You Get What You Pay for But I Don't: Effect of Construal Level on The Price-Quality Relationship

Dengfeng Yan, Hong Kong University of Science and Technology, China
Jaideep Sengupta, Hong Kong University of Science and Technology, China

EXTENDED ABSTRACT

Consider the following scenario: you observe that a friend has bought a well-designed, attractive bag for a surprisingly low price. What inference would you draw regarding the quality of that bag: high quality (because of its attributes such as design and materials) or low quality (because of the low price)? And would your quality inference be any different given a perspective shift—namely, would you be more or less inclined to assess quality on the basis of price if it were a bag you had bought yourself? Alternately, suppose you were evaluating the quality of a product for immediate use as compared to future use—when would you give greater weight to the product's price, as opposed to its attributes, when forming your judgment of quality?

In seeking to answer questions such as the above, this paper addresses the key issue of how consumers form inferences regarding product quality; and in particular, the extent to which they base these inferences on price as opposed to product attributes. The current research builds on construal level theory (Trope, Liberman, and Wakslak 2007) to propose a key contingency as to when the influence of price on quality perceptions may be diminished or enhanced. The central idea is that price has greater impact on consumers' quality judgments of psychologically distant vs. nearer purchases, with the reverse being true for the impact of product attributes. The concept of psychological distance subsumes several dimensions, such as interpersonal distance (e.g., whether an inference is drawn on the basis of one's own or another's behavior) and temporal distance (whether an inference has to do with the immediate or distant future). Thus, invoking construal level theory allows us to provide a unified answer to the seemingly disparate questions raised in the opening paragraph as to how price may influence quality perceptions in different scenarios.

Theoretical Background

Findings from the construal theory literature suggest that abstract information, compared with concrete information, tends to exert more impact on representations and judgments of psychologically distant events, while the reverse holds when the focal judgment is about psychologically near events (e.g., Liberman and Trope 2000). We argue that this premise contains direct implications for how quality inferences are formed in different situations. Compared to specific, concrete product attributes, price can be thought of as a more abstract, general cue, especially with regard to its implications for quality. One reason for the relatively more abstract nature of the price cue has to do with it being a universal component for practically all products; thus, the price-quality heuristic itself represents a generalized abstraction of a consumer's many observations and experiences. In contrast, the diagnosticity of attributes is usually specific to different product categories (e.g., hard disk capacity can be used to infer computer quality, but is inapplicable to judgments about cars; on the other hand, the physical attractiveness of the packaging is often used for quality judgments of food items, but less so for computers). Indeed, the idea that the price-quality belief is an abstract "theory" while product attributes are more concrete "data" has been widely adopted in previous consumer research (Baumgartner 1995; Broniarczyk and Alba 1994). In light of this distinction, and given the preceding arguments arising from construal level theory, it follows that:

Consumers' reliance on price for making quality inferences will be enhanced when the judgment is psychologically relatively distant. Information relating to product attributes, on the contrary, will be utilized more when the quality judgment is psychologically closer.

Studies

A series of five experiments provided convergent support for these predictions. The first three experiments used the "self" vs. "other" interpersonal dimension to operationalize psychological distance.

The first study looked exclusively at the influence of price on quality judgments. Participants were asked to predict the quality of a series of products whose prices (high vs. low) were given; they were told either that the purchase had been made by themselves ("self" condition, representing low psychological distance) or by others ("other" condition, representing high psychological distance). Experiment 2 assessed quality inferences after manipulating both price and the favorability of product attributes. Specifically, we asked participants to judge the tastiness of a dish of fried rice, on the basis of two cues: its price, and its physical attractiveness. In Experiment 3, we sought to replicate the previous findings obtained on quality assessments (Experiments 1 and 2) using a selection paradigm. Instead of simply being asked to make a quality judgment based on information about a single product, participants were asked to indicate which of two yogurts was tastier: one that was expensive and had an unattractive package, while the other was presented as being cheap but attractive. Experiment 4 then operationalized psychological distance through a different (temporal) dimension. Finally, experiment 5 provided strong support for the posited mechanism by directly manipulating construal level. In line with our hypotheses, and across different product categories, results across from all of these studies showed that participants relied more on price than on product attributes when predicting product quality from an "other" vs. a "self" perspective; in contrast, the weight accorded to product attributes followed the reverse pattern. It is noteworthy that convergent support for our predictions was obtained across a variety of product categories, different dependent variables (single-option quality judgments as well as the choice paradigm used in experiment 3), pre- and post purchase scenarios, and several different manipulations of construal level, including two different dimensions of psychological distance (interpersonal and temporal) as well as the direct manipulation used in experiment 5.

How Does Construal Level Influence Donations to Individuals and Organizations

Danit Ein-Gar, Tel-Aviv University, Israel

Liat Levontin, Interdisciplinary Center (IDC) Herzliya, Israel

EXTENDED ABSTRACT

The current research explores the interacting effect of individuals' construal level and the donation target (i.e., person or organization) on willingness to donate time and money.

According to findings from research on construal level (CLT, Trope & Liberman 2003), individuals' cognitive mindset influences the way they process information and, as a result, their preferences and behaviors. It is argued that psychologically proximal events are mentally represented via low level construal, while psychologically distant events are mentally represented through high level construal (e.g. Trope & Liberman 2003; Chandran & Menon 2004; Bar-Anan, Liberman & Trope 2006; Trope, Liberman & Wakslak 2007).

We suggest that a donation campaign may be processed differently depending on its psychological distance from the audience. For example, a campaign calling for immediate donations is more likely to be processed with a low level of construal while a campaign that is expected to be launched in the future is more likely to be processed with high level construal due to the differences in time distance. Also, a campaign for poor elderly people launched at a university campus is more likely to be processed by students via a high level of construal while a campaign for students in financial need is more likely to be processed via low level construal due to differences in social distance.

We hypothesize that individuals led to adopt a low-level construal mindset will be more willing to donate to a specific, rather than general, donation target. A campaign focused on a specific donation target, that is, on a particular individual in need, fits with low level construal representation because it focuses on specific categories, details and context-dependent information. On the other hand, individuals led to adopt a high construal mindset will be more inclined to donate to a general, rather than personal, donation target. That is so because a campaign focused on a general donation target, such as a charitable organization, fits with high level construal processing, as it focuses on broader categorization, general descriptions, and de-contextualized information.

STUDY 1

Expectancy and value are two components of the motivational force (Vroom, 1964). Thus, donations are based on the expectancy that a campaign will be successful and on the value of the campaign. We suggest that the fit between level of construal and the campaign message's personalization level increases both expectancy and value.

One hundred and thirty two participants were randomly assigned to one of four conditions in a 2 (construal level) x 2 (personalization) design.

Personalization: Participants were either asked to help an under-privileged boy (personal) or to assist under-privileged children who stay in care centers (non-personal) with their school assignments.

Construal level: Participants were either told that the campaign was expected to be launched in the next month (low level) or at the beginning of the next year (high level).

As expected, two-way interactions were found such that in the low construal condition, participants indicated a higher expectancy that the campaign would be successful and assigned more importance to it when the message was personalized. Conversely, in the high construal condition, participants demonstrated higher expectancy and attributed more importance to the campaign when the message was non-personalized (Expectancy: $F_{(1,128)}=3.23, p=.05$; Value: $F_{(1,128)}=4.33, p<.05$).

STUDY 2

In Study 2 we investigated that the fit between level of construal and the campaign message's personalization level increases participants' willingness to donate time.

One hundred and twenty two participants were randomly assigned to one of four conditions in a 2 (construal level) x 2 (personalization) design.

Personalization: Participants were either asked to help an immigrant settle-in (personal) or to help at an absorption center (non-personal).

Construal level: Participants were either told that the campaign focuses on helping immigrant students (low level), or that it focuses on helping elderly immigrants (high level).

Finally, participants were asked how many hours they were willing to give per month and how many months they would be willing to volunteer as well as report their expectancy and campaign importance.

As expected, under low construal participants were more willing to contribute time when the message was personalized. Conversely, under high construal participants were more willing to donate time when the message was non-personalized (Hours: $F_{(1,118)}=5.16, p<.05$; Months: $F_{(1,118)}=4.27, p<.05$).

Furthermore, replicating the results of Study 1, the cross over interaction was found significant for both expectancy ($F_{(1,118)}=6.17, p<.05$) and value ($F_{(1,118)}=3.92, p=.05$).

STUDY

Time and money are processed differently (Zauberman and Lynch 2005, Malkoc and Zauberman 2006; Liu and Aaker 2008). Specifically, when thinking about time, compared to money, people are more susceptible to biases in decision-making. The current study seeks to demonstrate that the fit effect also occurs in willingness to donate money.

Three hundred and fifty eight participants were randomly assigned to one of six conditions in a 2 (construal level) x 2 (personalization) x 2 (gender) design.

Personalization: Participants were either asked to help a person injured in a car accident (personal) or to assist in the department for rehabilitating individuals injured in car accidents (non-personal).

Construal level: When a potential donor's gender is congruent with the target's gender, information will be processed more with low level construal due to high psychological proximity than when gender is incongruent. Therefore, participants' gender was coded. Match conditions (e.g. male participant and male target) were coded as the low level condition while discordant conditions were coded as the high level condition.

Finally, participants were asked how much money they were willing to donate.

As expected, a three-way interaction was found ($F_{(1,350)}=4.64, p<.05$). Men were willing to donate more money to injured men in the low construal condition when the message was personalized. When the message was not personalized, men were willing to donate more money to injured women under the high construal condition. The same effect was found for women.

Socially Conscious Consumption and Civic Engagement: Mobilizing Collective Concern through Private Interest

Lucy Atkinson, University of Texas at Austin, USA

EXTENDED ABSTRACT

Consumer culture is often criticized for the deleterious effects it is assumed to have on civic connectedness and concern for the social good. The rising trend of socially conscious consumption, such as buying fair-trade products, offers a challenge to this view of consumer behavior. However, little research exists empirically testing the relationship between socially conscious consumption and civic and political engagement. The modest amount of research that does explore these connections is largely conceptual and assumes a negative relationship, with consumer preferences winning out over civic ones.

The research outlined here challenges these shortcomings. Using a series of depth interviews, I demonstrate that pro-social consumer orientations can have a positive influence on civic and political engagement. Accepted wisdom among critics of consumer-motivated civic involvement holds that this consumer orientation fosters individualism and self-interest at the expense of a collective focus, and that it redirects civic action away from the political realm to the corporate arena. The concern is that politically motivated consumers will be civic-minded only to the degree that their own issues can be resolved and will avoid collective action at resolving more generalized societal issues. The data, which were collected using an existential-phenomenological approach, suggest such fears may be overstated. Among socially conscious consumers, marketplace behaviors offer a viable and meaningful springboard to political engagement. It is by attending to private, individual concerns that consumers address moral and ethical issues at the collective level. Socially conscious consumption taps into and encourages a kind of enlightened self-interest whereby concern for the self, as expressed through consumption, breeds concern for the collective.

This study draws on Soper's (2008) notion of the alternative hedonist to understand how socially conscious consumers relate their private consumer practices to their public citizenship practices. It relies on a series of depth interviews with socially conscious consumers aimed at understanding the meanings they ascribe to their consumer choices. These meanings are uncovered through existential-phenomenological interviewing and hermeneutic analysis (Craig J. Thompson, 1997; Craig J. Thompson, Locander, & Pollio, 1989).

To explore the consumption as politics thesis, a group of white, middle-class, college-educated consumers who self-identify as socially conscious were interviewed using the E-P approach about their consumer practices and motivations. Literature about socially conscious consumption indicates that socially conscious consumers tend to be middle class, well-educated and white, as they are the individuals likely to have both the means and the opportunity to engage in socially conscious consumption.

Informants were recruited from a small Midwestern city in two phases: first, through the researcher's extended social network and second, through these informants' social networks. In total, eight informants were interviewed over the course of two months in spring 2009. Although all informants were white and middle class, they represent a relatively diverse group in terms of ages, occupations, genders and family structure. Six of the interviews took place in the informants' home, one took place in the researcher's home and one took place in a coffee shop. They were all semi-structured and lasted between 35 and 85 minutes, yielding 80 pages of transcribed interview notes. The interview format was informed by the E-P approach advocated by Thompson, Locander and Pollio (1989). As

such, although the researcher relied on a brief interview guide, the interviews were allowed to develop freely and naturally.

The results here expand on Soper's framework by offering an explanation of the process behind the self-interested attention to the wider social good. Specifically, it is proposed that consumers engage in a process of making pleasurable compromises and trade offs. Socially conscious consumers reap a number of benefits (beyond the simple acquisition of material goods or services) by engaging in prosocial consumption. Across each informant interview, four particular and interrelated themes emerged: socially conscious consumption as authentic, as socially embedding, as empowering and as self-actualizing. For each of the socially conscious consumers interviewed, the reasons behind certain consumer choices were clearly energized by personal concerns, such as family health. And while broader social concerns—such as the environment, animal rights—played into their consumption calculus, individuals did not differentiate between these different collective concerns nor did they prioritize one over the other. These collective benefits were thought of as a package and working toward them was part and parcel of enacting their own self-interest. This self-interest was tempered through a process of compromises and trade offs that were rationalized as enjoyable and pleasurable.

Each informant noted how their consumption choices entailed a degree of effort and sacrifice, but these sacrifices were made willingly. Rather than focus on the cost, both literal and figurative of leading a socially conscious consumption lifestyle, the informants concentrated on the enjoyment such compromises brought. By reframing the extra effort as a source of potential pleasure to another possible benefit, the informants were able to reconcile the burdensome side of prosocial consumption with the self-interested, private motivations that underpinned it.

Work by Hirschman and Holbrook (1982) offers insight into how consumers might transform consumption costs into benefits. Hirschman and Holbrook argue that commodities should not be thought of simply in terms of their utilitarian or functional attributes—as object entities—but as subjective symbols. Consumers engage in hedonic consumption when they impart subjective meanings to objects and incorporate emotion into their consumer practices. This emotional aspect muddies the simple cost-benefit analysis that rationalizing consumers are assumed to make but also explains why consumers will make decisions that are not always the easiest or most cost effective.

Instead of focusing on the problematic aspect of the consumption act (“the store is difficult to get to” or “I can't eat strawberries in January”), the informants emphasized the potential joy (“the store delights my senses” or “depriving myself of strawberries makes them taste that much sweeter when I can eat them”). One informant underscores this mental readjustment when she says: “We don't feel like we're sacrificing anything really. It's all a gain.” By understanding the informants' consumption practices through an “alternative hedonist” lens it is possible to understand how socially conscious consumers privilege their private desires while also benefiting the collective good.

Fabricating “Green” Meaning: An Empirical Examination of the Role of Indexical and Iconic Cues to Authenticity

Douglas Ewing, University of Cincinnati, USA
Chris Allen, University of Cincinnati, USA
Randall Ewing, Ohio Northern University, USA

EXTENDED ABSTRACT

Extant consumer concerning authenticity has imbued the literature with numerous definitions and conceptualizations of authenticity but little in the way of theory about its antecedent/consequent processes (cf. Leigh, Peters, and Shelton 2006). The present research attempts to bring authenticity into the lab and pursue the phenomenon in a unique way. We draw on research in semiotics (e.g. Grayson and Martinec 2004; Hoshino 1987; Mick 1986, 1998) and test explicit hypotheses about how indexical and iconic cues influence judgments about brands in a context of “green” consumption.

Indexical cues are attributes of an object that provide a spatio-temporal and/or verifiable link to a reference point (Grayson and Martinec 2004). Their presence provides overarching validation that a consumption object has the appropriate characteristics and abilities to bear a “green” meaning. Assuming that individuals recognize the connection suggested by a “green” indexical cue, they will be more likely to judge an object as having an authentic “green” meaning leading to increased beliefs that it is “green,” thus yielding more favorable attitudes (Fishbein and Ajzen 1975; Lutz 1977).

Iconic cues are qualities that suggest “schematic fit” with expectations for an authentic object but lack an externally-verifiable reference point or “correspondence of fact” (Mick 1986). These cues emphasize general congruence with a consumer’s idiosyncratic, internal frame of reference (Grayson and Martinec 2004; Leigh et al. 2006). Provided an individual has some expectations, he/she should judge an object as more authentic to the extent that there is matching between expected and observed iconic cues. As with indexical cues, this should have positive effects on both “green” beliefs and brand attitudes. However, given the straightforward meaning validation provided by a singular indexical cue, it seems plausible that these stronger cues will have a greater effect on beliefs and attitudes.

The efficacy of both indexical and iconic cues is likely to vary according to relevant characteristics of their associated product. One very basic product quality is whether it is an infrequently purchased durable or a more frequently purchased non-durable. Durable goods tend to have more features and be larger purchases in terms of cost, both of which may incline consumers to desire more information and engage in a more extended search (e.g. Brucks 1985). Thus, it is conceivable the information provided indexical and iconic cues will be less effective for a durable versus a non-durable.

Beyond predicted effects of indexical and iconic cues and a differential effect between durable and non-durable goods, a general assertion of this conceptualization is that semiotic cues enable a consumer to validate a “green” product meaning. This “green” meaning should lead to specific beliefs about a product as well as more positive attitudes. Hence, the effect of the indexical and iconic cues on brand attitude likely operates through brand beliefs (Ajzen 2008).

These general predictions were tested in a 2 (Indexical Cue: Green/Non-Green) x 2 (Iconic Cue: Green/Non-Green) x 2 (Product Type: Consumable/Durable) within-subjects design (n=140). Participants evaluated 8 durable or non-durable brands based on visuals and text information embodying indexical and iconic cues.

The indexical cue manipulation took the form of recognizable labels or co-brands intended to verify the target quality of “green.” The iconic cue manipulation comprised elementary information about such features as product composition or usable life to signal the target quality of “green.” The product type manipulation took the form of consumables versus durables. Each participant evaluated 4 consumable brands (2 laundry detergents and 2 batteries) and 4 durable brands (2 desktop computers and 2 car tires).

Participants reported their brand attitudes and beliefs via a 7-point semantic differential scale. Attitude items were favorable/unfavorable, pleasant/unpleasant, and good/bad. The belief items of primary interest were green/not green, thrifty/wasteful, and natural/artificial. Additional items belief items were collected to make memory-based comparison more difficult. The dependent variables retained for subsequent analyses were attitude and green-belief for each brand represented by a mean-centered sum of respective items. The data were analyzed with linear mixed models using maximum likelihood estimation to account for potential non-independence across ratings.

Results indicate that indexical cues and iconic cues had significant effects on green beliefs. Participants had more favorable green beliefs and attitudes when indexical and iconic cues signaled a “green” quality. Indexical cues were stronger than iconic cues in affecting green beliefs but not brand attitude. In addition to the cue types alone, results suggested that changes in green beliefs and attitudes towards durables were less sensitive to indexical cues and iconic cues than were consumables. A mediation analysis indicated that green beliefs fully mediated the effect of indexical cues and partially mediated the effect of iconic cues on brand attitude.

Overall, indexical cues had a more robust effect on green beliefs and attitudes and that these effects of both cue types are stronger upon consumables versus durables. Furthermore, the effectiveness of these semiotic cues varies according to a basic durable/non-durable distinction among products and green beliefs fully or partially mediate the effects of indexical and iconic cues manipulations on brand attitudes. Hence, it can be said that indexical cues and to a lesser extent iconic cues activate spontaneous inferences that manifest as new beliefs and corresponding brand attitudes. In addition, the pattern of results generally in line with predictions provides evidence that iconic versus indexical cues can be systematically manipulated to affect authenticity judgments. Taken together, the results provide evidence supporting a meaning validation process as the basis of authenticity judgments.

This research conceptualizes authenticity judgments in familiar terms for consumer researchers; that is, as a process involving spontaneous inferences about specific brand beliefs that then effect brand attitudes. Viewed this way, it is possible to bring authenticity phenomena into the laboratory and construct a nomological network to guide theory building. This research represents a first step on that path. Supplementing extant, interpretive research on authenticity with disciplined theory building represents a meaningful opportunity to inform the debate in a substantive domain where there is broad researcher and practitioner interest.

The Dark Side of Product Attachment: An fMRI Study of Reactivity of Users and Non-Users to Addictive Advertising Cues

Dante Pirouz, University of Western Ontario, Canada
Connie Pechmann, University of California at Irvine, USA
Paul Rodriguez, UC San Diego, USA

EXTENDED ABSTRACT

Advertising is a ubiquitous and pervasive environmental cue. The average consumer, for example, is exposed on average to three thousand ads per day (Schwartz 2004). Under normal circumstances, consumers choose which advertising cues to attend to both consciously and non-consciously (Bargh 2002; Grunert 1996). However for consumers, environmental cues may elicit a unique type of response affecting decision making and driving behavior (Bernheim and Rangel 2004). The aim of this research is to explore how environmental cues affect addictive product users and non-users using the brain imaging technique developed in neuroscience functional magnetic resonance imaging (fMRI) for cue-exposed users and non-users.

A great deal of debate, both in the literature and among advertisers and public policy makers, centers on how environmental cues influence people to engage in risky and addictive behaviors (Pollay 1986; Pollay et al. 1996a). Marketers and manufacturers argue that advertising and promotional materials offer consumers brand options and information that enhance the consumer's ability to make choices (Gilly and Graham 1988; Goldberg et al. 2006), while researchers and public health officials argue that there is a strong correlation between detrimental behavior and exposure to marketing for addictive products (Pollay 1986; Pollay et al. 1996b). There remain unanswered questions regarding how users and non-users respond to this type of stimulus. In addition, there are conflicting indications of how craving elicited by cues impacts cognitive processing, including cognitive depletion leading to impulsivity outside the addictive substance domain. Given the ongoing debate there is a need for a better understanding of the underlying psychological and physiological mechanisms that drive the reactive response to advertising cues by users and non-users.

The research question addressed in this research is whether environmental cues—namely cigarette advertising—cause a reactive response in the form of increased craving in users or non-users resulting in downstream impulsive behavior as a result of cognitive resource depletion. The study uses functional magnetic resonance imaging (fMRI) to examine the underlying neural response to addictive (cigarette) advertising versus non-addictive (non-cigarette) advertising in users (smokers) and non-users (non-smokers). Brain imaging data have been collected from 10 current, daily smoker and 10 non-smokers for this study. This study was a 2 (user type: smoker vs. non-smoker) x 2 (cue type: addictive ad cue vs. non-addictive ad cues) design using a 3T fMRI scanner.

A long history of addiction studies demonstrates how drug cues elicit craving via reactivity to the cue (for reviews see Carter and Tiffany 1999; Childress et al. 1993; Stritzke et al. 2004). There has also been evidence of attentional bias toward addictive cues in users (Robinson and Berridge 2003; Robinson and Berridge 2001; Robinson and Berridge 1993). Some studies have shown that this response may result in increased attentional bias and increased arousal (Bradley et al. 2004; Drobos 2002; Johnsen et al. 1997; Mogg and Bradley 2002; Munafò et al. 2003). However other studies have found that addictive product users, when exposed to these cues, may have an ability to inhibit the craving response and its effects (Artiges et al. 2009; Goldstein et al. 2007a; Stippekohl et al. 2010; Volkow and Fowler 2000; Volkow et al. 2010). On the other hand, non-users have been shown to be largely unaffected

by exposure to addictive cues (Due et al. 2002; Tapert et al. 2003). However, research on the uptake of addictive products by new users points to evidence that addictive product cues, such as advertising, do indeed have an effect on non-users (Altman et al. 1996; Pierce et al. 1991). Thus there remains a debate in the literature as to whether advertising enhances or attenuates the craving response in users and how it ultimately affects non-users.

This brain imaging data indicates neural activation of brain regions that are related to craving and self-control in smokers and non-smokers. For example, there is differential activation in regions associated with craving including the amygdala and the thalamus. Regions associated with self-control including the dorsolateral prefrontal cortex and anterior cingulate cortex are also differentially activated with significant deactivation in smokers exposed to cigarette ads. The results show significant differential activation for non-users when exposed to addictive ad cues versus non-addictive ad cues. In addition, the results show a different effect when users are exposed to addictive ad cues versus non-addictive ad cues. They demonstrate that a cue reactivity response elicits significant activation in brain regions associated with craving in both non-users and users. There is also significant activation in regions associated with cognitive resource depletion for non-users as a result of the increased craving activation. This may be due to the fact that non-users underestimate the effect of this type of advertising, assuming that because they do not smoke, there ads are not targeted directly to them. However, because these non-users have not built up the ability to resist the tempting urge response generated by the addictive product ads, brain regions necessary in order to resist the temptations are activated. Interestingly there is significant deactivation in brain regions of users associated with self-control indicating inhibition of the cognitive resource depletion possibly as a way for users to cope with stimuli that they feel is targeting towards them and an urge response for which they feel they cannot satisfy at that moment.

Subliminal Prime-to-Behavior Effects

Hélène Deval, Dalhousie University, Canada
Bruce E. Pfeiffer, University of New Hampshire, USA
Frank R. Kardes, University of Cincinnati, USA

EXTENDED ABSTRACT

A wide variety of consumer judgments, decisions, and behaviors occur automatically, or without conscious awareness or intention (Bargh 2002, 2007; Dijksterhuis 2010; Dijksterhuis, Smith, Van Baaren, & Wigboldus, 2005; Wyer 2008). Many different situational cues prime or activate consumer goals and traits in a nonconscious manner. Our research contributes to the understanding of prime-to-behavior effects by: (a) investigating the influence of subliminal goal primes and trait primes, (b) demonstrating that subliminal goal and trait prime-to-behavior effects are influenced by different moderating variables, and (c) investigating the influence of subliminal goal primes and trait primes related to money.

Prior research on subliminal priming has demonstrated that subliminal goal primes are influential only when the goal is already active (e.g., Strahan, Spencer, and Zanna 2002). Theoretically, however, the influence of subliminal trait primes on behavior should not depend on goal activation. Instead, the Active-Self model suggests that the influence of trait primes on behavior should depend on the extent to which these primes alter self-perceptions via selective processing of self-relevant information or on the extent to which these primes expand the self-concept (Wheeler, DeMarree, and Petty 2007). Both of these processes are influenced by individual differences in self-monitoring, or the extent to which consumers attempt to control their behavior to influence the impressions that others form of them (Snyder 1974). High self-monitors adapt their behaviors to their social environments, whereas low self-monitors behave consistently across situations.

Although prior research has shown that trait prime-to-behavior effects are often greater for low self-monitors than for high self-monitors (DeMarree, Wheeler, and Petty 2005), Wheeler et al. (2007) suggest that trait primes should have a greater influence on high self-monitors when social norms are invoked or when ought primes are activated. In addition, because the attitudes of high self-monitors frequently serve the social-adjustive function (Lavine and Snyder 2000), trait primes pertaining to the social-adjustive function should have a greater influence on high than on low self-monitors. Money frequently serves a social-adjustive function because money can be used to impress others (a self-presentational strategy) or to attain goals without assistance from others (the self-sufficiency principle; Vohs, Mead, and Goode 2006). Further, a strong association between money and consumption behavior has been illustrated in prior research. Briers et al. (2006) demonstrated that money related-supraliminal primes increased the consumption of candies.

In two experiments, we show that subliminal priming of goals and traits influence consumption behavior in goal-consistent and trait-consistent ways. Subliminal goal primes were influential only when a relevant goal was already active, regardless of individual differences in self-monitoring. Conversely, subliminal trait primes were more influential when self-monitoring is high rather than low, regardless of the level of goal activation.

In study 1, we predicted that subliminally priming hungry participants with either money related trait primes (rich and millionaire) or goal related primes (spend and money) would increase the amount of food eaten when compared to participants in the neutral prime condition (stone and picture). The effectiveness of the subliminal goal primes should depend on whether the goal is already active. Since all participants were instructed to arrive at the study in a hungry state, all participants in the goal prime condition

were expected to eat more than those in the control condition. In contrast, since trait primes influence self-perception, they should have a greater effect on high self-monitors than on low self-monitors. As a result, we predicted that the level of self-monitoring would moderate the eating behavior of those in the subliminal trait prime condition in such a way that high self-monitors would eat more than low self-monitors.

All participants were asked not to eat anything and not to drink anything but tea, coffee, or water for at least 3 hours prior to the study. The subliminal primes (goal, trait, or neutral) were imbedded in a lexical decision task (LDT). Following the LDT, participants were asked to perform a taste test in which they evaluated two types of candy. They were instructed to eat as much as they wanted in order to comparatively evaluate the two types of candy. Following the taste test, participants completed the 18-item Self-Monitoring Scale (Snyder and Gangestad 1986) and performed a subliminality check to insure the integrity of the priming manipulation.

The primary dependent variable was the amount of candy eaten by the participants during the taste test. To test our hypotheses, we submitted this measure to a hierarchical regression analysis using the prime conditions, the self-monitoring score, and their interactions as predictors. As expected, the presence of both goal and trait primes had a significant positive main effect on the amount of candies eaten. Further, the interactions revealed that participants in the trait prime condition ate more candies as self-monitor scores increased. Self-monitoring had no influence on participants in the goal prime condition.

Study 2 was designed to replicate that effect from study 1 as well as demonstrate that goal primes but not trait primes depend on whether the goal is already active at the time of priming. The primary difference in the procedure between study 1 and study 2 was the addition of a cookie taste test to manipulate satiation. Participants in the satiated condition performed the cookie taste test at the beginning of the study before the LDT and candy taste test. Participants in the hungry condition performed the cookie taste test after the LDT and candy taste test.

Consistent with study 1, participants in the trait prime condition ate more candies as self-monitor score increased, but self-monitoring had no effect on participants in the goal prime condition. Also, consistent with our predictions, participants in the goal prime condition ate more candies when they were hungry than when they were satiated, but satiation had no effect on participants in the trait prime condition.

Both these experiments contribute to the existing literature by providing further support for the strong cognitive link between money and consumption, extending prior findings from supraliminal priming to subliminal priming, and demonstrating that trait and goal primes operate under different boundary conditions.

Revealing an Advertising Myth: How Supportive is Editorial Support?

Claas Christian Germelmann, Saarland University, Germany

Andrea Groeppel-Klein, Saarland University, Germany

EXTENDED ABSTRACT

In public relations and marketing, positive media articles about companies or brands are considered to be “gold standard”. Yet, other than what has been learned from anecdotal evidence, little is known about their success with consumers. In two experimental studies we thus focus on two critical questions:

Does coupling positive news stories with advertisements leverage ad memory and attitudes toward the advertised brand?

Could coupling advertisements and editorial content actually backfire and damage brand and/or media brand image?

Research on Effects of Editorial Content on Brands in Consumer Research

Positive news stories about companies or brands are often deemed to be more effective in influencing attitudes than advertisements (Jo 2004; Putrevu 2005; Çelebi 2007). This has been explained by the higher credibility of editorial content due to a lack of “manipulative intent” (Hallahan 1999). Only a few studies deal explicitly with ads and editorial content about a brand in the same medium. Loda and Coleman (2005) and Micu (2005) tested whether sequencing of the same message presented either as an ad or as news has an impact on persuasion. Both established mildly positive effects of supporting ads with positive news stories. However, the studies lacked realistic contexts and relied solely on forced exposure procedures in which subjects were asked to examine the stimulus material closely and didn’t have the chance to avoid exposure altogether.

Repetition and “Memory Trace Refreshment” Effects on Brand Recall

From the perspective of memory research, coupling means repeating a brand message. Information that is perceived successively from two different sources (ad and news), and thus in two different contexts, leaves more “memory traces” to facilitate retrieval than information presented in only one context. Thus:

H1: If a positive editorial report about a brand appears in the same medium as an advertisement for the brand (“article/advertisement coupling”), consumers’ recall of the brand will be higher than if the editorial report were to appear alone.

Effects of Supporting Ads with News Stories on A_{Brand}

The mere exposure effect suggests that repeated exposure should lead to a more positive attitude toward the object (Zajonc 1968). Familiarity of the message is increased by repetition in both ad and news story, and coupling multiple sources leads to a “truth effect” (Roggeveen and Johar 2002). Based on these theories, a positive effect on A_{Brand} could be hypothesized.

Expecting a positive effect is based on the assumption that consumers do not notice the connection between a news story and an ad at all (due to typical low-involvement situations). If consumers *do* consciously notice the connection, or if they just feel that there might be manipulative intent behind the editorial support, a negative effect can be hypothesized. Friestad and Wright (1994; 1995) posited that consumers possess knowledge about persuasion strategies used in advertising. The use of such knowledge typically requires cognitive processing of messages. However, even when consumers are not willing or able to elaborate on persuasive messages, it is possible that they would unconsciously draw on former

experiences of perceived manipulation by editorial support. Such “tacit” knowledge about manipulative or covert ad strategies can work as a readily available quick heuristic that could alert consumers to intended manipulation. MacKenzie and Lutz (1989) pointed to the fact that, in low-involvement situations, an attitude can be shaped not only by the features offered but also by the advertising context. However, we focus first on A_{Brand} since we are interested in natural exposure situations in which A_{Ad} may not be the best indicator of immediate ad effectiveness (Coulter and Punj 1999). Weighing all arguments, we find stronger theoretical bases for a negative effect of couplings:

H2: If a positive news story about a brand appears in the same medium as an advertisement for the brand, consumers’ attitudes toward the brand will be more negative than if the news story were to stand alone.

The Persistence of Editorial Support Effects Over Time

Most studies on persistence of attitudes are based on the sleeper effect, positing that negative evaluations caused by the message source (in our case, the coupling of ad and news story) can phase out over time. However, two critical conditions for such an effect are not met here: the discounting cue “editorial support”, from which consumers could gather possible vested interests, is not conveyed beforehand, and the ability or motivation to think about the message and its context is usually low in standard media exposure situations. In such low-involvement situations, a second contact with the brand by way of supportive editorial support (e.g., in the course of a second survey), which was evaluated negatively after the first contact, could even trigger a reinstatement effect which could intensify the negative affective reaction to the ad itself and to the brand. Thus:

H3: If a positive news story about a brand appears in the same medium as an advertisement for the brand, after two weeks, consumers’ attitudes toward the brand and to the ad will be more negative than if the news story were to stand alone.

The Problem of Realistic Experimental Designs in Advertising Research

Experimental designs in advertising and media research differ from natural settings in two ways. In the first place, the stimuli often lack realistic contexts. Secondly, the typical paradigm in experimental advertising effectiveness research uses forced exposure, and this creates a risk that consumers start hypothesis-guessing and potentially adapt their behavior accordingly. Forced exposure provides no opportunity for non-selection of the medium, thus ruling out ad avoidance and making ad and ad context processing generally more likely than in biotic media contact situations (Schuman and Thorson 1990). Consequently, in a pretest, we tested for the effects of exposure in experimental research on editorial support by comparing forced exposure with quasi-biotic exposure (where consumers know that they take part in a study but they are not informed that the stimuli are part of the design).

Key Findings

Our two studies show that news stories consistently do *not* improve the impact of ads on *brand image*. On the contrary, over time, the image of A_{Brand} deteriorates due to the coupling, and H3

670 / *Revealing an Advertising Myth: How Supportive is Editorial Support?*

finds support. When consumers' active involvement with the medium is low, A_{Brand} deteriorates if the ad receives editorial support (H2 is supported). Thus, we presume to have observed a peripheral or heuristic process to be at work. In both studies we found a positive effect of coupling ad and news story on recall, thus confirming H1. However, the second study shows that this result can also be achieved by adding a reminder spot to a commercial break, because familiarity seems to be the reason for the improved recall rather than a multiple source effect.

From a methodological perspective, the forced exposure designs commonly used in advertising research run the risk of exaggerating positive evaluations of A_{Brand} . On the other hand, forced exposure experiments tend to downplay the memory effects.

Market Scarcity and Persuasion: An Information Congruity Perspective

Feng Shen, Saint Joseph's University, USA

EXTENDED ABSTRACT

In advertising theory and practice, atypicality is considered to be an effective creative strategy to break through the clutter, and to boost ad evaluations and memory for the ad and brand (Heckler and Childers 1992; Smith and Yang 2004). However, research on this issue is limited (Smith and Yang 2004). Moreover, most advertising research used long and forced ad exposures of up to thirty seconds or longer to investigate advertising processing and effectiveness (reviewed by Meyers-Levy and Malaviya 1999), whereas attention to ads is much shorter in practice, typically a few seconds or less (Pieters and Wedel 2004). It remains unclear whether the positive effects of atypicality carry over to these much shorter durations. In fact, considering people's basic need for certainty (Loewenstein 1994), there is reason to believe that the effects of atypicality may be different at shorter exposures.

The present research focuses on information processing within the first exposure to the ad, from 100 ms onwards. Motivated to identify the stimuli they are exposed to, people attempt to identify the ads that they encounter, i.e., what they are for. In three experiments, we show that, depending on the typicality of the ad, this identification process can take different forms over the course of a single exposure, which in turn influences how evaluations develop over time (experiment 1 and 2), the attention devoted to the ad (experiment 3), and subsequent memory (experiment 2).

Typical ads display objects and scenes that are expected for the advertised category (Mervis and Rosch 1981), such as a car in a car ad. The product category of these ads is rapidly identified and with certainty in 100 ms or even less ("Ha, it's a car ad"; Pieters and Wedel 2009), and this identification certainty contributes to an immediately positive ad evaluation (Loken and Ward 1990). Additional information that becomes available after the first glance confirms the immediate identification, leaving the ad evaluation at relatively high levels of positivity, until boredom eventually befalls these ads. We distinguish two types of atypical ads, hereafter referred to as "atypical" and "typical-other" ads. Atypical ads display objects and scenes that do not immediately bring up a product category, leading to identification uncertainty ("What is that ad for?"). This negatively affects the initial ad evaluation. When exposure to the ad continues, additional information and cognitive integration contribute to ad comprehension reducing identification uncertainty ("Aha, it's a car ad"). This increased certainty is appreciated, leading to a positive updating of the evaluation. Finally, typical-other ads display objects and scenes that are typical for another category, such as a lady misting her face in a car ad. These ads are initially identified with certainty ("Ha, it's a fragrance ad"), which is liked. However, new information that becomes available during exposure disconfirms the initial identification, which needs to be revised ("Oh no, it is a car ad"). This need to revise one's initial identification may lead to confusion and requires more cognitive effort, which is disliked and leads to a downward adjustment of the initially positive evaluation.

Thus, typicality determines the identification process—identification confirmation (typical), identification disconfirmation (typical-other) or uncertainty reduction (atypical)—which has predictable effects on how ad evaluations are updated within a single exposure. In addition, it influences attention and memory, and we predict different effects depending on whether recall or recognition performance is assessed. Typical ads do not retain attention well, since they are immediately identified and additional processing does not provide much "new" information. However,

because a connection between the ad and the advertised category is immediately established upon exposure, and the ad category serves as a useful retrieval cue (Goodman 1980), they are recalled well, even after brief exposures. Recall performance of atypical ads, in contrast, is relatively poor after brief exposures, but strongly improves when additional processing leads to ad comprehension (Bransford and Johnson 1982). Because atypical ads cannot be immediately identified, they retain attention longer, such that memory should be good. In case of typical-other ads, rapidly identified inconsistencies between the initial identification and newly processed information motivate people to prolong attention to the ad. However, recall performance remains relatively poor for these ads despite additional time attending, because of source-confusion (Roediger and McDermott 2000). Recognition performance, in contrast, is poor after very brief exposures for all three ad types, but strongly improves with additional time attending (Loftus and Bell 1975), except for typical ads, that remain relatively difficult to discriminate from other ads. Due to their typicality, these ads appear familiar regardless of whether they were presented or not, increasing false recognition (Silva, Groeger, and Bradshaw 2006).

We tested and found support for our predictions about the dynamic identification, evaluation and memory processes within a single exposure in experiments 1 and 2, where we systematically varied the exposure duration of ads between-conditions from 100 ms (which is less than a single eye fixation) up to 10 seconds (cf. Donders 1868). Finally, support for the prediction that atypical and typical-other ads retain attention longer than typical ads was provided in experiment 3, where participants freely viewed a large set of ads. These findings are the first to provide insights into the rapid advertising processes from 100 ms onwards. They reveal that the effects of typicality critically depend on the exposure duration, and require revision of the idea of atypicality as a universal creative strategy to improve advertising effectiveness. Although we observe the benefits of atypical ads, we also find that their effectiveness crucially depends on their ability to retain the consumer's attention. Typical ads, in contrast, do not require such sustained attention in order to develop positive ad evaluations and memory traces for the ad and brand. Moreover, we argue for careful consideration of the type of atypicality, since typical-other ads failed on almost all accounts in the present research. We believe that the proposed theory and methodology are applicable to other situations where initial feelings may be rapidly updated, and point to repeated ad exposures as a relevant area of future research.

Generation Y's Representations of Who They Are and How They Give

Caroline Urbain, University of Nantes, France

Marine Le Gall-Ely, ICI, Université de Bretagne Occidentale, France

Christine Gonzalez, LEMNA Université de Nantes, France

EXTENDED ABSTRACT

The emergence of each successive generation raises new questions on the transmission, continuity and rupture of social behaviors (work, consumption, daily life...). Also referred to as the *E-generation*, *Net Generation* or *Millennial Generation*, the generation Y is composed, in the western world, of individuals born between the late 1970s and the mid 1990s who grew up with the excesses of the consumer society and amidst the astounding development of the information society. This generation takes the social and societal transformations of the 1960s and 1970s for granted, or even considers them obsolete, and is immersed in growing debates on ecology, the harmful effects of globalization and tomorrow's uncertainties (Allain, 2009). Socialized in a world in profound mutation, it is made up of young adults liable to develop new and unexpected solidarity and giving representations and practices.

In the face of the emergence of these new lifestyles and mindsets, and of growing debate over monetary donation collection methods, how should associations and charities approach this generation? This question brings out two preliminary lines of investigation which are the focus of this research:

How do the individuals of this generation define themselves?
How do they represent giving?

Several conceptions of giving emerge from the human and social sciences literature: an instrument of power for the giver (Mauss, 1923-1924), of domination (Weiner, 1992) making the receiver dependent, or even alienated (Testart, 1982), a sacrifice (Lévinas, 1987, 1995), a deprivation, an impossibility (Derrida, 1991), a purely disinterested, altruistic gesture, a free exchange but which creates links, obligations, debts (Mauss, 1923-1924; Lévi-Strauss, 1949; Titmuss, 1970; Sahlins, 1972; Godbout and Caillé, 1992). This polysemy shows that giving is both a collective and an individual phenomenon which is represented by a wide range of practices (Authors, 2009b). Our work is assimilated with the comprehensive research trend which has developed within Consumer Culture Theory (Arnould and Thompson, 2005). Giving is thus regarded as a system (Sherry 1983) and revolving around consumption (Giesler, 2006 ; Marcoux, 2009).

Our research focus on social representations (SR), known as allowing individuals to interpret reality in their physical and social environment and direct their behaviors and social relations (Abric, 1994). SR studies can mobilize different methodological approaches (Viaud and Roussiau, 2002; Doise, Clemence and Lorenzi-Cioldi, 1993). The free association technique, already employed in marketing (authors, 2009a), was selected for this study. This technique "consists, based on an induction word (referring to the object of the SR), of asking the informant to provide all the words, expressions or adjectives which come to mind" (Abric, 1994).

In order to answer the research questions, an exploratory quantitative study was conducted on a convenience sample of 276 individuals born between 1979 and 1991 (people belonging to Generation Y aged 18 plus as they were presumed to have autonomous giving practices). In French language, the questionnaire began with the following open question: "*Generally speaking, what does the term giving evoke for you?*", in response to which informants were asked to provide five words. It carried on to cover giving practices, exchange behavior, entourage, knowledge of associations, to finish

with questions on identity (sex, age...), including "*give five words which come to mind to describe your generation*". The free associations generated were analyzed with the software EVOC2005.

These results show both an individualistic Generation Y and a very mobile generation seeking links which is united around technology and the consumer society. This generation is not marked by collective events (as previous generations may have been). Festivity appears to be a structuring element.

Over and above this specificity, Generation Y givers and non-givers express convergence in their representations of giving:

- A vision of giving which is becoming institutionalized: associations and volunteering are terms which structure the representation.
- The strong presence of a relationship with others: at the center or close to the representation we find the notions of solidarity, sharing, aid, charity and gifts.
- A freely consenting act: a free gesture, or a gesture belonging to a gratuitous approach, which reflects an individualist dimension.

Illness is the prominent element against which giving can be mobilized: it appears first, far ahead of poverty for instance. This risk is no doubt conveyed by the media more frequently than ecological risks or natural disasters (teletthon, AIDS, cystic fibrosis...) and is more easily associated with the person's close entourage.

Givers and non-givers have a pragmatic vision of giving: the objects of giving of blood, money and organs are central elements of the representation. Nevertheless, non-givers insist upon this functional component (blood and money are quoted significantly more). One hypothesis is the media coverage of giving blood or money, non-givers thus expressing a "media-broadcast" vision of giving (they more frequently employ the term *teletthon*). Furthermore, givers show a collective apprehension of giving, seen as a system, while, in an emerging trend, non-givers have a more personal vision.

Finally, two results are worth emphasizing. First, the almost complete absence of terms expressing a negative vision of giving. Secondly, the notions of constraint and commitment were rarely touched upon. This conception of giving is distant from the notion of obligation presented in the literature on the subject (Sahlins, 1972; Sherry, McGrath and Levy, 1993; Marcoux, 2009). This representation of giving is coherent with the way in which Generation Y describes itself: turned towards others, free, largely unconcerned with notions of duty and effort. Commitment and investment must undoubtedly be a pleasure.

From a managerial point of view, these results are the first to shed light on the factors liable to cause members of this generation to give : use of social networks such as Facebook or Twitter, use of factors such as pleasure, festivities and efficiency to encourage them to adhere to causes and actions rather than recourse to guilt and duty, encourage them to "work for the association" using their skills to improve its offer.

Exploring the Everyday Branded Retail Experience- The Consumer Quest for 'Homeyness' in Branded Grocery Stores

Sofia Ulver-Sneistrup, Lund University, Sweden

Ulf Johansson, Lund University, Sweden

EXTENDED ABSTRACT

This paper extends consumer culture theories of branded retail environments by analyzing the meanings that experiences of the everyday site of the branded grocery store hold for consumers. In consumer culture theory (CCT) (Arnould & Thompson 2005), despite a growing interest in branded retail environments, little interest has been paid to the ordinary and everyday experience of the grocery store. While this site has been the predominant focus in more evidence-based consumer marketing research (e.g. Burt & Carralero-Encinas 2002; Choi, Chan and Coughlan 2006; Collins-Dodd & Lindley 2003; McGoldrick 2002; Richardson, Jain and Dick 1996), in CCT, marketplaces of more spectacular character have made out the arenas of investigation (Borghini et al 2009; Kozinets et al 2004, 2002; Thompson & Arsel 2004; Sherry 2008). Among these the development of the concept 'themed flagship brandstore' (Kozinets et al 2002, 2004; Borghini et al. 2009) is of extra interest for our investigation, as it looks at the mythological appeal in the physical as well as symbolic structure of the store. However, as the symbolic properties of such spectacular brand venues were understood as constellations of mythotypic characteristics, creating "awe" and other intense sensations among its consumers, another cultural constellation was highly likely needed to understand the more ordinary, but yet meaningful, ideal consumer experience of the everyday branded grocery store. Noting the growth of heavily branded grocery retail chains with their accompanying private brands, some of these sites may in the future live up to the epithet brandstore, but is it the same symphony of impressions sought, in these venues for everyday visits, as it is in more entertainment-heavy brand arenas?

Using ethnographic data collection methods (photo-diaries, participant observations, long interviews, artifact collections) we studied the grocery shopping habits and life at home among six Swedish middle-class working women with children during a month in the fall of 2008. Through diligent and time-consuming hermeneutic data analysis, where we iteratively moved between data and theory (Thompson et al 1994), we found that Grant McCracken's (1989) cultural account of the properties making out the experience of 'homeyness' was readily applicable to our consumers' experiences of the ideal branded grocery retailer. In addition, the eight properties of 'homeyness'—the diminutive, the variable, the embracing, the engaging, the mnemonic, the authentic, the informal, and the situating—were infused with meanings in marketplace myths through which the meaning structure of homeyness was intensified. Such marketplace myths could be fantasies about the *bella viva* around the Mediterranean, the romantization of the simple life and the humble farmer etc.

The properties of 'homeyness' and myths inflected in the consumers' everyday retail experience were of a more subdued, less mind-blowing, kind than the mythotypic emotional state conveyed by Kozinets et al (2002, 2004) and Borghinis (2009) themed brandstores. Yet, highly meaningful. These consumers held strong ties to their favorite grocery retailer brand where the 'homeyness' constellation, despite its seemingly subdued character, executed power over these women that went beyond mere convenience. Still, in terms of retail brand ideology, where the immersion into marketplace myths supports the agendas of ideologies (Thompson 2004) the myths conveyed in these everyday marketplaces rather supported unreflected dominant ideologies, than paradigm-breaking

and emerging ideology which more spectacular arenas may strive for in their quest for an overwhelming consumer experience. Thus, the powerful and distinctive experience of homeyness demands an ideology-neutral surrounding supported by marketplace-crafted myths.

We discuss the alternative understanding of the data had we selected another group of respondents. Additional research is needed to see if and how the constellation of homeyness is applicable in other national, gender, class, ethnic and lifestyle contexts. Hence, the conceptual implications of our analysis for consumer research concern on one hand the possible transferability and appropriation of the specific constellation of 'homeyness' to other important consumer cultural contexts, and on the other hand more generally the importance for consumer cultural researchers to not primarily always aim for the spectacular but also direct their eyes towards experiences of the more ordinary, yet culturally rich, kind.

Rituals in Transition: Reciprocal Pig Feasts in Northeastern Rural China

Ann Veeck, Western Michigan University, USA

Hongyan Yu, Sun Yat-sen University, China

Gregory Veeck, Western Michigan University, USA

EXTENDED ABSTRACT

With the rapid globalization and urbanization occurring in many parts of the world, many celebratory rituals that have been practiced for generations are likely to become extinct in upcoming years. Examining rural traditions in transitional communities offers an opportunity to understand how ritual activities communicate social standing and provide structure to economic processes. At what point do the benefits secured through long-standing rituals cease to be worth the sacrifice of time, labor, and money necessary to participate in the traditions? Answering this question can not only provide increased understanding of the practice of rituals, but offer insight into the effects of economic development and privatization.

Research on ritualistic acts has shown that ceremonies and celebrations serve to initiate, strengthen, or reproduce social ties (Driver 1991; Marshall 2000; Mathwick, Wiertz, de Ruyter 2008). Consonant with this theme, a number of consumer culture theorists have approached some consumption activities as ritualistic practices that serve to maintain social cohesion (e.g. Belk and Costa 1998; Bonsu and Belk 2003; Wallendorf and Arnould 1991). The social solidarity nurtured through ceremonies makes the instrumental and symbolic value of these ritual events akin to similar benefits derived from gift giving (Belk 1976; Ruth, Otnes, and Brunel 1999; Sherry 1983; Wooten 2000), with ritual ceremonies functioning as “gift systems” (Geisler 2006). In rural settings, in which the roles of producer and consumer are tightly interwoven, ritual ceremonies can serve to establish embedded economies that operate independently from capitalist markets via norms of reciprocity and trust (Gouldner 1960). Some theorists argue that communal activities involving private citizens, such as ceremonies and celebrations, which produce an abundance of social capital, can help to create civil societies, which, in turn, provide individuals some protection from the vagaries of the external market and the state (Edwards and Foley 1998; Fukuyama 2002; Woolcock 1998).

With this theoretical backdrop, this research examines the annual pig roasts, hosted by Chinese families in Jilin Province during the Spring Festival (lunar New Year). Our fieldwork included sixteen in depth interviews conducted with farm families over the course of two summers. During the first trip, made during the summer of 2008, we conducted in depth interviews with nine families in Zhenlai County, located in western Jilin Province approximately 250 kilometers northwest of Changchun, the provincial capital of Jilin. The first round included five families in the township of Dongping, and four families in the township of Momoge. During the second trip, made during the summer of 2009 and using a slightly revised interview guide, in depth interviews were conducted with an additional seven families in Jiutai County, just fifty kilometers northeast of Changchun. These interviews included three families in the township of Lianhua and four in the townships of Longjiapo. The two counties represent two quite different conditions of rural economic development, with per capita income about twice as high for residents of Jiutai County as for Zhenlai County.

Each of the families we interviewed, following a long-standing rural tradition in northern China, raises pigs throughout the year and then slaughters the pig during the period shortly before Spring Festival and cooks part of it to host a feast for friends and relatives. Via the descriptions and interpretation of the pig feasts by farmers, we learned that these annual ceremonies have provided an

important role in stabilizing and maintaining rural societies through the generation of social capital (Bourdieu 1984; Coleman 1988; Putnam 2000). The pig feasts have served to establish and reinforce a social network of relatives and friends that can be relied upon for assistance throughout the year (Kipnis 1997; Yan 1994). We identified four kinds of social capital—identity, moral, emotional, and instrumental—that have provided distinctive, but interrelated, benefits to the participants of the social gatherings.

In less-developed Zhenlai County, the pig feast ritual continues to be practiced by every household that we encountered and appears to continue to provide an important purpose in affirming an informal market that serves to collectivize tasks that are necessary for survival in rural villages. In wealthier, better-connected Jiutai County, the pig feast ritual is no longer uniformly practiced. Even the households that continue to engage in the tradition do not all feel it is necessary to commit the time and labor necessary to sustain this ritual on an annual basis. As Jiutai County is becoming more economically developed, alternative means to acquire social capital have emerged, and a formal economic system is developing that operates to perform many of the activities (e.g. loans, farm tasks, house building) that previously might have been executed with the help of an informal social network.

The decrease in the practice of the pig feast in Jiutai County raises some broader issues related to globalization, modernization, and capitalization, including potential support for western theory that ties modernization to individualization (e.g. Beck 1992; Giddens 1991) and substantiation of a link between reciprocal feasts and egalitarian societies (Durrenberger 2008). Given the prevalence of ceremonies involving ritual transaction in most societies, this research suggests the usefulness of studying the rise and fall of rituals to gain greater understanding of the rules and meanings of rituals within the larger social and economic order (Arnould and Thompson 2005).

Cultural In-betweenness and Migrant Identity: Recreating Culture in Online Thirdspaces or Heterotopias

Teresa Davis, University of Sydney, Australia

ABSTRACT

This Cyberethnographic (Robinson and Shulz 2009) study follows migrant women living over 3 continents Beginning with Babha's (1994) "thirdspace" and cultural hybridity; this examines disjunctive notions of place, 'other space' and time. Foucauldian heterotopia is offered as an explanation of this 'Other Space' and as a metaphor for migrant experience.

Opportunity or Challenge?

The Impact of Exposure to Similar Extensions on the Extensions of Late Movers

Hakkyun Kim, Concordia University, Canada

Sharon Ng, Nanyang Technological University, Singapore

EXTENDED ABSTRACT

This research examines how consumers evaluate brand extensions in the context of rivalry and competition. Specifically, unlike the extant literature, which has investigated consumers' responses to extensions with isolated market situations, the current research investigates how consumers use their knowledge of previous similar brand extensions when generating evaluations toward similar extensions from follower brands. Because any market is shared by multiple competitors, and because consumers can be exposed to competitors' actions, it may be wrongful to assume that consumers will generate new product evaluations solely based on fit perceptions (i.e., how well an extension matches the parent brand). Rather, consumers who have been exposed to similar brand extension examples may use this cue when evaluating similar extensions of other brands. Thus, this research intends to extend the consumer brand extension model by incorporating consumer knowledge into the market situation, which is assumed to be a more realistic approach.

Motivated by the importance of considering rivalry and competition situations, this research draws on consumer learning by the analogy model (Gregan-Paxton and John 1997), which posits that consumers attempt to understand and form preferences toward something unfamiliar and new by relating it to something familiar. Such relational reasoning involves a process by which people transfer their knowledge of a well-known base to a lesser-known target. Moreover, the driving force behind this knowledge transfer via analogical reasoning is the perceived similarity between the base and the target (Moreau, Markman, and Lehmann 2001; Roehm and Sternthal 2001). For instance, when faced with a generic drug, consumers may be unsure about its performance. However, these people may predict how it will work when they are informed that generic drugs have the same active ingredients as the original formulation, and they rely on their knowledge about branded counterparts.

Such a human tendency to learn about and evaluate new targets hints at the possibility that consumers can base their evaluations on prior examples that they know. For instance, when evaluating Mercedes motorcycles, consumers may rely on how good (or bad) BMW motorcycles have been, since the BMW brand is similar to the Mercedes brand, and since consumers are aware of the performance of BMW motorcycles. Therefore, we reason that consumers who have knowledge of prior similar extensions (e.g., BMW entering the motorcycle category) may generate evaluations on new extensions from other brands by relying on such a prior example, but not necessarily on the extension fit perception. Extending the notion that consumers do not generate evaluative judgments in a vacuum, this research proposes that consumers may have other evaluative input on which they can rely more than perceived fit. To be more specific, we show that the performance of prior similar extension exemplars can be a factor more diagnostic than perceived fit. Furthermore, we expect that such an influence of prior examples (success or failure) will become greater as the base and the target brands are similar to each other. Therefore, we hypothesize that the degree of perceived similarity between brands will moderate the impact of prior extensions on consumer responses toward a new similar extension from a different brand.

Two experiments were conducted to test the above hypotheses. Experiment 1 aimed to assess whether prior success or failure of similar brand extensions influences consumers' responses to

similar types of subsequent brand extensions by other brands. To accomplish this goal, we employed a 2 (Prior Example: Success, Failure) x 2 (Fit Level: High, Moderate) between-subjects design and measured participants' evaluations of a new product idea from the BMW brand when the performance of a similar type of extension from the Mercedes-Benz brand varied. Providing support for our hypothesis, participants in the prior failure condition (i.e., those who were reminded that the same type of products introduced by the Mercedes-Benz brand failed) evaluated a moderate-fit extension (sunglasses) from the BMW brand less favorably than participants in the prior success condition (i.e., those who were reminded that the same type of products introduced by the Mercedes-Benz brand succeeded). However, there was no difference between prior failure and success conditions in terms of brand extension evaluations toward a high-fit extension (tires). This pattern of evaluations reflects relational reasoning involving a process by which people transfer their knowledge of a well-known base (prior examples) to a lesser-known target (a new extension).

In a follow-up study, we replicated these findings using a different set of brands and extensions. More importantly, we further investigated the moderating role of the perceived similarity between brands. The results from experiment 2 confirmed our premise that the transfer of knowledge is further facilitated as the similarity perception increases. Specifically, by using simple slope tests on extension evaluations when the perception of similarity was centered at 1 standard deviation above and below the mean, we found that only among participants who perceived these two brands as similar to each other (i.e., +1 SD above case), was the interaction between prior example and fit level significant, thus replicating our previous findings. Therefore, these findings supported our prediction about the moderating role of the perceived similarity between pioneer and follower brands.

Taken together, these findings add to an emerging stream of research that explores the contextual differences in consumer responses to brand extensions. In addition, the managerial implications from the current research can be important in that the first-movers (extending a new branding category for the first time) have to spend a great deal of resources to convince consumers to adopt new products from their brands, while other followers can gain an advantage by strategically following (or not following) trails of pioneer moves. Therefore, the results of the current research imply the possibility of free-riding in a competitive market structure: second-movers had better simply follow the successful route of the first-movers, and first-movers (who should avoid free-riders) have to build uniqueness of their own brands in order to disconnect them from their followers.

Perceived Entitativity and Accessibility-Diagnosticity As Moderators of Reciprocal Extension Effects

Joseph W. Chang, Paul R Jackson, Yung-Chien Lou

EXTENDED ABSTRACT

Conceptualization

Social cognition research has paid considerable attention to the influence of two characteristics of social groups on how they are perceived (e.g., Crawford, Sherman, and Hamilton 2002; Lickel, Hamilton, Wierzchowska, Lewis, Sherman and Uhles 2000), namely variability and entitativity. As the cognitive processes underlying the evaluations of objects and subjects are common (Loken 2006), it is expected that at least some influences on the perception of social groups apply also to the perception of family brands, which suggests that the feedback effects of brand extensions on high- and low-entitative family brands may also be disproportionate. However, relatively little empirical research has investigated this important issue. Therefore, in addition to categorical similarity and perceived variability, this study moves a further step to examine how family brand entitativity mediates feedback extension effects on its subsequent family brand evaluations. Crawford and colleagues (2002) proposes the model of group-level trait transference (GLTT; Figure 1) to discuss the influence of individual members on the group and other group members. In the GLTT model, perceived entitativity serves as a pre-determinant of a three-stage information processing: trait abstraction (or trait inference), stereotyping (or group impression formation), and trait generalization (or trait transference). As with social groups, the attribute transference across brand extensions is more likely to occur for high-entitative family brands and induces asymmetric effects on family brand evaluations. Given the same quality of brand extensions, high-entitative family brands shall be more favorably evaluated than low-entitative family brands because perceivers make more extreme judgments and form more disproportional polarized impressions on high-entitative groups (Hamilton and Sherman 1996; Sherman et al. 1999). Therefore, a high- (vs. low-) entitative family brand is more favorably evaluated (Hypothesis 1). Based on the cue-diagnostics model (Skowronski and Carlston 1987), as extreme cues receive more weight on impression formation (e.g., Anderson 1981), the diagnostic cue of positive extension information is perceived as more extreme to, and will have more positive impacts on, a low-entitative family brand, which yields extremity and positivity biases (e.g., Skowronski and Carlston 1987). In contrast, the diagnostic cue of negative extension information is perceived as more extreme to, and will have more negative impacts on, a high-entitative family brand, which yields extremity and negativity biases. In other words, a low-entitative (or moderate-quality) family brand is expected to be more significantly enhanced by positive extension information, whereas a high-entitative (or high-quality) family brand is expected to be more significantly diluted by negative extension information. This result yields asymmetric (or disproportionate) impacts of positive and negative extension information on family brand evaluations, which is likely mediated by the prior perceived entitativity of family brands. Hence, low- (vs. high-) entitative family brands are more significantly enhanced by positive extension information (hypothesis 2), whereas high- (vs. low-) entitative family brands are more significantly diluted by negative extension information (hypothesis 3).

Method

Two studies were conducted to examine the hypotheses under highly and lowly accessible conditions respectively. For the first

study (the high accessibility condition), following previous research (e.g., Loken and John 1993), two fictitious XXX (high-entitative) and YYY (low-entitative) family brands in Consumer Reports' format were portrayed representing high- and low-entitative family brands respectively. Anti-cavity toothpastes and pain relievers were selected as similar and dissimilar brand extensions respectively based on a pre-test which requested respondents to list possible similar and dissimilar brand extensions of the hypothesized family brands. The research design of the second study was similar to the first study, except intervening tasks were added to manipulate the low accessibility of brand extension information. The accessibility of extension information was manipulated by varying the intervening material between the experimental treatment of extension information and family brand evaluations. The intervening materials were confusing tasks designed to decrease the accessibility of experimental treatments (e.g., Feldman and Lynch 1988) including a filler task and a confusing task.

Major findings

The study's results indicated that, when extension information was highly accessible, family brand images were enhanced and diluted by positive and negative extension information respectively, regardless of the categorical similarity of brand extension and the perceived entitativity of family brand. However, while both high- and low-entitative family brands were enhanced and diluted by positive and negative extension information respectively, the dilution and enhancement effects on high-entitative family brands were different from those on low-entitative family brands. High- (vs. low-) entitative family brands were more significantly diluted by negative extension information (H2), whereas low- (vs. high-) entitative family brands were more significantly enhanced by positive extension information (H3). The asymmetric result was caused by the polarization effect of perceived entitativity on family brand evaluations. Based on the GLTT model, attribute transference should be more significant for high-entitative family brands. The abstracted attributes of high-entitative family brands transferred across brand extensions and, eventually, associated with each individual brand extension. The strongly associated attributes across brand extensions amplified consumers' impressions about the attributes of high-entitative family brands and led to the result that high-entitative family brands were more favorably evaluated (H1). The research results of the second study paralleled the first study. However, by comparisons, highly accessible positive extension information was more diagnostic and, thus, more enhanceive than lowly accessible extension information on family brand evaluations, while highly and lowly accessible negative extension information yielded similar dilution effects on family brand evaluations. In conclusion, except the factor of categorical similarity, the determination about the dilution and enhancement of brand extension information on family brands pretty much depended on the cue-diagnostics of extension information, rather than the accessibility.

Can Brand Commitment be Harmful to the Brand? The Moderating Role of Psychological Contracts

Sekar Raju, Iowa State University, USA

Kalpesh Kaushik Desai, State University of New York at Binghamton, USA

H. Rao Unnava, Ohio State University, USA

Nicole Montgomery, College of William and Mary, USA

EXTENDED ABSTRACT

Research on brand commitment has typically focused on the benefits that commitment provides in protecting the brand when brand failures occur (e.g., Ahluwalia 2007; Ahluwalia, et al. 2000; Raju and Unnava 2008). However, recent research has found that committed consumers may pose risks for brands, especially when brand failures occur. Researchers have found that when a brand fails to live up to some expected standard, committed consumers under certain circumstances are likely to retaliate, seek revenge, and change from loving the brand to hating it (Aaker, Fournier, and Brasel 2004; Gregoire, Tripp, and Legoux 2009). A possible reason that consumers in strong relationships turn around and retaliate against something they love might have to do with the belief that in such relationships the other partner (in our case, the brand) is obligated to them more than in weak relationships (Ward and Ostrom 2006).

We suggest that it is not the failure itself but the nature of the failure that leads consumers to support or not support the brand. That is, we propose that failures that violate perceived pacts or “psychological contracts” between the consumer and the brand create a greater likelihood of retaliation, while failures that do not violate such perceived pacts lead to support for the brand. The term psychological contract refers to the beliefs that a consumer has about the reciprocal obligations that exist between the consumer and the brand. These beliefs are based on perceived promises that the consumer deems the brand has made to them in return for their patronage of the brand (Rousseau 1989).

We argue that consumers committed to a brand are voluntarily restricting their consideration set by being psychologically tied to a brand and excluding other brands (Raju and Unnava 2005). Because committed consumers give up something, they are likely to believe that the brand owes them more than consumers who are less committed (Gregoire et al. 2009). Because committed consumers saddle brands with this reciprocal obligation, we propose that committed consumers are likely to have many more items in their psychological contract with the target brand compared than less committed consumers.

H1: Committed consumers will report more items in their psychological contracts than less committed consumers.

Further, if committed consumers believe that the brand is contractually obligated to perform at some level and it fails to do so, they will view the failure as a breach of the contract. However, as reviewed earlier, others have found that brand commitment also offers brands a buffering effect from negative information (Ahluwalia et al. 2000). We resolve this apparent discrepancy in the literature by arguing that committed consumers feel betrayed only when the brand failure relates to a feature that is part of the psychological contract (henceforth called “in-contract”). When the brand failure relates to a feature that is outside the psychological contract (henceforth called “out-of-contract”), we expect that the buffering effects of commitment will occur. In contrast, less committed consumers do not have as strong a tie to the brand as committed consumers; therefore, we do not anticipate any differences in their responses

to a brand failure regardless of whether they classify the failure as in-contract or out-of-contract

H2: Committed consumers will rate in-contract violations less favorably than out-of-contract violations.

H3: Less committed consumers will rate both in-contract and out-of-contract violations unfavorably.

Study 1

The objective of this study is to demonstrate that consumers who are more versus less committed to a brand will exhibit differences in the contents of their psychological contracts with a preferred brand. Participants either high or low in commitment to an existing brand in each of the two categories (online store and bank) participated ($n=201$). For each category, participants were asked to provide the name of their preferred brand, after which they were presented with the list of promise items obtained from a pretest. For each item on the list, respondents were asked to report the extent to which their preferred brand promised them each item using a four-point scale obtained from Conway and Briner (2005).

Consistent with the idea that psychological contracts exist and their contents differ for high versus low commitment consumers, the analysis revealed a different pattern of results for high versus low commitment participants for online stores and banks. Specifically, a larger percentage of high versus low commitment consumers indicated that their preferred brand either strongly suggested the promise of the item or explicitly promised the item in writing or verbally.

Study 2

This study directly tests whether a violation of an item in the psychological contract versus outside of the psychological contract results in different effects for high and low commitment consumers. A 2 (commitment: high or low) \times 2 (contract item violation: in-contract vs. out-of-contract) between-participants design was implemented.

Participants were presented with a description of a barbershop/hair salon that included a brand failure (i.e., unexpected price increase) and to two filler consumption descriptions. The primary dependent variable was their evaluation of a fictitious competitive barbershop/salon.

Our expectation was that high commitment consumers would evaluate the competitive brand more favorably if their preferred brand's failure pertained to an item in-contract versus out-of-contract. However, we expected low commitment consumers to evaluate the competitive brand equivalently, regardless of their inclusion of the violation item in their contract. Consistent with our expectations, this analysis revealed a significant interaction ($F(1, 205)=4.46, p<.05$). Low commitment participants that reported that “competitive prices” was not an item in their contract ($M=5.39$) evaluated the competitive brand equivalently to participants that reported that the item was part of their contracts ($M=5.23, t(103)=0.68, p>.1$), supporting H3. However, high commitment participants evaluated the new brand more favorably when the violation item was included in their contract ($M=5.37$) versus not perceived as part of their psychological contract ($M=4.81, t(104)=2.30, p<.05$), supporting H2.

The results of the two studies support the idea that the nature of the brand failure-whether it is in-contract or out-of-contract has a major role to play in determining whether committed consumers support or respond negatively to a brand failure.

Got to Get You into My Life: Do Brand Personalities Rub Off on Consumers?

Ji Kyung Park, University of Minnesota, USA

Deborah Roedder John, University of Minnesota, USA

EXTENDED ABSTRACT

Consumers often use brands as an instrument to create a more positive self-image. In particular, brands with appealing personalities, such as Cartier (sophisticated) and Harley-Davidson (adventurous), are particularly useful for consumers wanting to enhance a self-image in line with a brand's personality (Escalas and Bettman 2003). In this research, we ask the question, "Does using a brand with an appealing personality enhance the way consumers view themselves?" Prior research documents that consumers often prefer and choose brands in an effort to affirm and enhance their sense of self, but what happens when consumers actually have an opportunity to use these brands?

We propose that *only* consumers with certain implicit theories view brand experiences as opportunities to signal that they possess the same appealing traits as the brand, and *only* these consumers actually perceive themselves more positively after a brand experience. Implicit self-theories are lay beliefs people hold about the malleability of their personalities. Two types have been identified: entity versus incremental theory (Dweck 2000). Individuals who endorse incremental theory ("incremental theorists") view their personal qualities as something they can enhance through their own direct efforts at self-improvement. In contrast, individuals who endorse entity theory ("entity theorists") view their personal qualities as something they cannot improve their own direct efforts. Instead, they seek out opportunities to signal their positive qualities to the self or others. We predict and find that entity theorists (not incremental theorists) are responsive to the signaling value of brands with appealing personalities. They use a brand associated with an appealing personality to signal that they possess the same appealing personality as the brand, resulting in more positive self-perceptions.

Study 1: Does Victoria's Secret Make You Feel Better-Looking?

Consumers at a local shopping mall were asked to use a Victoria's Secret shopping bag (*brand experience*) or a plain pink shopping bag (*no brand experience*) during their shopping trip. This setting provided an initial test of our proposition in a natural environment where consumers could experience the signaling value of a brand through a common activity of carrying a shopping bag. Victoria's Secret was selected because of its appealing brand personality, associated with traits such as good-looking, feminine, and glamorous. Implicit beliefs about personality were measured (Implicit Persons Theory Measure: Levy et. al. 1998) prior to the shopping trip, with self-perceptions regarding personality traits (including those associated with Victoria's Secret) measured after the shopping trip.

After carrying the Victoria's Secret shopping bag (vs. plain pink shopping bag), entity theorists perceived themselves to be better-looking, more feminine, and more glamorous. However, incremental theorists were not influenced by their brand experience. Differences between these groups were not evident for personality traits unconnected to the Victoria's Secret brand, which rules out response biases, general affective states, and contextual factors as possible alternative explanations.

Study 2: Why Are Entity Theorists More Affected by Brand Personalities?

Study 2 extends prior findings by: (1) manipulating implicit self-theories to rule out the possibility that individuals who endorse entity or incremental theories may also vary on other dimensions

that influence response to brand experiences; and (2) examining the mediating process for why entity theorists, but not incremental theorists, are affected by brand experiences. Female undergraduate students were asked to participate in treasure hunt. To collect items during the treasure hunt, they used a Victoria's Secret shopping bag or a plain pink shopping bag. After using the shopping bag, participants were asked about their self-perceptions on traits associated with Victoria's Secret, and were also asked how much they used Victoria's Secret as signals of one's identity.

The results replicated the findings from study 1. Further, a mediation analysis revealed that relative to incremental theorists, entity theorists are more responsive to the signaling value of the Victoria's Secret brand experience and this difference mediates the influence of implicit self-theory on self-perceptions.

Study 3: Can Entity Theorists Recover From Self-threats Using Brand Personalities?

Entity theorists view personal qualities as something that they cannot directly improve through their own direct efforts. Dweck and her colleagues suggest that such pessimistic thinking about self-improvement reduces emotional and psychological resources available to cope with negative feedback on personal qualities. In study 3, we examined whether or not entity theorists can recover a threatened self through experiences with a brand associated with an appealing personality in a threat-related domain. After receiving negative feedback on a GRE test, participants were asked to use either a MIT pen or a regular pen, and then completed the self-perception measure.

The results showed that entity theorists recovered negative self-views after brand experiences; they perceived themselves to be more intelligent, harder-working, and more of a leader after using the MIT pen (vs. the regular pen).

Summary

We identify implicit self-theories as an important moderator of the influence of brand experiences on consumer self-perceptions. Only entity theorists view use a brand associated with an appealing personality to signal that they possess the same appealing personality as the brand, resulting in more positive self-perceptions.

It's all about THE GREENS: Conflicting Motives and Making Green Work

Kelly Haws, Texas A&M University, USA

Karen Page Winterich, Pennsylvania State University, USA

Rebecca Walker Naylor, Ohio State University, USA

EXTENDED ABSTRACT

Consumers frequently encounter decisions regarding whether to purchase environmentally-friendly products in place of more traditional products (e.g., reusable vs. plastic grocery bags, non-toxic, biodegradable cleaners). While there has been an increasing emphasis on green attributes of products in the marketplace, the potential goal conflicts of engaging in environmentally-friendly purchases are not well understood. We seek to determine how to identify green consumers, whom we define as those with a tendency to consider the environmental impact of their purchase and consumption behaviors, and distinguish their preferences from those of non-green consumers to aid the marketing of green products, considering both product positioning and product pricing.

Though there have been several efforts at identifying green consumers (e.g., Antil 1984; Roberts 1995; Webb, Mohr, and Harris 2008; Webster 1975 over the last few decades, such efforts have led to rather complex and often dated measures. We present a parsimonious, yet valid measure of green consumer attitudes, enabling managers and marketers to better determine potential responses to green-related efforts based on their consumer base. In doing so, we focus on characteristics of consumers that might provide underlying motivations for green consumption. Specifically, we expect those who are more green to be more conscientious of their monetary resources and more careful users of physical resources.

Study 1. We first develop a simple six-item measure to succinctly capture green attitudes. We find our measure correlates positively with socially responsible consumption behavior ($r=.69$; Antil 1984) and negatively with environmental claims skepticism (Mohr et al. 1998) and hindrances to buying green (adapted from Harris Interactive 2008). A separate follow-up study using an adult panel further validates the GREEN measure.

We also assess the relationship of green attitudes with both monetary and nonmonetary resources. Regarding monetary resources, consumers demonstrating a higher level of GREEN were also found to be more frugal, more self-controlled, and more value and price conscious suggesting that consumers who express green attitudes are also quite sensitive to the wise use of financial resources. For physical resource consumption, product retention tendency and use innovativeness were positively related to GREEN, suggesting that consumers with strong green attitudes are also reluctant to discard of possessions and likely to find new ways to use existing possessions.

Study 2. We examined the extent to which GREEN predicted behavioral intentions and product choice. Measuring GREEN three weeks in advance of reported behaviors and choice, results indicated participants choosing a reusable grocery bag (green option; $n=99$) had a higher average green score than those choosing the pens (non-green option; $M=4.23$ vs. 3.70 , $F(1, 235)=11.68$, $p<.001$). GREEN was also positively correlated ($r=.73$) with reported likelihood of engaging in eight green behaviors such as recycling (adapted from Straughan and Roberts 1999). This study provides evidence that our simple measure of GREEN predicts behavioral intentions and actual behaviors.

Study 3. Though high GREEN consumers conserve monetary and physical resources, they also value environmentally-friendly products. Goldsmith and Dhar (2008) state that green products can be positioned based on two distinct dimensions: self benefits (gentle on your skin) or earth benefits (save the planet). If costs are

equal, consumers with higher green attitudes are likely to be more concerned with earth (vs. self) benefits.

To test the effect of benefit framing, students responded to the 6-item green scale and were later asked to view an advertisement for a new natural dish washing liquid and indicate their purchase likelihood. The benefits of the product were described as leaving your dishes clean and shiny and helping to protect and soothe your skin (self benefits) or as posing no threat of harm to the environment and contributing to a healthier planet (earth benefits).

Results revealed an interaction such that the earth (vs. self) framing increased purchase likelihood among consumers high in GREEN whereas purchase likelihood did not differ among low GREEN consumers regardless of benefit framing. For GREEN consumers, positioning a green product with earth benefits is more effective than positioning with benefits for oneself, which may be of particular importance to marketers who may decrease green purchases if they attempt to capture a larger share of the market by emphasizing self benefits.

Study 4. In our final study, we directly examine the inherent conflict between the economic and the green motivations of consumers by examining environmental products with a price premium. Though we anticipate that green consumers will be more accepting of price premiums than will nongreen consumers, products that meet goals of both greenness and frugality will be most favorably received by consumers pursuing these multiple goals.

Student participants completed the 6-item GREEN scale in a battery of unrelated items and then completed the main study a week later. The main study consisted of a one-factor (price premium: none vs. 20% premium for more green product) between-subjects design. Participants were shown two laundry detergents which were identical except that one received an excellent environmental score whereas the alternative product received an average environmental rating. In the no premium condition, the two products were the same price, whereas in the price premium condition, the green product (high rating) was listed at 20% higher. Respondents indicated which of the two products they preferred on a 9-point scale.

Results indicated, as expected, an interaction of GREEN and price premium condition such that GREEN consumers are more likely to prefer premium-priced green products than are non-GREEN consumers. However, both GREEN and non-GREEN consumers significantly prefer the equally-priced green option. The significant decline in the price premium condition, even among GREEN consumers, demonstrates their value on both environmental and economic goals. Though important to equalize price of green products as much as possible, these results indicate there is a segment of consumers willing to pay the premium for green.

Clearly, understanding the multiple motivations underlying consumers' decisions regarding green products will help managers better market their environmentally-friendly alternatives. Furthermore, theoretical insights are provided by considering the goal conflict inherent in valuing green products while valuing conservation of monetary resources.

Green Requests: Issue Importance and Compliance with Assertive Language

Ann Kronrod, Ben-Gurion University, Israel
Amir Grinstein, Ben-Gurion University, Israel
Luc Wathieu, ESMT, Germany

EXTENDED ABSTRACT

Background

While any request limits the freedom of the addressee (Brown and Levinson, 1987), assertive language is even more restricting, as it leaves the addressee an even smaller option for refusal (Searle, 1969; Vanderveken 1990). Consequently, as it is shown in previous research, assertive message phrasings typically decrease compliance with the message, compared with non-assertive messages (e.g., Dillard and Shen 2005; Edwards, Li, and Lee 2002; Quick and Consideine 2008). However, some counterintuitive findings (e.g. Buller, Borland, and Burgoon 1998) imply that compliance with assertive language can be elevated in situations of higher issue importance.

We show this general phenomenon, employing the example of messages which relate to environmental behavior. Issue importance plays a great role in consumer's reaction to environmental campaigns because environmental issues bear a non-personal character and therefore are generally less close to the consumer's heart. While the common finding is that assertive environmental messages result in low compliance (e.g., Lord 1994; Shrum, Lowrey, and McCarty 1994), many environment-related issues are being promoted aggressively through assertive messages such as "*Use only what you need!*"—the Denver water economy campaign.

We suggest that issue importance not only diminishes non-compliance with assertive messages, but even leads to higher compliance with assertive messages than with non-assertive ones. The key reason for this suggestion is that when an issue is important, an assertive message supports one's attitude, while a non-assertive request may have the opposite influence as it implies a non-serious attitude toward the issue. Thus, we hypothesize that when an issue is considered important and the message is assertive, the fit between message phrasing and consumer's attitude leads to higher compliance. A non-assertive message in this situation would contradict consumer's ends and yield lower compliance. However, if an issue is not deemed important, a non-assertive message would be a higher fit than an assertive one, resulting in higher compliance with a non-assertive message.

METHOD

Study 1—Field Study

The purpose of the study was to measure compliance with an assertive versus a non-assertive ad as an effect of issue importance. To meet our hypothesis we created a 2 (assertiveness) by 2 (issue importance) design in the following way:

Assertiveness manipulation: We placed two sponsored links in Google Adwords advertising system, calling viewers to sign a petition to save the Mediterranean Sea: one assertive (*You must save the Mediterranean Sea!*) and one non-assertive (*You could save the Mediterranean Sea.*)

Issue importance conditioning: Two types of search words were identified: Sea-related (e.g. Mediterranean Sea pollution) and General (e.g. knitting machines). We relied on the assumption that people who type a sea-related search word deem higher importance to sea pollution than people who type in a general word.

We then compared the number of clicks on each of the ads, following a general or a sea-related search word. In line with our

prediction, we found significantly higher ratio of clicking the assertive ad after typing in a sea related search word, and significantly higher clicking on the non-assertive ad after typing in a general search word.

Studies 2 and 3

In order to support our socio-linguistic explanation which involves issue importance, we conducted two studies which were similar in their 2 by 2 design, but different in type of behavior and in operationalization.

Study 1 used an assertive and a non-assertive message regarding an important (water economy) and an unimportant (recycling plastic containers) issue for the specific society we examined (www.hh-law.co.il). Participants (N=102) were exposed to a short and simple message, which was either assertive or non-assertive and related either to water economy or to recycling plastic containers. The assertive message read: "*You must economize water/recycle plastic containers.*" The non-assertive message read: "*It's worth economizing water/recycling plastic containers.*" After reading the message participants filled out a questionnaire which measured issue importance and compliance intention. Results revealed a significantly higher compliance intention with the assertive message vs. a non-assertive message calling for water economy. As predicted, for recycling messages there was no difference in compliance intentions between people who read an assertive and a non-assertive message.

Study 2 manipulated issue importance by addressing two different groups: low issue importance (students of Business school, N=53) vs. high issue importance (students of Agriculture and Environment, N=52). Assertiveness was manipulated using the recycling related materials from Study 1. Our results showed an interaction for assertiveness and issue importance: while for Business students there was no difference in compliance as an effect of assertiveness, Environment students showed significantly higher compliance intentions with an assertive recycling message than with a non-assertive one.

Study 4

We hypothesized that the effect of compliance with an assertive message can be created by temporarily elevating issue importance. This is an important point because of its practical implications. In this study we temporarily elevated issue importance using a clip about air pollution. Participants (N=146) were divided into two groups: one group first completed a general environmental issue importance questionnaire, then saw the clip, and then completed an air-pollution issue importance questionnaire and compliance intention questions. The second group filled out all three measures in a row.

Results: While the groups did not differ in general environmental issue importance, the group that saw the clip showed significantly higher air-pollution issue importance. This evidence implies that issue importance can indeed be temporarily elevated. Further, the group that saw the clip revealed significantly higher compliance intention with the assertive pollution message than with the non-assertive message, while the group that did not see the clip revealed no difference in compliance intention. These results suggest that even a temporarily elevated issue importance can affect compliance with assertive environmental messages.

Summary

When compliance is the goal, issue importance appears to be a central variable in determining message phrasing. This is true not only for environmental issues, but also in health related promotion (e.g. sunscreen usage), and possibly even in encouraging the public to pay taxes regularly. We therefore hope to further explore this general and straightforward mechanism of the influence of issue importance on perception of assertive requests.

Green and Guilt Free: The Role of Guilt in Determining the Effectiveness of Environmental Appeals in Advertising

John Peloza, Simon Fraser University, Canada
Jingzhi Shang, Simon Fraser University, Canada
Katherine White, University of Calgary, Canada

EXTENDED ABSTRACT

Virtually every product available on the market can boast at least some environmentally-friendly attributes. But consumer response to marketers' positioning their offerings on the basis environmental attributes—so-called *green marketing*—is relatively unstudied, and has produced equivocal results. Consumers' concern for the environment does not predict responsiveness to green marketing, or marketing communications that positions itself on the basis of environmental attributes (Schuhwerk and Lefkoff-Hagius 1995). One promising stream of research examines the role of marketing communications in stimulating consumer demand for green products. However, the efficacy of green marketing strategies remains equivocal (e.g., Kangun, Carlson and Grove 1991; Montoro-Rios, Luque-Martinez and Rodriguez-Molina 2008) and research examining how consumers can be motivated to engage in environmentally friendly actions is relatively understudied (Goldstein, Cialdini and Griskevicius 2008).

In this article we examine the process by which the implicit anticipation of guilt leads consumers to make product selections in favor of marketing communications that highlight environmentally-friendly attributes. While previous research has examined explicit guilt appeals that directly induce consumer guilt, we find that the increased prominence of environmental information in advertising is itself enough to alleviate consumer guilt in situations where guilt has been implicitly activated. Across three studies we find that consumers respond most positively to environmental appeals when the product category is hedonic in nature, when the setting is public, and when relevant social norms are activated. We find evidence that green marketing can be successful in guiding consumer choice, and that this effect is mediated through anticipatory guilt.

