an equivalent transgression would be for another brand.

In study 2, participants were given information about an authentic or inauthentic brand and were then informed that this brand had committed one of three types of transgressions (moral, generic, or dangerous ingredient). While each transgression should be damaging to any brand, we hypothesize that the ingredient transgression will be especially damaging to the authentic brand (Burt's Bees) because the transgression undermines its authenticity (all-natural ingredients). As hypothesized, following the moral and generic transgressions, both the authentic and inauthentic brands' quality perceptions were damaged to a similar degree. However, following the ingredient transgression, the authentic brand's quality perceptions were damaged significantly more than the inauthentic brand's. This drop in quality perceptions was fully mediated by the decrease in participants' perceptions of the authentic brand's authenticity.

Drawing on the importance of “being what you say you are” in consumers' judgments of brand authenticity, we presented three studies that demonstrate positives and negatives of brand authenticity. Our findings show that consumers perceive more authentic brands to be higher in quality and suggest that they may also be willing to pay more for them. Additionally, consumers' confidence in their opinions about brands is directly tied to the extent to which they perceive those brands to be authentic. However, despite these advantages, we also demonstrated that authenticity can harm the brand if the brand commits a transgression that undermines its authenticity. Additionally, these studies demonstrate ways in which consumers' perceptions of a brand's authenticity can be manipulated.

Motivated Consumer Innovativeness: Concept, Measurement and Validation

Bert Vandecasteele, Lessius University College and Ghent University, Belgium

Maggie Geuens, Ghent University and Vlerick Leuven Gent Management School, Belgium

EXTENDED ABSTRACT

Since the early seventies, several researchers have tried to predict consumers' innovative buying behavior by means of different scales intended to measure innovativeness as a personality trait. However, most previous research disregards the consumer-product relation (Gatignon and Robertson 1985; Goldsmith and Flynn 1992) and ignores the different motivation sources. By constructing a new Consumer Innovativeness scale which incorporates a diversity of underlying goals and motivations for buying an innovation, we take the notion of product-consumer interactions in Consumer Innovativeness one step further: Consumers differ not only in level of innovativeness (i.e., personality trait of consumers) but also in type of innovativeness (i.e., motivations to buy the innovation).

Consumer innovativeness is "the tendency to buy new products in a particular product category soon after they appear in the market and relatively earlier than most other consumers in the market segment" (Foxall, Goldsmith, and Brown 1998, 41). This personality trait should provide an explanatory basis for innovative buying behavior, however, predictive validity still is problematic with the existing innovativeness scales (Im, Bayus, and Mason 2003). By including a wider spectrum of motivations, we are able to construct an innovativeness scale that performs better both in terms of content validity and predictive validity. Moreover, it may help marketing researchers and managers to identify and reach the motivated innovative consumer for their innovation more effectively.

We base our conceptualization on general motivation, goal and value taxonomies (Ford and Nichols 1987; Schwartz 1992) and can conclude that at least four motivational dimensions are of importance for Consumer Innovativeness: (1) Functionally Motivated Consumer Innovativeness (fMCI) is Consumer Innovativeness motivated by the functional performance of innovations which focus on task management and accomplishment improvement. (2) Hedonically Motivated Consumer Innovativeness (hMCI) is Consumer Innovativeness motivated by an affective or sensory stimulation and gratification. (3) Socially Motivated Consumer Innovativeness (sMCI) is Consumer Innovativeness motivated by the self-assertive social need for differentiation. And finally, (4) Cognitively Motivated Consumer Innovativeness (cMCI) is Consumer Innovativeness motivated by stimulation of the mind. These four motives often recur in general consumer behavior literature (Rossiter and Percy 1997; Sweeney and Soutar 2001), innovativeness literature (Arnould 1989; Fisher and Price 1992; Simonson and Nowlis 2000; Voss, Spangenberg, and Grohmann 2003) or different innovativeness scales (Baumgartner and Steenkamp 1996; Roehrich 1994; Venkatraman and Price 1990), however, hardly any innovativeness scale has been developed that includes a wider array of potential consumer motives.

We develop a 20-item 4-dimensional MCI scale based on a combination of eight studies (with about 2,600 respondents in total).

We start with an item pool of 254 items, based on literature review, existing Consumer Innovativeness scales, exploratory interviews and an exploratory quantitative study with 279 respondents who had to indicate to what extent 135 human motives (Chulef, Read, and Walsh 2001) are applicable to the purchase of innovations. Based on expert and consumer judgments of all items, taking content validity, representativeness, dimensionality, comprehensibility, and unambiguousness into account, 90 items remain. These 90 items are included in an online survey with 452 respondents. Based on principal component analyses and confirmatory factor analysis taking scale development procedures of Netemeyer, Bearden, and

Sharma (2003) into account, we can reduce the pool to 30 items, and can confirm the 4 MCI factors. These factors prove to possess high internal validity, sufficient discriminant validity, composite reliability, and average variance extracted. Furthermore, the 4-factor correlated model results in an acceptable overall fit and proves to be the best model. Moreover, we can prove convergent validity with Roehrich's (1994) Hedonic and Social Consumer Innovativeness scale, and discriminant validity with Baumgartner and Steenkamp's (1996) Exploratory Acquisition of Products scale and Eysenck, Eysenck, and Barrett's (1985) Extraversion scale.

We further refine the scale with a new survey including the 30 MCI items. Based on similar procedures, we have to remove 10 extra items, resulting in the 20 final MCI items. Again, the fit indices indicate a good model, which outperforms other models. In addition, MCI proves to be stable over time, as we can prove test-retest reliability. Moreover, MCI is not sensitive to social desirability bias.

Finally, an innovativeness scale also needs to predict innovative consumer behavior in everyday life. We check this with two studies: First, a predictive validity study is set up with fictitious innovations, which are manipulated towards the four innovativeness motivations. Moreover, as we add two existing general innovativeness scales to the survey, we can verify whether MCI performs better in predicting innovative behavior than existing scales. Second, we have another study with a list of existing innovations. Both studies prove that there is a unique relation between each motivation dimension and the attitude, the buying intentions or buying behavior of consumers regarding innovations that satisfy these specific functional, hedonic, social or cognitive needs. Moreover, we prove that MCI predicts innovation buying behavior better than the traditional Cognitive and Sensory Innovativeness scale of Venkatraman and Price (1990), and the recently developed Global Consumer Innovativeness scale of Tellis, Yin, and Bell (2009).

To conclude, this four-dimensional Consumer Innovativeness scale consisting of a hedonic, functional, social, and cognitive dimension is useful for several reasons. First, the eight studies show that the dimensionality, reliability, convergence, discriminant, and predictive validity of MCI prove satisfactory. Second, MCI measures more than existing Consumer Innovativeness scales: (1) MCI not only measures the intensity of Consumer Innovativeness, but also its origin. (2) MCI keeps the middle ground between existing general innovativeness scales, which are unimpressive in predicting innovative buying behavior, and the domain-specific innovativeness of Goldsmith and Hofacker (1991), which is product-specific and thus not very practical, leading to a better performance in terms of predicting innovative behavior. (3) Moreover, MCI disproves the general consensus that younger people are more innovative than older people: Older people are as innovative as younger people as far as functional innovations are concerned. As most existing innovativeness scales focus on hedonic and social innovativeness, and older people are less hedonically and socially motivated to buy innovations, these scales are not able to capture the innovativeness of older people.

Innovation Aesthetics: The Relationship between Category Cues, Categorization Certainty and Newness Perceptions

Miranda Goode, University of Western Ontario, Canada

C. Page Moreau, University of Colorado at Boulder, USA

EXTENDED ABSTRACT

Research suggests a disconnect between what marketers deem to be new and innovative versus what consumers actually perceive (Gourville 2006). Many factors may contribute to this, however, we investigate the factor that has significant potential to first attract a consumer to a new product, the product's visual aesthetic design. Despite the capacity for innovative product design to elevate a company's success in the marketplace, there has been little attempt to determine how this may influence newness perceptions. It is acknowledged that "product newness is a vital selling point," (Bloch 1995) and "widely respected" (Moreau and Dahl 2005), and visual design is often a central focus of new product managers; yet when considered together, there is limited insight into the factors that underlie their relationship. While research on innovation adoption has identified factors that influence consumer preferences, the majority of the studies assume product newness to be objectively perceived and appreciated by participants. In contrast, we introduce a unique perspective of consumer response to new products by examining newness perceptions as a dependent variable that is inherently comparative, highly subjective and dependent on the certainty of underlying categorization processes. By utilizing a categorization framework to examine the relationship between innovative visual aesthetics and newness, we are also able to provide support for the role of categorization certainty, a type of certainty that may account for the somewhat surprising subjectivity of newness perceptions.