Study 1 used brands in a hedonic category (Chocolate: Mars and Cadbury) and utilitarian category (Soap: Dove and Ivory), each positioned via a green appeal or a performance-based appeal (e.g., taste, cleansing ingredients). Information in each appeal was held constant. The design of either appeal was based on color, images and prominence given to environmental attributes.

Participants (n=99) in the hedonic category responded more positively to the green appeal (74% chose the brand promoted through a green appeal versus 26% for the brand that used a performance-based appeal). Those in the utilitarian category responded more to the performance-based appeal (67% versus 33% for the green appeal), $\chi^2(1)=22.365, p<.001$. Mediation analysis to test for the role of anticipatory guilt confirms that the preference for the green appeal is based on implicit guilt related to the product category. To test for mediation through anticipatory guilt, first guilt was regressed on the product category, which was significant ($\beta=-1.996, t=-10.269, p<.001$). Next, the product choice (choice corresponding to either the green or performance-based appeal) was regressed on guilt using logistic regression, which was also significant ($\beta=-1.904, Wald=26.124, p<.001$). Product choice was regressed on product category, which was also significant ($\beta=-2.070, Wald=20.456, p<.001$), and finally product choice was regressed on both product category and guilt. Product category was no longer significant ($\beta=1.029, Wald=1.565, p=.211$) while guilt was highly significant ($\beta=-2.239, Wald=22.388, p<.001$). A Sobel test (Baron and Kenny 1986) was significant as well, $z=4.583, p<.001$.

Study 2 (n=119) uses the presence of others as the basis for stimulating anticipatory guilt and promoting response to green marketing appeals. Two brands of granola bars (Kellogg's and Quaker) were used, and offered to participants through either a green or performance-based appeal. Participants viewed the ads and selected products either alone or as part of a small group. As expected, those in the group condition favored the green appeals (68% versus 32% selection based on the performance-based appeal). In the alone condition, appeals were equally successful (49% green versus 51% performance-based), $\chi^2(1)=4.518, p=.034$.

Mediation analysis again confirms the role of anticipatory guilt in the preference for green appeals. The regression of guilt on setting (group versus alone) was significant ($\beta=-.427, t=-2.63, p=.01$), as was the regression of product choice (product corresponding to either the green or performance-based appeal) on guilt ($\beta=-.831, Wald=10.671, p=.001$). Product choice was regressed on setting, which was also significant ($\beta=.803, Wald=4.452, p=.035$), and finally product choice was regressed on both product category and guilt. Product category was no longer significant ($\beta=.570, Wald=2.01, p=.156$) while guilt was highly significant ($\beta=-.771, Wald=8.95, p=.003$). The Sobel test was significant as well, $z=2.052, p=.02$.

In study 3 (n=111) we manipulate the relevant social norms and seek to either stimulate perceived expectations to respond to a green appeal, or give participants "permission" to choose a product based on performance-based (i.e., self-serving) appeals. The same brands of granola from study 2 were used, but prior to the experiment participants were primed with the relevant social norm (White and Peloza 2009). As expected, green appeals were more successful in the environmental norm prime condition (64% versus 36%) but in the product performance prime, participants responded to the performance-based appeal 57% of the time, $\chi^2(1)=5.020, p=.025$.

Mediation analysis again confirms the role of anticipatory guilt in participants' product selection. The regression of guilt on norm manipulation (environmental versus product performance) was significant ($\beta=-.818, t=-4.309, p<.001$), as was the regression of product choice (choice corresponding to either green or performance-based appeal) on guilt ($\beta=-.526, Wald=7.318, p=.007$). The regression of product choice norm manipulation was significant ($\beta=.854, Wald=4.943, p=.026$), and finally, product choice was regressed on both product category and guilt. Product category was no longer significant ($\beta=.534, Wald=1.653, p=.199$) while guilt was significant ($\beta=-.433, Wald=4.471, p=.034$). The Sobel test was significant as well, $z=2.689, p=.003$.

Trust of the Virtual eWOM Reviewer and the Role of Gendered Self-Constraint

Shahana Sen, Columbia University, USA

EXTENDED ABSTRACT

Summary of the Paper

Previous research has found that compared to men, women are significantly more likely to consider eWOM consumer reviews as informative, and report that they are more likely to use these in their decision-making. Women also exhibit the negativity bias, viz. find reviewers of negative eWOM significantly more trustworthy than those who write positive reviews, in comparison with men. We investigate the role of gender differences in consumers' self-construals in influencing these attitudes towards the virtual reviewers writing the eWOM consumer reviews. We find that the differences in a person's relational-interdependent self-construal is an underlying reason leading to this gendered difference in the trust of a virtual eWOM reviewer.

Conceptualization

Based on our research and the extant literature, we propose two hypotheses relating to the effect of gender on the trust of eWOM reviewers. In our first hypothesis, we propose how this relationship between gender and trust of the reviewer may be moderated by review valence and the type of product being reviewed. We draw from previous research (Sen and Lerman 2007; Sen (*forthcoming*)) and propose that women will more likely exhibit the negativity bias than men, and moreover, be more likely to trust a virtual reviewer writing a negative review for a utilitarian product than for a hedonic product. To investigate the process of this gendered difference, we explore the role played by the subject's relational-interdependent self-construal (RISC), since literature in social psychology has demonstrated that many gender differences in cognition, motivation, emotion, and social behavior may be explained in terms of men's and women's different self-construals (e.g., Sherif 1982; Banaji & Prentice, 1994; Baumeister 1998; Greenwald & Pratkanis, 1984; Markus & Wurf, 1987).

Method

A 2 (*Gender*: male, female) x 2 (*Review valence*: negative, positive) x 2 (*Product type*: hedonic, utilitarian) between-subjects experiment was conducted. Proposition 1 was tested using linear regression. Subjects' relational-interdependent self-construal (RISC) was measured using the scale developed by Cross et al. (2000), and used to test mediation of the effect of gender on the trust of an eWOM reviewer by the subject's RISC score (Proposition 2). The mediation was tested by using the 3 step regression analysis suggested by Baron and Kenny (1986).

Major Findings

We found support for our mediated moderation model in Proposition 2 which posited that relational-interdependent self-construal (RISC) would mediate the effect in Proposition 1 and would be the reason behind the gender differences in trust of the virtual reviewer. Our finding is consistent with Cross and Madson (1997)'s view that individuals' self facilitates their engagement in and adaptation to the environments, and we believe that in the case of women, their higher RISC motivates them to adapt their attitudes or behavior to the virtual reviewer, to ensure a smooth and harmonious interaction (e.g., having trust in the motivations of the virtual reviewer.)

Conversations Sell: How Dialogical Judgments and Goals Underpin the Success of Viral Videos

T. E. Dominic Yeo, University of Cambridge, UK

EXTENDED ABSTRACT

The potential for online videos to command widespread attention without the need for extensive resources or interference from traditional media gatekeepers has attracted millions of professionals and consumers alike to put up videos on media-sharing sites like YouTube in the hope that they will go viral. Highly successful viral videos can command a large following, obtain substantial media coverage, and may spawn a slew of remixes that feeds on their popularity. But viral phenomena are fraught with uncertainty. Without a clearer understanding of the forces driving individuals to pass on viral contents or engage in word-of-mouth communications about them, explicit efforts to stimulate buzz through deliberate viral attempts run the risk of backfiring.

This paper illustrates an approach to explicate virality by examining how individuals make sense of a viral phenomenon, and engage in interpersonal communication about it. Successful viral videos are typified by their phenomenological attributes—people typically mention a viral video by first talking about the elements for its popularity or about the attention it receives. In this way, a highly significant quality for virality is based on how the video becomes elaborated within the group it is popular with. What people find salient, meaningful and useful about the video, and the degree to which these knowledge structures are commonly shared within the group are fundamental to the communicative success of the video.

The present research examines the emergence of collective meaning of a viral video within a given socio-cultural context, and from which to form hypotheses and make predictions concerning individuals' choices and actions associated with it. Using the example of the "Bus Uncle" viral video—a man covertly filmed on a camera phone reviling a fellow Hong Kong bus passenger for interrupting his call—three studies were conducted to elicit participants' goals, judgments and collective meaning-making of the phenomenon. The case helps to exemplify the socio-cultural aspects of consumers' participation in viral phenomena, the nature of user-generated content, and the psychological mechanism of 'virality.'

The first two studies were conducted with local participants in Hong Kong. In Study 1, a laddering questionnaire was used to elicit participants' goals for viewing the Bus Uncle video and the linkages between these goals. Using means-end chain analysis, the structure of the viewing goals and their linkages was mapped. In Study 2 participants were asked to sort newspaper comments obtained from local press coverage of the phenomenon. The sorted comments were then subjected to multidimensional scaling (MDS) to uncover participants' common conceptual space and judgments. To elucidate contextual differences in the representations of the phenomenon, Study 3 replicated the procedures in Study 2 with British participants in the U.K.. Using a geometric analytical procedure, the concordance between the knowledge structures obtained from the MDS analysis of the two samples was tested.

Study 1 showed that the desire for common conversation topics among friends was the most salient goal for viewing the video. Study 2 revealed that participants' interpretations of press coverage on the video were guided by their judgments of whether the issues mentioned would make good conversations. These judgments converged with a relevant set of goals for viewing the video, suggesting that participants' interpretations were motivated by their goals. When Study 2 was replicated in Study 3, judgments that serve dialogical purposes in the out-group sample were notably missing.

This paper proposes that a video becomes a viral phenomenon when it is sufficiently elaborated within a social group and shared ideas begin to emerge. The ability to make conversations about the video is arguably the most proximal determinant in this process. Tracing the goals and linkages that preceded this goal can illuminate the process that leads a video to virality. The studies show that salient aspects of individuals' representations of viral videos do not arise from item characteristics but correspond to the relationships between people and the item, and the events represented by these relationships. They also reveal that the role of media coverage in facilitating a video going viral was not in raising the salience of any particular issue but in helping people understand what went on.

The findings suggest that the buzz and virality arising from the video were attributable to participants' goals to create and negotiate social relationships through conversations with others in their social group. The need for personal judgments about the video becomes attenuated when participants were initially drawn to the video owing to others' recommendations or to a lesser extent because it was widely talked about. In such circumstances, participants would rely on the judgments of others provided that their superordinate goal was to create conversation topics. This points to the importance of examining consumers' goal-directed behaviors when seeking explanations for the persuasiveness of word-of-mouth communication.

When Electronic Recommendation Agents Backfire

Joseph Lajos, HEC Paris, France

Amitava Chattopadhyay, INSEAD, Singapore

Kishore Sengupta, INSEAD, Singapore

EXTENDED ABSTRACT

Online nutrition retailers offer consumers an enormous selection of highly nutritious foods, drinks, and dietary supplements. For a novice health and fitness enthusiast, deciding which of these categories of products are likely to be helpful, and then choosing individual products within those particular categories, can be confusing, even when only a few options are available. For example, when selecting a nutrition bar, consumers may consider a diverse array of product attributes, including Calories, fat content, fiber content, glycemic index, protein to carbohydrate ratio, protein quality, and vitamin and mineral content, among others. Typically, the product that is best for a given consumer will depend on a variety of individual factors as well, such as age, eating patterns, exercise frequency and intensity, gender, and strength and weight goals, among others.

This example illustrates how the increasing selection of products and product features available in the marketplace, and especially online, has increased the complexity of many purchase decisions. Since consumers do not want more choices per se, but rather the more customized options that expanded choice can bring (Pine, Peppers, and Rogers 2005), it follows that the attractiveness of the expanded choice set offered by internet retailers depends on the ability of consumers to sort through it efficiently (Alba et al. 1997).

Product recommendation websites assist consumers in making complex purchase decisions in diverse product categories. These websites provide electronic recommendation agents that first ask users questions about individual factors and their preferences for product attributes, and then rate available products on the basis of their responses. The goals of these agents include improving decision quality and increasing satisfaction (West et al. 1999).

Although previous research has extensively examined the influence of electronic recommendation agent use on decision quality (e.g., Haubl and Trifts 2000), far less research has examined effects on satisfaction. Furthermore, those papers that have examined satisfaction have primarily focused on satisfaction with the choice process (e.g., Bechwati and Xia 2003), rather than on satisfaction with the choice itself. However, choice satisfaction is important to marketers, since it has been shown to influence attitudes and purchase intentions (Oliver 1980).

In this paper, we examine how use of an electronic recommendation agent for nutrition bars impacts consumers' choice satisfaction, attitudes, and purchase intentions over a period of one to two weeks, the time frame in which repurchase decisions for nutrition bars are typically made.

We conducted an experiment within the nutrition bar product category. The experimental design had two between-subjects conditions (recommendation agent vs. control). People recruited outside a behavioral laboratory near a large, urban university were assigned to one of the conditions and asked to examine descriptions of eight brands of nutrition bars (four of which were relatively utilitarian, and four of which were relatively hedonic) and to select one of these brands to sample at home. At the conclusion of the in-lab portion of the experiment, participants received a package containing five sample bars of the brand that they had selected. Then, one week later, they received an email that contained a link to an online follow-up survey that assessed their satisfaction with the brand as well as their attitudes, purchase intentions, and other measures of interest.

Based on Wilson et al.'s classic finding that when people carefully analyze the reasons underlying their decisions they become biased to overweight utilitarian considerations and underweight hedonic considerations (see Wilson and Dunn 1985), we predicted that participants in the agent condition would be more likely to choose one of the four relatively utilitarian brands compared to participants in the control condition. The data supported this prediction. The data also revealed that although the total amount of time that participants spent examining the brands did not differ between the two conditions (suggesting that participants in the agent condition did not blindly follow the recommendations provided to them), across these conditions participants who ultimately selected a utilitarian brand spent more time on average examining the brands than did those who ultimately selected a hedonic brand, consistent with the notion that utilitarian choices result from more intensive processing than do hedonic choices (Shiv and Fedorikhin 1999).

The data further revealed that, in addition to influencing participants' brand choices, use of an electronic recommendation agent reduced their satisfaction with the chosen brand. This is consistent with Wilson et al.'s (1993) finding that analyzing reasons can reduce post-choice satisfaction. Furthermore, the data revealed that among participants in the agent condition satisfaction was lower among those who chose a utilitarian brand than among those who chose a hedonic brand, whereas among participants in the control condition satisfaction did not differ between those who chose a utilitarian or hedonic brand. These findings suggest that the observed decrease in satisfaction among participants who used an agent resulted from the utilitarian bias that was induced by interacting with the agent. It seems that after some time had passed participants' decision bases returned to their normal levels, leading those who had selected a utilitarian brand after interacting with the agent to regret their choice.

We observed this same pattern of results with a rich set of additional dependent variables, including participants' taste ratings, their likelihood of purchasing the chosen brand, and their likelihood of recommending the chosen brand to a friend.

In a planned second study, which we will conduct before ACR, we will attempt to rule out alternative explanations based on the content of the agents' recommendations. In the study, participants who use an agent will either receive a set of recommendations that, unbeknownst to them, has been generated randomly, or, after providing their responses to the agents' questions, will receive a message saying that the recommendation agent server has malfunctioned and that the brands will therefore be displayed randomly.

By showing that including a product in an electronic recommendation agent can have negative consequences, our results give a word of caution to managers. In particular, our results suggest that marketers who manage relatively utilitarian brands within product categories in which both hedonic and utilitarian brands are established should be especially cautious. Although agents might help increase short-term sales of such products by leading consumers to overweight utilitarian product attributes and underweight hedonic product attributes, this boost may come at the cost of long-run profitability due to consumers' reduced satisfaction with their choices and a resulting decline in repurchasing behavior.

Balance as an Embodiment of Parity

Jeffrey Larson, Brigham Young University, USA

Darron Billeter, Brigham Young University, USA

EXTENDED ABSTRACT

Philosophers and linguists have long postulated that metaphorical language is more than a simple cultural construction, but reflects deeper cognitive relationships (Aristotle, circa 335 BCE). According to research on embodied cognition, our understanding of abstract concepts is grounded in physical experience (Lakoff & Johnson, 1999). New, unfamiliar, abstract concepts are understood through metaphorical association with familiar, physical activities in a process known as “scaffolding” (Williams, Huang, & Bargh 2009). Because language utilizes neural systems that were developed for other purposes, the activation of motor behavior can similarly activate the deeper cognitive associations that are scaffolded onto that motor behavior. Similarly, activation of an abstract concept can activate the motor regions of the brain upon which it was scaffolded.

We examine the balance metaphor, which has not been experimentally demonstrated to exhibit multi-modal influence. Balance is one of the earliest developing and most pervasive physical metaphors (Zaltman & Zaltman, 2008). Beginning in early childhood, people learn through repeated experiences the importance of maintaining physical balance. To bipedal mammals, balance is so fundamental for well-being that balance and anxiety disorders share neuronal circuitry and commonly co-occur (Balaban & Thayer, 2001; Furman & Jacob, 2001). As a learner encodes the actions required to obtain balance, they are also encoding other relevant information from the learning context. One of the important ways that a standing person obtains balance is by equalizing the weight placed across both feet. In the learning process, the concept of balance and the need for evenness are encoded concurrently, creating a strong mental association between these two concepts.

The neural connection between physical balance and the more abstract concept of evenness or parity is evidenced by many metaphorical phrases from the English language. Accountants “balance the ledger” while chemists “balance equations.” Fair-minded individuals ascertain “both sides of the story”, and someone in control of her emotions is said to be “even-tempered.” (Many of these metaphors are similar in other languages.) These idioms are best understood in the guise of a twin-pan balance scale evaluating opposing abstract states. The balancing apparatus reaches equilibrium when both pans hold equal portions. Similarly, accounts are balanced when they reflect equal parts debits and credits, while truth is ascertained when opposing viewpoints are weighed against each other.

These balance-based metaphors arise because of the strong neural connections between balance and parity that are encoded during infancy. Exposure to balance metaphors causes concurrent activation of the neural systems governing balance and the neural systems governing cognitions about parity, which strengthens the association (Lakoff & Johnson, 1999). Repeated exposure to symbolic representations of balance, for example the twin-pan balance scale and the yin and yang symbol, also reinforces the link between balance and parity.

Given this link between the neural systems governing balance and more abstract thoughts on parity, we expect that experiencing physical balance should consequently access the mental representation of the balance metaphor, which is closely associated with the need for parity, and thereby influence choice. Engaging in physical balance activities should activate instinctual desires for balance, and thereby enhance the desirability of metaphorically balanced choice options. Specifically, activation of physical balance should increase the desire for choice options that offer some form of parity.

In four studies, we activate physical balance through a variety of means and observe a consistent increase in the choice share of options that offer various forms of parity. In study 1, participants played one of three games on the Wii Fit™ while simultaneously responding to a verbal survey administered by a research assistant that was blind to the hypotheses of the study. Two of these games (Yoga and Penguin Slide) activated significantly more thoughts on physical balance than the neutral (Jogging) condition. Participants selected a printer and a car from a set of three choice options that included a compromise choice. Participants in the Yoga and Penguin Slide conditions demonstrated an increased selection of both a compromise printer ($M=40\%$ vs. $M=23\%$) and a compromise car ($M=55\%$ vs. $M=38\%$). The pooled test was significant ($z=1.99, p=.05$).

In study 2, physical balance is activated through mental simulation. Participants performed a fifteen second mental simulation of either walking across a balance beam in perfect balance, walking across a balance beam with poor balance, or swinging around a high bar. Those in either of the two balanced beam conditions selected the compromise computer ($M=66\%$ and $M=63\%$) more often than those in the high bar condition ($M=45\%$, $z=2.04, p=.04$). The results suggest that the strength of activation of balance metaphor is not dependent on the kind of physical activation, unbalanced or balanced. Furthermore, the results indicate that the activation of the association between balance and parity occurs even when balance is activated through mental simulation.

In study 3, the balance metaphor is activated through supraliminal exposure to balance symbols. In the balance condition, the four corners of the web survey displayed a crude silhouette of a balance (see Figure 2). In the control condition, no picture was shown. The survey asked participants to make six meal choices; each choice set showed two meals, with one meal being more balanced than the other (offering greater parity across food groups). In the balance condition, participants chose the balanced meal 68% of the time as opposed to only 56% of the time for the control. A logistic regression on meal choices showed that condition assignment was significant, $t(399)=2.3, p=.02$.

Finally, study 4 activates semantic representations of the balance metaphor. We asked half the participants to write for three minutes about a time when their life felt “out of balance”. These participants choose the compromise computer more often ($M=83\%$) than those who wrote about their typical day ($M=50\%$), $z=2.15, p<.05$.

Across four studies, we activate balance a number of ways and demonstrate that such activation consistently leads to an increase in the choice of options that offer parity.

Staying Warm in the Winter: Seeking Psychological Warmth to Reduce Physical Coldness

Yan Zhang, National University of Singapore, Singapore

Jane Risen, University of Chicago, USA

EXTENDED ABSTRACT

On a cold, snowy night, there is nothing better than sitting by the fire and drinking a hot cup of cocoa. It is a basic human drive to seek physical warmth when feeling cold. This research explores whether there also exists a drive to seek psychological warmth when feeling cold. On a cold, snowy night, are people especially interested in having a romantic dinner with a loved one or a phone conversation with a dear friend? More broadly, we ask: When people are physically cold, are they motivated to engage in psychologically warm activities?

Psychologically warm events are positive experiences that promote a feeling of social connection. Recent research on embodied cognition suggests that a link exists between physical warmth and psychological warmth (IJzerman & Semin, 2009; Williams & Bargh, 2008; Zhong & Leonardelli, 2008). For instance, people perceive a target individual to be “warm” (e.g., kind and charitable) when they are holding a hot cup of coffee (Williams & Bargh, 2008), they perceive themselves to be socially close to others when they are in a warm room (IJzerman & Semin, 2009), and they report feeling physically cold when they are socially excluded (Zhong & Leonardelli, 2008).

In this research we suggest that psychological warmth, like physical warmth, is perceived as a means of reducing the feeling of coldness. As a result, people are more interested in engaging in psychologically warm activities when they are physically cold. This argument goes beyond the “metaphor” or “priming” domain of embodied cognition research. Instead of asking whether activities will be perceived as psychologically warmer or colder, we focus on the goal-oriented nature of the phenomenon and test whether feeling cold motivates people to seek psychological warmth. We suggest psychological warmth and physical warmth are two means for satisfying the same goal of reducing a feeling of coldness.

Study 1 supports the basic prediction by showing that cold participants are especially interested in psychologically warm activities. Specifically, participants who completed a questionnaire outside in the cold in a Midwestern city’s winter showed more interest in warm events than in non-warm activities, but those who completed the study inside a heated building were equally interested in warm and non-warm activities. Study 2 extends the work to real-world behavior. Beginning a romantic relationship is perhaps the most powerful tool for forging social connection. We find that participants are more likely to start relationships in cold weather than end them. In Study 3, we primed people either with the goal of reducing physical coldness or the concept of coldness. The results showed that priming people with the goal of reducing physical coldness led to greater interest in both physically and psychologically warm events (relative to non-warm events), but priming people with the concept of coldness did not, suggesting that it is the motivation to reduce coldness that is central to people’s interest in warm events. Finally, in Study 4, to test whether psychological warmth and physical warmth are two means for satisfying the same goal of reducing a feeling of coldness, we asked participants to fill out the same questionnaire as in Study 1 either outside in the cold or inside a heated building. However, half of the participants were reminded that they would step into a heated building momentarily. We replicated the results of Study 1 in the no-reminder condition, showing that people showed greater interest in psychologically warm events if they were feeling physically cold than if they were not feeling cold; but this increased interest in psychologically

warm events is reduced when participants were reminded that their motivation to reduce coldness will be met through physical means, indicating that psychological warmth and physical warmth are two means for satisfying the same goal of reducing a feeling of coldness.

Our findings support the argument that while people satisfy their physical goals through physical means, the mapping between mind and body also leads them to satisfy their physical goals through psychological means. This research adds to the growing body of work supporting a theory of embodied cognition, and specifically to work suggesting that the mental concepts of psychological warmth and social connection are deeply rooted in the sensorimotor experience of physical warmth. In addition, the present work goes beyond demonstrating a conceptual mapping between the physical sensation of warmth and the psychological experience of warmth. It highlights the role of goals and motivation in the link between the mind and the body. We find that the link leads people to satisfy their physical goal with actions that could satisfy the matching psychological goal. Namely, when people are motivated to reduce physical coldness, they show interest in events that promote psychological warmth.

The Influence of Mirror Decoration on Food Taste

Ataollah Tafaghodi Jami, University of Utah, USA

Himanshu Mishra, University of Utah, USA

EXTENDED ABSTRACT

Recent studies show an alarming increase in obesity in the United States with 74.1% of the population over 15 years old considered overweight (Streib 2007). Various organizations are dealing with this issue and trying different weight-loss strategies such as low-carbohydrate diets, physical exercises, fat burning or appetite reducing pills, and fat removal surgeries. At the same time, others are looking for more self-driven ways of controlling obesity by changing people's eating habits and introducing standards of healthy eating. The aim of these standards is to promote eating of healthy foods and prevent unhealthy eating practices. Emphasizing by media and many food producers through calorie or fiber intake, smaller portions, and reduced fat or fat-free products, standards of healthy eating have been widely accepted. However, there are still many people who do not follow these standards though they believe that it is harmful for them.

One of the critical aspects of unhealthy foods, which attracts people's attention and convince them to choose it over a healthy option, is the taste of unhealthy foods. Research has shown that regardless of the actual taste, considering a food as less healthy makes it more tasty (Raghunathan, Naylor, and Hoyer 2006). Thus, making an unhealthy food less tasty could potentially reduce its consumption and help people to practice healthy food consumption. Therefore, in this research, we investigated the possibility of making unhealthy foods less tasty without changing their ingredients.

Past research has shown that self-focused people tend to compare themselves with standards of correctness (Duval and Wicklund 1972), and experience positive affect when they act in concert with standards, and negative affect when they act in opposition to standards (Duval, Silvia, and Lalwani 2001). The person who feels the positive or negative affect does not immediately know why he or she has such feelings (Oatley and Johnson-Laird 1996). Moreover, research has shown that self-focused people tend to attribute positive events to self and negative events to external factors (Duval, Silvia, and Lalwani 2001).

Since mirror, as a self-awareness enhancing tool, can be used as a decorative item in many food consumption settings, this research examined if, and under what conditions, eating a food product in front of a mirror affects its taste perception. According to the reviewed literature, it is expected that eating a healthy or an unhealthy food in front of a mirror generate positive or negative feelings since standards of healthy eating are widely accepted. Therefore, we propose that if people consume their food in a room decorated with mirrors compared to a room without mirrors, they will attribute the positive affect of eating a healthy food internally to self and the negative affect of eating an unhealthy to the food taste as an external factor.

The first study was designed to provide empirical evidence for the proposed effect of mirror decoration on food taste. We used fruit salad and chocolate cake to represent healthy and unhealthy foods. Results confirmed our expectations and showed that participants gave a lower overall taste evaluation to the chocolate cake when they consumed it in front of mirror compared to the no-mirror condition. However, the taste evaluations of the fruit salad were not significantly different between the mirror and no-mirror conditions.

Study 2 and 3 investigated two factors moderating the effect of mirror decoration on food taste. Research has shown that people must perceive themselves responsible for acting against standards in order to experience the negative feelings (Duval, Silvia, and

Lalwani 2001). Accordingly, the second study showed that when participants did not perceive themselves to be responsible for eating the unhealthy food (i.e., when they think that there is no choice and they have to do it), they did not give a lower evaluation to the taste of the unhealthy food in the mirror condition compared to the no-mirror condition.

Research has also found that simplicity of the connection between cause and effect is an important factor for the attribution system; and people tend to attribute the effects to the most plausible causes (Duval, Silvia, and Lalwani 2001). Therefore, we expected that introducing a more plausible cause for the negative affect would move the attribution of discomfort away from the unhealthy food taste. Study 3 supported this expectation and showed that when we introduced music as a more plausible cause of the negative affect, participants did not evaluate the taste of the unhealthy food to be lower in the mirror condition compared to the no-mirror condition.

In sum, this research contributes to the extant body of literature on the self-awareness theory by demonstrating the link between the self-awareness and the attribution of feelings induced by the self-standards comparison system. At a practical level, results of this research suggest that mirror decoration can be used in food consumption settings to decrease unhealthy eating practices as mirrors make the consumption of an unhealthy food less pleasant.

Boundary Conditions for Copy Complexity Enhancement Effects

Tina M. Lowrey, University of Texas at San Antonio, USA
Youngseon Kim, University of Texas at San Antonio, USA

EXTENDED ABSTRACT

Five experiments investigated copy complexity, length, level of involvement, medium, task attention, and reading level on persuasion. Experiments 1 and 2 investigated involvement, complexity, and length. Experiment 3 investigated involvement, complexity, and medium. Experiments 4 and 5 investigated reading level and task attention as boundary conditions.

EXPERIMENT 1

Experiment 1 involved a 2 (simple/moderately complex copy) X 2 (short/long) manipulation of direct mail pieces. Complexity should impact the persuasiveness of the offer but length should not (although this is a null prediction, it is important to demonstrate that complexity, isolated from length, exerts effects on persuasion). Motivation should also exert a main effect on order intentions (high involvement participants will have greater intentions than low involvement participants). Motivation should also moderate the effect of complexity. An interaction between complexity and involvement is expected, such that intentions will be greatest for those high in involvement exposed to complex versions.

Independent variables included complexity, involvement, and length. Involvement was a self-reported measure on two nine-point scales, with higher numbers indicating greater involvement. The two scales correlated significantly ($.63; p=.000$), so were averaged, and then dichotomized ($M=5.46$). The dependent variable was order intention on a nine-point scale (higher numbers indicated greater order intention).

Participants were 85 college students who provided informed consent to participate. Participants participated in groups of 12, seated at cubicles in a laboratory. Participants read the direct mail offer, then received the measurement booklet. Upon completion, the participants were debriefed and were free to leave.

A 2 (simple/moderate copy) X 2 (short/long) X 2 (low-/high-involvement) ANOVA was conducted. Complexity contributed to order intentions, as expected. Those who received the complex versions had higher intentions to order ($M=2.98$) than those who received the simple versions ($M=2.05; F(1,83)=3.99; p<.05$). There was also a main effect for involvement, as expected, such that those who reported high levels of involvement were more likely to order than those low in involvement (2.96 vs. $2.04; F(1,83)=3.78; p<.05$). Length did not contribute to order intentions, consistent with expectations.

Involvement moderated the impact of complexity on order intentions, as expected. High involvement participants who received the complex offer had higher order intentions than all other participants ($F(1,81)=9.24; p<.005$). Thus, complexity had a positive impact on those high in involvement. The expected results were obtained, but order intentions were quite low.

EXPERIMENT 2

Given this negative response, Experiment 2 used a more interesting item (otherwise, the replication was identical). Participants were 103 college students participating for extra credit.

Experiment 2 replicated Experiment 1—complexity exerted a main effect on intentions (moderate= 5.00 vs. simple= $3.77; F(1,85)=6.23; p<.05$). Involvement also exerted a main effect (high= 5.57 vs. low= $3.36; F(1,85)=23.48; p<.001$). Length had no effect. The pattern of results for the interaction between involve-

ment and complexity was as expected, and was significant ($p<.05$). Highly involved participants exposed to moderate copy had higher intentions to order than all other participants.

EXPERIMENT 3

Experiment 3 involved a 3 (simple/moderate/complex copy) X 2 (print/broadcast medium type) manipulation for the same item from Experiment 2. The addition of radio was intended to test the hypothesis that the persuasiveness of copy in commercials will decrease as copy gets beyond moderate complexity. An interaction between complexity, medium, and involvement (identical to procedures in Experiments 1 and 2) was expected.

Participants were 241 college students participating for credit in the same laboratory. Participants were randomly assigned to a cubicle with a computer monitor, which showed a randomly pre-selected condition. Participants in the print conditions read the offer on the screen and responded to the questionnaire. Participants in the radio conditions listened to the commercial on headsets and responded to the questionnaire. Six print and six radio versions were prepared, adding a very complex version. Order intentions were measured on a five-point scale.

There was no main effect for complexity but there was one for involvement (high= 2.91 vs. low= $2.16; F(1,239)=6.42; p<.05$). The interaction between medium, complexity, and involvement was also marginally significant ($F(2,239)=2.37; p<.10$). For those high in involvement exposed to the print version, complexity enhanced persuasion (even at the highest level of complexity), but for those high in involvement exposed to the radio version, complexity had a deleterious effect on persuasion.

EXPERIMENT 4

Experiment 4 involved a 3 (simple/moderate/complex copy) X 2 (item offered) within-subject design, measured reading level, and included an instructional manipulation check (IMC [Oppenheimer, Meyvis, and Davidenko 2009]). An interaction between complexity, reading level, and involvement was expected.

Participants were 93 college students participating for credit in the same laboratory. Participants were randomly assigned to a cubicle with a computer monitor, which showed a randomly pre-selected condition from Experiment 3 (print only). Order intentions were measured on a five-point scale. Participants engaged in a non-timed distraction task between presentation of the two offers.

There was no main effect for complexity, reading level, or involvement for the first offer. All but two participants passed the IMC. The interaction between complexity, reading level, and involvement was not significant ($p>.10$). The results for the second offer were difficult to interpret. Given the distraction task was non-timed, the low number of errors on the IMC, and the low cell size, Experiment 5 was conducted to replicate the basic design with a timed distraction task and a higher sample size.

EXPERIMENT 5

Experiment 5 replicated Experiment 4, but with a timed distraction task. An interaction between complexity, reading level, and involvement was expected. Participants were 117 college students participating for credit in the same laboratory.

There were no main effects for complexity or reading level, but there was one for involvement, such that those who reported high levels of involvement had greater order intentions than those

at low levels of involvement (3.19 vs. 2.60; $F(1,116)=5.64; p<.05$). Again, errors on the IMC were quite low. The interaction between medium, complexity, and involvement was not significant ($p>.10$). It would appear that, at least for college student participants, neither reading level nor task attention serve as boundary conditions.

Color Harmony and Aesthetic Self-Design: Empirical Tests of Classical Theories

Xiaoyan Deng, Ohio State University, USA

Sam Jui, New York University, USA

Wesley Hutchinson, University of Pennsylvania, USA

EXTENDED ABSTRACT

In this paper, we aimed at identifying and testing principles that can explain and predict color harmony perception. Color harmony is a function of distance between colors in the color space. We first briefly described different models of color space and reviewed the color harmony literature, based on which we summarized three classic principles of color harmony (i.e., identity, similarity, and contrast) that were relatively well-accepted in this literature. Because the coordinate system underlying the classic color solids does not provide a straightforward distance metric to represent color similarity or difference (i.e., do not satisfy perceptual uniformity), we adopted the theoretical background of a more recent, alternative coordinate system (i.e., CIELAB coordinate system), which was designed to approximate human vision thereby provides a straightforward distance metric for color perception. We then reviewed prior empirical tests of classic color harmony theories that are similar to the principles we summarized. Some of these tests were conducted using the classic cylindrical coordinate system, others using the modern CIELAB color space. Nevertheless we found that these tests generate mixed results.

For our own test of the color harmony principles we adopted a unique and realistic context: aesthetic self-design of an athletic shoe (which has seven areas: base, secondary, swoosh, accent, lace, lining, and shox). This specific type of self-design task is especially suitable for testing color harmony principles because, first, the task environment allows for interactive color harmony judgment and, second, color harmony plays a major role in consumers' decision. Based on this context, we proposed hypotheses about the relationships between the observed frequencies of color combinations in self-designed athletic shoes and color distance for identity, similarity, and contrast. Further, we hypothesized that a "small palette" can meet the need for color harmony if it is indeed determined by identity (if a single color is used repeatedly then less colors are needed in the palette) or contrast (colors that are mutually complementary spread evenly in the color space and the number of such colors is limited).

Results from our empirical tests provide evidence for our hypotheses. First, the principle of identity was supported for color pairs involving minor shoe areas (e.g., swoosh, lace, lining, and shox). Second, the principle of similarity was supported for the two major shoe areas (i.e., base and secondary). Third, the principle of contrast was supported for color pairs involving a major and a minor shoe area (e.g., base-lining, base-shox). Finally, the "small palette" hypothesis was also supported as the number of colors actually used in self-designed athletic shoes was smaller than the number expected based on assumption of statistical independence.

Taking these results together, we can picture the color coordination strategy consumers use during the self-design process, in which they make seven sequential color decisions for base, secondary, swoosh, accent, lace, lining, and shox (ordered as such). First, they pick a color for base according to their own preference. Second, anchoring on the base color, they choose a secondary color that is similar to that of base. Third, when making color decisions for the remaining five minor areas, consumers tend to use the same color for most of these areas, and this color oftentimes is a color contrasting to the base color. Taking into account the relative area of the seven shoe components, this strategy leads to a harmonious design where large areas define the overall color scheme of the

shoe while small areas deviate from the basic scheme and "spice up" the overall design. This shows that when coordinating multiple colors, consumers are guided by intuitions about color harmony and their intuitions are consistent with the principles of identity, similarity, and contrast.

The identification and confirmation of several robust principles of color harmony provide some practical insights for managers of aesthetic self-design programs. First, these well-defined principles can be used as guidelines to design the color palettes. Second, the number of colors included in the color palettes can be greatly reduced therefore the size of the solution space of the self-design configurator can be largely reduced as well. Third, based on color harmony principles, the configurator can be designed to generate automatic recommendations to the user regarding her color choice. Last but not least, although in this paper we implicitly assume that most people prefer color harmony, those who are fond of disharmonious color combinations can also benefit from our research findings. Online product configurators include a simple survey about personal color taste to categorize their customers and, for some of them, provide "clashing" color palettes.

When *I* becomes *We*: Interpersonal Ties in Product Co-Creation

EXTENDED ABSTRACT

Customer knowledge has been extensively discussed in terms of objective and subjective knowledge, where subjective knowledge is what the individual perceives s/he knows and objective knowledge is what they truly know (Alba & J. W. Hutchinson, 2000). Knowledge exerts a significant and fundamental influence on customer decision-making; customers' decisions vary as a function of what they think they know (Moorman, Diehl, Brinberg, & Kidwell, 2004). In the case of choosing to co-create, it is their subjective knowledge about their perceived competence that will drive the process.

Customers can use their social networks as an external memory, blending the social and cognitive seamlessly into a social hard drive holding vast amounts of information (Ward & Reingen, 1990). Viewed under the service-dominant logic definition of co-creation (Lusch & Vargo, 2006), social networks are part of the customer's operant resources, which means the customer can tap into them to co-create value. Companies have used the Internet to give customers the opportunity to engage in the production process (Xie et al., 2008).

Even with access to Internet, people seem to prefer turning to other people for information (Cross & Sproull, n.d.; Levin & Cross, 2004). In other words, a customer facing a perceived lack of competence to complete a task will seek what s/he needs from other individuals (Arias, Eden, Fischer, Gorman, & Sharff, 2000; Salomon, 1993).

H1: Customers with higher (*lower*) perceived competence are more likely to engage (*not engage*) in co-creation

H2: Customers engaging in individual co-creation will have higher perceived competence than those engaging in collaborative co-creation

H3: Customers engaging in collaborative co-creation will elicit partners with higher perceived competence

The willingness to engage in co-creation requires a strong degree of product involvement (Bendapudi & Leone, 2003). Customers will not only need to use their knowledge but must also be willing to invest their time, which is a scarce and premium resource for most (Etgar, 2006, 2008). In addition, involvement with the product category and the brand itself can determine their choice to co-create since customer's product involvement can lead to increased perception of attribute differences, greater product importance and greater commitment (Howard & Sheth, 1968; Zaichkowsky, 1985). When product differences are perceived to be of greater importance, customers can be more willing to get involved in co-creation and dispense the required effort and time (Etgar, 2008). If under low involvement individuals involve in minimal searches while high involvement results in extensive searches then it follows that involvement would also moderate the amount of time a customer is inclined to spend on his/her purchase—in this case, in co-creation.

H4: Customers with higher (*lower*) product involvement are more likely to engage in co-creation (*not engage in co-creation*).

Marketers are increasingly interested in how consumers use products and brands to build and maintain a social identity, and previous studies have emphasized that self brand congruence alone can determine consumer choice (Malhotra, 1988). Brands, as social objects, are socially constructed and imbued with meaning, and

customers actively engage in that creation using brands as bridges towards or fences against other people (Douglas & Isherwood, 1979; Escalas & Bettman, 2003, 2005; Muniz & O'Guinn, 2001). Research on brand communities shows that customers can use commercial offerings (brands) and brand associations as ways to create and further their self-image and shape their reality (Schau & Gilly, 2003). Co-creation may be seen as a way of self-expression through production of their own products and experiences, and taking pride while strengthening their self-identity and fulfillment (Holt, 1995). Customers engaging in co-creation have a tendency to take ownership and pride in their co-creation.

H5: Customers who choose to engage in co-creation will develop stronger self-brand associations.

Methodology

Two-hundred and forty students from a large northwestern and southeastern university participated in an the online survey, where they read a pretested scenario to make one of three decisions: (1) purchase what is available at the store (2) engage in individual co-creation or (3) engage in collaborative co-creation. A final sample size of 233 students was attained. Participants were aged 21–22 (58.3%) and between 18–21 years of age (41.8%). Gender was evenly distributed with 53% males and 47% females. There was no university effect on the main dependent variables ($F_{(2,232)}=.65, p=.52$; Levene $_{(2,232)}=1.08, p=.34$).

Competence was significantly different across co-creation groups ($F_{(2,229)}=30.10, p<.01, w^2=.16$) with participants' perceived competence highest among those choosing individual co-creation ($M_{IndCC}=7.18, SD=1.47$; $M_{CollCC}=6.38, SD=1.64$; $M_{NoCC}=5.15, SD=2.07$). These results support H1 and H2.

The competence of participant's selected tie(s) was significantly higher ($t_{(49)}=4.94, p<.01$) than participants' competence ($M_{Participant}=6.35, M_{tie}=7.33$), supporting H3.

Involvement was not significantly different across co-creation groups ($F_{(2,232)}=1.19, p=.31$) although it noted some directional results with those choosing Coll CC having higher involvement ($M=5.90$) than participants choosing IndCC ($M=5.69$) or purchasing at the store ($M=5.74$). Therefore H4 was not supported.

There were significant differences ($L=.815, p<.01$; $F_{(1,228)}=51.65$) between the SBB ($M_{SBB}=3.75, SD=1.53$) and SBA ($M_{SBA}=4.55, SD=1.66$).

SBB and SBA were significantly different across groups ($F_{(2,228)}=20.683, p<.01$), with those choosing IndCC ($M_{SBB}=3.75, M_{SBA}=4.93$) and CollCC ($M_{SBB}=3.85, M_{SBA}=4.84$) having significantly higher *after* brand associations ($p<.01$), supporting H5.

Discussion

The results reported bring new challenges for companies wanting to implement co-creation strategies. First, they need to consider a customer's ability. The companies interface with the customer must be easy or make customers feel competent to take on the task at hand.

Second, companies must consider the possibility that customers will not be acting alone, and this can affect not only their relationship with the individual customer but also gives the company the opportunity to present themselves to a new set of customers—those invited to help.

The Distortion of “Objective” Scales: A Theory of Context Effects in Sequential Judgments

Shane Frederick, Yale University, USA

Daniel Mochon, Yale University, USA

EXTENDED ABSTRACT

We propose that even on so called “objective” scales (e.g. pounds, calories, meters, etc.), many contextual effects, such as anchoring, are often best interpreted as scaling effects—reflecting changes in the use of the response scale rather than a change in respondents’ perception of the focal stimulus. We present a theory which details how prior responses act as comparative standards for the interpretation and use of other numbers on that scale.

In support of our theory of scale distortion, we first show that a contextual stimulus only affects subsequent judgments that share the response scale. In our first demonstration, we randomly assigned 467 picnickers to one of three conditions. One group judged only the weight of a giraffe in pounds. A second did this after first judging the weight of a raccoon in pounds. The third group was like the second, except that they raccoon’s weight on a 7-point heaviness scale.

The giraffe estimates averaged 1254 pounds among the group who made only that judgment, but just 709 pounds among those who first judged a raccoon’s weight in pounds. Thus, the presence of the raccoon in the judgmental sequence induced a pronounced assimilation effect when judgments of its heaviness were rendered in units identical to the target judgment. However, when judged on a subjective heaviness scale (from 1 to 7), the raccoon judgment had no effect on estimates of the giraffe’s weight (which averaged 1265 pounds).

The second set of studies also implicate a pure scaling effect, by showing that contextual manipulations which affect the target response have no influence on conceptually affiliated judgments of the target stimulus rendered on different scales. All participants then estimated three features of a giraffe: its weight (in pounds), its height (in feet), and its weight relative to a grand piano, on a seven point scale. Half of the 218 respondents made only these judgments. The other half had first estimated the weight of a raccoon in pounds. Again, the giraffe was judged to weigh less by those who had first judged the weight of a raccoon [760 pounds vs. 1117 pounds], but, notably, the raccoon had no appreciable effect on conceptually affiliated estimates rendered on other scales.

The final two studies bear further hallmarks of scale distortion: In one, a total of 157 participants recruited from an online survey site examined a list of fifteen animals ordered by weight, from very small (mouse) to very large (elephant) and were asked to select the one whose average adult weight was closest to 1000 pounds. Half of the participants estimated the weight of an average adult wolf before making this judgment while the other half did not. As predicted, estimating the weight of a (comparatively light) wolf increased the perceived size of the animal corresponding to ‘1000 pounds.’ Respondents in the “wolf” condition selected animals whose true weight averaged 2170 pounds, whereas those in the control condition selected animals whose true weight averaged 1385 pounds.

In the second study, a total of 206 students were given a brief paper and pencil survey which listed thirteen food items ordered from least caloric (hard-boiled egg) to most caloric (Burger King Whopper with cheese) and were asked to select the item closest to 400 calories. Half of the participants first estimated the number of calories in an average apple before making this judgment, while the other half did not.

The conceptual replication succeeded. Prior estimates of the number of calories in an apple appeared to increase participants’ perception of what ‘400 calories’ means. Respondents in the “apple”

condition picked items that were significantly more caloric [$M=394$] than respondents in the control condition [$M=330$]. Unlike previous studies 1 and 2, in which the numeric contrast effects specified by our theory manifest as assimilation effects in the responses (since a smaller number of units will seem adequate to represent the mass of a giraffe), here the proposed numeric contrast effects are transmitted directly to the overt response.

In summary, we suggest that objective scales may be susceptible to the same sorts of response scale effects that plague the interpretation of subjective scales. Though judgments on objective scales (such as pounds) are markedly affected by preceding judgments, we find no evidence that this effect is accompanied by a corresponding change in the underlying representation of the judged stimulus. Thus, we propose that the presence of contextual effects on objective scales *cannot* be assumed to reflect changes in the mental representation of the target stimulus, and that response scale effects play a much larger role in these results than is customarily acknowledged. Our findings resurrect the challenge of distinguishing representational effects from response language effects across a broad array of judgments where that distinction formerly seemed secure.

Effects of Alphanumeric Brand Names: A Selective Anchoring Perspective

Dengfeng Yan, Hong Kong University of Science and Technology, China

Rod Duclos, Hong Kong University of Science and Technology, China

EXTENDED ABSTRACT

Airbus A330, 7-Up, Coke Zero, Miss Sixty: these are just a few examples of the many brands and products featuring numbers in their name. Given the astronomical and ever growing budgets spent today on brand-building advertising, this research examines whether the presence of seemingly innocuous numbers in brand names bears any impact on consumers. More specifically, we focus our efforts on understanding how and when alphanumeric brands names (i.e., those containing both letters and numbers) may influence consumer judgments.

Building on anchoring theory, our central proposition is that consumers may use the number contained in alphanumeric brands as an anchor which can subsequently bias either up- or downward their appreciation of a product's price, weight, volume, etc.

We qualify this proposition, however, by arguing that such anchoring effect should occur mostly when (a) the numeric component of a name appears *relevant* for the judgment at hand, and (b) consumers evaluate attributes on the basis of *heuristics* (rather than systematic deliberation).

THEORETICAL BACKGROUND

Across industries, marketers dedicate nowadays colossal sums of money (i.e., billions of dollars in the US alone) to branding activities. Not surprisingly, academic research focusing on brand naming has soared in the last two decades (Klink 2000; Schmitt et al.1994; Zhang and Schmitt 2001). Interestingly, much of this research focuses primarily on linguistics (e.g., understanding the interplay between morphemes, sounds, and the mental images they trigger in consumers). But despite this rich work, little research examines the impact of alphanumeric brand names on consumer behavior and decision-making. In one of a few exceptions, Pavia and Costa (1993) found that alphanumeric brand names are more suitable for technically complex, manufactured items (e.g., stereos, computers, cameras) and/or unemotional, formulated products such as vitamin-oriented cereals.

Drawing from anchoring theory and previous work in psychology and BDT, we propose that consumers may sometimes derive product information from alphanumeric brand names, regardless of the original meaning of the latter. That is, consumers use alphanumeric brand names as self-generated anchors to infer unknown product attributes. For example, consumers may assume that the Airbus A330 has roughly 330 seats, even though its name has little to do with seat capacity.

For this anchoring effect to occur, however, we argue that at least two conditions should be met. First, consumers must perceive the numeric component of the brand name as *relevant* to the attribute under consideration (e.g., "330" in the Airbus example should appear relevant to the number of seats in the aircraft). Second, consumers must process information heuristically (i.e., superficially) rather than systematically. In the next section, we report four studies aimed at testing our anchoring hypothesis and its boundary conditions.

EXPERIMENTS

Study 1 aimed to demonstrate our basic proposition that the number contained in alphanumeric brand names can indeed function as an anchor and subsequently bias consumers' judgments. To this end, we randomly assigned participants to one of two conditions (Boeing B767 vs. Airbus A330) and asked them to estimate

the number of seats in their aircraft. As predicted, subjects in the Boeing condition believed their aircraft had more seats than their counterparts in the Airbus condition.

Seeking to extend these results and test our first boundary condition, we randomly assigned participants in study 2 to two new conditions (Sprite vs. 7-Up) and asked them to estimate the price, volume, launch year, calories, and vitamin content of their drink. Whereas both products sell for approximately HK\$5 in Hong Kong (i.e., the country where this study was run), subjects in the 7-Up condition estimated their drink to be more expensive (and closer in price to HK\$7) than their counterparts in the Sprite condition. Importantly, however, the two groups did not differ on any other dependant variable. These results further confirm our anchoring proposition and shed light on the first boundary condition hypothesized earlier: I.e., for anchoring to occur, consumers must perceive the numeric component of the brand name (e.g., "7") as related to the attribute under consideration.

Building on the "relevance" argument aforementioned, we asked participants in study 3 to review information about one of two MP3 players (named M-200 vs. M-900) before estimating the price of the product. To test our second boundary condition, we manipulated participants' processing style (heuristic vs. systematic) by manipulating the order and lay-out of our study materials. As predicted, subjects in the M-900 condition perceived their product to be more expensive. This anchoring effect was reduced, however, when subjects processed information systematically.

Study 4 mirrored study 3 with the exception of the processing-style manipulation. To extend our results, we adopted here a classic cognitive-load manipulation known to reliably favor heuristic vs. systematic processing. While rehearsing an 8- vs. 2-digit number for an alleged memory task, participants estimated the price of one of two MP3 players (cf. study 3). As expected, subjects in the M-900 condition perceived their product to be more expensive. Yet, this effect vanished in the low cognitive-load (i.e., systematic-processing) condition.

DISCUSSION

This research examines how and when seemingly innocuous alphanumeric brand names (e.g., 7-Up, Coke Zero) can bias a variety of consumer judgments (e.g., price estimates) by anchoring them either up- or downward. In four experiments, we find that consumers do indeed utilize the numbers contained in alphanumeric brand names as self-generated anchors to infer ostensibly relevant product attributes. For this effect to occur, however, consumers must process information heuristically, not systematically.

These findings provide new theoretical insights to two distinct lines of research. First, our results contribute to the brand-naming literature by proposing another mechanism through which numeric brand names can influence consumer judgment. Indeed, compared to prior work, our conceptualization is more general and therefore could be applied to a variety of numbers, product classes, and cultures. Second, our findings contribute to the psychology and BDT literatures by showing that anchoring can occur automatically (i.e., without the need for explicit or heavy-handed manipulations). As such, our studies suggest that anchoring might be more pervasive in consumer's daily life than previously assumed.

Whether You Win or Whether You Lose: The Differential Risk of Priming the Deliberative and Affective Systems in On-line Auctions

Yael Steinhart, University of Haifa, Israel

Michael Kamins, Stony Brook University, USA

David Mazursky, The Hebrew University of Jerusalem, Israel

Avi Noy, University of Haifa, Israel

EXTENDED ABSTRACT

Consumers' decision processes are generally influenced by both emotional and cognitive systems (Damasio 1994; Lee, Amir and Ariely 2009; Loewenstein and O'Donoghue 2004). For example, Loewenstein and O'Donoghue (2004) have developed a comprehensive two-system model in which a person's behavior is the outcome of an interaction between a *deliberative system* that assesses options with a broad, goal-based cognitive perspective and the *affective system* that encompasses emotions such as fear and is primarily driven by affective states that are currently activated.

The present research examines the role of the two-system model as a basis for further understanding the loss aversion phenomenon (Kahneman and Tversky 1979). This is important because the marketing literature has paid relatively scant attention to the question of how the deliberative system influences loss aversion. Overall, the marketing literature has focused to-date almost solely on the affective system.

We posit that each system has an opposite effect on the perception of loss aversion and therefore on the price bidders will be willing to pay for a given product. The direction of effect is contingent on the expected outcomes of the auction. In the case that the affective system is activated, bidders are proposed to pay higher prices when they are primed to anticipate losing the item rather than winning it. That is, the fear of losing the item is expected to override the joy of winning and consequently enhance the willingness to pay. On the other hand, when the deliberative system is made more accessible, bidders should pay higher prices if the potential of winning is made salient as opposed to losing. In this case, priming the goals of winning the auction, increases the cognitive focus on the product benefits, and therefore makes the perceived risk of losing the item less acceptable.

The first study manipulated two between-subject factors, thus creating a two (winning vs. losing outcome expectation) by two (affective vs. deliberative orientation) matrix. Its findings demonstrated the contradicting effects of the two-model system and the expected outcomes of the auction in determining the price bid for the product as well as the perceived risk of losing the item. The perceived risk of losing was also found to mediate the interactive effect of one's winning expectation and the two-model system on the placed bid.

The second study confirmed our expectations in terms of the placed bid, in a field setting. The field study was conducted on eBay over the period of four months. It consisted of four different conditions of actual auctions of the identical product, in which we activated either the affective or deliberative system and the type of outcome expectation via the product description.

The third study examined the robustness of the proposed effect when priming the winning or losing orientation in an unrelated prior task. This study is extremely important because it shows that one's success or failure in environmental tasks can have a behavioral effect on subsequent totally unrelated tasks. Findings supportive of our hypotheses would present the tantalizing suggestion that the way one sees oneself through the looking glass (i.e., as a "winner" or as a "loser") may have important implications in terms of which orientation is appropriate to use in inducing task specific behavior. Specifically, this study manipulated one's perception of performance

in a game through winning or losing points when completing a task by deciphering jumbled brand names. After this task, subjects were then subsequently asked to participate in an auction. Hence, a winning or losing orientation was independently induced prior to participation in the auction rather than win or loss expectations for the auction itself.

In future research, it would be interesting to examine the effect of expected outcomes on different types of products: emotional oriented products (such as a wedding ring) and cognitive oriented products (such as a scientific book). It is likely to assume that the type of product may differentially prime the influence of cognition and/or affect in the two model system and possibly make it easier to observe field effects. It will also be interesting to explore the association between this research and the regulatory focus stream of research. This research stream suggests that consumers are driven by either the prevention orientation (e.g. their duties, obligations, and responsibilities) or the promotion orientation (e.g., their hopes, aspirations, and dreams) (Higgins 1997, Freitas and Higgins 2002).

From a practical perspective, this research offers marketers simple and effective tools for activating the loss aversion effect among consumers. It shows that inserting a short note within the product description from a deliberative or affective perspective regarding the possible outcomes of winning or losing the product, can have a dramatic influence on the consumers' decision processes and behavior.

Can I Correct My Errors without Knowing?: The Effect of Nonconscious Priming of a Target Attribute on Judgmental Errors

Ki Yeon Lee, University of Toronto, Canada
Andrew Mitchell, University of Toronto, Canada

EXTENDED ABSTRACT

Attribute substitution (Kahneman and Frederick 2002) has been used to explain why people rely on heuristics and show biases. Attribute substitution occurs “when an individual assesses a specified target attribute of a judgment object by substituting another property of that object—the heuristic attribute—which comes more readily to mind” (p53). Substituting the target attribute with the heuristic attribute inevitably introduces systematic errors because these two attributes are different. What would happen if the target attribute is more accessible by subliminally priming words related to the target attribute? We expect that people are less likely to make the errors because the target attribute is made more accessible. The purpose of the present research is to examine whether and how subliminal priming of a target attribute can reduce the errors (e.g., base-rate neglect) and whether this correction process elicited by nonconscious priming requires cognitive resources, which implies the involvement of reasoning.

Experiment 1 examines whether the subliminal priming of a target attribute can correct judgmental errors by using the Kirkpatrick and Epstein (1992)’s jelly beans task which shows the *ratio-bias (RB) phenomenon*. The RB phenomenon refers to “the perception of the likelihood of a low-probability event as greater when it is presented in the form of larger (e.g., 10-in-100) rather than smaller (e.g., 1-in-10) numbers” (Pacini and Epstein 1999, p303). This phenomenon is attributed to a tendency to focus on the frequency of the numerator (i.e., heuristic attribute) instead of the overall probability (i.e., target attribute). Selecting one of two trays that offer equal probabilities is, in itself, not a judgmental error. However, the preference for a 9% over a 10% probability is (Denes-Raj and Epstein 1994).

In experiment 1, participants were asked to choose one of two trays from which they could participate in a lottery where they could win \$50 if they drew a red jelly bean: tray A (10% tray) containing 1 red and 9 white beans and tray B (9% tray) containing 9 red and 91 white beans. Since the target attribute is the ‘objective probability’ of drawing a red bean, if participants choose a tray based on the target attribute instead of the number of red jelly beans, they should be more (less) likely to choose the 10% tray (the 9% tray).

Participants were randomly assigned to either a control or a target attribute priming condition. The priming task was disguised as a perception task. Words related to the objective probability (e.g., probability, proportion) were *subliminally* (i.e., 20 ms) shown to participants depending on the priming conditions. The primed words were masked by a string of letters (e.g., addick). Participants were asked to identify whether each string of letters presented on a computer screen contained two vowels or not. After finishing the perception task, participants were asked to complete the next task—the jelly beans task. They were asked to indicate their own preference between the two trays on a five-point scale. Next, they were asked to choose which tray they wanted to draw from for a real drawing.

We found main effects of attribute priming in self-preference scale and tray choice. Participants primed with the target attribute were more likely to prefer the correct 10% tray than those who were not primed. Consistent with this result, participants primed with the target attribute chose the 10% tray significantly more than those who were not primed.

Experiment 2 extends the findings in Experiment 1 to a different judgmental bias, base-rate neglect by using an analogue of the engineer-and-lawyer problem (Kahneman and Tversky 1973). In the engineer-and-lawyer problem, people are given the base rate of engineers (e.g., 30 engineers out of 100 individuals) and the description of a person (e.g., typical characteristics of an engineer such as having no interest in political and social issue and spending time in home carpentry). Although the base-rate of engineers in a given sample is very low (e.g., 30%), people’s estimation of the probability that a person is an engineer is much higher (e.g., 80%) than the base rate due to their tendency to rely on the description of the person rather than the base rate. The base-rate neglect in probability judgment is problematic because it induces people to violate the fundamental Bayesian rule of statistical prediction.

The procedures in experiment 2 are similar to those in experiment 1. We used Betsch et al. (1998)’s professor-and-non-professor item. Participants were randomly assigned to either a control or a target attribute priming condition. After finishing the priming task, participants were given a description of a person. They were told that this description was one of a survey sample which contained 17.6% professors and 82.4% non-professors. Their task was to rate the probability that the person is a professor given the description of the person and the base rate.

We found that participants primed with the target attribute were more likely to estimate the probability to be lower (closer to the base rate of professors) than those who were not primed. This finding provides further evidence that subliminally priming the target attribute reduced the judgmental error.

Experiment 3 examines whether the process of correcting judgmental errors requires the involvement of System 2 by manipulating cognitive load. Since the processes of System 1 are automatic and effortless whereas those of System 2 are slow and effortful, if System 2 is involved in the correction process, a high cognitive load should interfere with this correction process which is facilitated by subliminally priming the target attribute.

The procedures in experiment 3 are similar to those in experiment 2 except the manipulation of cognitive load. Participants were randomly assigned to a 2 (target attribute priming: no priming vs. target attribute priming) x 2 (cognitive load: low vs. high load) between-subjects design. We manipulated cognitive load by asking participants to memorize either a 2- or 9-digit number. To rule out the alternative explanation of mood effect, we measured their mood using PANAS scale (Watson, Clark, and Tellegen 1988).

Our manipulation check was successful in that participants found it more difficult to memorize the 9- than the 2-digit number. In the low cognitive load conditions, participants primed with the target attribute were more likely to estimate the probability to be lower (closer to the base rate) than those who were not primed. However, in the high cognitive load conditions, participants’ probability estimates were equally high (far from the base rate). This finding implies that cognitive busyness impairs the process of correcting the bias (i.e., the base-rate neglect). We ruled out the alternative account by showing no differences in the PANAS scale as a function of cognitive load. The findings of experiment 3 suggest that System 2 is involved in the process of correcting judgmental errors.

These studies provide evidence for the idea that priming the target attribute *nonconsciously* can reduce judgmental errors. We believe that this research is important for two reasons: First, it contributes to extend our understanding of the underlying mechanism for reducing judgmental errors by demonstrating that not only explicit/conscious methods but also *implicit/nonconscious method* (i.e., priming a target attribute) can reduce the judgmental errors. Second, it shows that the process of correcting judgmental errors requires cognitive resources, which implies the involvement of System 2.

Attainment Versus Maintenance Goals: Differences in Cognitive Processing and Goal Attractiveness

Antonios Stamatogiannakis, INSEAD, France
Amitava Chattopadhyay, INSEAD, Singapore
Dipankar Chakravarti, Johns Hopkins University, USA

EXTENDED ABSTRACT

Consumers and firms across many domains (e.g., dieting, saving, exercising) use goals to regulate behaviour. For example, HSBC offers the “Premier Investor Savings” account, which requires the maintenance of a \$25000 minimum balance, but at the same time offers higher interest rates with higher balances.

Depending on the relation between the actual and the desired state of the goal, these goals are classified in two categories: Attainment and maintenance goals. Attainment goals are those for which the actual state differs from the desired state (e.g., increase your balance to get a higher interest rate). Maintenance goals are those for which the actual and the desired states coincide, but there is a time difference between the present and the goal time horizon (e.g., maintain your balance to be eligible for this savings account).

Given the mixed use of these two goal types, it is surprising that we know very little on how attainment and maintenance goals compare with each other. Recent comparisons between these two goal types revealed that people are overoptimistic for attainment goals, but not for maintenance goals. As a result, attainment goals are perceived as easier than objectively easier maintenance goals (Stamatogiannakis, Chattopadhyay and Chakravarti 2010).

This paper adds to the above results in two important ways. First, it investigates the content of thoughts triggered by attainment versus maintenance goals, and tests whether it can account for differences in the perceived difficulty. We predict that people will tend to focus on the comparison between the actual and the desired state more for attainment goals, relative to maintenance goals. As a result, they will be overoptimistic for attainment goals’ achievement (Dunning 2007), and will perceive them as easier (Stamatogiannakis et al. 2010).

Second, it examines whether attainment or maintenance goals are more attractive. Easier and more achievable goals are more attractive (Kruglanski et al. 2002). We predict therefore that attainment goals will be more attractive than maintenance goals, because they are perceived as easier.

To test these two predictions we examine in depth the open ended responses collected by Stamatogiannakis et al. (2010), and we conduct two scenario based experiments. In all three studies goal type (attainment vs. maintenance) is manipulated between participants. Scenarios about weight, GPA, daily working out time, money, and weekly sales goals are used.

Stamatogiannakis et al. (2010) asked participants to rate goal difficulty and list their thoughts on what would make goal achievement more or less likely. To uncover differences in thoughts generation between attainment and maintenance goals, we did an in-depth analysis of these thoughts. These were coded across two dimensions, valence and content. In valence coding, each thought was categorised as favorable (i.e., a success thought), unfavorable (i.e., a failure thought), or neutral (i.e., unrelated thought) for goal achievement. In content coding, each thought was categorised as related or not to the following: effort/ motivation put for goal achievement, the person pursuing the goal, goal context, specific plans for goal achievement, and goal level. Finally, statements related to the goal level were further categorised depending on whether they involved a comparison between the actual and the desired state, or not.

The results suggest that attainment goals evoke more thoughts comparing the actual and the desired state, and more plan-related

success thoughts, but less context-related failure thoughts relative to maintenance goals. Only the first mediate the effects of goal type on difficulty.

The next two experiments examine effects of goal type on goal attractiveness. We predicted that attainment goals will be more attractive than maintenance goals, because they are perceived as easier.

Experiment one uses a 2 x 2 between participants design. Some participants judged maintenance goals and some attainment goals. Further (to draw attention to possible goal difficulties), the action required for goal achievement was explicitly stated only for some of the participants. Goal attractiveness and difficulty were the dependent measures. The goal type x required action interaction was significant for both. When no action was provided, attainment goals were seen as more attractive and easier than maintenance goals. However, when attention was directed to required action, the two goal types were seen as equally attractive and difficult. The interaction on attractiveness ratings was mediated by the difficulty ratings.

Experiment two uses a 2 x 2 x 2 between participants design. Some participants judged maintenance goals and some attainment goals. Further (to draw attention to possible goal difficulties), some participants rated only goal attractiveness, but some rated goal difficulty before that. Finally the difficulty question was negatively framed (i.e., “How difficult?”) for some of the participants, but positively framed (i.e., “How challenging?”) for others. The goal type x attractiveness question order interaction effect on attractiveness was significant. Attainment goals were judged as more attractive than maintenance goals when the attractiveness question was asked first. However, when the difficulty question was asked first, drawing attention to goal difficulty, the results reversed. Finally, difficulty framing did not moderate the above result.

To conclude, this paper adds to previous literature comparing attainment with maintenance goals. It demonstrates that maintenance goals evoke more contextual interference thoughts, but attainment goals evoke more success plans and actual-desired state comparison thoughts. The latter cause attainment goals to be perceived as easier and more attractive than maintenance goals. Effects on goal attractiveness are attenuated or even reversed, when consumer attention is drawn to possible difficulties for goal achievement.

Maintenance versus Attainment Goals: Influence of Self-Regulation Goal Type on Goal Pursuit Behaviors

Napatsorn Jiraporn, State University of New York at Binghamton, USA
Kalpesh Kaushik Desai, State University of New York at Binghamton, USA

EXTENDED ABSTRACT

The extant goal literature has focused mainly on *attainment goals*, in which the desired state is positively discrepant from the current state, but has neglected the *maintenance goals*, in which the current state is equal to or better than the desired state. This casts doubt on whether the implications of findings from the literature can apply to the challenges related to maintenance goals. We address these gaps by contrast the two goal types and examine the mechanisms underlying each of them. Our findings suggest that consumers in the two groups are attracted to different self-regulation strategies. Therefore, firms can provide different products for consumers in these two groups.

What differentiate maintenance goals from attainment goals? First, by their definitions, the two goal types differ in the distance between the current and the desired states. Second, the two goal types differ in the clarity about temporal ending of goal pursuit (H1). In case of an attainment goal, achieving the desired state suggests end of goal pursuit. However, in case of a maintenance goal, there is less clarity about the temporal ending because the current state is already better than the benchmark. Moreover, some maintenance goals are to be pursued over long term such as health-related goals (e.g. exercise goal) so these goals are not temporally bound.

Moreover, the two goal types differ in their underlying mechanisms. We propose that maintenance goals activate retrospective (vs. prospective) thought because maintenance goals indicate the past actions of consumers were good enough. In contrast, attainment goals activate prospective thought because attainment goals suggest that the past actions did not bring about the desired state so consumers focus more on future actions (H2). Moreover, maintenance goals trigger more process-focused (vs. outcome-focused) thinking while attainment goals trigger more outcome-focused thinking (H3). The reason is that thoughts in retrospection tend to have richer context (Van Boven, Kane, & McGraw 2009) and make consumers think at more concrete (vs. abstract) level. Thoughts at concrete level involve feasibility aspects and process of means to goal but thoughts at abstract level focus on consequences of means or goal (Liberman & Trope 1998; Trope & Liberman 2003). Hence, when considering goal pursuit strategies, maintainers tend to focus more on processes of the strategies whereas attainers focus more on outcomes of the strategies.

The two underlying mechanisms lead to different goal pursuit behaviors. First, we predict that maintainers will construct smaller consideration set of goal pursuit strategies than attainers (H4). This is because maintainers' retrospective thoughts constrain them with reality (Van Boven et al 2009) and prevent them from choosing strategies that are less practical. Consistently, process-focused thinking makes maintainers consider only strategies with easier implementation process. In contrast, attainers are less constrained by reality and more outcome-driven so they consider any strategies which appear to deliver satisfactory outcomes.

Furthermore, based on the difference in clarity about temporal ending of the two goal types, maintainers will prefer strategies that require less (vs. more) effort because the temporal ending of their goal pursuit is not clear. On the other hand, attainers might be more willing to exert higher effort as they perceive that the goal pursuit is more temporally bound (H5a). In addition, the outcome-focused thinking might make attainers prefer strategies that require higher

effort because they rely on 'instrumentality heuristics', naïve belief that higher effort leads to better outcome (Labroo & Kim 2009). Along the same line, we predict that maintainers prefer a disaggregated framing of strategy implementation (e.g. exercise 15 minutes for 6 days per week) than an aggregated framing (e.g. exercise 45 minutes for 2 days per week) (H5b). This is because maintainers might perceive the former as easier to implement.

In three studies, the two goal types were manipulated. All three studies successfully established that maintenance goals are characterized with less clear temporal (H1). Study 1 with a 2 (maintenance vs. attainment goal) x 2 (domain replicates) between-subject design ($n = 225$) tested the consideration set size hypothesis in two goal domains, cholesterol and money saving. The results were consistent across two domains and showed that maintainers considered fewer strategies than attainers ($M_{\text{Maintainers}} = 3.61$ vs. $M_{\text{Attainers}} = 4.12$, $F(1, 207) = 4.16$, $p < .01$). Thus, our H1 & H4 were supported.

Study 2 ($n = 56$) replicated the results of Study 1 with stronger measures of psychological processes. The analysis revealed that attainers engaged more in prospective than retrospective thoughts ($M_{\text{Retro}} = 4.44$ vs. $M_{\text{Pro}} = 5.10$, $t(28) = 2.14$, $p < .05$) but maintainers engaged in thoughts in both time frames. Thus, H2 was partially supported. Further analysis showed that attainers engaged more in outcome-focused thinking than process-focused thinking ($M_{\text{Proc}} = 4.56$ vs. $M_{\text{Out}} = 5.25$, $t(28) = 3.28$, $p < .01$) but maintainers did not differ between the two thinking styles. Thus, H3 was also partially supported. We added measures of whether consumers consider old versus new strategies. The results indicated that maintainers considered both old and new strategies but attainers tended to consider new strategies ($M_{\text{Old}} = 4.31$ vs. $M_{\text{New}} = 4.93$, $t(28) = 1.98$, $p = .06$).

Study 3 ($n = 28$) tested our effort-related hypothesis (H5) with a 2 (maintenance vs. attainment goal) x 2 (aggregated vs. disaggregated framing) design with framing as within-subject factor. The results revealed that maintainers evaluated a disaggregated framing (workout 15 minutes for 6 days per week) more positively than an aggregated framing (workout 45 minutes for 2 days per week) ($F(1, 25) = 2.85$, $M_{\text{disagg}} = 5.08$ vs. $M_{\text{agg}} = 4.78$, $p < .1$). In addition, maintainers rated the former as less effortful than the latter ($M_{\text{disagg}} = 3.36$ vs. $M_{\text{agg}} = 5.36$, $t(11) = 2.97$, $p < .05$). However, attainers did not differ in their attitude between the two framings. Thus, H5 was partially supported.

Across three studies, the results showed robust supports that maintenance goals differ from attainment goals in characteristics, underlying processes, and pursuit behaviors. The research helps managers recognize that consumers striving different goal types are not homogenous and distinct marketing strategies are needed to serve the two consumer groups.

Squeezing a Dry Towel: Reducing Consumers' Optimistic Prediction Biases

Kyeong Sam Min, University of New Orleans, USA

Hal Arkes, Ohio State University, USA

EXTENDED ABSTRACT

Consumers tend to be optimistic in predicting when they will complete an upcoming activity. Optimistic predictions are often more problematic than pessimistic predictions, because they not only delay other planned projects, but they also make consumers use unexpected additional resources to complete the current project. Even though research to date has proposed various bias reduction aids in the context of optimistic time predictions (e.g., Roy, Christenfeld, and McKenzie 2005), many of them were not empirically supported or earned only mixed support. The purpose of this paper is to propose and test new debiasing strategies that help to reduce consumers' optimistic prediction biases.

One of the possible causes of the optimistic prediction bias is that individuals overestimate the likelihood of the occurrence of a chain of events in completing a project. As shown in the explanation bias literature (e.g., Hirt, Kardes, and Markman 2004), people tend to view a particular outcome as more likely to occur if they have explained a sequence of steps required to complete the project. Because individuals often base their judgments upon the information that is readily available, the project that has been explained is more accessible and thus gets higher likelihood estimates. Thus consumers who can easily simulate the sequence of an event may be optimistic in concluding that the event is likely to take place soon.

Drawing upon the literature in judgment and decision making, we argue that the magnitude of planning difficulty effects will be mitigated when an individual planner's accountability increases, a planner write a pessimistic scenario, or a planner is led to believe that ease is bad. First, accountable individuals tend to thoroughly process the information and do not heavily rely upon heuristics such as ease of generation (e.g., Tetlock, Lerner, and Boettger 1996). Thus, we predicted that the influence of planning difficulty on optimistic prediction bias would be weaker when individuals' *accountability* for their prediction outcome was high, rather than low. Second, following up Sanna and Schwarz (2004), we predicted that individuals' optimistic prediction bias would be smaller when it was easy, rather than difficult, to generate a *pessimistic* scenario about an upcoming event. Third, building upon Briñol, Petty, and Tormala (2006), we predicted that experiencing ease in generating an optimistic scenario would reduce optimism when people interpreted *ease* of generation to be *bad*, rather than good.

Using "real world" planning activities, each of these predictions were tested across three experiments, respectively. In Experiment 1 we examined how planning difficulty would influence individuals' optimistic prediction biases. We also tested the role of accountability as a debiasing aid. People who were engaged to be married were first asked to identify one of their pre-wedding activities that would be completed soon. Then they were told to describe how they would complete the activity by writing about it in relatively easy or difficult steps. They were also assigned to one of two accountability conditions. Next the participants estimated the time that the target activity would be completed and then evaluated their planning processes. Lastly, participants reported their actual completion times when they were contacted 10 days after the predicted deadline of the chosen activity. As predicted, people who were engaged to be married made more realistic time estimates for the project completion when they were asked to write a relatively difficult, rather than easy step, optimistic scenario. However, unlike our prediction, accountability did not play any moderating role. Each individual in the high accountability condition seemed to have been

less susceptible to our accountability instruction because his or her responses would be ultimately examined by the experimenter as well as the other member of the couple. In Experiment 2 we tested how planning difficulty would interact with scenario type: optimistic versus pessimistic. As predicted, the planning difficulty effect shown in Experiment 1 was qualified by the type of scenario that people generated. The optimistic prediction bias decreased when individual planners generated the difficult, as opposed to the easy, optimistic scenario or when individuals generated the easy, as opposed to the difficult, pessimistic scenario. In Experiment 3 we tested how planning difficulty would interact with shoppers' interpretation of the feeling of ease. As expected, the planning difficulty effect was qualified by the subjective meaning of ease. Planners who generated a difficult, rather than an easy, optimistic scenario were less likely to exhibit the optimistic prediction bias when they positively interpreted the feeling of ease. In contrast, planners who generated an easy, rather than a difficult, optimistic scenario were marginally less likely to exhibit the optimistic prediction bias when they negatively interpreted the feeling of ease.

In sum, across three experiments using "real world" planning activities we found support for two important debiasing aids. We hope our new debiasing strategies will not only help illuminate the processes behind the optimistic prediction bias but will also assist all of us in making more realistic plans.

When Small Steps Become Big Leaps: Goal-Consistency Judgments and the Illusion of Goal Progress

Andrea Bonezzi, Northwestern University, USA
Alexander Chernev, Northwestern University, USA

EXTENDED ABSTRACT

Goals play a central role in driving consumers' mental processes and ultimate behaviors. Whether consciously held (Bagozzi & Dholakia, 1999; Locke & Latham, 1990), or activated outside of awareness (Bargh & Chartrand, 1999; Chartrand & Bargh, 1996) goals act as motivational drives (Gollwitzer, 1999) prompting people to engage in actions functional to achieving the desired end-state.

An important aspect of achieving a goal involves monitoring progress toward the desired end-state. Monitoring goal-progress plays a fundamental role in regulating consumer behavior by informing individuals about the contribution of each action to reaching the desired end-state.

In line with this idea, monitoring goal-progress has been conceptualized as a process involving comparing a behavioral outcome with a relevant standard of reference (Carver & Scheier, 1998). For example, one can adopt either the initial or the final state as the standard of reference and monitor goal-progress by considering either what has been achieved so far, or what still needs to be achieved (Koo & Fishbach, 2008). Consequently, perceived goal progress is typically measured by asking participants to indicate on a Likert scale the extent to which a particular decision contributes to advancing toward an active goal (Fishbach & Dhar, 2005; Louro, Pieters, & Zeelenberg, 2007). We refer to such judgments as *degree-of-progress* evaluations.

Building on previous research we propose that often people evaluate progress toward a goal by judging whether their actions are consistent with the active goal (i.e., "Will this help me reach my goal?"). For example, a person who is trying to save money could evaluate progress toward the goal by judging whether dining at home rather than at a restaurant is consistent with the goal to save money, without accurately considering how much money he is actually saving. We refer to such judgments as *goal-consistency* judgments.

Goal-consistency judgments are frequently triggered both by external and internal constraints. Often, the choice task induces people to categorize actions as consistent or inconsistent with an active goal. For instance, people are often bounded to choose the best option among the available ones. Moreover, due to limited mental resources, people often tend to simplify judgments by employing mental shortcuts, simplifying rules and heuristics (Tversky & Kahneman, 1974). Previous research has argued that one simplifying approach to judgment involves categorical or qualitative thinking (Rozin, Ashmore, & Markwith, 1996). Thus, people engage in categorization to easily make sense of the complexity of the world (Allport, 1954; Fiske & Taylor, 1991).

Does engaging in goal-consistency judgments influence degree-of-progress evaluations? In this research, we argue that consumers focused on goal-consistency are likely to overestimate the degree-of-progress granted by an action that provides a marginal contribution toward reaching a desired end-state. We test the proposition that goal-consistency judgments influence goal-progress evaluations in a series of four experiments.

In Experiment 1 we show that goal-consistency judgments lead to overestimating goal-progress. We test this basic proposition across three domains, representing three different goals: saving money, controlling calorie intake and caring for the environment. We find that respondents making goal-consistency judgments

overestimated goal-progress compared to respondents not focusing on goal-consistency. This effect was directionally consistent across all three domains.

In Experiment 2 we provide further evidence for the phenomenon and show that the goal progress overestimation is not a function of progress valence. In particular, we show that goal-consistency judgments lead to overestimating the movement toward a goal produced by a goal-consistent action, as well as the movement away from a goal produced by a goal-inconsistent action.

In Experiment 3 we identify boundary conditions and show that the influence of goal-consistency judgments on goal-progress evaluations is a function of the magnitude of actual progress. In particular, goal-consistency judgments lead to overestimating goal-progress only when the actual progress is marginal, but not when the actual progress is large.

Finally, in Experiment 4 we show that goal-consistency evaluations can be spontaneously triggered by the choice task. In particular we show that a series of goal-consistent choices is perceived to yield more progress than a single choice producing the same final result.

Overall, the four experiments reported in this research offer converging evidence for the proposition that goal-consistency judgments bias goal-progress evaluations. In particular, we show that consumers focused on goal-consistency are likely to overestimate the degree-of-progress granted by an action that provides a marginal contribution toward reaching a desired end-state. Our results point to the importance of investigating how different strategies consumers use to monitor progress toward a goal might create the illusion of goal-progress and eventually backfire.

Film Festival 2010

The Last Picture Show

Russell Belk and Robert Kozinets, York University

Unlike the movie theater in Peter Bogdanovich's *The Last Picture Show*, the 2010 ACR Film Festival will not be the last. But after 10 years of co-chairing the Festival, we have turned over the reigns to the very capable hands of Marylouise Caldwell and Paul Henry. Over the past 10 years we have seen videographic consumer research grow, mature, and ripen into something quite amazing. Both the quality and quantity of consumer research videos have grown over this period. The North American ACR Film Festivals have shown more than 125 films and the ACR Conferences in Europe, Latin America, and the Asia Pacific have developed their own exciting and locally-flavored Film Festivals as well.

From its inception, the North American festival itself has always had strong international representation among filmmakers and topics. If one of the challenges of consumer ethnography is to make the strange familiar and the familiar strange, consumer videography has excelled in meeting this challenge. Many of these films have found their way into classrooms and a number of them have been included in special DVD issues of several journals as well as into print journal articles and chapters. With its origins in an ACR Special Session in 2000, the Film Festival is now an ACR institution. We hope that no one could imagine a future ACR that did not offer researchers the option of representing our knowledge of consumer in an audio-visual format. As industry increasingly embraces videographic techniques for representing consumer realities and portraying their marketing research findings, it is useful for our field to follow suit and, in many ways, lead the charge towards finding new, rich forms for understanding the consumer.

The format of video and video editing over this period has been non-linear and digital throughout the past decade. Technologies have evolved and have driven the costs of video storytelling down to quite affordable levels. Thanks to the conference chairs, at the 2010 ACR Film Festival we not only had trailers available on the conference hotel CCTV, but also on the conference web site. For the upcoming Beijing ACR Conference in 2011 we will be receiving and reviewing (jurying) Film Festival entries on the Internet. ACR Films over the past decade have gone from standard definition analog VHS tapes to high definition DVDs. Camcorders have become smaller, cheaper, and more sophisticated. Digital still photography cameras are no longer so still. These technologies have also become ubiquitous as even the convergent technologies of mobile phones are capable of capturing high definition video. And editing equipment and software that would have been prohibitively expensive for the individual videographer two decades ago is now inexpensive or included free with computer operating systems and cameras. But it is not just technologies that have changed, so have the skills of filmmakers. We don't mean by this that the ACR videos have been produced by film school graduates (although a few have), but rather that ACR members have learned from practice, by watching other ACR films, through videos on YouTube, Vimeo, and similar sites, and from occasional consumer videography workshops and classes. Over the past decade, we have witnessed dramatic improvements in the quality of Consumer Research Videography as a field. We have been fortunate to watch as several stars of the field emerged and excelled in this medium.

The medium of video has allowed experimentation with different ways of representing consumer behavior. Resulting films have varied from two and one-half minutes to ninety minutes. They have represented consumption on every continent. No doubt the medium is best used when there is behavior to be shown rather than the talking heads of interviews. Many of these stories are allowed to unfold without much narration or voice-over, but "voice-of-god" storytelling has not disappeared. Much more use is now made of video montages, quick-cuts, music, and other cinematic devices for sustaining audience interest and managing the pace and flow of the video. These techniques too have evolved and kept pace with what's on TV and what's on the Internet. Some films have had amusing topics and approaches while others have been deadly serious. Interestingly, both of these extremes have resulted in award-winning films.

We have had a People's Choice Award from the first ACR Film Festival, but over the past six years we have also had a Juror's Award. The latter award also has a monetary prize, thanks to the generosity of Gary Bamossy, Alladi Venkatesh, the Center for Consumer Culture, and the University of California, Irvine. The criteria for evaluating submitted films and the Juror's Award have also evolved over the first decade of ACR Films. We have described these criteria in several papers (Belk 2006; Belk and Kozinets 2006a, 2006b; Kozinets and Belk 2005). They include the "Four Ts" of topical, theoretical, theatrical, and technical considerations.

This year's ACR Film Festival showed ten films out of 19 submitted for a 53 percent acceptance rate. The films are a good example of the geographic and cultural diversity noted above. The films focus on consumption phenomena in Botswana, Brazil, China (Tibet), Japan, Qatar, and the United States, with filmmakers from Australia, Brazil, Canada, Japan, Norway, Qatar, Spain, and the U.S. As noted in the abstracts below, the topics were equally diverse, ranging from Twitter, videogamers, and World of Warcraft to Green Consumption, AIDS in Africa, Beer in Montana, Japanese tea ceremonies, Arab Gulf homes, and Shangri-La.

This year for the first time, both the People's Choice Award and the Juror's Award went to the same film: "Walk the Talk, Talk the Walk," by Marylouise Caldwell, Ingeborg Kleppe, and Stephen Watson. Congratulations go to these filmmakers for their powerful and moving film about a competition for positive role models for HIV positive men in Botswana. It is fitting that we should turn over the film festival at this time in its history to one of its top award-winning film-makers. We are looking forward to the next decade of successful ACR Film Festivals.

BRIEF ABSTRACTS

Beer Country

Caroline Graham Austin, Montana State University, USA

Since the first settlers arrived at the St. Mary's mission in the mid-19th century, Montanans have loved beer --- they love making it, sharing it, talking about it, and drinking it. In this film, we investigate the historic, economic, cultural and aesthetic values that make Montana America's own Beer Country.

Retweet: A Digital Meditation on the Power of Twitter

Donna Hoffman, University of California, Riverside, USA

Thomas P. Novak, University of California, USA

The phenomenal growth of Twitter, a popular microblogging application, is testament to consumers' desires to instantaneously connect with other consumers. Though many deride the seeming meaningless of the "twitter stream," consumers are putting the application to use in surprisingly potent ways. This video offers a brief reflection on the recursive power of Twitter.

Talk The Walk, Walk the Talk

Marylouise Caldwell, University of Sydney, Australia

Ingeborg Kleppe, Norwegian School of Economics and Business Administration

Stephen Watson, e+b media, University of Sydney, Australia

This documentary shows how HIV+ people in Botswana radically transform themselves from AIDS victims to become public role-models of Positive Living, a health life-style that prolongs infected people's lives and prevents them from infecting others and reinfecting themselves. They learn to deal with stigma, ignorance and limited social or financial support.

Tea for Two: Luxury in Japanese Tea Ceremony

Hiroshi Tanaka, Chuo University, Japan

Junko Kimura, Hosei University, Japan

This study aims to anatomize the mechanism of luxury generation in the Japanese tea ceremony. Based on detailed interviews, we found that (1) Teamwork, (2) Theme-orientation, and (3) Game, are the three key concepts which depict the interactions between host and the guests and thus lead to generate sense of luxury.

Is Green?

Gary Bamossy, Georgetown University, USA

Basil Englis, Berry College, USA

This film examines consumers' reactions to the marketing practices of "Green Washing" --representing products as being environmentally friendly in ways that result in consumers feeling confused, skeptical, and cynical about those claims, and more generally, about the green movement towards sustainable consumption practices. The public discourse around "environmentally friendly" offerings is becoming increasingly contentious, socially divisive, and politicized, and this film explores these dynamics.

Domains of Privacy in Arab Gulf Homes

Sobh Rana, Qatar University, Qatar

Russell Belk, York University, Canada

Globalization has both ameliorating and exacerbating effects on traditional cultural patterns. Based on ethnographic fieldwork over a three-year period, we analyze how local Islamic cultures affect consumption and marketing amid this swirl of new influences.

Paradise Lost: The Making of Shangri-La

Russell Belk, York University, Canada

Rosa Llamas, University of León, Spain

Once upon a time, there was a peaceful Himalayan Fairyland that was a Garden of Eden, an earthly Paradise, and a Heaven on Earth. Its name was Shangri-La. And now the harried city dweller can vacation there. In 2002 the county of Zhongdian in China's Yunan Province changed its name to Shangri-La. Based on fieldwork in 2009, we consider the positive and negative effects of this bid to attract tourists and transform the local economy.

Sustainability: A New Consumer Movement

Adam Schmidt, Saint Joseph's University, USA

Thomas Ferraro, Saint Joseph's University, USA

Diane M. Phillips, Saint Joseph's University, USA

Consumers define sustainability in different ways and enact a variety of different behaviors to construct, maintain, and enhance their sustainable lifestyles. Further, those resulting multi-dimensional lifestyles are clearly personal. They tap into deeply held values, connect to communities, and evoke strong emotions. Sustainability is a new consumer movement.

Gamerz

João Fleck, Universidade Federal do Rio Grande do Sul, Brazil

Stefânia Almeida, Pontifícia Universidade Católica, Brazil

Utpal Dholakia, Rice University, USA

José Mazzon, Universidade de São Paulo, Brazil

We aimed at analyzing and understanding the peculiarities of video game consumption interviewing hardcore players that interact in Microsoft Xbox 360 virtual communities. The results allowed us to infer that the virtual experience and the online interaction are key elements presently in the consumption of games.

World of Warcrafters

João Fleck, Universidade Federal do Rio Grande do Sul, Brazil

Carlos Rossi, Universidade Federal do Rio Grande do Sul, Brazil

Rodrigo Segabinazzi, Universidade Federal do Rio Grande do Sul, Brazil

Getúlio Reale, Universidade Federal do Rio Grande do Sul, Brazil

Diego Costa, Universidade Federal do Rio Grande do Sul, Brazil

Marco Martins, Universidade Federal do Rio Grande do Sul, Brazil

We aimed at understanding, through a videographic study, what caused the reputed online game, World of Warcraft, to become such a phenomenon of consumption. Our results indicate that the involvement of players results from the achievement of goals, through the manipulation of an avatar that cooperates with others to compete.

Uma Karmarkar, Stanford University, USA
Theo Noseworthy, University of Western Ontario, Canada

Extended Abstract

Topic and Motivation. Two exciting recent developments in consumer research have been the burgeoning use of *decision neuroscience* to explore unanswered questions about consumer psychology and behavior, and *transformative consumer research* taking the express aim of investigating and improving personal and collective well-being. For the former, an ongoing undertaking has been the identification of explanatory niches in which neuroscience can most offer major conceptual advances above and beyond behavioral approaches alone. In contrast, the task of transformative consumer researchers is to identify important questions for consumer welfare, and integrate diverse research strands to best answer those questions and yield new insights.

This roundtable centers on a topic that ideally melds these goals of both movements, one that is both a core issue in transformative research and that can be studied with unique and essential depth using neuroscientific techniques: the effects of marketing actions on *vulnerable and at-risk consumers*, and the consumption patterns exhibited by these individuals. Vulnerable consumers are defined as individuals who have personal or situational disadvantages in the marketplace that can create negative outcomes for either themselves or for society as a whole. These vulnerable consumers include age segments such as children, adolescents, and the elderly; those suffering from addiction and substance-abuse problems; and those with behavioral control problems in other domains such as spending money, gambling, eating and weight management, and even problematic overuse of the internet and video games. Vulnerable consumers also include those compromised by medical conditions, including neurological damage, deficits, or disorders, or by medications and medical interventions meant to deal with such conditions.

Such consumers often exhibit distorted patterns of consumption within and across domains, and unusual susceptibility to various types of marketing actions. The typical consumer is exposed to numerous marketing messages every day. Under normal circumstances, consumers are generally able to process which to attend to and which to filter out in order to successfully regulate their overall consumption. However, this is often not the case for vulnerable and at-risk consumers. Consequently, an area of critical importance in transformative research and its public policy applications is the protection of vulnerable and at-risk consumers from the adverse effects of products and their marketing.

Neuroscientific techniques can provide detailed and direct insight into the most basic biological, pharmacological, and psychophysiological mechanisms responsible for the deficits and risk factors characterizing vulnerable consumers. Such efforts can leverage much existing research regarding neurological changes over the lifespan, effects of specific brain impairments, and how different neural circuits predict, adapt to, and develop sensitivity and tolerance to specific stimuli. As such, they can reveal much about the nature, fundamental bases, and underlying conceptual constructs and interactions responsible for diverse decision-maker vulnerabilities. Doing so in a manner informed by theories and conceptual constructs from behavioral research, decision neuroscientists can contribute distinctively to the construction of more enlightened and biologically informed policy viewpoints and recommendations. Thus, revealing the bases of consumer vulnerabilities is an area where decision neuroscience has clear promise and value to consumer research overall and transformative consumer research in particular, in terms of both generating novel conceptual insights and revealing key results for consumer well-being.

This roundtable will be a chance to discuss these possibilities for advancing theory and social welfare, and to develop interesting and promising new research directions from behavioral, neural, and integrative perspectives. We have drawn together a diverse panel of experts in neuroscience, decision research, and transformative consumer research, who are eager to explore these questions and issues regarding vulnerable consumers. Several specific issues already identified to be discussed are:

1. How research should be conducted and communicated when it has both clinical and managerial antecedents and consequences.

2. Identifying vulnerable consumer groups that can be most effectively studied and whose well-being has most potential for improvement by integrating neural and behavioral approaches.
3. Discussion of past experiences of panel members who have researched various vulnerable consumer groups using behavioral and neural techniques—what was found, and what couldn't be ascertained but is important to further explore.
4. How findings from disparate areas may be best communicated both to researchers in distal fields, and more broadly in order to influence critical public policy issues.
5. The most promising conceptual and methodological frontiers for studying vulnerable consumers, both in terms of specific populations deserving deeper study, and novel or integrative approaches with high potential for revealing important new insights.

Interested and Likely-to-Benefit Audiences

A wide range of attendees would benefit from attending this roundtable. Those interested in transformative consumer research, clinical consumer research, public policy, and consumer well-being would find this roundtable illuminating and informative regarding results from a burgeoning consumer research sub-field with particular relevance to key questions of interest. In addition, those working in neuroeconomics and decision neuroscience, as well as the larger community of consumer researchers who recognize the growing importance and promise of neuroscientific approaches and results, would also find this roundtable valuable for identifying novel consumer domains in which neuroscientific investigation could offer important insights.

To a large degree, each of these groups is only infrequently exposed to the discoveries and approaches of the other. Hence, a key benefit of this roundtable is in bringing these groups together in active discussion.

Facilitating Pre-Conference Discussions

The roundtable organizers are committed to fostering vigorous informal discussion amongst participants prior to the conference. We plan to facilitate such discussions primarily using either the ACR Knowledge Exchange forum or through moderated e-mails. Prior to the conference participants will be encouraged to develop and share with the group discussion points of most interest to them, as well as informal summaries of relevant research they have been conducting themselves or are interested in learning more about through discussions. All such materials will be collated by the organizers as needed and distributed to the group, and interactions regarding the issues, questions, and research results brought to the fore will be both encouraged and actively initiated by the organizers. Through these pre-conference efforts we hope to maximize the value and meaningfulness of the session itself.

ROUNDTABLE
Barbara Stern's Legacy to Consumer Research

Chairs:

Cristel Antonia Russell, University of Auckland, New Zealand
Stephen J. Gould, Baruch College, USA

Participants:

Aaron Ahuvia, University of Michigan, Dearborn, USA
Barbara Olsen, SUNY Old Westbury, USA
Brett Martin, Queensland University of Technology, Australia
Craig Thompson, University of Wisconsin, USA
David Mick, University of Virginia, USA
Ed Mcquarrie, University of Santa Clara, USA
Eileen Fischer, York University, Canada
Eric Arnould, University of Wyoming, USA
Gita Johar, New York University, USA
Jennifer Escalas, Vanderbilt University, USA
Jonathan Schroeder, University of Exeter, UK
Laurie Meamber, George Mason University, USA
Margo Buchanan-Oliver, University of Auckland, New Zealand
Mark Ritson, Melbourne Business School, Australia
Marla Royne Stafford, University of Memphis, USA
Michael Mulvey, University of Ottawa, Canada
Sandy Bennett, University of Auckland, New Zealand
Steven Kates, Simon Fraser University, Canada

Extended Abstract

The purpose of the roundtable is to review and discuss the contributions of Barbara Stern's literary approach to the field of consumer research. Participants who have worked with Barbara will provide a brief review of her contributions in key areas and solicit participant discussion around each topic. The discussion of Barbara's legacy has already begun in email exchanges between roundtable participants and the co-organizers. We have created a Barbara Stern listserv'. Once the roundtable is accepted, an online forum will be activated on the ACR website so that anyone will be able to post comments and thoughts. The proposal incorporates contributions from others who, while unable to attend this year's conference, have shared how Barbara Stern's work influenced their own research. These scholars will contribute to the discussion via the online board, pre- and post- conference.

In Barbara Stern fashion, the proposal begins with an etymological analysis of the word legacy. Legacy is something transmitted from the past. It is also defined as a gift and this second meaning is just as suited to describe Barbara's contributions to the field of consumer research. Gifted herself, she gifted us with novel insights and theoretical perspectives from English literature. In organizing this roundtable, we solicited statements from scholars who knew Barbara and/or her work. Some worked directly with her, all found her work inspirational. The purpose of the gathering will be to review and uphold her thriving legacy to consumer research.

Barbara's pioneering contributions to consumer research are best stated in Morris Holbrook's words: "she transformed the possibilities for interpretive work in marketing research. By virtue of her training and experience in critical analysis—her ability to draw on a wealth of literary material not available to the typical marketing scholar—Barb infused her research with an authoritative command of interpretive methods not heretofore found in our discipline... She has incorporated key ideas from feminism, has made a case for advertising as a species of drama, has applied influential taxonomic and structural models borrowed from the basic discipline, and has even ventured forth into an exploration ... of deconstructionism she loads her critical approach with insights into the meaning of consumption and other marketing-related phenomena. These discoveries make her work a constant challenge—and joy—to read ... one is constantly impressed by the high level of originality, imagination, creativity, and wisdom that she has brought to her work." (Holbrook 2009, 6).

The roundtable will proceed as an open discussion guided by the topics brought up in pre-conference discussions amongst participants. Since the exchange has already begun, emerging topics are listed here, using or paraphrasing (or quoting but unattributed) the participants' own words in describing Barbara's contributions to themselves personally and to the field as a whole.

Literary Theory. Barbara's work brought to light the centrality of the humanities in general and literary approaches to the study of marketing in particular. She covered such topics as the uses of literary devices (allegory, personae, rhetorical irony) in advertising and the relationship of literary criticism to consumer research. In her breakthrough article (JM 1988) Barbara compared advertising to medieval allegory in that it provides didactic instruction to consumers. In 1989 (JCR), she introduced us to the role literary criticism can play in consumer research, etching out the different schools and how they focus on different elements, including author, reader and text (e.g., reader response, genre analysis, deconstruction). She then playfully applied deconstruction to Joe Camel (JCR 1996) in a subversive, destabilizing reading to reveal how his behavior hovers in undecidability (*différance*) between various gendered-sexualities including dominant masculinity, repressed male homosexuality and implied femininity.

Advertising. Barbara's research offered new insights into the study of advertising text and narrative. She transformed our understanding, for instance, of the traditional communications model in advertising (source, message, recipient) by treating advertising as crafted text rather than as mere everyday speech as the model implies (JA 1994).

Feminism. Barbara was an "embodiment of the kind of feminist who opened up opportunities for others both because of her exemplary scholarship and because of her supportiveness of specific individuals" (female participant). She was "a true 2nd wave feminist as well as having overcome a bad marriage and all the obstacles professional women faced in the 60s. She was pretty fearless" (male participant). This topic will undoubtedly lead to lively discussion about feminism and how it has been manifested in the marketing academy. In 1993 (JCR), Barbara introduced us to feminist-deconstructive reading of ads suggesting that consumers engage in gendered reading such that males and females exhibit different reading styles.

Pluralism. Barbara believed that pluralistic research projects drawing from different paradigmatic strengths (Kuhn 1962; Laudan 1984) contributed to each other (Lakatos 1978) in fruitful knowledge exchanges. She viewed the humanities as a source of theoretical insights and hypotheses testable by empirical methods but, although she was intrigued by experimental research, she had no background in it. She walked the talk of synergy between humanities theory and scientific method (Geertz 1988; Holbrook 1987), collaborating with researchers with complementary background to hers in experimental design (e.g., Escalas and Stern 2003).

Likely Audience. Seasoned and novice consumer researchers will benefit from attending this session. We anticipate that the discussion will evolve more generally from Barbara Stern's legacy of literary criticism to more general ways in which theory advances and the contribution of other disciplines to consumer research.

ROUNDTABLE

The Evolving Definition of Rationality

Chair:

Rajagopal Raghunathan, University of Texas at Austin, USA

Participants:

Christopher Hsee, University of Chicago, USA

Michel Tuan Pham, Columbia University, USA

Ming Hsu, University of California at Berkeley, USA

J. Edward Russo, Cornell University, USA

Itamar Simonson, Stanford University, USA

Dan Ariely, Duke University, USA

Eduardo B. Andrade, University of California at Berkeley, USA

Extended Abstract

The concepts of rationality and utility are irrevocably intertwined, since rationality is generally defined and conceived as utility maximizing behavior (e.g., Edwards 1954). Thus, to understand what rationality means, it is important to understand what utility means.

From a classical economist's perspective, utility can be taken to mean whatever it is that an individual (or a group) wishes to maximize. In this view, even the so-called "dark" consumption behaviors—such as addiction to drugs or alcohol (Solomon 1980), the inability to save sufficient money for the future (Thaler and Shefrin 1992), or the inability to prevent oneself from compulsive shopping (Rook 1987)—can be conceived as rational. As such, many scholars interested in examining these types of (dark) behaviors have been careful to avoid characterizing these types of behaviors as irrational, and prefer, instead, to use less loaded terms such as, *time-inconsistent preferences*, or *myopia* to refer to them (e.g., Hoch and Loewenstein 1991).

If utility can mean anything and everything, however, the concept of rationality is rendered meaningless, since *any* judgment or decision could be considered rational. To circumvent this conceptual impasse, one yardstick that has often been applied is whether the judgment/decision in question conforms to logic (Kahneman 1994); in this view, people are rational if their "beliefs, judgments, choices and actions respect certain standards of logic" (Pham 2007, p. 156). For instance, judgments or decisions that do not satisfy transitivity (Birnbbaum 2008) or do not sufficiently account for base-rates (Bar Hillel 1980) would be considered irrational. But is conformance to norms of logic alone enough? Some scholars appear to think so; for instance, Sharif and Leboeuf (2002, p. 492) note that "the predominant theories of rationality are predicated on notions of consistency"; thus, in the eyes of these scholars, even behaviors that would be considered patently irrational by lay-people (e.g., addiction to drugs or extreme impulsivity) could be construed as rational so long as these behaviors are, in some logically justifiable way, consistent and coherent.

Other scholars, however, have taken a different stance: by implicitly equating utility to subjective well-being or happiness, they appear amenable to characterizing judgments/decisions that diminish emotional positivity—even if they are logically justifiable—as sub-rational (e.g., Thaler and Sunstein 2008). This perspective, of equating utility to emotional well-being, also appears to be echoed in the work of some other scholars (e.g., Hsee et al. 2003; Wilson and Schooler 1991), in as much as they portray the more (vs. less) enjoyable options as being superior, even though the choice of other options may be logically defensible.

A third perspective on rationality adopts a societal-level lens through which judgments and decisions are evaluated; in this view, judgments/decisions that maximize societal (vs. individual) well-being are rational. This, so-called, "ecological" perspective of rationality (e.g., Miller 2009; Haidt 2001, 2007) would characterize judgments/decisions that serve the higher-purpose of enhancing the utility of the society or group to which the decision-maker belongs as rational, even if these judgments/decisions come at a cost to the decision-maker himself.

One framework that could prove useful in clarifying the pros and cons of subscribing to a particular definition of utility (and, therefore, rationality), is that offered by Kahneman and his colleagues (e.g., Kahneman Wakker and Sarin 1997). These researchers distinguish between two types of utilities—decision and experienced utility—where decision-utility refers to the "wantability" of options whereas experienced utility refers to the amount of pleasure (minus pain) provided by them. Thus, an option that provides higher levels of pleasure (minus pain) would be the rational choice from the perspective of an individual aiming to maximize experienced utility, and yet be sub-rational from the perspective of someone interested in concerns other than just enjoyment. For example, some people may attach great importance to making choices that appear (to oneself or to others) as justifiable (e.g., Simonson 1989), and to such people, the hedonic superiority of an option may not guarantee its choice.

The primary objective of this session is to provide clarity on the various ways in which rationality and utility have been conceptualized and to shed light on the subtle (and not-so-subtle) ways in which these conceptualizations differ. As a result of such clarity, we expect the audience to be able to judge for themselves the pros and cons of adopting different perspectives of utility and rationality. Time permitting, the panelists in the session may also discuss other related questions, including the following: (1) What is the role of consciousness in making rational judgments or decisions, that is, could a decision be rational if it were made sub-consciously (*a la* Dijksterhuis 2004)? Or is it necessary for the decision-agent to have been conscious of the process underlying the calculation of utilities?, (2) What is the role of stability of preferences, and to what extent is the assumption of stability of preferences valid (Ariely, Loewenstein and Prelec 2003)?, and (3) When are preferences constructed and when do they appear to be based on inherent tastes (Simonson 2008)?

The session is expected to have broad appeal, since assessing the quality of a judgment or decision (whether one refers to such assessments by the use of the term rationality) is central to all of consumer research.

Extended Abstract

Although the economists' assumption, that "more of a good thing is better" has come under increasing scrutiny and criticism in recent years—for example, it has been shown not to be true for many things, including jam (Iyengar and Lepper 2000), TV channels, and babies (personal experience 2010)—, it seems to be true for at least one thing: happiness. We all want to be as happy as we can be, and the happier we are, well, the happier we feel! But, what does it take to be happy?

According to Freud, the two biggest determinants of happiness are: (1) satisfaction with work and, (2) satisfaction with love. So, the more productive we are at work, and the greater the sense of intimacy/belongingness we have with our chosen social circle (which includes our partner, kids and friends), the happier we are likely to be. But, given that being productive at work and maintaining a healthy social-life take time, effort and (sometimes) money, and given that we have a limited pool of these resources, it can be a challenge to maintain a good work-life balance. So, how do we decide how much resource to allocate to work vs. family vs. friends?

This is a tough nut to crack, as most of us (especially those with kids) have found out the hard way. Some of us decide to allocate more resources to family/friends, only to feel bad that we haven't been as productive as we could have been. (And those pesky, super-productive single colleagues don't help!) Others decide to devote more resources to work, only to feel socially isolated and miserable.

In sum, the challenge of leading a happy life—through an ideal mix of "work" and "love"—presents an optimization problem that is more challenging than the health-care problem currently facing the US government (some may disagree with us on this, but we have anecdotal and apocryphal data to back our stance). So, who better to turn to, than the elite set of marketing faculty who have it all—productivity at work, a great family life, an intimate circle of friends, and more! Yes, our esteemed panel members lead enviable, "happily now (vs. ever after)" lives because they have hit the work-life balance sweet-spot!

But, before you let that tinge of envy (which is no doubt creeping up your spine) develop into a full-blown bout of uncontrolled jealousy, let me assure you that the happy position in which our panelists find themselves wasn't easy to achieve. They had to endure a long, harrowing period of struggle, with periodic attacks of spasmodic back pain, carpal tunnel syndrome, thou-art-neither-here-nor-there syndrome and spontaneous spousal spurnment. (Some of these are new diseases.)

But, despite all the hardships that they had to endure to painfully assimilate their pearls of wisdom, the panelists are eager to share their perspectives on this important topic (bless their hearts!). Each panelist will spend about 5-8 minutes first, outlining their preferred solution to the "work-life balance dilemma". In the course of doing so, they will share their views on a number of issues, including the following:

What are some creative ways by which one can have "one's cake and eat it too" (i.e., be productive at work and enjoy a healthy social life)? Who are some people who stand out as good exemplars of maintaining a good "work-life" balance and what are their strategies?

Should the allocation of resources vary depending on where (in which stage) one is? For instance, should one devote more resources to work (vs. social life) before tenure, and more to social life (vs. work) after having kids?

For those who have chosen to devote more time to family (vs. work), how can they cope with feelings of inadequacy that comes with a (hopefully temporary!) dip in productivity?

For those who have chosen to devote more time to work (vs. family), how can one get "one's groove back" (i.e., develop and maintain healthy social relationships)?

Are there any resources (e.g., books, agencies) that can help us out with this issue?

Once the panelists have had a chance to share their perspectives, the floor will be opened to a question and answer session, which is expected to last about 30 minutes.

The session is expected to have broad appeal, since most of us value both our work life and our social life. The session will be particularly valuable for junior faculty (and PhD students) with an active social/family life.

ROUNDTABLE

Green, Ethical, Sustainable Consumption

Chair:

Andrew Gershoff, University of Texas at Austin, USA

Participants:

Susan Dobscha, Bentley College, USA
Amitav Chakravarti, New York University, USA
Julie Irwin, University of Texas at Austin, USA
Karen Page Winterich, Pennsylvania State University, USA
Michael Luchs, William and Mary, USA
Bram Van den Bergh, Erasmus University Rotterdam, The Netherlands
Rebecca Walker Naylor, Ohio State University, USA
Kelly Haws, Texas A&M University, USA
Vladas Griskevicius, University of Minnesota, USA

Extended Abstract

Over the last decade there has been a steady increase in sales and consumer interest of environmentally friendly, ethically produced, and so-called sustainable products (Freedonia 2009). Mainstream manufacturers and retailers such as Walmart, Home Depot, P & G, and General Electric have increased their offerings of products labeled “green” and they have altered many business practices in order to decrease or offset their impact on the environment.

Research on consumer attitudes and response to green, ethical, and sustainable marketing has also begun to take root in a number of important directions, especially as it becomes apparent that despite positive attitudes toward such products, in many product categories consumers still don't buy or use them (Luchs, Naylor, Irwin, Raghunathan 2010; UNEP 2005). As a result, questions of when and why these products will be adopted have been on the forefront. For example, a number of researchers have explored questions associated with the traits and indicators of consumers who tend to be green consumers (Haws, Winterich, Naylor 2010; Webb, Mohr, and Harris 2008). Others have asked about consumer response to the real or inferred trades-offs that consumers must make between the green benefits of the products and other primary benefits of the products (Luchs et al. 2010). In addition, many researchers have begun to uncover a potential dark side associated with purchase of green products. For example Ehrich and Irwin (2005) found that consumers may intentionally avoid learning about a product's negative ethical connections in order to protect a favored status of a preferred product. Others have shown that a licensing effect appears to occur with either the purchase of green products or beliefs about one's own past green behavior. This may result in consumers becoming *less likely* to make subsequent green purchases, and may even be more likely to engage in other immoral or selfish behavior (Becker-Olsen, Bennett, Chakravarti 2010; Mazar and Zhong 2010). Finally, even when people do purchase green products, the benefits they seek may not be associated ethical, nor altruistic goals. Instead, the decision to purchase a green product may be driven by a goal of signaling status (Griskevicius, Tybur, and Van den Bergh 2010).

Although a respectable body of knowledge in green and sustainable consumer behavior has clearly been established, this area is still both young enough and important enough to society to merit further inquiry. Rather than simply reviewing the work that has been completed thus far, the purpose of this roundtable will be to discuss and develop key questions and research priorities for future study of green, sustainable, and ethical marketing. At least nine recognized researchers this area have agreed to attend and contribute. Toward developing these research priorities, a number of areas for discussion have been proposed.

One area for consideration is consumer response to the way in which green and sustainable benefits are introduced and manifest in the products they consume. For example, products may become more green in a number of ways. First, manufacturing and transportation methods may be used by a company to reduce any negative impact on the environment or society but these changes may not alter the product or consumer experience in any way. Second, materials used in the product or package may have a reduced impact on natural resources either by reducing material use, reusing materials, or using alternative materials. These methods may have an impact on the environment, but it may affect the product experience as well. Third, design of products may be altered so that when used the products have less impact on the environment by reducing their energy consumption or pollution. Finally, products may be designed so that when they are disposed of they have less impact on the environment. Each of these methods may result in a similar impact on the environment, but they may differ in consumer reactions. For instance, tangible and observable aspects of the greenness of products may lead to inferences that the product is less effective in other ways, which may reduce demand, yet it may facilitate public signaling of the purchase, which could increase demand through perceived benefit to status (Griskevicius et al. 2010). Further, even unobservable changes may influence demand for green products depending on where in the consumption stream the change has occurred. For instance, upstream improvements toward the greening of a product (i.e. alterations in manufacturing transportation processes) may be perceived as more desirable than downstream benefits because the greening of the product has already taken place when the consumer makes the purchase decision, while downstream changes (i.e. alterations in design that improve efficiency during use of disposal) may be perceived as more desirable than upstream benefits because they allow the consumer to be a cooperative player in the green benefit being realized.

While aspects of the product may be one area for consideration of key research objectives, a second area is in aspects of consumers' identities. Recent work suggests that people have many identities, or self-construals, that may be activated at different times, leading to differences in motivations, information processing, and behaviors (Oyserman 2009). Such identity activation may be important for facilitating consumer compliance with behaviors and purchase of products that benefit a common good, rather than their own self interest. In other domain this has been shown to be effect. For example, identity congruent appeals have been shown to be effective for influencing decisions to exercise and to reduce alcohol and drug use (Martin and Leary 2001; Werch 2007, 2008).

The session is expected to have a very broad appeal as research in this area continues to take off. Further, the questions posed in this line of research also dovetail with many other areas of research including the role of emotions in decision making, common goods decisions, attitude formation and change, and self presentation. As a result it is expected that this session will draw both attendees immediately interested in green, ethical and sustainable marketing, as well as those interested in these varied, yet influential, research topics.

ROUNDTABLE

Developing a Dissertation Idea

Chair:

Eduardo B. Andrade, University of California, Berkeley, USA

Participants:

Clayton Critcher, Cornell University, USA
Jeff Galak, Carnegie Mellon University, USA
Chris Janiszewski, University of Florida, USA
Peter McGraw, University of Colorado, USA
Tom Meyvis, New York University, USA
Leif D. Nelson, University of California, Berkeley, USA
Joseph P. Simmons, Yale University, USA
Stacy Wood, University of South Carolina, USA

Extended Abstract

To generate a dissertation idea is a daunting task. Those who have gone or are going through this process know it well. Interestingly, there is unfortunately little discussion about (1) how PhD students (should) develop their dissertation ideas and (2) how professors (should) involve themselves in the process. This roundtable is meant to address this issue. Specifically, it will discuss descriptive and normative aspects related to: research topics of interest, hypothesis generation, faculty involvement, and differences between psychology and marketing departments.

Choosing an Area of Interest Within Consumer Research. Given its interdisciplinary approach, consumer research topics can vary dramatically. After being exposed to wide range of areas, how does a student decide on a topic of interest? Moreover, how much is the choice process influenced by intrinsic vs. extrinsic considerations (e.g., passion for the area vs. whom to work with vs. likelihood of publication)? How to balance these two aspects? How variation is there between schools and between students? Are there specific rules of thumb to be followed?

Selecting a Specific Idea/Hypothesis. Once a research area is identified, how does the student identify a novel research question and a testable research hypothesis? Are there specific strategies to facilitate this process?

Faculty involvement. How much should the faculty adviser be involved? The answer to this question is hotly debated. Should faculty contribute to idea generation or should they merely step back? How should students navigate the considerable cultural differences between universities?

Psychology/Consumer Research. The fact that many marketing professors have been trained in psychology also raises the question on whether or not the preceding topics vary systematically depending on the nature of the faculty adviser's personal training. Where systematic differences exist, is there room for identifying a strategy that synthesizes the best tactics from both?

In short, this roundtable will shed light into the different strategies employed by individuals, departments, and disciplines, in the generation and consolidation of a dissertation idea. We hope to attract the interest of senior and junior faculty, and, most importantly, doctoral students.

ROUNDTABLE

Understanding Prosocial Behavior Among Consumers and Organizations

Chair:

Extended Abstract

The interest in prosocial behavior has increased in the last few years as consumers seek greater meaning in their everyday lives. Many companies and consumers are paying attention to the impact their choices have on society at large, and an increasing number of consumer behavior scholars have begun to look at the causes and consequences of prosocial behavior among consumers and organizations.

This roundtable will appeal broadly to those scholars interested in the factors influencing different types of prosocial behavior as well as the effects of different types of prosocial behavior on consumers' lives. Beyond this, it will also appeal to those interested in research examining the effects of prosocial behavior on the part of organizations and the effects of CSR on both employees and consumers. Our relatively large panel of committed attendees purposely includes scholars from a diverse mix of methodological backgrounds as well as a broad range of topics relating to understanding the causes and effects of prosocial behavior. Researchers on our panel are doing research on many important subjects that fit under the "prosocial" umbrella. These include exploring factors affecting charitable giving and volunteerism, the effects of charitable behavior on consumer welfare and satisfaction, cause marketing, sustainability and green consumer behavior, how prosocial activities within organizations affect employee morale and job satisfaction, and the many factors influencing consumer responses to corporate social responsibility (including the type of CSR, the nature of the product, the nature of the consumer, the communication strategy, and prior CSR activities by the organization). Our panel includes scholars with diverse backgrounds and interests, so that we can learn from each other and foster a community that keeps the big picture in mind, rather than focusing on one type of research methodology or paradigm.

We aim to encourage dialogue before, during and after the roundtable. This will include identifying key areas of current research, discussing potential synergies between different streams of work, identifying directions for future research and discussing the challenges of doing research in this area. Due to the huge appeal of this topic to many scholars with diverse perspectives, we hope to not only attract a wide range of scholars from different backgrounds and interests, but also to help foster a community that will continue to be active even after ACR 2010 has passed. Due to the diverse backgrounds of those on our panel, this roundtable will be of interest to both qualitative and experimental researchers. The topics covered will be relevant to those interested in broadening our theoretical understanding of prosocial behavior, those dedicated to doing research with prosocial benefits (TCR), and those focused on managerial implications. Indeed, many on our panel are dedicated to doing research that addresses all three of these goals.

While many of our confirmed participants are impressive, we are particularly happy to have David Mick, who is considered by many to be the founder of the currently active Transformative Consumer Research community. In his ACR presidential address several years ago, Mick described transformative consumer research as "consumer research in the service of quality of life" (Mick 2006, p. 3). This roundtable will appeal to a large portion of the TCR community, but will also attract a range of scholars who are not (currently) part of the TCR group. One of the "big picture" questions we will address in our discussion is whether or not it is prosocial

to study prosocial behavior. Obviously, prosocial behavior is not always motivated by purely by altruistic motives. Indeed, researchers our panel have demonstrated a connection between prosocial behavior and happiness (Liu and Aaker 2008; Dunn Akin and Norton 2008), while others have identified the effectiveness of appealing to rather selfish status-seeking motives to encourage seemingly prosocial behavior in certain contexts (Torelli, Monga, and Kaikati, 2010). More and more, nonprofits are focused not only on helping the causes they support, but also on keeping their donors and volunteers feeling appreciated and happy, if not downright entertained (Strahilevitz 2010). Still, understanding that prosocial behavior is not always motivated purely by a desire to help others can still help us to encourage actions that benefit society. Given the importance and “bigness” of these topics, we will ask David Mick to briefly speak on the potential value of doing research in this area, with a focus on work that is both rigorous in terms of theory, but also potentially helpful in terms of service to society. We will also, as a group, briefly discuss strategies for promoting the value of research on prosocial behavior within a business school setting.

Before and after the conference, continued dialogue will be facilitated via a combination of email exchanges (facilitated by the roundtable chair), postings on the ACR Knowledge Exchange Forum, and postings on our newly created FaceBook group “Prosocial Consumer Research.” The FaceBook group is open to any scholar interested in research in this area, but will begin with invitations to the roundtable participants. In our pre-ACR dialogue, we will develop a plan for organizing breakout sessions focusing on issues such as factors affecting consumer responses to CSR, causes and consequences of different types of prosocial behavior by consumers, the prosocial nature of research on prosocial behavior, and the challenges that come with research in this area.

The Impact of Preannouncements and Rumors on Consumer Evaluations

Jun Wang, Delft University of Technology, The Netherlands
Maria Sääksjärvi, Delft University of Technology, The Netherlands
Erik-Jan Hultink, Delft University of Technology, The Netherlands
Tripat Gill, University of Ontario Institute of Technology, Canada

In the contemporary high-tech markets, products are rarely launched unexpectedly, as new product preannouncements have become common practice (Kohli, 1999; Lilly and Waters, 1997). Besides new product preannouncements, or “formal, deliberate communication” (Eliashberg and Robertson, 1988), informal communication, such as rumors, often take place prior to the launch of a new product. Rumors provide signals on the incoming new product and together with preannouncements develop market anticipations (Schatzel and Calantone, 2006) and build prior-to-launch expectations of the forthcoming new product (Nagard-Assayag and Manceau, 2001).

Rumors have become especially important due to the internet, in which rumors spread quickly through online-blogs and various websites. The most active participants of online-blogs often are lead users and early adopters (Dorge, Stanko and Pollitte, 2010), who play an important role in new product adoption (Rogers, 1962). Despite their increasing importance, the role of rumors in new product adoption has received little research attention (Kamins, Folkes, Perner, 1997). The present two studies explore the impact of rumors and preannouncements on consumer evaluations of new high-tech products. Specifically, we investigate the role of two factors—(1) type of innovation (incremental versus radical) and (2) extent of ambiguity of the rumors—on the consumer curiosity and purchase intentions towards high-tech innovations. We propose that rumors stimulate consumer curiosity towards a new product, which subsequently influence consumers purchase intention. In addition, we hypothesize that rumors about a radical innovation involve more novel content that could create greater curiosity than that about an incremental innovation.

Study 1 used a content analysis to explore both preannouncements and rumors about two types of innovations: radical versus incremental innovations. We selected the iPhone as a radical innovation as it was the first touch-screen mobile phone that radically changed how consumers interact with their Smartphones. Sony’s PlayStation 3 was chosen as the incremental innovation as it was an improvement over the previous two generations of the PlayStation gaming consoles. We followed the preannouncements and rumors about these two innovations through press releases and blogs from credible sources. As rumors are mainly transmitted through blog postings, we chose Engadget and Gizmodo as the main research sites because of their consistently high ratings, popularity and focus on new product information (Dorge, Stanko, Pollitte, 2010).

We collected a sample of 49 postings on the iPhone (1999–2007) and 47 postings on the PlayStation 3 (1999–2006). We analyzed the content as well as the timing of these postings. The content of the postings was classified based on the core elements of the marketing mix: namely, content related to product (including product name and performance features), price, distribution and promotion. The majority of the content was related to the product (iPhone: 80%, PlayStation 3=79%). There were more discussions on the price of PlayStation 3 (16%) than that of the iPhone (6%). Nearly a quarter of the postings discussed launch timing (iPhone 18%, PlayStation 3: 26%), while only a few mentioned distribution (iPhone: 4%, PlayStation 3: 4%) and promotional programs (iPhone: 2%, PlayStation 3: 4%). An analysis of the timing revealed that the rumors started well in advance of the company’s official preannouncement. Rumors on Apple’s iPhone and Sony’s PlayStation 3 started eight and six years, respectively, before the two companies officially preannounced the product releases. One major difference between the preannouncements of the two products was the ambiguity of the information. Apple remained ambiguous in their responses to rumors. It did not discuss product specifics before the official announcements. In contrast, Sony’s executives responded to rumors and made specific comments about the product features in the press.

In Study 2, we decided to further investigate the effect of ambiguity of rumors on consumer curiosity and purchase intention. We used a 2x2 between-subjects design manipulating product innovativeness (radical innovation versus incremental innovation) and rumor ambiguity (ambiguous rumor versus unambiguous rumor). Consumer curiosity served as a mediator and the dependent variable was purchase intention. We collected data from 71 participants aged between 18 and 42, who first read a rumor about a new product, and we measured their extent of curiosity about the product. Subsequently, they read an official preannouncement about the product by the firm, and we measured their purchase intentions. The type of innovation (radical versus incremental) and the ambiguity of the rumor (ambiguous versus unambiguous) was manipulated in the scenarios read by the participants.

We found a significant effect of product innovativeness on consumer curiosity [$F(1,69)=25.612, p<0.001$]. The mean score on curiosity towards the radical innovation ($M=5.026, SD=0.877$) was significantly higher than that for the incremental innovation ($M=3.888, SD=1.019$), $t(69)=5.061, p<0.001$. Rumor ambiguity did not have a significant influence on curiosity [$F(1,69)=0.067, p=0.797$]. We further found an interaction between product innovativeness and rumor ambiguity leading to a positive effect on consumer curiosity ($F=8.242, p<0.01$). Respondents have stronger curiosity towards the radical innovation in an ambiguous rumor ($M=5.253, SD=0.718$) than the radical innovation in an unambiguous rumor ($M=4.800, SD=0.978$). Conversely, respondents are more curious about the incremental innovation in an unambiguous rumor ($M=4.244, SD=0.866$) than that in an ambiguous rumor ($M=3.460, SD=1.051$). Finally, we found that consumer curiosity had a positive effect on purchase intention (regression coefficient=0.456, $p<0.001$).

The results of our two studies suggest that new product rumors spread much earlier than the official preannouncements, indicating that consumers’ first impressions of a new product are formed based on rumors rather than on preannouncements. Moreover, the preannouncements for an incremental innovation were less ambiguous than that for radical innovations. Companies intentionally remain ambiguous about radical innovations, while being clear on incremental innovations. This strategy is supported in study 2, which shows that people are more interested in radical innovations when the rumor is more ambiguous, while they are more interested in an incremental

innovation when the rumor is unambiguous. It suggest that companies should be clear about their incremental innovations, while remain ambiguous about their radical innovations in order to make their product interesting in the eyes of the consumers.

Frisbee for Friends, Furniture for Family: The Influence of Products on Network Activation and WOM Intentions

Lalin Anik, Harvard Business School, USA
Michael Norton, Harvard Business School, USA

People use different products to signal desired identities to different social networks—iPods to impress their friends, briefcases to impress their employers. We suggest that this behavior causes those products to become linked to specific social networks, such that mere exposure to products can prime different social networks, making some relationships more salient than others. We furthermore explore how people perceive the closeness of these salient networks as a possible mechanism to examine subsequent WOM intentions.

Previous research has demonstrated that situational and environmental cues or primes can activate associated representations, making them more accessible (Berger and Fitzsimons 2008; Higgins, Rholes, and Jones 1977). As priming a given construct leads to the activation of related constructs in memory, it can also have impact on the perceptually-related objects, and furthermore on the product choice and evaluations (Lee and Labroo 2004; Whittlesea 1994). In this project, we use products belonging to different categories as our primes, and explore whether exposure to these primes makes certain social networks more accessible.

The literature on goal instrumentality previously showed that active goals lead to the activation of different relationship partners, specifically of those who are goal congruent (e.g., Fitzsimons and Shah 2008). We, however, look at the salience of relationship partners in relation to product categories rather than personal goals or motivations. Moreover, we argue that the products as primes influence social perceptions and as a result offer people's changing perceptions of network closeness as a mechanism for following WOM behavior. To examine this linkage of products to networks to WOM, we ran three studies.

In Study 1, we investigated whether exposure to products belonging to various categories make related networks more salient than others in the minds of people. One hundred and thirty-five participants were randomly assigned to one of four conditions: *family*, *friends*, *co-worker priming* and *control* conditions where they were presented with products belonging to family, friends, co-worker categories respectively, and asked to indicate their preference in a set of four. Those in the *control condition* didn't see any products. Subjects went through a total of twenty trials, viewing eighty different options. Afterwards, participants were asked to write down the initials of the first five people that came up to their mind and subsequently, instructed to indicate their relationship to each of the five people they listed.

The dependent variable was the number of family members, friends and co-workers listed in each of the four conditions. Our results showed that participants in the *family priming* condition listed significantly more family members than those in the *friends priming*, *co-worker priming*, and *control* conditions. These results were parallel for the *friends* and *co-worker priming* conditions, such that when primed with *friends* related products, people thought of their friends more so than when they saw *family* or *work* related products. Finally, those people in the *co-worker priming* condition reported significantly more number of colleagues than the participants in the other conditions.

Having shown the increase in the salience of networks as a result of being exposed to related products, next we wanted to examine whether exposure to products from different categories impacts people's perception of network closeness, and as a result who they think of passing on information to. In Study 2, one hundred and eight participants were again randomly assigned to one of the four (*family, friends, co-worker priming or control*) groups and exposed to the same product priming tasks as in Study 1. After the priming tasks, participants were randomly presented with five print ads and asked "Who would you forward this ad to?" With this question, we aimed to capture word of mouth intentions. Participants were furthermore instructed to specify the relationship of the person.

We predicted that the priming categories would impact who participants listed as possible recipients of print advertisements. In line with our previous findings, participants who were in the *friends priming* condition listed more friends who they would forward the ads to than those in the *family priming, co-worker priming, and control* conditions. Our results again held in the *family* and *co-worker priming* conditions as participants in those groups listed many more family members and co-workers, respectively, than those in the other conditions.

So far, we showed that exposure to different product categories increases salience of category-related network members, who are then considered more accessible in word of mouth considerations. Next, we tested whether product categories influenced the salience of network members in WOM considerations via changing the perception of network closeness. In Study 3, one hundred and twenty seven participants were randomly assigned to *family, friends* or *no priming* conditions where the products task was the same as in the previous two studies. Following the priming task, they were shown three products they had not seen before. Participants were presented with announcements about a new model of each of the three products (printer, MP3 player, coffee maker) and were asked to indicate three people to whom they thought of passing this info. In order to understand whether the WOM intentions were mediated by network closeness, we asked subjects how close they perceived their family and friends networks.

Replicating our previous findings, participants in the *family priming* condition listed significantly more friends and those in the *friends priming* condition significantly more friends when asked about their WOM intentions than the listings in the other conditions. Additionally, our results showed that people in corresponding priming conditions feel their networks to be both closer to themselves and also closer to each other. Further analysis showed that the relationship between *family priming* and preference for sharing information with family members was mediated by the perception of family network closeness. Perception of network closeness was also a significant mediator for the *friends priming* condition.

These initial experiments provide insights about how products can influence people's perception of and interaction with various networks they are a part of. Our investigation demonstrates how the self can be linked to specific networks, which can subsequently alter WOM intentions. We are currently running a field study where we manipulate social interactions of people via product primes and look forward to engaging in deeper discussions about our findings with ACR members.

Hopelessly Devoted? Word-of-Mouth and Diagnosticity in a Stable Preference Context

Martin Pyle, Queen's University, Canada
 Peter Dacin, Queen's University, Canada
 Ethan Pancer, Queen's University, Canada

Consumption-related word-of-mouth (WOM) is considered one of the more persuasive forms of information exchange among consumers (Dichter 1966), receiving considerable attention in the marketing literature (e.g., Bearden and Etzel 1982; Herr, Kardes and Kim 1991; Stephen, Lehmann and Toubia 2010). Much of the research on the persuasiveness of WOM occurs in contexts where the audience does not have an initial preference for a product (e.g., innovations), or in which the audience demonstrates no initial commitment to the product (e.g., Herr et al 1991). Many consumers, however, have strong, stable preferences for a given product, leading to questions of whether and how WOM can affect these preferences? We address these questions by examining conditions under which WOM might convince consumers with stable brand preferences to, at least, consider switching brands.

We hypothesize two conditions under which stable preferences may be swayed by WOM. These are the motivation of the consumer receiving the WOM and his or her perceptions regarding the diagnosticity of the WOM message. With respect to motivation, based on the concept of naïve realism, we suggest that although consumers may perceive that others use biased reasoning, consumers view their own evaluative judgments as objective and unbiased (Robinson, Keltner, Ward and Ross 1995). Consequently, consumers will tend to process information with an accuracy motivation, and likely view arguments that positively highlight a clear alternative choice, as opposed to suggesting something negative about their preferred brand, as more persuasive.

Although accuracy motivations tend to lead consumers to process information with an open mind and give greater diagnostic weight to negative information (Ahluwalia 2002), we argue that when consumers have stable preferences, the diagnosticity of WOM lies not in its valence, but rather in the degree to which it makes it easier for the consumer to provide reasons to discriminate between choices and highlight decisions (Darke and Chaiken 2005, Herr et al 1991). In short, diagnostic messages can provide the reasons to support a new choice (Shafir, Simonson and Tversky 1993). We also argue that the diagnosticity of WOM messages is related to the type of WOM message—be they WOM against the current preference (WOM-ACP) or WOM in favor of an alternate brand (WOM-IFA)—such that WOM-IFA will be seen as more diagnostic by clearly demonstrating reasons for a better choice. In addition, the speaker's expertise and evident biases will also affect the diagnosticity and persuasiveness of the WOM in that perceptions of WOM messages from a biased source should be neither diagnostic nor persuasive, while WOM messages from experts should be both diagnostic and persuasive. When both bias and expertise are low, however, we expect WOM-IFA rather than WOM-ACP to be more diagnostic and persuasive.

In the first of two studies, subjects listed a product that was important to them in a category (personal grooming products) in which pretests revealed consumers develop strong preferences. Participants then read a scenario describing a hypothetical exchange about the product with a colleague. In the scenario, we manipulated three factors, i) speaker's expertise (high vs. low), ii) speaker's bias (strong vs. weak), as well as iii) WOM type (WOM-IFA vs. WOM-ACP). We randomly assigned each of 145 participants to one of the eight cells and measured diagnosticity and persuasion (the latter via consideration of switching brands).

As expected, there was a significant main effect on persuasion for both bias (weak-bias was more persuasive) and expertise (higher expertise was more persuasive). WOM-IFA was significantly more persuasive than WOM-ACP. That is, when the bias manipulation offered a clear reason to dismiss the message (i.e., high bias) or the expertise manipulation gave a clear reason to accept the message (i.e., high expertise), we found no significant impact of WOM type on persuasion. However, when these reasons were absent, our participants revealed a noticeable difference in both diagnosticity and persuasion and WOM-IFA was more persuasive than WOM-ACP. This supports our expectation for greater persuasion when WOM offers a clear choice.

To ensure that accuracy goals formed the basis of the motivation for processing WOM, we conducted a second study in which we manipulated two factors: i) diagnosticity (higher vs. lower) and ii) WOM type (WOM-IFA vs. WOM-ACP). This second study also allowed us to demonstrate that the message valence (i.e., a positivity effect) was not driving the outcomes from Study 1. The procedure mirrored Study 1, as we again asked participants to think about a brand in a given product category (juice) for which they held strong preferences. In the higher diagnosticity condition, WOM either mentioned the alternative brand as the only one using fresh fruit (WOM-IFA) or the current preference as using frozen fruit (WOM-ACP). In the lower diagnosticity condition, WOM mentioned either the alternative brand or current preference as being *one of many* companies that used a certain process. We also included self-monitoring as a covariate to examine whether effects were driven by social impression goals.

With persuasion as the dependent variable the analysis revealed no effect for self-monitoring; no main effect for WOM type; a significant main effect for diagnosticity; and a significant interaction effect between WOM type and diagnosticity. In the lower diagnosticity condition, WOM-ACP was less persuasive than WOM-IFA, while in the higher diagnostic condition there was no difference in effect on persuasion between WOM types. This is consistent with our expectation of participants using an accuracy motivation to maintain their sense of naïve realism. Results also revealed no relationship between message valence and perceived diagnosticity.

We posed the questions of whether and how WOM can persuade consumers with stable preferences to consider switching brands. The results demonstrate that many consumers hold strong preferences only so long as they believe they can reasonably support their choice. When presented with unbiased, credible and diagnostic WOM highlighting a better choice, consumers' accuracy goals are activated, and they are willing to consider another option. Furthermore, reasons for preferring or switching brands do not appear to be rooted in the valence of the message but rather in their ability to clearly specify a better choice.

Information But at What Cost? The Positive and Negative Impact of Informational Social Influence

Kashef Majid, George Washington University, USA
Vanessa Perry, George Washington University, USA
Johny K. Johansson, Georgetown University, USA

Under conditions of uncertainty the presence of an informational social influence has long been thought to impact consumer judgments (Asch 1955). Originally conceptualized as the influence to accept information from another as evidence of reality (Deutsch and Gerrard 1955, pg. 629), prior work has found that informational social influence can positively impact consumer judgments, encourages product usage, and creates positive perceptions towards products (Cohen and Golden 1972). However, the creation of informational social influence is not without its harmful consequences. A nightclub owner may keep patrons waiting in long lines outside of the establishment in order to signal the popularity of the venue; by doing so potential patrons may be scared away at having to wait for a long period of time or the possibility of not being afforded enough personal space once inside. When assessing the validity of informational social influence consumers must ascertain whether the informational social influence signals a positive or negative outcome. The purpose of the present paper is to explore the conditions under which the deployment of informational social influence causes impacts negative judgments and when informational social influence impacts positive judgments.

The context for the present study was a virtual environment. Over 30 years has passed since the pioneering work on informational social influence and product judgments conducted by (Cohen and Golden 1972) as well as (Pincus and Waters 1977). However, the impact of the construct in judgments towards products is as relevant if not more so than ever. The growth of virtual environments and e-commerce in particular, has fueled an environment rich in informational social influence. Much of this influence is deliberately created by consumers as a means to share their experiences and communicate their recommendations, such as the writing of user reviews or the rating of certain products (Chevalier and Mayzlin 2006). However, in a virtual environment, informational social influence is also created inadvertently by consumers. For example, each time a consumer downloads a piece of music or software online that download is accumulated and then displayed to other potential users as a sign that others have made the same decision that the consumer is considering. Thus, when forming a product judgment regarding a product viewed in a virtual environment, consumers must interpret the informational social influence that they are faced with and use it to assess the product either positively or negatively.

One of the greatest concerns consumers have when purchasing products in a virtual environment is that the product will appear to be one thing online and then actually be something else once it arrives (Trocchia and Janda 2003). At best the product in question has slight deviations from what was expected; at worse, the product is a fake or a forgery. Through exposure and experience, consumers have gained a level of knowledge that helps them to ascertain the quality of the product before purchase (Pavlou and Gefen 2004). For example, consumers which purchase certain luxury brand name apparel may be apprehensive of purchasing the product online if it is selling for a third of the price that it does at the local retailer regardless of the number of the consumers that have purchased the product before. We argue that when knowledge of the product category is high consumers may be less susceptible to informational social influence and would be more likely to view the negative aspects of the informational social influence. Conversely, when consumers are uncertain as to the quality of the product then we believe that informational influence will play an enhanced role in reducing that uncertainty and will positively impact judgment towards the product.

The predictions above were tested using a 2 (familiarity: high vs. low) x 2 (informational social presence: present vs. absent) study design. A total of 133 undergraduate students from a large private university in the South Eastern United States participated in the study in exchange for course credit. Familiarity was manipulated by product category. A total of 22 participants drawn from the same sample as the study population participated in the pretest and were asked to rate their familiarity and purchase frequency of several different product categories. We ultimately chose DVDs and a universal remote control as our products for this study based on the differing levels of familiarity that the sample had of these two products ($M_{DVD}=5.87$ vs. $M_{Remote}=3.35$, $F(1, 43)=4.46$, $p<0.05$) and the high rate of counterfeiting in each of these two product categories. Two popular DVDs were chosen so as to eliminate unique effects of using one DVD that the participants may be familiar with.

The research team then searched for versions of these products for sale on the popular online marketplace "eBay.com". Once found, the web pages displaying these items for sale was then saved and edited by a graphics design team in order to remove any previous feedback the seller of the products had previously received and to standardize the information given by each seller for each of the products. Informational social influence was manipulated by either adding bidders for the item or removing any bidders from the item. In the informational social influence condition several bidders were competing for the item while in the non informational social influence condition there were no other bidders. All of the DVDs were priced at \$9.50 while all of the Universal Remote Controls were priced at \$79.95. Participants used their personal computers to log into the school's intranet where they were then able to access the study. Once the study was activated the participants would then see the edited eBay seller page and were asked to state the probability that they thought the product was counterfeit and to state the maximum amount of money that they would pay for the item.

Our findings revealed a significant interaction between product familiarity and informational social presence in terms of the product being viewed as counterfeit ($F(1, 110)=3.95$, $p<0.05$). Participants rated the DVDs as more likely to be counterfeit if others had bid on it ($M_{dvd_social\ presence}=43.86$ vs. $M_{dvd_social\ presence\ absent}=35.43$); conversely, the universal remote control was viewed as less likely to be counterfeit if others were bidding on it than if there were no other bidders ($M_{Remote_social\ presence}=51.67$ vs. $M_{Remote_social\ presence\ absent}=35.43$). Main effects for familiarity or social presence were not significant.

For the DVDs the presence of other bidders adds cost increases to the price of the DVDs but provides little value in terms of signaling the authenticity of the product. The presence of others may actually have signaled to consumers that the price was previously lower and thus more likely to be counterfeit. With the unfamiliar good, the universal remote control, the presence of other bidders seems to have provided a signal to consumers that the product is authentic. Furthermore, we tested between group differences on the maximum

amount that participants were willing to pay for the both products. A between groups analysis revealed that participants were willing to pay significantly more for the DVDs when there were no other bidders versus the condition where there were multiple bidders ($F(1, 59)=7.93, p<0.01, M\$DVD_social\ presence=10.114$ vs. $M\$DVD_social\ presence\ absent=7.749$). There were no observed differences between the two groups in the willingness to pay for the universal remote control.

In conclusion, our findings demonstrate that under conditions of uncertainty, informational social influence can enhance the perceived quality of products. However, when consumers are familiar with the products in question, informational social influence can create negative byproducts through its employment which we have demonstrated can decrease the value of the product as well as its perceived quality.

Investigation of Differences in Diffusion Between Positive and Negative Word-of-Mouth

Andreas M. Kaplan, ESCP Europe, France

Michael Haenlein, ESCP Europe, France

Extended Abstract

Word-of-Mouth (WoM) is a topic that has received regular interest among Marketing researchers over the last 50 years in both traditional (e.g. Day 1971; Katz and Lazarsfeld 1955; Thorelli 1971; Udell 1966) and electronic settings (e.g. Dellarocas 2003; Dwyer 2007; Godes and Mayzlin 2004; Hennig-Thurau et al. 2004; Kozinets 2002). Within this stream of research, we investigate how WoM valence (i.e. positive vs. negative WoM) influences WoM diffusion characteristics based on data from a French virtual world, similar to the US-based "Second Life" application.

Study 1

Study 1 investigates the impact of valence on WoM diffusion frequency (i.e. the number of contacts WoM is spread to) and speed (i.e. the time elapsed between receiving and retransmitting the information). With respect to WoM diffusion frequency, it is commonly believed that negative WoM is spread to more contacts than positive WoM (e.g. Silverman 1997), triggered by several research studies showing that negative WoM from dissatisfied customers exceeds the amount of positive WoM by satisfied clients (e.g. Bearden and Teel 1983; Richins 1983a, b; Westbrook 1987). However, East, Hammond, and Wright (2007) show that differences in aggregated WoM volume are caused by differences in WoM penetration (i.e. the share of the population spreading WoM) instead of differences in individual-level diffusion frequencies. Given that people take account of the needs of others when engaging in information transmission, the same customers are likely to spread both positive and negative WoM (with equal frequency), depending on the information needs of the receiver (East et al. 2007; Mangold, Miller, and Brockway 1999). We therefore assume that WoM diffusion frequency is independent from WoM valence. Regarding diffusion speed, we expect negative WoM to spread faster than positive WoM as unpleasant or potentially dangerous situations lead to a strong negative reaction, the negativity bias (e.g. Ito et al. 1998). This is supported by studies in the Finance discipline showing that stock prices tend to reflect bad news faster than good news (Lobo 2000) and that good news have more pronounced lagged effects than bad news (Marshall and Walker 2002). This leads to the following two hypotheses:

H₁: There is no impact of WoM valence on individual-level WoM diffusion frequency.

H₂: WoM diffusion speed is higher for negative WoM than for positive WoM.

Study 2

Study 1 provides insight into the impact of WoM valence on basic WoM diffusion characteristics (i.e. how often and when). Study 2 analyzes the influence of social network-related variables on WoM transmission (i.e. to whom). We expect that strong ties are activated more frequently than weak ties in WoM diffusion as strong tie relationships tend to be more influential as information sources (Brown and Reingen 1987; Reingen and Kernan 1986) and their presence leads to higher levels of WoM (Fitzgerald Bone 1992; Wirtz and Chew 2002). Concerning WoM valence, we assume a moderating influence in the sense that this strong-tie preference will be even more pronounced for negative than for positive WoM. One the on hand, we expect people to be reluctant to transmit negative WoM to weak tie relationships as it tends to be associated with unpleasant messages and a notion of complaining, potentially resulting in

a negative impression that the transmitter may want to avoid (Sperduto, Calhoun, and Ciminero 1978; Tice et al. 1995). On the other hand, WoM to strong ties is likely to be caused by altruistic motives and the desire to help the receiver making better decisions. Given that the sender is likely to have a good level of understanding of the needs and likes of strong ties (Kiecker and Hartman 1994), s/he may be sufficiently confident sharing even negative information (Frenzen and Nakamoto 1993; Wirtz and Chew 2002). This leads to the following two hypotheses:

H₃: Strong ties are activated more often than weak ties in the WoM diffusion process.

H₄: The preference for strong ties gets stronger with increasing WoM negativity.

Study 3

Studies 1 and 2 analyze WoM diffusion by focusing on messages received by some source and passed on to social contacts of varying degree of closeness. Study 3 addresses the question whether WoM that reflects hearsay shows different diffusion patterns than WoM originating from a personal and direct experience made by the WoM sender. Generally, we expect that personal experiences lead to higher degree of WoM than hearsay as they result in unique and less ambiguous information that people feel more confident to transmit (Fazio and Zanna 1981; Kardes, Allen, and Pontes 1993). With respect to WoM valence, we expect a moderating impact in the sense that information based on hearsay is more likely to be transmitted when it is of negative compared to positive valence. This is based on Kamins, Folkes, and Perner (1997) who showed that consumers are more inclined to spread negative than positive rumors and (Donavan, Mowen, and Chakraborty (1999) who indicate that urban legends with negative information are associated with higher levels of communication intent. This leads to the following two hypotheses:

H₅: WoM based on personal experience will be transferred more often than WoM based on hearsay.

H₆: For WoM based on hearsay, negative WoM is more likely to be transmitted than positive WoM.

Research Methodology

We plan to investigate the aforementioned hypotheses based on data we collected from a French virtual world, which is targeted toward children and teenagers. We chose this setting over traditional laboratory-style experiments as we expect it to provide a higher degree of external validity. Within this virtual world we launched 16 different messages (4 message per cell within a 2 levels of message strength x 2 levels of message valence design) and recorded the resulting WoM activities generated by the virtual world users (diffusion frequency, diffusion speed, type of social tie activation). Currently, we are in the process of coding the data obtained from the virtual world platform (weblogs) in order to prepare our data analysis.

Are Bad Reviews Stronger than Good? Asymmetric Negativity Biases in the Formation of Online Consumer Trust

Dezhi Yin, Georgia Tech, USA
Samuel Bond, Georgia Tech, USA
Han Zhang, Georgia Tech, USA

This research examines biases in the formation of trusting beliefs and intentions in an online environment. Interactions with unfamiliar sellers contain an element of uncertainty and risk (Reichheld and Schefter 2000), but modern consumers have access to various forms of information to help resolve this uncertainty, including online consumer reviews. Empirical studies have demonstrated a negativity bias whereby even a limited number of "bad" reviews from prior consumers have stronger impact than good reviews on sales and price premiums (Ba and Pavlou 2002; Chevalier and Mayzlin 2006). However, measurements of trust and corresponding beliefs are generally unavailable in secondary data. On the other hand, survey-based studies in the trust literature have tended to measure relevant constructs without regard to potential biases. To address this gap, we take an experimental approach and ask the following: Do consumers exposed to online reviews of a seller exhibit bias in the formation of trusting beliefs and intentions? If so, is the bias always negative? Drawing upon prospect theory and models of person perception, we propose that although consumers may exhibit a general negativity bias, the magnitude of this bias will depend on the dimension of seller behavior involved.

That tendency to weigh negative information more heavily than positive information has been established as a general principle of human judgment (Baumeister et al. 2001; Rozin and Royzman 2001). This tendency follows directly from Kahneman and Tversky's (1979) prospect theory, which posits that people derive value from gains and losses according to a nonlinear "value function" that is concave for gains and convex for losses; losses loom larger than gains. Applied to the risky environment of e-commerce, consumers will be more concerned with potential losses than with potential gains. In particular, when considering positive and negative information related to the trustworthiness of a seller, they will overweight the negative information, and this bias will subsequently lead to more negative trusting beliefs and eventual intentions

However, evidence from the arena of person perception suggests that when judging others' behavior, "bad is not always stronger than good". For example, Skowronski and Carlston's (1987) category diagnosticity model separates person-relevant information into 'competence' and 'morality' domains. The model suggests that most individuals possess schemas in which moral people exhibit moral behaviors all the time; therefore, a single immoral behavior is a reliable indicator of immorality. The same is not true for competence, where even competent individuals occasionally fail; a single success is a more reliable indicator of competence, while a single failure is generally discounted. Online trust literature also breaks trusting beliefs into "competence" and "integrity" dimensions among others

(McKnight, Cummings, and Chervany 1998). Applying this domain-specific approach to the current setting, we predict that consumers' trusting beliefs pertaining to a seller's integrity will be more negatively biased than their trusting beliefs pertaining to a seller's competence.

We conducted two studies to test our hypothesis in a typical e-commerce setting involving word-of-mouth. Study 1 presented 36 undergraduate participants with aggregated profile 'ratings' regarding different characteristics of online sellers. The study utilized a 2 (profile dimension: competence, integrity) \times 2 (store rating manipulation: treatment, control) within-subject design. Participants were told that they were shopping for a camera and asked to read profiles summarizing consumer reviews of four different online stores. Each store's profile was composed of two sections, one related to competence and the other related to integrity; each section listed three relevant items along with an average rating for each item. All ratings were presented using a 5-point "smiley face" scale ranging from "very negative" to "very positive". The ratings for treatment stores' first profile section were (0, -2, 2) or (0, 2, -2), while those for control stores were all neutral; ratings in the second profile section were identical between treatment and control stores. Participants were asked their competence and integrity beliefs after the first profile section, and their overall trust and purchasing intention after the whole profile of a store. As predicted, results indicated that negativity bias implied by a lower evaluation of the treatment stores was not universal, but rather depended on the category of seller behavior involved. Participants in the *integrity* condition were negatively biased in their trusting beliefs, overall trust and purchasing intention; however, none of these biases were significant for participants in the *competence* condition.

Study 2 extended our investigation from simple, numeric seller ratings to the more elaborate domain of written reviews. The study involved a mixed design in which participants were asked to read five consumer reviews about a particular online store before deciding whether to buy a camera from that store. The first three 'baseline reviews' were the same for all participants and had been pretested to be neutral in their implications regarding the sellers' competence and integrity. Next, participants read two additional 'treatment' reviews pertaining to either competence or integrity, depending on condition. The two treatment reviews were pretested to be opposite in valence and similar in extremity. In order to capture belief changes, participants were asked to report their trusting beliefs and overall trust before and after reading the two treatment reviews. Analysis of belief changes revealed that as predicted, both groups exhibited significant negativity bias, but the extent of bias was dramatically greater for the integrity condition. Furthermore, analysis of overall trust revealed a negativity bias for participants in the integrity condition, but no significant bias for the competence condition.

This research contributes to literature on trust formation and e-commerce in several ways. Theoretically, we break new ground by identifying the existence of negativity biases in the formation of trusting beliefs and intentions and by exploring whether "bad is always stronger" in B2C commerce. Our studies indicate that although negativity bias does impact trust formation in this setting, it is much more prevalent for information regarding sellers' integrity than for information regarding their competence. Our results also have practical implications for retailers seeking to establish trust among potential customers: e.g., negative word-of-mouth regarding integrity is particularly difficult to overcome, and should be handled proactively.

The Impact of Negative Online Reviews: When Does Reviewer Similarity Make a Difference?

Ali Faraji-Rad, BI Norwegian School of Management, Norway

Radu-Mihai Dimitriu, BI Norwegian School of Management, Norway

Extended Abstract

The advent of the internet has brought major changes to the way consumers search for information and express their opinions about products or services. Message boards, blogs, user review websites, etc. have become increasingly important for today's online consumers to exchange opinions and experiences related to both companies and their offerings. Although online reviews have been mainly perceived to be anonymous, recent improvements in the design of websites have enabled individuals to have different degrees of profile disclosure (picture, name, age, gender, short biography) which, contrary to the general assumption in the word of mouth literature, introduces cues on which consumers can rely and base their judgments on. We conduct a study to investigate whether the perceived homophily between the reader and the reviewer has any impact on the influence of the word of mouth message. Homophily is defined as "the degree to which pairs of individuals who interact are similar with respect to attributes, such as beliefs, values, education, social status, age, gender, lifestyle, etc" (Rogers & Bhowmik, 1970). We also seek to qualify this effect by focusing on the different nature

of hedonic and utilitarian consumption (Adaval, 2001; Batra & Ahtola, 1991). Because utility maximization is considered to be more tangible and objective, consumers should be just as willing to rely on other consumers' evaluations whether that consumer is similar to them or not. In contrast, the evaluation of hedonic products is linked to expectations which could be subject to individual lifestyle. Therefore, we hypothesize that *higher (vs. lower) homophily influences the effect of negative product reviews on product evaluation for hedonic products, but not for utilitarian ones.*

The hotel industry was chosen as the context of the study. One hundred and eleven bachelor students participated in a 2 (Hedonic vs. Utilitarian) X 2 (Homophilous vs. Non-homophilous) between-subjects experiment in class. The dependent variable was participants' evaluation of the hotel.

After an introductory first page, participants read a scenario which was designed to manipulate the hedonic or utilitarian consumption situations. In the utilitarian case, participants were asked to imagine themselves trying to book a hotel for a stay in Frankfurt with a colleague. In the hedonic scenario, they were asked to imagine themselves going to Paris with their partner and choosing a hotel which would ensure their enjoyment. Participants were then presented with two online reviews about the hotel. Each review included a profile, a comment (one-two lines explaining how the reviewer saw the hotel), and a rating (a star ranking of the hotel given by the reviewer on a seven star system). The first review and its corresponding profile were kept constant for all the groups and was a neutral review (rating of 5 out of 7) coming from a journalist. Negative word of mouth and homophily were manipulated through the second review and its corresponding profile. The negative comment (rating of 2 out of 7) was kept constant for all the groups. For the homophilous group, the reviewer was a business student and in the non-homophilous group the reviewer was a researcher for "a major chemical company". Next, eleven items measured the product evaluation, manipulation checks and two covariates. Two questions were asked to measure the participants' product evaluation (good choice; favorable attitude). Homophily manipulations were checked using a three item scale. Two items measured the extent to which participants perceived the hotel to be hedonic (fun; enjoyable and exciting) and two items the extent to which they perceived it to be functional (cover functional needs; practical considerations). The two covariates were the perceived degree of expertise of the reviewer and importance of the decision of choosing the hotel. Manipulation checks and covariate question were presented last in order.

An analysis of the data revealed that the manipulations worked as intended. For testing the hypothesis we first ran an ANOVA test with hotel evaluation as a dependent variable and "homophily" and "product type" as independent factors, and using the two covariates mentioned earlier. The expertise covariate had a significant effect on the dependent variable ($F(1,105)=3.93$, $p=.05$), whereas the choice importance did not ($p>.7$). The ANCOVA model suggested that the main effect of "homophily" failed to reach significance (3.86 vs. 4.19 , $F(1,105)=2.74$, $p>.1$). Meanwhile, the main effect of "product type" was significant, with the evaluation of the hedonic product being significantly lower than the one for of utilitarian one (3.81 vs. 4.23 , $F(1,105)=4.26$, $p<.05$). Supporting the hypothesis, the interaction was significant ($F(1,105)=4.49$, $p<.04$). Planned contrasts analyses revealed that the effect of "homophily" was not significant when the hotel was perceived to be utilitarian (4.28 vs. 4.19 , $F(1,105)=.13$, $p>.7$). However, when the hotel was perceived to be hedonic, the hotel evaluation was significantly lower when the reviewer was "homophilous" rather than not (3.44 vs. 4.19 , $F(1,105)=7.26$, $p<.01$). Also, a similar analysis revealed the same results, not including the covariates.

Therefore, consistent with the hypothesis, homophily increases the influence of negative product reviews only in case of hedonic products.

From a theoretical perspective, this study sheds light on how the cues consumers use in the face-to-face environments map into online environments. To our knowledge, this is also the first research that qualifies the influence of homophily in the word of mouth literature.

From a managerial perspective, the study provides insights into how reviews on websites can influence consumers' product evaluations. It shows that negative word of mouth is riskier for experiential (hedonic) products and that this risk is higher when it comes from similar consumers providing reviews. In terms of segmentation, managers should be encouraged to pay more attention to consumer complaints about experiential products, especially when they are coming from company's target or core customers. Such customers are more likely to form a unitary and similar group. This will prevent target customers from engaging in word of mouth that is most harmful for the company.

Best-Seller or Your-Style Recommendation Sign?: Effect of Self-Construal on Inclination Towards Inter- vs. Intrapersonal Norm

Jae-Eun Namkoong, University of Texas at Austin, USA
Susan Broniarczyk, University of Texas at Austin, USA

Extended Abstract

Modern consumers are often loaded with options. Despite the initial pleasure one might feel when provided with many goods to choose from, it is very likely that s/he will feel frustrated by how difficult a choice is to make (Iyengar & Lepper, 2000; Schwartz, 2005). Product recommendations are intended to aid consumers with their decision making process and to promote sales by highlighting a

particular product. The present research focuses on two broad types of norm-based product recommendations and demonstrates how the level of self-construal determines the way consumers react to these recommendations.

Recommendations can be based on *intrapersonal* norm or *interpersonal* norm. An *intrapersonal* norm is realized through a repeated behavioral pattern within a single individual (Kahneman & Miller, 1986). People have the need to act in a coherent manner (Swann Jr, 1983), and technology has allowed retailers to generate recommendations designating a product alternative as “Your-Style” based on consumers’ purchase histories, browsing patterns, and preferences. On the other hand, an *interpersonal* norm is formed through observing other people’s behavior. Simply observing what other people are doing could influence one’s own decision, even when there is no apparent pressure (Aarts, Gollwitzer, & Hassin, 2004). The most common example of an interpersonal norm in a consumption setting would be the indication of “Best-Seller” that captures consensus between individuals.

Which norm-based recommendation is more effective, however, will depend on one’s level of self-construal. An independent construal of the self “requires construing oneself as an individual whose behavior is organized and made meaningful by reference to one’s own internal repertoire of thoughts, feelings, and actions,” whereas the *interdependent* self-construal entails understanding oneself “as part of an encompassing social relationship and recognizing that one’s behavior is determined, contingent on, and, to a large extent organized by what the actor perceives to be the thoughts, feelings, and actions of others in the relationship” (Markus & Kitayama, 1991, pp. 226–227). Because of the differential sensitivity towards internal vs. external repertoires among independent vs. interdependent individuals, we predict that interpersonal (vs. intrapersonal) norm-based recommendations have a stronger effect on recommendation evaluation, choice of the recommendation, and post-choice evaluation among highly interdependent (vs. low interdependent or independent) people. Specifically, we compare inter- and intrapersonal norm recommendations operationalized as Best-Seller and Your-Style recommendation signs, respectively. Three studies examine the moderating effect of self construal via priming (pilot study), measured as a chronic trait (study 1), or operationalized by culture (study 2).

A pilot study confirms that evaluation of the two norm-based recommendations differed as a function of self-construal. Participants read a scenario describing either a Best Seller or Your Style recommendation. Self construal was primed using the established scenario of Trafimow, Triandis, and Goto (1991). Supporting our prediction, a Norm Recommendation Type x Self-Construal interaction showed that interdependence-primed (vs. independence-primed) participants reported the Best-Seller (vs. Your-Style) recommendation as more attractive ($F_{(1,90)}=3.569$, $p=.062$) and had stronger intentions to follow ($F_{(1,90)}=3.698$, $p=.058$).

Study 1 examines how the presence of either a Best-Seller or a Your-Style sign affects participants’ choice of office chairs as a function of self-construal. Although the product recommendations were in fact placed on the same product across all conditions, participants were lead to believe that the Best-Seller sign was generated based on the retailer’s customer database and the Your-Style sign based on their own previously revealed preferences. In order to make it a strong test, the recommendation was always placed on the second most attractive product. Self construal was measured using the classic self-construal scale of Singelis (1994). Consistent with our prediction, the Norm Recommendation Type x Self Construal interaction revealed the likelihood of participants choosing a recommended product over the most attractive product was higher when the product recommendation was based on a norm that was highly relevant to their given self-construal ($b=1.432$, $t=1.737$, $p=.082$). Specifically, highly interdependent (vs. independent) participants were more likely to choose the recommended product when presented with a Best-Seller (vs. Your-Style) sign recommendation.

Study 2 then explores whether the interaction between norm recommendation type and self-construal extends to post-choice satisfaction. Moreover, instead of examining compliance behavior, study 2 looks at the effect of *deviating* from recommendations. Norm based recommendation was manipulated similar to Study 1 and self construal was operationalized as individualistic vs. collectivist cultures (Markus & Kitayama, 1991). The product stimuli was sofa chairs. In all conditions, the recommendation was placed on an objectively unattractive option so subjects would choose a non-recommended option (93%). This allowed us to gauge the effect of deviating from a recommendation on participants’ choice satisfaction after choosing a non-recommended option. Supporting our conceptualization that the presence of a self-relevant recommendation would impact people’s post-choice evaluations, there was a significant Norm Recommendation Type x Self Construal interaction on post-choice satisfaction ($F_{(1,90)}=5.425$, $p=.022$). Specifically, when participants from a highly interdependent (vs. independent) cultural background were presented with a Best-Seller (vs. Your-Style) recommendation and rejected it, they felt lower choice satisfaction. This result suggests that even when a person strongly disagrees with a recommendation and decides not to follow it, the fact that s/he has been presented with and had to forgo a self-relevant recommendation can undermine his consumption experience.

The present research introduces self-construal as a meaningful predictor in determining which type of norm-based recommendation has a more powerful influence on people’s evaluation of the recommendation, compliance to recommendation, and post-choice satisfaction after deviating from recommendation. Presenting consumers with a self-relevant norm could be an efficient way to aid consumers’ decision as it increases the appeal of the recommendation and the probability of choosing the recommended item. However, when a relevant norm is misplaced it could also be a source of consumer dissatisfaction and regret. Practical implications and future research extensions are discussed.

Prospective Motivated Reasoning in Charitable Giving: Making Sense of Our Future Behavior and Protecting Our Future Self

Jae-Eun Namkoong, University of Texas at Austin, USA

Julie Erwin, University of Texas at Austin, USA

Extended Abstract

The present research also falls under the large umbrella of motivated or biased reasoning (Bem 1972, Greenwald & Ronis 1978, Wicklund & Brehm 1976). It is similar to previous work showing that people alter their attitude to reduce the gap between what they believe and how they have behaved, in order to restore a favorable self-view. However, our design differs from previous research in two ways. First, our research looks at people's tendency to make sense of their *prospective* (rather than retrospective) behavior, and second, our findings do not depend on the respondents actually behaving in the way they fear they might behave. While a decision has not yet been made, people may reason in a forward looking manner, preparing a basis or a safety net for their potentially undesirable future behavior. We look into this effect of prospective biased reasoning in the context of donation or charitable giving. Even without the conventional form of "products" involved, the topic of altruistic consumer behavior is highly relevant to marketing because the structure or relationship between providers and suppliers remains largely similar. Moreover, understanding people's altruistic behavior gives insight into the consumption of ethically enhanced products.

Acting against one's own self-interest to satisfy a moral imperative (such as helping others) is likely to involve struggle or conflict between one's actual and ideal self. The present research examines how this struggle or conflict plays a role in people's prospective reasoning—specifically, how people prepare a safe pathway to escape from the perceived obligation to help others, without hurting their positive and moral self-view.

In our experiment, participants were told that the study was a collaborative project with a non-profit organization. Before starting, they were given information about this organization to read and learn about its identity, goal, and activity. One group of participants were informed at the beginning of the survey that they will be asked to donate a part of their compensation to the organization at the end of the experiment, while the other group was not told that they would be asked to make donations to this organization. Whether the donation was made by real or hypothetical money was also manipulated as a proxy for motivational strength to talk oneself out of making a donation. Thus, there was a 2 (donation request revealed at beginning vs. not revealed) X 2 (real vs. hypothetical donation) design. We were particularly interested in the change in participants' beliefs regarding the seriousness of the social issues being addressed by the organization (AIDS and poverty). We found a number of two-way interactions, including for rated seriousness of the AIDS problem ($b=.199, t=.230, p=.022$) and rated seriousness of poverty ($b=.146, t=1.772, p=.078$). Participants in the real money condition who were informed (vs. not informed) about the donation opportunity prior to the evaluation of social issues were more likely to believe that the social issues were less serious. ($b=-.437, t=-3.005, p=.003$ for AIDS and $b=-.281, t=-2.039, p=.043$ for poverty).

We were also interested in the effect on behavior. Those who saw (vs. did not see) the donation information prior to the evaluation questions donated significantly less hypothetical money ($b=-.411, t=-2.744, p=.007$). However, this behavioral effect was non-significant in the real money condition, probably because most people in this condition did not donate (i.e., a floor effect). Interestingly, however, when participants were asked to donate their real money, those who were informed about the donation opportunity ahead of time perceived higher level of financial constraint, compared to those who were informed about the donation opportunity later ($b=.477, t=1.805, p=.076$). We also found a mediating pattern where a set of negative moods (e.g. afraid, scared, and hostile) explained why knowing ahead about the donation opportunity led to lowered perception of issue seriousness ($\tau=-1.69, p=.08$).

Overall, our findings suggest that informing people that they may be asked to donate in the future causes a particular type of "potential dissonance" reduction process in a prospective direction, even when respondents do not donate anyway. That is, knowing about a donation opportunity earlier makes people feel uncomfortable because there is a potential threat on one's positive self-view in case one decides not behave in an altruistic manner in the future. While people have not yet made any decision, they may still prepare for this potential threat by creating a safety pathway to escape if necessary, while keeping their positive self-view intact. Consequent (proposed) studies aim to discover whether people have already made their decision to donate at an implicit (or may even at an explicit) level once they are informed about the donation opportunity. This will clarify the question about how similar or different the effect is from classic dissonance theories. Another research direction is to examine whether one's level of self-esteem serves as a moderator, as the motivation seems to come from the restoration or defense of positive self-view. In addition, whether or not the changes in attitudes persist after the experiment also a matter of interest; it would be good to know whether the denigration of the issue and the organization persists after the threat is gone.

Promoting Products versus Outcomes to impact the Decision Making Process: the Power of Recommending One Product

Mirjam van Ginkel, Erasmus University Rotterdam, The Netherlands
Benedict Dellaert, Erasmus University Rotterdam, The Netherlands

Extended Abstract

When going online to buy a product, consumers are often exposed to several product variants instantly on the introductory page of the website. This can be a presentation of the web shops' bestsellers, or a presentation of the available assortment within the specific product category. An immediate confrontation with concrete products may stimulate consumers to buy, but it may suppress consumers' goal oriented thinking. In other words, consumers may choose a product to buy, but may neglect to formulate personal goals or benefits previously. Although it might have a positive effect on sales, this can be unfavorable in situations in which you want consumers to think about their decision behavior in a structured way. For example, in the current health debate we want to make people more conscious about their food decisions.

We distinguish two types of messages in purchase settings. Specific product exposures, on the one hand, recommend specific products because of a certain benefit. Generic messages, on the other hand, recommend a product category because of a certain benefit—for example "Yoghurt is healthy-and are not specific on product level.

Within the decision making process of daily goods, we distinguish two decision stages. In the first stage consumers investigate their need for the product being considered and weigh the pros and contras of buying a product. This leads to a goal-oriented mental representation with more attention and better recall of goal related information. The second stage incorporates the decision which of the alternatives consumers prefer. This type of decision making leads to a comparative mental representation (Xu, Wyer, 2008).

A message functions as a stimulus, which leads to a mental representation. Exposing consumers to a generic recommendation, moves consumers in a goal-oriented mental representation. Exposing consumers to a specific multiple product recommendation moves consumers in a comparative mental representation (Xu, Wyer 2008). These mental representations in turn impact the processes of benefit activation and choice. A good understanding of the impact of different types of messages on the mental representations in the defined decision stages is still lacking. In this paper a theoretical framework is developed to understand the impact of different types of messages on the decision making process.

Our contribution is to give insight in how generic and specific product recommendations can be combined best to steer consumers' mental representations of daily decisions and therefore to promote the product choices anticipated by the recommender. The first contribution of this paper is that we show that generic recommendations are more effective in activating benefits than specific multiple product recommendations. We give evidence why specific multiple product recommendations are not very effective in benefit activation. Recommendations are more effective in benefit activation when generating a goal-oriented mindset. Specific multiple product recommendations seem to bring people in a comparative mindset. The second contribution is that specific multiple product recommendations are more effective in activating choices, which are anticipated by the recommender, than generic recommendations. The third and main contribution of this paper is that it shows that a specific single product recommendation has best of both worlds; it is able to activate benefits-as well as a generic recommendation-and to translate these activated benefits into choice activation—as well as a multiple product recommendation. In the end we show that the above relationship between recommendation type and task performance is moderated by the focus of the respondent. For example, for respondents with a health focus, health benefit activation is attenuated for the reason that health benefits already are activated.

In five experiments under students in between-subject designs, we examined the impact of the different types of health recommendations on health benefit activation and healthy product choice.

The Use of Rankings in Uncertainty Reduction Efforts: A Basis Paradigm

Simon Quaschnig, Ghent University, Belgium

Iris Vermeir, Ghent University, Belgium

Mario Pandelaere, Ghent University, Belgium

During the last years there has been a huge increase in available choice options for customers (Schwartz et al. 2002), a phenomenon called hyperchoice (Mick, Broniarczyk, and Haidt 2004). But confrontation with an overload of alternatives makes decision making more difficult (Schwartz 2004), partly because customers feel more responsible for their choices (Iyengar, and Lepper 2000). The result is a decrease in choice confidence (Chernev 2003), leading to greater uncertainty (Anderson 2003). In addition, consumers often face decisions involving unfamiliar goods (Chocarro, Cortiñas, and Elorz 2009). According to Berger and Calabrese (1975) there is a human drive to reduce uncertainty. Consumer will engage in uncertainty reduction efforts by searching information, where especially the opinions of others are often consulted (Weiss, Lurie, and MacInnis 2008). One possible source of information is rankings. Ranking are applied in an increasing number of situations, yet no relevant research has been conducted so far. In this study we will explore the effect of rankings on consumer decisions.