The relation between innovative visual aesthetics and newness perceptions has not been well defined. There are at least two reasons for this. First, studies on new products have typically made visual product information non-essential in the evaluation of an innovation by not providing product pictures and focusing participants explicitly on written descriptions of a product's non-visual features, functionality, and benefits (e.g., Alexander et al. 2008; Castano et al., 2008; Hoeffler 2003; Lajos et al. 2009). Second, research investigating consumer response to design has used products that do not deviate visually in any substantial way from typical category members (Cox and Cox 2002; Page and Herr 2002; Veryzer and Hutchinson 1998). In contrast, our focus is on innovative visual aesthetics. When the exterior of a product differs significantly from known category members, identifying the product's category may be difficult, uncertain or impossible. With the innovative Roomba vacuum, for example, even if consumers were provided with the product's category, uncertainty in the vacuum label may arise because its design is drastically different from that of a prototypical vacuum. It is this uncertainty in a new product's categorization that we predict will explain the influence of innovative aesthetics on newness perceptions.

We define categorization certainty as the level of confidence an individual has in their categorization of a product. This parallels a construct in attitude persuasion, thought confidence (Petty, Brinol, and Tormala 2002). Similar to how thought confidence is proposed to influence attitudes, we propose that how certain a consumer is in the categorization of a product will influence newness perceptions. The source of categorization uncertainty may vary. For instance, Gregan-Paxton et al. (2005) and Lajos et al. (2009) explored categorization uncertainty associated with products that possess features and functionality from different categories. We build on this, by explicitly defining and measuring categorization certainty

and its independent effect on newness perceptions in response to innovative aesthetics. Specifically, we predict that when categorization certainty is low (high), an aesthetically innovative new product will be rated as less (more) new (hypothesis 1).

When faced with innovative product design, consumers will first seek to identify the new product's category. Innovative aesthetics may make categorization difficult and reliance on all available category cues will be necessary to identify a product's category with certainty. In our attempt to isolate the effect of innovative visual aesthetics on newness perceptions, we treat product function and brand name as additional sources of category information or cues, as these may be processed in addition to visual aesthetics to confirm a product's categorization. Thus, we anticipate that when additional diagnostic category cues are available, the more certain consumers will be in a product's categorization and the newer they will perceive an innovative product. We predict that categorization certainty will mediate the influence of category cues on newness perceptions (hypothesis 2).

In studies 1 and 2, we manipulated the availability of supplemental category cues, during exposure to a new product, to examine how additional category information affects the relation between categorization certainty and newness perceptions. In study 1, the number of category cues available to participants was manipulated through the presence or absence of a brand name on the product's exterior. In study 2, category cue level was manipulated by having participants either view a picture of a new product or a video demonstration. Support for both hypotheses was found in studies 1 and 2. In study 3, we contrasted two products from the same category, through a manipulation of design prototypicality, to further demonstrate that innovative visual aesthetics exacerbates the negative effect of categorization uncertainty on newness perceptions.

Prior investigations have not defined or isolated the effect of categorization certainty on judgements, like newness perceptions, that occur early in the new product adoption process, nor examined the role of visual aesthetics and availability of category cues as antecedents to categorization uncertainty. We demonstrate that if a consumer cannot categorize a new product with certainty, as can happen with innovative aesthetic design, a product's newness is likely to be underappreciated. Our findings do not imply that product designers should be conservative in the visual design of their new products. In fact, Verganti (2006) points out that radical innovations actually tend to have longer commercial success, higher margins and increased consumer receptivity. Rather, our findings suggest that there is a potential danger in letting consumers self select and validate a new product's category membership. Consistent with Verganti (2006), our research emphasizes the importance of "preparing the public" for "ground-breaking products". When introducing new products with innovative visual aesthetics, this preparation should come through the careful and deliberate disclosure of a product's category membership.