Making a choice in the modern purchasing environment, that is characterized by an ever growing consumption, increasing assortment sizes, and a growing number of brands and products (Mick 2008), requires the access to information. It has repeatedly demonstrated that information search increases systematically with experienced uncertainty (Lanzetta, and Driscoll 1968; Urbany, Dickson, and Wilkie 1989). It enables the decision maker to evaluate alternatives on relevant traits and to make a thoughtful choice, reducing the risk and probability of a non-optimal outcome (Mitchell 1992). Additionally, in situations where the consumer possesses little knowledge about the products, no prior experience is present and it is assumed that consumers depend on information available in the choice itself (Bettman, and Park 1980). One kind of information often consulted for this is the opinion of others. Available in numerous forms, other's opinion have been shown to influence consumers' evaluations, when relevant product attribute information was not accessible (Bearden, and Etzel 1982). Information sources in the form of online forums, book recommendations and newspaper columns are therefore of great value for the customer.

While former research focused on some of this information sources, we will investigate the effect of rankings. From the New York Times Best Seller list, the Nielsen Ratings and Billboard charts, to the top 10 lists in our local video and music stores, rankings are a part of our everyday life. They structure our ways of thinking about comparisons, contrasts and order and may be another way for consumers to reduce their uncertainty (Hakanen 1998). The purpose of this study is to investigate what role rankings play in the preference formation task. We hypothesize that in a situation of uncertainty, consumers will use rankings in order to form their preferences.

In order to test our hypothesis, we administered a questionnaire to eighty-eight respondents, asking them to express their preferences for 10 rather unknown brands of champagne. We randomly divided the respondents into 4 conditions each facing a different ranking. Condition 1 provided a simple top 10 list, while condition 2 additionally included expert scores. Condition 3 also was a simple ranking, but the 2 top brands of condition 1 were ranked as the two "worst" brands, and vice versa. Condition 4 simply was a list, without any ranking implied. Respondents had to indicate their willingness to pay (WTP) for each of the brands. We also included measures concerning the familiarity with the product category and the different brands (showing no familiarity with the brands included), and a scale measuring respondents' preference for numerical information. In order to test our hypothesis we estimated a multilevel regression model.

Our results indicate that rankings may indeed strongly affect consumer preferences. In particular, we found that our respondents' evaluation of a given brand (expressed by the WTP) depended on the rank of the brand in the list. Respondents are willing to pay more for brands that are ranked higher (versus lower). In addition, for the 10 brands involved, respondents indicate a higher WTP than for those same brands when the order of presentation reflected no ranking (condition 4). We assume that the ranking itself could offer respondents some indication about the value of the brand. Interestingly, the effect of rank was moderated by preference for numerical information (PNI). A high PNI indicates that respondents have an eye for numerical information and use it in their decision making, especially in settings that require only a minimum level of mathematical ability (Viswanathan 1993). Our results show that individuals with a high PNI are more likely to use rankings, compared to individuals with a low PNI. The effect of rank was also moderated by familiarity with the product category. For respondents not familiar with champagne, rankings show less effect. That is, the slope relating rank position and WTP was less steep for them. Finally, we also observed a main effect of product category familiarity: respondents unfamiliar with champagne indicated a lower WTP for champagne brands.

To conclude, our results show that rankings have an influence on the preference formulation in uncertain situations. Further research must indicate the robustness and generalizability of the current findings. Investigating the potential moderation by other customer characteristics, such as the difference between maximizers and satisficers or the need for closure on the use of specific rankings would also add to the literature.

Citations and Herding: Why One Article Makes It and Another Doesn't

Simon Quaschnig, Ghent University, Belgium

Mario Pandelaere, Ghent University, Belgium

Iris Vermeir, Ghent University, Belgium

The information era has brought with it the well-known problem of 'information explosion' (Hanani, and Frank 2000): researchers face an ever-increasing amount of information and with the arrival of the internet and search engines they have more options in seeking and obtaining information than ever before (Junni 2007). At the same time, the number of marketing-related journals has increased rapidly in recent years (Baumgartner, and Pieters 2003) and journals expand into broader fields of research. This proliferation of information comes with greater uncertainty (Anderson 2003) and increases the difficulty to select an option (Schwartz et al. 2002). According to the uncertainty reduction theory (Berger, and Calabrese 1975), people will engage in uncertainty reduction efforts to alleviate and eliminate the risk caused by uncertainty and to maximize outcome value. One kind of information often used in these efforts is the number of citations. While the number of citations may not be a perfect indicator of quality (Walter et al. 2003) it does play an important role in the evaluation of academics and papers (Stremersch, Verniers, and Verhoef 2007). In this study we will explore the role of herding in citing behavior.

In order to select sources for their research, one has to make a choice out of a seemingly endless amount of articles. In such a context of uncertainty, Parker and Prechter (2005) have seen a default to a herding impulse: people may imitate each other out of a desire to be safe. They may believe that persons before them had better information on the quality of articles than they themselves do, and therefore may include the articles in their own research (Bonabeau 2004). We assume that the number of citations serves as a quality cue for a given paper. As individuals follow the previous citing behavior of others without taking their own information into account, they will concentrate on a limited amount of articles with an established citation record. When this imitation occurs in large numbers, informational cascades can be formed (Banerjee 1992; Bikhchandani Hirshleifer, and Welch 1992). The limited number of papers that is already cited tends to accumulate citations increasingly rapidly while a larger set of initially uncited papers tends to be (virtually) ignored.

While former research (Stremersch et al. 2007) focused on static determinants of citations (e.g. quality and domain of the article, visibility and personal promotion), we focus on herding behavior of researchers, a dynamic determinant. In order to investigate our hypothesis, our study will be divided into two parts, the demand and the supply side: On the one hand, we will examine the herding effect of citations by the means of citation counts. On the other hand, we will look at the possible increase in the supply of journals and its articles.

For the first part of our study we collected citation data via Web of Science. We sampled six major marketing journals: *JCR*, *JRM*, *JM*, *MKS*, *JCP* and *IJRM*. We inventoried all articles published in these journals in 1985, 1990, 1995, 2000 and 2005. For each article we tallied the number of citations made in each of the 5 years following its year of publication. The herding effect will be examined by means of a mixed model approach, where the number an article got cited each year is the dependent variable and the year of publication, the year after publication, the journal and the number of citations in the first year serve as independent variables. In the absence of herding, the cites that a paper receives in the first five years after publication should be distributed uniformly over those five years. In case of herding, on the other hand, a steady increase of the number of cites that a paper attracts should be observed. Moreover, this increase should be more pronounced for papers that are already heavily cited in the first year after publication.

The results confirm our expectations. We can see a significant increase in the number of citations each year, therefore indicating a more than linear rise in the cumulative number of citations. This herding effect is moderated by the year of publication, the specific journal as well as by the number of citations in the first year. The herding effect is more pronounced in 2005 than in 2000 ($p=.07$). In addition, stronger herding is observed in 2000 than in 1985, 1990 and 1995; the latter three do not significantly differ. The stronger herding in 2000 and 2005 can partly be explained by the growing use of electronically retrieved information, causing a larger amount of information. The difference between 2005 and 2000 can be explained by the introduction of Web of Science, making citation-oriented search even more convenient and common. The herding behavior observed for *JM* also differs significantly from that of *JCR*, *JMR*, *MKS*, *JCP* and *IJRM*. It exhibits strong herding. We also found stronger herding for articles that are heavily cited in the first year.

The second part of the study investigates whether the information supply for researcher has increased over the past decade (years 1998 to 2008). To do so, we developed a list of the different journals that were cited in the 6 target journals. We also tallied how often a specific journal was cited. If the supply of relevant information has increased, we would expect that the number of cited journals has also steadily increased.

Our findings confirm this expectation. Interestingly, the number of cites that come from the Top 5–cited journals have increased. This implies that the distribution of citations has become more lopsided: an increasing amount of journals are hardly cited while another, small proportion is heavily cited. This again testifies to the herding phenomenon in citing behavior.

To conclude, our results show that citing behavior is characterized by significant herding. In addition, herding has become more pronounced over the past decade. Finally, increased herding may be attributed to the increased supply of relevant information. The latter is exhibited by an increase of the number of used journals.

Living a Second Life: The Role of Goals and Mental Imagery on Satisfaction Online

Diogo Hildebrand, Baruch College, USA

Sankar Sen, Baruch College, USA

Online Virtual Environments (OVE), a new technology launched during the late 1980s, are revolutionizing the way products are consumed. OVEs are environments in which synthetic sensory information leads users to perceive the virtual environment as if it was not synthetic (Blascovitch et al. 2002). Because of this unique characteristic, OVEs allow users not only to buy or sell products, but also to consume products online. For instance, in Second Life, a virtual world available on the web, consumers may purchase and drive a virtual Mercedes-Benz, wear virtual Giorgio Armani shirts or visit the Smithsonian's Virtual Latino Museum.

Because of its ability to enable online consumption, OVEs are gradually gaining attention from both managers and consumers. Recently, the CIO of the Smithsonian Institute affirmed that the institution's investment in the virtual world is supported by the prediction that 80% of active Internet users in 2008 will be consumers in virtual worlds by the year 2011 (Smithsonian Institute 2008). Furthermore, consumers in the virtual world spent, in 2009 alone, around \$400 million in products and services from thousands of companies such as Mercedes-Benz, Nike, and Dell. However, although the importance of the OVE as a marketing channel and branding tool is increasing (Barnes and Mattsson 2008), the main determinants of individual satisfaction with online consumption are still unknown (Hoffman and Novak 2009).

In the present research, we rely on literature from the general web-browsing context to build a model of online consumption. As a starting point, state of flow is a central antecedent of user satisfaction on the web (Hoffman and Novak 1996; Novak, Hoffman and Yung 2000). Furthermore, researchers have presented significant evidence of the importance of website content in inducing state of flow and user satisfaction with online experience (Novak, Hoffman and Duhachek 2003). Building on this basic idea, because use of OVEs is strongly associated with the satisfaction of experiential and symbolic needs (Vicdam and Ulusoy 2008; Yee 2006), we propose that the extent to which the OVE allows users to satisfy experiential and symbolic needs will be an alternative content feature that influences both state of flow and user evaluation of online consumption experience.

Moreover, the dynamics of online experiences are structurally different than those of real world experiences. Specifically, unlike in the real world, the consumption in OVEs is reportedly an indirect experience (Hamilton and Thompson 2007). Importantly, in indirect experiences, sensory information is not presented directly, but depends on individual capability to emulate the sensations elicited by the OVE. As a result, the extent to which sensory information is presented in working memory (i.e., level of mental imagery processing (MacInnis and Price 1987)) will be a key moderator of the extent to which an OVE can satisfy aroused individual goals. Particularly, for high mental imagery processing, consumers will process the sensory information elicited by the OVE intensively. In this case, since consumers will have a significant amount of sensory information to support assessments of progress toward their aroused goals, the extent to which the OVE can satisfy these goals will have a positive effect on flow and, consequently, on individual evaluation of the online consumption experience. On the contrary, because under low imagery processing, consumers will process a lesser amount of sensory information, they will have a limited basis to judge the extent to which goals are being satisfied. As a result, even though consumers might still present moderate levels of flow (Novak et al. 2003), consumers under low imagery processing will not be sensitive to the extent to which experiential goals can be satisfied online. We test these hypotheses in one study.

We manipulated level of mental imagery and the extent to which goals can be satisfied online and measured individual state of flow and satisfaction with the online experience. Seventy-seven undergraduate students participated in the research. The virtual environment of the National Museum of Natural History of the Smithsonian Institute was chosen as the OVE. Participants were first asked to write an essay to arouse goals that either could (i.e., learn new things) or could not (i.e., share experience with others) be satisfied online. Next, following previous manipulations of mental imagery (Petrova and Cialdini 2005), participants read the instructions to browse in the museum's virtual environment, being either encouraged or discouraged to use their imagination.

The results of an ANOVA supported the hypotheses. Particularly, the extent to which a goal can be satisfied online had a positive effect on both flow ($p < 0.05$) and evaluation of the online experience ($p < 0.01$). Additionally, we found a significant interaction between the extent to which goals can be satisfied in the OVE and level of mental imagery on both flow ($p < 0.05$) and satisfaction with the online experience ($p < 0.01$). Specifically, individuals in high mental imagery processing felt higher state of flow and evaluated better the online consumption experience when they were able to satisfy aroused goals online. On the other hand, individuals in low imagery processing presented no difference in both state of flow and experience evaluation, regardless of the extent to which their goals could be satisfied in the OVE. Finally, using the bootstrap technique (Preacher, Rucker and Hayes 2007), we verified that flow is a significant mediator of the interaction on the "evaluation of online experience" for individuals in high mental imagery processing but not for those low in imagery processing.

The present research is, to the best of our knowledge, the first attempt to unveil the process underlying consumers' consumption in this novel environment. Past research in psychology and marketing has linked individual state of flow with the pleasantness of the activity. In the present research we show that the extent to which goals can be satisfied in the OVE and level of mental imagery processing will be important variables in the process of online consumption experience.

Putting the Roots Back in Grassroots: Consumer Activism through Social Media

Pia A. Albinsson, Appalachian State University, USA
B. Yasanthi Perera, New Mexico State University, USA

"The existence of united groups of online consumers implies that power is shifting away from marketers and flowing to consumers" (Kozinets 1999:258).

Social movements are activists' collective efforts to transform the social order (Buechler 2000) often with respect to consumption and marketing (Kozinets and Handleman 2004) in terms of anti-brands (Hollenbeck and Zinkhan 2006) and other forms of resistance to consumption (Penaloza and Price 1993). Such movements organized to resist various industrial or marketing practices, comprises of the goal, the activists, and their adversary (Melucci 1989; Touraine 1981). While activism traditionally entailed activists meeting and engaging in protests, the Internet has given rise to web-based activism. Vegh (2003) classifies web-based, or web-enhanced, activism into three categories: awareness/advocacy, organization/mobilization, and action/reaction. Awareness/Advocacy entail providing contrary information to raise awareness on a given issue, organizing the movement, and engaging in lobbying efforts; Organization/Mobilization may comprise of calling for offline action, and calling for offline action that maybe more effectively conducted through the internet; finally, Action/Reaction involves online attacks on various sites of interest by hackers or "hacktivists" (Vegh 2003).

Social media has facilitated the rise of a new form of activist known as the 'slactivist.' While this term is somewhat derisive, it aptly describes consumers who care for social causes but only up to a certain point of engagement and effort. These consumers will sign on-line petitions and join Facebook activist pages but do not have the desire, and/or resources to engage in traditional activism such as protests (Caplan 2009). We contend that Internet activists who influence slactivists to the point that they engage in real-life action ways create win-win situations. The consumers win in terms of garnering psychological well-being thorough their contributions towards societal welfare; the corporations win through being rewarded for their efforts to adopt socially responsible practices; the society at large benefits through these practices; and the activists win through achieving their goals of encouraging corporations to adopt socially responsible practices, thereby planting seeds for industry-wide changes. This win-win situation mirrors the latest AMA definition of marketing perfectly and illustrates the power of consumers in today's world. In this paper we focus on examining the way consumer activists, interested in forming cooperative relationships with firms, engage with other consumers using social media to influence their typical purchasing behaviors in order to create a win-win situation for all involved parties. Therefore, we explore Carrotmob, an online consumer activists' movement, which exemplifies cooperative consumer activism and word-of-mouth (WOM) activities facilitated by Internet and social media.

Carrotmob

Carrotmob, focusing upon fostering cooperation between consumers and corporations, are organized in cities across the US and the world. The organization hosts events that entail businesses competing to do the most social good (e.g., increasing energy efficiency, reducing carbon footprints or start recycling). Carrotmob is essentially a viral phenomenon that is spread through consumer word-of-mouth (WOM) through YouTube, Facebook, Twitter and the Carrotmob blog. Consumers register on Carrotmob's website, (www.carrotmob.org) and organizers send alerts (through email, blog, Twitter and Facebook) when a local store or firm adopts socially responsible practices. Carrotmobbers then mob the business or perform a "boycott" (Friedman 1996) and purchase products that they normally would en masse. In addition to their primary Facebook site with nearly 6,000 members, organizers create a new page for each town in which a mob is organized (e.g., carrotmob NYC, carrotmob Berlin, carrotmob Portland). As the company's website notes Carrotmob's master plan and "model is not threatening, not expensive, not time-consuming, not uncomfortable, not "radical," not confusing, and not negative." (www.carrotmob.org). Through engaging in friendly competition, the Carrotmob movements for specific locales generate new ideas, urge new cities to participate, and challenge existing movements to continue their efforts.

Method

The authors engage in netnography (Kozinets 2002), otherwise known as online ethnographic research (Maclaran and Catterall 2002) of the Carrotmob website, its blog and affiliated social media pages on Twitter and Facebook and other media coverage of their events. Both authors accessed the above social media cites and made individual field notes of their experiences, thoughts and ideas as they emerged from the member's interactions and commentaries before any comparisons were made in the analysis stage.

Discussion and Conclusion

Our data analysis illustrates how consumers use social media to transform consumer behavior to reward companies that choose engage in practices that benefit the society at large, for example green efforts focusing on benefiting the environment. We present a model of how contemporary social media drive consumer action through the power of viral marketing where consumer activists target other consumers.

Due to the widespread use of computers and the Internet, online consumer activists have the means to reach a wide range of fellow consumers through listservs, online communities, and even spam e-mails similar to Kozinets et al.'s (2010) *The Network Coproduction*

Model. However, the present research involves consumer activists, not outside marketers, marketing their own events to other consumers in the network. Consumers in the social media network become one-time participants in the events that generate excitement and, we contend, are of some psychological benefit to the participants. In response, companies who wins a bid for a mob event may promote their business as being “more green” to other consumers at a later stage.

We contend that the ever-rising popularity and access to the internet has given rise to this class of ‘casual’ activists. Thus, the key to effective consumer activism that targets the casual consumer is to propose action, on the consumers’ part, that does not require much effort. In addition, we posit that Carrotmobs essentially entail value co-creation. While consumers may not co-create an actual product, or a service, they contribute to co-creating the firm’s overall value chain proposition through the firm adopting greener practices that, for this consumer segment, adds value to products or services. In the bargain, these consumers change the industry as corporations compete to gain the carrotmobbers’ business realize that consumers are essentially rewarding them for adopting greener practices. This insight may encourage more firms to become green, thus contributing to changing industry practices, as they realize that socially responsible behavior can be profitable.

Source 2.0: Reading Source Cues in Online Communities

Catherine Coleman, Texas Christian University, USA

Marie-Agnès Parmentier, HEC Montreal, Canada

“Granted when he is actually playing basketball there maybe scowls on Lebron’s face but darn this is Vogue not Sports Illustrated! He should have been in a great suit.

You also have to keep in mind that Vogue has only had a handful of Black People on their covers in their 100 plus history so when they do it stands out. This is the reason why diversity is needed in the editorial rooms of these magazines that we enjoy so much. If I saw the proofs of those pictures I would have vetoed it right away. And maybe just maybe it wouldn’t kill Vogue and other fashion magazines to try models/actresses of different hues on their covers.

This is about perspective and the acknowledgement that loyal readers of this magazine have different perspective and that should be taken into account.

Vogue you are not alone in this. There’s plenty of blame out there.” (Style.com; March 27, 2008; online participant DcetStyle30)

The quotation above is from an online discussion of a controversial *Vogue* magazine cover that some critics deemed racist and derogatory. African American NBA player Lebron James and supermodel Gisele Bündchen are featured together to promote the magazine’s annual “shape” issue celebrating the human body. The controversy arose when an image was circulated online and in the media that juxtaposed the cover with a WWI propoganda poster for the U.S. Army featuring King Kong and its demsel in distress (see appendix). Claims that the two celebrities had re-enacted the essence of the poster and that the black athlete had been portrayed as a dangerous predator of the white woman brought up heated discussions amongst Internet forums posters. In this paper, we develop theoretical insight

on how consumers interpret and negotiate source cues both in relation to historical, experiential, and cultural knowledge they bring to the interpretation and in relation to their engagement with community and the development of shared meaning.

In basic communication models, the source is a person or organization with information to share. In advertising, a source can be the sponsor (i.e., a company or organization), the agency that authors the advertisement, or the persona within the text, often in the form of a spokesperson or model (Arens et al. 2009). The latter source, the spokesperson or model, has been a topic of great interest in scholarly works. To date, the advertising and marketing literatures have focused on experimental research perspectives derived from psychology (e.g., Micu et al. 2009; Bower and Landreth 2001; Kamins 1990; Petty et al. 1983). This stream of research emphasizes individual responses and attends to source characteristics such as credibility (expertise and trustworthiness) and attractiveness (similarity, familiarity and likeability).

While we acknowledge the valuable contributions these models have made, we heed the call of McCracken (1989), whose meaning model incorporates cues that include cultural codes such as gender, race and class and how they interact and inform people's interpretation of the advertisement. For example, if we take the instance described above and adopt the point of view of the source literature to date, we most likely would attend to elements of credibility and trustworthiness of the two celebrities. We would not, however, account for the complex and dynamic ways that audiences may attribute meaning to the celebrity based on their own cultural knowledge, such as historical and contemporary understanding of race, gender, sports, fashion, specific media vehicles, knowledge about celebrity personal and professional lives, and the ways in which these various factors may interact. A more encompassing view of advertising sources is needed because the source literature to date has yet to treat consumers as readers of ads (Scott 1994; Scott and Vargas 2007).

McCracken's model also implies that certain audiences share cultural codes and, because culture is not static, neither are shared meanings. Interpretation and negotiation of sources frequently happens at the collective level via the information, knowledge and opinions that people share. Consumer culture researchers have investigated the influence of interpretive communities in creating meaning in the consumer world (Arnould and Thompson 2005). However, there is still little theoretically and empirically informed insight into the collective reading of source cues. When McCracken developed his meaning model, the web 2.0 had not yet developed. We have found it timely to re-envision the source literature to accommodate more complex aspects of consumer engagement with meaning; with social media we now have the opportunity to observe these effects in sites such as online forums that extend beyond traditional boundaries of space and time. Our inductive, qualitative study thus draws on over 500 pages of netnographic data (Kozinets 2002) collected from two online communities, Foxsports.com and Style.com, following the controversy surrounding the infamous *Vogue* cover. This context is an ideal site to develop theory about how collectives read source cues. In brief, it is characterized by multiple layers of meaning, emerging from both the ad itself and from the dynamics between online posters who bring in their own knowledge and subjectivity.

The intended contribution of this paper is to extend the prior literature by examining interpretive practices of readers of ads in consumer collectives as they negotiate the dynamic interaction of various source cues. It posits that as readers engage in discussions with one another, interpretations of source cues do not remain static but evolve over short periods of time and shape further readings. Data analysis is ongoing but has already begun to illuminate the complex, socially constructed ways in which people engage with and create meaning through source cues. We find that various source cues move from the periphery to the center of the discussion, and back to the periphery again and so on, as readers negotiate interpretations of the cover and its sources' representations and intentions. For example, race, gender, celebrity meaning, intentionality of image encoding and media context move and develop in relation to the controversy and to audience articulation of subjectivity. We anticipate that our findings will further articulate contemporary reading of source cues and offer nuances of readings in consumer collectives.

Virtual Worlds: New Marketing Channels or Emperor's New Clothes? (Consumer Perceptions of Innovation in Product-oriented vs. Service-oriented Companies)

Sonja Propopec, ESSEC Business School, France

Lakshmi Goel, University of South Florida, USA

Abstract

We examine the impact of brand presence in virtual worlds on consumers' perceptions of brand innovativeness for product-oriented and service-oriented companies. Results from a pilot study show that the consumer's perception of innovativeness significantly decreases with brand presence in virtual world for product-oriented companies, but significantly increases for service-oriented companies.

Outline

Virtual worlds are increasingly gaining attention in popular media as well as academia (Nelson, 2007), and growth in the virtual worlds is now building at a more reasonable and sustainable level. For example, consumers are spending more time online, there is has been an increase in the revenues generated as well as in the number of interactions (McCormick, 2009). Second Life continues to be an active playground for brands and there are more than 1000 virtual worlds in production around the globe (McCormick, 2009).

Research on what constitutes a successful strategy for entering and operating in virtual worlds is still limited (Goel and Mousavidin, 2007). Previous research shows that virtual worlds differ from traditional websites along several dimensions in terms of their interface and user experience (Goel et al., 2009), warranting further investigation. To better understand the success of an entry strategy one could look at the change in consumer perceptions after visiting the virtual world store for the first time. More specifically, we examine how the brand presence in virtual worlds impacts consumer perceptions of brand innovativeness, a factor that has been shown as important (Christensen, 1997; Christensen and Raynor, 2003; Keller, 2003). Additionally, our research aims to examine whether consumers in virtual worlds perceive product-oriented and service-oriented companies differently.

Majority of the research in virtual words has until now focused on marketing of products (e.g. Goel and Prokopec, 2009; Hemp, 2006). However, with more and more service-oriented companies opening their stores in virtual worlds such as Second Life, it is important to examine whether the consumer perceptions change and if so, in which aspect does the change occur. Services are different from products because they are intangible, unique (heterogeneous) and co-produced with the customer (inseparable) (Anderson, Fornell, and

Rust, 1997). The production and consumption of service occurs simultaneously, whereas the production and consumption of products occurs sequentially. Furthermore, customers are often co-producers of the services they consume (e.g. social networking sites)(Prahalad and Ramaswamy, 2004). Inseparability means that consumers ultimately buy the organization's capabilities and expertise, not merely their immediate offers.

Intuitively, it might seem that presence in a new channel like virtual worlds would be perceived as being innovative. In our research, we propose to explore this line of thought. We argue that perceptions of innovativeness may depend on whether the company is product oriented, or service oriented. In product-oriented companies, a new channel may not yield benefits in terms of consumer perception since innovativeness may be tied to the actual product offering (e.g. a car), and not necessarily the channel (e.g. a dealership/ website). On the other hand, for service-oriented companies, due to the intangibility of the offering and the inseparability between the production and the consumption part of the offering, a consumer visiting the virtual world store (i.e. an university) is more likely to perceive the brand to be more innovative.

Thus we hypothesize:

H1: Virtual world brand presence will not impact the perceived level of innovativeness of product-oriented companies.

H2: Virtual world brand presence will positively impact the perceived level of innovativeness of service-oriented companies.

In order to measure the impact of virtual world brand presence, we plan to conduct an experiment that measures consumers' perceptions of innovativeness before and after they have visited the virtual world. Since there are several factors that need to be considered to ensure internal and external validity of such a study, we conducted a preliminary pilot to help guide our future data collection and analysis. We present details of our pilot next.

Pilot Study Methodology

Thirty-five subjects participated in the pilot study. The virtual world selected was Second Life (SL). None of the subjects had a SL avatar prior to the study, although they were very familiar with using computers, the Internet, and social networking sites.

A survey was administered to the subjects that asked questions pertaining to their perceptions of brand innovativeness. Of the four companies selected, Toyota¹ and Sony/BMG were considered representative of product-oriented companies, and Princeton and University of Southern California (USC) of service-oriented. The subjects were asked the question "Rate the brand on the level of innovativeness" for each of the four companies. Next, the subjects were asked to create SL avatars, and spend two weeks exploring the virtual world. After the subjects had completed their assignment, a second survey was administered with the same question for each of the four companies.

Preliminary Results

Given that $n=35$, we present our results with the caveat that this is intended to be a pilot study. Paired sample t-tests were conducted to measure differences between brand perceptions before and after the virtual world exposure. We find support for H2, i.e. perceptions of innovativeness increased for service-oriented companies (Princeton: $M_{PRE}=3.26$, $M_{POST}=4.11$, $p<.001$ and USC: $M_{PRE}=3.14$, $M_{POST}=3.14$, $p<.001$). However, for H1, we find that perceptions significantly decreased due to brand presence in virtual worlds for product-oriented companies (Sony/BMG: $M_{PRE}=4.26$, $M_{POST}=3.09$, $p<.001$ and Toyota: $M_{PRE}=4.2$, $M_{POST}=3.20$, $p<.001$). These results, though simple, have significant implications for companies that wish to leverage the new channel of virtual worlds. A significant negative change in perception of innovativeness may result in harming the brand image, rather than helping, and it might be better for such companies to steer clear of the virtual world channel. Though this study is focused on innovativeness, consumer focus, and brand quality were also measured as part of the pre-and post- tests. These factors also significantly dropped for product-oriented companies. However, service-oriented companies, such as universities, would benefit significantly from a presence in the virtual world channel.

Next Steps

The study presented is intended to spur a broad research agenda in virtual worlds that includes several brand perception dimensions. We are interested in how consumers react to the virtual world channel, thus providing practitioners with guidelines for entry strategies in virtual worlds. A wider range of product and service-oriented companies need to be sampled to represent different types of products and services (e.g. hedonic, utilitarian etc).

Social Production Of Medicine in a Virtual Health Community Organization

Handan Vicdan, Eastern Kentucky University, USA

Extended Abstract

This research explores new systems of marketing developing as a result of transformations in technology (Web 2.0), consumer/marketer value systems, forms of discourse and institutional roles. I aim to provide insights into developments in healthcare provision as systems that utilize social networking and engage in reconstitution of roles and relations in healthcare develop. I revisit previous theories of market relations to understand why/how new perspectives need to be incorporated into our frameworks. Scholars have articulated the structure of relationships between consumers and organizations in the market largely exhibiting dialectical processes: (1) Marketer/Consumer constitution in dominant/dominated dialectic (Peñaloza and Price 1993; Slater and Tonkiss 2001; Zwick et al. 2008), and (2) unidirectional provisioning and hierarchical relations that give control and primacy to the marketer (Firat and Dholakia 2006). These views rest mainly on modern conceptions of power including domination, confrontation (Venn 2007) and unilateral govern-mentality, and emphasize maximizing/normalizing discourses by marketers. Such discourses in healthcare include fear of loss of life, normalization of body and maximization of lifespan (Rose 2007), and make human body an object of one-way surveillance by a superior medical gaze (Foucault 1975).

I aim to discover new forms of organizing roles and relationships in healthcare through a non-participatory netnographic inquiry (Kozinets 2002) of a web-based Medicine 2.0 community organization, *patientslikeme.com* (PLM). PLM is a co-mediated market platform for real-time partnership among patients, physicians, pharmaceutical companies, healthcare researchers, and administrators of the website. PLM cultivates collaboration through proactive and complementary relations, intensifies connectedness among market actors, and contributes to social production of medicine. These relations seem to be qualitatively different from conventional market relations that treat organizations and consumers as distinct entities (Firat and Dholakia 2006; Peñaloza and Venkatesh 2006). Patients actively engage in real-time clinical research and generation of new medical knowledge, and determine their and others' care along with other market actors. I attract attention to the meso level institution(alization)s or legitimation processes that develop and maintain these new forms of interaction, make people become a part of these systems and enable their continued participation in sharing their private health data and experiences as a result of synergistic discourses among actors with an increasing appreciation for difference, and decreasing desire to contest, confront and establish supremacy. Findings are organized in two core themes: (1) provisioning diluted in healthcare through reorganization of business by PLM, and new roles patients and physicians/researchers adopt in this community, and (2) meso level dynamics of how actors relate to each other and maintain their participation in the market order constructed in PLM, and how these relations influence relations among market actors outside of the community. In doing so, sharing/privacy distinction will be articulated, forms of sharing in PLM—which encourage disclosure of private health information—will be exemplified, and the why and how of sharing/not sharing in this community will be explicated.

I reconsider Foucauldian notions of govern-mentality (1982) and biopower (1990) to articulate the theoretical/conceptual explanations of how and why such a system may be attracting patients and other healthcare actors and (re)organizing their relationships, and how their interest and participation in the system are maintained. I attract attention to the shift from government intervention to the multitude of diverse healthcare market actors in organizing sharing of private health information, and negotiating meanings of privacy/disclosure. PLM enables organized decentralization of private health data sharing, and mobilizes market actors as a non-state institution through non-dominating discursive regimes (Rose 2007) (e.g., hope based versus fear based culture, sharing/openness versus privacy, quality of life and personalization). Consumers are governed by and govern through different institutionalizations that produce discourses through which roles and relations are legitimized and institutionalized (Thompson 2004). Through institution(alization)s grown out of these new business models, community participants make decisions to share private health information and stay in the community, which emerge from mutual, non-linear, and multi-way negotiations. Govern-mentality increasingly takes multiple forms that may not be categorized as either top down (domination) or bottom-up (domination over consumers through constituting them as free subjects) (Zwick et al. 2008) perspectives. As we observe the abandonment of unidirectional provisioning and overly deterministic actions of marketers –prominent in dominant marketing approaches –, and the realization that consumers and marketers are both a part of a social system and a market system, reflecting the multifaceted and multilayered nature of organizing roles and governing relations among market actors in the world of social networking necessitate the theorization of govern-mentality in productive and meridian (Cova 2005, p.210) terms. PLM as a meso level institution also becomes the locus of legitimation in sharing and organizing private health information and generating medical knowledge, and contributes to (re)institutionalizing surveillance in healthcare through clinical research with and intensified multilevel connectedness among healthcare actors.

The Consequence of Screening Strategies on Decision Accuracy: The Roles of Perceived Uncertainty and Consideration Set Size

Rajani Genesh Pillai, North Dakota State University, USA

Xin He, University of Central Florida, USA

Raj Echambadi, University of Illinois at Urbana-Champaign, USA

Extended Abstract

Consumers screen from all available alternatives (Beach 1993) and consider a smaller subset of alternatives for further evaluation, called the consideration set (Bettman 1979; Nedungadi 1990). Two types of screening strategies are commonly utilized by consumers to form consideration sets: an *exclusion (rejection) strategy* wherein alternatives not worthy of further consideration are eliminated and an *inclusion (choice) strategy* wherein worthy alternatives are included into the consideration set (Shafir 1993; Yaniv and Schul 1997; 2000). Despite the understanding that an important motivation for consumers to engage in screening is to search and choose the best option (Beach 1993; Beach and Mitchell 1990), there is limited understanding of the consequences of the screening strategy on decision quality. This paper attempts to fill the void by investigating how screening strategies impact decision quality as well as the factors that moderate this relationship.

Two outcomes of using the screening strategy that have been investigated are the number of alternatives considered (consideration set size) and the accuracy of the decision (Heller, Levin, and Goransson 2002; Levin et al. 2001; Yaniv and Schul 1997, 2000). Evidence for the impact of the screening strategy on the size of consideration set is robust, such that sets created by exclusion screening strategy are significantly larger than those created by inclusion (Heller et al. 2002; Levin et al. 2001; Yaniv and Schul 1997, 2000). However, there is little consensus about the impact of the screening strategy on decision quality. Past studies demonstrated that consideration sets created by exclusion strategy are more accurate, but only when the consideration set size is not taken into account. Accuracy in these studies was defined by the outcome of the screening strategy itself (i.e. the percentage of sets that contain the correct answer) which is different from the accuracy of the final choice. In addition, existing research does not consider a wide range of contingent factors that might influence the screening strategy—decision accuracy relationship. In this paper, we focus on the accuracy of the final choice because it is the ultimate performance criterion of the screen strategy employed. We contend that, the accuracy of the decision should be analyzed in terms of the ability of the screening strategy to improve the likelihood of making a good decision, depending on both perceived uncertainty and consideration set size.

Consumers frequently experience varying levels of uncertainty while making choices (Hansen 1976; Kahn and Sarin 1988). We argue that highly uncertain consumers who use inclusion screening strategy make more accurate decisions and consumers with low perceived uncertainty are better off using exclusion screening strategy. We draw upon the literature on decision making to suggest that screening by inclusion involves greater search for information (Levin, Huneke, and Jasper 2000). Greater search intensity of the inclusion strategy would facilitate highly uncertain consumers to improve decision accuracy by helping to clarify their preferences. Conversely, it would distract consumers with low perceived uncertainty from making accurate decision because more information encountered during search will dilute their true preferences. Because search intensity of a screening strategy depends on consideration set size, we further argue for an interesting reversal of this interactive effect when consideration set sizes are varied. Since exclusion screening strategy involves greater search than inclusion strategy when forming larger consideration sets, we predict that highly uncertain consumers are better off using exclusion screening strategy in such context while consumers with low perceived uncertainty make better decisions using inclusion screening strategy.

Empirical Study

We conducted an experimental study ($n=130$) using an actual choice task that followed a 2 (perceived uncertainty: high or low) x 2 (screening strategy: inclusion or exclusion) x 2 (consideration set size: high or low) design. In this study, perceived uncertainty was measured whereas screening strategy and consideration set size were manipulated. Following Creyer, Bettman, and Payne (1990), the measure of decision accuracy is derived by comparing the weighted additive value of the chosen alternative to that of the best and worst alternatives in the set. Consistent with our predictions, there was a significant three-way interaction among screening strategies, perceived uncertainty, and consideration set size on decision accuracy ($F(1,122)=8.34, p<.01$). Initial results were directionally supportive for our predictions under smaller consideration sets (such that participants with low perceived uncertainty made slightly more accurate decisions with exclusion strategy while participants with high perceived uncertainty made slightly more accurate decisions using inclusion strategy) although the effects failed to reach statistical significance. More importantly, the pattern of results was reversed when participants formed larger consideration sets. Those with low perceived uncertainty made higher quality decisions with inclusion as compared to exclusion screening strategy when forming larger consideration sets. On the other hand, participants with high perceived uncertainty made more accurate decision with exclusion as compared to inclusion screening strategy and both mean comparisons were significant. Thus, results were generally supportive of our predictions as indicated by a significant three-way interaction, although the effects under large consideration sets seem to be stronger than those under small consideration sets.

Discussion

This paper seeks to address the issue of decision accuracy of screening strategies, given the perceived uncertainty consumers experience during the choice process. Further, it also highlights the important moderating role played by consideration set size on the interactive relationship between perceived uncertainty and screening strategy on decision accuracy. Drawing upon literature in consumer decision making, we show that, the process benefits of information search and learning that are obtained by choosing and applying the right screening strategy can greatly enhance the quality of decisions. This paper contributes to our understanding regarding the consequence of using the screening strategies. Decision accuracy is an important outcome of the decision making process and has huge public policy and consumer welfare implications. For instance, this research highlights that consumers could make suboptimal choices through the use of a wrong screening strategy. Such suboptimal choices can have seriously negative and long lasting consequences in various situations like medical decision making, financial and investment decision making, and partner selection that are rife with uncertainty.

The Influence of Assortment Size on Preference-Consistent Choice

Maarten Elen, Ghent University, Belgium

Ineke Uytersprot, University College Ghent, Belgium

Maggie Geuens, Ghent University and Vlerick Leuven Gent Management School, Belgium

Iris Vermeir, Ghent University, Belgium

Extended Abstract

Decades of research on the effects of variety and assortment size have focused on the affective and motivational consequences of having personal choice (Iyengar, & Lepper, 2000). Providing consumers with choice has been linked to increases in perceived control, task performance and life satisfaction (Iyengar, & Lepper, 2000). When choosing from a large number of options, the likelihood that decision makers will be successful in finding an option that matches their preferences, increases (Chernev, 2003; Iyengar, & Lepper, 2000). Large assortments also help people satisfy their needs for variety, whether the reason for seeking variety simply reflects some desire for change or having multiple needs to satisfy (Hermann, & Heitmann, 2006).

While much of the earlier work on variety provided support for the notion that more variety is better, a growing body of research suggests that more variety does not always lead to better choices. Research on the choice overload hypothesis suggests that having much choice can initially seem desirable, but prove to be demotivating in the end (Iyengar, & Lepper, 2000). Choosing from larger assortments demands a greater amount of cognitive effort from the decision maker and increases choice difficulty (Chernev, & Hamilton, 2009). An increased number of options to choose from has also been associated with greater anticipation of post-decisional regret (Hermann, & Heitmann, 2006; Sela, Berger, & Liu, 2009). These cognitive and emotional costs of decision-making out of large assortments have been shown to lead consumers to defer decision, choose the default option or to simply not choose at all (Iyengar, & Lepper, 2000; Sela et al., 2009; Scheibehenne, Greifeneder, & Todd, 2009).

Both positive and negative consequences of assortment size on choice difficulty, choice likelihood and satisfaction are thus well-documented. Studies assessing the impact of assortment size on the option people actually choose are limited.

In this study we will examine how assortment size influences the choice of the preferred option and preference-consistent behavior. We argue that assortment size can have an important influence on preference-consistent choice. More specifically, we suggest that in small assortments; where making a choice is less difficult and results from a deliberative decision-making process (Hermann, Heitmann, Morgan, Henneberg, & Landwehr, 2009), people might not always choose their preferred option, even if this option is available. To support this claim, we integrate two research streams; assortment size and deliberation.

Studies on the influence of assortment size on decision-making processes have shown that as the complexity of making choices rises, people tend to simplify their decision-making process by relying on simple heuristics (Iyengar, & Lepper, 2000; Hermann et al., 2009). Therefore, we suggest that when choosing from larger assortments consumers will rely on readily available “cues”, whereas in small assortments they will evaluate the alternatives and compare and contrast different attributes before making a choice. Recent research has demonstrated that this kind of conscious thought and deliberation can have an influence on people’s judgments and preferences, often reducing the consistency of preferences over time (Dijksterhuis en Nordgren, 2006; Nordgren & Dijksterhuis, 2009).

As heuristics are often used in decision-making in large assortments, we hypothesize that when the most preferred option is available in a choice set, this option will be chosen in case of a large assortment. Consumers will use their initial positive evaluation of this option as a cue to select it. When choosing from a small assortment, the deliberative decision-making process might lead consumers to focus on attributes of the attitude object that seem like plausible causes of the evaluation but were not weighted heavily before (Nordgren, & Dijksterhuis, 2009), resulting in less preference-consistent choices.

The experiment examining this prediction comprised two stages. In the first stage, participants’ preferences for twenty different ice cream flavors were measured. They were asked to rank their top six from a menu of twenty flavors (e.g. vanilla, pistachio, strawberry, ...), and rate every flavor on a 7-item scale ranging from “totally unfavorable” to “totally favorable”. After this preference-measure task, respondents participated in an unrelated study of about 45 minutes to divert attention from the current study. In the second stage, participants were informed that they could win a bucket of ice cream and were asked which flavor they wanted if they would win. The assortment they could choose from consisted of either six (i.e. small assortment) or twenty (i.e. large assortment) different ice cream flavors. The latter assortment consisted of all twenty initial flavors, while the former assortment consisted only of the top six ice cream flavors they ranked earlier. Thus, participants’ top six flavors were presented in both the large and the small assortment. This was done to enhance comparability between choices from both assortments.

In order to test our hypothesis regarding the effect of assortment size on preference-choice consistency, we first calculated whether there was a match between the participants’ preferences in the first stage and their choice in the last stage. Thus, for each subject, we calculated whether their choice was consistent with the option they had ranked at the top in the first stage. This comprised the dependent measure of the study.

Next, we looked at the influence of assortment size on the preference-choice consistency. Chi-square analysis revealed a significant effect. Significantly more subjects were consistent in the large assortment condition (67.1%) than in the small assortment condition (52.4% %) ($\chi^2(1)=3.853$, $p<.05$). Thus, this result supports our hypothesis.

Our results seem to indicate that as the variety of options to choose from decreases, the likelihood of choosing the most preferred option decreases as well—supposedly confirming the idea that, in terms of preference-choice consistency, more is indeed better. However, we propose that in other situations, preference-inconsistent choices will be more likely in large than small assortments. Specifically, we hypothesize that when readily available cues favor a less-preferred option, the likelihood of this option being chosen over the most-preferred option increases. Several experiments are being set up to investigate this prediction.

Investigating the Strength of Affectively and Cognitively Based Attitudes

Ineke Uyttersprot, Ghent University, Belgium

Iris Vermeir, Ghent University, Belgium

Maggie Geuens, Ghent University and Vlerick Leuven Gent Management, Belgium

Extended abstract

Attitude strength is often defined in terms of four characterizing features which strong attitudes are thought to possess. That is, strong attitudes are said to be persistent over time, more resistant to attack, more influential of information processing and more predictive of judgments and behavior (Krosnick & Petty, 1995). Affective attitudes are supposed to be stronger than cognitively based ones (Giner-Sorolla, 2001) because empirical evidence shows that attitudes based on emotions tend to resist cognitive persuasion appeals, whereas attitudes based on cognitive beliefs do not resist affective appeals, and affective attitudes appear to be more stable over time.

Several studies exploring the accessibility of affect-based attitudes compared to cognition-based ones tend to support this supposition. Accessibility has been indicated as one of the strength-related dimensions of attitudes, with highly accessible attitudes being stronger than less accessible ones (Fazio, 1995). Responses to affective evaluations have been shown to be formed more quickly than responses to cognitive evaluations (Huskinson & Haddock, 2006; Verplanken, Hofstee & Janssen, 1998), possibly indicating that evaluations based on emotions and feelings are more accessible in memory than evaluations based on cognitive beliefs. Giner-Sorolla (2001) also found an accessibility advantage of affective over cognitive base, but only when attitudes were more extreme; when attitudes were less extreme, affective attitudes tended to be expressed more slowly, whereas cognitive attitudes were expressed faster (Giner-Sorolla, 2001). In some situations then, cognitively based attitudes seemingly are stronger than affectively based attitudes.

Accessibility, however, is not the only attitudinal variable proposed as a measure of attitude strength; several other dimensions have been identified as well, such as certainty, knowledge, importance, extremity, ... (Krosnick, Boninger, Chuang, Berent & Carnot, 1993; Visser, Bizer & Krosnick, 2006). Yet, besides accessibility, none of these strength-related dimensions has been examined in relation to the structural base of attitudes.

In this study we take a look at two other strength-related dimensions, certainty and knowledge, and explore whether affectively versus cognitively based attitudes differ on these dimensions. We hypothesize that cognitively based attitudes are held with more certainty and more subjective knowledge, since some of the main antecedents of attitude certainty are made up of cognitive factors such as the amount, clarity and consistency of the information available (Gross, Holtz & Miller, 1995). Further, the amount of cognitive elaboration of attitude-relevant information has been proposed as a determinant of attitude certainty, mediated by subjective perceptions of knowledge (Smith, Fabrigar, Macdougall, & Wiesenthal, 2008). Since cognitions about an attitude object are believed to be formed based on deliberative and controlled information processing, whereas affective reactions are formed in a relatively automatic manner without much deliberate elaboration (Shiv, & Fedorikhin, 1999), a certainty and knowledge advantage for attitudes based on cognitive beliefs over attitudes based on affective reactions is proposed.

To investigate the level of certainty and amount of subjective knowledge associated with affectively versus cognitively based attitudes, an experiment was conducted. We manipulated the structural base of participants' attitude toward a fictional animal by exposing them to either an affective or cognitive passage about the animal (see Fabrigar & Petty, 1999). The affective passage described a person's encounter with the animal and was designed to evoke positive emotions about the animal. The passage designed to induce a cognitive attitude contained positive information about the same fictitious animal and was presented as an excerpt from an encyclopedia of marine life. Following the attitude base manipulation, participants were asked to complete the measures of attitude, affect and cognition validated by Crites et al. (1994). Next, attitude certainty and subjective knowledge were assessed.

In order to investigate whether the attitude formation manipulation resulted in affective and cognitive attitudes, we tested whether attitude-affect and attitude-cognition consistency differed across both formation conditions. This was done by computing two discrepancy scores, obtained by calculating the absolute value of the difference between the attitude score on the one hand and the affect and cognition

score on the other hand. High consistency between the attitudinal base and the overall attitude is indicated by small numbers on these discrepancy scores.

A 2 (attitude-affect discrepancy vs. attitude-cognition discrepancy) \times 2 (affective attitude formation condition vs. cognitive attitude formation condition) mixed-design ANOVA indicated that we were successful in creating affectively or cognitively based attitudes, since the predicted crossover interaction between type of discrepancy score and attitude formation condition was obtained, $F(1,118)=9.134$, $p<.01$. In the affective formation condition the affective discrepancy scores ($M=.53$) were significantly smaller than the cognitive discrepancy scores ($M=.76$), $t(59)=3.605$, $p<.01$; whereas in the cognitive formation condition a nonsignificant tendency for cognitive discrepancy scores ($M=.41$) to be smaller than affective discrepancy scores ($M=.51$) was obtained, $t(59)$, $p=.374$.

To assess the difference between affective and cognitive attitudes concerning attitude certainty and subjective knowledge, an Independent Samples T-test was conducted with attitude basis as the independent variable. Both for certainty, $t(109)=-2.599$, $p<.05$, and subjective knowledge, $t(109)=-3.845$, $p<.001$, a significant effect of attitude basis was found. Cognitive attitudes were both held with greater certainty ($M=5.13$) as well as associated with greater subjective knowledge ($M=2.95$) than affective attitudes (respectively $M=4.57$ and $M=2.00$), thus supporting our hypothesis.

Based on these results we can conclude that, contrary to previous research where affectively based attitudes seemingly are stronger than cognitively based attitudes when accessibility was used as a strength measure, cognitively based attitudes appear to be stronger than affectively based ones in terms of certainty and knowledge. These results provide useful insights in light of future studies. Possible research entails to explore which type of persuasive appeal, cognitive or affective, is most suitable to create strong attitudes.

When More is Merrier Indeed: The Impact of Product Involvement on Choice

Maria Aladjem, VU University Amsterdam, The Netherlands

Ulf Böckenholt, McGill University, Canada and Northwestern University, USA

Extended Abstract

Although generally extensive assortments are believed to benefit consumers, more recent research has highlighted the negative consequences of large assortments. Notably, research on the "More-is-Less" effect (Iyengar and Lepper 2000, Chernev 2003) established that extensive assortments can hinder choice and lower choice satisfaction. These adverse consequences are often explained with the decision difficulty consumers experience when choosing from extensive (as opposed to limited) choice sets. However, a recent meta-analysis (Scheibehenne, Greifender and Todd, forthcoming) invites a discussion on the generality of the "More-is-Less" effect since multiple studies failed to replicate the adverse effects of large assortments on choice satisfaction (Scheibehenne, Greifender and Todd 2009). Clearly, there is a need for a deeper understanding of the possible effects of extensive assortments on consumer choice and a thorough investigation of possible moderator variables and boundary conditions of the More-is-Less effect.

This work argues that choice from extensive assortments can trigger multiple sources of experiential information that affect choice satisfaction. Thus, going beyond experienced difficulty, we show that intrinsic pleasure from exploring the choice options can increase

choice satisfaction and lead participants to be more satisfied when choosing from a larger assortment size. We refer to this finding as the “More-is-Merrier” effect. The involvement level of a consumer is an important moderator variable for this effect: Larger assortments can lead to greater choice-process difficulty and thus reduce the choice satisfaction of consumers with low levels of product involvement. In contrast, consumers with high levels of involvement experience choosing from the same large assortments as more enjoyable and report greater choice satisfaction. Perhaps similar to baseball fans enjoying recalling arcane statistics or splitting hairs over particular teams, high-involved consumers enjoy exploring and comparing options and are—if at all—to a much smaller degree affected by the difficulty of a choice task than low-involved consumers.

Experiment 1 examined whether choice-set size would differentially affect the choice satisfaction of consumers with different levels of product involvement. Based on a large-scale online pretest, we selected participants with high and low levels of involvement with night clubs based on the Personal Involvement Inventory (Zaichkowsky 1994). Several weeks later, the same participants were randomly assigned to one of two conditions with either a limited (6) or an extensive (16) choice set of night clubs and were instructed to choose a night club for a company party paid for by the firm. Care was taken to ensure that not the composition of the choice sets, but their size would be the underlying reason for the ease or the difficulty of the choice task. As predicted, we found that high-involved consumers liked better their choice after choosing from the extensive choice set and that this effect was mediated by involvement-induced task enjoyment measured by a three-item scale. Conversely, low-involved consumers liked better their choice when choosing from the limited choice set and this effect was mediated by experienced difficulty, in agreement with previous findings on the More-is-Less effect (Iyengar and Lepper 2000, Chernev 2003). Importantly, perceived variety in the choice sets and experienced difficulty were both found to increase significantly with choice set size and not to vary across involvement conditions.

The objectives of Experiment 2 were two-fold: First, the experiment was designed to test the sensitivity of high- and low-involved consumers to choice task difficulty in their judgment of choice satisfaction. For this purpose, we introduced a default option in the choice task that was expected to lower choice task difficulty and hence to increase the choice satisfaction of low-involved consumers. For high-involved consumers we expected no effect of the default option on choice satisfaction. Second, we selected a customization task to demonstrate that choice-option exploration can trigger task difficulty for low-involved consumers and enjoyment for high-involved consumers.

Participants were asked to customize a weekend trip, consisting of multiple choices among hotels, restaurants and activities. For each choice, we provided a default option in the low-difficulty condition. As in Study 1, we conducted a large-scale pretest to identify respondents’ involvement levels with planning and going on trips. Several weeks later, high- and low-involvement participants were invited to the lab and asked to customize a hypothetical complementary weekend escape for two in a popular winter resort. As predicted, we found that although the presence of a default option in a self-customization task reduced significantly the perceived difficulty of the task, it increased satisfaction with the customized offer only among respondents with low levels of involvement. Further, the exploration of the choice option mediated the effect of task enjoyment on choice satisfaction for high-involved respondents.

Study 3 considered temporal distance as a moderator variable of task-induced enjoyment. High-involvement participants were asked to plan their weekend trip—as in Study 2—but with the additional instruction that the trip would take place a year later. We predicted and found that this temporal distance manipulation both reduced significantly the exploration of choice alternatives and lowered experienced enjoyment: Compared to participants of Study 2 who did not have to wait for the trip to take place, participants of Study 3 reported significantly lower choice satisfaction with their customized weekend trip.

In sum, the contributions of this research are three-fold. First, the findings point to the importance of affective consequences of involvement, in addition to the motivational and cognitive ones considered in the Elaboration Likelihood Model (Petty et al. 2005, Petty and Cacioppo 1990). Critically, it demonstrates that unlike task-unrelated affect (Bless et al. 1990), task-related affect increases the depth with which people explore and compare choice options. Experienced difficulty has no adverse effects on choice satisfaction. Second, this work adds to the literature on the More-is-Less effect by showing that involvement is an important moderator of this effect. Finally, this work is also of clear importance to practitioners since it demonstrates the need for differentiation of marketing strategies for consumers with high and low levels of involvement with a product category.

Should Variety Seeking Be Measured at the SKU, Brand, or Category Level? Does It Matter

Marina Girju, University of Texas at Dallas, USA
B. P. S. Murthi, University of Texas at Dallas, USA

In a two-week period, the average US consumer snacks 32 times on 17 different brands coming from 4.5 different snack categories, e.g. salty, sweet, salsa/dips, fuel, grain and non-macro (fruits, vegetables). She switches among the brands 29 times and among the categories 22 times. Virtually no brand is eaten twice in a row and only 1.5 brands are from the same category. Thus, the US consumer seeks high variety in her snack consumption. Past research has focused on only one form of variety-seeking, usually at the brand level. In this research, we offer a comprehensive view of individual variety-seeking behavior in the snacks market, in which we associate consumer variety-seeking behavior at the SKU, brand, and category levels. We seek to understand the correlations between the different types of variety-seeking and study the effect of demographic, psychographic, environment (location), and consumption factors (needs, time of day/week, activity) on different types of variety-seeking.

Extensive consumer behavior and empirical marketing literature provides a benchmark of variety-seeking models and findings (Khan 1995, McAlister & Pessemer 1982). More recent research shows that variety-seeking is more likely to occur on taste than on brand (Inman 2001) or when consumers derive greater hedonic characteristics from the product category (Van Trijp, Hoyer and Inman 1996). However, past research had several restrictions. It looked at variety-seeking as a trade-off between flavor and brand (Inman 2001, 2008). It analyzed single product categories, e.g. potato chips (Maier et al. 2007) and considered variety-seeking at the brand level. Variety-seeking research that is based on scanner data explains variety-seeking at the household level, not the individual level. Last, it did not explain how variety-seeking changes over time, around holidays or seasons. Our proposed research circumvents these restrictions. We focus on consumption patterns at the individual level, thus, avoid the aggregation bias in studies of household demand. We measure variety-seeking across the entire US snack market, and get a better view on consumers' overall snacking behavior and their consumption trade-offs when switching among brands/categories. The length of our study (2004-2009) allows us to show how variety-seeking evolved and how consumers seek more variety in some categories at the expense of others. Using over 80 variables of consumption, we can explain how variety-seeking changes with time of day (Roehm and Roehm 2004) or week, location, activity, needs, social occasion (Ratner and Kahn 2002).

To analyze variety-seeking in snacking for the whole US population, we rely on an extensive dataset monitoring the entire snacking behavior of 30,000 consumers located across the US. The respondents, chosen randomly, are weighted on six demographic variables that ensure a nationally representative sample. They self-report their snack consumption over 2-week periods and provide demographics and other personal information, such as weight/height, physical activity levels, household size, age, gender, race, marital status, income, etc. At each snack occasion, the panelist also records the consumption details: time of day/week, location, consumed on its own or with food or drinks, in public/private, needs (e.g. good to eat with others, to relax) and the activity the consumer was doing during the consumption (shopping, watching TV, socializing) etc. Each consumer reports the exact brand-flavor consumed by choosing from a list of 900 snacks ranging from leading brands (Pringles, Hersheys, etc) to regional and private label. Using the industry's market structure, these brands are further categorized into 60 subcategories (potato chips, gum, salsa) and 6 snack categories (salty, sweet, accompaniments, fuel, grain, non-macro). Thus, this comprehensive dataset allows us to create a detailed map of the whole US snack market and to understand the overall snack consumption not only at the individual consumer level but also aggregated for the whole US population.

We use several measures of variety-seeking at the brand, subcategory, and category level and employ a model with a linear system of equations to understand and paint a comprehensive picture of overall variety-seeking in US snack consumption. First, we draw on the previous research literature and quantify variety-seeking as 1.) number of unique brands consumed, and 2.) number of switches among the brands consumed. Second, accounting for the brands' dissimilarity, we perform the analysis not only at the brand level, but also at the subcategory and category level, e.g. when a consumer snacks on Lays, Orbit, and Hersheys, we record 3 different brands, 3 subcategories (potato chips, gum, candy) and 2 different snack categories (salty, sweet). Third, due to high correlation among the variety-seeking measures either within or across categories, and endogeneity, we use system of equations analysis to understand what factors explain variety-seeking. We model the different measures of variety-seeking at the brand and category levels, within and across categories as dependent variables, regressed on 80-140 independent variables: demographics, psychographics, situational factors, seasonality, trend in consumption. With high R-squares (60%-80%), the models fit the data well and give a comprehensive understanding of the factors that explain variety-seeking.

Some of the research questions we asked and the partial results we obtained are:

1. The correlation between brand and category level variety-seeking is high but not for all individuals.
2. What consumption factors impact VS?—An interesting finding is that doing sports and shopping/running errands decreases variety-seeking.
3. How do demographics influence VS?—Heavier and older people switch less on brands; Men snack on fewer brands/categories and switch less; Hispanics seek more variety. Less educated consumers are high variety-seekers.
4. Is variety-seeking seasonal?—Overall, variety-seeking does not change throughout the year, but consumers seek more salty variety in the Fall and more non-macro variety in the Summer and Fall. Some holidays also impact variety-seeking positively, e.g. Valentine, Halloween for sweets.

The research seeks to understand the big picture idea "Should variety-seeking be studied at the category, brand or SKU level?" How do different measures of variety-seeking change if the analysis is done at different levels of variety-seeking? What is the magnitude of correlation between the different types of variety-seeking? This is the first research study that offers a comprehensive map of brand and within-across category variety-seeking for snacks for the whole US population.

Leaky Preferences: Fluency Effects in Perception and Choice

Mark Schneider, University of Connecticut, USA

Keys and Schwartz (2007) have argued that "psychological processes that affect decisions may be said also to "leak" into one's experience." Perhaps analogously, the ease of certain computational tasks may leak into one's perception of the content that is being processed. That is, certain stimuli or environmental features may be preferred *because* they are easier to process. We will refer to this hypothesis as the "leaky preferences" assumption.

The leaky preferences assumption can be applied to both abstract and concrete stimuli, with different implications. When applied to abstract stimuli, the assumption predicts consumers to systematically share a set of aesthetic preferences for features such as symmetry, consistency, straightness, similarity, simplicity, familiarity, and certainty. Each of these environmental features serves to reduce the processing load and aids in the efficient compression of information.

It should be noted that the "leaky preferences" assumption is an instance of a more general fluency effect. Research which varies the ease or difficulty of reading certain fonts, or of searching for information from memory, for instance, can lead people to make attribution errors, generally favoring stimuli which can be processed with a greater degree of fluency. Oppenheimer (2008) notes, that "Fluency—the subjective experience of ease or difficulty associated with completing a mental task- has been shown to be an influential cue in a wide array of judgments. . . . Fluency impacts whether information is represented in working memory and what aspects of that information are attended to." In applying the "leaky preferences" assumption we are proposing that certain environmental features are routinely processed with high degrees of fluency, and thus these stimuli are generally preferred.

The leaky preferences assumption may also operate on a more concrete level. Specifically, we propose that when no available option in a choice assortment is clearly superior to the others (and hence, preference uncertainty is high) people will base their decision on effort-reduction factors rather than on the content of the choice. That is, when appeal to preference is uninformative, people choose the option which simplifies the decision process. We will call this tendency, the *choice-simplicity heuristic*.

In the standard dual-process framework (e.g. Kahneman and Frederick, 2002), consumers are postulated to have two families of cognitive processes- one that is relatively automatic, affective, and intuitive (System 1) and the other that is more effortful, deliberative, and logical (System 2). In our view, the choice-simplicity heuristic applies to both cognitive systems. When System 2 is dominant (and preference uncertainty is high), the choice simplicity heuristic selects the option which simplifies the decision process *by calculation*. Likewise, when System 1 is dominant, the choice simplicity heuristic selects the option which simplifies the decision process *by affect*. In both cases, the decision process can be simplified by attending to certain cues in the choice environment.

Seemingly irrelevant contextual cues (i.e. features of the choice environment which do not relate to the content of the choices being considered), can nevertheless simplify the decision process. For instance, we can simplify the decision process for System 2 by selecting the option which involves the least tradeoffs. Selecting the option which minimizes tradeoffs *between products* leads to variety seeking behavior (Simonson, 1990). Similarly, selecting the option which minimizes tradeoffs *between attributes* leads to the compromise effect (Simonson, 1989; Simonson and Tversky, 1992). This approach significantly simplifies the calculations and deliberations in the choice process.

The choice-simplicity heuristic suggests that people often look for simplifying cues in the choice environment to aid them in the decision process. In particular, consumers may consider objective cues (such as the presence of a default option), perceptual cues (such as the recognition that one option dominates another), affective cues (such as a positive affective response toward a stimulus) or cognitive cues (such as minimizing the need to make tradeoffs). This perspective suggests that extremeness seeking, endowment effects, and asymmetric dominance effects are under the purview of system 1 since the (objective, perceptual, and affective) cues which generate

these effects are relatively automatic. Similarly, we would suspect that variety seeking and compromise effects result from System 2 processing since making tradeoffs is a more deliberative activity. This hypothesis gains some support in recent work (e.g. Bettman et al. (2008), Pocheptsova et al. (2009)).

Overall, the leaky preferences assumption may serve to integrate aspects of computational efficiency (ease of processing), aesthetic preferences (easily processed abstract stimuli), and difficult choices (easily processed concrete stimuli), into a basic model of perception, preference, and choice. At the abstract level, this assumption provides a simple framework for identifying potentially universal aesthetic preferences, and determining how these preferences are related. At a more concrete level, the leaky preferences assumption suggests that in the face of preference uncertainty, consumers may select an option simply because the structure of the choice environment makes that option easier to process. This leads to the choice simplicity heuristic which, in turn, can account for some notable behavioral anomalies.

Choice Under Pressure: Perverse Outcomes of Enhanced Familiarity Preference

Ab Litt, Stanford University, USA
 Taly Reich, Stanford University, USA
 Senia Maymin, Stanford University, USA
 Baba Shiv, Stanford University, USA

Extended Abstract

Consumers often have to evaluate options and make decisions under time pressure, which can affect these behaviors in diverse and important ways (Chowdhury et al., 2009; Nowlis, 1995). Extensively documented in both animal research (Griebel et al. 1993; Heinrichs & Koob, 1992; Shephard & Estall, 1984) and cases such as preferences for "comfort foods" (Kandiah et al., 2006) is that pressure of various forms increases preferences for familiar stimuli and options. Familiarity signals safety, which gains heightened importance and appeal under stress. Similarly, in a converse case, happy moods can eliminate preferences for familiar stimuli by independently signaling safety (de Vries et al., 2010).

Sometimes, however, a familiar option is also the most *disaligned* with the very source of one's felt pressure. Imagine that you drive the same route to work every day, along a frequently congested highway. You know of a likely quicker route involving various side-streets, but have only taken it a few times. When you're running late and have a big meeting to make, the pressure to arrive on-time, by magnifying the attractiveness of taking the familiar but longer route, may make it *more* likely that you'll be late. Similarly, time pressure may increase a consumer's willingness to wait for their "usual" option (such as a regularly called cab driver, but who is ten minutes away) and foregoing other, more immediately available alternatives.

Of course, it is not that these familiar options are guaranteed to have worse outcomes: an unfamiliar driving-route might take longer if you get lost; an unfamiliar cab driver may drive slowly, get lost, or choose a bad route. But even with no objective evidence for these possibilities, pressure may increase worry over their prospect and conversely enhance the "warm glow" of safety associated with a familiar option, even if evidence suggests it is a worse choice.

Study Method. We tested such counterposing of familiarity and communicated option-characteristics in the case of selection between task options for completion under time pressure. In part 1 of the experiment, participants ($n=145$, from a national pool) encountered ancillary biographical information about a pictured person (name, birthday, number of siblings, hometown, etc.). In the second part, they were told that, if they solved a word-puzzle task correctly, they would be entered into a prize-drawing. In the *No-Pressure* condition, participants were told they could take as long as they wished to complete the task. In the *Time-Pressure* condition, they were told they would have at most four minutes to complete the task.

Participants were offered a choice between two puzzle-task options: one listed as having two passages of text to work through, and the other listed as having three. The only other information provided about these options was the name of the person who created each of them. In the *Both-Unfamiliar* condition, neither of these individuals had been encountered in the experiment. In the *Longer-Familiar*

condition, the person associated with the three-passage option was the same one for whom participants encountered irrelevant biographical information in part 1 of the experiment. Crossing the pressure and familiarity manipulations, we explored how time pressure affected preferences for seemingly longer but incidentally familiar options.

Results. Cross-tabulations yielded significant differences in task-choice between the four cells ($\chi^2(3)=12.25, p<.01$). As hypothesized, time pressure increased choice of the three-passage (i.e., objectively longer-seeming) option when it was associated with a familiar person, in comparison to when both options were associated with unfamiliar people ($p<.01$), and also compared to both No-Pressure cases, regardless of whether a familiar option was given ($p<.05$). Thus, time pressure enhanced familiarity bias, even when objective information indicated the familiar choice would actually take longer, and when the shorter option was preferred in the absence of any familiarity difference between options.

We also queried several process measures after the primary experimental sections that support our results. In both No-Pressure conditions and the Time-Pressure/Both-Unfamiliar condition, concern prior to the puzzle task about finishing in time was significantly correlated with choosing the *two*-passage task ($r's>.43$), whereas in the Time-Pressure/Longer-Familiar case, this concern significantly correlated with choice of the *three*-passage task ($r=.34$). In contrast, perceived stress and pressure *during* the task was greater amongst those who chose the three-passage task, regardless of associated familiarity. Thus, despite their preference for the familiar option, individuals under time pressure choosing the longer task did not experience less stress or find the task less difficult.

As evidence for the bases of familiar-option preferences, under time pressure, choosing the longer task was correlated with higher risk aversion, as measured by lower minimum sure-gains preferred to a 95% chance to win \$100 ($r=-.29$). In both Longer-Familiar conditions, choice of this longer option correlated with beliefs (for which no objective evidence existed) that this task would be easier ($r's>.35$) and give a greater chance of success ($r's>.30$), and also with beliefs that this choice was less risky ($r's>.34$) and fit better with one's "gut feeling" about the best choice to make ($r's>.50$).

Ongoing Work and Extensions. In follow-up investigations we are exploring familiarity established through *negative* experiences, such as unpleasant interpersonal encounters. Whereas such familiarity commonly leads to biases *against* associated stimuli (Lewicki, 1986), our results suggest perceived pressure may reverse this preference. As well, we are exploring non-time forms of stress, such as performance pressure, and cases where objective evidence indicates familiar options are again more likely to aggravate such pressure.

Conclusions. Results indicate that not only does pressure magnify the attractiveness of familiar choice options, it can do so even when such options are contrary to the very source of the pressure one feels. These results are driven by heightened perceptions of safety and comfort with familiar options, even when objective evidence disfavors them. Consumers may thus make perversely distorted choices when available alternatives differ in their perceived familiarity, and objectively superior choices when choice-sets are limited to unfamiliar options.

When Ambivalence Increases Attitude-Behavior Correspondence

Lifeng Yang, Ohio State University, USA

H. Rao Unnava, Ohio State University, USA

Much of the past research has focused on the consequences of attitudinal ambivalence in terms of reduced attitude-behavior consistency, and the antecedents of ambivalence (Priester et al, 1996; Conner et al, 2002; Cavazza et al, 2008). There has not been much attention devoted to studying *conditions under which attitudes may be predictive of behavior even when they are held with high ambivalence*. The objective of this research therefore is to study ambivalent individuals' attitude-behavior correspondence under conditions where one's positive (negative) reactions are made more (less) diagnostic at the time of choice. We use different levels of mood to manipulate individual's perceived diagnosticity of their initial reactions toward the attitudinal object. We argue that when individuals are put in a happy mood, they would perceive mood congruent (thus positive) aspects the product as of being more diagnostic; however when individuals are put in a sad mood, they would perceive mood congruent (thus negative) aspects of the product to be more diagnostic. The perception of reaction diagnosticity is believed to act as the key role determining whether an individual is more or less likely to behavior according to their attitude.

Theoretical Conceptualization

Attitudinal ambivalence is characterized by a person experiencing both positive and negative reactions to an object. Dominant reactions are those that are greater in number, whether positive or negative; Conflicting reactions, on the other hand, are those that are fewer in number, and are opposite in valence with the dominant reactions (Priester et al., 1996; Priester & Petty, 2001; Priester, Petty & Park, 2007). The idea that ambivalence is linked separately in memory to positive and negative components is important because it suggests that a different attitudinal reaction emerges depending on which of the components is activated in memory (e.g., Petty & Briñol, 2009). In normal conditions, if people hold a positive attitude without ambivalence, it is expected that primarily the positive reactions would come to their mind whenever they think about the attitudinal object. However, if individuals have ambivalence in their attitude, even though their overall evaluation of the attitudinal object is one-directional, the encountering of the object may invoke both positive and negative reactions within these individuals. Whether ambivalent individuals' choice consistent with their overall attitude would depend on which reactions are perceived to be more diagnostic at the moment.

Thus, while ambivalent attitudes are characterized by positive and negative components of the attitude being retrieved simultaneously, they may experience a hard time making up their mind for decisions. At this time, the mood one is in may serve as the trigger for spreading activations of the positive aspects of the attitudinal object. Ambivalent individuals may have an easier time retrieving the positive (negative) associations about the attitudinal object when they are in a happy (sad) mood. The easier retrieval of the positive (negative) associations may increase the perceived diagnosticity of the retrieved associations thus affects the later behavior.

Explicitly, we predict that:

H₁: For highly ambivalent attitudes, being in a happy (sad) mood will affect choice to be more (less) consistent with the positive component of the attitude while being in a neutral mood will make the choice to be less consistent with the positive component of the attitude.

H₂: For attitudes held with low ambivalence, being in a happy (sad) mood will affect choice no differently from being in a neutral mood, in terms of consistency between the positive (negative) component of an attitude and choice.

Methods & Results

We conducted a 2 (low vs. high ambivalence) X 3 (happy vs. neutral vs. sad mood) study to test our hypotheses above. We randomly assigned subjects to different mood induction conditions then had them responded to a choice question of either a free order of French fries or a free order of parfait as reward for the participation of the study. The attitudinal object of the study was Wendy's French fries. Subjects for the study all hold an overall positive attitude toward French fries (attitude scores >6 in a 9-point scale where 1=extremely negative and 9=extremely positive). Among all, sixty of these individuals hold a positive but low ambivalent attitude toward French fries ($M_{attitude}=6.85, SD=1.04; M_{ambivalence}=3.73, SD=.69$); and the other seventy four participants hold a positive but high ambivalent attitude toward French fries ($M_{attitude}=6.63, SD=.88; M_{ambivalence}=6.81, SD=.99$). Subjects from the low vs. high ambivalent groups were significantly different in ambivalence ($F(1, 132)=418.057, p<.000$) but they did not differ much in their attitude or attitude extremity toward French fries ($F(1, 132)=1.723, p>.192 NS$).

Our hypotheses call for an interaction between mood and ambivalence such that choice probabilities of French fries are unaffected by mood in the low ambivalence conditions, but affected positively in the happy mood condition and negatively in the sad mood condition. In other words, while choice probabilities are about equal in four experimental conditions (low ambivalence neutral, happy and sad mood conditions; and high ambivalence neutral mood condition), there would be an increase (decrease) in the choice probability of French fries in the happy (sad) mood, high ambivalence condition(s).

For the whole sample, 66.4 % of the participants (89 out of 134) chose French fries with the rest of the sample choosing Parfait. Overall, individuals' attitude toward French fries was positively correlated with their choice ($r=.22, p<.01$). The fact that more than 50% of the participants choosing French fries was not surprising but was predicted because all participants chosen for this study had indicated that they had an overall positive attitude toward French fries ($M=6.73$ in a 9-point scale where "1" = very negative "9" = very positive). Choice probabilities for French fries do not vary much for the low ambivalent groups ($\beta=-.158, p>.68$) (

$F P obability_{Low+neutral} = 8.6\%$ $F P obability_{Low+sad} = 7.9\%$ $F P obability_{Low+happy} = 6.1\%$
 p for each pair-comparison all >.60). However, attitude consists with behavior the most likely for those the high ambivalent

individuals in happy mood condition ($F P obability_{High+happy} = 9.7\%$, $F P obability_{High+neutral} = 6.8\%$,

$F P obability_{High+sad} = 8.7\%$).

Consistent with past literature pertaining that ambivalent attitudes are less predictive of behavior than less ambivalent attitudes, we find in this research that individuals who hold a positive but less ambivalent attitude toward French fries to show a more stable attitude-behavior correspondence than those who hold a positive but high ambivalent attitude. Further, individuals with less ambivalent attitude should tend to choose toward French fries regardless of what mood condition they are in. In contrast, high ambivalent individuals would have a more fluctuated behavior pattern in choosing for French fries because of the existence of conflicting reactions, and that the conflicting reactions can be perceived as deterministically diagnostic if they are made salient to them.

It's More Likely...But Can It Be Worth It? Perceived Similarity, Probability and Outcome Value

Hui-Yun Chen, Virginia Tech, USA
Elise Chandon Ince, Virginia Tech, USA

Extended Abstract

Individuals are prone to developing naïve theories about the likelihood of event occurrences because what is reckoned to happen determines their subsequent judgments and actions. Prior research suggests that intuitive probability judgments are susceptible to extraneous cues such as descriptions of the event (Tversky and Koehler 1994), the representativeness or availability of exemplars (Kahneman, Slovic, and Tversky 1982), moods (Wright and Bower 1992), and cognitive orientation (Wakslak and Trope 2009). In this research, we propose that individuals employ an extraneous cue, perceived similarity, to infer the probability of an event, and in turn, use the probability judgment to evaluate the impact level of the event.

In order to understand, evaluate, and predict the outside world, individuals are motivated to develop naïve theories from cumulated life experiences (Stevens 2000) or knowledge (Springer 1995). For most daily life cases, the proximity to the target person and the likelihood of event occurrence are highly correlated. For example, sharing a living space with someone with a cold makes us more likely to get sick. Another common example is that individuals who have a family history of heart disease are high in risk as well because of genetic factors. Recently, research on probability judgment has also shown that lottery participants estimate their chance of winning as higher when the winner of previous round is similar to them than when the former winner is dissimilar (Laporte and Laurent 2009). Thus we posit that individuals build from the observations and experiences of such events the naïve theory that they are more prone to experience events that strike their close others than events that strike unknown individuals. Moreover, even though this naïve theory facilitates and leads to correct judgments in general, it does lead to inflated likelihood when people infer higher probabilities from proximities that are irrelevant.

Intuitive probability judgments in turn affect individuals' judgments of the target event. For example, increasing individuals' perceptions of their own risk leads to more favorable attitudes and intentions toward practicing HIV precautionary behaviors (Raghubir 1998). However, we argue that probability judgments would undercut the perceived impact level of events in situations where the outcome of an event is ambiguous or unknown. That is, when the information about event outcome is absent, event probability serves as indirect information and signals the impact level of events. Previous research has shown that limited, scarce resources are deemed more desirable (Inman, Peter, and Raghubir 1997; Lynn 1992). Drawing on this logic, we further hypothesize that the inflated probability judgment based on perceived proximity would downplay perceived impact level of the event. In other words, an event that is related to a similar individual will appear more likely to occur, which in turn, will render the event less impactful.

Two studies tested the present predictions. Study 1 investigated the influence of probability information on perceived impact level. Participants read scenarios about winning a store gift card in a store lottery and getting a flight upgrade on a trip and then judged the outcome values. We manipulated the probability of each event (70%, 30%, and 5%). The dependent variable was the outcome value (i.e., value of the store gift card and value of the flight upgrade). The results confirmed our hypothesis. When the event is of lowest likelihood (5%), the highest outcome value estimation was achieved. Furthermore, the estimated outcome value decreased as the event probability increased.

Study 2 directly tested whether embedding a similar social cue (vs. dissimilar) in the description of events (winning a store gift card in a lottery and getting a flight upgrade on a trip) would construe the events to be more likely to occur, and the inflated probability would subsequently decrease the perceived impact level of the events. Participants were asked to read scenarios that contained different social cues (e.g., a friend or a stranger) and then rated the likelihood that the events would occur to them and how long the effect of events would last. As expected, we found that the presence of a similar social cue leads to a higher probability judgment. Furthermore, probability judgments negatively predicted the number of days participants believed the positive effect would last.

Probabilities are often difficult to assess objectively, and research has indicated various cues employed to infer probabilities. The present studies suggest that perceived proximity acts as such a cue. Specifically, our initial findings demonstrate that probability judgments may be biased by the presence of social cues because individuals make probability inferences from perceived proximity to the

target person. In addition, the probability judgment itself serves as a cue when the information about the event outcome is ambiguous, and thus affects the perceived impact level of an event. When an event is judged as more likely to occur due to perceived proximity, it is also judged as less impactful.

Consumers Do Compare Apples with Oranges: Investigating Cross Category Referencing in Consumer Decision-making

Vanessa Patrick, University of Houston, USA

Weixing Ma, University of Houston, USA

Apples have a golden skin or red without and white within. An orange has a tangy rind and a color that is distinct. Unless you have an axe to grind or some other devious design then I would say that the differences are like night and day. - Anonymous

Prior research has demonstrated that consumers use references to facilitate decision-making. The literature examined consumer's reliance on reference points with comparable attributes within a product category (Rajendran and Tellis 1994; Rosch 1975). The current research aims to reveal that consumers often rely on a previous purchase from a different, often unrelated product category in order to justify a current purchase decision.

Literature

Consumers usually need various strategies to make/justify a purchase decision. In classical economics, a consumer's decision is derived from her preferences for competing alternatives, as revealed by the indifference curve given a budget constraint. Little attention has been devoted to the formation of such indifference curve due to the subjective nature of preferences (Georgescu-Roegen 1936; Hauer and Urban 1986). Marketing scholars, especially consumer behavior researchers, have been dedicated to explore such subjectivity of consumers' preferences.

Prior research focused on *how* consumers discover their own preferences through various decision-making strategies or tactics, for instance, framing (Kahneman and Tversky 1984), anchoring (Strack and Mussweiler 1997; Tversky and Kahneman 1974), and relying on a reference (Rosch 1975; Rajendran and Tellis 1994; Huber et al. 2008). Notably this research stream focuses on the comparison between products or attributes that are closely related or comparable, for example, different brands or different prices, respectively, within a given product category.

Recent research also acknowledged the possible influence of unrelated or cross-category products on consumer decision-making: for instance, the shopping momentum phenomenon (Dhar et al. 2007), the devaluation effect (Brendl et al. 2003), and the role of incidentally activated shopping goals (Chartrand et al. 2008). In these studies, unrelated or cross category purchases or products emerge as situational/environmental influences or consumer mindsets, rather than as references consumers actively use to evaluate a focal purchase decision.

The current research aims to broaden the view of reference by investigating situations in which consumers refer to an unrelated (cross-category) product as a reference to make a current purchase decision. We present a theory of "motivated anchoring" to understand (1) when consumers rely on cross-category referencing, (2) its impact on consumer decision-making, and (3) its underlying mechanism.

Cross Category Reference in Consumer Decision-making

The literature on motivated reasoning has studied how people's motivational states can influence their perceptions and judgments (Kunda 1990). We present a theory of "motivated anchoring" to understand how a consumer may use seemingly incomparable references to help her justify a highly (less) desired target product as being more (less) worthy of purchase.

We argue that when a consumer desires to own a product, this form of biased evaluation will justify the purchase. In other words, a consumer driven by her desire for the target product is motivated to retrieve a cross category reference that helps justify her purchase

decision and ease the pain of paying the price. Consider the following: a consumer is debating whether she should buy another pair of designer shoes. She then thinks about the tax she “gives away” to the government every year. Suddenly, the price of the shoes is no longer hefty and in fact, is very reasonable for such gorgeous shoes. Similarly, “motivated anchoring” can also justify *not* making a purchase.

Empirical Investigation

We already conducted an exploratory critical incident analysis and one experiment. Additional studies are underway.

Eighty-eight undergraduate students participated in the critical incident survey. We collected open-ended data of participants' experience of using cross category references in their decision-making. The survey provided ample evidence for the phenomenon. Coding of the open-ended data revealed the following key findings: 1) consumers were more likely to use cross-category references to help make/justify purchase decisions of discretionary and hedonic products, 2) most references were at a similar price range as the target product, and 3) individuals were more likely to rely on a less expensive unrelated (cross-category) reference to justify a spontaneous purchase.

Next, we conducted an experiment to demonstrate how different references can have different impact on consumers' decisions. We propose that a negative reference which emphasizes negative utility upon consumption such as medical expense and tax payment will make consumers increase their subjective evaluation of the utility of the target product and downplay its cost, and hence, they are more likely to purchase the target product. On the other hand, a positive reference which focuses on the pleasure of consumption such as a wonderful dinner at one's favorite restaurant will make the current target product appear to be more costly and less enjoyable, and therefore a less attractive purchase option.

We recruited 150 real world consumers to participate in a between-subjects experiment in which the nature of a reference product (negative vs. positive) was manipulated. We measured its impact on consumers willingness to select from a set of vacation options that varied from being very expensive (hedonic), moderately expensive, cheap to forgoing the vacation. The results reveal that participants who were exposed to a negative reference (paying tax) were more likely to choose the most expensive vacation plan compared to participants exposed to the positive reference (purchase of an electronic product; 36.4% vs. 20%, $p < .05$). The positive reference was more likely to induce the choice of the compromise option compared to the negative reference (49.1% vs. 34.5%, $p < .05$).

We aim to contribute to the literature in the following ways: 1) establish the impact of an unrelated purchase on consumer decision-making, 2) present and test a theory of motivated anchoring to illustrate how consumers use unrelated products from different product categories to view a target product as more or less desirable and worthy of purchase, and, 3) to identify managerial and public policy implications that stem from these findings.

Should You Kill Two Birds with One Stone?

The Diluting Influence of Having Multiple Goals on Goal Pursuit

Weixing Ma, University of Houston, USA

Vanessa Patrick, University of Houston, USA

One man; two loves. No good ever comes of that. -----Euripides, Greece

People are often engaged in a single activity which serves multiple goals simultaneously. Intuitively, we applaud the efficiency of “killing two birds with one stone”. But is “more” necessarily better? This research aims to demonstrate the dilution effect of multiple goals on the effort level exerted through a single activity. Moreover, we investigate this, keeping in mind the between-goal relationships, by asking: Are all goals created “equal”? Does the commitment to one goal strengthen or undermine the attention to other goals? This research seeks answers to these questions, and discovers the structure of these multiple goals and their relationship with the single means.

Literature

Goals constitute the focal points around which human behavior is organized (Fishbach and Ferguson 1996). Prior literature on goals has examined the cognitive, affective, interactive and dynamic perspectives of goal related phenomena and mechanisms. The recently developed goal system theory explored the cognitive perspective of goals and their related means (Bargh et al. 2001; Kruglanski et al. 2002; Shah and Kruglanski 2003; Fishbach et al. 2003; Fishbach et al. 2004). Successful goal attainment typically results in positive affect (Dweck and Leggett 1988; Carver and Scheier 1990). Conversely, such affect may be transferred to its cognitively associated means (Fishbach et al. 2004). The research which focused on the interactive and dynamic aspects of goals has explored three configurations of multiple goals: multiple goals of similar centrality (Shah and Kruglanski 2002), different centrality and the effect of multiple goals on a sequence of actions that unfold over time (Fishbach and Ferguson 1996).

The same dilution effect of multiple goals served by a single means was previously examined by Zhang, Fishbach and Kruglanski (2007), but from a different vantage point than the current research. In their study (Zhang et al. 2007), the dilution effect was observed only through the perceived instrumentality of a shared goal-means path, where goal distinctiveness and perceived means-goal associative strength were considered as mediating factors.

The current research aims to tap into the interplay and dynamics between affect and cognition in the multiple goals-single means relationship. Specifically, we not only replicate the dilution effect of multiple goals (Zhang et al. 2007) on the shared single means, but aim to uncover a unique mechanism that leads to the dilution effect.

Theory and Hypotheses

We first propose a general construct of ‘goal-means linkage’, which is the general indicator for the relationship between a goal and a single means that serves the goal. Then we explore the major facets of this general construct, namely, cognitive, affective, dynamic, and interactive, which compose the second level refined constructs for the general “goal-means linkage”: goal momentum (dynamic and interactive), goal valence (affective), and goal instrumentality (cognitive).

We then investigate how such cognitive, affective, interactive and dynamic aspects of the multiple goals have impact on the efforts exerted through their shared single means. Furthermore, we examine what happens to the effort level when the number of the goals served by a means increases. We propose the following key hypotheses: (1) when multiple goals are served by a single means, as the number of the goals increases, the effort level exerted through the means decreases. This is the dilution effect in the multiple goals-single means setting. (2) A goal of higher momentum is likely to result in the exertion of greater effort (3) A goal of positive valence is likely to exert more effort than the goals of negative valence, and, (4) A goal with higher perceived instrumentality is likely to exert more effort through the single means.

Studies

We have conducted two preliminary studies. The first was a survey in order to develop the scales for the constructs and examine the multiple goals-single means relationship. Next, we conducted a study using donation-to-a-charity as the decision-making context to test the basic proposition: Does increasing number of identified goals lead to increased dilution (lower donation)?

In the survey, we first gave the participants some examples of people engaging in a single activity in order to achieve more than just one goal. Participants were then asked to recall similar multiple goals-single means situations which they have experienced in the past. After they wrote down the single means and all the goals served by this means, they were instructed to rate each goal-means pair on a seven-point semantic differential scale on the following: effectiveness, measurability, pleasantness, importance, urgency, uniqueness, and attentiveness. Each variable was followed by a brief description and a detailed example. The descriptions and examples were pretested to ensure clarity of instruction. Seventy-eight undergraduate students participated in the survey. Three constructs were refined through exploratory factor analysis of the survey data: (1) *goal momentum* as measured by importance, urgency, uniqueness, and attentiveness, (2) *goal instrumentality* as measured by effectiveness and measurability, and (3) *goal valence* as measured by pleasantness. Confirmatory factor analysis was conducted to assess the convergent and discriminate validity of these constructs. The survey data also supported the four hypotheses on goal structure and the dilution effect.

Next an experiment was conducted using a charity donation decision-making context, in which participants identified the goal(s) they would like to achieve via their charitable donation, and then determined the amount they would like to donate. The data indicated that as the number of goals increased, individuals tended to donate significantly less money ($\beta = -21.1$, $p = .015$).

The preliminary results are promising and a set of experiments are planned to further develop this research. We expect to have completed a comprehensive set of studies by ACR.

Summary

This research aims to contribute to the literature on the multiple goals-single means setting in the following ways: (1) we demonstrate that goals are not created equal in terms of their momentum, instrumentality and valence; (2) more goals are not necessarily better in terms of the effort level they exert through the shared single means.

How Goals Affect the Impact of Product Attributes on Product Evaluation: The Role of Attribute Ability, Goal Activation and Goal-Product Fit

Na Xiao, Queen's University, Canada

Laurence Ashworth, Queen's University, Canada

Extended Abstract

Understanding how consumers evaluate products is a central topic in marketing research. Most approaches focus on the way in which consumers use information about specific features of the product to reach an overall judgment. Some research focuses on the way consumers *compare* attributes across products (e.g. Bettman, Luce and Payne, 2008), while other research examines how consumers *combine* attribute information (e.g. Cohen, Fishbein and Ahtola, 1972). Still other research focuses on the way consumers *process* arguments (e.g. information about attributes; e.g. Chen and Chaiken, 1999). While each approach is clearly important, very little work examines what makes particular attributes important to consumers in the first place.

The current work adopts the broad perspective that product attributes are important to the extent that they can fulfill consumers' activated goals. Product evaluation involves judging the "goodness" or "usefulness" of a product, which implicitly involves references to consumers' underlying goals. This is consistent with the perspective that objects, more generally, are evaluated as good or bad depending on their ability to help meet or hinder individuals' goals (Markman and Brendl 2000).

This leads to a number of specific predictions about the way in which goals and attributes are likely to jointly impact product evaluation. First, attributes related to goals should be more likely to impact product evaluation. Specifically, the better able the attribute is perceived to fulfill the activated goal, the more positive the product evaluation. There is some evidence consistent with this in the satisfaction literature. Garbarino and Johnson (2001) found that consumers were more satisfied with a theatre performance when it fulfilled the particular goals they held (e.g. cultural enrichment versus relaxation). Moreover, this effect should be moderated by the activation of the goal (i.e., whether it occupies consumers' thoughts)—this means that the ability of an attribute to fulfill a goal should have a greater impact on overall product evaluation when the goal is activated than not. We test this idea in our first study.

Second, while activated goals might render relevant attributes more important to the overall evaluation of the product, not all goals are likely to be relevant to all products. In fact, some products are likely to be viewed as unlikely candidates for fulfilling certain goals. For example, consumers rarely seem to consider the environmental impact of the wine they purchase, or whether or not the tea they drink comes from fair trade sources. Yet many consumers fret about the environmental impact of the bottles their water comes in and frequently consider whether their coffee is fairly traded. In short, certain products are likely to "fit" well with certain goals, and poorly with others. If the product and goal do not fit, then attributes relevant to that goal should be unlikely to exert an important influence on the overall evaluation, even when the goal is important. We test this idea in our second study. Specifically, we attempt to manipulate the extent to which consumers perceive a "fit" between a particular product and goal, as well as the ability of the product to fulfill that goal.

Study 1

One hundred and thirty-nine students participated in a 2 (Attribute Ability: Low vs. High) x 2 (Goal Activation: Yes vs. No) between-subjects factorial design. Students were presented with information for a brand of coffee that, among other attributes, was said to contain either 5% (low ability) or 75% (high ability) fair trade beans. Goal activation was manipulated in an article ostensibly from an online coffee guide that participants read prior to product evaluation. Both articles were identical except for a short addition in the Goal Activation condition that mentioned fair trade could bring many benefits to coffee farmers. Participants then completed thought listings (i.e. to measure goal activation) and measures of their evaluation of the coffee. Examination of the thoughts listings showed that participants generated more thoughts related to the fair trade in the Goal Activation conditions ($X^2(136)=4.53, p<.05$). Consistent with our predictions, a significant Attribute Ability x Goal Activation interaction ($F(1, 135)=5.59, p<.05$) indicated that the effect of attribute ability on product evaluation was more pronounced when the goal was activated (goal activated: $M_s=3.69$ vs. 5.06; $F(1, 135)=21.72, p<.05$; goal not activated: $M_s=4.20$ vs. 4.58; $F(1, 135)=1.72, p>.1$).

Study 2

One hundred and twenty-one students participated in a 2 (Attribute Ability: Low vs. High) x 2 (Goal-Product Fit: Low vs. High) between-subjects factorial design. Participants saw information about a pair of binoculars that, among other attributes, contained information about the lens material. Half of the participants were told that the lenses were made from optical eco-glass (a lead and arsenic free product) (high ability to fulfill environmental goals). The remaining participants were told simply that the lenses were constructed out of optical glass (low ability to fulfill environmental goals). Goal-product fit was manipulated in an article, ostensibly from an online binocular guide, that participants read prior to product evaluation. The article was identical in each condition except for a short addition in the High Goal-Product Fit conditions that mentioned binoculars, as with all products, are associated with certain environmental impact. A significant Attribute Ability x Goal-Product Fit interaction ($F(1, 117)=5.13, p<.05$) indicated that High Ability led to more favorable product attitudes when Goal-Product Fit was high ($M_s=5.23$ vs. $4.30; F(1, 117)=6.22, p<.05$), but not when it was low ($M_s=5.13$ vs. $5.41; F<1$).

To summarize, existing work shows that individual product attributes contribute to its overall evaluation, but little work addresses the question of what makes particular attributes important to consumers. The current work demonstrates that the importance of individual attributes depends, in part, on the extent to which they can fulfill activated consumer goals. Our research further contributes to this literature by making specific predictions about the way in which goals influence the role of attributes in product evaluation. First, goals that are activated were more likely to strengthen the impact of goal-relevant attributes on product evaluation. When a goal not activated, the ability of the attribute to fulfill the goal had little effect on product evaluation. Second, for goals to influence the impact of attributes on product evaluation there needs to be a perceived fit with the product. That is, products should be seen as appropriate means to fulfill particular goals if relevant attributes are to impact the overall evaluation of the product. Consistent with this, good performance on an attribute was more likely to result in more favorable product attitudes when goal-product fit was high.

The Rebound of the Forgone Alternative

Zachary Arens, University of Maryland, USA
Rebecca Hamilton, University of Maryland, USA

Consumers often face choices requiring a trade-off between valued alternatives. Consider a consumer who wants to purchase a relaxing massage as well as a new pair of sneakers for exercising. Looking in her wallet, she finds that she only has enough money for one of these purchases. After difficult consideration, she decides to purchase the massage and forgo the sneakers. In this research, we examine what happens to her desire for the forgone alternative, the sneakers, after she has chosen and consumed the massage.

There are two bodies of literature that offer conflicting predictions as to the fate of the forgone alternative. The free choice paradigm suggests that consumers derogate the value of forgone alternative relative to the value of the chosen alternative. This spreading-of-alternatives effect is based on cognitive dissonance theory, which argues that dissonance is created by focusing on the positive attributes of the forgone alternative and negative attributes of the chosen one (Brehm 1956; Festinger 1957). Thus, consumers alter their attitudes towards these alternatives postchoice to support their choice behavior. In the first demonstration of this effect, Brehm (1956) asked participants to rank the desirability of a variety of small gift items (e.g., a toaster, coffee-maker, art book) and then choose between two products to take home as a thank-you gift. After participants made their choices, Brehm re-measured the desirability of each item and found that when the choice produced dissonance (i.e., the choice set alternatives were both highly valued) the desirability of the selected alternative increased but the forgone alternative decreased.

However, research on motivation suggests a different outcome. It proposes that the forgone alternative will remain desirable regardless of the choice. In other words, choosing one alternative does not deactivate the goal associated with the forgone alternatives and thus, goal instrumental objects should remain desirable (Markman and Brendl 2000).

This research seeks to reconcile these two views by demonstrating that both are correct depending on the stage in the consumption process. Once a choice has been made, potential distractions, such as the forgone alternative, are automatically devalued to help ensure effective action toward achieving the chosen alternative (Brendl, Markman, and Messner 2003; Harmon-Jones and Harmon-Jones 2002). After the action is complete (i.e., the chosen alternative is consumed), though, the desirability of the forgone alternative will rebound. Specifically, we predict that *after choice but prior to consumption* consumers will derogate the desirability of the forgone alternative relative to the desirability of the chosen alternative, in accordance with the cognitive dissonance paradigm. However, *after consumption*, consumers will enhance the desirability of the forgone alternative but derogate the desirability of the chosen alternative. In short, the value of the forgone alternative will rebound.

Our first study sought to replicate the free choice paradigm and show that after consuming the chosen alternative, the desirability of the forgone alternative rebounds. Participants read short descriptions of the eight questionnaire topics (fashion, restaurants, movies, vacations, music, cell phones, beverages and books) and rated how much they would like to complete each questionnaire. Based on these ratings, participants were asked to choose between two of these alternatives. Those in the high dissonance condition chose between two highly desirable alternatives, while those in the low dissonance condition chose between a highly desirable and a less desirable alternative. Half of the participants then re-rated all eight alternatives before completing the questionnaire (postchoice-preconsumption stage), while the other half re-rated them after completing it (postconsumption stage). The results replicated the free choice paradigm, showing that in the high dissonance condition, the desirability of the forgone alternative declined from the prechoice stage to the postchoice-preconsumption stage in comparison to the chosen alternative. Supporting our predictions, however, the desirability of the forgone alternative rebounded after participants completed the chosen questionnaire.

The second study used a similar procedure which involved rating nine different activities, making a choice between two and then re-rating the activities. However, this study sought to demonstrate that the rebound effect was moderated by whether the forgone and chosen alternatives were substitutes. The substitutability of the choice set was manipulated by varying the similarity of the other activities in the rated set. While the alternatives in the choice set always involved viewing photographs of wild animals (e.g., gorillas, penguins), the other activities were either similar (e.g., viewing photographs of kangaroos, bison) or dissimilar (e.g., reading a news article about Asia, playing a math puzzle game). Thus, by comparison, the forgone appeared to be a non-substitute or a substitute for the chosen alternative, respectively. As expected, when the forgone did not appear to substitute for the chosen alternative, the desirability of the forgone alternative decreased in the postchoice-preconsumption stage, but not in the postconsumption stage, replicating the findings of the first study. However, when the forgone alternative was viewed as a substitute for the chosen alternative, the desirability of the forgone and chosen alternatives exhibited the same pattern: they decreased in desirability in the postconsumption stage but not in the postchoice-preconsumption stage.

Our second study also ruled out regret and option attachment (Carmon, Wertenbroch, and Zeelenberg 2003) as alternative explanations. Regret did not differ by condition, nor did it correlate with desirability of the forgone alternative, suggesting that it does not explain the results. Option attachment, which was manipulated by having participants list three reasons why they would enjoy viewing the photographs in the choice set, did not affect the change in the desirability of the forgone alternative across consumption stages, suggesting that it is not an alternative explanation.

These studies reconcile earlier work on cognitive dissonance with later work on goals by demonstrating that consumers' attitudes towards a forgone alternative vary with the stage in the consumption process. Our results suggest that consumers will be unlikely to purchase a forgone alternative until their chosen alternative has been consumed, at which time their motivation to obtain the forgone alternative rebounds. As the familiar adage suggests, timing is everything.

The Impact of Negative Information on Perceptions of Own Country Products: A New Perspective on Country of Origin and its Influence on Consumer Behavior

Rania Semaan, Baruch College, USA

Chen-Ho, Baruch College, USA

Andreas Grein, Baruch College, USA

Extended Abstract

Country of origin (COO) research has examined how consumers evaluate products and make purchasing decisions based on their perceptions of country image. Country of origin refers to "information pertaining to where a product is made" (Zhang, 1996: 51). Negative country images cause consumers to evaluate products from that country poorly (Han & Terpstra, 1988). Although useful, the existing evidence of country of origin and country image effects on product evaluations is somehow limited. Researchers have mainly studied *foreign* consumers' product evaluations and purchase intentions relative to negative country image. To the best of our knowledge, the literature has overlooked *domestic* consumers' perception of their own products relative to their own country's negative image.

An interesting example occurred in summer 2007, when Mattel announced massive recalls of toys manufactured in China, due to lead contamination (in the paint) and small parts which could be accidentally swallowed by children resulting in creating a negative image to China (Anonymous, 2007). Not only was this an international trade conflict event, but also, it occurred at the same time as

Chinese consumers' preferences were shifting towards Chinese products over foreign-made products (Dyer, 2007). And so contrary to the evidence provided by previous literature and to conventional wisdom, in China's case a negative country image resulted in a positive evaluation of products.

In this research, we aim at investigating how consumers' preferences change when confronted with negative information about their *own country's* products.

Social Identity Theory argues that groups become part of the self affecting thoughts, feelings, and behavior (Tjafel & Turner, 1986). Moreover, strong emotions can develop as a result of group memberships (Smith, Seger, and Mackie 2007), for example anger when a source of information from outside the group presents negative information about the group. Intergroup Emotions Theory (Mackie, Devos & Smith, 2000; Mackie & Smith 1998) states that when an individual acquires in-group social and emotional significance, events that intrude on the in-group are appraised for their emotional relevance, just like events that occur in an individual's personal life (Smith & Henry 1996). Further, Anger has been shown to be elicited when social identity is threatened (Yzerbyt et al. 2003). Building on Social Identity Theory and Intergroup Emotions Theory, we propose that exposure to own country negative information increases the level of anger and the willingness to buy domestic products.

Study 1

The objective of study one is to investigate the main effect of negative information on domestic consumers' willingness to buy products of their own country. Chinese subjects living in China were recruited for this study based on Hofstede's (1980) intercultural dimensions such as collectivism and individualism. For example, a person is seen as a separate entity in individualist societies, whereas the person's identity is defined as part of a larger group in collectivist societies.

Method: Undergraduate Chinese students participated in this study. Nagashima (1970) has shown that highly ethnocentric consumers may prefer products from their own country. Specifically, Chinese consumers' ethnocentrism was positively correlated to favorable attitudes towards domestic products (Wang and Zou 2003). Moreover, country of origin effects may be exacerbated if other countries may engage or have engaged in military, political or economic acts which a consumer finds difficult to tolerate and hence may cause animosity towards the offending country's products (Klein *et al.*, 1998). Therefore, First participants filled out the ethnocentricity scale developed by Shimp and Sharma (1987) followed by the animosity scale (Klein *et al.*, 1998), followed by a filler task.

Participants then moved to the second portion of the study, which involves reading an article and evaluating it. This serves as our information manipulation. Participants in the negative news read a fictitious article about an American Firm recalling children's sleepwear from China. Participants in the neutral news read a real article adapted from the Wall Street Journal, "Seeing through Buyers' Eyes" Jan 29, 2007, WSJ, B4.

Next, participants were given a scenario where they are in need of a laptop. They were also told that the store they visited only had two brands, Chinese (Made in China) and American (Made in USA). Finally, participants were asked to evaluate the article using a seven-point four item scale anchored at, dislike-like, favorable-unfavorable, negative-positive, and bad-good. This serves as a manipulation check.

Results: The manipulation check indicated that the negative news elicited more negative evaluations ($M=4.86$) than did the neutral news ($M=6.77$, $F(1, 238)=62.21$, $p=0.00$).

As mentioned above, ethnocentricity and animosity need to be accounted for; therefore they were used as covariates. A one way analysis of variance indicated that there was a main effect of the news manipulation on choice. Those in the bad news condition chose the Chinese product ($M=0.704$) more than those in the neutral news condition ($M=0.467$, $F(1, 224)$, $p=0.00$). Both the covariates were not significant ($p>0.05$).

Discussion

Several studies have shown that negative country image leads to lower willingness to buy products made in that country. Study 1 showed that this is not always the case. Negative country image of consumers' own country actually increases their preference for their own products. However, there are many other issues to consider and in ongoing research, Study 2 aims to explore two gaps in Study 1. First, the study does not assess the mediating role of intergroup emotions on domestic product preferences. Second, it does not assess whether consumers' choices differ if the domestic product were not only pitted against a hostile outgroup product but also against a neutral one.

The Compromise Effect in Choosing for Others

Shih-Chieh Chuang, National Chung Cheng University, Taiwan

Yih-Hui Cheng, National TaiChung University, Taiwan

Sun Ya-Chung, Vanung University, Taiwan

Sui-Min Wang, National Chung Cheng University, Taiwan

Extended Abstract

In daily life, people need, or are forced to, make choices for others, such as buying souvenirs for relatives, helping others, at their invitation, to buy something, or buying a birthday gift for a friend. Such decision making is a common but little-discussed phenomenon. People are often faced with situations in which they have to predict whether others, not themselves, will be satisfied with the choices they have made. Do people make the same choices for others as they do for themselves? When choosing for others rather than oneself, uncertainty arises and makes one more concerned about the judgment of others.

Early social, psychological, and decision-making research found that people have a variety of motives for justifying their decisions to themselves and others. The need to justify decisions to oneself and others reflects a desire to enhance one's self-esteem (Hall and Lindzey, 1978), cognitive dissonance (Festinger 1957), the anticipation of the possibility of regret (Bell 1983), and people's perception of themselves as rational beings with reasons for preferring one option over another (Abelson 1964). Therefore, people expecting to be judged by others may make the safest option (averaged) to be favorably evaluated by others, decrease criticism, and minimize potential errors (Simonson 1989).

The compromise effect is a crucial determinant in the decision-making process that is based on the context effect. This effect is based on the notion that "an alternative would tend to gain market share when it becomes a compromise or middle option in the choice set" (Simonson, 1989). Consumer preference is dynamic with new alternatives in choice sets (Bettman, Luce, and Payne, 1998), and is based on the principle of value maximization. Therefore, the difference between choosing for oneself and for others should be analyzed in relation to the compromise effect.

One is more familiar with the needs and conditions of people with whom one is friends or with whom one frequently communicates. When people make choices for those with whom they are intimate, they are confident that their decisions will take into account the preferences of the latter. Hence, making choices for people to whom one is not close and with whom one communicates infrequently will result in greater uncertainty, and decision makers may easily overestimate unknown negative outcomes and tend to choose the middle option as the safe one.

Making choices for others is deeply influenced by interpersonal relationships. Bearden and Etzel (1982) stated that susceptibility to interpersonal influence can be defined as an individual's willingness to accept information from other people about purchase decisions. Then, that the compromise effect will be greater among those who are highly susceptible to interpersonal influence.

Accountability leads people to be more concerned about decision accuracy and helps strengthen the beliefs of decision makers. It increases decision accuracy because the need to justify past decisions leads decision makers to engage in more unbiased evaluation of alternatives (Tetlock 1983) and to focus more on cues (Johnson and Kaplan 1991). In addition, accountability leads people to consider additional relevant evidence and improve their estimates (Kruglanski and Freund 1983).

Anticipation of regret is used to examine the prediction. It refers to the regret that consumers anticipate that they will feel if their decision results in negative outcomes. Cox and Rich (1967) proposed that risk is composed of negative consequence and uncertainty. However, choosing for others induces anticipation of regret, compared to no anticipation of regret, will correspond to an increase in the fear of making a wrong choice (negative outcome) and result in the greater likelihood of choosing the compromise option as the safe option.

Because of the influence of interpersonal relations, it is useful to investigate whether people will be more inclined to choose a compromise option to reduce the effect of the loss or tend to choose what they favor when choosing for others. Building on the findings of Simonson (1989), this paper aims to uncover the underlying mechanisms of the self-other difference in the compromise effect.

Study 1

The goal of Study 1 was to test the hypothesis that the compromise effect is greater when choosing for others than for oneself. Two factors were manipulated in a 2 X 2 (self or others vs. either two or three options in the choice set) between-participants design. A total of 160 undergraduate and graduate students participated in Study 1. In the experiment, participants were randomly assigned to two conditions (self or others), and in these two conditions randomly assigned to a binary (A, B—two alternatives) or trinary (A, B, C—three alternatives) scenario to choose for themselves or others.

The results confirmed our hypotheses. It shows that choosing for others leads to a greater compromise effect compared to choosing for oneself.

Study 2

To broaden the knowledge of others, Study 2 tests whether the level of intimacy of a relationship influences the compromise effect, and whether this influence depends on the level of susceptibility to interpersonal influence of the decision maker. Participants were randomly assigned to one of eight cells in a 2 (two or three options in the choice set) X 4 (target person: self, family member, friend, or classmate) between-participants design. A total of 120 undergraduate students participated in this experiment.

The results support the prediction that the compromise effect varies with the level of intimacy of the relationship with others of the decision maker, and is not as different among those with a low level of susceptibility compared to those with a high level of susceptibility.

Study 3

Study 3 examined the effect of accountability on the choice of the middle option. Participants were randomly assigned to one of eight cells in a 2 (two or three options in the choice set) X 2 (self or others) X 2 (accountability or no accountability) between-participants design. A total of 320 students participated in this experiment.

The results support the hypotheses. The findings of study show that the compromise effect when choosing for others is weaker under the accountability condition than under the no accountability one.

Study 4

The goal of this experiment was to test the impact of the anticipation of regret (negative outcome) on the compromise effect. Participants were randomly assigned to one of eight cells in a 2 (two or three options in the choice set) X 2 (self or others) X 2 (anticipation of regret or no anticipation of regret) between-participants design. A total of 320 students participated in this experiment.

The results are as expected, the compromise effect in choosing for others is significantly greater in the anticipation of regret than in the no anticipation of regret condition.

General Discussion

The purpose of this paper is to explore the relationship between self-other difference and the compromise effect. This research can explain why one has chosen one product over another for someone else makes one more concerned about decision accuracy. It also helps strengthen the beliefs of decision makers such that they will be less likely to choose the compromise option. In addition, this paper has general implications for the marketing of new and existing products. The positioning of new products, especially those often bought for others (e.g., gifts, souvenirs, domestic products) could focus on developing the average attributes to avoid the product becoming the extreme option. For existing products, sales staff could be trained to ask consumers for whom they are buying and then give appropriate advice.

Skill- versus Effort-Based Difficulty: The Role of Emotion in Motivating Difficult Actions

Kirsten Passyn, Salisbury University, USA

Mita Sujun, Tulane University, USA

Extended Abstract

Health protection campaigns have traditionally relied on fear appeals to promote behaviors. These campaigns have also demonstrated the necessity of self-efficacy and the particular problems of motivating difficult behaviors (Sturges & Rogers, 1996; Keller & Block, 1996). For difficult behaviors, for which individuals generally have low self-efficacy, fear appeals have been found to be particularly ineffective.

More recent research has looked at the motivating influence of other emotions over fear including anger, (Lerner & Keltner, 2000, 2001), pride (Higgins et al, 2001) and regret (Zeelenberg & Pieters, 2007). Specifically, in the health domain Passyn & Sujan (2006) found the motivated action response of regret which is to prevent or correct wrongs, to be more effective at motivating simple health-preventative behaviors, such as using sunscreen and choosing high fiber foods, than fear with its action response to avoid or deny. Higgins et al. found that pride was positively related to diet maintenance. However, the conditions of the study were an imagined diet and an imagined piece of pizza likely limiting perceptions of task difficulty.

This research makes several important contributions to understanding task difficulty. First, we delineate the independence of the constructs of self-efficacy and task difficulty. These constructs have often been confounded in research as procedures used to enhance perceptions of self-efficacy typically make the task less difficult resulting in the constructs being treated as synonymous (Hu, Huhman, & Hyman, 2007). However, we show that perceptions of task difficulty and perceptions of self-efficacy are indeed independent. Second, we distinguish among different types of task difficulty. Based on the aptitude versus effort distinction for outcomes, we forward the argument that a task can be perceived as difficult for two main reasons: a task can be perceived as difficult because it requires skill-based difficulty—or because it requires exerting effort—effort-based difficulty.

The main purpose of this research is to understand what type of emotions best spur different types of difficult health behaviors. Specifically, we examine if anticipated regret for the mistake and the heightened potential for failure—and hence regret—when task effort-difficulty is made salient will erase self-efficacy doubts, and motivate effortful action. In addition, we examine if anticipated pride for task accomplishment and the heightened potential for pride when the behavior is considered challenging will erase self-efficacy doubts, and motivate challenging action. In pretests and two studies, we examine the effectiveness of these emotions in comparison to each other and fear. The first study compares the effectiveness of fear versus regret at motivating simple versus effortful behaviors in the context of condom usage. The second study compares regret and pride at motivating simple, effortful, versus challenging behaviors in the context of CPR training.

Surveys (Essien, Ross, Eugenia, & Williams 2006) suggest that condom usage on campus is so low because young adults find it too effortful to interrupt the mood and say, “We need to use a condom.” Study one a 2(emotion: fear versus regret) X 2 (task difficulty: easy versus effortful) demonstrates how consumers can be motivated to act when taking action is effortful. A pretest confirmed that undergraduate students report that condoms are effective protection against STDs. Furthermore, we document the reality of “in-the-moment” feelings during a sexual encounter at heightening task effort difficulty, reducing perceptions of self-efficacy, and intentions to use condoms. The results of study 1 confirm our predictions that regret will motivate effortful behaviors with a task difficulty x emotion interaction ($F(1, 67)=5.87, p<.02$). Specifically, we replicate the general finding of Protection Motivation Theory that under conditions of fear, increasing the salience of the difficulty of the task significantly decreases perceptions of self-efficacy ($M_{\text{fear-control}}=3.68$ vs. $M_{\text{fear-difficult}}=2.76; t(67)=3.24, p<.01$) and behavioral intentions ($t(67)=1.92, p<.05; M_{\text{fear-control}}=5.45$ vs. $M_{\text{fear-difficult}}=4.14$). However, under conditions of regret, we find a reversal effect; increasing the salience of the difficulty of the task, significantly enhances perceptions of self-efficacy ($M_{\text{regret-control}}=3.77$ vs. $M_{\text{regret-difficult}}=4.30; t(67)=2.56, p<.01$) and behavioral intentions ($t(67)=1.95, p<.05; M_{\text{regret-control}}=6.97$ vs. $M_{\text{regret-difficult}}=8.12$). Thus not only is regret robust in its ability to promote both easy and effortful behaviors, but the motivational impact of regret is improved under conditions that make the task effort-difficulty salient.

Study 2 is a 2(emotion: pride versus guilt) X 3 (task difficulty: easy versus skill-based versus effort-based) between-subjects design. Half the participants were primed by words that cue pride (mastery type words) and the other half by words that cue regret (repentance type words). In an “unrelated” study that follows, participants were asked to sign up for a CPR class. Administering CPR was described as potentially life saving in all conditions to produce the necessary level of arousal for emotion and action. In addition CPR was described as easy (for 1/3 of the participants), described as a difficult skill that not everyone can perform correctly (for 1/3 of the participants), or described as needing significant time commitment (for 1/3 of the participants). Pretests confirmed that the priming tasks produced felt pride and regret and that the three descriptions of CPR resulted in easy, skillful, and effortful assessments of task difficulty. Although, data collection and analysis is still in progress preliminary results confirm that as in study one regret results in a reversal effect under conditions of effort-based task difficulty, with significantly enhanced perceptions of self-efficacy, increased behavioral intentions and increased behavior (as measured by on-line signing up for CPR courses). In addition, pride also results in a reversal effect for skill-based task difficulty, with significantly enhanced perceptions of self-efficacy, increased behavioral intentions, and increased behaviors. However, regret was not effective at motivating skill-based task difficulty and pride was not effective at motivating effort-based task difficulty.

In summary, the big impact of this research is finding how to best motivate big health behaviors, those that require a big effort are best motivated by regret, those that require big time skills are best motivated by pride.

Emotion in Isolation: Crossing Valence with Certainty Leads to Unexpected Results

Julian Saint Clair, University of Washington, USA

Extended Abstract

Emotions have multiple dimensions (Smith & Ellsworth, 1985; see Han et al., 2007 for a review). One such dimension receiving more recent attention is that of certainty. A positive relationship between emotional certainty and risk taking has been demonstrated (e.g. Raghunathan & Pham, 1999; Lerner & Keltner, 2001). Specifically, the experience of emotional certainty reverses the pervasive risk-aversion tendency for gains while uncertainty reverses the risk-seeking tendency for losses.

Two theories have been proffered to explain these results: one states that certainty influences motivation via mood regulation goals (Raghunathan & Pham, 1999), the other states that certainty influences risk perceptions (i.e. optimism; Lerner & Keltner, 2001). The present study tests these two theories by isolating and manipulating the dimensions of interest rather than priming specific emotions. Results show that neither theory is sufficient. Instead, certainty is interacting with valence in an unpredicted fashion.

Specifically, it appears that while certainty is indeed impacting perceptions of risk, valence is determining which outcome is receiving the subjects' certain/uncertain attention. This theoretical explanation put forward to explain this interaction is that negative (positive) valence leads to increased (decreased) depth of processing, causing subjects to focus attention on less (more) salient aspects of the decision task – the more salient possibilities of gains and losses vs. the less salient possibilities of non-gains and non-losses.

In the remainder of this document, I describe the above statements in more detail. I summarize the two previous theories and the results they are based on, I describe the present study and outline the theoretical predictions, and I report the unexpected results and describe the new explanatory theory.

Certainty and Mood Regulation Goals

Raghunathan & Pham, 1999. Across three studies, Negative/Uncertainty (Anxiety) primed subjects selected risk-averse choices for gains (i.e. prefer a 6/10 chance to win \$5 vs. 3/10 chance to win \$10). The choice was theorized to be motivated by the underlying mood regulation goal of Uncertainty Reduction.

Comparatively, the authors also demonstrated that Negative/Certainty (Sadness) primed subjects selected risk-seeking choices for gains (i.e. the 3/10 chance to win \$10). It is contended that sadness, associated with loss or absence of reward (Lazarus, 1991), results in reward seeking behavior motivated by the mood regulation goal of Mood Repair.

Certainty and Risk Perception

Lerner & Keltner, 2001. Using the classic Asian Disease Problem, subjects primed with Negative/Uncertainty (Fear; Negative/Certainty: Anger) were risk-averse (risk-seeking) across choices framed as gains as well as choices framed as losses, preferring the sure (risky) gain and the sure (risky) loss. The explanation was that the sense of uncertainty (certainty) associated with fear (anger) leads to perceptions of high (low) risk (i.e. pessimism/optimism). This in turn causes subjects to focus on worst (best) case scenarios and prefer the riskless (risky) options. To support their theory, the authors showed in a separate study that increased certainty led to increased optimism

The Present Study and Predictions

Is the certainty dimension impacting perceptions of risk or is it impacting mood regulation goals?

In our study, we simply crossed valence by certainty in a 2 (positive/negative) by 2 (certain/uncertain) between subjects design. Rather than cloud the results by using specific emotions with varying underlying dimensional properties, we isolated the dimensions of interest by directly manipulated emotional certainty and valence themselves. For example, we asked subjects to describe in detail an emotional event in which they felt extremely negative and uncertain. We then administered the 'Financial Decision Making' task as an onstensible filler task before a manipulation check, suspicion probe, and demographics questions completed the study. The decision task was similar to Raghunathan and Pham (1999), e.g. 60% chance to win (lose) \$5 vs. 30% chance to win (lose) \$10.

Both the 'mood regulation goals' theory and the 'risk perceptions' theory would predict that negative/certainty (vs. negative/uncertainty) leads to increased risk taking for losses and gains. However, they have differing predictions for *positive* emotions. Specifically, due to 'mood maintenance' goals, mood regulation theory would predict that positive/certainty (vs. positive/uncertainty) would lead to decreased risk-taking for gains and increased risk-taking for losses. Risk perception theory would predict no difference between gains and losses – that positive/certainty leads to increased risk-taking for both.

Results and Discussion

Gains. Subjects in the positive/certain (vs. positive/uncertain) were more risk-seeking, choosing the 30% \$10 gain more often than the 60% \$5 gain. Subjects in the negative condition were the exact opposite. Negative/certain (vs. negative/uncertain) were *less* risk seeking.

Losses. Subjects in the negative/certain (vs. negative/uncertain) were more risk-seeking, choosing the 30% \$10 loss over the 60% \$5 loss. The positive-valence subjects were the opposite: positive/certain (vs. positive/uncertain) subjects were *less* risk seeking.

These actual results supported neither the Mood Regulation Theory nor the Risk Perceptions Theory as conceptualized by previous research. However, the results are consistent with a new theoretical framework wherein depth of processing interacts with risk perceptions. This interaction is further described below.

I manipulated 2 dimensions that have been shown to impact both content of processing and depth of processing. The content of processing argument is what I sought to test: do these dimensions affect content via Mood Regulation Theory or Risk Perceptions Theory? However, it is possible that I actually influenced *depth* of processing as well as content, and results show that the two interact.

Results suggest that certainty simply influenced cognition in a manner consistent with risk perceptions theory: subjects who felt more certain perceived 'unlikely' events as more likely. However, the events on which subjects directed this certain/uncertain attention seemed to be moderated by the depth of processing caused by valence (see Schwarz, Bless, and Bohner, 1991 for a review on valence

and processing). Results suggest that subjects in the positive valence conditions attended more to surface cues (i.e. heuristic processing) while those in negative valence conditions attended to information implied but not overtly highlighted (i.e. systematic processing).

Specifically, subjects in positive valence conditions focused their attention on the highlighted possibilities of gains and losses while subjects in the negative valence conditions attended to the implied possibilities of non-gains and non-losses.

Retail Therapy or Rose-Tinted Glasses? The Effect of Mood on Impulse Buying

Debra Trampe, University of Groningen, The Netherlands

Extended Abstract

Opportunities to give in to the sudden impulse to buy have never been more abundant. Marketing developments like 24-hour retailing, outlet stores, credit cards, and online shopping make it easier than ever for consumers to purchase products or services when they experience the impulse to do so. Paralleling consumers' often heard claim that they were "overwhelmed by an irresistible impulse to buy" (Rook 1987) are estimations that impulsive consumption annually accounts for over \$4 billion of sales in the US alone (Mogelonsky, 1998). At the same time, household debts are at an unprecedented high and show no sign of diminishing (Vohs & Faber 2007). Considering its potentially self-destructive nature, increasing our insight into impulse buying is essential.

Though a number of factors that may contribute to impulse buying have been investigated, one important but relatively understudied factor is mood. Ironically, in recent reviews of the relevant literature, impulse buying has been related to positive as well as negative mood states. Consumers are more likely to act on their buying impulses when they are in a positive mood . . . and when they are in a negative mood (Rook and Gardner 1993; Silveira, Lavack, and Kropp 2008). How is that possible? We argue that people may engage in impulse buying to repair negative moods, whereas in positive moods impulse buying may occur because happy consumers are more likely to act relatively capriciously and carefree. And indeed, shoppers report making impulsive purchases to alter an unpleasant mood (Baumeister 2002; Silveira, Lavack, and Kropp 2008), reflecting the idea of "retail therapy". Also, research on self-gifting (Mick and DeMoss 1990) has observed that consumers tend to indulge after stress or depression by acquiring self-gifts. Conversely, impulse buying in positive mood states seems common as well. For example, when a group of consumers were asked to select the one mood that would be most likely to encourage them to make an impulse purchase, "pleasure" was most frequently named, followed by "carefree" and "excitement" (Rook and Gardner 1993). On a more general level, research has shown that objects are typically evaluated more positively when individuals are in a positive rather than a negative mood (Cohen, Pham, and Andrade 2008; Gardner 1995). Thus, a positive affective state may make mood congruent associations more accessible, and the offerings consumers encounter to be evaluated more positively, which in turn leads consumers to engage in impulsive purchasing. Stated otherwise, consumers can at times engage in mood-congruent behavior, by looking at the (consumption) world through so-called "rose-tinted glasses."

In three experiments we aim to clarify the role of mood in impulse buying and uncover the mechanisms at work in positive and negative moods in promoting impulse buying. As experimental research is still lacking, our first goal is to offer a straightforward demonstration that both positive and negative moods compared to a control condition would increase impulse buying tendencies. Our second goal is to shed more light on the mechanisms underlying the positive and negative antecedents of impulse buying. We hypothesize that increased impulse buying results from a motivation to improve one's mood, whereas increased impulse buying in a positive mood is driven by mood-congruent behavior. This hypothesis should manifest itself in at least two ways: first, the type of products that are bought on impulse in positive and negative moods should differ. As hedonic products provide more fun and pleasure and more so than utilitarian products trigger an urge for immediate consumption (Dhar and Wertenbroch 2000), consumers in a negative mood (vs. a positive mood) should be more likely to impulse buy hedonic products. Utilitarian products are primarily functional and instrumental and hence the likelihood that they are bought on impulse should not differ between positive and negative moods. Second, the motivational component in impulse buying in response to negative moods should make it more goal-directed in nature than impulse buying in response to positive moods. Goal-directed behavior is known to be different from non-goal-directed behavior: it is persistent through obstacles, it increases following a delay, and decreases when the goal is fulfilled (Förster, Liberman, and Freedman 2007). Thus, if impulse buying in negative moods is a motivational process, impulse buying tendencies should be larger after a delay than immediately after the mood induction.

In the first two experiments, following Vohs and Faber (2007), impulse buying was conceptualized as willingness to pay (WTP). In Study 1, both positive and negative moods, relative to a control condition, were found to increase WTP for a number of diverse products. In Study 2, we differentiated between hedonic and utilitarian products. Results showed that the pattern for utilitarian products replicated Study 1: both positive and negative moods enhanced WTP, compared with a control condition. For hedonic products, however, the pattern was different. For hedonic products, a negative mood produced higher WTP compared to both a positive and a control mood. The latter two conditions did not differ in WTP for hedonic products. In Study 3, the impulse buying measurement was modeled after Rook and Fisher (1995). Participants were presented with a scenario that described a shopping situation with an opportunity to make an impulse purchase. They then indicated their level of impulsive urge and buying behavior. In addition, Study 3 also explored the moderating role of trait impulsiveness. Using a 3 (mood: positive vs. negative vs. control) x 2 (delay: yes vs. no) between-subjects design, participants in a negative mood experienced stronger urges to buy after a delay and indicated that they were more likely to make an impulse purchase than participants in the no-delay condition. For participants in a positive and neutral mood, there was no such difference.

As impulse buying has been suggested to account for up to 80% of all purchases in certain categories (Kacen and Lee 2002), insight into this widespread phenomenon is imperative. This research focused on the role of mood in impulse buying and illustrates that (1) both positive and negative mood states enhance impulse buying relative to neutral moods, and (2) the mechanisms underlying both mood states differ profoundly.

When Is It Better To Be Bad? Schema-Congruency Effects in Moral Evaluations of Products

Jennifer S. Danilowitz, Yale University, USA

George E. Newman, Yale University, USA

Extended Abstract

All things being equal, people prefer good things over bad. People seek pleasure, and avoid pain (Bentham 1779, James 1890, Higgins 1997). Within psychology, the approach-avoidance hierarchy has dominated the motivation literature (Elliot 2006). Perception researchers have shown that stimuli are classified into positive and negative with only 30 milliseconds of subliminal presentation (Stapel, Koomen & Ruys, 2002, Osgood 1955). Across multiple disciplines, people are believed to quickly classify targets into high level categories of "good/approach" and "bad/avoid".

Managers have embraced this perspective in their marketing communication tactics. Brands spend hundreds of millions of dollars each year on celebrity endorsements, with the logic of associating their product with a persona that consumers already like to gain some halo affect. Recent events have shown that if a spokesperson's image shifts to bad or immoral, managers are quick to disassociate themselves from the disgraced endorser. Yet is it always the case that any association with an immoral figure is bad for a product? The present research proposes that in certain cases a product may benefit from association with an immoral persona.

Previous research has demonstrated that individuals' appraisals of a new product may be dependent on the degree to which the product's features and the activated category schema are congruent (Aggarawal and McGill 2007; Meyers-Levy and Tybout 1989). In general, objects that are schema congruent are evaluated more favorably than objects that are schema incongruent because people tend to like objects that conform to their expectations. People may transfer positive affect about the fit between the product's features and their beliefs about the category (e.g., satisfaction for schema congruent products) to the object itself (Fiske 1982).

Consistent with the findings of previous schema congruency research, we hypothesized that consumers would be more likely to prefer vice products invented by immoral creators as compared to vice products invented by moral creators or virtue products invented by immoral creators. Specifically, if a product is framed for use in a vice behavior context, we predict that consumers will be more interested in purchasing it when it was created by an immoral person.

The present studies directly tested the effects of a product's moral history on consumer preferences. Across four studies we manipulated the moral history of the product and the product's framing. In study 1 participants read a story describing the inventor of an energy drink as moral or immoral, then were told that the energy drink was intended to "provide the extra energy needed for studying for exams and working hard (partying with friends and having fun) throughout the long hours of the night". The results of Study 1 support our predictions. Specifically, when a product (e.g., an energy drink) is positioned for use in a virtuous context, people prefer the moral inventor, $F(1,190)=6.92, p=.009, M_{study/moral}=3.82, M_{study/immoral}=2.82$). However, when the same product was framed in a vice behavior context (i.e., partying), participants instead preferred the product to have been invented by the immoral person compared to a moral person ($M_{party/moral}=2.25, M_{party/immoral}=2.78$).

We believe that Study 1 provides initial evidence for a congruency effect between the moral valence of the product's creator and the moral valence of a product's intended use, such that people prefer the immoral inventor when the drink is intended for a vice-like use. However, these results might be due to a general semantic priming of a vice-like frame of mind, which could result in increased purchase intent for any party aid. Another possibility is that people believe that an immoral inventor would make a better party-aid than a moral inventor—perhaps due to expertise on the part of the inventor in the behavioral domains. We conducted Study 2 in order to rule out

these alternate explanations, and to investigate the role of similarity between inventor and framing as a possible mediator of the effect. In Study 2 participants read the same history and framing background story, but we added additional conditions so that some subjects were told that the manufacturer had been unable to secure the rights to that formula invented by the immoral(moral inventor), and instead was using a different recipe to produce the energy drink. The results indicate that participants prefer the energy drink as a party aid only when it was made from the EXACT FORMULA of the immoral inventor $F(1, 637)=5.36, p=.021$. Next, when probed for beliefs about the effectiveness of the drink at keeping them awake, subjects in the vice (virtuous) framing did not believe that the drink would be less effective for a virtuous (vice) activity, ($M_{party}=2.25, M_{study}=2.32, F(1,641)=2.38, ns.$). Study 2 replicated our initial findings, ruled out two major alternative explanations, and provides initial evidence of schema congruency as a mediator.

Study 3 replicated the effect in another domain: that of art and artists. Subjects were presented shown an ambiguous piece of art (“Tunnel”) and the moral history of the artist and his intended framing of the art were manipulated. The predicted interaction emerged for history (moral, immoral, very immoral) X framing (positive or dark), $F(2,165)=3.02, p=.051$, providing further evidence that when products are framed in dark or vice ways, people tend to prefer immoral creators.

This congruency effect persists across multiple product domains and in spite of the fact that participants explicitly rate the immoral target as morally corrupt and unlikable. Therefore, in addition to providing a test of the effects of moral judgments on product evaluations, these studies provide some of the first experimental evidence that in certain contexts, people may prefer products associated with immoral individuals. These patterns are interpreted within the broader framework of essentialism and schema congruency, and the implications for marketing, social policy and academic theory are discussed.

Anchoring Unveiled

Jennifer S. Danilowitz, Yale University, USA

Shane Frederick, Yale University, USA

Daniel Mochon, Yale University, USA

Extended Abstract

Nearly all studies of anchoring ask participants to first make a comparative judgment, and then render an estimate. Within this paradigm, the dominant psychological account of anchoring is that people actively compare their estimate to the anchor, thereby increasing the accessibility of anchor consistent information (Strack and Mussweiler 1997). A second account suggests a more deliberate process in which people start with the anchor value, and then adjust it until the proximate boundary of plausible ranges is reached (Jacowitz and Kahneman 1995). A third account implicates the conversational norm that provided information is relevant (Grice 1975, Schwarz 1999).

Though anchoring effects have been found even in contexts that should help control for some of these possibilities (like the use of manifestly random anchors, Tversky and Kahneman 1974), little work has attempted to assess the comparative influence of these different forces either between or within studies.

The present research is intended to test the comparative importance of these mechanisms in the traditional paradigm. We manipulated the source of the anchor and quantified the magnitude of the anchoring effect. In condition A, anchors were manifestly unrelated to the comparative question: they were generated by the participants (e.g. by taking a bill out of their wallet and entering the first two digits of the serial number as the anchor). This design was intended to minimize inferences about the informational value of the anchor. The other three conditions were “yoked” to the numbers these respondents self generated, resulting in 90 perfectly yoked “quartets”. Within each quartet, for each value entered by a participant in condition A there was one and only one condition B, C and D participant who saw that value as their respective anchors. In condition B, the yoked anchors were provided and the instructions indicated (falsely) that the anchor

was randomly generated by the computer. In condition C, there was no mention of anchor origin included in the instructions, but the anchors were presented in red and participants had to re-type the value. In the final condition D, the anchor appeared as a comparative question, as in the traditional paradigm.

Each respondent made 6 judgments. Because each value generated in Condition A was a two digit number, the judgments were chosen such that the range of possible answers was naturally bounded between 0 and 100. Three of the questions asked for a percent estimate, and three of the questions asked for estimates where the only possible answers would be between 0 and 100. Specifically, the six items were:

1. Is the percentage of American adults who have a passport higher or lower than that number?
2. Is the number of U.S. senators who have law degrees higher or lower than that number?
3. Is the percentage of adults in the world who are Christian higher or lower than that number?
4. Last year, was the average interception return in the National Football League higher or lower than that number of yards?
5. Among all Major League Baseball players currently playing, is the percentage who are married higher or lower than that number?
6. During the last century in the U.S., is the number of years in which Michael was the most common name for baby boys higher or lower than that number?

To compare the strength of an anchor's influence on the estimates across conditions, we regressed numeric judgments against anchor values and measured the size of the coefficient. For the transparently random anchor condition A, there was a small but significant positive relationship between anchor and estimate; $b_A = .08$, $SE = .03$, $p < .01$. For conditions B and C the anchor interaction term also predicted the estimates in a positive direction, and the relationship is slightly steeper than in condition A, 1; $b_B = .11$, $SE = .05$, $p < .01$, and $b_C = .13$, $SE = .05$, $p < .01$. Finally, condition D, which closely mirrors the traditional comparative anchoring paradigm, showed the strongest effect of anchor on the estimate, $b_D = .25$, $SE = .05$, $p < .01$. In a secondary analysis, we also observed an interaction between question type and anchoring effect. There was markedly less anchoring for items involving a percentage response than items involving a count, even though for both types all responses ranged from 0 to 99.

In sum the values ranged from a small (but significant) value of 0.08 in the "dollar bill" condition to 0.25 in the "standard" paradigm. Conditions B and C yielded similar results and the results were intermediate. These findings suggest that in the standard paradigm, inference plays a very substantial role in generating the anchoring effect, and increases the size of the effect threefold.

Key Results

Condition A—Anchor is generated by participants and transparently irrelevant. Effect: $b = .08$

Condition B—Instructions explain that anchors are "randomly generated". Effect: $b = .11$

Condition C—Anchor is presented in odd font/color and had to be retyped. Effect: $b = .13$

Condition D—Anchor included in the comparative question. Effect: $b = .25$

All p 's $< .01$

Aligning Consumers Around Low-carbon Competitiveness: Evidence from an Online Experiment

Julia Joo-A Lee, Harvard Kennedy School, USA

Behavioral change in consumer demand is not only critical in determining the size of an individual's carbon footprint, but also motivates business leaders to respond to increased climate-awareness among consumers by supplying lower carbon products. Thus, many public and non-profit organizations are concerned with creating credible and reliable messages that will help motivate consumers to change their consumption decision-making and to reduce their carbon footprint. This study addresses an important question of how

behavioral economics could encourage more environmentally sustainable consumer behavior. The goal of this study is to improve the ways in which government and non-profit organizations communicate consumption and climate-related information to consumers.

What are the factors that influence change in consumer behavior? First of all, a consumer's need for more information in part confirms what the standard economic theory of the rational choice model predicts: consumers should have access to sufficient information to make optimal, informed decisions about available options (Bord et al. 2000; Viscusi & Zeckhauser, 2006; Fischer, 2008). However, providing more information to the public does not necessarily change the consumer's environmentally significant behavior. Among the many reasons for the difficulty in behavioral change, including cognitive and motivated biases that distort how people process information, recent research found that emotions could powerfully influence individual processing of information and decision-making related to climate change (Leiserowitz, 2007).

Drawing on the recent theoretical and empirical developments in the study of emotions, this research project is designed to test whether incidental emotions such as guilt and shame can elicit different degrees of pro-environmental consumption behavior. Due to the difficulty in observing consumer behavioral change directly, it is important to identify dependent variables that are strong predictors of behavioral change in environmental decision-making; i) consumer's willingness-to-pay (WTP) for more pro-environmental products, ii) consumer's perceived self-efficacy, measured by their willingness to address the climate change problems, and to act on their intentions. Given the two dependent variables, it was hypothesized that consumers who know their own carbon footprint to be higher than the national average are more likely to show higher measures of pro-environmental consumption behavioral predictors. It was also hypothesized that eliciting guilt prior to calculating carbon footprint is more effective in changing consumer behavior than eliciting shame.

One hundred participants were recruited using the subject pool at the Harvard Decision Science Lab, which ensured a reasonably representative subject population. A general introduction informed the subjects about the experimental procedure. Participants were notified that they would be asked to answer two different surveys that are unrelated. The format of the two surveys differed in order to enhance the "unrelatedness" of the two surveys.

In the first survey, all participants were randomly assigned to one of three different emotion conditions of the survey (guilt, shame, and control). The first two groups of participants were asked to complete the emotion induction exercise, which consists of a directed-writing task designed to manipulate their emotions. This study replicated the guilt and shame elicitation method developed and administered by Shaver et al. (1987) and Tangney (1996: p. 1259). This exercise asked participants to "describe in detail the one situation that has made you feel the most [guilty/ashamed]." In order to help participants bring up memories of the emotional experience more vividly, additional prompts were given. Questions included "Why did it happen? Describe as much detail as you can what you were feeling and thinking. How did you respond? What did you say, if anything, and how did you say it? What are the physical signs of guilt you showed, if any?" Participants in the control group received a set of neutral questions asking them to describe their emotions that they feel at the moment. These incidental emotions were unrelated to the subsequent questions asked in the second part of the survey.

The second part of the survey included measurement of one's own carbon footprint, using a link to a publicly available carbon footprint calculator. After reporting one's own carbon footprint, participants were also asked to compare their carbon footprint with the U.S. average of national carbon emissions, and then to report whether their footprint was above, or below, average. After completing this task, participants were asked to report their WTP for environmentally friendly products in percentage terms, as well as their PSE. Calculating one's own carbon footprint was designed to improve the external validity of this study by realistically measuring one's culpability.

Results from this study demonstrate that the mean dependent variables (WTP and PSE) differed for consumers who had done three different writing tasks (guilt, shame, and control). That is, consumers who received guilt induction had statistically significantly higher ratings of both WTP and PSE measures, compared to those who received shame induction. Also, the differences in WTP and PSE between guilt and shame conditions were more pronounced in the low-carbon group than in the high-carbon group. It is also important to note that the level of carbon footprint could be a boundary condition for the influence of emotional states on environmental decisions; unlike what was hypothesized, high-carbon consumers were not particularly different in their decisions from low-carbon consumers.

Hiding Guilt

Christina I. Anthony, University of Sydney, Australia

Elizabeth Cowley, University of Sydney, Australia

Mario Pandelaere, Ghent University, Belgium

Consider Jane who is shopping for a present for a friend's birthday party that evening. She gets distracted and ends up shopping for a new pair of jeans for herself. She hears an announcement, that the store will close in 5 minutes, and that customers need to make their way to the check out. She buys her new jeans, but did buy a present. Jane feels guilty about this transgression. Will this affect Jane's liking of her new jeans? This paper investigates whether feeling guilty affects the liking of the product that reminds people of a transgression. We propose that guilty people, compared to non-guilty people, will evaluate the jeans less favorably, but only if the jeans are visible after the transgression. Why? Because people believe that seeing the jeans will interfere with effective affect regulation efforts, therefore reducing their evaluation of the reminder. Our results provide the first insight into why people adopt covert coping behaviors, such as hiding the tainted product in the closet (Dahl, Honea, and Manchanda 2003).

Consumers engage in affect regulation to alleviate feelings of guilt, such as suppressing unwanted thoughts and feelings about the event (Tice and Bratslavsky 2000). Different strategies exist for this process (Gross 1998). The strategy chosen depends not only on the effectiveness of the tactic, but also on people's metacognitive intuitions regarding the perceived effectiveness of the strategy (Loewenstein 2007). Therefore, having the object involved in the transgression subsequently in sight, may be perceived as interfering with this process, and result in a devaluation of the object.

Method

One hundred participants were randomly assigned to dyads. In the no-guilt condition, one member of each dyad was presented with a black pen and two green pens and asked to choose one and give another pen to the other dyad member. In the guilt-condition, the dyad member that was allowed to choose a pen was informed that participants with a green pen would have to stay 20 minutes longer than participants with a black pen. We expected participants to choose the black pen and to feel guilty. This is exactly what happened. Participants in the not guilty condition were not given a choice, nor were they aware of any differences in the timing of their condition.

Participants were assigned to one of the four conditions of a 2 (guilt: guilt, no guilt) X 2 (pen visibility: visible, not visible) design. There were two different color pens: green and black. Participants were informed that if they chose the green pen, they would not have to do an extra task, but that the person next to them would have to stay for an extra 20 minutes. However, if they chose the black pen, they would have to stay instead. A manipulation check confirmed that participants in the guilty condition felt more guilty than those in the not guilty condition.

Following the guilt manipulation, participants were required to complete a second consumer choice task. During this task the pen was either removed, and participants completed the choices on a computer (not visible) or the pen was placed in a clear plastic pen holder beside the computer. Finally, participants evaluated the perceived cognitive difficulty of the consumer choice task, and evaluated the pen (0=very bad, 100=very good) as part of a general survey of the lab experience.

Results

Guilt Compliance Rate. Overall, 87% of participants in the guilt condition chose the 'leave early' pen. Therefore, the analysis comprised of 87 participants.

Pen Evaluation. A 2 (guilt: guilt, no guilt) X 2 (pen visibility: visible, not visible) ANOVA conducted on participants pen evaluation revealed a significant interaction ($F(1, 83)=5.70, p<.02$). Guilty participants rated the pen less favorably when the pen was in sight ($M=66.96$) compared to out of sight ($M=81.74$). In contrast, in the non-guilty participants, participants rated the pen more favorably when visible after the pen choice task ($M=82.25$), compared to when the pen was removed from sight ($M=67.38$).

Perceived Difficulty. A 2 (guilt: guilt, no guilt) X 2 (pen visibility: visible, not visible) ANOVA conducted on participants perceived difficulty revealed a significant interaction ($F(1, 83)=3.70, p<.05$). Guilty participants rated found the binary choice task more difficult when the pen was visible, compared to the not visible condition. The perceived difficulty suggests that guilty participants with a visible reminder were engaged in more effortful affect regulation, which is cognitively taxing (Richards and Gross 2000).

Discussion

We show that guilt may result in a less favorable evaluation of a reminder object when in sight. We propose that this occurs because guilty participants believe that a visible reminder interferes with attempts at affect regulation. Our current work examines whether the effect is driven by the pen in sight (interfering with affect regulation 'haunting effect') or the pen removed from sight (allowing for successful regulation). We did not include a subsequent measure of guilt in the present study. Alternatively, the reminder may merely support intuitive beliefs that thought suppression is an effective strategy for regulating guilt, regardless of whether there is an actual reduction in experienced guilt. If this is the case, we might expect a misattribution of anger to the reminder object due to perceptions of goal inhibition. Hence, we are also investigating how people monitor their progress when affectively regulating. To sum, our results suggest that hiding a guilt ridden reminder—a seemingly unusual reaction—may in fact be an adaptive strategy for guilt regulation.

The Big Cost of Small Problems: Ironic Effects of Malfunction Severity on Enjoyment

Neil Brigden, University of Alberta, Canada

Gerald Häubl, University of Alberta, Canada

Consumers frequently face product malfunctions that vary in severity. One might reasonably assume that the negative impact of a malfunction on consumer enjoyment is proportional to the severity of the malfunction. In other words, larger malfunctions should lower enjoyment more than smaller malfunctions. In this paper, we propose that this is not always true and that more minor malfunctions can reduce enjoyment more than objectively larger malfunctions. This paradoxical result is possible because of the persistence of smaller malfunctions. Consumers tend to address larger malfunctions immediately while allowing smaller malfunctions to persist.

We hypothesize that smaller malfunctions are allowed to persist because of an affective forecasting error in which the long-term impact of the malfunction is underestimated. We also hypothesize that following an initial decision to not repair a product problem, inaction inertia takes over reducing the likelihood that the decision will be revisited.

The underestimation of a smaller malfunction's long-term negative impact on enjoyment is an affective forecasting error where the individual inaccurately predicts how a future state will make them feel. The idea that small problems could be more harmful than larger ones has been suggested previously in the affective forecasting literature (e.g. Wilson & Gilbert 2003). Wilson, Gilbert and colleagues have also demonstrated that this effect can occur in the domain of emotional experience because psychological processes that ameliorate distress are only triggered when a certain threshold of distress is reached (Gilbert et al. 2004).

The affective forecasting error that we explore in the domain of product repairs is atypical in its direction. In general, research has found evidence of a consistent impact bias, whereby individuals *overestimate* the continued impact a specific event will have on their future emotional experience (Wilson & Gilbert 2003). Here we believe underestimation is more likely because the malfunction is a persistent state rather than a discrete event and because consumers may fail to account for the malfunction at all in their forecasts due to a perception that the malfunction is too minor to impact enjoyment.

Once a consumer has decided not to repair a malfunction, inaction inertia prolongs the malfunction. Inaction inertia refers to the decreased likelihood of taking an attractive course of action when a similar and superior course of action has been previously foregone (Tykocinski & Pittman 1998; Tykocinski, Pittman & Tuttle 1995). Therefore, even if consumers recognize that a persistent malfunction should be repaired, they will be unlikely to repair it because they have missed a superior opportunity to repair in a previous time period.

Two experiments tested these hypotheses. In both experiments, participants experienced a malfunction with a hedonic product, had the option of repairing it and then continued to use the product in its repaired or unrepaired state. The key dependent measure in both studies was participants' self reports of enjoyment with the product.

Experiment 1 used a video viewing experience in which participants watched stand-up comedy on a computer screen. The malfunctions in this study were 2-4 second bursts of audio static. In the larger malfunction condition they occurred 8 times per minute, while in the smaller malfunction condition they occurred 2 times per minute. Malfunction severity was manipulated between subject. In both conditions, participants saw a 30 second preview clip and then watched a 10 minute clip. Participants could fix the malfunction at any time during the 10 minute clip by pressing a button. The cost of fixing the problem was one minute of mute (no audio at all). As predicted, participants in the larger malfunction condition were more likely to fix the problem, fixed the problem earlier in the clip and reported enjoying the video more than participants in the smaller malfunction condition.

Experiment 2 used a computer game experience in which a repair to the malfunction could only be made prior to the start of the experience. Participants played a game called Snake, in which they used the arrow keys to control a snake on screen and attempted to eat apples without crashing into the sides of the game area or the snake's body. The malfunctions in this study were random moves that turned the snake without the participant's control. These occurred 20 times per minute in the larger malfunction condition and 5 times per minute in the smaller malfunction condition. In line with our predictions, participants in the larger malfunction condition were more likely to repair the malfunction and reported enjoying the game more than participants in the smaller malfunction condition.

The decision of whether or not to fix a minor malfunction has important consequences for both the consumer and the marketer. The decision will directly affect the consumer's short and long-term enjoyment of the product. The marketer will be indirectly affected by the consumer's retrospective evaluation of the product experience which in turn will influence behaviors such as repeat purchase and word-of-mouth communications with other consumers.

It is not the case that all malfunctions should be fixed, but we find evidence suggesting that there is a class of minor malfunctions that consumers typically do not fix that significantly impair enjoyment. Our results suggest that consumers may not always make normative repair decisions and that marketers might improve consumer experience by offering decision assistance to the consumer.

**The Abandonment of Unprofitable Customer Relationships:
An Analysis of Emotional Reactions**

Michael Haenlein, ESCP Europe, France
Andreas M. Kaplan, ESCP Europe, France

The proactive termination of customer relationships that lack profitability ("unprofitable customer abandonment") has previously been discussed in academic literature and shown to be associated with substantial value (Haenlein et al. 2006). Nevertheless, there is only insufficient insight into its impact on existing customers the abandoning firm would like to retain. Our study therefore investigates (a) the emotional reactions of the abandoning firm's current customers in response to unprofitable customer abandonment, (b) how the tie strength towards the abandoned customer influences these reactions, and (c) the relationship between emotional reactions and behavioral intentions in response to unprofitable customer abandonment.

Following the work of Clore et al. (1987) we use the term emotion to describe internal mental affective conditions. We classify emotions along the two dimensions valence (positive/ negative) and focus (ego-focused/other-focused) (Kitayama et al. 2000; Kitayama et al. 2006). Consistent with attribution theory (Mizerski et al. 1979), we assume that unprofitable customer abandonment will result in causal attributions that lead to emotional reactions (Weiner 1985). We furthermore assume that strong tie relationships are more consistent with an interdependent (vs. independent) construal of the self and therefore with other-focused (vs. ego-focused) emotions (Clark 1984; Clark et al. 1986; Frenzen and Nakamoto 1993):

H₁: The tie strength toward the abandoned customer will have (a) a negative impact on the occurrence of ego-focused emotional reactions and (b) a positive impact on the occurrence of other-focused emotional reactions.

Prior research indicates that different emotions are related to different action tendencies (Roseman et al. 1994; Shaver et al. 1987). We assume that the valence of emotional reactions will have a relationship to the choice between positive (i.e. loyalty, positive WoM) and negative behavioral intentions (i.e. exit, negative WoM, boycott). In addition, we postulate that the focus of emotional reactions will be associated with the choice between individualistic (i.e. exit, voice, loyalty) and collective (i.e. boycott) reactions (Klein et al. 2004; McGraw and Tetlock 2005; Sen et al. 2001):

H₂: Positive emotional reactions will have a stronger association with positive and a weaker association with negative behavioral intentions than negative emotional reactions.

H₃: Other-focused emotional reactions will have a stronger association with collective and a weaker association with individualistic behavioral intentions than ego-focused emotional reactions.

Data collection was carried using an online experiment. We collaborated with a US market research firm who distributed our questionnaire via e-Mail to an online consumer panel. This resulted in a usable sample size of 428 respondents. Respondents were first asked to provide the name or initials of "a casual acquaintance" (weak tie condition) or of "one of their closest friends" (strong tie condition, Frenzen and Nakamoto 1993). They were then exposed to a scenario text describing an unprofitable customer abandonment decision implemented by a mobile phone provider. Respondents are approximately equally split by gender, on average 43 years old with an annual income of approximately \$40,000.

Emotional reactions were measured following the work of Kitayama and Markus (2000; 2006). Behavioral intentions were measured building on Hibbard et al. (2001) for threatened withdrawal, constructive discussion, passive acceptance, and venting; Ping (1993) for exit, voice, and loyalty intentions; Bougie et al. (2003) for negative WoM; Sen et al. (2001) for boycott; and East et al. (2007) for positive WoM. To test for demand artifacts we asked respondents whether they could imagine an actual mobile phone provider behaving in the way described in the situation (M=3.11, SD=1.07) and whether they believed that the described situation could happen in real life (M=3.49, SD=1.01) on a scale from 1 to 5. The effectiveness of our tie strength manipulation was verified based on four items used by Frenzen and Nakamoto (1993).

Our analysis shows that hearing about unprofitable customer abandonment leads to emotional reactions among the abandoning firm's current customers. Surprisingly, we observe a relative high occurrence of positive ego-focused emotions: 20% of respondents report to (very) likely feel good about themselves while 15% feel self-esteem and 11% pride. With respect to the impact of tie strength, other-focused emotions are significantly more likely for the abandonment of strong tie than of weak tie relationships. H₁ is therefore supported.

Regarding behavioral intentions in response to unprofitable customer abandonment, negative emotional reactions are more strongly correlated with negative action tendencies (i.e. exit, threatened withdrawal, venting, negative WoM, boycott) while positive emotional reactions show higher correlation with positive action tendencies (i.e. collaborative voice, loyalty). Combined, this provides overall support for H₂. Yet, although other-focused emotions are experienced more frequently than ego-focused ones, virtually all action tendencies (with the exception of collaborative voice) show a stronger correlation with ego-focused than with other-focused emotions, leading to rejection of H₃.

These findings result in three theoretical contributions: First, we show that unprofitable customer abandonment can lead to positive ego-focused emotions and that these emotions are associated with positive behavioral intentions (i.e. loyalty). Second, we show that by terminating some client relationships and maintaining others, the company signals to its remaining customers that they are of higher importance to the firm. This apparently leads to the same positive ego-focused emotions as formally upgrading them to a higher loyalty program tier (Dreze and Nunes 2009). Finally, our work enhances the concept of ego- and other-focused emotions by extending it from a cross-cultural to an interpersonal context.

From a managerial perspective, our work provides two important insights: First, we show that unprofitable customer abandonment does not necessarily only lead to negative emotions within the current customer base. Second, our results indicate that the type of relationship toward the abandoned customer matters and influences the emotional reactions experienced in response to unprofitable customer abandonment. Although it is mainly ego-focused emotions that drive subsequent behavioral intentions, customers who are related to the abandoned customer through strong ties should be of specific concern to the abandoning firm.

Understanding Conformity in Consumption Contexts: Individual Differences in Need for Approval and the Propensity to Conform

Victor Barger, University of Wisconsin-Madison, USA
Joann Peck, University of Wisconsin-Madison, USA

Extended Abstract

The propensity of consumers to conform to social pressure is of great consequence to the marketing community. This is due in part to the wide-ranging implications of social conformity, from its influence on rates of adoption to the attractiveness of market segments. To date the marketing literature has focused mainly on personality traits that predispose individuals to conform to or resist social pressure. Research on traits that lead to acquiescence has revolved around constructs such as consumer susceptibility to interpersonal influence (Bearden, Netemeyer, & Teel, 1989) and attention to social comparison information (Bearden & Rose, 1990). Studies of factors that encourage resistance to social pressure are less common, but constructs such as consumers' need for uniqueness (Tian, Bearden, & Hunter, 2001) have been identified.

This paper hypothesizes that a hitherto overlooked individual trait, consumers' need for approval, underlies social conformity in consumption contexts. A review of prior attempts to measure need for approval sheds light on the construct, but reveals significant flaws in the extant measures. Currently, the primary measures of need for approval are the Demand for Approval dimension of the General Attitude and Belief Scale, the Approval by Others dimension of the Dysfunctional Attitude Scale, and the Crowne & Marlowe Social Desirability Scale. All three have roots in research conducted in the 1960's, the first two drawing on work in clinical psychology by Ellis (1962) and Beck (1967), respectively, and the third resulting from Crowne & Marlowe's (1960) research on accurate measurement of personality traits.

Based on our review of the literature, we define need for approval as *the extent to which an individual behaves in ways that he thinks others will approve of in order to get them to like him*. This conceptual definition proposes three features common to individuals who are high on need for approval: (1) they believe that they can get others to like them by behaving in ways that others approve of, (2) they are motivated to act on this belief, even if it requires subjugating their own desires and preferences, and (3) although they try to behave in ways that others approve of, they may or may not be successful at anticipating the behaviors that will garner the approval of others.

Consistent with the domain sampling model of measurement (Churchill, 1979), a pool of items was generated to capture the construct of need for approval. This was accomplished in three stages: (1) items were developed based on personal experience and understanding of the construct; (2) items from extant personality inventories were screened for appropriateness given the construct definition; and (3) undergraduate students were provided with the construct definition and asked to generate lists of items. Overlapping items from the pool were deleted and the remaining items were edited for clarity. The pool of items was then evaluated for content validity, and those that met the criteria were retained for further evaluation. In total, 64 items were obtained.

The pool of items was administered to a sample of undergraduate students at a large Midwestern university. Specifically, students enrolled in an introductory course in marketing were invited to participate in the study for extra credit. The questionnaire was administered in a computer lab, and responses were coded on 5-point Likert scales. Of the 425 students enrolled, 397 completed the questionnaire, for a response rate of 93%. After purification of the items using item-total correlations, Cronbach's alpha, and factor analysis, six items remained.

The purified measure was administered to a second sample of undergraduate students to assess construct validity. In addition to the need for approval items, items from related measures, such as need to belong (Leary, Kelly, Cottrell, & Schreindorfer, 2007), need for uniqueness (Snyder & Fromkin, 1977, 1980), and self-esteem (Rosenberg, 1965), were included. The 181-item questionnaire was administered in a computer lab, and responses were coded on 5-point Likert scales. Of the 264 students enrolled, 226 completed the questionnaire, for a response rate of 86%. Analysis of the responses support the convergent validity, discriminant validity, and nomological validity of the six-item measure of consumers' need for approval. In addition, support was found for the hypothesis that consumers' need for approval predicts consumer susceptibility to interpersonal influence when moderated by attention to social comparison information.

Similar to Bearden & Rose (1990), a conformity study in the guise of a soda pop taste test was conducted to ascertain the predictive validity of the measure. Undergraduate students who had previously completed the need for approval questionnaire were invited to participate. A 2 (social pressure vs. no social pressure) \times 2 (need for approval: high vs. low [determined by a median split]) design was employed, with the first factor manipulated between subjects and the second factor measured between subjects. In the no social pressure condition, subjects were asked to taste two sodas, Soda A and Soda B, and privately indicate their preferences on ballots. In the social pressure condition, subjects participated in the taste test one at a time with three student confederates; after tasting the two sodas, each student was asked to state their preference. The confederates were instructed to say that they preferred Soda B, and the subject was always asked last. A pre-test had revealed a strong preference for Soda A among students in general. A total of 238 subjects participated in the study, with 107 in the social pressure condition and 131 in the no social pressure condition. As hypothesized, subjects high in need for approval were more likely to choose Soda B than subjects low in need for approval when social pressure was exerted.

Social conformity lies at the heart of a wide range of marketing phenomena. As a driver of social conformity, need for approval offers promise for enhancing our understanding of social conformity. This paper proposes a measure of consumers' need for approval and demonstrates its utility in ascertaining the propensity of individuals to conform to social pressure in consumption contexts.

Trust or Not: The Role of Self-construal in Interacting with Salespeople

Wenxia Guo, University of Manitoba, Canada

Kelley Main, University of Manitoba, Canada

Extended Abstract

Today's marketplace is one that is internationally diverse. Individuals from different cultures have distinct self-construals (Resnick 1991), which suggest that marketing messages need to be tailored to their individual backgrounds. Individualist (Western) cultures tend to hold independence in high regard which makes the independent self chronically accessible, while collectivist (Eastern) cultures focus on interdependence which makes the interdependent self chronically accessible (Cousins, 1994). Cultural research on persuasion reveals that North American consumers have more favourable attitudes toward persuasion appeals that focus on the independent self, whereas persuasion appeals that focus on interdependent self have more positive effects on Asian consumers (Han & Shavitt, 1994). However, these persuasion appeals that are effective in advertisements may not operate the same way in retailing contexts in which salespeople interact directly with consumers. The current paper attempts to investigate the potential ways for salespeople to communicate with consumers from different cultures in which people may form distinct self-construals (independence vs. interdependence).

In a dynamic interaction between salespeople and consumers, trust is crucial to facilitate the purchase experience. As a result, it is important to understand how culture and trust interact and how to develop trust based on cultural differences in an interpersonal marketplace. Over time, consumers develop knowledge about the behaviours of salespeople they encounter and persuasion attempts used by advertisements. Persuasion knowledge (Friestad & Wright, 1994) is a resource that influences how, when, and why consumers respond to marketer's persuasion attempts. The situation in which persuasion messages match with consumers' self-construals has been applied in advertisements, so the same situation that occurs in retailing contexts may make consumers easily activate persuasion knowledge and lead to low trustworthiness. However, the situation in which persuasion messages from salespeople mismatch their self-construals is less used in advertisements, so the situation used by salespeople may be less likely to activate persuasion knowledge and result in higher trustworthiness. But, this effect may be moderated by situational salient self-construal.

Self-construal is a way in which people think about themselves. An independent self-construal emphasizes uniqueness or distinctiveness from others, while an interdependent self tends to focus on harmony and connectedness with others (e.g., Markus & Kitayama, 1991). Further research has provided evidence that the two selves can coexist within an individual (e.g., Zhang & Shrum, 2009). Accordingly, people's perceptions and cognition styles are influenced by a salient self-construal activated at a given time (Trafimow, et. al., 1991). The coexistence of two types of self-construals makes it possible for marketers to link their marketing communications with consumers' activated self-construals by making it salient through the use of external cues (Reed II, 2004). An independent self-construal is oriented toward people instead of social contexts (Morris & Peng 1994) and is likely to apply a context-independent cognitive style (Nisbett et al. 2001), so a consumer with a salient independent self-view may form impressions toward a salesperson based on dispositional attributions, leading to higher persuasion knowledge and lower trustworthiness toward salespeople who are perceived as making a sale regardless of whether persuasion messages from salespeople do or do not match the salient independent identity. In contrast, an interdependent self tends to apply a context-dependent cognitive style (Nisbett et al. 2001) and is oriented toward social contexts rather than people (Miller 1984), so a consumer with a salient interdependent identity may rely more on situational attributions as opposed to dispositional ones.

H1: When an independent self is salient, persuasion attempts either matching or mismatching with salient independent self will make no difference in terms of consumers' perceptions of trustworthiness toward salespeople. However, when interdependent self is primed, persuasion attempts mismatching with a salient interdependent self will lead to higher trustworthiness than matching persuasion attempts.

Study 1

This was a 2 (Persuasion attempt: focus on independent self-construal vs. focus on interdependent self-construal) X 2 (self-construal priming: independence vs. interdependence) between-subjects design (N=60). Half of the participants were presented with 18 scrambled sentences to activate an independent self and the other half were given sentences to activate an interdependent self (Skrull, 1978). Next, all participants were asked to imagine an interaction with a salesclerk where they were going to buy a camera. Half of participants were told

“That’s a great camera. Whenever you are together with family and friends, you can take pictures with them...” (focus on interdependent self-construal). The remaining was told: “That’s a great camera. Whenever you go for a trip, you can take those impressive and unique pictures...” (focus on independent self-construal). The primary dependent measure was trustworthiness ($\alpha=0.74$).

Results showed a significant interaction between persuasion attempt and self-construal priming ($F(1,55)=4.52, p<0.05$) and a main effect of priming ($F=5.52, p<0.05$). As expected, when participants were primed with an independent self-construal, a persuasion attempt that either matched or mismatched their salient independent self-identity made no difference in terms of trustworthiness toward the salesperson, whereas when participants were primed with an interdependent self-construal, a persuasion attempt mismatching the salient interdependent self resulted in higher trustworthiness than one matching with salient interdependent self. This result supported H1.

Discussion

Overall, this study contributes to the literature by demonstrating the different effect of persuasion attempts which match or mismatch with consumers’ temporarily activated self-construals (interdependence versus independence) in retailing contexts as compared to its effect in advertisement. Prior research finds that when persuasion attempts match with either an independent or interdependent self, there is a positive evaluation toward ads (e.g., Aaker & Maheswaran 1997). However, the current study indicates that in interpersonal settings, messages from salespeople have little influence for consumers whose independent self-view is accessible. In contrast, messages mismatching with consumers’ interdependent self led to higher trustworthiness than matching messages. This finding suggests that a salient self may play a role when trying persuasion attempts. In future, we would like to identify marketing related self-construal priming and also test the robustness of the result by using participants from different cultures, as research shows that people in Western cultures tend to hold independent self, while people from Eastern cultures focus on interdependent self (Cousins, 1994).

The Fundamental Attribution Error in Salespeople and Its Correction by Stealing Thunder: Evidence from Agents and Consumers

Wenxia Guo, University of Manitoba, Canada

Kelley Main, University of Manitoba, Canada

Extended Abstract

When you go shopping and encounter a salesperson, what is your first impression? Do you spontaneously think “untrustworthy” or “helpful”? When you automatically think untrustworthy, a stereotype toward salespeople is activated. Research has demonstrated that people are suspicious of salespeople’s behavior (Main, Dahl, & Darke, 2007) and have a negative stereotype toward salespeople (Babin, Boles, & Darden, 1995). This negative stereotype may influence consumers’ perceptions. Specifically, when dealing with salespeople, consumers may fall prey to the fundamental attribution error (Ross, 1977), which holds that when forming impressions, people tend to misattribute others’ behavior to dispositional factors (e.g., untrustworthy) while underestimating the impact of situational factors.

We argue that consumers who have no work experience as salespeople may easily apply FAE when processing feedback from salespeople, as their early negative impressions may bias the interpretation of later information. In turn, the application of FAE may lead to high persuasion knowledge (Friestad & Wright 1994). In contrast, consumers who have worked as salespeople may hold relatively accurate perceptions of salespeople, so they are less likely to apply the FAE.

H1: Consumers with experience as salespeople will have higher perceptions of trust toward salespeople who provide them with positive feedback than consumers without experience as salespeople.

A second question is how to counteract the negatively biased judgments of salespeople’s trustworthiness (i.e. the sinister attribution error) evidenced in retail settings (Main et al. 2007). One possibility is the use of stealing thunder which is a dissuasion tactic in which people self-disclose potential weaknesses to reduce its negative impact on others’ evaluations (Dolink et al, 2003). That is, salespeople may use the stealing thunder tactic by self-disclosing a plausible ulterior motive to increase their perceived trustworthiness. However, this effect may be moderated by work experience as salespeople. Consumers who have worked as salespeople may recognize stealing thunder as a tactic, so they are less likely to trust the message. Therefore:

H2: Flattery with stealing thunder will lead to higher perceptions of trust toward salespeople than flattery alone for consumers without salesclerk experience. However, this stealing thunder will have negative effects on consumers who have worked as salespeople.

Study 1

Method. This was a 2 (flattery: alone vs. combined with stealing thunder) \times 2 (consumer types: salesperson experience vs. no experience) quasi experimental between-subjects design (N=74). Participants self identified whether they worked as salespeople previously. They imaged an interaction with a salesclerk where they were going to buy a pair of sunglasses. Participants were either told that: “That’s a great pair of sunglasses. ... (flattery)” or “You may think that I am just trying to make a sale, but that’s a great pair of sunglasses. ... (stealing thunder)” The dependent measure was trust (Main et al., 2007; $\alpha=0.81$).

Results showed a significant interaction ($F(1,70)=6.41, p<0.05$). Planned contrasts showed that for flattery alone, participants with sales experience had higher trust in the salesclerk than those without experience ($F(1,70)=8.48, p<0.01$), as per H1. Planned contrasts also supported H2. Participants without experience perceived salespeople as more trustworthy when flattery was combined with stealing thunder than when provided alone ($F(1,70)=3.43, p=0.068$). In contrast, participants with sales experience rated lower trust for flattery used with stealing thunder than flattery alone ($F(1,70)=3.0, p=0.088$).

Study 2

It is well established that motivations have an influence on information processing (Chen & Chaiken, 1999). A motivation for accuracy may drive people to “use all attribution-relevant information” (Vonk, 1999, p.383) instead of dispositional bias like the FAE. Consequently, under accuracy motivation, flattery combined with or without other tactics (e.g., stealing thunder) will have little influence on consumer’s information processing. On the contrary, defense motivation is a desire to hold attitudes that are congruent with one’s prior beliefs (Chaiken, Giner-Sorolla, & Chen, 1996). In retailing contexts, when defense motivated, flattery may lead to lower perceptions of trust for consumers without sales experience than consumers who have, as the former may be more likely to attribute causation to salespeople’s dispositions than the latter. However, flattery combined with stealing thunder will result in the opposite effect under defense motivation.

H3: Stealing thunder will be only effective for consumers without sales experience under defense motivation, while it will make no difference under accuracy motivation.

Method. It was a 2 (flattery: alone vs. combined with stealing thunder) \times 2 (consumer types: salesperson experience vs. none) \times 2 (motivation: accuracy vs. defense) between-subjects design (N=141). The manipulation of flattery was the same as Study 1. Participants were asked to image an interaction with a salesclerk. Half of them were told to buy a pair of sunglasses. Given that buying sunglasses is the primary shopping goal, this should lead them to want to avoid being tricked by the salesclerk (defense motivation). The remaining participants were asked to go shopping for a jacket and try on sunglasses beforehand (accuracy motivation).

Trustworthiness. A 2 X 2 X 2 ANOVA on trust yielded significant two-way interaction between flattery type and consumer types in support of H2 ($F(1, 133) = 5.14, p < 0.05$) and three-way interaction ($F(1, 133) = 4.87, p < 0.05$). Planned contrasts supported H3. Under defense-motivation, participants without experience rated higher trust with the use of stealing thunder than the use of flattery alone ($F = 8.48, p < 0.01$), while under accuracy-motivation, there were no significant effects ($F = 0.28, p = 0.60$ (flattery) and $F = 0.24, p = 0.63$ (stealing thunder)). Further, under defense-motivation, higher trust was evidenced with the use of stealing thunder for participants without experience than those with experience ($F = 7.74, p < 0.01$), while for flattery alone, participants with experience had higher trust than participants without experience ($F = 4.04, p < 0.05$).

General Discussion

This research demonstrates that after flattery, consumers with sales experience rated trust higher than consumers with no experience. Salesclerks can provide positive feedback to consumers without experience when used in combination with stealing thunder. Defense-motivation influences the interpretation of these tactics, while accuracy-motivation does not. The present study contributes to the literature by: (1) identifying when salesclerks can provide positive feedback and be trusted, (2) demonstrating evidence of the application of FAE by salespeople, and (3) demonstrating the impact of motivations.

To Punish or to Forgive: Examining the Effects of Consumer Penalties on Perceptions and Behavioral Intentions towards the Service Provider

Lan Xia, Bentley University, USA

Monika Kukar-Kinney, University of Richmond, USA

Price penalties are imposed on consumers in various industries especially services. For example, retailers charge a restocking fee when consumers return unwanted products; airlines charge a cancellation or re-ticketing fee when travelers change their plans; and banks charge a late payment fee when consumers fail to pay their credit card bills on time. While service providers claim that penalties are imposed to enhance compliance and compensate for the loss when customers fail to comply, consumers may not agree. Research showed that the presence of a penalty only slightly enhances compliance (Fram and McCarthy 2000). In contrast, there is a prevalent feeling among consumers that service providers abuse their power and perceive the penalties as revenue enhancement rather than covering costs (Fram and Callahan 2001). As a result, many penalties are perceived as unfair and consumers develop negative emotions

and vengeful feelings. These undesirable perceptions and emotions subsequently lead to behavioral consequences including switching service provider and negative word-of-mouth (Fram and McCarthy 2000, Kim and Smith 2005).

Research on consumer penalties is sparse. The existing research is exploratory in nature and has mostly focused on consumer negative perceptions and behavioral intentions. However, research showed that about 50% people challenge the penalties (Fram and Callahan 2001). Consequently, not all penalties will result in negative consequences for the consumer, as the provider may decide to lift the penalty after the consumer contacts them. The way in which service providers handle the interactions with customers who challenge the penalties should significantly influence subsequent consumer behaviors. Service provider's flexible handling of penalties may have a positive influence on customers' responses (Kim and Smith 2005). Penalties also create opportunities for service providers to interact with their customers. Therefore, the long-term effect of the penalty may well depend on these interactions.

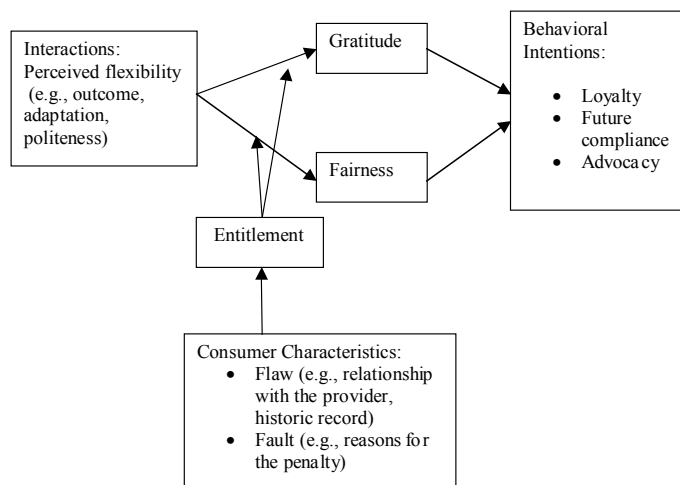

In this research, we focus on potential positive effects of a penalty arising from customer-service provider interaction (see Figure 1). We propose that consumers perceive flexibility of service provider in handling requests regarding penalties based on various factors arising during the interaction (e.g., outcome, whether consumers' specific situation is considered, the emotional exchanges, etc.). Perception of provider's flexibility will induce feeling of gratitude as well as reduce unfairness perceptions associated with the penalty procedure or outcome. Recent research shows that emotions, such as gratitude, play an important role in strong relationship building (Palmatier et al. 2009). Thus, it is expected that customers who positively resolve the penalty will appreciate provider's flexibility and will consequently develop a stronger relationship with the provider. Therefore, grateful customers will not only stay loyal, but will also serve as an advocate for the service provider via generating positive word-of-mouth, and will be more likely to comply with the providers' requirements in the future. In addition, perceived provider's flexibility will also enhance consumers' fairness perceptions and hence loyalty intentions. We also propose that the effects of customer-service provider interactions are moderated by additional consumer characteristics. Finkel (2001) suggested that when misfortune happens (e.g., being penalized), fairness judgment is influenced by assessment of whether the person is flawed (e.g., a bad person deserves to get a bad outcome) or at fault (e.g., the person is responsible for the bad outcome). In the context of penalties, consumers' consideration of factors such as whether the penalty is due to their fault and whether they have a good record with the provider may influence their feeling of entitlement and expectation of the penalty resolution, and hence the feeling of gratitude and fairness judgment.

To test the above propositions, we conducted an online experiment in the context of late fee for credit card payment (n=290). We manipulated customer relationship with the bank (loyal vs. new customer), whether the customer is at fault (controllable vs. non-controllable situation), and resolution outcome upon contact (penalty imposed vs. lifted). Participants were provided a scenario describing the late fee penalty, reasons for being late, customer relationship with the service provider, and interactions with the provider upon contact. Then they responded to a set questions including their emotions, feeling of entitlement, perceived flexibility of the bank, perceived fairness of the late fee procedure and outcome, and their future behavioral intentions with respect to the provider (loyalty, intention to advocate, and future compliance).

Results show that participants who get the penalty due to their own fault feel less entitled to have the penalty lifted than those who are late due to uncontrollable factors. Loyal customers feel more entitled to have the penalty lifted than new customers. Feeling of entitlement reduces fairness perceptions of the penalty procedure. Consumers who perceive the penalty practice and outcome as more fair are more likely to stay loyal to the provider. However, entitlement does not reduce feeling of gratitude. On the other hand, we find that the perceived provider's flexibility in handling the penalty (induced by whether the service provider lifted the penalty upon request) has an important positive effect on perceived fairness. In addition, outcome resolution influences perceived flexibility which contributes to feeling of gratitude. When consumers feel grateful, they not only stay loyal to the provider, but also express greater intention to advocate for the provider. Finally, neither fairness nor gratitude has a direct effect on tendency to comply in the future. Loyalty intentions are the only driver of increased future compliance.

In addition to the above study, we are planning new studies to examine both consumer and consumer-provider relationship factors in other contexts as well as additional factors influencing perceived flexibility of the service provider in handling penalties such as whether they adapt to consumers' specific background or situation.

Given the potential tensions, conflicts, and opportunities created by consumer penalties between service providers and their customers, it is important to fully understand the effects of these punishments on customers' evaluations in order to properly administer and manage these penalties. We believe our research will provide important theoretical and empirical implications.

Make a Funny: Humor Production and the Benign Violation Theory

Bridget Leonard, University of Colorado, USA

Caleb Warren, University of Colorado, USA

A. Peter McGraw, University of Colorado, USA

Popular sentiment maintains that if you can make someone laugh, you can make someone buy. Humor attempts are common in marketing communications (e.g., commercial interludes, print ads) and entertainment products (e.g., television, web-content). Humorous products, such as hit films like *The Hangover*, can generate hundreds of millions of dollars in revenue (www.the-numbers.com 2010), and an estimated 10% to 30% of advertisements attempt to elicit humor (Lee and Lim 2008; Krishnan and Chakravarti 2003; Weinberger and Spotts 1989). Consequently, understanding how to create humor is important for both marketers and consumers.

Since Plato, scholars have offered many explanations of what makes things humorous (Morreal 1987; Provine 2000). Some of these explanations account for particular types of humor, such as verbal humor (Raskin 1985) or irony (Giora 1995). As discussed below, others attempt to account for all types of humor. Although many empirical tests address how well different humor theories explain humor (see Martin 2007 for a review), we are unaware of research that examines how understanding a theory of humor improves humor production. Knowing how to create humor, however, is far more useful for marketers than simply knowing how to explain it.

We investigate if learning about a humor theory will facilitate the creation of humor. The three most prevalent general theories of humor are superiority theory, incongruity theory, and relief theory (Martin 2007; Raskin 1985; Speck 1991). Incongruity theories suggest that humor occurs when one perceives something that does not match their expectations or is inconsistent with their beliefs (Elpers, Mukherjee and Hoyer 2004; Suls 1972). Superiority theory suggests that humor requires feeling better than someone else and typically requires some form of aggression or disparagement. Relief theory suggests that humor occurs when arousal from repressed drives is released (Freud 1928; Spencer 1860). Relief theory, however, has largely fallen out of favor because (1) it proposes mechanisms most researchers consider implausible, and (2) its predictions are not supported by empirical evidence (Martin 2007).

Recently, McGraw and Warren (2010) proposed a general humor theory called the benign violation theory (BVT). The BVT suggests that humor occurs when people perceive a violation, or something that threatens their beliefs about how the world ought to be, but simultaneously see the violation as benign. We suspect the BVT may facilitate the production of humor relative to other humor theories because it suggests a wide array of potentially humorous stimuli. For example, unlike incongruity theory and superiority theory, the BVT predicts that the mock aggression in play fighting and tickling will arouse humor in the recipient (Gervais and Wilson 2005; Koestler 1964; Matsusaka 2004). Additionally, we suspect that incongruity theory and superiority theory may encourage the production of stimuli that are incongruous and disparaging but are distressing because the attempt "goes too far."

Our study tests which general humor theory best facilitates the production of humor for a print advertisement. We asked 57 marketing undergraduates to create a humorous headline for an advertisement for an online thrift store (thriftonline.com) that contained a photo of a male and female couple wearing mismatched clothing. Participants were randomly assigned to one of four conditions. In three experimental conditions participants were instructed to create a funny headline using a (randomly assigned) description of a humor theory: superiority theory, incongruity theory, or the benign violation theory. In the control condition participants were simply instructed to create a funny headline. Participants were told that they had ten minutes in which to make their headline as funny as possible for an audience of their peers. Afterwards, participants answered manipulation check questions to determine the degree to which they had used the theory for the task.

In a second phase of the study, 26 undergraduate students rated the funniness of each headline on a scale from 1 to 5 with higher numbers indicating higher levels of perceived humor. Perceptions of humor were reliably correlated ($\alpha=.76$) so we averaged the ratings of the 26 judges for each headline. Participants who used the BVT created the funniest headlines ($M=2.38$), followed by participants in the control condition ($M=2.30$), participants who used incongruity theory ($M=2.17$), and finally, participants who used superiority theory ($M=2.13$). Contrast analysis revealed that participants who used the BVT produced funnier headlines than participants who used either superiority theory or incongruity theory ($F=3.26, p<.08$). The analysis reached standard levels of significance when we controlled for the participant's gender ($F=4.3, p<.05$).

We examined the degree to which participants used the humor theory that they were assigned. Participants reported using the BVT to the same degree, on average, as the other theories ($M_{BVT}=4.50, M_{Others}=4.46$). Participants, however, were more likely to report using superiority theory than incongruity theory ($M_{superiority}=5.50, M_{incongruity}=3.46, t=-3.2, p<.01$). Importantly, the judged use of the humor theory helped participants who used the BVT but not participants who used either incongruity theory or superiority theory. For participants in the BVT condition, use of the theory had a strong positive correlation with the average funniness rating ($r=.70, p<.01$). For participants in the other humor theory conditions, however, use of the theory was uncorrelated with average funniness

rating ($r = -.14$, $p > .6$ and $r = -.07$, $p > .8$, respectively). That is, participants who reported using the BVT created funnier headlines than participants who learned about the BVT but did not use it. Conversely, using the theory did not appear to help participants exposed to either incongruity theory or superiority theory.

“Is That a Real Song or Did You Just Make It Up?” Styles of Authenticity in the Cultural (Re)production of Music

Jon Littlefield, Berry College, USA
Robert Siudzinski, Washington College, USA

Extended Abstract

Music as an art form has many linkages to consumption. While music itself is consumed in the form of songs, videos, and concerts, its consumption is also integral in the consumption of other art forms such as films (Holbrook 2008; Suisman 2009) and commercial forms such as advertising (Scott 1990) and retail atmospherics (Kellaris and Kent 1993; Kotler 1973/1974; Milliman 1986). Similarly, music often serves as the background in consumers' lives—commercial radio accompanies us on our daily errands or newer subscription-based services free us from the commercial (usually including musical) intrusion into our otherwise quiet lives while we dine, shop, or ride elevators (Bradshaw and Holbrook 2008).

Music is also consumed in its live form (Deighton 1992). Bands perform publicly and privately in venues as diverse as symphony halls and local blues clubs, and from marching band performances during athletic events to weddings and other gatherings. While we see performances as consumption, we might also see the production of music as a consumption activity (Bradshaw, Sherlock, and McDonagh 2003; Kerrigan, O'Reilly, and Lehn 2009). Musicians use instruments, amplification equipment, and pursue education; and put a great deal of effort into both individual practice and group rehearsal. Distinctions between musicians and non-musicians are difficult because musical groups may perform frequently, occasionally, or not at all. Similarly, the lines between professional and amateur musicians (Stebbins 1979; Thompson and Tambyah 1999) and between performer and audience member (Drew 1997; Minor et al. 2004) may at times be vague or nonexistent. Simply getting together with other musicians and “jamming” represents a community activity with its own set of norms and values that include respect for others' abilities, turn-taking, and providing support; and songwriters gain particular respect in this community for their originality¹ and authenticity.

FOOTNOTE

¹The title of this paper is derived from a CD of original music produced by a local songwriter's group.

In consumer research, authenticity is desired when cultural resources are used in the production of the self-identity (Beverland and Farrelly 2009; Hesmondhalgh 2008; Holt 2002). Authenticity is seen in opposition to the commercial (Belk, Wallendorf, and Sherry 1989;

Kozinets 2002) and may be seen as “staged” if a commercial connection becomes apparent to consumers (Murray 2002). In contrast, authenticity may be seen as a desirable consequence of a commercial transaction (Arnould and Price 1993) and may serve the role as a marker of status (Schouten and McAlexander 1995; Belk and Costa 2001). This paper reports the preliminary results of a study of local musicians’ expressions of authenticity. We were interested in assessing the varied nature of authenticities found in the culture of musicians (Bennett 1991), and in learning the degree to which the equipment required to produce music would be associated with these expressions.

The study uses qualitative methodology, including participant observation and depth interviews. The first author became immersed in the local music community by playing in a band, attending musical performances, participating in guitar circles, and attending meetings and monthly performances of a local songwriter’s group. We have, to date, conducted in-depth interviews with 8 musicians. Interview participants were recruited through the first author’s contacts within the community, and were questioned about their early influences, performance experiences, and equipment. As the topic of authenticity emerged early in the study, the interview guide was altered in order to more thoroughly capture what is authentic to these musicians. Data are analyzed using a hermeneutic approach (Thompson, Pollio, and Locander 1994; Thompson 1997). First, each interview was read to develop a perspective of each informant’s lived experience as a musician. This involved constructing a summary of that musician’s data and writing a narrative summary for each musician. Second, the interviews were thematically coded, the coded texts were sorted, and each code was analyzed across interview participants.

Preliminary findings suggest that, while authenticity is a moving target (Beverland and Farrelly 2009; Holt 2002; Rose and Wood 2005), musicians seek to capture and signal authenticity in a number of ways, some of them related to their equipment. Moreover, musicians’ legitimacy as performers is potentially contested terrain, and they seek to signal this legitimacy through use of appropriate equipment. For instance, some brands represented a higher degree of authenticity and use of equipment from previous eras in music was one path to legitimacy and authenticity (Grayson and Martinec 2004; Grayson and Shulman 2000; Holbrook 1993).

During the early phases of the study, we suspected that an authentic music experience was related to a nostalgic connection with the past (Holbrook 1993) or with particular music groups, and this expectation was consistent with our first finding. Perhaps ironically, other participants suggested that authenticity is attained through transcendence of the awareness of equipment and brands in favor of a focus on being in the moment with the music. For them, equipment and its use are necessary in creating music, but focus on equipment takes the artist away from that creational process (Heidegger 1962). This group was likely to suggest that authenticity is located in creativity and is represented in originality of music. For these musicians, often singer-songwriters, authenticity derived from a movement away from the ordinary into new musical terrain. Routes to this authenticity included writing music that was lyrically complex, melodic, and new.

In Search of an Authentic Conceptualization for Authenticity in Marketing Offerings

Kisson Lin, University of Hong Kong, China

Felix Tang, Hang Seng School of Commerce, China

Michelle So, University of Hong Kong, China

Extended Abstract

This research reviews and synthesizes the existing conceptualizations of authenticity. Authenticity is becoming a popular topic in contemporary literature and business practices. It has been applied to tourism experience (e.g., Wang 1999), music (e.g., Peterson 2005), leadership behavior (e.g., Bass and Steidlmeier 1999), culture (e.g., Linnekin 1991), education (e.g., Breen 1985), social study (e.g., Erickson 1995) and in marketing domains such as service delivery (e.g., Chalmers 2008), consumer rituals (e.g., Wallendorf and Amould 1991), consumer possessions (e.g., Grayson and Shulman 2000) and advertising (e.g., Stern 1994). However, the different conceptualizations of authenticity create great confusion for both academic researchers and marketing practitioners.

Confusion still exists when the scope of investigation is narrowed down to the domain of describing authenticity in marketing offering. In some articles, while authenticity has been named differently, their meanings are very similar if not identical. For instance, an offering which has the characteristic of unbroken commitments to tradition and place of origin, Beverland et al. (2008) calls it *pure authenticity*, while Grayson and Martinec (2004) refer to it as *indexical authenticity*. More commonly, authenticity (or its component) are named the same but referring to totally different aspects of it. For example, it means being genuine and natural when describing a commodity or person (e.g., Trilling 1972); trustworthiness when describing messages like advertisements (e.g., Chalmers 2008); being historically grounded and/or rooted in traditional modes of production (e.g., Peterson 2005); or similarity between two objects when describing products or individuals (e.g., Grayson and Martinec 2004). Therefore, it is vital to clear up this confusion to allow progress to be made in this stream of research.

This research provides a qualitative review on the existing literature on authenticity in marketing and identifies fourteen existing concepts, namely, indexical, iconic (Grayson and Radan Martinec 2004), natural, original, exceptional, referential, influential (Gilmore and Pine II 2007), existential, absolute, symbolic (Leigh, Peters and Shelton 2006), synthetic (Cloud, John, Time 2008), pure, approximate and moral (Beverland, Lindgreen, and Vink 2008).

The qualitative review includes two stages. In the first stage, the authors compare and contrast the fourteen conceptualizations of authenticity through logical induction. For each dimension, we review the definitions and examples from the article. Then, a panel of expert judges in linguistic and in communication reviews each of the conceptualizations and categorize them into four groups based on each of their definition and explanation. Afterward, the authors review and pick a conceptualization that best represents the group. We avoid creating new names that would lead to more confusion.

The four groups are: 1) indexical authenticity, which contains originality (which further includes true self or true origin, not a copy or imitation), and absolute connection with some time, venue, or person. It incorporates pure authenticity and absolute authenticity. The definition of exceptional authenticity is also partially incorporated; 2) iconic authenticity, on the other hand, requires no connection, but instead emphasizes on being similar to the object one resembles. It incorporates referential, approximate, symbolic, moral, and synthetic

authenticity; 3) existential authenticity, which describes one's sensation in the whole purchasing experience vis-à-vis the offering alone, incorporates the concept of influential authenticity; 4) natural authenticity, which focuses on the natural state of an object, represents a unique dimension of authenticity.

In the second stage, we run four focus groups in a large university in Hong Kong. The four groups comprise a good mix of student and non-student informants. The purpose is to examine the conceptualization's similarities and differences from a consumer's perspective and to explore how the four dimensions may link to different consumption behaviors. Informants share their past consumptions and views on various market offerings. Attention was drawn to their perception of various conceptualizations of authenticity describing marketing offerings, along with other marketing concepts, such as ethicality, loyalty, satisfaction, and quality.

Some interesting insights are found. Consumers may use indexical authenticity in judging the quality of a marketing offering and the ethicality of a purchase (e.g., counterfeits), but their satisfaction evaluation may be associated more with the iconic and existential dimensions. Natural authenticity is highlighted when the marketing offering is edible (e.g., ice-cream) or when it can be applied to the skin (e.g., skin care product). Furthermore, consumers focus on different dimensions of authenticity when describing different types of products and services. In general, the informants find that it is simple and easy to use the four proposed dimensions to describe the authenticity of their past consumptions.

This research contributes to the existing literature by reviewing fourteen existing conceptualizations of authenticity and synthesizing them into a simple and systemized four-dimensional framework. For academicians, our theoretically based framework eliminates overlapping categories in the existing conceptualizations and avoids confusion when one looks up the concept of authenticity. Perception of authenticity seems to be product category-specific. The framework should facilitate discussion from different streams of research on authenticity. Specifically, future research should explore which dimensions of authenticity are more important in different product categories. For practitioners, our framework gives them a simplified big picture as to the major dimension of authenticity that customers care about when they evaluate the authenticity of a marketing offering. From a strategic perspective, the four dimensions should be studied when offerings are positioned to be authentic.

Experiential Consumption: A Look at the Performing Arts

Gail Leizerovici, Richard Ivey School of Business, University of Western Ontario, Canada

Today's marketplace can be described as one which provides and sells experiences. Our economy has seen a natural progression from one which started with a focus on commodities during the early part of the 20th century, moving to a goods and services focus, with a final orientation on experiences (Pine and Gilmore, 1998). The question of what comprises positive experiences is difficult for consumers to articulate (Arnould and Price, 1993). Experiences are vague, and consumers do not necessarily know what to expect nor how to evaluate them. In the performing arts context, a more complicated question of how such experiences are received and assessed arises. Specifically, this context does not provide a tangible good for a consumer to take home at the end of a performance (except for the show program, for example). Arguably, the only "take-away" for the money rendered is the individual's memory of that experience.

This research is, to the best of my knowledge, the first attempt to unravel the underlying mechanisms that influence why individuals choose to consume performing arts experiences and, what makes these experiences successful for those involved. A four stage process is proposed in order to demonstrate the underlying mechanisms. These four proposed stages are: 1) Engagement, 2) Absorption, 3) Attachment of Meanings, and 4) Moment(s) of Utopia. While literature in philosophy and psychology have touched upon these various concepts using a variety of language, the ultimate contribution of this research is to develop a parsimonious, comprehensive framework of the relationships among these concepts. At this point in the research, it is hoped that this framework will provide a better understanding of the uniqueness of performing arts experiences, while also providing some insight into how these experiences typically unfold.

In support of this framework, the first proposed stage is *engagement* and is defined as the individual's willingness to attend the performance and therefore be involved in the impending experience. According to Arnould and Price (1993), individuals undergo a "rite of integration" when engaging in an experience-related event. Rites of integration can be defined as "planned social interactions that consolidate various forms of cultural artifacts...with the objective of achieving 'a temporary sense of closeness'..." (Siehl, Bowen, and Pearson, 1993). This *engagement* can be further described as one where the individual allows a "letting be of the process" (Arnould and Price, 1993) and where a converging of moods can occur (Totterdell, 2000). This emotion or mood component is further supported in Joy and Sherry's (2003) description of multi-sensory engagement. That is, the individual is not only aware of the surrounding environment and context in which they have become engaged in, but they have also submitted themselves to the impending power and emotion of the performance experience.

The next step proposed in this framework is *absorption*. This stage can be characterized by a complete focus and high level of involvement where the individual becomes disengaged from external distractions and constraints (Charters, 2006). According to Arnould and Price (1993), in a group consumption context individuals can experience an intensely positive experience due to the merging of actions, sharpness of focus, personal integration and awareness of enjoyment. Such intensity of experience and level of involvement reflects a high level of attention, interest and excitement, which can be a direct result of the individual's physical and sensual engagement. This can be observed via emotional responses among audience members, as well as the underlying cognitive processes which characterize such events (Holbrook and Hirschman 1982).

Following the engagement and absorption stages, the next proposed level in this framework is described as *attachment of meanings*. Research has shown that people imbue goods with symbolic meaning to supplement concrete attributes (Hirschman and Holbrook 1982). This is done in order to facilitate in imagining alternate realities, subsequently allowing a certain degree of disengagement from "real world" boundaries or constraints. Such psychological processes are said to occur because individuals like to pretend that something else is happening during consumption. An example relevant to the performing arts context is when individuals choose to attend a theatrical production because they identify with a particular character and imagine that they are the actor (Hirschman and Holbrook 1982). Performances are said to only acquire meaning because consumers attach meanings to them (Deighton, 1992). This imposition and attachment of meanings is what gives the consumer a greater level pleasure, allowing this process to facilitate their disengagement from external, worldly distractions.

The last stage in this framework is *moment(s) of utopia*. Utopia can be defined in this context as an ideal state. Literature in the areas of psychology and philosophy has also provided similar concepts to describe such a state, namely peak experience and flow (Csikszentmihalyi and LeFevre, 1989; Wild et al, 1995). This moment of utopia is a direct result of the build-up and integrative process proposed thus far (engagement, absorption, and attachment of meanings). Specifically, when the attachment of meanings is undertaken, and the individual perceives that their skill in interpreting and attaching these personal meanings matches the complexity of material from the multi-sensory input, then a state of utopia, flow or peak experience is achieved. When a moment of utopia, flow or peak experience is achieved, the temporal frame can be described as "standing still". Time no longer has a salient influence on the individual at this particular moment; instead, one is completely immersed with the experience (Thompson et al., 1990).

Ultimately, this paper presents a conceptual framework suggesting a number of interesting avenues for future empirical work. The initial phase of the data collection is on-going, and involves the use of semi-structured depth interviews with both performers and audience members at local musical performances. Future work could explore additional performing arts contexts as well as a broader range of geographic locations.

Adolescent Motivations to Watch Reality Television

Anthony Patino, Loyola Marymount University, USA
Velitchka Kalcheva, Loyola Marymount University, USA
Michael Smith, Loyola Marymount University, USA

Amongst the most watched programs on television today are reality programs (Nielsen 2008). For example, four of the ten most popular 2005-2006 television programs among viewers under 17 were reality programs, such as *American Idol* (Nielsen 2006). Because reality programs influence the buying behavior and consumption habits of adolescents (Strasburger, Wilson, and Jordan 2009), it becomes vital to investigate the popularity of reality television with adolescent viewers. We therefore conducted an exploratory study with the objective to examine adolescents' motivations to watch reality programming. In the next section, we review earlier research investigating people's motivations to watch television programming.

Prior Research on Television Viewer Motivations

Television motivation research is based on the Uses and Gratifications Theory developed by Blumler and Katz (1974). The central tenet of the Uses and Gratifications Theory is that viewers differ in their motivations for media use (Blumler 1979). People make decisions as to what program to watch—and whether to watch television at all—based on the needs and wants they seek to satisfy.

Adopting the tenets of the Uses and Gratifications Theory, earlier research identified motivations of adult viewers across multiple television genres (McQuail 1987; Rubin 1984) and for reality television specifically (Barton 2009). Prior research however did not investigate adolescents' motivations for watching reality programming. Studying adolescent viewers separately from adults is important for two reasons. First, there are significant age-related differences in social and cognitive development between adolescents and adults (for a review, see Roedder-John 1999), which are likely to result in dissimilar viewer motivations. Second, as previously discussed, research shows that adolescents are increasingly knowledgeable and influenced by reality television (Strasburger, Wilson, and Jordan 2009). We therefore conducted an exploratory study that begins to address this gap in the literature. Because our study is designed to generate preliminary insights into adolescent viewer motivations for reality programming, we do not offer formal hypotheses. Next, we describe the sample and measures, and then discuss the results.

Method

A national random sample of 800 adolescents, ranging from 13 through 18 years of age, completed online surveys. The sample was obtained from the Harris Poll Online (HPOL) opt-in panel. Respondents were first asked "What is the name of your favorite reality television show? If you do not have a favorite reality television show, please type 'none.'" Those who wrote the name of a program were then asked: "Why is [the listed program] your favorite reality television program?" Participants responded in their own words.

Results

Of the 800 respondents, 339 (46.13%) did not list a favorite reality program, and 30 (3.75%) listed a favorite program that was not a reality program. These 369 respondents were not included in the analyses. Of the 431 respondents who were included in the analyses, each listed on average 1.55 motivations. We divided the sample into two age groups: younger teens (12 to 15 year olds) and older teens (16 to 18 year olds), and analyzed adolescents' viewer motivations separately for males and females within each of the two age groups.

Two coders who were unfamiliar with the objectives of the study were asked to independently code participants' viewer motivations. Because of the exploratory objective of this research, we refrained from imposing an a priori structure on the data by suggesting content categories (viewer motivations) to the coders. We adopted the procedure described by Kaltcheva and Weitz (2006). First, each coder independently coded the responses to determine a set of relevant content categories. Next, through discussion, the two coders established a common set of content categories, and the definitions of those categories. Then, each coder used the established common categorization scheme and independently coded all responses. The intercoder reliability, evaluated with Perreault and Leigh's (1989) reliability index, was 86%, which is considered to be an acceptable level of inter-coder reliability (Saldana 2009). The coders resolved disagreements through discussion.

Because both the independent (four age x gender groups) and the dependent (viewer motivation categories) variables in our study are nominal variables, the data was analyzed using correspondence analysis, which is known as "factor analysis for categorical data" (Myers and Mullet 2003, p. 305). Correspondence analysis creates a two-dimensional space. The categories of the independent and dependent variables are located in that space in such a way that categories with similar (dissimilar) distributions are close to each other (far apart) (Clausen 1998).

In our study, the two dimensions accounted for 88% of the variance. One viewer motivation—entertainment/excitement—was located in the center of the two-dimensional space, and it was approximately equidistant from all age x gender groups, suggesting that watching reality programs for entertainment is an equally important motivation for all adolescents. Other viewer motivations were

differentially important across the four age x gender groups. Both male and female adolescents in the 16 to 18 age range (older teens) seek reality programs that incorporate dramatic situations and relationships among the program participants. Gender differences were found for the younger adolescents (the 13 to 15 age range). Whereas younger males prefer reality programs that involve humorous and/or inspirational elements, females of the same age watch a reality program because of one or more of the participants/characters featured in the program and the program's realism (real people placed in real-life situations).

Our results are consistent with extant developmental theories which show that the appreciation of dramatic content and human relationships typically requires a higher level of cognitive and emotional sophistication, which is gradually developed throughout adolescence (Vorderer and Knobloch 2000; Zillman 2000). Our research offers insights that would be helpful to television programmers, advertisers, and public policy makers. For example, television programmers and advertisers can utilize motivation-based segmentation when developing more targeted programming schedules and media buys with quality rationale. By understanding adolescent motivations to watch reality programming, public policy experts can appeal to the same motivations and encourage adolescents to engage in non-television activities, such as reading and exercise.

Consuming Stardust: The Consumption of Celebrities Beyond Product Endorsements

Diego Rinallo, Bocconi University, Italy

Eduardo Savi, Independent Scholar

We live in a world obsessed with celebrity. Michael Jackson. Madonna. Sofia Loren. Paris Hilton. Tiger Woods. These names are familiar to many people around the world and bring with them memories and emotions, positive and negative, both in those who actively follow their careers and life vicissitudes and in those passively exposed to the media hype surrounding the famous. Consumer researchers have long investigated celebrities for their role as product endorsers. Research in this domain, initially conducted from a social psychological perspective, views celebrities as particularly source of advertising messages (for a review see Erdogan 1999). In the consumer culture theory tradition (Arnould and Thompson 2005), celebrities are understood as receptacles of cultural meanings that are transferred to consumption goods through the act of endorsement (McCracken 1986, 1989). Both psychological and cultural perspectives have thus investigated celebrities from a narrow point of view. Following this year's call for big picture research at the North American ACR conference, in this paper we draw attention to the complex and multifaceted manners through which consumers consume celebrities—beyond the consumption of endorsed products.

Our study draws on data obtained from 18 informants (half men, half women; aged 13 to 50; mostly Italian) with varying levels of interest in celebrities (i.e., worship/fandom; active search for information; passive exposure to news). We conducted phenomenological interviews (McCracken 1988; Thompson 1997) lasting on average 90 to 120 minutes. Informants were asked about their views on celebrities, what they like/dislike about them, and several narratives of consumption stories and rituals centered upon the famous were elicited. We also resorted to photo-elicitation and autodiving (Heisley and Levy 1991) by showing informants pictures of appropriately selected celebrities and by asking them to bring pictures, videos and other relevant material (e.g., autographs). Interviews were transcribed

verbatim from digital records. Informants were given access to their transcribed interviews for correction and/or amplification. The interviews totaled more than 30 hours of conversation, resulting in approximately 360 pages of single-spaced discursive material and 47 auto-driven artifacts.

We found that celebrities can be consumed in highly complex manners. Specifically, in this paper we introduce the idea of three different layers of celebrity: the performer, the character, and the private self. These layers represent specific aspects of the flow of goods, news, performances and media images based on the celebrity. The *performer* refers to the celebrity's recognized performances—for instance, the Oscar-winning actor or the professional athlete whose skills earn her a gold medal at the Olympics. The *character* consists of the attitudes, looks, narratives, lifestyle and those other aspects that constitute the celebrity's public image beyond performances. Celebrities are sometimes known more for these aspects than for their professional achievements and a theme that reverberated throughout our interviews is the opposition between the “real” celebrities and the new brand of people “who are famous because they are famous” through the exposure gained with Big Brother, American Idol and countless other television shows. The third layer, the *private self*, is not easy to see through the looking glass of celebrities' manufactured public image. This aspect can only be imagined or glimpsed at by most consumers.

Each of these layers is consumed in its own specific manners. The performer is consumed through the output of his/her profession. The *consumption of professional excellence* entails a variety of consumption practices. For example, in the case of an actor, such practices include going to a movie theatre in the opening weekend of the star's new film; watching DVDs of those movies alone, with the partner or with friends; downloading legally or illegally those movies and collecting them. A second way to consume the performer is the *integration of their skills*. Dancers who imitate Michael Jackson's moonwalk, young kids' emulating famous skaters' moves, drummers who play according to Jimmy Hendrix's style are just a few examples of how this consumption practice can be expressed. This is particularly frequent in sports, where amateurism is widespread and champion role models are sought after.

Also the character is consumed in multifaceted ways. The *consumption of products* endorsed, designed or somehow linked to the celebrity is the most visible way of consuming the character. Consumers are willing to buy books, make-up, perfumes, fashion and other products because they are a way to feel close to their idols. However, the character may be consumed in other manners, without the mediation of consumer goods, by *reading/watching the news stories* regarding the celebrity, by *imitating their looks and attitudes* and, in some cases, by *integrating their ideas and values* into one's own life.

The person behind the media image is both the most difficult layer of celebrity and the most satisfactory object of consumption for a fan. The primary consumption practice involving the private self of a celebrity is the highly craved *personal contact* during or, even better, outside of professional contexts. Meeting a celebrity is often a fulfilling moment leading to cherished memories—although consumers may also be disappointed by the real person behind the celebrity's character. A less intense experience is the *indirect contact* with the celebrity through acquaintances' storytelling of personal encounters that give a voyeuristic a look at the idol's private self. Another related set of consumption activities involves *artifacts*, pictures of or with the celebrity and autographs being the most recurring ones.

Our emerging research findings extend understanding of celebrities' role in today's consumer culture by highlighting the multifaceted consumption practices centered upon the famous, which as we show go much beyond the consumption of endorsed products. We show that shared beliefs, social practices, consumption rituals and cultural meanings circulate also among non-fans, including those who are even annoyed by the media hype centered and consider them as anti-heroes, negative role models and scapegoats for society's ills. Our findings also have implications for celebrities themselves, who may be viewed as iconic brands (Rein et al. 1987). Specifically, the three layers of celebrity we identify lend themselves to different paths of celebrity legitimization through authentication acts that may converge or conflict among themselves.

Logo Image Effects on Consumer Perceptions of Packages

Adriana Madzharov, Baruch College, USA

Lauren G. Block, Baruch College, USA

Extant research has established that package size plays an important role in consumers' choice, preference and purchase quantity decisions (Raghubir and Greenleaf 2006; Wansink and Van Ittersum 2003). In addition, it has been found that consumers rarely search for and utilize volume information on package labels (Cole and Balasunbramanian 1993). Instead, in order to conserve mental effort, consumers make visual judgments of size easily and automatically using external and sometimes unrelated cues (Krishna 2007).

Consumers tend to utilize the most salient to them cue which leads to biased judgments of package size (e.g.: container shape, Folkes and Matta 2004; elongation of package, Raghurir and Krishna 1999).

So far research on perceptual biases has only looked at the structural elements of packaging (e.g., size, shape). In the present research, we argue that package size estimations are also biased by the graphics (images) displayed on the package. In particular, we examine how the size of the image on the package interacts with individual differences in visual processing and leads to differences in perceptions of package size, purchase intentions and opinion of the brand. We examine this effect in the context of package shelf facings that display a logo and a background frame that surrounds the logo.

We base our argument on visual perception theories which posit that appearance and perception of a visual entity depend on the attributes of the images presented on it (Arnheim 1954); and that the magnitude and accuracy of size judgments of a target depend upon its visual attributes (Baird 1970). Thus, we propose that the sizes of the images displayed on the package influence size estimations for the whole package. In addition, there are consistent individual differences in the relevant salience of cues (Kahneman 1973) where depending on their level of visual processing people articulate on different parts of the visual entity and find some cues more salient than others. In particular, people with high level of visual processing apply more global, top-down processing (Kirby, Moore and Schofield 1988). They are field dependent and are more influenced by the frame in a visual entity (Witkin 1950). Therefore, we propose that people with high visual processing will articulate more on the background area and will use its size as a cue for size of the whole package. On the contrary, people with low level of visual processing are more internally directed and apply detailed, bottom-up processing (Kirby et al., 1988). They are field-independent and are more influenced by the smaller figures in the visual entity (Witkin 1950). Therefore, we propose that people with a low level of visual processing will articulate more on the logo and will use its size to estimate size of the whole package. We hypothesize that people at low level of visual processing will perceive the package as bigger in size when the logo is larger; and that people at high level of visual processing will perceive the package as bigger when the background area around the logo is larger. Furthermore, previous studies have demonstrated greater preference for larger packages (Raghurir and Krishna 1999), thus we hypothesize that subjects will have higher purchase intent for packages they perceive as bigger.

We conducted one study with 108 participants that were randomly assigned to two conditions (size of images displayed on the package: small logo and large background; large logo and small background). Level of visual processing was measured using the Style of Processing Scale (Childers, Houston and Heckler 1985). Participants saw packages of detergents on a computer screen. Three regression analyses revealed significant interactions between condition and mean-centered visual processing on package size, purchase intent and opinion of the brand. Consistent with our hypotheses when the logo was big, subjects at low level of visual processing perceived the package as having more loads, and had higher purchase intentions and opinion of the brand. When the background area was large (the logo was small) subjects at high level of visual processing perceived the package as having more loads, and had higher purchase intentions and opinion of the brand.

The present research contributes to perceptual biases theory in the context of packaging by incorporating package images and individual differences in visual perception. Package size influences consumers in their preferences, willingness to pay and consumption, thus extending research on perception biases in packaging has not only theoretical significance but also important managerial implications.

The Psychology of Color in Promotion Design: A Regulatory Fit Perspective

He Jia, Nanjing University, China

Extended Abstract

Sales promotion is an important component of the marketing mix, which provides a direct and effective stimulus for purchasing behavior. Several studies have investigated the differentiated effects of free offer and monetary discount from a behavioral perspective. On the one hand, researchers have analyzed the advantage of the free offer over the monetary discount. For example, a free offer is processed more independently of price than a monetary discount (Chandran and Morwitz 2006; Nunes and Park 2003). Based on this assumption, Nunes and Park (2003) argue that compared with an equivalent cash discount, a free offer is less likely to suffer from diminishing marginal returns, and Chandran and Morwitz (2006) find that free offers appear more salient to consumers and therefore can isolate target products from the influences of negative product quality information.

On the other hand, there is a stream of research focusing on the different perceptions related to the two basic types of promotion. A monetary discount may be perceived as a nonloss by consumers since consumers can save some money by enjoying the discount, compared with the original price of the product. In contrast, a free offer may be perceived as a gain by consumers since consumers obtain additional utility beyond what the base product originally provides when they get free offers (Palazon and Delgado-Ballester 2009; Ramanathan and Dhar 2010). This conceptualization opens up an avenue for us to investigate how to enhance the effectiveness of promotional offers from a perspective of regulatory fit theory (Higgins 2000).

Drawing on regulatory fit theory and prior findings of promotion research and color research, this research aims to examine (1) which color to use in the poster of a specific type of promotional offer in order to enhance consumers' evaluation, (2) the mechanism underlying this effect, and (3) the boundary condition for the effects of color and promotion type on consumers' evaluation of the promotional offer.

Recent research in color implies that red can activate a prevention focus, whereas blue can stimulate a promotion focus (Mehta and Zhu 2009). As regulatory focus theory suggests, promotion-focused people are more sensitive to gains and nongains, whereas prevention-focused people are more sensitive to losses and nonlosses (Higgins 1997). When people with a prevention focus (versus a promotion focus) process a piece of information framed with losses/nonlosses (versus gains/nongains), they will experience regulatory fit which is driven by processing fluency (Lee and Aaker 2004). Regulatory fit can enhance consumers' evaluation of the focal object (Higgins 2000; Lee and Aaker 2004). Since consumers may perceive a free offer (versus a monetary discount) as a gain (versus a nonloss), and the blue color (versus the red color) can stimulate a promotion focus (versus a prevention focus), I hypothesize:

H1: A free offer is evaluated more favorably when its poster is colored with blue than red, whereas a monetary discount is evaluated more favorably when its poster is colored with red than blue.

H2: Processing fluency mediates the interaction effect between promotion type and color on consumers' evaluation of the promotion.

Since the effect of color and promotion type on consumers' evaluation of the promotional offer is driven by processing fluency, this effect is expected to occur when consumers in low involvement rely on heuristic processing (Wang and Lee 2006). Therefore, the price level of the focal product may moderate the effects of color and promotion type on consumers' evaluation of the promotional offer through altering consumers' involvement. When the price of the focal product is low, consumers are less motivated to process the relevant promotion and therefore more susceptible to the effect of processing fluency. On the contrary, when the price level of the focal product is high, consumers tend to elaborate on the relevant promotion information. In this condition, the effect of processing fluency will disappear. Hence, I propose the high price level as a boundary condition for the effects of color and promotion type on promotion evaluation:

H3: The interaction effect between promotion type and color on consumers' evaluation of the promotional offer is evident when the price level of the focal product is low.

Three experiments are scheduled to provide convergent support to the relevant hypothesis. In Experiment 1, I plan to adopt a 2 (Promotion-type: free offer versus monetary discount) \times 2 (Color of the poster: blue versus red) between-subjects design and measure participations' evaluation of the promotional offer. Using this design, I can investigate how promotion type and color of the poster interactively influence consumers' promotion evaluation (H1).

The purpose of Experiment 2 is to generalize the findings of Experiment 1 and obtain evidence for the process underlying the effects of promotion type and color of the poster on consumers' evaluation of the promotional offer (H2). Experiment 2 will be different from Experiment 1 in two ways: (1) Experiment 2 will adopt a different stimulus and (2) a process measure of processing fluency will be adopted.

Experiment 3 will be designed to clarify the mechanism in which color and promotion type influence consumers' evaluation of the promotional offer by investigating the boundary condition for the proposed effect (H3). This experiment will modify the design adopted by Experiment 2 by adding one more between-subjects factor (Price level: high versus low).

From a theoretical perspective, the current research investigates the relationship between the two ostensibly unrelated variables, color and promotion type, and therefore adds new knowledge to the promotion literature. Given that color is a common visual element to shoppers, this research is of special significance to practice in designing the poster of promotional offer. The findings of this research can provide practitioners with managerial implications which are highly actionable, since color of the poster is very easy to manipulate. The suggestion is that when presenting consumers with a free offer, the marketers had better use the blue color in the poster rather than the red color. On the contrary, it is more advantageous for marketers to color the poster of a monetary discount with red rather than blue.

Unanticipated Marketing Effects of Color: Empirical Tests in Two Contexts

Jungsil Choi, University of Kansas, USA
Surendra Singh, University of Kansas, USA

Extended Abstract

Marketers use colors extensively for a variety of reasons, from attempting to induce positive product attitudes and beliefs (Middlestadt 1990) to making customers linger longer in malls and have a more positive shopping experience (Bellizzi and Hite 1992).

Interestingly, humans perceive colors as cold (e.g., blue) and warm (e.g., red, orange) regardless of actual temperature (Stone 1998). [Note: A color consists of hue determined by its wavelength, chroma, and value, only hue is commonly used to describe a color]. And, cold colors tend to have shorter wavelengths compared to warm colors (Yildirim et al. 2007). Research shows that people feel more comfortable if they stay in cold-colored environments when feeling hot and warm-colored environments when feeling cold (Kearney 1966). Blue-colored workplaces tend to feel colder than warm-colored ones (Stone 1998). It is surmised that different temperature perceptions of color occur due to associative learning by associating the colors red and orange with objects such as fire and the sun, and associating the color blue with objects such as a deep sea and ice.

Furthermore, colors also influence emotional responses to the stimuli. For instance, warm colors are perceived as arousing and exciting, while cold colors are relaxing and calming (Bellizzi et al. 1983, 1992; Crowley 1993; Gorn et al. 2004; Valdez and Mehrabian 1994; Dijkstra et al. 2008).

Surprisingly, to date no one has investigated the effect of these inherent qualities of color (warm/cold; arousing/calming) on marketing communications and on consumer choice behavior. In two studies, we demonstrate that the type of color used affects the effectiveness of persuasive messages as well as the degree of risk-taking behavior. More specifically, we show how the type of color used in designing a message interacts with the type of message appeal to determine its effectiveness and how the type of color used for a stimuli background affects risk-taking behavior in terms of a positive and a negative event.

Color and Message Effectiveness of a Charitable Appeal

Charitable appeals can be broadly classified as either heartwarming, depicting hope, or heartbreaking, depicting desperation and misery (Bendapudi, Singh, Bendapudi (1996). We design two types of flyers soliciting help. A pretest showed that the heartwarming flyer aroused emotionally warm feelings of pleasantness and happiness, whereas the heartbreaking flyer aroused emotionally cold feelings of guilt, depression and sadness. Reasoning that it is a natural human tendency to find a warm place when feeling cold and a cool place when feeling warm, we propose that a heartbreaking (heartwarming) message will be more effective when presented in warm (cold) colors.

Using a 2 (message type: heartwarming vs. heartbreaking) x 2 (background color of the flyer: blue vs. orange) between subjects design, we randomly assigned 129 student participants to the various conditions. We measured informativeness, persuasiveness, and intention to donate. The results show an interaction effect of the type of color and the type of message on informativeness ($p < 0.01$). The post hoc analysis shows that the heartbreaking (heartwarming) flyer is more informative with orange (blue) background (respectively, $p < 0.05$). [Note: In designing stimuli, we control chroma and value but vary the hue]. We also find an interaction effect on persuasiveness ($p < 0.05$), such that the heartbreaking flyer with the color orange is more persuasive than that with blue ($p < 0.1$), but the heartwarming flyer with blue is not more persuasive than that with orange ($p > 0.1$).

The results also show an interaction effect on the intention to donate ($p < 0.01$). The post-hoc analysis shows that the heartwarming (heartbreaking) flyer with blue (orange) is more effective in enhancing the intention to donate ($p < 0.1$). It appears that the informativeness of the message mediates the interaction between the type of color and the type of message on the intention to donate. A color compatible with the message enhances the informativeness of the message. Although we did not measure it, it appears that the effect is due to greater attention derived to the message processing. The increased informativeness in turn affects the effectiveness of the message. Previous studies have shown that perceived sensory quality enhanced by a suitable atmosphere affects buyer's information and affective state

(Menon and Kahn 2002; Kotler 1973) and enhances consumers' attention, purchase intentions and shopping time (Baker, Grewal, & Levy 1992; Kotler 1973) in an online shopping mall as well as in a traditional store.

Effect of Color on Risk-Taking

We hypothesize that warm colors boost the felt excitement associated with risk-taking behavior in a positive event. Likewise cold colors dampen tension associated with a negative event. We use Hsee and Weber's (1999) stimuli to manipulate risk-taking behavior. In a 2 (background color: blue and orange) x 2 (event type: a lottery prize vs. a traffic fine) design, 86 students were randomly assigned to various conditions. We find the interaction effect between the type of color and the type of event on risk-taking behavior ($p < 0.05$). The post-hoc analysis shows that orange, compared to blue, induced more risk-taking in choices ($p < 0.05$) in a positive event but that blue, compared to orange, does not significantly increase risk-taking in choices ($p = 0.144$) in a negative event. In a follow-up study, we raise the stakes (by increasing the amount of prize and fine) and find that the effect of color on risk-taking behavior vanishes. These results demonstrate that color is likely a peripheral cue, and that its effects are attenuated under high involvement conditions.

These findings have clear implications for managers. Colors, be they in the background of a message or in a store could have profound effects on consumers and we need to take this fact into account in all facets of marketing decisions.

Empathy Drivers in the Uncanny Valley

Kristen Smirnov, University of Alberta, Canada

John Pracejus, University of Alberta, Canada

Extended Abstract

For several decades the idea has existed that there exists a state of "almost real" for humanoid figures that causes a strong negative reaction in the viewer (Mori, 1970). First suggested by a Japanese roboticist who had noticed the phenomenon in his daily work, Mori's concept of the "Uncanny Valley" went relatively unstudied for decades after its proposal. The past decade has seen a sudden surge of interest in the behaviors it describes. Robotics researchers have looked at this idea of poor reactions to something that cannot quite pass as real, but the idea has yet to be seriously studied outside their field; furthermore, their focus has been largely on elements of applied practicality to physical designs.

While this lack of research is understandable in decades prior, marketers are now studying consumers who are exposed to unreal figures in their daily lives. These figures range from entirely virtual to actual humans with a veneer of artificiality over them. Films that are entirely created with computer animation software earn hundreds of millions of dollars in the global box office. Photographs of models and celebrities are modified to remove imperfections and improve their proportions to a rigid standard of beauty (Reaves et al., 2004). Web sites use computer-generated avatars to guide users through the site's activities (Holzwarth, Janiszewski, & Neumann, 2006; McGoldrick, Keeling, & Beatty, 2008; Bauer & Neumann, 2005). Some companies choose to pursue the most realistic creations

they can manage in this arena, with such film examples as *The Polar Express* and *Beowulf*; others like Nintendo state that “[their] goal has never exclusively been to make things as likelike as possible” (MacMillan, 2007).

Research into portrayal of unrealistic figures has been relatively uncommon in the marketing field despite its presence in consumers’ daily lives. It tends, unsurprisingly, to focus on elements related to commercial applications (e.g. Holzwarth, Janiszewski, & Neumann, 2006). There has been no apparent attempt within marketing to investigate the concept of the Uncanny Valley from a more fundamental approach: how do people react in general to a figure that is not quite real, and why? We sought to investigate these behaviors through a series of studies.

Multiple hypotheses were in place as the studies began. Firstly, under Mori’s proposition, there should be a greater identification of inhuman features for an uncanny figure relative to a cartoonish one, even though the cartoon is by definition less human. Secondly, we expected to find that people’s own typical empathetic behaviors have an impact on how they react to uncanny figures. This, if true, would be an entirely new addition to the literature.

Poser software was used to model a woman’s face. (This particular software was chosen due to its previous use in psychological research on virtual facial imagery and its accessibility to business operations as a source of virtual figures (Karpouzis et al. 2003; Riva 1997; Spencer-Smith et al. 2001).) A rendering at maximum detail was made, including such specific levels of detail as individual hairs, freckles and pores. After this woman, dubbed “Aiko”, was rendered, a simplified cartoon version was made that traced her facial proportions but reduced the three-dimensional presentation of her face into a two-dimensional cartoon. This served as Condition 1 and the full rendering as Condition 5; Conditions 2, 3, and 4 blended these two images together at 75/25%, 50/50%, and 25/75% strengths, respectively. This mimics previous stimuli presentations for Uncanny work (MacDorman 2006).

A large single study has been the primary work so far on this research. Subjects (N=264) were randomly assigned to one of these five facial presentation conditions. They looked at Aiko’s picture for ten seconds after being told a cover story, at which point they were told to proceed to the next page and begin answering questions. Four empathy measures previously used toward Uncanny figures (Lee 2006) were taken on seven-point center-anchored scales: (1) “Do you hope this person succeeds?”, (2) “Would you let this person comfort you if you were upset?”, (3) “Do you think you know what this person feels?”, and (4) “Would you go to this person if they were crying?” Following this page was an adapted version of the PANAS (Watson, Clark, & Tellegen 1988) to measure the affective response to Aiko, where participants responded (also on a seven-point center-anchored scale) how strongly the picture had made them feel “bad,” “fearful,” “joyful,” etc. Participants then completed the 28-question Interpersonal Reactivity Index (Davis 1980, 1983) for measures of their own empathetic behaviors.

Results related to the figure itself were significant at a $p < .001$ level across the extremes (i.e. between the fully uncanny and fully cartoon image) in the expected direction, but were only significant at better than a $p < .05$ level between conditions 3 and 4. This suggests two things: one, that we have found the point at which behaviors begin to dramatically change, but also that we may have not used the best possible stimulus in this first attempt at a study. New figures will also be used in future work to avoid reactions specific to one model. However, we believe that a key finding here is that one element of individual empathy was significantly ($p < .05$) related to reactions to uncanny figures: the “fantasy” factor in Davis’ scale. Those people, possessing strong imaginations, both liked the cartoon version more and were more unsettled by the uncanny version. Considering these are the types of consumers who would likely be most interested in presentations of fictional characters and spokespeople, this seems a highly relevant finding to investigate further, to see if modern design choices will only serve to alienate this consumer group. We believe pursuing this type of subject with a greater variety of figure types, as well as showing moving figures rather than simply static ones, will help us further understand this topic which would be an entirely new entry into the consumer behavior field.

Come Closer: Anthropomorphized Products as Intimate Companions

Ana Valenzuela, Baruch College, CUNY, USA

Rhonda Hadi, Baruch College, CUNY, USA

Extended Abstract

Many of us have heard a friend say: "I just want to go home and curl up with a good book." Likewise, it is not rare to see a person eating at a restaurant alone, with only a book as his or her dining companion. These observations motivate the question: to what extent do books function as "friends"? The idea that books potentially assume roles of human companions is linked to the more general study of anthropomorphism. Anthropomorphism can be described as the inclination to attribute humanlike properties, characteristics or mental states to nonhuman agents and objects (Guthrie 1993; Epley et al. 2007).

In a consumer behavior context, anthropomorphism is most often examined with regards to brand personality, which refers to the set of human-like traits associated with a brand (Aaker 1997). Research has suggested that brands with strong positive brand personalities are perceived to be more familiar and less risky to consumers (Freling 2005). While anthropomorphism of *brands* has been explored, research regarding the anthropomorphism of *objects* is rare in consumer behavior journals. One notable exception is research by Agaarwal and McGill (2007), which investigated the role of schema congruity on product anthropomorphism. Their research, using cars and beverage bottles as stimuli, indicated that the ease with which a product is anthropomorphized depends on the congruity between the proposed human schema and the product features.

Since researchers have examined constructs such as product attachment and product involvement (Schultz et al. 1989; Kleine et al. 1995; Zaichkowsky 1985), it is not far-fetched to propose that consumers may develop relationships with products as well. In fact, Shimp & Madden (1988) applied Sternberg's (1986) triangular theory of love to the study of consumer-object relations. One component of consumer-object relations highlighted by Shimp & Madden (in reference to Sternberg's theory) was intimacy, which they described as the feelings of closeness and connectedness with consumption objects (Shimp & Madden 1988, pg. 163). The study of product intimacy and the conditions under which it develops defines the focus of our research.

Researchers have attempted to pinpoint potential explanations for why people anthropomorphize. One explanation is sociality, which refers to our innate need to establish social connections with other people (Maslow 1943; Epley et al. 2007). One recent set of studies found that people who are either chronically lonely or induced to feel lonely are more likely to anthropomorphize objects and religious agents (Epley et al. 2008). In fact, research by Luczak and colleagues (2003) suggests that individuals may compensate for their social interaction deficiencies by relating to technical products. That indicates that a lack of traditional socialization may lead to increased anthropomorphization. We expect that people with a high preference for solitude would be more likely to anthropomorphize products in general. Further, we hypothesize that these participants will anthropomorphize products with human traits (e.g., a book with a human face on the front cover) more than products without those traits, and that product anthropomorphism will lead to an enhanced role of the book as an intimate companion.

Study 1 examined the hypotheses above. Specifically, it examined whether people with a high preference for solitude differed from people with a low preference for solitude, in that the former would more likely anthropomorphize and bond with a product (a book) with human traits (a book with a human face on the cover as opposed to a book with a geometrical pattern on the cover). We employed a 2 (preference for solitude (measured): high vs. low) \times 2 (book cover prime: human vs. non-human) between-subject design. Participants completed the preference for solitude scale items (Burger 1995) before evaluating one of the two book covers. The dependent variables measured companionship tendencies, as the participant's indication of whether he/she would take the product along to undertake certain activities (e.g., sit in a cafe, travel, eat in a restaurant). Further, respondents answered the question "Can a book become a best friend?" on a 7-point Likert scale.

A significant book cover by preference for solitude interaction was found for all activities to be undertaken with the book ($F(1, 45)=3.242, p<.08$) and their agreement with the statement that a book could be a best friend ($F(1, 45)=5.184, p<.03$). The results show that participants with a high preference for solitude reported to be more likely to undertake these activities with the book that had a human face on the cover (as compared to the book with a geometrical pattern), while responses of participants with a low preference for solitude did not show such pattern. Similarly, participants with a high preference for solitude were more likely to agree with the idea that a book could be a best friend when primed with the human face cover (as compared to the non-face cover), while participants with a low preference for solitude did not. These results may seem counterintuitive at first. However, the previously mentioned literature regarding compensatory anthropomorphic tendencies (Epley et al. 2007; Luczak et al. 2003) indicate that to make up for their lack of socialization, those with a high preference for solitude may gravitate towards products with more outwardly human-like traits. This same lack of socialization may be the cause of what makes them more prone to taking a book with a human face in the cover as a companion.

This research builds upon previous findings by further examining to what extent an object can actually take on the functions of a human friend. Further, it highlights that while anthropomorphism may lead to increased companionship for some people (those with a high preference for solitude), other people may not display the same pattern, and may even prefer objects that are *non* human-like.

These results may also have implications for research regarding the endowment effect (Thaler 1980, Kahneman et al. 1990). Recent research has documented that emotions play a role in the endowment effect, and that merely touching an object results in increased perceived ownership of that object (Lin et al. 2006; Peck & Shu 2009). It is possible that anthropomorphism of an object partially explains the tendency to over-value objects once they have come into one's possession. Further, research by Ruble (2008) suggests a "proximity effect" based on the idea that affective stimuli reactions are polarized when proximal. In the context of anthropomorphism, this finding suggests that the extent to which human-like traits lead consumers to treat products as an intimate companion may be moderated by the physical and perceived closeness of the product's humanity. In our next study we will consider these moderators, and broaden its scope by including stimuli from product categories other than books. Further, we will attempt to measure consumer-object intimacy by relying on additional constructs in the literature (Sternberg 1986; Shimp & Madden 1988).

The Interplay between Form, Function, and Expertise in Consumer Choice

Jianping Liang, SunYat-sen University, Taiwan
 Kyle B. Murray, University of Alberta, Canada

Extended Abstract

We know that consumers make purchase decisions based both on what products do (i.e., functionality) and how they appear (i.e., form) (e.g., Bloch 1995; Chitturi, Raghunathan and Mahajan 2007; Veryzer and Hutchinson 1998). For example, when the compact fluorescent (CFL) light bulb was first introduced, many consumers were hesitant to switch from their traditional bulbs, in part, because the CFL's "swirl" shape was so unusual (Fishman 2006). The early adopters of CFLs were consumers who put more emphasis on the functional improvement in energy efficiency than on the bulb's unconventional appearance. Yet, although marketing research has extensively examined how differences in functionality affect the choices that consumers make between new and existing products, very little research has addressed how product form affects such decisions (Bloch 1995; Rogers 2003).

Nevertheless, form is becoming an increasingly important part of new product development. Electronics companies are relying more and more on form to differentiate products whose core functionality¹ varies little between competitors (e.g., TVs, computers, cameras, coffee makers, toasters, etc.). Even when the core functionality of these products does differ in important ways, those differences are not always clear or meaningful to the average consumer. For example, what will the impact be on my television viewing experience of a 120Hz versus 240Hz refresh rate or a screen resolution of 1080p versus 1080i? Similarly, will I notice a difference in picture quality between a 2 versus 8 megapixels camera or one with an ISO rating of 400 versus 1600? For consumers that do have the required expertise, these differences in functional attributes may very well play a key role in the products that they choose. However, in this paper we predict

that for the many consumers that do not have the requisite knowledge, the form of a new product will be a critical determinant of the choices that they make. Specifically, we predict that consumers lacking product expertise (i.e., novices) will be risk averse and tend to select products that have a conventional appearance over those that have an unconventional form.²

FOOTNOTES

¹In this paper we define *core functionality* as the ability of a product to fulfill its fundamental utility (such as transportation for a vehicle, writing for a pencil, picture taking for a digital camera, and information processing for a computer).

²We define *form* as a combination of attributes related to the appearance of the product (e.g., size, shape and color), which does not affect the product's core functionality.

We hypothesize that expertise plays a critical role in determining the weight that consumers place on these two general types of products attributes. In addition, we propose two key boundary conditions on the basic effect: 1) experts discount product form only when they have enough time to systematically process functional information; and, 2) novices discount product form when they expect to have experience with the product that compensates for their lack of functional knowledge (e.g., they are able to try using a new camera before committing to buy it). Finally, we predict that differences in the decision weight given to form versus function by novices and experts can be explained by the level of risk that they perceive in different product forms—that is, the perceived risk of adopting a new product mediates the impact of form on preference. We test, and find strong support for, these hypotheses in a series of three laboratory experiments.

In Study 1, we manipulated the form and the core functionality of a new product and measured the participants' expertise to conduct a 2 (form: same-as-status-quo vs. unconventional) by 2 (core functionality: same-as-status-quo vs. improved) by 2 (consumer expertise: experts vs. novices) experiment. We found that that expertise plays a critical role in determining the weight between form and function.

Study 2 was designed to test the assumption that experts give less weight to form in new product adoption decisions because they are better able to process functional information. Study 2 employed a 2 (expertise: experts vs. novices) by 2 (time pressure: low vs. high) between subjects design and found supportive evidence for the above assumption.

Study 3 was designed to explore the role that risk plays in consumers' willingness to adopt a new product in an unconventional form. Study 3 employed a 2 (form: conventional vs. unconventional) by 2 (expertise: experts vs. novices) by 2 (type of decision: try vs. switch) between subjects experimental design. Moderated mediation test found supportive evidence that the perceived risk of adopting a new product mediates the impact of form on preference.

In these studies, we ruled out alternative explanations such as Need for Variety (NFV), Need for Uniqueness (NFU), and innovativeness. Variables such as demographic variables (i.e., age, gender, and native language), product involvement, task involvement, and aesthetic evaluation were controlled.

We aim to make four key contributions to the extant literature. First, this paper demonstrates that form can play a critical role in the choices that consumers make between new and existing (i.e., status quo) products. Second, we show that the effect of form on consumer choice is especially strong among novice consumers, but can also affect expert decision making under specific conditions (e.g., time pressure). Third, we show that the potentially negative impact on choice of an unconventional form can be overcome if consumers are given the option to try the product out without committing to purchasing it. Fourth, our results provide insight into the psychological mechanism that underlies the effect of form on consumer choice—specifically, novice consumers tend to avoid products with unconventional forms because they perceive greater risk in the adoption of such products.

Gender Differences in Responses to Form and Function

Jianping Liang, Sun Yat-sen University, Taiwan

Kyle B. Murray, University of Alberta, Canada

Extended Abstract

It has been argued for decades that stereotypically, women are associated with concepts of feeling, imagination, intuition, and subjectivity, while men are associated with concepts of mind, rationality, and objectivity (Korsmeyer 2004). However, it is still not clear whether such a stereotypical perception exists and how it may influence consumers' decision making. Consumers make purchase decisions based both on what products do (i.e., functionality) and how they appear (i.e., form) (e.g., Bloch 1995; Chitturi, Raghunathan and Mahajan 2007; Veryzer and Hutchinson 1998). Recent research demonstrated that information processing on form may be more superficial and heuristic whereas processing of functional information may be deeper and more rational (Liang and Murray 2009; Townsend and Sood 2010). If males and females have access to the gendered stereotypical perceptions in minds when making purchase

decisions, they are very likely to exhibit different behavioural patterns, compared with the situation where they do not have access to such perceptions. In other words, males (females) consumers are more likely to make purchase decisions on functionality (form) when they take the stereotypical perceptions between genders into consideration. However, little research in the marketing and consumer research has investigated similar issues. Therefore, this paper attempts to explore whether such stereotypical perceptions of gendered preference on form and function exist in consumers' mind and under what conditions such perceptions may or may not influence consumers' decision making.

Methodology. To the best of our knowledge, this is the first study to explore the perceived gender differences in responses to form and function of products in the consumer literature. We conducted in-depth interviews with twenty-seven college students at a large North American university. The informants' responses were coded by two research assistants blind to the study hypotheses. Generally accepted criteria (including credibility, transferability, dependability, and confirmability; Hirschman 1986) were used to assess the quality of the data, which were subsequently analyzed.

Major Findings. From the in-depth interviews, participants were found to perceive that gender difference may exist in consumers' response to form and functionality of products, depending on the product types, the product's usage situations, and the consumer's background and characteristics.

In particular, we found that the perceived gender differences may be smaller for highly utilitarian products (e.g., food and medicine) and highly hedonic products (e.g., paintings) than for products that are somewhat in the middle (e.g., highlighters, shoes, bags, wallets, digital cameras, laptops, watches and cars).

We also found that the perceived gender difference may exist when the product is consumed in public. One (female) said: "*Men will choose the most comfortable shoes to go out even if they are not the most stylish or brand names. Women will spend a night with blisters just to be more stylish and wear the Steve Madden heels.*" Even though some products are consumed in private, they may be shown in public, which could also lead to the gender difference, as one (male) said: "*While she (my sister) went for the one (shower) that looked like a waterfall, I choose the one that had a giant face and more pressure. Now anyone who visits her washroom complements her shower and no one has anything to say about my mine. While she was really happy with her shower for that reason, she would often use mine when she wanted to take a quick shower because hers was too slow!*"

However, it does not mean that the perceived gender difference won't exist when the product is consumed in private. One (female) said: "*A huge gender difference of aesthetics versus functionality would be decorating a room/house. Men want comfort and practical furniture such as a table by their TV chair, where they can put their drink. Women want to put things where they look pretty, even if it is not practical.*"

In addition, the perceived gender difference may be larger for products that one gender happens to be more interested in, more knowledgeable about, and use more frequently than the other gender, as one (male) said: "*If a person is more familiar with a product they will care about its functions. If they aren't too familiar with a product they will choose one that looks better.*"

But this is not always the case. In the cosmetic category, one (female) said: "*women's perfume is usually in fun-shaped, colourful, pretty-looking bottles, and men's cologne is usually in a more simply-designed bottle.*" Another (male) said: "*Women tend to have more facial products even though most of them serve the same function. They overbuy them because of the new scent, or some added ingredients. Men usually wouldn't mind too much about that as they believe all facial cleansers serve the same function.*"

Furthermore, the perceived gender difference may indicate potential conflicts in relationships between females and males in situations where they have to deal with each other's purchases (e.g., shopping for both genders or gift giving for the other gender): "*As we were looking at the cameras, I focused more on the models that come with a variety of colours to choose from. My brother, on the other hand, compared all the different functions among the models. At last, we couldn't compromise*" (female). "*Our family decided to buy my sister a camera as her birthday present. We bought a petite and easy handle camera which we all thought it will be suitable for her, but turn out that she rather wants a SLR camera, which is heavier to carry and more complicated to use. We are all surprised*" (male).

However, in certain situation, males and females may agree with each other on the importance of form over function, as one (male) said: "*When a guy takes a girl out for the first date, the guy would also think of aesthetics as important. He wouldn't bring her to a fast food chain restaurant for the first date as fast food just serves as an eating function. Instead, he would bring her to a more upscale restaurant for dinner, which serves the eating function as well but with the addition of atmosphere.*"

Is there a Universal Positivity Effect? A Cross-Cultural Perspective

Jianping Liang, Sun Yat-sen University, Taiwan

Zengxiang Chen, School of Business, Sun Yat-sen University, Taiwan

Haizhong Wang, Sun Yat-sen University, Taiwan

Kyle B. Murray, University of Alberta, Canada

Extended Abstract

Literature in the judgment and decision making and consumer behaviour found prevalently that consumers tend to evaluate the negative information to a larger extent than the positive information (“loss aversion”, Kahneman and Tversky 1979; or “negative bias”, Herr, Kardes and Kim 1991). Some researchers argued that such results are found in the product domain because negative information is considered as more diagnostic (Skowronski and Carlson 1989) or permits categorization of a product more easily (Herr et al. 1991). However, when it comes to service perceptions, it is totally different. As indicated in Folkes and Patrick (2003), services are not as homogenous as products are. Instead, consumers have heterogeneous service experience. They also have positive expectation for service provider’s behaviour. Hence, for a novice consumer, negative information about an individual service provider is not diagnostic of the firm and s/he may consider negative individual as an outlier (Herr et al. 1991). Folkes and Patrick (2003) found that American consumers who have little experience with a service tend to have a “positivity effect”, i.e., from positive information about one employee, American consumers infer the firm’s other service providers to be similarly positive to a greater extent than, from negative information, they infer the firm’s other service providers to be similarly negative.

More research is called for to examine the boundaries and the underlying cognitive processes of this positivity effect (Folkes and Patrick 2003). To the best of our knowledge, the literature is still silent on two important assumptions: although it is true that services tend to be more heterogeneous than products in reality, consumers may *NOT* necessarily perceived (1) that services are heterogeneous and (2) that negative information in such a situation is not diagnostic, even when the other conditions are met (e.g., novice consumer and positive expectation). Therefore, this paper attempts to investigate these issues from a cross-cultural perspective: whether and how a different inference mechanism in a collectivist culture, Chinese culture in particular (i.e., a stronger tendency to infer and generalize from one individual sample to others, including both service experience and members in the same group) (Spencer-Rodgers et al. 2007) may influence the positivity effect.

Study 1: Positivity Effect for Chinese Consumers: Correction of Cultural-Based Judgments?

Spencer-Rodgers et al. (2007) found that Chinese may view diverse groups as more entitative, to attribute more internally consistent dispositions to groups and their members, and to stereotype more readily than do Americans. Thus, in the context of service experience, it is possible that Chinese may be more likely than Americans to not only consider service experience to be more homogeneous (generalization from one service experience), but also infer and generalize behaviours from one individual employee to the other members in the same firm. Consequently, negativity effect, instead of positivity effect, may be the default effect for Chinese consumers. In other words, Chinese consumers are more likely to infer the firm’s other service providers to behave negatively from information that one individual service provider behaved negatively than they are to infer the firm’s other service providers to behave positively from information that one individual service provider behaved positively.

However, the generalization from one individual to the whole group is not a logical and persuasive reasoning, especially when consumers have positive expectation and can make thoughtful deliberation (e.g., negative information about an individual is not diagnostic of the firm and they should consider him/her as an outlier), regardless of their cultural background. Briley and Aaker (2006) found that culture-based judgments can be corrected by personal knowledge (e.g., logical and persuasive internal reasoning), in particular, when processing is thoughtful and more deliberative. Therefore, negativity (positivity) effect may occur when Chinese consumers make initial and automatic (deliberate) reactions to the individual sample.

Study One was a 2 (behaviour valence: positive vs. negative) X 2 (deliberate vs. intuitive thinking) between-subject experiment, in which 101 Chinese consumers participated. We found that Chinese consumers exhibited positivity effects when they were asked to think deliberately. When they were asked to think intuitively, they exhibited a strong negativity effect.

Study 2: Why does culture matter?

Spencer-Rodgers et al. (2007) argued that private interests are expected to be suppressed and personal attributes are to be adjusted for members of collectivist cultures to fit in with the group (Markus & Kitayama 1991; Triandis, 1995). Hence, the cultural difference between Chinese and Americans on the inference from one individual sample to a whole group may be due to different modes of thinking: interdependent (Chinese) vs. independent (Americans) thinking (Kühnen, Hannover and Schubert 2001). Thus, we predict that when Chinese consumers are in a mode of interdependent thinking (about their relationship with others), they may be more likely to consider the individual to be part of the group and thus s/he represents the group’s attributes, which should be the same for other members in the group. However, when Chinese consumers are in a mode of independent thinking, they may be more likely to think that each individual is independent from others and does not represent the group. It has been found that both culture and situational priming may lead to the accessibility of different mode of thinking (Kühnen et al. 2001). Briley and Wyer (2001) found that after a contextual prime (e.g., exposing Chinese people to pictures of American cultural icons) prompting a challenge to the cultural guidance, Chinese people feel no more emotionally connected to important others than American people do. Therefore, we propose that by priming an independent mode of thinking, Chinese consumers may show a positivity effect as Americans, while by priming an interdependent mode of thinking, Chinese consumers may show negativity effect.

Study Two was a 2 (behaviour valence: positive vs. negative) X 2 (mode of thinking: independent vs. interdependent thinking) between-subject experiment, in which 120 Chinese consumers participated. We found that Chinese consumers showed negativity effects when they were primed to think interdependently, while they showed positivity effects when they were primed to think independently.

The Link between Usability, Preference Reversal, and Decision Making

Na Wen, Georgia Institute of Technology, USA

Nicholas Lurie, Georgia Institute of Technology, USA

Whether it's browsing thousands of digital cameras on eBay or making sense of a myriad number of coffee makers on Amazon.com, it is clear that today's consumers face large amounts of information. Online retailers have tried many approaches to help consumers deal with increasing amounts of information; including electronic agents that recommend particular products based on consumer preferences or the similarity of their shopping histories to other consumers (Diehl 2005; Häubl and Murray 2003); presenting information in matrix format that allows alternatives and attributes to easily be compared (Häubl and Trifts 2000); and providing tools for sorting, selecting, and filtering alternatives (Todd and Benbasat 1991; 1992; 1999).

Prior research suggests that the navigability of a retail website is a key determinant of the likelihood that browsers turn into buyers, the extent to which they learn to efficiently use the website, and the likelihood they return to the website for future purchases (Johnson, Bellman, and Lohse 2003; Nielsen 1993; Palmer 2002). One widely used approach to improve navigability is to use visual design elements such as visual separators between rows or between columns of data in a product matrix. For example, both Travelocity and Intel display alternatives in columns and attributes in rows on their websites but Travelocity uses vertical lines to separate alternatives while Intel uses horizontal lines to separate attributes. Although each approach may increase consumer understanding of the environment by making navigation easier (Huizingh 2000; Nielsen 1993), it is unclear which is better from a decision-making perspective.

Most assessments of website design involve usability testing, with a focus on user understanding, the extent to which users get lost, and the speed of information retrieval (Huizingh 2000; Nielsen 1993; Palmer 2002). In contrast, research on decision making tends to examine how task aspects of a decision problem, such as the amount of information in a choice set; or context aspects, such as the correlation among product attributes, affect decision processes and outcomes (Bettman, Johnson, Luce, and Payne 1993; Payne, Bettman, and Johnson 1993; Lurie 2004). In general there has been little examination of how design elements, that make no changes to task or context variables, affect consumer preferences and decision making.

In this article, we propose that design elements, such as visual separators, can act as cognitive constraints that systematically affect the acquisition and processing of information with implications for preferences as well as decision processes and choices. To the extent that consumers adapt their decision processes to the task and context variables in the decision environment (Bettman et al. 1993; Payne, Bettman, and Johnson 1988; Payne et al. 1993), visual separators may discourage these adaptive responses. However, by encouraging the uniform use of particular information acquisition strategies, visual separators should also serve to enhance decision efficiency. To the extent that decision processes have a larger impact on choice quality in environments where consumers need to make tradeoffs among attributes (Bettman et al. 1993; Payne et al. 1988), we expect that visual separators will have the greatest effect on choice quality in such environments.

In a series of studies we examine how design elements such as visual separators affect decision processes and outcomes in different choice contexts. Although a pretest suggests that there is no clear agreement, even among computer science students, on whether it is better to visually separate alternatives or attributes, experimental results show these design elements affect choice quality. These effects, however, depend on the characteristics of the decision context; in particular, the intercorrelation among product attributes.

Study 1 shows that visual separators shift the preference reversal effect between joint and separate evaluations of alternatives found in Hsee (1996) such that visual separators between alternatives increase the difference of willingness to pay for two alternatives while

visual separators between attributes reduce such a difference. A second process-tracing study shows that visual separators reduce the extent to which consumers adapt their choice processes to the choice context but enhance decision efficiency (i.e., lead to faster decisions). A third study process-tracing study manipulates time pressure. Results show that, under time pressure, visual separators between attributes as well as between alternatives improve decision quality when product attributes are negatively correlated. Process tracing measures show that under time pressure, visual separators lead to more systematic information acquisition, faster processing of information, and consideration of more information. Under time pressure, this more systematic and comprehensive processing of information appears to compensate for reductions in decision quality due to by-attribute versus by-alternative information acquisition.

By examining how visual aspects of electronic environments affect preferences as well as decision processes and outcomes, this article provides a link between research on design and usability of information environments (Huizingh 2000; Nielsen 1993) and research on decision making (Bettman et al. 1993; Payne et al. 1988; Payne et al. 1993). More generally, this research adds to understanding about the links between perception and cognition (Fiske 1993; Johnson et al. 2003), with implications for decision making. From a managerial perspective, this research provides insights into how seemingly innocuous design changes may affect consumer decision making and those conditions in which visual separators are likely to be helpful or harmful to consumers.

Retail, Beauty Services and Masculinity: When Brands Face Retailers' Resistance to Changing Masculine Market

Nacima Ourahmoune, ESSEC Business School, France

Gender is an important issue in consumer research. Yet few studies have addressed the relationship between retail strategies and masculine consumption and values. Some scholars developed a framework to understand male consumption (Holt and Thompson, 2004, Schroder and Zwick, 2004, Elliott and Elliott, 2005, Rinaldo 2007, Ourahmoune and Nyeck 2008). While sociocultural changes are taking place, traditional masculine and feminine values are evolving, leading to changing gender roles and having impact on the market place (Kimmel and Tissier-Desbordes, 1999).

Men are becoming concerned with appearance and beauty, in the traditional feminine way, and sales of male cosmetics and fashion are increasing. Trendy words are used to describe this "new man" sensitive to appearance, body conscious: metrosexual, übersexual... (Tuncay 2006, Rinaldo, 2007).

Context

This paper intends to understand and describe how the new postmodern masculine values and codes shape retailing strategies and services. Despite the fact that hair beauty brands developed recently a range of professional products dedicated to men (Tigi, Wella,

Goldwell, Redken, L’Oreal Professionnel...), they face haircut salons managers’ reluctance to engage in transformations of their salons’ aesthetic codes and practices. The vast majority of them believe men are less profitable customers than women and neglect adaptation to changing beauty market for men. Moreover, hairdressers are the unique retail channel for professional hair products in France. They are the key contact with male consumers and brands rely on them. Then, it seems relevant to explore their rep about this new masculine segment.

Then, This research deciphers existing and emerging masculine codes in merchant beauty spaces. It also identifies lagging factors to the emergence of new beauty services for men expressed by salons managers.

Methodology

A multi-method study is performed to get a “thick description” (Geertz 1982) of the phenomenon under study. We use structural semiotics (Floch 2005) to discover the meaning of very diverse hair salons narratives: 20 in Paris, 10 in London, 8 in Barcelona, 5 in Spanish Pays Basque, 7 in Athens. Salons are unique retail spaces for professional hair beauty brands (Redken, L’Oreal professional...). Also, 19 semi-structured interviews with hair salon managers were performed in Paris to understand their representations of male consumers as well as lagging factors to a renewed offer for men. In addition, 2 managers from a worldwide beauty company were interviewed to better understand challenges they face on the Male Market. Finally, 200 men in Paris answered our questionnaire about their practices and expectations as regard hair salons. Men were from 15 up to 68 years old, with very diverse occupations and backgrounds.

Results

Hair salons are Gendered spaces: 18% go to *only for men* hair salons, 37% Unisex salons, 40% both in Unisex and only for men salons 5% never go to hair salons (home). Male who prefer *Only for men* salons emphasize male hairdressers expertise- *A masculine “in between us” know how. Instrumental/ utilitarian values prevail* in terms male consumers expectations: Hygiene (86%), next-door salon (82%) nice haircut (84%). However, nice atmosphere and beautiful design were important criteria for consumers under 39 years old (42%) as well as nice scalp massages (64%). These results express *the rise of hedonic/ aesthetic values*. Also, a vast majority of men would like more of insights and tips from their hairdresser. If most of them never buy male professional hair products and are not able to quote professional brands, 76% state they were never offered to buy them in a salon AND 81% say they would buy them if it were the case! Then, there is a gap between male consumers expectations and retailers’ rep and practices as observed in salons and through retailers’ discourse analysis.

We refer in our semio-analysis to the 5 masculine archetypes (i.e “Traditional Man”, “Tough guy”, “Melancholic Man”, “Postmodern Man” and “Effeminate Man”) that were identified by previous research on brand communication and masculinity (Ourahmoune and Nyeck 2008). We use the same semiotic square (Floch 2005) to compare and analyze our international salons gender narratives. We then were able to map salons rep of gender identity in terms multiple masculinities (Schroder and Zwick 2004). We discovered that most of the salons address “traditional men” and « tough guys » in their communications on POS (visuals, space organization, staff behavior, practices and offer). Very few emphasize other masculine values: new territories are then left empty. *In Unisex salons, feminine values prevail* and lead to social conformity: men do not often dare cross the barrier by asking “unexpected/illegitimate masculine services”. Some men in touch with new masculine beauty trends might find an offer that suits them better in traditional *only for men* salons (scalp massage, manicure...). However, those salons are not appealing to Melancholic and Postmodern customers who do not identify with the very traditional mise-en-scène.

Yet, hair product brands are captive of their retailing channel. Professional hair products do sell only in a selective channel (salons).« *We just launched our professional hair product dedicated to men, we believe it should really perform very well...but we do face a serious obstacle when it comes to our retailers... » (Hair professional manager, Leader international cosmetic brand, Paris).* Then, the brand engaged in an expensive change process through events, learning sessions and communication with their retailers ...

Implications

Existing literature on changing masculinity and consumer research is mainly consumer or brand discourse oriented; this paper proposes to address a lack by exploring services, retailing/ retailers’ point of view.

This research identifies that retailers’ resistance consists in internalized traditional gender schemes connecting with “social fears” identified in the literature on male consumers (Kimmel and Tissier-Desbordes 2000, Rinallo 2007, Ourahmoune 2009). This resistance impacts the way beauty services providers address new male consumers beside an evidence of renewed expectations from a significant number of consumers in our sample.

In addition, our research suggests that business resistance to changing socio-cultural values is an insufficiently researched area.

Investment of Self through Process Involvement

Sukriye Atakan, University of Michigan, USA

Richard P. Bagozzi, University of Michigan, USA

Carolyn Yoon, University of Michigan, USA

Extended Abstract

Imagine that you are working on your car, building a patio, or making a bookshelf. The process may require your physical involvement (changing a particular part of the engine, placing stones for the patio, cutting and staining the wood for the shelves) and/or intellectual involvement (determining the problem with the car, designing the patio or choosing the color of the shelves). How would these types of involvement affect your evaluation of the final product? Which factor will be the most important for you? Do you think intellectual involvement in the production process will have different results than physical involvement?

These questions are important if companies want to influence and optimize value derived from consumers' involvement in the production process. Little is known about participation of consumers in the production process (i.e. what Toffler referred to as "prosumption"). Our goal is to investigate the factors that affect the value derived from prosumption behavior and the specific consequences of being involved in the production process.

We draw on findings from person-object literature (Belk 1988; Richins 1994; Pierce, Kostova and Dirks 2003) to investigate prosumption. This stream of research indicates that investing the self into the target (creating, shaping or producing an object) results in the most powerful association between the self and the object since one invests labor, time and one's self in this process. During the production or modification process, investment of self into the product can be through intellectual and/or physical involvement. Intellectual involvement entails intellectual stimulation, creativity and/or choice in the process. If one uses his/her intellectual labor during production of the product, then the product may represent the ideas the person has generated and become part of the extended self. Therefore, intellectual stimulation in the process may transfer part of the self to the focal product, and affect personal relevance and evaluation of the product.

Labor creates a sense of ownership. Marx (1867) indicated that a person is the owner of his labor and has rights over production that involves his labor. You may feel that a sweater you have knitted, or a car you have worked on, is special since it absorbed your labor and time. In some cases, people may value self-made products even more than expert-made ones (Norton and Ariely, 2007). Therefore, physical labor may contribute to the value derived from prosumption.

The first study examined the relationship between products and consumers in detail by looking at how intellectual investment during production shapes how consumers relate to products. We hypothesized that higher levels of intellectual investment will enhance product evaluation. Also, we proposed that identification with (hypothesized to be the cognitive dimension of person-object relationship) and attachment to the product (hypothesized to be the affective dimension) mediate the impact of intellectual investment on product evaluation. The study was a three-group between-subjects design where intellectual investment in the process was manipulated at three levels; high, low, none (control condition). In all conditions, participants were given a travel mug with a customizable blank insert. One could remove the insert, draw/write on it and place it back. In the low condition, participants were provided with 12 stickers from which they could choose one to stick onto the blank mug insert. In the high condition, participants were provided with colored pencils and an example sheet which included the same 12 figures from the low intellectual investment condition. They could use this to get ideas, or they could use other figures/shapes they wanted. In the control condition, participants were encouraged to examine the mug but couldn't modify/change it. To equate the time spent with the product, in the control and the low intellectual investment conditions, participants worked on a filler task while the mug was in front of them. Then, all the participants answered identification, attachment,

and product evaluation questions. As predicted, the product was valued more highly when the production process allowed higher levels of intellectual investment. Moreover, results showed that identification and attachment mediated the impact of intellectual investment on product evaluation.

Next, we investigated how physical investment in the production process affects person-object relationship. Participants were randomly assigned to one of the three physical investment conditions: high, low and none (control condition). In the high condition, participants were provided with all the supplies to make a picture frame from cardboard. In the low condition, the participants were given pre-made pieces that would be used to make the same frame. In both conditions, detailed step-by-step instructions allowed no creativity or choice. In the control condition, participants were given a pre-made cardboard frame and asked to examine it. To equate the time spent with the product, in the control and the low physical investment conditions, the participants worked on a filler task before evaluating the frame. Then, they answered the same dependent variables from the previous study. Results indicated that even low levels of physical investment enhanced product evaluation. Attachment to the product increased as the level of physical investment in the production process increased. However, identification didn't differ among the three conditions. Physical labor alone doesn't result in identification. Analysis indicated that attachment fully mediated the effect of physical investment on product evaluation. When consumers can invest their physical labor into the product through the production process, they become more attached to but not necessarily identify with the product.

We make several contributions to the literature. First, we operationalize identification with and attachment to a product in measurable terms. This enables us to measure personal relevance of products when consumers are involved in the production process. Next, we demonstrate that intellectual investment enhances product evaluation by enhancing both attachment to and identification with the product. On the other hand, we show that physical investment affects only attachment to but not identification with the product. Physical involvement alone doesn't give the consumer the opportunity to reflect his/her taste, preferences, that's his/her identity, through the product. Therefore, physical involvement affects product evaluation only through attachment. Furthermore, we show that attachment and identification are two different dimensions of person-object relationship.

Consumer-based Perceived Product Innovativeness: the Big Seven

Jean Boisvert, American University of Sharjah, United Arab Emirates

Growing market competition in consumer goods has led to increased concerns regarding the competitive advantage conferred to firms offering innovative products. While insights from consumers are often used as starting point in the design process, what is thought to be innovative by a team of engineers and designers may not be perceived in the same way by target market consumers. Marketers would benefit by knowing more about the specific dimensions underlying consumer perceptions of innovative products.

Personal innovativeness as a personality trait has been addressed in the literature (Cotte and Wood, 2004; Manning et al., 1995; Midgley, 1977; Midgley and Dowling, 1978). The goal of this paper, however, is to clarify the construct of consumer-based perceived product innovativeness. Perceived product innovativeness from the firm's and customer's perspective has been addressed in previous research (Garcia and Calantone, 2002; Danneels and Kleinschmidt, 2001) but definitive construct dimensions have not been identified and systematically tested (cf. Calantone et al., 2006). In reviews of the literature, Danneels and Kleinschmidt (2001) as well as Garcia and Calantone (2002) identified many dimensions that may underlie perceived innovativeness. They noted that specific dimensions have not been employed consistently across studies. Our ultimate goal is to develop a standardized measure that can be employed across future studies so results of studies can be more comparable.

In their meta-analysis on antecedents of product performance, Henard and Szymanski (2001) specified product characteristics as a predictor of product innovativeness. According to the authors, product innovativeness can be defined as perceived newness, originality, uniqueness and radicalness of the product. Sethi et al. (2001) used two factors to define product innovativeness: a) novelty broken down into novel and original, and b) appropriateness broken down into useful and appropriate. Product innovativeness has also been confounded with product uniqueness as defined by customers (Daneels and Kleinschmidt, 2001; Troy et al., 2000; Ali et al., 1995). Uniqueness has also been viewed as a distinct measure of innovativeness in defining product advantage (Henard and Szymanski, 2001; Langerak et al., 2004). Conversely, product newness and uniqueness have also been used as sub-measures of product innovativeness (Salavou, 2005).

Positive product attitudes have been associated with new products perceived to be innovative (i.e., novel and useful to consumers; Troy and Davidow, 1998). It also appears that when the innovativeness measure includes a "meaningfulness" dimension it yields a stronger relationship with product success (Szymanski et al., 2007). In addition to novelty dimension, Fang (2008) found dimensions like "challenging existing ideas," "creative and interesting," underlying perceived product innovativeness. In one of the original studies identifying factors underlying perceptions of new product launches, Cooper (1979) identified product uniqueness superiority further broken down into newness, uniqueness, and superiority to meet customer's needs, cost reduction and higher quality.

In sum, inconsistencies exist in the literature in terms of how to define the construct and dimensions underlying product innovativeness as perceived by consumers. The ultimate is our research to provide a tool that will allow more consistency across studies. In addition to using concepts identified in the reviews of the literature, in-depth interviews were conducted in order to gather the widest possible range

of adjectives related to perceived product innovativeness from the consumer point of view. Inspired by a methodology used by Li et al. (2008), 34 student interviewers were asked to conduct several in-depth interviews each. They were required to recruit campus across ages, genders and education among students and non-students of over twenty years of age. Based on a methodology used by Krishnan (1996) for generating brand associations, 340 participants were asked to provide top-of-mind thoughts using open-ended questioning. The initial set of statements / items was screened by faculty judges, independent of the study, to group the ones with similar meanings but also to eliminate redundant and non relevant attributes in order to reduce the pool of adjectives to a manageable size (Bearden et al., 2001). As a result, a final list of 68 attributes was compiled.

A questionnaire was developed based on a 7 point bipolar Likert scale where the resulting set of 68 items was submitted to principal component analysis. The decision to use principal component analysis was driven by the fact that the theory behind consumer-based perceived product innovativeness has not been clearly conceptualized and sufficiently detailed regarding the relations between indicators and the construct (Gerbing and Anderson, 1988). A survey was conducted and the questionnaires administered to a sample of 218 adults around a campus community of an American university. Participants were selected based on a wide range of ages, gender and education. After a series of iterations, an optimal 7-factor solution accounting for a significant 61.4% of the variance explained appeared to be meaningful and interpretable. The uncovered factors are in order: 1) Usability, 2) Novelty, 3) Desirability, 4) Newness, 5) Sophistication, 6) Uniqueness and, 7) Worthiness.

In conclusion, this study confirmed underlying dimensions of consumer-based perceived product innovativeness found in past research and, importantly, also uncovered distinct dimensions that have not been addressed in previous research. Results of our research confirm that consumer-based perceived product innovativeness is a multi-dimensional construct. The conclusion of our study proposes that a new scale be developed and tested across different types of product categories. This scale would then be used in future research on perceptions of innovative products.

Negative Dimensions of Brand Personality

Jenny Jiao, Virginia Tech, USA
Jane Machin, Virginia Tech, USA

Extended Abstract

Brand personality is the set of human characteristics or traits that consumers attribute to a brand (Aaker, 1997). Brand personality is of great importance to both consumers and marketers. Among other outcomes, research demonstrates that the brand personality construct helps consumers to: evaluate brands and build relationships (Fournier, 1998); develop emotional attachments to brands (Landon, 1974); differentiate brands (Crask & Laskey, 1990) and increase brand preference and usage (Sirgy, 1982).

This research seeks to extend our understanding of the brand personality construct by focusing specifically on the *negative* dimensions of a brand's personality. We define negative brand personality as the set of *negative* human characteristics or traits that consumers attribute to a brand. For example, some consumers might associate Paris Hilton perfume with the human personality traits of "fickle" and "naïve." We believe prior work has overlooked the negative dimensions of brand personality.

The study design in Aaker's (1997) seminal paper on brand personality promoted the generation of predominantly positive personality dimensions. First, the process likely led to the complete omission of some negative traits. Participants were asked to assess the descriptiveness of an initial pool of traits by imagining how descriptive the trait was when thinking about *positive, liked* brands such as Wrangler jeans. It is likely that many initial negative traits were not considered descriptive of such positive brands and thus omitted from the subsequent generation of dimensions.

Second, participants were presented with the positively valenced end-point of any particular trait pair (e.g. "exciting" not "boring"). This was purposeful, because "the ultimate use of the scale is to determine the extent to which brand personality affects the probability that consumers approach (versus avoid) products (Aaker, 1997, p 350)." However research in many different domains such as attitudes (Thompson & Zanna, 1995), emotions (Watson, Clark, & Tellegen, 1988), decision making (Park, Jun, & Macinnis, 2000; Shafir, 1993; Tversky & Kahneman, 1986) and motivation (Higgins, 1997) suggests that approach and avoid processes are independent and not mirror images of one another. In a similar manner, consumers may associate brands with both negative and positive personality traits simultaneously. Examining the negatively valenced end-point therefore may lead to a richer conceptualization of the brand personality construct.

Indeed, while many brands are positively viewed, by no means are all of them (Winchester, Romaniuk, & Bogomolova, 2008). Oftentimes we believe that brands are avoided because consumers dislike aspects of the brand's personality, not because of defective functional performance. For example, previous research suggests that consumers boycott brands they view as "egregious," "unintelligent" or "foolish" (Kleine & Hubbert, 1993; Kozinets & Handelman, 2004). In some extreme cases, we believe this can even lead consumers to avoid brands whose performance they enjoy but whose personality they do not. For example, the lead author likes the smell of Paris Hilton perfume but will never use it because she dislikes the negative personality traits associated with it.

Finally, noteworthy that while Aaker's dimensions map closely to three of the original "Big Five" human personality factors (Briggs, 1992), there is no equivalent for the most negative of the human dimensions—neuroticism. The equivalent brand traits that this dimension captures—"disturbing," "irritating," "fickle"—are thus missing from current brand personality construct.

In these studies we seek to understand the number and nature of negative brand personality. Planned research that examines the interaction between negative and positive personality dimensions on decision making is also outlined.

Personality Trait Generation

We began by collecting negative personality traits from academic literature and original qualitative studies.

First, 281 non-redundant personality traits were collected from literature, including Big Five, International Personality Item Pool, Traits of Human Consciousness, 16 Personality Factors (Cattell 1946, 1947). Second, we took the antonyms of the positive traits in Aaker's (1997) study to add a further 202 traits. We also collected 219 unique negative traits from five focus group studies. In total, 530 non-redundant negative personality traits were generated.

Next, we reduced these 530 traits to a more manageable number by asking 93 participants to rate how descriptive of brands they considered the traits. Similar to Aaker (1997) we wanted participants at this stage to think about lots of different brands, not one in particular. Unlike Aaker however, the brand examples we gave, as well as the personality traits, were more negative (e.g. State Farm—boring, old-fashioned, and slow). Participants rated how descriptive the 530 traits were of brands in general on a 7-point scale (1=Not at all descriptive to 7=Extremely descriptive.) The ratings ranged from 2.25 to 5.35. We set the cut off at one standard deviation (0.55) above the mean (3.37) for each trait leaving 158 personality traits for the next stage.

Stimuli Selection

Drawing from extant research (Aaker, 1997; Batra and Ahtola, 1991; Subodh & Srinivas, 1998) sixty representative brands were selected from twenty product categories. Each product category included hedonic (e.g., Cardiac Car), utilitarian (e.g., Ford Car) and both hedonic & utilitarian (e.g., Toyota) brands, as determined by a pre-test.

Negative Brand Personality Dimensions

We are currently in the process of asking participants to rate the extent to which the 158 negative personality traits describe each of the sixty specific brands. (To eliminate, participants only rate a subset of the brands, with one brand being rated by all to ensure inter-rater agreement. Procedures mimic Aaker (1997) and are omitted for brevity's sake). These ratings will be subjected to factor analysis to identify the underlying negative brand personality dimensions. Finally, facet analysis will be conducted to identify the three traits that best represent each dimension. *The results from these two stages will be available by the conference.*

Future research will investigate how the positive and negative dimensions of a brand's personality interact. For example, if consumers are *uncertain* about the options in a choice set, we hypothesize they will focus more on negative personality traits. We also believe that negative personality traits may help to find stronger support for brand-self congruity effects. This study fills up the gap between brand personality and brand avoidance, by demonstrating that a brand not only has positive personality traits but also negative brand personality traits. This study contributes to the anti-consumption and consumer-avoidance research by exploring the phenomenon of negative brand personality and brand avoidance, this study also contributes to the measurement research by building the first measurement for negative brand personality.

Is Abercrombie Making Me Arrogant? The Impact of Brand Personality Traits on Post-Consumption Behavior

Lauren Trabold, Baruch College, USA
Pragya Mathur, Baruch College, USA

Research has documented that consumers are influenced by brands that they encounter (Ferraro et al. 2009). In general, brand influence on behavior has been explained through a motivational account in which the brand's traits activate an underlying goal, which subsequently elicits goal-directed consumer behavior (Fitzsimons et al. 2008). This is possible when the brand is associated with a goal that represents a desirable end-state (Sela & Shiv 2009). Although extant literature documents robust findings across positive traits, the influence of negative brand traits has yet to be explored. Furthermore, the potential effect on downstream behavioral intentions has not been addressed. We explore these two important areas of interest in our research.

Brands may have positive trait associations (e.g. upper-class: Calvin Klein) or negative trait associations (e.g. arrogance: Abercrombie). Although consumers may be influenced by brands through goal-activation, this account is limited to desirable outcomes and does not explain the influence of brands with negative trait associations. A possible explanation is semantic priming, in which exposure to a brand subsequently elicits congruent behavior which is not restricted to desirable outcomes (Sela & Shiv 2009).

Beyond the immediate effect of brand exposure, the downstream effect on behavioral intentions is not well understood (Chartrand et al. 2008). In the current research, we propose that brands may influence consumers even when the end-state is not desirable. Importantly, we suggest that brand exposure may influence consumer perceptions of their own traits. In three studies using real brands, we suggest that brands may influence consumers through trait priming, and show that this influence may impact downstream behavior.

Study 1 was designed to test if brands associated with specific traits can influence both self-trait perceptions and downstream behaviors, even when the respondent does not possess chronicity for the given trait. Respondents participated in a 3 (brand: Calvin Klein, Gap, Timberland) x 2 (time: pre and post brand exposure) mixed design study. Brands were pre-tested for associated traits: Calvin Klein: up-to-date, successful, and upper class; Gap: down to earth, honest, and reliable; Timberland: outdoorsy, tough, and rugged. Respondents first filled out a self-reported personality trait index adapted from Aaker's brand personality scale (1997); then they began an ostensibly unrelated study, guised with the intent to "Get to know the undergraduate student." Respondents imagined that they were planning to get dressed for the day and were shown a picture of a closet from which they would take their clothes; their clothes for the day were a t-shirt and jeans branded with Calvin Klein, Gap, or Timberland depending upon the experimental condition. Subjects then indicated their plans to engage in various activities including pro-social behaviors and, finally, completed the self-reported personality trait scale again.

Analysis revealed that, as expected, brand consumption significantly impacted downstream behavioral intentions. Respondents were asked to indicate the activities that they were likely to engage in from a diverse list which included pro-social behaviors (volunteering, community service), prestigious behaviors (shopping in prominent neighborhoods, vacationing in exclusive places), daring behaviors (bungee jumping), and everyday behaviors (spending time with family, cleaning). Importantly, significant results were concentrated in the area of pro-social activities.

After imagining the consumption of Calvin Klein and Timberland (versus Gap), respondents rated themselves significantly more likely to engage in behaviors such as volunteering (Calvin Klein: $p < .05$; Timberland: $p < .01$) and performing community service (Calvin Klein: $p < .05$). Respondents' increased likelihood of engaging in pro-social behaviors suggests that trait adoption has ramifications beyond the consumption domain and reveals an alternative way of influencing consumers to adopt pro-social behaviors. While neither Calvin Klein nor Timberland actively promote community service or volunteering, respondents were significantly more likely to do so after consuming these brands versus Gap, a brand that does engage in social marketing.

Study 2 was designed to illuminate the process by which downstream behavioral intentions are influenced (as shown in Study 1) and to establish that consumers can be influenced by negative traits. We offer evidence that impact on downstream behaviors is due to trait priming and not goal-activation due to the undesirable outcomes elicited by negative trait influence. Respondents participated in a 4 (brand: Calvin Klein, Timberland, Everlast, Abercrombie) x 2 (time: pre and post brand exposure) mixed design study. The two negative brands introduced in this study were pretested for trait associations. Everlast: lethargic, old-fashioned; Abercrombie: arrogant, deceptive. The procedure was identical to that of Study 1.

Analysis illustrated that consumers can be influenced by negative traits and that they may elicit undesirable downstream behaviors. After imagining consumption of Abercrombie, Everlast, or Timberland, subjects were significantly more likely than those who consumed Calvin Klein to joke about someone's appearance (Abercrombie: $p < .01$, Everlast: $p < .05$, Timberland: $p < .01$), to make fun of others (Abercrombie: $p < .05$), to skip school (Abercrombie: $p < .05$, Everlast: $p < .05$), and to lay on the couch all day (Abercrombie: $p < .05$). Of further interest, the measure of several self-reported negative personality traits (deceptive, lazy, selfish) varied between pre and post brand exposure such that respondent's rated themselves significantly lower post exposure. We expect that this is due to social desirability effects. We plan to run Study 3 to address this issue.

A proposed Study 3 will be nearly identical to Study 2, with the addition of a cognitive load task after the pre-exposure personality trait inventory. We expect that in the cognitive load condition, respondents' ability to adjust their self-reported negative traits post-brand exposure will be diminished, resulting in post-traits that may be consistent with behavioral intentions, thereby supporting our process.

In three studies, we expect to demonstrate that consumers may be influenced by brands that have both positive and negative trait associations and that these associations may result in important downstream behaviors. Our work aims to add to the growing understanding on how incidental brand influences alter human behavior.

Sharing the Reward or Blaming the Failure: The Moderating Role of Self-Brand Connection on Attitude towards the Brand

Marina Carnevale, Baruch College, USA

Extended Abstract

Imagine that Susan and Jenny would like to purchase a Gucci handbag. Susan has just received a job promotion and decides to reward herself shopping. Jenny, instead, has just learned that the promotion she was hoping to have didn't go through; to cheer herself up, she decides to do some shopping. Will these differences in the psychological contexts that prompt the purchase decision be reflected in Susan and Jenny's attitude towards Gucci? Will it vary depending on the extent to which they feel connected to the brand? The purpose

of this research is to address these questions by exploring how the psychological context in which attitude towards a brand is solicited may affect the way consumers evaluate such brand.

Self-Brand Connection (SBC) represents the extent to which individuals have incorporated brands into their self-concept (Escalas and Bettman 2003). Research suggests that increasing one's feeling that a brand is "me" will lead to more favorable attitude towards that brand (Mogliner and Aaker, 2009). The assumption is that individuals are motivated to view themselves favorably (Allport 1961; Taylor and Brown 1988). Consequently, people hold positive automatic associations with almost anything that is associated with themselves (Greenwald and Banaji 1995; Hetsch, Sakuma, and Pelham, 1999). This might explain why when individuals feel that they had achieved some extraordinary work, a need to gratify the self prompts towards the consumption of products that would reward such feeling (Kivetz and Zheng 2006), likely those that consumers feel connected to. Hence, it is expected that the positive associations that consumers hold about themselves should transfer to such "reward" brands by means of self-connection. Simply put, when self-brand connection is high, consumers seeking to gratify the self are likely to exhibit positive post-purchase evaluations, such as attitude towards the brand.

The abovementioned effects would suggest that when individuals instead view themselves unfavorably, negative associations to the self tend to transfer to anything individuals feel connected to, and thus decrease the attitude towards a brand they feel connected to. Interestingly, however, research has shown that the act of purchasing a product might on the contrary be prompted by the need to compensate for some bad feeling about the self (Tice, Bratslavsky, and Baumeister 2001). For example, the inability to make the self perform or monitor specific actions may motivate individuals towards some immediate pleasure (i.e., purchase) that could compensate for such bad feeling (Baumeister 2002). I expect that purchases made as self-compensation will reflect such negative feelings about the self in less favorable post-purchase attitudes. These effects, however, should only happen when consumers feel connected to the brand. The case of "prestige possessions", such as designer jeans or handbags, appears to be particularly interesting since they are a category of goods where spending a large amount of money on the products reflects one's identity (Bearden and Etzel 1982).

Study 1 examines whether purchases made as self-gratification (self-compensation) will evoke more (less) favorable post-purchase attitudes as opposed to a control condition. Further, I expect that such effects arise only in the case of high self-brand connection.

Study 1

Method. Eighty-two undergraduate students participated in the study. Subjects were randomly assigned to one of three conditions (Motivation to purchase: self-gratification vs. self-compensation vs. control). Then, participants were asked to list the brand that they had considered in the purchase scenario. Next, participants' feelings of self-brand connection were measured by adapting Escalas and Bettman's (2003) scale. Next, subjects reported their attitudes towards the brand using a two item 7-point scale (Like/Good), anchored at "not at all" and "very much so". Manipulation checks followed. Also, measures of self-esteem and of involvement with the product category were taken to avoid potential confounds (Escalas and Bettman 2003).

Participants in the self-gratification [self compensation] condition read the following scenario: "It is the end of the semester. You just got your grades and learned that you received an A [C] in your marketing course. This was really exciting [devastating] because you worked really hard all semester. To reward yourself [compensate] for this good [bad] grade you decide to go out and buy yourself a pair of designer jeans. Even though you don't need them, you decide to buy them anyway to reward yourself [make up] for the A [C] grade". In the control condition there was no mention of the class grade.

Results. Findings showed that the manipulation worked successfully. The key dependent variable was attitude towards the brand. Motivation to purchase, mean-centered SBC, and the interaction between motivation to purchase and SBC were included as independent variables. As expected, results showed a significant interaction of motivation to purchase and SBC. To explore the nature of the interaction, I compared whether there were significant differences across motivation to purchase conditions at both low and high levels of SBC. As SBC is a continuous measure, I performed a spotlight analysis at plus and minus one standard deviation from the mean of SBC (Aiken and West 1991; Fitzsimons 2008). The planned contrasts revealed that for low SBC, individuals' attitudes towards the brand do not significantly vary across motivation to purchase conditions ($p > .1$). However, as hypothesized, for those individuals who hold high levels of SBC, attitude towards the brand significantly differs across motivation to purchase conditions ($p < 0.05$). No other measures (i.e., self-esteem and product category involvement) varied significantly across conditions ($p > .1$).

Discussion

By illustrating how individuals' feelings about the self may affect post purchase evaluations for brands they feel connected to, this research develops a greater understanding of how brands are related to the self concept. In study 2 I want to explore whether the different psychological contexts that solicit attitude may also directly influence consumers' brand choice. Consumers might be very strategic in their choices when there is some asset they feel should be protected (Zauberman, Ratner, and Kim 2009). This suggests that individuals might decide to preserve their favorite brand from the negative feelings associated with the choice they are about to do. On the contrary, consumers might be "strategically" motivated to choose their favorite brand when such brand is going to be associated with the positive feelings about the self and the reward achieved.

Determinants of Consumer-Brand Reunion After a Break-up

Svetlana Bogomolova, University of South Australia, Australia

Extended Abstract

This research uses a framework of consumer-brand relationships (Fournier 1998) and extends the work into consumer-brand 'break-ups' (Fajer and Schouten 1995; Mai and Canti 2008) by examining which factors influence consumers to restore relationships with previously abandoned brands.

Breaking up with a brand could be a significant event in consumers' lives (Fajer and Schouten 1995; Mai and Canti 2008). Terminating brand relationships can take a lot of consumers' time, resources and emotions (Keaveney 1995). Therefore, the break-up experience might have a strong impact on consumers' future decisions, in particular, whether to deal with the same brand again (Stauss and Friege 1999). Consequently, it is important to understand the effects circumstances prior, during and following a consumer-brand break-up have on consumers' future propensities to revive those relationships.

Only a few academic studies have directly examined the notion of lost customers' reunion with their former brands (Homburg, Hoyer, and Stock 2007; Stauss and Friege 1999; Thomas, Blattberg, and Fox 2004; Tokman, Davis, and Lemon 2007). Stauss and Friege (1999) presented a conceptual base for profitable regain management and segmentation of lost customers. Thomas et al. (2004) proposed an optimal pricing strategy for winback offers. Homburg et al (2007) focused on factors during a revival process that increase the winback propensity. Finally, Tokman et al. (2007) proposed a model of the perceived value of winback offer. Principally, these studies examined the issue from the brand's perspective, assessing what managers can do to lure lost customers back. However, there is a need for a study that looks into the focal issue from the consumers' perspective, taking into account the dynamic nature of the consumer-brand break-up process.

Firstly, it is important to understand the relationship consumers held with a brand before the break-up (Fajer and Schouten 1995). Focusing on more objective determinants (such as facts of prior behaviour) avoids potential bias in consumers' post-termination responses (as per Cognitive Dissonance Theory (Festinger 1957)). The first determinant of prior relationship is its length before termination (Thomas et al. 2004). Another determinant is consumer loyalty or disloyalty to the brand, in a form of variety-seeking behaviour (Givon 1984) that results in sole or multiple brand usage (Bird, Channon, and Ehrenberg 1970).

The next set of items describes the process of relationship termination. Attribution Theory (Weiner 2000) suggests that depending on whom consumers hold responsible for the break-up (the brand itself, attraction of competition or themselves-in case of changes in personal circumstances), it will affect how consumers evaluate the experience. Indeed, the reasons for defection were found to have a strong impact on the likelihood of winning back lost customers (Stauss and Friege 1999; Tokman et al. 2007). In a multi-product financial relationship, complete or partial termination could also describe the nature of a break-up.

Finally, factors occurring after the break-up include consumers' post-defection opinions of the former brand, in the form of positive or negative associations and overall evaluations (Bogomolova and Romaniuk 2009). The time lapsed since the event has also been described as an important moderator of consumers' opinions (for example, due to the Cognitive Dissonance Adjustment (Festinger 1957)). Additionally, consumers' demographic characteristics are also believed to have an impact on consumer decisions (Homburg et al. 2007; Tokman et al. 2007).

This research used the context of financial service relationships, which is typically characterised with high involvement (both financial and emotional), long-term (due to its subscription nature) and multi-product relationships, with personal interaction components (Berry 2000). Customers who have terminated relationships with a financial service provider were identified using the provider's records. They were approached by phone for a 15-minute interview, achieving a 30% response rate. The demographic profile of the final sample (141 respondents) was similar to the profile of all provider's lost customers. A hierarchical regression model estimated the relative impact of each factor on the propensity of consumers who have previously terminated relationships to return to their former provider (measured by an 11-point Juster probability scale (Juster 1966)). The factors were inputted in four consecutive models, starting with demographic characteristics, followed by groups of factors occurring before, during and after the termination.

The results showed that the following five (out of eleven) factors significantly contributed to the propensity of lost customers' reunion with the former brand. First, the higher was the number of positive attributes associated with the former brand ($\beta=0.26, p<.01$) and the

higher was the overall evaluation ($\beta=0.47, p<.01$), the higher was the propensity for consumers to return. This suggests that consumers who feel positive about their former provider (even after defection) are more likely to consider returning. Furthermore, the number of different brands respondents had used, had a significant negative impact on the propensity to return ($\beta=-0.18, p<.01$), suggesting that consumers who have other providers or are experienced in switching providers are less likely to return. Next, the longer the time lapse since defection (but still within a year), the higher was the propensity of winback ($\beta=0.15, p<.05$). This suggests that consumers are more likely to return after they had some time to reflect on the decision ('to cool their heads off'), but not so long that they could forget about those relationships. Finally, an increase in household income had a negative relationship with the propensity of return ($\beta=-0.11, p<.01$). This suggests that consumers who have more money (who are perhaps, more savvy at managing finances) are less likely to return to their former brand.

In summary, this study offers a contribution to consumer research in the area of consumer-brand reunion after break-up, by identifying factors that moderate the likelihood of future reunion.

Consumers' Investments in Brand Relationships: An Explorative Investigation of Specific Investments in Consumer-Brand Relationships

Tarje Gaustad, Norwegian School of Management, Norway

Extended Abstract

The literature on consumer-brand relationships is heavily influenced by research on inter-personal relationships from social psychology (Fournier 2009). One factor known to influence persistence in an inter-personal relationship is the size of relational specific investments (Rusbult, Martz & Agnew 1998). Such investments are defined as resources that are invested in the relationship and that lose a significant part of their value if the relationship is ended (Rusbult 1980). Invested resources enhance commitment to the relationship because the act of investment serves as a powerful psychological inducement to persist and it increases the costs of termination (Cox, Wexler, Rusbult & Gaines 1997).

In a similar vein, the concept of asset specificity and specific investments is common in the literature on inter-organizational relationships (Heide & Stump 1995). In the transaction cost perspective, specific assets create dependence on the transaction partner and, if not balanced, create a potential threat of opportunism (Wathne & Heide 2000).

Despite the focus on specific investments in both inter-personal and inter-organizational relationships, there have been a few attempts to understand the nature of such investments in consumer-brand relationships. The lack of learning from the inter-organizational literature is addressed as a shortcoming in the research on brand relationships (Fournier 2009).

30 semi structured in-dept interviews on consumers' investments in brand relationships related to three different contexts (Apple Inc., a national soccer team, and the mobile phone brands the participants had at the time, with 10 interviews in each context) were conducted.

Based on this, and existing research on specific investments in related disciplines, a typology of consumers' specific investments in brand relationships is proposed.

The in-depth interviews indicate that consumers, both directly and indirectly, invest in their relationships with brands. The investments are found to be both of an economic nature, as well as time, effort, and other psychological investments. These are investments that are uniquely related to a specific brand relationship and consequently lose their value outside the relationship. Therefore, consumers' specific investments increase commitment to the brand relationship and build brand loyalty, safeguarding the brand in situations of dissatisfaction and/or presence of attractive alternatives. The proposed typology distinguishes between investments that are direct and indirect to the relationship, as well as extrinsic (directed towards external objects) and intrinsic (driven by internal dynamics) motivations for the investments.

Explicit investments are resources that are directly invested in the relationship and that create commitment as a consequence of external objects and conditions. Examples identified are direct financial investment in physical products and start-up costs, direct financial investments in complementary products, contractual commitment, and other direct switching costs.

Exertion investments in the brand relationship are direct in nature and create commitment as a consequence of the consumer's intrinsic involvement and efforts. The examples found in the present explorative research are efforts the participants have made in terms of learning and personalization, existing knowledge about the brand, as well as past engagement in word-of-mouth, and brand related feelings and memories.

Social investments are indirectly related to the relationship and create commitment based on extrinsic motivations. This type of investments can be related to Holt's (1995) typology of consumption as play, meaning that the consumption act is a part of socialization and a basis for relations and networks among consumers. Such relations among consumers are likely to also create an indirect commitment towards the brand, as it forms the hub of the consumer networks. The types of social investment identified in this research are group identification, sense of belonging to a larger group, friends, user networks, and special objects and events.

Integrated investments are indirect and create commitment as a consequence of intrinsic motivation. This form of relationship investment can be related to Holt's (1995) classification of consumption as integration and classification. One could argue that classification also could be understood as a form of social investment. However, it is probably driven by an inner motivation related to the definition of the users self, and thereby best understood as an intrinsic indirect investment. Examples are assimilation of values and associations of the brand and its reference groups, as well as dissimilation of associations and values of other brands and out groups.

The types of specific investments presented in this work are based on different motivations and have diverging implications for brand relationship management. *Explicit* and *Exertion* investments are assumed to create constraint-based commitment (Johnson 1982) and exchange norms (Aggarwal 2004), as they are instrumental, create dependence and are based on a negative motivation not to lose resources that are invested in the relationship. On the other hand, *Social* and *Integrated* investments are assumed to create dedication-based commitment (Johnson 1982) and communal norms (Aggarwal 2004), because of the value of social networks, affiliation and consumers' self-construal through identification with the brand.

Knowledge about the motivations for the relationship, and the types of investments that function as antecedents of commitment is vital for strategies employed in brand relationship management. For example, the use of tactics based on an instrumental logic and exchange norms might be successful in the case of relationships mainly based on explicit investments, but detrimental for relationships that are heavily based on integrated investments.

Further research should investigate to what extent type of investment influence relationship commitment at different stages of the relationship life cycle, and eventually relationship outcome (behavioral loyalty, interest in alternatives, functional conflict, word-of-mouth, and more), in order to enable companies to craft more tailored and effective strategies for brand relationship management.

Does Consumers' Product Involvement with Sponsors' Products Matter in Sponsorship?

Cindy Lee, West Virginia University, USA

Boyun Woo, Endicott College, USA

The growth of corporate sponsorship has been phenomenal throughout the world for the past two decades. For example, in the U.S., corporate investment in sponsorship has increased from \$850 million to \$12.1 billion between 1985 and 2005 (IEG, 2005). In addition, the areas of sponsorship have been diversified including art, social cause, sports, and entertainment tour. Yet, among the different areas of sponsorship, sports has been one of the most popular venues because of its abilities to attract public interest and reach almost all classes in a more subtle way. Therefore, marketers increasingly view sports sponsorship as an alternative to traditional marketing communications making corporate sponsorship as one of the fastest growing types of marketing communications (Roy & Cornwell, 2003).

As the amount of money spent on sponsorship increases and as the needs to justify the money spent on sponsorship increases, there is more interest in measuring sponsorship effects and its influencing factors. Although many influencing factors on sponsorship effects have been studied (e.g., congruency between sponsors and sponsored events/products, fan identification toward sponsored entities, terms of sponsorship contract, and brand dominance in market), consumers' product involvement with sponsors' products has not been studied much. This is surprising considering the fact that product involvement is a critical factor in explaining various consumer behaviors (e.g., attitude change, decision making). Therefore, this study attempts to see whether consumers' involvement with sponsors' products influences sponsorship effects. In addition, fan identification was included as a variable because much literature (Branscomb & Wann, 1993; Trail, Anderson, & Fink, 2000) attests that fan identification is an essential component which makes sponsorship effects possible.

Product involvement refers to the degree to which an individual is involved with a given product on a regular basis (Zaichkowsky, 1985). Products can be classified as high- or low-involvement depending on factors such as price, importance to self, the level of risk involved in the product's purchase, frequency of purchase, and durability (Dholakia, 1997). There are many companies with different ranges of products that sponsor sport teams, and consumers have various levels of involvement with sponsoring companies' products. For example, sponsorship companies includes Buick(automobile), Coke(soft drink), Geico(insurance) and Campbell(soup). In fact, changing attitudes or behaviors toward high involvement products is harder than low involvement products, because consumers are involved very much in information gathering, decision making, and information processing for high involvement products. This notion is supported by Meenaghan (2001) who assumed that influence of sponsorship for high-involvement products would not be great. Elaboration Likelihood Model (Petty, Cacioppo, & Schumann 1983) and the Consumer Decision Process model (Blackwell, Miniard, & Engel, 2001) provide theoretical background of this phenomenon.

Fan identification makes it possible for sports sponsors to achieve their marketing objectives. The influence of fan identification on sponsorship can be explained by three mechanisms: mere exposure effects, extension of goodwill, and/or social identity/group norms. In essence, fans' responses to sponsors are influenced by their identification level and sponsorship effects tend to be more evident among highly identified fans compared to casual fans.

The objectives of corporate sponsorship varies from increasing sales, generating and raising awareness, reaching new target markets, to enhancing corporate image, and sponsorship effects have been measured in terms of increased awareness (i.e., recall and recognition), attitude change, and increases in sales. In this study, consumers' attitudes and purchase intention toward product were measured. An experiment study format was adopted to control any external factors such as promotion, advertising, or any other marketing communication activities.

Six potential product categories were selected as sponsor products. Using Zaichkowsky's Product Involvement Inventory (PII), the level of involvement toward each product category was measured. Top two (i.e., auto insurance and athletic shoes) and bottom two (soft drink and soup) product categories were selected, and t- test was conducted and confirmed that there is a significant difference between high ($M= 26.71$, $t(39)= 38.29$) and low ($M= 14.28$, $t(39)=14.05$) product categories at the $p < .001$ level. Next, a brief advertisement/description was developed for each product and a pilot test was conducted with 40 students. Participants' attitude and intention to purchase were measured after they read the description of each product. Then, participants' level of team identification with a professional football team in the region was measured. Lastly, participants were told that the brands were actually the sponsors of this team and asked to re-rate their attitude and purchase intention to see whether there are any changes due to this newly revealed association between the brands and the sponsored team.

A series of MANOVA was conducted for each high and low involvement product with independent variable of fan identification and dependent variables of changed attitudes and changed purchase intention. The results showed that there was a significant difference between highly identified and lowly identified groups. Highly identified fans evaluated sponsoring brands more favorably and showed more willingness to purchase the products than those people with low level of fan identification after they were told that the brands were sponsors (Auto insurance, $F(2,37)=4.29$, $p < .05$; Athletic shoes, $F(2,37)=7.47$, $p < .05$; Soft drink, $F(2,37)=5.76$, $p < .05$; Soup $F(2,37)=6.38$, $p < .05$). However, there were no significant differences found between high and low involvement products.

As seen in the previous studies, this study confirmed that fan identification is an important factor in sponsorship effects. However, the current study failed to show the role of product involvement in sponsorship. This may be due to the fact that fictitious brands were used in the study. It seems that fictitious brands made it hard for the participants to actually evaluate each brand in purchase situation. Therefore, further study with actual sponsors will be needed with combination of qualitative methods. However, controlling other external factors in the market could be challenging with real brands.

Consumer Chronic Affect and Persuasiveness of Nostalgia Advertising Appeals

Guangzhi Zhao, University of Kansas, USA

Darrel Muehling, Washington State University, USA

Surendra Singh, University of Kansas, USA

Junwu Chai, University of Electronic Science and Technology of China, China

Extended Abstract

As the nostalgia boom in the popular culture continues to expand in its depth and scope, nostalgic themes are frequently seen in advertising campaigns as well (Crain 2003; Goulding 2001; Muehling and Spratt 2004; Naughton and Vlasic 1998; Stern 1992). A growing number of marketers (e.g., Ford, Mars, PepsiCo, and GE) often connect or pair their brands with words, pictures, scenes, or music in their promotions by portraying a by-gone era to evoke nostalgia among viewers (Bussey 2008; Naughton and Vlasic 1998; Vranica 2009).

Even though the use of nostalgia as a promotional tool is on the rise, research on the topic—especially nostalgia in an advertising context—remains scarce, and the effectiveness of such marketing practice is not well understood (Bussey 2008; Crain 2003; Muehling and Spratt 2004; Stern 1992). Some research has found that nostalgic cues are capable of triggering positive thoughts in consumers and may result in positive attitude toward the advertised brand (Muehling and Spratt 2004). Nevertheless, others have viewed the use of nostalgia ads as a minefield (Bussey 2008; Crain 2003), noting that although nostalgia may be a useful approach for advertising, it has the likelihood of potentially alienating consumers and may even cause boomerang effects if nostalgic appeals are not accurately matched with target consumers.

Though previous research has demonstrated that nostalgia advertising can evoke positive thoughts and emotions in viewers and can subsequently enhance persuasion, few studies have examined the role of viewers' characteristics on the effectiveness of nostalgia advertising. In the literature, researchers have long hinted that consumers' characteristics play an important role in understanding individuals' nostalgic experience. For example, Baker and Kennedy (1994) proposed that individuals' responses to nostalgia would vary by gender and personal life experience. Holbrook (1993) proposed and empirically demonstrated that consumers could be segmented by their nostalgia proneness (i.e., individuals' susceptibility and tendency to feel nostalgic). Extending this line of research to nostalgia advertising, it seems reasonable to expect there are important individual differences in how consumers will respond to nostalgia advertising, i.e., other individual characteristics may moderate the persuasiveness of nostalgia advertising.

One individual characteristic that bears consideration is consumers' affective state. A considerable body of research has shown the impact of consumers' affective state on the advertising persuasion process (see Cohen, Pham, and Andrade (2008) for a review). In addition, consumers' affective state can usefully be differentiated by time frame, e.g., feelings at the present moment, chronic feelings during the past few days, and chronic feelings during the past few weeks and beyond (Watson, Clark, and Tellegen 1988). In our opinion, consumers' chronic affect is especially important for nostalgia advertising since it is expected to influence viewers by evoking memories of the past, thereby, activating positive emotional resonance. In general, the more positive the emotional resonance, the more effective is the nostalgia advertising in influencing ad and brand attitudes. It is our contention, however, that the efficacy of nostalgia advertising at evoking positive emotional resonance depends on both the ad itself and on the viewer's affective state (i.e., is the viewer's general state of mind one that would be considered positive?). Holding the nostalgia advertising constant, we expect that the higher the viewers' chronic positive affective state, the more positive emotional resonance will be evoked and subsequently the more persuasive the nostalgia advertising will be.

Thus, we expect the persuasiveness of nostalgia advertising to be moderated by viewers' affective state, specifically, viewers' chronic positive affect. For viewers who are high on chronic positive affect, nostalgia ads will work together with affective state (i.e., an additive effect) and subsequently arouse more positive emotional resonance in viewers, which in turn should boost nostalgia advertising persuasiveness. For viewers who are low on chronic positive affect, nostalgia ads are expected to mismatch with viewers' affective state and, as a result, are expected to be less effective at arousing positive emotional resonance and be persuasive.

In the preliminary research reported here, one hundred thirty-seven undergraduate students (54.7% male, ranging in age from 18 to 25) participated in a two-factor between subject factorial experiment for course credits: 2 (Ad appeal: nostalgia ad vs. control) x 2 (viewers' chronic positive affect: high vs. low). Participants' chronic positive affect was measured using the positive affect sub-scale of the PANAS Scale, which measures the extent to which participants perceived they had experienced positive affect during the past few weeks (Watson, Clark, and Tellegen 1988). Consumer researchers have widely adopted and relied heavily on the scale in consumer

studies as well (Cohen, Pham, and Andrade 2008). Participants were placed into high and low chronic positive affect groups via a median-split procedure.

Two fictitious ads for Kodak digital cameras were adapted from the literature: one nostalgia ad and one non-nostalgia ad (i.e., control) (cf. Muehling and Sprott 2004). The ads featured a picture of a group of boys posing after a backyard basketball game on a summer afternoon. The two ads were comparable in visual format, color, illustration, length of ad copy, description of product features, and placement of brand logo, but differed in several important ways. Nostalgic cues replaced comparable, though non-nostalgic, cues in the headline (“Re-live the Moment” for the nostalgia ad versus “Capture the Moment” for the control ad), in the date inserted below the dominant picture (“Last day of Summer, August 28, 1998” versus “Last day of Summer, August 28, 2009”), in several statements placed in the ad copy (e.g., “It was a time like no other. . . . Remember?” versus “A moment just like this. . . . A stop in the action”), and in the tag line (“And, Kodak was there” versus “And, Kodak is there”). It is important to note that the highlighted product features (e.g., 10.2 MP, 3X optical zoom lens, etc.) were held constant across the two ads.

A set of two-way ANOVA analyses were conducted on the dependent measures including *purchase intention, brand attitude, ad attitude, and ad-aroused positive emotion*. Standard scale items were borrowed from the literature. Our hypotheses were all supported. A two-way ANOVA on intention to purchase revealed a significant interaction effect between ad appeal and viewers’ chronic positive affective state ($F(1, 133)=6.47, p<.05$). Subsequent pair-wise comparisons showed that, when participants were in a high chronic positive affect, those who viewed the nostalgia ad had a higher intention to purchase the advertised product ($M=4.28$) than those who viewed the non-nostalgia ad ($M=3.75$) ($t(133)=2.00, p<.05$). On the other hand, when participants were in a low chronic positive affect, those who viewed the nostalgia ad reported an intention to purchase the advertised product ($M=3.52$) comparable to those who viewed the non-nostalgia ad ($M=3.92$) ($t(133)=1.59, p=.11$). Similar results were found on other dependent measures.

Temporal Construal, Categorization Processes, and Brand Extension Evaluation

Pronabesh Banerjee, University of Kansas, USA

Sanjay Mishra, University of Kansas, USA

Guangzhi Zhao, University of Kansas, USA

Junwu Chai, University of Electronic Science and Technology of China, China

Extended Abstract

Categorization involves treating two or more distinct entities as equivalent (Medin 1989). Research in categorization has shown that perceptual similarity and conceptual coherence often serve as the two most common bases for judging the equivalence and subsequent categorization of objects into a particular group. For example, a robin and a nightingale can be classified into the same category of bird since they are perceptually similar such that both have feathers, wings and beak. In contrast, children, money, photo album and pets cannot be grouped together based on their physical appearance (i.e., perceptual similarity), but they may form a group based on their conceptual coherence (e.g., “things to take out of one’s house in case of fire”) (Barsalou 1983).

The basic difference in the above two types of categorization (which we term as perceptual and conceptual categorization, respectively hereafter) is that perceptual categorization involves mainly feature-matching among the category members, while conceptual categorization requires the identification of causal relationships or conceptual relatedness among the category members.

Various factors (e.g., cultural background and expertise) are found to moderate use of perceptual similarity or conceptual coherence in forming groups (Murphy and Medin 1985). We propose that the way an individual construes an event in time (near vs. distant future)–temporal construal of an individual, as another factor moderating the use of the two bases of categorization. Temporal construal

theory proposes that events which are closer to the present (e.g., taking a trip tomorrow) are likely to be construed as containing more concrete, peripheral and situation specific details of the event. Conversely, construing the same event six months from now leads to the consideration of more abstract, central and goal related features of the event (Trope and Liberman 2003). Thus, we propose that more concrete (abstract) features or perceptual similarity (conceptual relatedness) will be used for forming a group when one thinks in near (distant) future terms.

In the first study participants' temporal construal was manipulated by asking them to enlist the thoughts while thinking of taking an exam either tomorrow (near future prime) or six months from now (distant future prime). Then they were presented with a focal brand (Nike) and asked to pick three brands from a set of ten brands (Asics, Hush puppies, Timberland, Prince, Wilson, Casio, Polo Ralph Lauren, Dr Scholl's, Caterpillar and Esprit) that forms a "coherent" group with the focal brand. The meaning of the word "coherent" was neither defined nor explained to the participants. Supporting our propositions, we found participants in the near (distant) future prime used perceptual (conceptual) similarity for forming a "coherent" group with Nike—as is evident in the analysis of the following dependent measures, (i) reasons for forming the group (ii) listing of common characteristics between Nike and the chosen brands (iii) the thoughts which went through the participants' mind as they were making the choices and (iv) names given to the chosen group.

Recent research has demonstrated that the way in which products are categorized influences subsequent decision making in an unrelated context (Ulukumen, Chakravarti and Morwitz forthcoming in JMR). For example, the purchase of a new type of candy at the checkout counter is influenced by a prior categorization task—categorizing a DVD into a narrow (e.g. comedy movie) vs. a broad category (e.g., movie). Arguing on a similar vein, we posit that categorizing objects on perceptual similarities or narrower categories (e.g., Nike running shoes) vs. conceptual coherence or broader categories (e.g., Nike for sports) will influence a subsequent decision making task later in the study—evaluation of an ad. In a second study, supporting our hypothesis we find that participants in the near (distant) future prime evaluated the ad promoting brands' perceptual similarity (e.g., NIKE RUNNING SHOES) more favorably than the one promoting brands' conceptual coherence (e.g., NIKE EMPOWER YOURSELF) ($F(1,105)=14.41, p<0.00$).

In a third study, we seek to extend our findings in the context of brand extensions, as extensions are often evaluated on the basis of similarity to the category that the brand stands for (Boush and Loken 1991). However, extensions like Jeep strollers and Godiva ice-cream are notable exceptions to the above logic. Bridges, Keller and Sood (2000) argues that as long as the target customers are able to find an explanatory link between the extension and the parent brand, perceptual similarity is not deemed necessary for evaluating an extension's similarity with the parent brand. We propose that consumers' ability in finding such exploratory links will be enhanced when they are primed with distant vs. near temporal orientation.

The hypotheses was tested in a 2 (temporal orientation—near vs. far) \times 2 (type of brand extension—perceptual similarity vs. conceptual coherence) between subjects design. Johnson & Johnson skin care lotion (perceptually similar to the line of J & J lotion) and stuffed toys (conceptually related to the brand—a brand known for babies) were used as experimental stimuli. As expected, J&J stuffed toys was more similar to the parent brand in the distant (vs. near) future prime ($M=6.44(1.20)$ vs. $M=4.07(1.88)$, $p<0.00$) and the participants listed more exploratory links between stuffed toys and the J&J brand when they were in the distant (vs. near) future prime. However, due to the obvious similarity of the skin care lotion to the J&J brand no differences either in similarity judgment or listing of exploratory links was found was observed across conditions.

Findings of our research contribute to the categorization literature by identifying temporal construal as another factor influencing such a process. Categorization is found to be the basic cognitive mechanism underlying several key decision making processes like consideration set formation (Desai and Hoyer 2000), brand extension evaluation (Boush and Loken 1991) and assimilation and contrast (Levy 1993). Thus, future research may explore temporal construal as a key factor moderating the above cognitive factors and its attendant marketing implications.

How Does Power Affect Evaluation of Brand Extensions?

Youngseon Kim, University of Texas at San Antonio, USA

Extended Abstract

Brand extension is an important topic in consumer behavior research. Extant research highlights fit between a parent brand and its extension product as a major determinant of brand extension success, and focuses on identifying brand related factors or individual factors that affect the perceived fit and the evaluation (Ahluwalia 2008; Keller 2002; Park, Milberg, and Lawson 1991). However, a very important aspect of social factor such as power has been largely ignored in the literature. Power has recently gained attention from the consumer scholars, who found that power has a systematic effect on consumer decisions such as spending propensities (e.g., Rucker and Galinsky 2008).

Power has been defined as an individual's relative capacity to control resources and outcomes, both one's own and others' (Keltner, Gruenfeld, and Anderson 2003; Thibaut and Kelley 1959). It has been well documented that people with high power tend to engage in more abstract thinking than those with low power. For example, Smith and Trope (2006) found that high power primed participants in the task of categorization were more inclusive in their categorization than low power primed participants, and rated the weak exemplars as less atypical. High power primed participants chose a greater number of a higher level of alternatives than low power primed participants in a Behavior Identification Form (BIF) task, a measure of different levels of abstractness of behaviors (Vallacher and Wegner 1989). The research findings on the relationship between power and abstract thinking suggest that power might have a role in brand extension evaluations.

Perceiving fit is a global judgment of the relations that exist between a brand extension and its parent brand, based on factors such as being in similar product categories, sharing important attributes (Aaker and Keller 1990; Kim and John 2008). People who process information at an abstract level may perceive more fit between the brand extension and the parent brand (Aggarwal and Law 2005; Monga and John 2007). Thus, I propose that high power people will process brand extension evaluations at a higher level of abstraction, perceive a moderate brand extension as being more similar to the parent brand category, and evaluate the extension more favorably than low power people. Previous research has shown that consumers tend to be likely influenced by situational factors in their brand extension evaluations when the brand extension was moderate than extreme (Barone, Miniard, and Romeo 2000). However, no differences between high power people and low power people are predicted in the evaluation of a near brand extension since it would already be rated as a member of the parent brand category, regardless of the different status of power. Thus, the formal hypotheses are as follows:

H1: High power people will evaluate a moderate brand extension more favorably than low power people.

H2: High power people and low power people will not show a difference in the evaluation of a near brand extension.

EXPERIMENT

Method

Design and Participants. Seventy eight undergraduate students from a large southwestern university participated in a 2 (power priming: high vs. low) x 2 (extension fit: near vs. moderate) between-participants study. They were randomly assigned to one of the four conditions.

Stimuli. BMW was used as the parent brand. Two hypothetical extensions for BMW were chosen after a pretest (N=25): BMW motorboat as a near extension, and BMW golf clubs as a moderate extension ($t=4.32, p<.001$).

Measures. Participants' evaluation of a proposed brand extension (1=poor to 7=excellent scale), brand extension fit judgment (1=inconsistent/not fit to 7=consistent/fit scales), and their familiarity (1= not familiar to 7=familiar scale) and attitude toward BMW (1=poor to 7=excellent scale). The two items for brand extension fit judgment was averaged ($r=.74$).

Results and Discussion

Brand familiarity and brand attitude were used as covariates in the analyses. A 2 x 2 ANOVA was run on the brand extension evaluation. The interaction between power and extension fit on the evaluation emerged ($F(1, 76)=4.52, p<.05$). Specifically, simple contrasts showed that high power-primed participants evaluated the moderate extension more favorably than low power-primed participants ($M_{\text{high power}}=4.52, M_{\text{low power}}=3.28, F(1, 76)=5.64, p<.05$), whereas such a difference was not observed in the evaluation of the near extension ($M_{\text{high power}}=5.1, M_{\text{low power}}=5.0, F(1, 76)=.11, p=.74$). Therefore, H1 and H2 were supported.

Mediation analyses (Baron and Kenny 1986) confirmed mediation by perceived fit on the extension evaluation. Power emerged as a predictor of the evaluation ($\beta=.22, t=1.92, p<.06$) as well as brand extension fit judgment ($\beta=.23, t=2.03, p<.05$). When both power and the fit judgment were included in the same regression equation, the effect of power became insignificant ($\beta=.09, t=.96, p=.34$), whereas brand extension fit judgment was significant ($\beta=.53, t=5.44, p<.001$). The analyses suggest complete mediation of the effect of power on the evaluation by perceived fit (Sobel test-statistic=1.91, $p<.05$).

This research makes important contributions with implications for further research. Foremost, it discovers the new role of power as moderator in brand extension evaluations while most current research has focused on the effect of power on consumers' spending propensities such as status consumption. Second, it is the first study that investigated the role of social power in brand extension research, whereas most research in the literature has examined individual factors or brand related factors to affect the evaluation of brand extension. Third, it demonstrates that different social power groups tend to view the same brand extension differently. The finding signals that brand extensions may be more segment specific phenomena rather than universal ones.

Finally, the next step for this research is to generalize the findings in different settings, and to further test whether the moderating role of power in the brand extension evaluation would be tempered by a parent brand factor, e.g., whether the parent brand is status-associated.

Brand Synergy in Multi-Product Experiences

Ryan Rahinel, University of Minnesota, USA

Joseph Redden, University of Minnesota, USA

Products are often used together to form a single experience (e.g., toothpaste and toothbrushes jointly form a teeth cleaning experiences). A natural question stemming from this phenomenon is: "How does the set of brands used across the multiple products affect the consumption experience?" Surprisingly, there has been little research on the experience of using two products in tandem. In this research, we demonstrate that experiences involving products of the same brand are evaluated more positively than experiences involving products of different brands. Our data suggests that a sizable part of this effect can be attributed to consumers' desire to have a single "coordinator" for experiences.

Previous research has shown that evaluations of a consumption experience are formed through a combination of intrinsic and extrinsic cues. For example, the primary intrinsic cue in the experience of eating a potato chip is the gustatory perception. In contrast, extrinsic cues are cues that arise from the context of consumption or the external environment (Shiv et al., 2005; Allison and Uhl, 1996; Bellizzi & Martin, 1982; LeClerc, Schmitt, & Dube, 1994). As shown by Allison and Uhl's (1964) classic beer study, brands can serve as an extrinsic cue for the consumption experience, particularly through the brand's function as a signal of quality.

In this research we investigate a new function of brands, namely as agents of coordination. In single product experiences, brands can be seen as coordinating the component parts of the product, essentially ensuring that all the parts work together effectively. Research in the area of co-branding lends some preliminary support to this idea. A common phenomenon examined in this literature is the effect of header and modifier brands (e.g., in the co-branded product Oral-B Rembrandt whitening strips, Oral-B is the header brand and Rembrandt is the modifier brand; Kumar, 2005; Park, Jun, and Shocker, 1996). That these co-branded products tend to have header and modifier brands points to the possibility that consumers wish to think of these products as having been coordinated primarily by the one brand (the header) with only specific component expertise provided by the modifier brand. In this work we extend this thought into where the evaluation target is the joint experience of two products. If consumers really do prefer to have one coordinator of experiences, then one should observe that (1) consumers tend to prefer multi-product experiences involving one (vs. two) brands (which we term the brand synergy effect), (2) the effect should be for brands only (not for other benign matching properties), and (3) the effect should be larger for experiences with more risk or complexity. We tested these predictions in five studies.

The first study tested whether people's liking ratings in a range of product categories would display the brand synergy effect. This study employed a 2 (Product 1 Brand: Brand A vs. Brand B) x 2 (Product 2 Brand: Brand A vs. Brand B) X 4 (Product Category Pair: laundry detergent + fabric softener, toothbrush + toothpaste, chips + dip, MP3 player + headphones) within-subjects design using real brands (brand names available upon request). On each of the 16 trials, subjects were asked to consider using two brands of products together. As the dependent variable, the subject was asked to "Imagine using these products together. How do you think they would be for [insert experiential goal here]?" The subject then provided their rating on a 101-point visual analog scale anchored by very bad/very

good. Results across all four categories showed the brand synergy effect. That is, subjects' ratings for experiences involving one brand were significantly higher than those for two different brands.

The second study and third studies tested the effect actual experiences. Study 2 employed a 2 (Product 1 Brand: Brand A vs. Brand B) x 2 (Product 2 Brand: Brand A vs. Brand B) x (2 Product Category Pair: jellybean flavors vs. chips and salsa) mixed design using real brands. Product category pair was a within subjects factor, with the other two factors varying between subjects. Although subjects were told that the foods were from particular brands, the foods themselves were actually from the same brand for all subjects. Subjects were asked to indicate how the foods tasted together on a 131mm line scale. Contrasts from a repeated measures ANOVA showed that across the two product category pairs, subjects perceived that the foods tasted better together when they were of the same (vs. different) brands. We replicated this finding in a third study using the same basic setup (i.e., crossing real brands in a factorial design) for a more utilitarian category pair—printer and ink. Subjects were asked to evaluate the quality of a picture on a printout. Results showed that subjects felt the picture was sharper when the printout was generated using a printer and ink from the same (vs. different) brands.

In the fourth and fifth studies, we sought to gain some process evidence for the synergy effect. Study 4 tested whether the effect was local to brands or any other matching attribute. We asked subjects to consume and rate the taste of chips and dip that were either described using generic labels (“festivity” or “party time”) or as brands (“Festivity® brand” or “Party Time® brand”). As expected, we observed the brand synergy effect emerge when we described the chips and dip as registered brands, but not when they were merely described using generic labels. Study 5 again used the printer and ink paradigm. If brands are truly seen as coordinators, then the effect should be enlarged when there is risk in the quality of experiences. Thus, we used reports from *Consumer Reports* to frame the risk of the experiential category as either being high or low prior to the printout evaluation task described in the third study. Results showed that those in the high risk category showed the brand synergy effect much more-so than those in the low risk category.

Can Moral Identity Enhance Out-Group Brand Evaluations?: The Moderating Role of Thinking Style

Woo Jin Choi, Texas A&M University, USA

Karen Page Winterich, Pennsylvania State University, USA

Extended Abstract

The pervasive impact of moral identity (hereafter, MI) has largely been limited to altruistic or prosocial behaviors (e.g., Reed and Aquino 2003; Shang et al. 2008; Winterich et al. 2009). Can MI influence other consumer behaviors, such as brand evaluations? If so, how and under what conditions? We examine the influence of MI on evaluations of brands associated with an out-group (hereafter, out-group brand evaluations), demonstrating that consumers' thinking styles moderate the effect of MI on out-group brands and brand extension evaluations.

Due to the general tendency of people toward in-group favoritism and out-group hostility (Reed and Aquino 2003; White and Dhal 2007), brands associated with in-groups receive more favorable brand evaluations and have stronger self-brand connections whereas brands associated with out-groups are evaluated less favorably (Escalas and Bettman 2005). Therefore, it is plausible that the evaluation of an out-group brand will depend on the amount of “social distance” (Sagiv and Schwartz 1995) that an individual perceives as existing between himself/herself and the outgroup. We predict that MI will play an important role in determining consumers' out-group brand evaluations.

MI refers to “a commitment to one's sense of self to lines of action that promote or protect the welfare of others” (Hart et al. 1998). Building on this work, Reed and Aquino (2003) suggest that MI can influence out-group hostility by altering the psychological boundaries that define in-group membership such that a highly self-important MI is associated with an expansive circle of moral regard toward out-group members. We draw upon this prior research on MI and out-group evaluations to theorize that consumers with a highly self-important MI will evaluate out-group brands more favorably. We reason that this effect occurs because consumers with high MI importance tend to expand the boundaries of ingroups to include more individuals, including individuals otherwise perceived as out-

group members. In doing so, these consumers perceive themselves as being closer to members of outgroups, responding less negatively toward out-group brands, even if the brands are perceived as out-group brands.

Furthermore, we predict that consumers' thinking styles will moderate the effect of MI on out-group brand evaluations. Thinking style refers to individuals' preferred ways of processing information (Zhang and Higgins 2008). Prior research on thinking styles acknowledges that individuals' thinking styles can vary between cultures (Nisbett et al. 2001; Nisbett and Miyamoto 2005) as well within cultures (Choi et al. 2007). Considering that social identity is just one piece of information used in brand evaluations and that consumers hold multiple identities that may differ in salience at any specific point in time (Reed 2004), consumers' cognitive mechanisms may systematically affect the way in which they select which self-identities form the basis of their brand evaluations.

Although holistic thinkers take into consideration the salient identity (herein, MI) as well as their other identities (herein, their customary beliefs and attitudes towards the out-group), the latter will have a stronger effect on holistic than analytic thinkers because comprehensive thinking styles of holistic thinkers better enable them to recall their habitual attitudes toward out-groups. In contrast, individuals with analytic thinking styles are more likely to limit their attention to the currently salient MI, thereby resulting in their evaluations being less affected by their habitual attitudes toward the out-group.

We conducted two studies to test these hypotheses. The first study was a 2 (brand: in-group vs. out-group) X 2 (moral identity: low vs. high (measured continuously)) X 2 (thinking styles: analytic vs. holistic (measured continuously)) mixed design with brand as a within-subjects factor. Participants listed a brand associated with an ingroup and an outgroup. Then participants completed the 24-item thinking style scale (Choi et al. 2007) and the 10-item MI scale (Reed and Aquino 2003). We expected that participants' MI would be heightened, or made salient, while responding to the MI scale. Then, participants evaluated both the in-group and the out-group brand as well as several other filler brands, randomly ordered.

Results indicated that consumers evaluated their in-group brands more favorably than out-group brands, which is consistent with results reported in previous studies (White and Dhal 2007). Furthermore, as we theorized, MI was positively associated with out-group brand evaluations but did not affect in-group brand evaluations. Most importantly, the results demonstrated that the three-way interaction of thinking style, MI, and reference group influenced brand evaluations. Exploring the pattern of this interaction, we found that the effect of MI on out-group brand evaluations was significant for analytic thinkers but not for holistic thinkers. Among analytic thinkers, those with higher MI evaluated the out-group brands more favorably than those with lower MI, demonstrating that they reflect their MI in an unbiased manner. However, the evaluations of holistic thinkers did not differ according to their MI, suggesting that they evaluate out-group brands mainly based on their customary attitudes, rather than their MI.

Study 2 extends the results of Study 1 to consumers' evaluation of brand extensions. The design was the same as that of Study 1 with three important distinctions: 1) MI was manipulated using the procedure from Aquino et al. (2007), 2) all participants saw the same in-group (Nike, Polo) and out-group (Toms, American Apparel) brands, based on a pretest, and 3) evaluation of each brand's extension into the jewelry category was the dependent variable.

The results replicated those of Study 1 for brand extension evaluations. For out-group brand extensions, analytic thinkers reported more favorable evaluations when they were in the high MI salience condition. In contrast, holistic thinkers evaluated the out-group brand extensions less favorably, irrespective of their MI condition. Thinking style and moral identity did not influence in-group brand extension evaluations.

This research makes two important contributions to the literature. First, we demonstrate that MI, which has been neglected in the previous research on consumer-brand relationships except for CSR, is a means through which marketers can enhance consumers' brand evaluations, particularly for out-group brands. Second, we provide insights into the effect of social identity on brand evaluations, demonstrating that the identity salience effects (herein, MI) can vary according to consumers' thinking styles.

Consumer Memory for Easy-to-Pronounce Non-Word Brand Names: The Effect of Attitudes

Paula Chesley, University of Minnesota, USA

Dawn Lerman, Fordham University, USA

Extended abstract

Among the many criteria that marketers should consider when creating new brands names is ease of pronunciation (Kohli and LaBahn, 1997). An easy-to-pronounce name may be critical when the consumer must ask for the brand (Lerman, 2003) and as Bao, Shao and Rivers (2008) argue may also aid processing and retrieval. This is important as brand name memorability is considered important for marketplace success (Keller, 1993).

Generally, word names best fit the ease-of-pronunciation criterion as they have been learned previously by the consumer and are already represented in the consumer's lexicon. However, the task of finding new easy-to-pronounce and thus memorable brand names is complicated by the fact that the vast majority of English words have already been trademarked. This challenges marketers to create non-word brand names that are easily pronounceable. Two types of non-word brands names fitting this criterion are acronyms (e.g., UPS) and morphemic non-words. A morphemic non-word may be a derivation (base + affix as in *Wheatables*=Wheat + -able + -s) or a blend (combination of two words, e.g., *flackers*=flax + crackers or *dunch*=dinner + lunch).

Conventional wisdom (see, for example, Robertson, 1989) suggests that the use of acronyms and/or morphemes in brand naming aids memorability. However, the results of empirical research are mixed, particularly for morphemic non-word names. For example, Lerman (2003) found that the use of morphemes aids memory whereas Lowrey, Shrum and Dubitsky (2003) found that at least one type of morphemic device—blends—impedes memory, particularly for less familiar brands. In the case of acronyms, consumer researchers cite a single study conducted by Bower in 1972 suggesting that acronyms aid memory.

Our study seeks to address this gap in the literature by examining consumer memory for easy to pronounce non-word brand names. We propose that memory for easy-to-pronounce brand names is a function not only of name type (i.e., acronym, blend, morphemic derivation) but also of consumer attitudes toward the name. We expect, for example, that the perceived utility or humor that a consumer associates with a name will influence memory. The results of an empirical study suggest that name type and consumer attitudes toward the name do indeed influence memory retention of new words.

We ran a combined lexical decision and eye-tracking experiment with new acronyms, blends, and derivations that have appeared on websites and in a variety of media including television. A pre-test determined that our 45 participants were unlikely to have seen these words beforehand. Each word appeared with its definition one at a time on a computer screen. With the word and definition still visible, participants responded to a series of attitudinal questions about the word's perceived utility (Corbin, 1987), emotional content (Kensinger & Corkin, 2003), humor (Metcalf, 2004), and degree of formality. Immediately following completion of the attitudinal measures for the last word, half of the participants were tested on recall. We tested the other half after one night's sleep; this allowed us to examine the consolidation of new words into long-term memory.

We fit mixed-effects models for reaction time (RT), lexical decision accuracy, number of fixations, number of regressions, and free recall. Control variables included participant sex, age, and education level, word length, and frequencies of initial component words. Although shorter in length overall, acronyms took significantly longer than blends or derivations to read, and decision accuracy for acronyms was significantly lower than for blends and derivations. This effect holds for acronyms that can be pronounced as letters (*FSBO*, "For Sale By Owner") as well as words (*BITGOD*, "Back In The Good Old Days"). Both groups of participants (i.e., immediate and delayed recall groups) fared worse on acronyms, as an intervening night's sleep significantly shortened RTs and improved accuracy for only blends and derivations. This improvement after one night's sleep is in line with recent research suggesting sleep is helpful in memory consolidation of new vocabulary items (Dumay and Gaskell, 2007). Unlike Lowrey et al. (2003), we find no inhibitory effect for blends: no significant difference between blends and derivations appeared in any dependent variable. Furthermore, the only significant attitudinal question that was consistently significant was, "Would you use this word at a party with your friends?" The more participants said they would use a new word at a party, the shorter their RT and the better their accuracy and free recall. Hypothetical use in other social contexts like "at work or school" was only a significant predictor for free recall and was negatively correlated with memory retention.

These findings indicate that both word formation type and attitudes about the social utility of a new word are important factors in whether consumers remember words that are new to them. There are several implications of this work for marketing. First, by any measurement of memory retention, acronyms appear especially difficult to remember. Moreover, participants often volunteered their distaste for acronyms with comments like "I hate acronyms. . . they sound like jargon." These findings suggest that at least new brand names that are acronyms will be more difficult to remember than blends and derivations. Blends, for their part, were less problematic than expected—perhaps this is due to their ever-increasing presence in advertising and the lexicon in general.

The findings concerning consumer attitudes highlight the importance of social context in remembering new lexical items. In addition to examining responses to individual questions such as "Would you use this word at a party with your friends?", we also took the first

and second factors in a principal component analysis as predictor variables. Responses to the party question were more robust than the first principal component, which implies a specific judgment concerning utility and social context as opposed to an overall impression about the word. The “party effect” could be an exciting link between individual cognitive entrenchment and in-group vocabulary choice. This suggests that marketing for new brand names which focuses on in-group usage of the word, if applicable, could be an effective strategy for consumer memory retention.

Two Small Steps, One Giant Leap: Effect of Movement Signals on Consumers’ Walking Speed

Gaby Schellekens, Erasmus University Rotterdam, The Netherlands
Bram Van den Bergh, Erasmus University Rotterdam, The Netherlands

This research examined the effects of movement signals, such as path of footprints or squares on consumers walking path and walking speed. Three studies demonstrated that exposure to a path of movement signals causes following behavior even if the route is less attractive, and that the distance between of movement signals has an effect on walking speed.

In-store shopping movement paths of consumers have received increasing attention lately (Hui and colleagues, 2009; 2010). Arrows or a depicted path of footprints on the floor of the store are attempts to guide consumers movements paths. It avoids inconvenient store traffic flow, and can pull customers deeper into a store. Rather surprisingly, the actual effect of these movement signals on the travel patterns has remained unstudied. This research examined the implicit effects of depicting a path of movement signals on consumers walking behavior.

From past experiences, people know that a path of footprints, stripes or arrows indicate a route to follow. For instance, arrows in a subway station or a row of light dots in an airplane direct the route to the nearest exit. Frequent exposure to these environmental cues can lead to an automatic association between exposure to a depicted path and the behavior of following this path, which leads to automatic following behavior (H1). When consumers are exposed to footprints in a path, they may attempt to mimic the indicated steps by placing their feet on the footprints. Mimicry of other people’s behavior is an inborn tendency, based on the notion that we simply *do* what we *see* (Dijksterhuis & Bargh, 2001). Evidence for the mimicry of other people’s body posture, facial expression and speech related variables is abundant (Chartrand & Bargh, 1999; Chartrand, Maddux & Lakin, 2005). While, previous research mainly focused on the mimicry of observable human behavior, we argue that even in the absence of a human model, human-like cues, like a depicted path of footsteps suggestive of a human walking path could also automatically trigger mimicry. Correspondingly, it is hypothesized that when the distance between the depicted movement signals is larger (vs. smaller) than an average human footprint, consumers will walk faster (H2). We argue that consumers do not have to be aware of the influence of (the distance of) the footprints on their motion path, nor of their walking speed for these effects to occur.

In study 1 we used footprints that look like the print of a shoe placed on a human walking rhythm. For a *smaller distance* between the footprints the average foot size is used, which is about 30 cm (Agnihotri, Shukla, & Purwar, 2007). For a *larger distance* between the footprints, an average foot size was added to the average footprint (which is 74 cm: Judge, Davis, & Ounpuu, 1996), summing up to about 100 cm. The movement signals were printed on white sticker paper, and were pasted on a grey linoleum floor.

In study 1 the participants (N=60) were randomly assigned to one of three movement signal conditions (small distance vs. large distance vs. no footsteps). First, this study tested if peoples’ walking paths can be affected by a path of footprints; footprints were placed on a non dominant path (‘alternative route’) of an Y-junction on the participants walking route after finishing a filler study. The participant’s walking time and chosen route unobtrusively recorded by research assistant. As expected, without a depiction of footprints,

70% of the participants choose the dominant route, while this dropped to 40% when footprints (both smaller and larger distances) were depicted on the alternative route ($\chi^2(1)=4.13, p<.05$). Second, this study revealed (contrast analyses of an ANOVA) that participants walked faster with a larger distance between the depicted footprints ($M=18.77, SD=5.60$), compared to a smaller distance between the footprints ($M=24.15, SD=2.84; F(1, 56)=12.79, p<.001$) (one outlier was removed according to Interquartile Range; Tukey, 1977).

The goal of study 2 was to replicate these findings with non human shapes (squares) on a human walking rhythm. This study ($N=50$) had a between subject design (small vs. large distance between footsteps), and the participants' walking behavior was taped by the surveillance camera of the research lab. Afterwards an independent judges coded the walking time of the participants. As expected, a t-test revealed with a smaller distance between the depicted squares the participants walked slower ($M=11.639, SD=1.1858$), than with a larger distance between the squares ($M=11, SD=0.922$), ($t(48)=2.03, p<.05$) (one outlier was removed).

The goal of study 3 ($N=78$) was to examine if people follow an indicated rhythm of movement signals independent of both human shape and human walking placement by placing squares in a row. We used a between subject design (small distance vs. large distance vs. no footsteps), and the procedure was equal to study 2. As expected, we found (contrast analyses of ANOVA) that participants walked slower when there was a smaller ($M=8.57, SD=1.45$) compared to a larger distance between the squares ($M=7.87, SD=0.73; F(1, 65)=3.24, p=.077$). Planned contrasts also revealed that participants in both the smaller ($F(1, 65)=46.57, p<.001$), and larger distance conditions ($F(1, 65)=59.53, p<.001$) walked significantly faster than participants in the control condition ($M=11.16, SD=1.49$) (four outliers were removed).

The influence of a shopping environment on consumer behaviour is an important aspect of marketing research. We showed that walking route and speed are significantly influenced by movement signals: the bigger the distances between the depicted signals, the faster people walk. Our findings have important marketing implications. For instance, to achieve high profits, a store manager can try to 'lead' the consumer to high margin products, and 'sway' customers to walk slowly in the vicinity of these products. We argued that movement signals automatically trigger mimicry of these signals, but based on the current studies we cannot exclude possible alternative processes, such as visual information.

Consumer Willingness to Purchase Counterfeit Brands: Frequent Change in Fashion as a Determinant

Kaleel Rahman, American University in Dubai, United Arab Emirates

Extended Abstract

The objective of this research is to examine the determinants of consumers' willingness to buy counterfeit brands within the context of UAE market. According to the International Anticounterfeiting Coalition (IACC, 2008), almost five percent of all products are counterfeits. Hence, from different perspectives, many consumer researchers have attempted to identify the non-price related factors as to why consumers buy counterfeits (e. g., Bamossy, and Scammon, 1985; Ferreira and Pereira, 2010; Kim et. al., 2010). Although actions to limit counterfeit can arise from both supply side and demand side, supply side has dominated most of the research work to date, where issues of controlling the source and flow of counterfeit products are examined to make recommendations to policy makers (Albers-Miller, 1999). This practice is very clear in UAE. For example, a cursory scan of over four hundred newspaper clippings in regards to counterfeiting in UAE demonstrates this trend where most of them relate to some form of seizures but nothing about understanding why consumers like or are willing to buy counterfeits.

Until recently, the UAE government may have been turning a blind eye on the counterfeit industry as it has been a large aspect of tourism. However, since becoming a member of WTO in 1996, the government has been combating counterfeit trade. A massive amount of counterfeit trade currently present in the country is inconsistent with its attempt to portray a positive image in terms of luxury, tourism, business and real estate developments. The following points provide an overview of the scale of counterfeit trade in UAE and its impacts: About 35 per cent of software sold in the UAE is counterfeit (Gulfnews, November 15, 2008); value of fake products in the

UAE reached \$696 million in 2006 (Gulf News, January 18, 2008); compared to the year 2006, 2007 shows a greater loss for concerned industries seeing a 52% increase in counterfeits (Gulf News, August 8, 2007). Despite counterfeit dilemma often being attributed to UAE (IACC, 2008), no study on counterfeit has been conducted in UAE from a consumer research perspective. Hence, in this research we examine the reasons why consumers prefer counterfeit brands, in the UAE market in particular.

We developed our measures using a projective technique in that fifty seven respondents (as part of their class exercises) were asked to write as many non-price related reasons as possible as to “why people buy counterfeit brands”. These responses were then categorized into eight meaningful themes (i.e., reasons as constructs). Several of these constructs overlapped determinants identified in prior studies (e. g., Gentry et. al., 2006). We then developed scales to measure these constructs using the procedures suggested by authorities in construct development in marketing (e.g., Churchill, 1979; Nunnally, 1978). We adapted scales from prior studies to measure attitudes toward counterfeit (Huang et. al., 2004) and intention to buy counterfeits (Ang et. al., 2001). Constructs are listed below with respective coefficient alpha, number of items, and a sample item in parenthesis:

Fashion changes quickly ($\alpha=.78$, 3 items, “Fashion changes so quickly so it is ok to buy counterfeits”)

Superior quality of counterfeits ($\alpha=.61$, 3 items, “The quality of counterfeits measure up to the quality of the original brands”)

Trialability of new brands ($\alpha=.64$, 3 items, “Some consumers use counterfeits to test it, then buy the original if they like it”)

Novelty/ curiosity of brand names ($\alpha=.68$, 4 items, “I like counterfeit for the novelty of having that brand name”)

Aspect of tourism ($\alpha=.74$, 3 items, “It is quite acceptable for tourists to buy counterfeits”)

Friendly/ approachable sellers ($\alpha=.66$, 6 items, “Sellers of counterfeit products are friendlier than sellers of original brands”)

Availability/ accessibility ($\alpha=.76$, 2 items, “Sometimes counterfeits are available before the originals are released”)

Household usability ($\alpha=.55$, 2 items, “For rough and in-house wear, I got no problem with counterfeits”)

Attitudes toward counterfeit ($\alpha=.86$, 4 items, “Buying counterfeit goods generally benefits the consumer”)

Intention to buy counterfeit ($\alpha=.88$, 4 items, “What is the chance that you think about a counterfeit product as a choice when buying something?”)

We collected data using a 7-point Likert scale from a total of 348 consumers, both students and non-students who live in UAE. The questionnaire also included several other items beyond the scope of this paper. We averaged the items under each construct to create a single item measure. In analyzing the data, we used stepwise regression analysis in SPSS in order to gain some preliminary insight. Using standardized beta coefficients, we summarize the results below:

Attitudes toward counterfeits (R Squared=0.63, F=135, p=0.000)

= β_1 fashion changes + β_2 trialability + β_3 superior quality + β_4 household use

= [.51 fashion changes] + [.17 trialability] + [.14 superior quality] + [.13 household use]

Intention to buy counterfeits (R Squared=0.40, F=152, p=0.000)

= β_1 fashion changes + β_2 superior quality + β_3 household use

= [.33 fashion changes] + [.25 superior quality] + [.17 household use]

This can be interpreted that 63% of total variance in *attitudes toward counterfeit* was explained by fashion changes, trialability, superior quality and household usability of counterfeits. Other variables mentioned by respondents in the projective technique did not make a statistically significant contribution. When it comes to *intention to buy counterfeit* brands, the result was somewhat different where trialability of counterfeit was not a predictor of intention. These results are quite insightful as frequent changes in fashion emerged as the strongest determinant of consumers' preference for counterfeit brands, a determinant ignored in prior research. Interestingly, several factors strongly expressed by projective technique respondents were not supported by our large-sample regression model. For example, “counterfeit sellers are very friendly”, “they come to your door”, “they are available even before the originals” were reasons frequently mentioned by respondents. Currently, we have planned to do further modeling using Amos and analysis on differences between groups such as Arabs versus non-Arabs, and the users versus non-users of counterfeits.

New Business, New Babies: Proposing a Sociological Analysis of Consuming Early Childhood Development Service in China

Gehui Zhang, University of Illinois at Urbana-Champaign, USA

China's Early Childhood Development (ECD) industry is at its very outset; however, by all means uprising. It was estimated that the current China ECD market scale is approximately worth four billion US dollars per year and will maintain a fast growth compared with other industries¹. It was reported in 2006 that over 50% urban Chinese parents are willing to purchase professional ECD services for their young children². This research aims to examine the cultural contexts in which the development of this relatively new market and the consumption of ECD service have embedded in China.

FOOTNOTE 1 and 2

¹"An Analysis of Early Childhood Education Industry," retrieved from <http://www.ci123.com/article.php/22877>

²Yang, Gu (2007), "Early childhood education on fast track in China," retrieved from http://en.ce.cn/Insight/200707/26/t20070726_12321002.shtml

Consumption on young kids' early development education is an economic action, a consumer behavior, a familial practice, and with a more general view, a reflection of the interaction between social institutions and individual agents. Gary Becker (1991) uses rational choice theory to explain a series of familial relations and activities, such as marriage, fertility, education investment, and domestic division of labor. In his theoretical model, individual are not only social beings but foremost economic agents. Social and culture forces such as traditions and values may shape individuals' decision making process however say little about how people act. Instead, one can only understand individual's action as a consequence of a careful calculation on efficiency and utility maximization, regardless conforming or challenge social norms. Zelizer (2005), however, argues that the context-free analysis of market and the rational choice orthodox advocated in neoclassical approach of economic activities are inadequate to understand economic exchange. Adopting Weberian tradition, Zelizer (2005) proposed an "alternative approach" to analyze the interaction between social and cultural characters and market as well as economic activities, in which a market is neither treated in dominance nor in subordination, but recognized as one of the social categories (Zelizer 1988).

In current capitalist markets, child is one of the most central subjects which have been commercialized in most of the social aspects. However, parents' consumption on early childhood development (ECD) services has been portrayed as either an investment or altruism based on parents' sacred love, which may contribute to its understudies in existing literatures. Scholars, such as D. Cook (2000), argue about the reconciliation between "scared" childhood and the "profane" market was achieved through redefining certain commodities or services beneficial or useful to child's development—the process of the early life course moving through predictable, specifiable, and sequential stages (Seiter 1993). However, the "naturally" perceived child development periods and their commodification are nothing given but culturally and historically constructed. The dominant moral standard of economically useless but emotionally priceless child was a consequence of an ideological victory of the sacred view of childhood over the productive one (Zelizer 1985).

Gymborree, recognized as "the global leader" in early childhood development program, was founded in 1976 in the United States and became an international brand in offering classes, trainings, and programs in early childhood development for under 5-year old children and their parents globally. The key philosophy as it publicizes is to "focus on the whole child in order to help children acquire the key ingredients--motor skills, social skills and self-esteem--they need to grow up to be confident, happy and successful adults."³ Gymboree Play & Music Program entered Mainland China's market in 2003 and the franchise business has grown rapidly through licensing over 50 Gymboree centers within four years. Market operators expect to have over 200 centers by 2010, which will make China the biggest market for Gymborree's ECD business. This working paper, using Gymborree, one of the best renowned global brands in early childhood development industry as a case study, aims to provide an alternative theoretical framework to understand the recent development of ECD market in China through a preliminary analysis of Gymborree's rapid franchise expansion in China. By reviewing the literatures on parents' consumption on children's education, I propose the cultural embeddedness approach as a valuable tool to study the markets which are ingrained in the "presumable" or "unquestionable" moralities, such as consumption in ECD services. I argue that the booming ECD market and its swift popularity in China is culturally embedded phenomenon which deserves a more careful examination on the impact of social values and relations out of the money nexus on the formation of consumer culture and culture of consumption. The creation of consumption discourse in ECD market, I suggest, parallels with the on-going transformation of parenting and childhood ideologies in Chinese society, which needs to be understood with the formation of modern child and personhood in neo-liberalism social condition.

It Leaves a Bad Taste In Your Mouth: The Impact of Negative Company Information on Consumption Experience

John Pelozo, Simon Fraser University, Canada
Jingzhi Shang, Simon Fraser University, Canada

Extended Abstract

Consumers' attitudes toward brands are impacted by corporate social responsibility (CSR) information, and firm-level CSR can translate into improved attitudes toward products of the firm (e.g., Brown and Dacin 1997). But attitudes stemming from CSR information aren't always good predictors of actual consumer behaviors. For example, products that have social attributes are sometimes perceived as inferior in quality to those that do not (Obermiller et al. 2009), and consumers will not sacrifice quality for social features (Auger and Devinney 2008). This gap between CSR attitudes and behaviors (see Cotte and Trudel (2009) for a review) suggests additional research is necessary to understand how CSR information can impact consumers beyond attitudes. Further, the impact of CSR information on subjective, post-purchase consumption experiences remains unstudied. This represents a theoretical and managerial gap since many consumers acquire CSR information *after* they have already purchased a product or developed a relationship with a brand.

On the other hand, research examining how information can alter subjective consumption experience is plentiful. One of the consumption experiences most fertile for researchers is taste (Lee, Frederick and Ariely 2006). This is because consumers generally lack taste discrimination and are unaware of their ineptitude (Lau, Post, and Kagan 1995), making it highly susceptible to the forces of information. Indeed, taste is a commonly used dependent variable (e.g., Allison and Uhl 1964; Braun 1999; Hoegg and Alba 2007; Lee et al. 2006; Levin and Gaeth 1988; Obermiller et al. 2009; Wansink, Payne and North 2007). Further, a wide variety of information has been used to manipulate taste evaluations including product labels (Allison and Uhl 1964; Nevid 1981), advertising copy (Braun 1999; Elder and Krishna 2010), product color (Hoegg and Alba 2007), and nutritional content (Wardle and Solomons 1994). However, the information used in these studies is closely linked to product attributes with high salience to product performance (i.e., taste). For example, Elder and Krishna (2010) prime multiple senses through advertising copy since taste is enhanced when multiple senses are engaged. Despite broad consensus that information can influence consumption experiences, the impacts of firm-level information such as CSR (as opposed to attributes more salient to product performance) are relatively unknown.

Our research aims to address the gaps in these two disparate research streams, contributing to each in the process. Across two studies we examine how CSR information impacts consumer evaluations of product taste.

Our research is based on the idea that CSR information can activate emotions in consumers, and those emotions in turn will impact their taste evaluations of products. The prevailing social norm is that consumers who support firms that perform CSR are engaging in positive behavior, and those who support firms engaged in corporate social irresponsibility (CSIR) are engaging in negative behavior. This effect is particularly strong for CSIR; consumers are much more willing to punish firms who engage in CSIR than they are to reward firms who perform CSR (Sen and Bhattacharya 2001). With CSIR, the perceived violation of a social norm stimulates guilt which in turn diminishes enjoyment.

Study 1 tests this hypothesis through a chocolate taste test. Participants were told that a company was market testing a new line of chocolate. Company information was presented in one of three conditions. The first condition was neutral, and merely presented some generic company information (years in business, etc.). The positive condition stated that the firm had been a leader in employee policies, and the negative condition described several violations in the area of employee policies. The issue of employment was chosen because a pretest rated it as most important from a range of other social and environmental issues.

The results from study 1 support the hypothesis that CSIR information can diminish taste perceptions. However, CSR information does not enhance taste perceptions. The neutral and CSR conditions were not significantly different ($M_{NEUTRAL}=7.10$ and $M_{CSR}=7.01$ on a taste scale of 1 to 10) but the CSIR ratings were significantly lower ($M_{CSIR}=6.15$; $F(2, 107)=4.865$, $p<.01$). Bonferroni tests confirm that the CSR and neutral conditions are not statistically distinct, but that the CSIR condition was statistically different from both the CSR and neutral conditions.

Study 2 seeks to examine the underlying process behind this effect. Enjoyment of food is not only determined by the quality of the food itself (bottom-up processes) but by knowledge of how the food was prepared and other information about the manufacturer (top-down processes). Information received prior to evaluation should lead to greater coding of the information (Hoch and Ha 1986; Lee et al. 2006). Therefore, the cognitive top-down process related to CSIR should have a greater effect on taste perceptions when consumers receive the information prior to tasting rather than after. This is because the consumer is in a negative mindset prior to experiencing the relatively enjoyable taste of chocolate. When they taste the chocolate first, the enjoyment is more likely to overshadow the negative valence from CSIR. Study 2 used the same procedure as study 1, except only the CSIR condition was used, and participants were instructed to taste the chocolate either before or after the information was provided.

The results from study 2 are significant, but in the opposite direction than predicted. Participants who received the CSIR information before they tasted the chocolate rated the taste significantly *higher* than those who received it after ($M_{\text{BEFORE}}=7.04$, $M_{\text{AFTER}}=6.26$, $F(1, 82)=4.288$, $p=.042$).

Study 2 suggests that when consumers learn about CSIR from a brand they currently consume it is more damaging than if they are not current consumers, and provides fruitful direction for future studies. One possible explanation is that the relatively pleasant taste of chocolate did not conform to the negative expectations intended by the CSIR information. On the other hand, the presentation of CSIR information after the taste has the effect of “tainting” the memory of the taste. Future studies will further examine the role of guilt as well as memory and recency.

The Effect of Systems of Thought on Brand Scandal Spillover: Holistic versus Analytic Cognition Moderating Scandal Spillover and Denial Effects

Yun Lee, University of Iowa, USA

Nara Youn, Hongik University, Korea

Extended Abstract

Recent high-profile product recalls (Tang 2008) and more stringent product-safety legislation (Birch 1994; Patterson 1993) have led to increased consumers’ exposure to negative brand publicity. Product-harm crises or brand scandals lead to significantly decreased preferences and purchases for the scandalized brands and their family (Sullivan 1990) as well as their competing brands (Roehm and Tybout 2006). Recent research has demonstrated that consumers engaged in different systems of thought are more or less susceptible to negative brand publicity (Monga and John 2008).

Extending prior work, our research examines how different contents of negative publicity and systems of thought jointly affect consumer reactions to brand scandals and the spillover correction effects of denials. We argue that whether the contents of negative brand publicity are intrinsic or extrinsic to the product itself determines the degree to which individuals process the negative information as a focal point versus a context and that this relative difference subsequently affects the type of judgment bias they make. Holistic thinkers tend to focus more on relationships among objects and events and analytic thinkers tend to focus more on a discrete focal point from its context (Nisbett et al. 2001).

These distinct differences between holistic versus analytic cognitive styles lead us to predict that when negative publicity is directly associated with issues intrinsic to the product itself, for example, poor product quality or risks of injury threatening consumer safety, the focal components of negative publicity become more salient, and thus analytic thinkers might make more biased judgments for the scandalized brand than holistic thinkers might. Monga and John (2008) depicted this case and showed that when participants were presented with negative publicity about a new car with manufacturing problems, analytic thinkers were prone to more biases than holistic thinkers. We argue that the converse should show the opposite results. When negative publicity is not directly associated with the product itself, but related with issues extrinsic to the product, for example, manufacturing process causing a water pollution or recent Tiger Woods' multiple mistress scandal linked with brands using him in their ads (e.g., Nike or Gatorade), consumers would attend more to the contexts of the brand scandals than the focal points of the scandalized brand itself, thus it leads to more biased judgments of holistic thinkers.

Furthermore, we argue that the effects of brand scandal denials will also depend on which cognitive thinking mode is active. Since scandal denials are perceived to be informative, when consumers consider the brand scandal as diagnostic, but to be redundant when they do not we argue that when the contents of the negative brand publicity are intrinsic to the product itself (Roehm and Tybout 2006), denials will attenuate the harmful effects of the brand scandal for analytic thinkers, but not for holistic thinkers. In contrast, when negative brand publicity information is extrinsic to the product itself, scandal denials will be more effective for holistic thinkers than for analytic thinkers.

We begin our hypothesis testing by demonstrating the effects of holistic versus analytic cognitive styles on brand scandal spillover in a fictitious situation where a brand scandal is extrinsic to the brand itself (Experiment 1). Next, we investigate the moderating role of thinking modes on the effects of scandal denials involved with the negative publicity extrinsic (Experiment 2), and intrinsic (Experiment 3) to the brand.

In Experiment 1, participants were asked to read a fictitiously created water pollution scandal regarding Nike athletic shoe factories and then indicate brand attitudes for Nike in general and the likelihood of its competing brand, Reebok, polluting nearby waters. Then they responded to ten items on a holistic scale (Choi et al. 2003). Regressing thinking styles (holistic versus analytic) on brand scandal spillover supported our prediction. In the context of negative publicity involved in the issues extrinsic to the product itself, holistic thinkers evaluated its parent brand more negatively and indicated the higher likelihood of Reebok's water pollution than analytic thinkers did ($\beta_{\text{Nike}} = -.490, t = -2.694, p = .013; \beta_{\text{Reebok}} = .51, t = -2.65, p = .015$).

To investigate the role of cognitive modes moderating the effects of brand scandal denials, in Experiment 2, participants were primed with holistic versus analytic thinking styles by completing sentences in a short story about a trip to a city by filling in proper pronouns (i.e., I, my, me, mine versus we, our, us, ours; Kühnen et al. 2001). Then they were presented with a brand scandal about Nike's water pollution and then an article introducing its competing brands, Adidas or Converse's launching new athletic shoes with or without the denial of water pollution. Participants indicated the likelihood of Adidas or Converse' polluting nearby waters. A 2(thinking styles: holistic versus analytic) \times 2 (brand similarity: high, Adidas versus low, Converse) \times 2(denial: yes versus no) between-subjects ANOVA revealed a significant three-way interaction ($F(1,103) = 9.277, p = .003$). Subsequent analyses showed that there was a two-way significant interaction between thinking styles and denial in the high brand similarity condition ($F_{\text{Adidas}}(1,53) = 9.245, p = .004$). We also found a marginally significant main effect for thinking style, indicating that holistic thinkers are more susceptible to the brand scandal spillover ($F(1,53) = 3.258, p = .077$) than analytic thinkers are. Contrasts revealed a marginally significant brand scandal spillover correction effect of a denial for holistic thinkers, but its boomerang effects for analytic thinkers. When denial was provided in the article, holistic thinkers indicated decreased likelihood of Adidas' water pollution compared to when denial was not included in the article ($M_{\text{no}} = 4.69, M_{\text{yes}} = 4.408; F(1,25) = 3.021, p = .09$). In contrast, analytic thinkers indicated significantly increased likelihood of Adidas' water pollution when denial was included in the article ($M_{\text{no}} = 3.292, M_{\text{yes}} = 4.405; F(1,28) = 6.547, p = .016$).

In Experiment 3, we tested our prediction in the context of negative publicity intrinsic to the product itself. Thinking style manipulation was the same as used in Experiment 2. Participants were presented with a fictitiously created McDonald's food hygiene law violation scandal about using expired hamburger meat and breads. After reading the scandal story, they indicated the likelihood of Burger King and Outback's food hygiene law violations and also of other filler brands. They then read an article introducing KFC or Outback's new programs employing organic produce from environmentally friendly farming methods. The new program article was also varied with or without denial of food hygiene law violation. Participants then indicated the likelihood of KFC or Outback's food hygiene law violation. A 2(thinking styles: holistic versus analytic) \times 2 (brand similarity: high, Burger King versus low, Outback) repeated-measures ANOVA with thinking styles as a between-subjects factor and brand similarity as a within-subjects factor revealed a marginally significant main effect for thinking styles ($F(1,220) = 3.048, p = .08$) and a significant main effect for brand similarity ($F(1,220) = 73.33, p < .001$).

Replicating the results of Monga and John (2008), the data showed that holistic thinkers were less susceptible to the negative brand publicity than analytic thinkers were ($M_{\text{holistic}} = 5.095, M_{\text{yes}} = 5.603$). This effect was greater for the participants in the conditions of Burger King than Outback ($M_{\text{burger king}} = 5.919, M_{\text{outback}} = 4.779$). As expected, a 2(thinking styles: holistic versus analytic) \times 2 (brand similarity: high, KFC versus low, Outback) \times 2(denial: yes versus no) between-subjects ANOVA revealed a significant three-way interaction ($F(1,211) = 8.207, p = .005$). This interaction effect qualified the main effects for thinking styles ($F(1,220) = 4.459, p = .036$), indicating that the brand scandal spillover effects occurred to analytic thinkers than holistic thinkers ($M_{\text{holistic}} = 5.104, M_{\text{analytic}} = 5.760$). Subsequent analyses revealed a marginally significant two-way interaction between thinking styles and denial in the condition of KFC ($F(1,138) = 3.119, p = .08$). As expected, contrasts indicated that the brand scandal spillover correction effects occurred to analytic thinkers, when the article was with the brand scandal denial compared to when it was not ($M_{\text{no}} = 6.72, M_{\text{yes}} = 5.5; F(1,69) = 6.752, p = .01$), whereas denial or no denial was equally effective to holistic thinkers.

By employing a 2(thinking styles: holistic versus analytic) \times 2 (brand similarity: high versus low) \times 2(denial: yes versus no) \times 2(scandal content: intrinsic versus extrinsic) between-subjects design in Experiment 4, we intend to increase the robustness of previous results and directly test the effect of the scandal content. The results of Experiment 4 will be presented at ACR 2010 with a complete working paper.

Is Negative Brand Publicity Always Damaging? The Moderating Role of Power

David A. Norton, University of South Carolina, USA

Alokparna (Sonia) Monga, University of South Carolina, USA

William O. Bearden, University of South Carolina, USA

As consumers have increasing access to multiple sources for product information (e.g., blogs, television, news outlets, etc.), the ability to manage negative publicity becomes increasingly difficult. Prior research has demonstrated that consumers place more weight on negative than positive information in forming judgments (Eagly and Chaiken, 1993) showing that negative publicity can cause substantial harm. For example, the recent events surrounding Toyota's faulty accelerator and brake pedals have led to detrimental effects on the brand.

Surprisingly, little research has focused on characteristics of the message recipients and how they might influence responses to negative publicity. In this vein, we examine the effect of consumers' power on responses to negative publicity. Power is an important characteristic to study, as it is ubiquitous and highly malleable. In many instances throughout our daily life, we may be shifting between a powerful (e.g., meeting with a subordinate) and a powerless (e.g., meeting with a boss) mindset. Further, ambient marketing activity (e.g., advertising, point-of-sale displays, etc.) can influence a consumer's sense of power. Aside from these situational variations, power may also be conceptualized as an individual difference variable which varies across consumers (Anderson et al. 2005).

We know that negative publicity can be damaging for brands (Ahluwalia, Unnava and Burnkrant 2000; Monga and John 2008). In this research, we suggest that powerful individuals are less likely to be affected by negative publicity than powerless individuals. Galinsky et al. (2008) find that powerful people possess more freedom from influence of external forces compared to powerless people. Powerful people are less influenced and constrained by salient information in the environment, because power increases sensitivity to internal states and increases confidence in one's own thoughts (Brinol et al. 2007). This sensitivity to internal states suggests that powerful individuals may rely more on their own thoughts about the brand and are less likely to be influenced by negative publicity information, compared to powerless individuals. Thus, upon exposure to negative publicity, brand evaluations of powerful individuals would be more favorable than those of powerless individuals.

In study 1, we test our hypothesis using a power manipulation (Galinsky et al. 2008). In the powerful condition, participants wrote about a situation in which he/she controlled the ability of another person or persons to get something they wanted. In the powerless condition, participants wrote about a situation in which another person controlled the ability of the participant to get something he/she wanted. Next, participants were exposed to a press release stating that Mercedes Benz was experiencing manufacturing problems on their new line of cars. Subsequently, participants rated the new line of cars and the Mercedes Benz brand. As expected, participants in the powerful condition rated the brand more favorably than participants in the powerless condition.

In study 2, we examine the role of source credibility (Brinol et al. 2004). We anticipate that for a less credible source, we would expect that powerful individuals would be less susceptible to the negative publicity than powerless individuals (as in our prior study). However, for a more credible source, we expect that powerful individuals would be more likely to attend to the negative publicity and their brand evaluations would decrease. As a result, differences in brand evaluations between powerful and powerless individuals would dissipate.

In study 2, participants were exposed to the same power manipulation as in study 1. The source of the press release was indicated as either a highly credible source (*The Wall Street Journal*) or a significantly less credible source (*The National Enquirer*). We also included a control condition to assess baseline evaluations for the brand. Participants in this condition were not exposed to the negative publicity. Thus, we used a 2 (Power: High, Low) x 3 (Source Credibility: High, Low, Control) between subjects design. Our results show a significant interaction between power and credibility on brand evaluations, such that in the low credibility condition powerful individuals evaluate the brand higher than powerless individuals. However, this difference is not significant in the high credibility condition or in the control condition.

The findings in our paper contribute to the negative publicity literature and to the largely understudied area of consumer power. Prior research shows that negative publicity can adversely affect the brand. We show that this effect is more likely to happen for powerless than powerful consumers.

Disaster Zone! Maximizing the Impact of Corporate Contributions to Disasters or a Different Way of Thinking of Fit

Yoshiko DeMotta, Baruch College, USA
 Diogo Heldebrand, Baruch College, USA
 Ana Valenzuela, Baruch College, USA
 Sankar Sen, Baruch College, USA

Corporations are often willing to help when a major disaster, such as the recent earthquake in Haiti or the 9/11 terrorist attacks, happens. For example, American companies already donated \$146.8 million to the relief of the earthquake victims in Haiti (U.S. Chamber of Commerce 2010). Regardless on the motives behind these humanitarian contributions (e.g., altruistic or strategic nature), it is of chief importance to maximize corporate return in terms of consumers' attitudes and corporate image (Porter and Kramer 2006). Along this line, the concept of fit, or perceived link between a brand and a CSR cause, has been pointed as having central importance in consumers' attitudes (Pracejus and Olsen 2004). For example, support for breast cancer research by Yoplait yogurt is considered to have a good fit since both brand and cause serve a similar customer base (Nan and Hao 2007). Although this conceptualization of fit is useful in order to understand the effect of firms' ongoing CSR programs, we propose that consumers may use different dimensions of fit to evaluate CSR programs directed toward non-recurring causes such as disaster relief efforts. In this paper, we research the idea that type of contribution (monetary vs. non-monetary) may be pertinent to this judgment of fit, having an important effect on consumers attitudes toward the company after the disaster relief.

There are two main approaches used by companies to contribute to the relief of victims in disasters—monetary contributions and non-monetary contributions (i.e., products, services and employee volunteerism). Because the later are considered more effortful than the former, it is generally accepted that non-monetary contributions will have a more positive impact on consumers' attitudes toward the company (Ellen, Webb and Mohr 2000). However, we propose that sometimes monetary contributions may be considered more adequate. Specifically, we suggest that the fit between characteristics of the cause (i.e., nature-made or man-made) and the contribution type (monetary or non-monetary) will influence consumers' attributions and attitudes toward the company that helped in the disaster relief.

A disaster is the tragedy of a natural-made or human-made hazard that negatively affects society. Consumers may perceive nature-made disasters as phenomena beyond human control, but from predictable sources (Quarantelli 1993). In this case, non-monetary contributions, for being considered less flexible but more hands-on and specialized, will be considered more adequate. On the contrary, since human-made disasters are originated on much more varied and unpredictable number of sources (Quarantelli 1993), more flexible and versatile monetary contributions might be considered more adequate. We formalize our hypotheses as follows:

H1: Fit between contribution type and cause of disaster will increase consumer evaluations of corporate contributions for disaster relief.

Consumers will evaluate a firm's non-monetary contribution to nature-made disasters more positively than a firm's monetary contribution to such disasters.

Consumers will evaluate a firm's monetary contribution to man-made disasters more positively than a firm's non-monetary contribution to such disasters.

We examined this hypothesis using a 2 (contribution type) x 2 (cause of disaster) between-subjects design. One hundred and sixty undergraduate students participated in this study. Participants read fictitious news about a large scale fire in California and a disaster relief effort of a logistics company. In the news, the company's contribution was either one million dollars (monetary) or logistic services that worth one million dollars (non-monetary). Disaster was caused either by arson (man-made disaster) or lightning (human-made disaster). After reading the story, participants assessed their evaluations of the company in a three items ($\alpha=0.87$) 7-point semantic differential scale (favorable, effective, helpful).

Results of an ANOVA analysis supported our hypotheses. Personal relevance of the disaster was included as a covariate. Contribution type and cause of disaster presented significant main effects on consumer evaluations. More importantly, the interaction term was significant

($p < 0.02$). In the nature-made disaster condition, the evaluation was more positive when the company made non-monetary contributions, whereas in the man-made disaster condition, the evaluation was more positive when the company made monetary contributions.

Moreover, Ellen, Webb and Mohr (2006) observed that if there is a perceived lack of fit on CSR initiatives, consumers will attribute corporate efforts to be of a negative self-centered nature. Hence, if it is perception of fit the mechanism underlying consumers' evaluation, negative self-centered attributions shall mediate the effect of the interaction between contribution type and disaster characteristics on company evaluation. We measured consumer negative self-centered attributions using 4 items ($\alpha = 0.84$) (Ellen et al. 2006). Meditational analysis (Baron and Kenny 1986) corroborates our process explanation. Particularly, the interaction between contribution type and cause of disaster significantly affected negative self-centered attributions ($p < 0.01$). Furthermore, egoistic attributions, contribution type, cause of disaster and the interaction term significantly affected individual evaluation of the company ($p < 0.05$). Nevertheless, when regressing company evaluation on egoistic attributions, contribution type, cause of disaster and the interaction term, the interaction term had its significance reduced (from $p = 0.013$ to $p = 0.038$).

The partial mediation effect of negative self-centered is a clear indicative that consumers evaluations of the company is centered on consumers perception of fit, explanation that demands closer attention in future studies. Furthermore, future studies should also verify the robustness of the effect here presented under different operationalizations of corporate contributions and disaster characteristics.

Corporate contributions to the community are considered a strategic tool for company survival and success (Porter and Kramer 2006). The present paper contributes to the literature of consumer response to CSR by showing the effect of a new dimension of fit between contribution type and non-recurring causes on consumers' evaluations of the company.

Impact of Primary-Secondary Control on Donation Behavior

Yoshiko DeMotta, Baruch College, USA

Lauren G. Block, Baruch College, USA

Stephen Gould, Baruch College, USA

Control, one of fundamental human motives (Baumeister 2005; Fiske 2002), is so valued that individuals rarely abandon their quest for it, even in uncontrollable circumstances (Rothbaum, Weisz, and Snyder 1982). Donation requests often imply external, uncontrollable factors that cause beneficiary's needs (e.g., poverty, disease). In such seemingly uncontrollable circumstances, a quest for control may serve as a motive to help, but effects of control are unexamined in existing frameworks in the donation literature. Drawing on primary-secondary control theory (Rothbaum et al. 1982), we develop and test a new theory of persuasion that induces people to help social causes.

Primary-secondary control theory posits two paths to a feeling of control (primary vs. secondary control) (Rothbaum et al. 1982); primary control occurs when individuals attempt to alter the environment (e.g., circumstances, symptoms, other people) so that the environment fits the self's needs, whereas secondary control occurs when individuals attempt to align themselves with the environment by accepting the environment and adjusting the self (e.g., expectations, perceptions, attitudes). Although seemingly passive, secondary control differs from helplessness; in this process, an individual believes that the situation, or a part of it, can be improved through acceptance (Thompson, Nanni, and Levine 1994). An individual tends to emphasize one type of control, either primary or secondary, as a central role in everyday life, but often shifts from one type of striving for control to another (Rothbaum et al. 1982). We conceptualize donation behaviors as both primary control and secondary control. It is an act of primary control when a person donates in order to change the environment to his desired wishes. It is an act of secondary control when a person donates in order to adjust himself to the environment.

In a persuasion context, we suggest that compliance to a donation request is a behavior that falls into the category of secondary control because implicit within any prosocial act is the individual's acknowledgement of an unchangeable environment, resulting in the adjustment of the individual's behavior to fit within that environment. For example, when a donation request for cancer research is presented, an individual who uses secondary control may accept that cancer affects people's life (i.e., an unchangeable environment) and may adjust his action to this environment by donating—even though this individual may perceive that his single action is insignificant to the magnitude of the environment as a whole. On the other hand, an individual who relies on primary control is unlikely to comply with this request because the request itself may not provoke the self's needs.

Within the secondary control process, we further propose that the effectiveness of donation requests may be enhanced through the use of positive frames. Past research found that when individuals are highly motivated to process information, they tend to perceive that

negatively framed information is more persuasive (Block and Keller 1995; Maheswaran and Meyers-Levy 1990). From a perspective of secondary control, however, even in a high motivation setting, positively framed messages may be more effective because positive frames are more likely to appeal to people's goal of accepting the positive environment that is described in a request and adjusting the self to that environment. Negative frames are not directly tied with desired outcomes and thus will not motivate people to exert compliance to a request.

H1: Individuals with high primary control are less likely to donate than those with low primary control.

H2: Individuals with high secondary control are more likely to donate than those with low secondary control when positively framed messages are presented. This effect will diminish when negatively framed messages are presented.

One experimental study examined our hypotheses. One hundred and sixty three undergraduate students participated in this study. Participants were presented with a one page donation request ostensibly written by a non-profit organization (animal shelter) and are asked to answer series of questions. The participants are randomly assigned to two conditions, which manipulated the type of message framing. In the positive (negative) frame condition, the message read: "With (Without) your help, the life of homeless animals will improve (deteriorate)." After presented with the description, participants are asked to choose one of donation options. After making a donation choice, degrees of primary-secondary control were measured using a scale developed by Heeps (2000).

Binary logistic regression was used to examine the impact of framing and primary-secondary control on donation behavior. IVs are framing (positive vs. negative), primary control, secondary control. DV is donation choice (1 if donated and 0 if did not donate). Consistent with H1, there was a main effect of primary control on donation; as primary control increased, the probability of donation decreased ($p=.010$). There was also a main effect of secondary control; as secondary control increased, the probability of donation increased ($p=.005$). Supporting H2, the interaction between message framing and secondary control was significant ($p=.003$). In a positive frame condition, participants high (vs. low) in secondary control were likely to donate more frequently. In a negative frame condition, degrees of secondary control did not make a difference on donation likelihood. There was no interaction effect between framing and primary control.

In conclusion, these results demonstrate that the effectiveness of donation requests can be enhanced through the use of a specific type of message framing moderated by control strategies. Our next study will further investigate the underlying psychological processes of the effects found in study 1.

Expanding Time: Altering Consumers' Experience of Time through Temporal Perspective

Melanie Rudd, Stanford University, USA
Jennifer Aaker, Stanford University, USA

The consumer of today lives in a fast paced society. Over the years, technological breakthroughs allowed them to trade in their bicycles for cars and their handwritten letters for emails. Although these advancements enabled consumers to save time by performing tasks more quickly, they also altered consumers' perceptions of time. As a result, consumers often struggle to keep up with the pace of technology and meet the expectations of a society that highly values time efficiency. Indeed, the percentage of adult Americans who feel "always rushed" increased from 22 percent in 1971 to 35 percent in 1992 (Robinson and Godbey 1997).

This tendency for consumers to live rushed lives often leads to negative consequences. For instance, feeling pressed for time can result in high stress levels. If poorly managed, stress leads to a wide range of health issues, such as fatigue, heart disease, and obesity (American Psychological Association 2007). Feeling rushed also encourages dangerous behaviors, such as multitasking at inappropriate times (e.g., while driving; Nationwide Mutual Insurance Company 2007).

Our research addresses the question of how consumers can avoid some of the consequences of living fast-paced lives. Specifically, how can consumers feel less rushed and hurried? We propose if the perceived passage of time is slowed down, consumers' feelings of being rushed and hurried will be reduced. This research focuses on how one specific factor, attention to a particular temporal domain (the present vs. the future), is capable of altering the subjective passage of time, and thus able to reduce these negative feelings.

To date, the subjective experience of time has been predominantly assessed by retrospective duration estimates (Danckert and Allman 2005). Though duration judgments are important for assessing time estimate accuracy, this research focuses on a relatively overlooked measure, the perceived passage of time (the subjective impression of how slowly or quickly time is passing), as it is better equipped to measure how time is experienced "in the moment." Additionally, prior research has yet to investigate the influence temporal perspective (Liberman and Trope 1998) has on the subjective passage of time. This research concentrates on temporal domain attention (Mogilner, Kamvar, and Aaker 2010), one specific aspect of temporal perspective, because this factor can be manipulated, and illuminate conditions under which the perceived passage of time can be deliberately altered. This is important, as most extant research focuses on how the experience of time is influenced by relatively unalterable factors, such as age (McCormack et al. 1999), gender (Block, Hancock, and Zakay 2000), and culture (Hill, Block, and Buggie 2000).

We hypothesize focusing on the present (vs. the future) slows down the subjective passage of time. Support for this idea comes from research on self-regulation and time perception. Specifically, prior research found the perception of time lengthens during self-regulation. This occurs because self-regulation increases awareness of current behaviors and emotions, which is thought to better attune one to the passage of time (Vohs and Schmeichel 2003). We propose focusing on the present results in an attention to the time that is lacking when focusing on the future. When thinking about the present (vs. the future), current emotions and behaviors should increase in salience. This heightened awareness of the "present self" could promote greater attention to time passage, just as it does during self-regulation. And, as attention to time elongates one's perception of time (Block and Zakay 1997), this could decrease the perceived passage of time. We also hypothesize slowing the perceived passage of time in turn reduces feelings of being hurried and rushed, because when time is perceived to be passing at a slower rate, individuals may feel they have more time to complete or experience the task at hand.

Study 1 was a qualitative exploration of the predicted relationship between temporal domain attention and feelings of being rushed. All participants (28 students) responded to two open-ended questions that asked them to describe how they feel when they think about the present and how they feel when they think about the future. The feelings participants provided as answers to these questions were analyzed by two independent judges who were blind to the hypotheses. Each distinct feeling was classified as either (a) highly related to being rushed, (b) highly related to being unrushed, or (c) neither. Repeated measures t-tests revealed the mean number of rushed-related thoughts reported per subject was greater and the mean number of unrushed-related thoughts reported per subject was fewer when participants described how they feel when they think about the future as opposed to the present.

Study 2 directly manipulated temporal domain attention and measured the resulting effect on the subjective experience of time and feelings of being rushed and hurried. Participants were told we were interested in how people communicate information about themselves on social networking sites. Participants first responded to questions "sometimes used by social networking sites to elicit status updates from their members." To manipulate temporal domain attention, participants in the present [future] condition were asked to use up to 140 characters to answer the following: "What are you doing right now? [What are you going to do later?]," and "Where are you right now? [Where are you going to go later?]" Participants then reported how slowly or quickly time was currently passing, and how rushed and how hurried they were feeling. One-way ANOVAs showed those in the future (vs. the present) condition felt time was currently passing by more quickly, and felt more rushed and hurried. Importantly, mediation analyses confirmed the perceived passage of time mediated the relationship between temporal domain attention and feeling hurried or rushed.

In conclusion, this research both identifies a novel way in which the perceived passage of time can be altered and assists consumers who wish to reduce the feelings of being rushed that are often brought about by a fast-paced lifestyle. Future studies will be aimed at better understanding the precise mechanisms through which temporal domain attention exerts its influence on the subjective experience of time.

I'd Rather Wait 30 Days Than One Month: The Unit Effect in Time Perception

Charles Y. Z. Zhang, University of Michigan, USA

Norbert Schwarz, University of Michigan, USA

Extended Abstract

Suppose you inquire how long it would take for your order to arrive if you placed it today. Would it make a difference if the merchant told you that it takes "one month" vs. "four weeks" vs. "30 days"? Although those terms are often used interchangeably ways, they may convey different information about the speaker's knowledge about the likely arrival of your order. Three experiments show that this is the case: time estimates expressed in more fine-grained units are perceived as more precise and consumers infer a more uncertain waiting period from "one month" than from "30 days".

As the philosopher Paul Grice (1975) noted, conversations follow the tacit assumptions of a cooperative principle. Speakers should provide as much information as the listener needs (maxim of quantity), but not more information than the speaker actually has (maxim of quality). One implication is that estimates should be neither unnecessarily vague, nor more precise than the speaker's knowledge warrants. One familiar way in which speakers hedge their bets is the use of vague quantifiers, such as "some" or "many", which recipients interpret by drawing on contextual information (Pepper 1981). In many cases, the purposeful vagueness of the expression serves to convey the speaker's uncertainty about the quantity (Powell 1985).

Going beyond the use of vague quantifiers as indicators of uncertainty, we propose that different levels of certainty can also be conveyed by the speaker's choice of a coarse (e.g., "one month") rather than fine-grained (e.g., "29 days") unit. Indeed, the maxim of quantity would urge a speaker who is aware that an order will take 29 days to convey this knowledge, which is insufficiently captured by "one month". If recipients are sensitive to this implication of the maxim of quantity, they should have more confidence in estimates that are expressed in fine-grained rather than coarse units, even if the quantity conveyed is largely identical. Three experiments test this rationale, which has important implications for the format in which information should be conveyed to customers.

In *Study 1*, 90 business undergraduate students were told that a construction team just started a project that would take "1 year" vs. "12 months" vs. "52 weeks" to complete; however, the project might be finished earlier or later. Participants then received a calendar for the next year and circled the *earliest* and *latest* date on which they thought the project might be finished.

The difference these two dates serves as the measure of participants' perception of how precisely the construction team's estimate captures the actual completion time. As expected, the difference between the estimated earliest and latest completion date was 140 days in the "one year", 105 days in the "12 months", and 84 days in the "52 weeks" condition, indicating a significant unit effect ($\beta=0.33, p=.001$).

Study 2 replicated this finding in a different context. University of Michigan students ($N=267$) were approached on campus and asked to imagine that their cars needed repair. The dealership estimated that it would take 1 month vs. 30 or 31 days to receive the relevant parts and repair the car. Participants were asked for their best and worst case estimates—that is, the minimum and maximum number of days they might have to wait. As expected, the difference between their best and worst case estimates was larger in the one month ($M=24.8$ days) than in the "30" ($M=20.6$ days) and "31 days" ($M=20.3$ days) conditions; $t(266)=1.97, p<.05$, for the contrast between 1-month vs. 30/31-days conditions.

In *Study 3*, 188 participants from an online sample were asked to imagine that they needed to buy a camera for an upcoming vacation trip. They were presented with two options, a currently available model and an upgraded new model, said to become available in "3 months" vs. "13 weeks", which is about 10 days before the start date of their vacation trip. The new model dominated the available model on all attributes, except current availability. Participants estimated the latest possible date on which the new model may actually be available in the store and indicated their purchase preference on a 7-point scale (1= definitely buy old model; 7=definitely buy new model). Replicating the earlier findings, participants in the one-month condition assumed that it might take up to 47 extra days for the new camera to be in the store; for participants in the 13-weeks condition the same estimate was 41.6 extra days. More important, participants were more willing to wait for the new model when the unit "week" ($M=3.6$) rather than "month" ($M=4.3$) was used to describe the wait period, $t(186)=2.00, p<.05$. Lastly, this difference in preference was fully mediated by the difference in perceived wait length.

The present studies consistently show that consumers are sensitive to the unit in which firms express time estimates: The finer the unit used, the more precise consumers assume the estimate to be. This has important implications for marketing and public relations

communication. On the one hand, coarse units are likely to make consumers wonder whether the estimate is reliable; on the other hand, fine units are likely to elicit increased anger when delivery is delayed beyond the apparently precise estimate. Ongoing studies address these implications.

“I Like Goods and I Want Them As Soon As Possible”: The Impact of Materialism on the Time-Money Trade-Off in Consumer Decisions

Christophe Lembregts, Ghent University, Belgium
Mario Pandelaere, Ghent University, Belgium

Extended Abstract

Time is an important factor influencing consumer's decisions. For instance, during an online purchase, consumers can often choose between a normal delivery and a faster, but more expensive express delivery. This requires making a time-money trade-off. It has been repeatedly shown that people perceive an amount of money to be received in the future as worth somewhat less compared to the equivalent amount received in the present (Frederick, Loewenstein & O'Donoghue, 2002; Thaler, 1981). Several factors have been shown to be influencing this time-money trade-off. For instance, future outcomes that are equivalent in magnitude, but different in valence (i.e. a gain vs. a loss) are valued differently. People need a larger amount of money to defer gains, but are only willing to pay a small amount to defer losses (Thaler, 1981).

In this study, one of potentially most important psychological determinants of temporal discounting, namely materialism, is examined. Materialism refers to a value system in which material goods and their acquisition are central determinant of a successful and happy life (Richins & Dawson, 1992). In the temporal discounting literature, there are few studies about the psychological factors such as materialism underlying this temporal bias. This paper proposes that materialism is an important determinant of temporal impatience. Given the importance materialists attribute to the possession material goods, it could be that materialists are growing more impatient when confronted with a delay in a consumer good delivery, compared to non-materialists. If the acquisition of goods is central in one's life, one could argue that the sooner one receives a consumer good, the better. Dittmar and Bond (2010, in press) provided some support for this claim when they found that materialists are more impulsive buyers of identity expressive goods compared to non-materialists. These propositions will be tested in two studies.

Study 1 assessed if materialists are more willing to pay a surcharge for an earlier delivery of a commodity. 221 participants were exposed to 18 product offers which consisted of 2 choice options: a sooner but more expensive offer and a later but cheaper option. In particular, participants had to make a choice for all combinations of 3 products, which differed in price. We used 3 price differences (5%, 10%, 15% surcharge for sooner delivery) and 2 temporal distances (delivery in 2 vs. 3 months or delivery in 11 vs. 12 months). Materialism was measured using the Material Values Scale by Richins and Dawson (2004). Results confirm that participants who value the possession of material goods as central in their lives and as an important source of success were more prepared to pay an amount of money to avoid a delay of one month.

Study 2 had two objectives. First, we wanted to replicate the findings of study 1. Second, instead of including only a delay for material goods, we included two other delays: for experiential purchases and money. It has been shown that money and experiential purchases elicit different discounting. For instance, consumers are more patient for money compared to consumable goods (Estle, Green, Myerson & Holt, 2007; Odum, Baumann & Rimington, 2006; Rosati, Stevens, Hare & Hauser, 2007). Furthermore, experiential purchases tend to make people happier than material purchases (Van Boven & Gilovich, 2003). From this, it can be argued that respondents will be more impatient for experiences. 154 participants were asked to repeatedly choose between 2 different offers. The delay difference (1 month) and surcharges for an early delivery were identical to study 1. Type of outcome (money, experiences, goods) was manipulated between subjects. In the experiential and material goods conditions, participants were repeatedly exposed a buying offer containing two choice options, similar to study 1. Participants in the money condition were told to imagine they possessed two identical goods, and decided to sell one of them. Due to time constraints, they were only able to sell it after two months for a certain selling price; if they waited one month longer (after three months), resulted this in a better selling price. So participants had to make a choice between either receiving a smaller amount of money earlier or receiving a larger amount later. Four amounts were chosen for the money condition. Identical amounts were used in the goods and activities conditions. Overall, results indicated that participants were more impatient when exposed to experiences compared to money and goods. For materialists, an interesting pattern emerged. In the goods condition, participants who indicated that the possession of material goods is central in their life preferred the expensive offer more compared to non-materialists. This replicated in part the findings of study 1. When experiential purchases were stalled, participants who regard the possession of material goods as a necessary condition for a happy life opted *less* for the more expensive offer compared to participants who scored low on the happiness subscale of materialism. In the selling condition, materialists (success subscale) opted more for the sooner offer compared to non-materialists.

Results indicated that materialists and non-materialists differ in trading off time and money. Materialists are more impatient (compared to non-materialists) for consumer goods and money. In the money condition, a substantial number of materialists was prepared to sell a consumer good (which is seen as an important sign of success) earlier even when they received less money for it. This is quite striking given the importance materialists attribute to material goods. A potential explanation for this could be our use of a manipulation where two identical products were involved. Materialists possibly want to buy another good with the received money as soon as possible, even when this results in a lower selling price. Non-materialists spend more money on having pleasant experiences sooner. This could be attributed to a possible preference of materialists for consumer goods, which are central in their lives, and money, which can be used to buy consumer goods, over experiences.

Comparability as the Determinant of Reward Evaluation in Frequency Program

Lei Su, The Chinese University of Hong Kong, China
 Leilei Gao, The Chinese University of Hong Kong, China
 Jianmin Jia, The Chinese University of Hong Kong, China

Extended Abstract

Frequency programs have two main components: required effort and earned rewards. A question that naturally arises is how the two interact to affect consumer behavior. We propose the effort consumers need to make to earn rewards can influence perceptions of those rewards in two opposite directions. The comparability of effort and reward determines which direction dominates. Specifically, when effort and reward are comparable, relative processing is employed to evaluate the reward. Effort made decrease the perceived value of a reward by shifting the reference point of the reward's value function. In contrast, when effort and reward are non-comparable, the reward is evaluated holistically by referring to both the effort made and the additional value derived from actually making that effort. Consequently, the value function of the reward is steepened by the effort requirement.

Research Hypothesis

The expenditure of effort can shift the preference point in the value function of a reward. According to traditional economic theory, consumers always calculate what they get by subtracting costs from gains, which means that the perceived value of the reward is always considered relative to the effort made to obtain it. Kivetz (2003) argues that the effort made can serve as the reference point when gauging the reward's utility by providing a higher level of expectation. Based on prospect theory (Kaheman and Tversky 1979), an increased reference point will lead to a decreased perceived value of the reward. Relative processing of effort and reward is conducted in this situation.

Effort can also add value to a reward, which results in a steeper value function for that reward. Recent behavioral decision theory has suggested that a reward acquired from protracted effort is different from that acquired normally. Prior research has indicated that making effort can enhance the personal connection or attachment with the final result (Morales 2005). According to Mogilner and Aaker (2009), personal connections can boost consumer attitudes about products. Ariely and Simonson (2003) find that products with increased attachment are more attractive. Effort can also be an indicator of the value of a reward when consumers cannot judge it clearly (Hoch and Deighton 1989). Taken together, these findings suggest that the perceived value of a reward increases with the effort required to obtain it.

Product comparability is the degree to which consumers consider products using the same attributes (Johnson 1984). The comparability between effort and reward can thus be defined as the comparability between the product involved in the accumulated consumption (effort) and the free product (reward). While relative processing is pervasive among comparable alternatives, holistic processing dominates for non-comparative alternatives when consumers need to incorporate all related information (Johnson 1984). Taken together with our argument about the two different effects of effort in frequency programs, we hypothesize that the perceived value of reward decreases with an increase in the effort requirement when effort and reward are comparable, and the opposite is the case when effort and reward are non-comparable. According to construal level theory (Liberman, Trope, and Wakslak 2007), high level construal results in holistic

information processing, and even the most non-comparable alternatives can be compared according to overall worth or utility using this type of processing. Thus, we further propose that the aforementioned effect is attenuated at a high (vs. low) construal level.

Method and Results

In experiment 1, a total of 114 participants were first presented with one of four frequency programs, in which a certain reward was given after accumulated cups of coffee were consumed. The magnitude of effort needed to receive the reward was manipulated by changing the number of the cups of coffee to be consumed. The comparability of effort and reward was manipulated by changing the product category of the reward (another cup of coffee vs. an umbrella). The results were consistent with the predicted direction, and there was a significant interaction effect between the magnitude of effort and comparability ($p < .01$). The results of the thought listing and choice task provided further evidence that relative evaluation was employed when effort and reward were comparable and holistic evaluation was employed when they were not.

In experiment 2, a total of 120 participants were required to make real efforts of different magnitudes (solving easy vs. difficult mathematic questions) to gain a real reward (postcards) after being primed with construal levels (high or low). After completing a construal-level manipulation developed by Freitas, Gollwitzer, and Trope (2004), the participants were then required to solve several mathematic questions with the ostensible purpose of evaluating teaching materials for a middle school. Several online postcards were distributed as a reward, and the participants' evaluations of the postcards were measured at the end of the experiment. The results revealed a significant interaction effect between effort magnitude and construal level ($p < .01$). In addition, participants' evaluation of the reward decreased with the level of effort needed to obtain it at the low level of construal, with the opposite direction prevailing at the high level.

Small Change: Subjective Valuation Of Coins And Paper Money

Eric Dolansky, Brock University, Canada

Extended Abstract

According to the official website of the U.S. Mint, the U.S. treasury would save \$500 million per year if individuals used one-dollar coins rather than bills. As a result, on several occasions in the past, the U.S. mint has issued dollar coins, most recently in 2007. None have proven to be very popular (Unser, 2009). So what is preventing Americans from adopting dollar coins?

Individuals tend to exhibit biases when valuing money, despite the explicit denomination of the coin or bill. Mishra, Mishra and Nayakankuppam (2006) found that individuals valued large-denomination bills more highly than an equivalent amount of money presented in smaller bills. Work by Alter and Oppenheimer (2008) indicates that familiarity of the money has an impact on how highly it is valued. A more recent finding ties denomination of money to self-control in spending (Raghubir and Srivastava 2009).

This research aims to extend previous findings by determining if individuals have a bias towards higher valuation of bills as opposed to coins. This topic has been mentioned in the relevant literature (Alter and Oppenheimer 2008; Mishra et al 2006; Raghubir 2006) as worthy of further exploration, however the idea has not been empirically tested. Raghubir and Srivastava (2009) incorporated coins vs. bills as a condition in one of their studies, but it was inconclusive.

In nearly every currency in the world bills are of a higher denomination than coins. This difference in objective valuation could have an impact on subjective valuation, as a representativeness bias (Kahneman and Tversky 1973). As such, coins would tend to be valued less than bills, even when the denominations are the same. It has also been found that people will take an instance and average it to its own category. Thus a coin would be valued to the average value in its category, which would be lower than the average for the bills category (Huttenlocher, Hedges and Bradburn 1990). This leads to the key hypothesis of this paper:

H₁: An amount of money presented in paper form (i.e. bill) will be valued higher than an equivalent amount of money presented in coin form.

To test this prediction, study 1 was conducted. Participants ($n=52$) were given either one Trinidad and Tobago dollar bill or one Trinidad and Tobago dollar coin and were asked how much of each of nine inexpensive items (e.g. pencils, paper clips) they could buy with that money. Participants were also asked to estimate how many Canadian dollars they could purchase with the money.

Unfamiliar currency was used to eliminate the possibility that familiarity with the money was a cause for any differences found, as in previous research (Alter and Oppenheimer 2008). Participants were told that the exchange rate was approximately 1:1 (the real exchange rate is \$5 TT to \$1 CDN and would result in too little purchasing power for useful estimates) and were instructed that the purchase amounts they estimated should reflect costs in Canada. Participants were also asked how familiar they were with the currency prior to the experiment. Four participants were removed from the analysis because they were previously familiar with the currency.

While some of the results are mixed, overall H_1 is supported. When all of the estimates are standardized, there is a marginally significant difference between the objects purchasable with bills (1.34 standard deviations above the mean) than with coins (1.39 standard deviations below the mean, $p=0.096$). Some individual items exhibited significant or marginally significant effects as well, such as paper clips ($p=0.046$), napkins ($p=0.05$), and thumbtacks ($p=0.073$). The lack of strong results in the individual item estimates is likely due to the high variance in the estimates from one participant to another.

The exchange valuation prediction is more conclusive: participants given coins estimated they could exchange their \$1 TT for \$0.798 CDN and those given bills estimated \$1.192 ($p=0.02$), despite being told that both the coins and bills were worth approximately \$1 CDN.

Study 2 is planned to refine and extend this effect. It is believed that the effects found here would be moderated by the relative value of coins or bills in an individual's home country. For example, in Canada, coins are used up to the two-dollar denomination and bills are used for denominations of five dollars and larger. This is in contrast to the U.S., where denominations of one dollar or larger are represented by bills, and denominations less than one dollar use coins. A study that includes both Canadians and Americans could find such a difference. Study 2 will be conducted at Niagara Falls, Ontario, and will use nationality as a found condition.

Study 3 is an investigation into the physical properties of coins and bills themselves. At the most basic level, coins are metal tokens and bills paper certificates. Would individuals value non-money tokens and certificates the same way? It is expected that they would not; in fact, the opposite valuation is predicted. This is because of the relative weight and permanence of a metal token as opposed to a paper certificate. Furthermore, even real money, when abstracted from its role as money, may have reduced subjective value. As in study 1, it is expected that money coins will be valued less than money bills (demonstrated as the difference between the number of ounces participants drink). The opposite effect is expected for the non-monetary rewards: it is believed that participants receiving non-monetary tokens will drink more than those receiving non-monetary paper certificates.

This work provides insight into how individuals value money and implications for research, management, and policy. Policy implications are the most salient here, as it is possible that a shift from bills to coins for a particular denomination (e.g., one dollar in the U.S.) could have an impact on valuation of money overall, as individuals ascribe less purchasing power to the coin than to the bill.

Can Money and Religion Substitute for Each Other?

Ezgi Akpınar, Erasmus University Rotterdam, The Netherlands

Kathleen Vohs, University of Minnesota, USA

Money and religion both act as coping aids that people can call upon to make themselves feel strong. A growing stream of research on money has shown that activating the concept of money evokes a state of self-efficacy that implies that each person can and will take care of him/herself (Vojs, Mead, and Goode 2006; Zhou, Vojs, and Baumeister 2009). In parallel, religion too is associated with a feeling of strength or efficacy. When people face threatening, stressful events, religious coping can offset some of the negative consequences of such events (Pargament, Koenig, and Perez 2000). In this research, we investigated to what extent these two sources of strength can substitute each other. Specifically, we tested whether being reminded of money would lessen a need for religious coping, and whether reminders of religion would produce a weakened desire for money.

There is a growing research on the psychological effects of money. Money is a distinct entity, which implies that it is attached to a meaning apart from its incentive and functional abilities (Lea and Webley 2006). Empirically, participants reminded of money evince higher personal goal pursuit and reduced dependency on others compared to participants not reminded of money (Vojs et al. 2008). Additionally, money stimulates a general sense of confidence and strength, which therefore helps people to cope with difficulties such as physical pain or social exclusion. Money provides a feeling of confidence that problems can be solved and needs can met (Zhou et al. 2009).

Like money, religion is another source of support within the social system. When people are confronted with threatening events, religion offers a sense of mastery and control. Religion can provide internal and external sources for coping stressful life events such as terrorism or the death of an infant child (Kay, Gaucher, McGregor, and Nash 2010; McIntosh, Silver, and Wortman 1993).

The commonality between the psychological effects of money and religion suggests that money and religion might be interchangeable, in their ability to help people cope with negative life events. Because money stimulates self-sufficient state, being reminded of it was predicted to reduce participants' need to cope via religious resources. Because religion also seems to draw out a sense of efficacy, we predicted that mentally activating it would lessen a desire for money.

In Study 1, we manipulated the salience of money by having some of the participants count coins and Euro bills and then list their monetary expenditures for the past 30 days. Participants in the neutral condition counted glass beads and listed the weather conditions over the past 30 days. Then, all participants remembered a negative event that had occurred in their life and wrote down the event and their reactions towards it. Thinking on the negative event they had described, participants completed RCOPE scale (Pargament et al. 2000). RCOPE is a scale developed to assess the degree to which various types of religious coping are involved in dealing with negative events. In line with the substitution hypothesis, there was a main effect of money priming on religious coping. Participants who were reminded of money reported being less likely to rely on religious coping compared to participants under neutral conditions.

In Study 2, half of the participants were primed with religious concepts using the scrambled-sentence paradigm (Shariff and Norenzayan 2007). The other half completed the scramble task using neutral words. Next, participants were given a list of eleven pleasant things (watching TV, sunshine, spring, chocolate, beach, mobile phone, sport, dancing, Internet, snow, holiday) and asked how willing they would be to forgo those items permanently in exchange for 1 million Euros (Zhou et al. 2009). As predicted, there was a significant effect of religious priming on desire for money. Participants primed with religious concepts were less willing to exchange pleasant things for money. This finding suggests too that money and religion can compensate for each other.

Study 3 sought to replicate the effects and to test whether self efficacy mediated the effect of religion on desire for money. Religion-primed participants completed a word-search puzzle that consisted of religious words (Pichon, Boccato, and Saroglou 2007). In control condition, participants completed a word-search puzzle with neutral words. Next, perceived self-efficacy was measured by the General Self-Efficacy Scale (Schwarzer and Jerusalem 1995). Last, desire for money was measured again using the likelihood of exchanging pleasant items in life for 1 million Euros (see study 2). Our results confirmed that religious priming reduces the desire for money, and that this was partially mediated by self efficacy.

This research takes a broad look at the interconnectedness of money and religion, two powerful forces in human life. Although there is growing literature on the consequences of reminding people of money, an understanding of religion vis-à-vis other key constructs such as money remains poor. The present studies demonstrate that money and religion can compensate for one another, such that being reminded of money lessens a desire to have the other. What links these two disparate constructs is that they both stimulate a feeling of efficacy, which is elicited by small, subtle reminders. In addition to theoretical value, our results imply exercising caution when using religion to promote products for marketers.

The Effect of Evaluation Mode on Nine-Ending Price Perception: Separate, Joint, and Sequential Evaluation

Shih-Chieh Chuang, National Chung Cheng University, Taiwan

Yih-Hui Cheng, National TaiChung University, Taiwan

Chih-Cheng Huang, National Formosa University, Taiwan

Hsiu-Chu Li, National Chung Cheng University, Taiwan

Extended Abstract

The evaluation of nine-ending prices usually is used in the actual purchasing behavior. Those digits are converted into an analog quantity for each price, which is allocated a magnitude based on an internal analog magnitude scale. It is this conversion from numerical symbol to magnitude that affects number encoding precision (Dehaene 1997). The evidence of the effectiveness of nine-ending pricing from prior studies has significant experimental value; however, the models used are inconsistent with real-life consumer evaluation settings. Nine-ending and zero-ending prices are mostly evaluated separately in experimental designs, whereas they are generally evaluated side by side by consumers during actual in-store purchasing. This difference in the form of evaluation creates a gap between theoretical results and reality. Hence, the development of new evaluation models that examine the nine-ending pricing effect from a practical purchasing perspective is important.

This research offers further evidence of the effect of nine-ending pricing on the magnitude perception of price. The conceptual framework of the present study is developed based on the left-digit effect (Bizer and Schindler 2005), drop-off mechanism (Thomas and Morwitz 2005), and separate and joint evaluation conditions (Hsee 1996) to examine the varying effect of nine-ending pricing on consumer magnitude perception under different conditions. Bizer and Schindler (2005) developed a new experimental approach to demonstrate numerical drop-off and avoid two major causes of failures in research into the nine-ending pricing effect: high variation among open-ended responses in free-recall tasks (e.g., short-term price recall in the study of Schindler and Kibarian 1993) and unrealistic conditions (e.g., respondents were given several minutes to examine an advertisement showing only one price in the study of Schindler and Kibarian 1993). Another commonly proposed explanation of the nine-ending pricing effect is the left-digit effect (Thomas and Morwitz 2005), which suggests that it is the change in the leftmost digit, rather than the ending digit(s) to its right, that influences the magnitude perception of numerical symbols. This research adopts the left-digit effect as the fundamental explanation of the nine-ending pricing effect, with the drop-off mechanism supporting certain aspects of the study. Based on Hsee's (1996) evaluability hypothesis, separate and joint evaluations are utilized herein for further analysis of this effect. In addition, extending Hsee's (1996) evaluability hypothesis of the separate evaluation (SE) and joint evaluation (JE) conditions, this study is interested in investigating a third condition together with the existing two. Thus, a new evaluation condition is proposed, termed the "sequential evaluation" ("SQE") condition, which serves as a bridge between the two abovementioned evaluation conditions. It is constructed as the midpoint between the SE and JE conditions with the stimulus options evaluated back-to-back in a sequence.

Although various experimental conditions have been constructed to investigate the nine-ending pricing effect, they often do not correspond to real purchasing settings. In the latter, consumers do not evaluate nine-ending and zero-ending prices separately; rather, they evaluate both simultaneously. Therefore, to determine whether nine-ending pricing influences actual purchasing decisions when nine-ending and zero-ending prices are presented side by side (e.g., product prices printed on DM and in-store shelves), this study investigates different evaluation conditions.

Study 1

The aim of Study 1 was to examine whether the difference in magnitude perception between nine-ending and zero-ending prices is greater in the separate evaluation (SE) condition, in which the nine-ending pricing effect manifests, than in the joint evaluation (JE) condition, in which the nine-ending pricing effect diminishes. This study utilized a one-factor three-level (separate nine ending, separate zero ending, and joint nine ending and zero ending) design. The stimuli for this study were nail clippers, batteries, and baseball caps. A total of 146 undergraduate students were recruited from a large southern university. The participants were randomly divided into three subgroups, each of which was randomly assigned to one of three conditions.

The results support our hypotheses, which postulated that the nine-ending pricing effect increased the difference in perceived magnitude of price between nine-ending and zero-ending prices in the SE but not the JE condition.

Study 2

Study 2 was conducted to further examine the difference in the nine-ending pricing effect in the separate and joint evaluation conditions. Its aim was to examine whether the difference in quantitative estimations between nine-ending and zero-ending prices is greater in the separate evaluation (SE) than in the joint evaluation (JE) condition. This study utilized a one-factor three-level (separate nine ending, separate zero ending, and joint nine ending and zero ending) design. A total of 130 undergraduate students were recruited from a large southern university. The participants were randomly divided into three subgroups, each of which was randomly assigned to one of three conditions.

The results support the hypotheses, which postulated that the nine-ending pricing effect increased the difference in perceived quantitative estimations between nine-ending and zero-ending prices in the SE condition, but less so in the JE condition.

Study 3

Study 3 was conducted to further examine the differences in the nine-ending pricing effect among the separate, sequential, and joint evaluation conditions. Its aim was to examine whether the difference in quantitative estimation between nine-ending and zero-ending prices is greatest in the separate evaluation (SE) condition, followed by the sequential evaluation (SQE) and the joint evaluation (JE)

condition. This study utilized a one-factor, four-level (separate nine ending, separate zero ending, joint nine ending and zero ending, and sequential nine ending and zero ending) design. A total of 158 undergraduate students, seventy-eight males and eighty females, were recruited from a large southern university. The participants were randomly divided into four subgroups, each of which was randomly assigned to one of four conditions.

The results also support the hypotheses. These findings demonstrate that the nine-ending pricing effect manifests in the SQE condition more strongly than in the JE condition but less strongly than in the SE condition.

General Discussion

The results of the present research offer practical implications for predicting actual purchasing behavior, as people constantly encounter buying circumstances involving either separate or joint evaluations in daily life (Hsee 1996). The diversity in evaluation conditions provides an advantage in marketing campaigns depending on the managerial approach. Alternatively, a zero-ending priced item could be advertised jointly with the comparable nine-ending priced items of competitors if a retailer wishes to generate the perception of equivalent prices.

Maneuvering or Cheating? Perspective-taking and Numerical Anchoring in Price Negotiation

Guang-Xin Xie, University of Massachusetts–Boston, USA

Hua Chang, Drexel University, USA

Extended Abstract

Extant research has examined the extent to which externally presented numerical anchors on buyers' perceptions of sellers in price negotiation (e.g. Bolton Warlop, and Alba 2003; Ofir 2004; Rajendran and Tellis 1994). However, the existing literature remains relatively silent on the effect of buyers' self-generated anchors and the related boundary conditions. Based on the recent studies on perspective-taking (e.g. Galinsky, Maddux, Gilin, and White 2008) and numerical anchoring (e.g. Wegener, Petty, Blankenship, and Detweiler-Bedell 2010), we propose that buyers have a "comfort zone" about the degree to which sellers can deviate from the fact (i.e. some tactics are acceptable). Further, buyers' capacity to consider the market norms from a seller's perspective can shape the range of the comfort zone and affect the perceived deceptiveness of the seller (i.e. tactics may be considered cheating anyway).

In general, when sellers provide a false numeric anchor that deviates from the fact, buyers are more likely to think they are deceptive and not acceptable. In this study, we intend to find out whether perspective-taking could change the extrinsic numeric anchor when buyers (e.g. consumers) evaluate the deceptiveness of sellers (e.g. a salesperson working for a car dealer). Perspective-taking is a cognitive capacity to consider the world from other viewpoints and allows an individual to anticipate the behavior and reactions of others (Galinsky and Mussweiler 2001). As Mazar, Amir and Ariely (2008) suggested, even honest people sometimes cheat, as long as the deviation is small enough to maintain a positive self-concept. Therefore, if buyers think from a seller's perspective, they may be more forgiving because they will probably cheat as well in that position. The perspective-taking heuristic, however, may or may not be factored in when buyers bargain with a seller. We speculate that without this mindset, buyers are more likely to focus on the factual aspect of a seller's negotiation tactic and therefore remain defensive. In comparison, buyers can be more tolerant about the fact-claim discrepancies if they will also cheat as a seller given a chance. In three experiments, we tested this hypothesis and the related boundary condition.

In study 1, seventy-one undergraduate students were randomly assigned to two experimental conditions. First, participants in both conditions were told to imagine they work at a car dealership as a salesperson who is selling a car with a markup of 7%. Next, they were asked what they would tell their customer if the customer asked what the markup is. After a filler task, participants were presented the same scenario from the customers' standpoint. They were told that a salesperson said the markup rate is 7.5% in one condition and 15% in another condition, while the true rate is 7%. Then they were asked to rate the salesperson in terms of being deceptive, misleading, trustworthy, and appropriate.

We first distinguished the participants by how much they would like to cheat as a salesperson. The absolute values of deviation from the true rate (7%) were calculated, followed by a median split to categorize participants as high or low deviation from the true markup. We ran a 2 (salesperson's deviation: low 7.5% vs. high 15%) x 2 (participants' deviation from the true markup: high vs. low) ANOVA. As expected, the main effect of the salesperson's deviation was significant: participants across conditions rated the salesperson as more deceptive when he said the true rate was 15% compared to 7.5%, $F(1, 67)=7.60, p=.008$. The main effect of participant's willingness to deviate was not significant. Interestingly, the interaction was significant, $F(1, 67)=3.97, p=.04$. Those who didn't cheat or cheated just a little as a seller considered the 7.5% rate much less deceptive than the 15% rate. In comparison, those who cheat a lot as a seller considered the salesperson equally non-deceptive despite the deviation. The role of perspective-taking was evident.

One possible explanation for the observed effect is that the perspective-taking task prior to the deviation manipulation adds an anchor about how much deviation is appropriate. Participants used this self-generated anchor rather than the actual anchor 7% to evaluate the salesperson. To test this hypothesis, we flipped the task order in Study 2.

Two-hundred and seventy-four undergraduate students participated in Study 2. They were first presented with the seller evaluation task, comparing the deceptiveness of 7.5% and 15% markup rates. After a filler task, they indicated the markup rate to tell their customer if they assumed the role as a salesperson. The results indicate a significant main effect of seller deviation: 15% rate was considered more deceptive than the 7.5% rate. As expected, the interaction was not significant anymore. Participants who deviated a lot from 7% as a seller considered 15% rate was more deceptive than 7.5% as well. More interestingly, we found that participants were less likely to cheat when the evaluation task was presented first. Much more participants in terms of percentage (53%) were willing to tell the customer the true rate 7% than those in Study 1 (18%), $\chi^2(1, 355)=21.57, p<.001$. Participants in Study 2 appeared to be much more honest because they engaged in the seller evaluation task first. In Study 3, we further pushed the boundary of deviation to test whether the findings hold.

One hundred and forty-five undergraduate students participated in Study 3. The design was the same as Study 2, except that the salesperson told the customer the true rate 7% or a much higher rate 21%. The rate 21% was chosen to exceed the upper bound of participants' self-reported deviation in Study 2, while maintains some level of realism. The results replicated the patterns found in Study 2.

Combined, the results in three studies supported that at least three heuristics could influence the perceived deceptiveness of a seller: 1). how much the deviation from the fact is; 2). how much buyers would like to cheat as sellers, and 3). the extent to which the perspective-taking mindset is activated. This study contributes to the literature by offering one of the first empirical evidence about the effect of self-generated anchor on judgments: the internal anchor is a moving target bounded by the situational salience and market norms.

SAS (Un)fairness

Sungchui Choe, University of Northern British Columbia, Canada

Mike Stanyer, University of Northern British Columbia, Canada

Extended Abstract

The "Scratch and Save (SAS)" promotion is emerging in North America as a store-level promotional strategy. SAS promotions offer potential discounts on all regular-price items in the store for a very short time period. Unlike the more established Tensile Price Claim (TPC), for which consumers are given the exact discount on a *specific* product, the SAS offers a variable discount on all products: the exact discount is determined from the deal's parameters (e.g. "up to 40% off" or "5%-30% off") by a scratch-off card at the point of purchase. Therefore, the SAS discount is characterized by uncertainty of savings until purchase. The variable outcome introduces a gambling component (note that a similar mechanism is used in "scratch-off" lottery cards) and customers buying the exact same item will inevitably receive different discounts from each other. The variable and unequal outcomes introduced by SAS promotions raise concerns about fairness. Two studies presented here explore how consumers approach (un)fairness in SAS promotions, and how their (un)fairness judgments influence emotion, satisfaction, and post-purchase behavior. In study 1, we employed a one-factor (actual discount), three-level (10%, 15%, and 20%), between-subjects design using a 15% reference discount. Study 2 manipulated levels of reference discount and inequality with a 2 (reference discount level: low (15%) vs. high (25%)) x 2 (inequality: advantageous vs. disadvantageous) x 2 (inequality level: low ($\pm 5\%$) vs. high ($\pm 10\%$))

We propose that consumers consider disadvantageous inequality to be more unfair than advantageous inequality. Furthermore, consumers will consider a deal to be unfair, even though they receive a discount, if the discount is lower than the average discount received by other customers. Therefore, we distinguish between dissatisfaction, as discussed in the "disconfirmation" (e.g., Oliver, 1980; Oliver and Swan, 1989) and "counterfactual-thinking" (e.g., Walchli and Landman, 2003) literature, and unfairness as prompted by a comparison to deals that other customers receive.

SAS promotions provide a maximum ceiling for their discounts (i.e., "up to 30%"), a minimum guaranteed discount (i.e., "10% or more"), or a range with explicit minimum and maximum bounds (i.e., "10% to 30%"). Regardless of the discount parameters, consumers will arguable consider the possibility of receiving the lowest possible discount, as they must commit to the purchase in order to discover

the exact discount. The price, after applying the minimum discount, is then assumed to be satisfactory. This judgment is informed by consumers' internal and external reference prices: their expectations of what the price should be. Assuming that prices have not been increased to compensate for discounts, a consumer's reference price may very well be similar to the regular price, or base price (without any discount applied) in the SAS deal. It is intuitive, then, that the price can be satisfactory with little or no discount. But consumers will also have internal and external reference discounts, and it is important to distinguish between reference *discounts* and reference *prices*. For the sake of brevity, this study does not discuss the multitude of influences that can affect a consumer's internal and external reference price. Instead, the reference *discount* is under examination: particularly the external reference discount. While the resulting price from the SAS deal may be satisfactory, consumers may be unsatisfied if they regard the discount as unfair.

The fairness literature makes frequent reference to distributive fairness (the equal balance of inputs and outputs in a transaction) and the dual entitlement principle (stating that sellers are entitled to a fair profit). A deep discount, then, may be considered unfair because consumers are giving too little and receiving too much. Recent fairness studies, however, show that consumers do not perceive fairness objectively: they tend to report fairness in an egotistical manner (e.g., Maxwell, Nye and Maxwell, 1999). A result that is not in their favor is regarded as unfair, while an outcome to their advantage is regarded as "fair," regardless of the seller's outputs. Meanwhile, a consumer's inputs, even in a retail transaction, are not necessarily monetary; consumers may invest trust in the offer. Despite receiving a guaranteed discount, they could feel that the discount (particularly one below the reference discount) is too low, weighed against their expectation of a higher discount (meeting or exceeding the reference discount). For this reason, perhaps, consumers may consider their own outcome as unfair, despite getting a deal and clearly receiving a benefit compared to the seller.

The studies herein establish consumers' subjective, egocentric approach to fairness, and also find that unfairness and fairness perceptions operate according to the Prospect Theory: the loss function is steeper than the gain function (Thaler, 1985; Kahneman & Tversky, 1979), or perceptions of unfairness are more severe than those of fairness. Participants report the negative outcome of low discounts (inequality in the seller's favor) as severely unfair, but report the positive outcome of high discounts (inequality in their own favor) as only minimally fair. Even when the deviation from the average savings is equal (i.e., plus or minus 5%), consumers' evaluation of unfairness is unequal, being more sensitive to their losses than their gains.

These studies also collect participants' affective, satisfaction and post purchase responses to positive and negative outcomes. As expected, the level of perceived unfairness increases the magnitude of emotional responses such as anger, happiness, surprise and perceptions of exploitation and obligation. These responses are measured in addition to satisfaction because SAS discounts offer a unique situation in which discount inequality exists for the same item being purchased by different customers. Resulting affective reactions based on perceptions of unfairness, therefore, may sully an otherwise satisfactory price. Furthermore, the level of perceived unfairness influences post-purchase behavior, particularly the possibility of returning an item and repurchasing it. Dissatisfaction with the outcome of a purchase may encourage consumers to make a gamble by repurchasing an item in hopes of scratching a greater discount.

This paper continues research concerning fairness, affect and satisfaction. It extends research on (un)fairness to the new "Scratch and Save" form of discount, in which (un)fairness is a prominent concern in due to the discount's variable outcomes between customers.

Do "Locally Made" Products Affect Price Perceptions? Not Always

Rajneesh Suri, Drexel University, USA

Mrugank Thakor, Concordia University, Canada

Umit Koc, LeBrow College of Business, Drexel University, USA

Consumers often use an array of extrinsic and intrinsic attributes to infer product quality and to assess intentions to pay. Though an intrinsic attribute normally dominates extrinsic cues when formulating evaluations because it is deemed more useful, such intrinsic information is often scarce, not useful or consumers might have little opportunity to process it (Miyazaki, Grewal and Goodstein 2005). Hence it is not surprising that extrinsic cues are more often used to make product decisions. Though research suggests positive relationships between a positive country-of-origin and perceptions of product quality, the literature reveals little about how and if consumers would use cues like country-of-origin (e.g., made in USA) differently than a region-of-origin cue like "locally made" when evaluating a product. Furthermore, since consumers when making purchases integrate inferences about product quality derived from an extrinsic cue with assessments of monetary sacrifice derived from another extrinsic cue, price, an intriguing question remains as to how consumers will integrate information from two cues, price and region-of-origin, to form product assessments. Though Miyazaki, Grewal and Goodstein (2005) concluded that consumers form stronger price-quality associations in the presence of consistent pairing between the price and other cues to product quality research is elusive as to how a dual cue like price which provides inferences about

not only quality but also monetary sacrifice will be integrated with inferences from region-of-origin when determining product quality and also willingness to pay for such products.

Following Krishnan, Biswas and Netemeyer (2006) it is argued that compared to a national origin, a local region-of-origin will be perceived as a more relevant and a concrete extrinsic cue making such cues less ambiguous and more effective in reducing additional search for quality information. We also use insights from cue-consistency theory (Maheswaran and Chaiken 1991) and information integration approaches to suggest that region-of-origin will be integrated with price cues to form perceptions of quality when both are positive. Furthermore since integration of information requires cognitive resources it is predicted that an enhanced impact of region-of-origin cue on product evaluations would be observed when consumers are otherwise motivated to process information. Consequently when motivated to process information, consumers would be willing to pay a higher price for a locally made product while there would be no difference between the region-of-origin and country-of-origin cues on consumers' willingness to pay when motivation to process information is otherwise low.

In two studies we collect initial information on whether a region-of-origin cue affects consumers' willingness to pay for products differently than a country-of-origin cue. Study 1 assessed the proposition directly by measuring consumers' price acceptability limits and price they expected to pay for locally made office furniture. Participants (105 undergraduate students) randomly assigned to a 2(motivation: low vs. high) x 2 (product origin: local vs. national) between subjects design read a scenario manipulating their purchasing goals (or lack thereof) for the target product before indicating their price acceptability limits. Results revealed that motivated participants had significantly higher willingness when the target was associated with region-of-origin information than "made in USA." In low motivation conditions, there was however no difference between these two cues on participant's willingness to pay for the target product.

Study 2 further assessed the evaluation of a relatively high price target. To assess participant's integration of information from multiple extrinsic cues to quality, past consumers' product quality reviews for this product were included. Study design and execution was similar to study 1 but with an additional variable of quality reviews (superior vs. inferior) for the target product. Perceptions of product quality and monetary sacrifice for the target product along with individual difference measures of regional attachment and price sensitivity were collected. Results were interesting and revealed that motivated participants perceived this high price target that was "locally made" to be less expensive than the one with "made in USA" provided that the target accompanied superior product quality reviews. Interestingly in low motivation conditions, participants perceived the target with the national origin and superior product reviews as less expensive than that with regional credentials. The cognitive response further revealed an enhanced depth of processing was associated with the region-of-origin cue in high motivation conditions but with heuristic processing of quality reviews and the country-of-origin cue in low motivation conditions.

Though research suggests that for agricultural commodities state-level appeals enhance consumer willingness to pay (Govindasamy et al. 2000), little marketing research has examined the effects of such "buy local" campaigns on price perceptions for other manufactured non-agrarian products (e.g., Noble et al 2006). The initial evidence from this research suggests interesting effects of locally made products on consumers' price perceptions. While it may be assumed that a cue like region-of-origin is likely to affect product evaluations in a manner similar to the country-of-origin, we argue that the concreteness and relevance of a regional cue will have a more positive effect on consumers' price perceptions for consumers motivated to process information. These results also add to our understanding of how integration of multiple cues will be impacted by consumers' processing goals extending our current understanding of the impact of multiple cues on price perceptions.

Effects of Sorting Competitive Prices on Product Evaluations

Rajneesh Suri, Drexel University, USA

Prabakar Kothandaraman, Drexel University, USA

Shan Feng, Drexel University, USA

Umit Koc, LeBow College of Business, Drexel University, USA

Online shopping has not only increased the availability of information to consumers but also resulted in an increased reliance on electronic decision aids that assist shoppers in organizing information. Decision aids that arrange products on utility have been shown to influence overall evaluations of the sorted set of alternatives (Diehl and Zauberma 2005) and also consumers' choice quality (Haubl and Trifts 2000). Though this research used customers' expected utility to create sorted sets of alternatives, several online retailers are likely to provide decision aids that simply arrange alternatives on attributes like price. Furthermore, brick and mortar retailers might not

have access to consumers' utility and arrange their merchandise displays simply on basis of an attribute like price. Such marketplace reality of using price instead of consumers' utility suggests a research gap and our understanding of the effects of price sorts. Available results from past research on decision aids that focused on utility may not shed light on the impact of alternatives arranged on price. This is because the relationship between price and consumers utility is not straightforward and depends upon whether consumers use price more in its role to assess monetary sacrifice or product quality (Monroe 2003).

Past research on numerical cognition suggests that infants often grow up learning natural numbers that are arranged in ascending order from one upwards (Ripps, Bloomfield and Asmuth 2008). Hence adults have an innate tendency to similarly order numeric information (prices) in memory and are distracted by tasks that uses a descending numeric order (Nairne 1983). More importantly descending numeric orders constrain cognitive resources to process task relevant information. Integrating these conclusions with research on cost benefit effects of information presentation and information flow (Ariely 2000), we predict that compared to alternatives sorted on ascending prices, a descending price sort will constrain cognitive resources to process target information especially when participants are motivated to process such information. Specifically, in high motivation conditions, a low price target would be perceived lower in monetary sacrifice when alternatives are sorted on ascending than on descending prices. In low motivation conditions, however, there will be no difference in the effects of the two sorts on the evaluation of a target product.

In four studies, we gather initial evidence for the effects of price sort on the evaluation of a target product. Study 1 used a 2 (motivation: low, high) x 2 (price sort: ascending, descending) between subjects design to assess perceptions of sacrifice for a relatively low price target DVD player accompanied by a sorted list of 20 other players. The results revealed that in high motivation conditions the target was perceived low on monetary sacrifice when the accompanying alternatives were arranged on ascending than on descending prices. In low motivation conditions there was no significant difference between the two sorts on evaluation of the target product.

Study 2 replicated the effects of sorting using an online website with the server inconspicuously capturing participants' mouse clicks and assessed depth of information processing for both the target product and the accompanying alternatives. The effects of price sort on evaluation of the target's monetary sacrifice were similar to those observed in study 1. More informative was the result that in high motivation conditions, compared to an ascending price sort, those exposed to descending prices viewed far fewer alternatives and spent significantly less time on the target.

Using a dual task approach, study 3 assessed cognitive constraints imposed by price sort by including an additional variable, memory load (low, high) to the research design used in the previous studies. In high motivation conditions, the higher memory load disrupted processing of target information more when the alternatives were sorted on ascending prices but not when they were sorted on descending prices. Thus descending prices were cognitively onerous and consequently the target's evaluation was not impacted by the memory load on participants.

Study 4 used another manipulation of motivation conditions and replicated the debilitating effects of memory load on ascending price sort observed in study 3 by using different range of prices for the accompanying alternatives. In high motivation conditions, despite the alternatives being sorted on ascending prices, the perceptions of sacrifice for a low price target increased when wider range of prices was used for the accompanying alternatives.

Overall, the results appear to indicate that compared to an ascending price sort, a descending price sort made it harder for consumers to assess monetary sacrifice. Interestingly, results also indicate that though ascending prices are more amenable to a thorough assessment of monetary sacrifice, such evaluations can be impeded by contextual influences like cognitive loads on memory or the uncertainty created by price range of the accompanying alternatives. Additional research is however needed to understand processing differences due to such sorting of alternatives and to examine whether location of a target's price in a sorted list of alternatives will influence consumers' assessment of its monetary sacrifice.

Not Everyone Loves Buffets: Pricing Preference of Frugal Consumers

Olivia (Wan-Ting) Lin, Texas A&M University, USA

Kelly Haws, Texas A&M University, USA

Extended Abstract

"Being frugal is back in fashion again... People who spent every dime of their disposable income two years ago are now saving... They're scrimping with more vigor and tenacity than economists have seen in decades," reported the Los Angeles Times. The recent recession has significantly changed Americans' spending habits and consumption attitudes (Time magazine, 2009). For example, many

mobile phone users, who used to opt for a fixed-fee, unlimited postpaid plan, are pursuing frugality and switching to a usage-based prepaid plan. “Prepaid is growing at an unprecedented rate with consumers keenly focused on value,” said Sprint’s Chief Executive Officer Dan Hesse (CNET 2009). The return to frugal living seems to offer counter-evidence for the flat-rate bias—a term dubbed by Train (1991) to describe the phenomenon that many users prefer a flat rate even though their billing amount would be lower with a pay-per-use tariff.

Lambrech and Skiera (2006) attribute consumers’ bias toward flat rates to three causes: 1) insurance against sudden large bills due to fluctuating demands, 2) reduction of the taxi meter effect (The ticking of the taxi meter reduces the pleasure of a taxi ride.), and 3) overestimation of product demand. Several studies have demonstrated the prevalence of flat-rate bias in product categories such as internet access (Lambrech and Skiera 2006), health club membership (DellaVigna and Malmendier 2006), online grocery shopping services (Nunes 2000), cruises (Prelec and Loewenstein 1998), and telephone service (e.g., Kridel, Lehman, and Weisman 1993; Train, McFadden, and Ben-Akiva 1987). However, consumers’ preference for pay-per-use rates receives scarce attention in extant literature. An exception is Miravete (2002), who claims that underestimation of product demand could also lead to a pay-per-use bias. In response to Lambrecht and Skiera’s (2006) call for further research into pay-per-use preference, the present paper seeks to address this literature gap.

Lastovicka et al. (1999) define frugality as “the degree to which consumers are both restrained in acquiring and in resourcefully using economic goods and services to achieve longer-term goals” (p.88). DeYoung (1986) investigates the psychological aspects of reduced consumption behaviors and finds that careful use of resources and avoidance of waste can contribute to individuals’ satisfaction. Frugal consumers enjoy (or are accustomed to) minimizing the quantity purchased or the money spent, and maximizing the utility of each product acquired. Thus, while their non-frugal counterparts resent the taxi meter effect, frugal consumers may enjoy (or cannot help but) carrying their own mental meters and keeping track of how carefully they have managed anything valuable. Accordingly, frugality can potentially lead to preference for pay-per-use rates, which facilitate achieving the goals of restrained acquisition and resourceful usage.

Just and Wansink (2008) as well as Litvak and Morewedge (2009) find that owing to consumers’ loss aversion and sunk-cost psychology, they usually adopt a breakeven strategy after paying flat rates. Choosing between flat rates and pay-per-use rates is relatively easy when the breakeven quantity falls far above or below the expected demand quantity. However, the decision gets complicated when no clear gap exists between the breakeven and the expected demand quantities. The present research thus investigates how frugal consumers’ pricing preference changes under varying demand uncertainty levels. We present two pricing options (one-day pass and pay-per-ride) in an amusement park scenario (and in an all-you-can-eat buffet restaurant scenario in another study). We manipulate the variances of our subjects’ anticipated consumption quantities and then ask them to choose their favorite pricing method. After seeing some filler pictures for distraction purposes, our college student participants answer questions designed to measure their frugality levels. We adopt Lastovicka et al.’s (1999) eight-item scale for the measurement of frugality.

The preliminary results of our experimental studies indicate that frugal consumers show stronger preference for pay-per-use pricing under low demand variance and equal liking for flat rates under high demand uncertainty compared with their non-frugal counterparts. Under low demand uncertainty, frugal consumers deem it more likely or more favorable for them to consume under the breakeven quantity. Accordingly, they choose the usage-based pricing to accomplish their goals of restrained spending and resourceful utilization. However, under high demand uncertainty, their confidence in consuming under the breakeven quantity decreases. Since losses loom larger than gains, frugal consumers increase their preference for a flat rate plan that provides insurance against potential large bills.

An interesting extension of the current research is to study frugal consumers’ consumption quantity and satisfaction under a flat-rate pricing policy. Do frugal consumers, compared to their non-frugal counterparts, suffer greater pain of paying, feel more vulnerable to the sunk cost psychology, and accordingly have a greater increase in their consumption quantity? As flat rates relieve their restraint on spending, frugal consumers may increase their consumption of the goods that incur no marginal cost to them. However, since frugal consumers resent wasting resources, they could end up consuming well beyond their satiety level and below their optimal satisfaction level.

Findings of our research should help retailers understand the pricing preference of frugal consumers and design pricing structures that meet their needs and increase their consumption satisfaction. Moreover, our findings have policy-making implications. Since overconsumption and resource wastage are contributing to environmental depletion and degradation (Cohen et al. 2005), the answer to a sustainable future seems to point to the re-establishment of frugality (Bove, Nagpal, and Dorsett 2009). Government should consider promoting pricing methods that encourage frugal behaviors to alleviate problems such as increasing economic debt, diminishing natural resources, global warming and disposal of waste. For instance, the U.S. Environmental Protection Agency developed a Pay-As-You-Throw (PAYT) system, where households pay directly for collection services based on the amount of waste thrown away. Some communities that have implemented the PAYT system have seen their overall waste disposal decline 25~45 percent (EPA 2009).

Can Consumers Cope with Visual Rhetorical Figures in Advertising?

Steven Andrews, University of Oregon, USA

Guang-Xin Xie, University of Massachusetts-Boston, USA

Over the past several decades print advertisements relied less on verbal language in either the headline or the body of the ad and more on complex, stylized visual messages delivered with rhetorical devices such as metaphor (Phillips and McQuarrie, 2002). McQuarrie and Mick (1996) defined rhetorical devices used in advertisements as "artful deviations" from the typical, expected communication structure. These deviations are generally pleasant to process and they encourage reinterpretation and/or reading additional meanings; therefore, rhetorical devices inherently yield weak persuasive arguments (McQuarrie and Phillips, 2005). Previous research suggests that ads with rhetorical devices generate greater ad liking, greater ad elaboration, and greater ad recall compared to ads without rhetorical devices. Specifically, visual rhetoric in ads are complex information devices (Scott, 1994a, 1994b) that enjoy universal processing advantages over ads with verbal rhetoric devices (McQuarrie and Mick, 2003b). Visual rhetoric elicits strong, immediate persuasive impact (McQuarrie and Phillips, 2005) which persists during incidental exposure (McQuarrie and Mick, 2003a) when verbal ads of any kind have virtually no persuasive impact. Given the pervasiveness of metaphor (Hirschman, 2007) in the marketplace and given the important differences in how the visual and the verbal systems process information (Franks, 2003) the present study examined more deeply the persuasive impact of visual metaphor ads in contrast to verbal ads. Specifically, we looked more closely at how effectively consumers cope with visual metaphor as a persuasive tactic.

The Persuasion Knowledge Model (PKM: Friestad and Wright, 1994) described how consumers cope with persuasive attempts in the marketplace. The PKM considers consumer beliefs, attitudes, and choices about persuaders and their tactics, and consumer perceptions of the effectiveness and appropriateness of persuasion attempts. Previous research examined the persuasive impact of rhetorical devices in ads within a persuasion knowledge context. Aluwahlia and Burnkrandt (2004) showed that the persuasion knowledge (PK) dimension of consumer self-confidence (Bearden, Hardesty, and Rose, 2001) determined how people processed rhetorical questions—a non-sensory rhetorical device—in the headlines and/or the body of verbal ads. People high in PK (based on median splits of the 6-item scale) rated the ads based more on source perceptions of a well-known brand. Conversely, people low in PK rated the ads based more on the strength of the persuasive claim. Persuasion was enhanced (weakened) by stronger (weaker) persuasive claims.

Based on previous research using visual rhetoric in print advertisements we hypothesized that in contrast to verbal metaphors, visual metaphors would not conform to the Aluwahlia et al (2004) model. Specifically, even though visual metaphors yield weak persuasive arguments print ads using these devices would show strong persuasive impact irrespective of PK scale scores. With 646 student subjects we used a 3 (ad style: verbal literal, verbal metaphor, visual metaphor) x 2 (PK scale score: high, low) between groups design. Ad stimuli were taken from previous research (McQuarrie & Phillips, 2005) on the persuasive impact of visual rhetorical ads. Factorial ANOVAs confirmed our expectations that consumers perceived visual metaphor as a persuasive tactic to a much greater extent than the other ads. Despite that visual metaphors showed much higher ad and brand attitude regardless of PK level. In contrast, verbal metaphor had much lower attitude scores for the low PK vs. high PK consumers as shown previously for weak arguments. Consistent with previous research (McQuarrie & Mick, 2003a), consumers in study one rated the ads with visual metaphors more interesting, more artistic, and more likely to possess multiple meanings than the verbal ads. Consumer PK scale scores did not impact elaboration ratings.

Based on the higher involvement ratings for visual metaphors in study one, study two explored the possibility that visual rhetorical ads penetrated PKM persuasion filters more thoroughly because the visuals worked through affective, meta-cognitive processes such as visual fluency (Winkielman, Schwarz, Reber, and Fazendeiro, 2003). Specifically, visual fluency theory suggests that the pleasant experience consumers have when processing more fluent stimuli gets interpreted as relevant information regarding the stimulus being processed. Stimuli that are more perceptually fluent and more conceptually fluent are liked better and they are perceived to be more truthful (Reber, Schwarz, and Winkielman, 2004). Perceptual fluency studies have shown that when a visual stimulus is limited in the duration of exposure, putting stress on the viewer's mind, the stimuli are liked less and perceived as less truthful (Reber, Winkielman, and Schwarz, 1998).

Study two explored whether perceptual fluency effects influenced the positive ratings of visual metaphors despite the greater perception that the ads were using a persuasive tactic. Using the same ads, we manipulated exposure duration: 110 student subjects either had unlimited time to view the ads or were restricted to one standard deviation below the pre-tested mean for adequate minimum processing time for all the ads (3-seconds). A two (exposure duration) x 3 (ad styles) mixed design based on McQuarrie and Phillips (2005) showed that the limited duration exposure resulted in decreased ad attitude ratings and decreased perception of honesty ratings for both verbal ads. The limited exposure duration had no effect on attitude or honesty ratings for visual metaphors, which remained higher than both the verbal ads across both exposure conditions.

In summary, study one demonstrated that persuasion knowledge: a rational, cognitive measure of persuasion coping (Campbell and Kirmani, 2008) had virtually no effect on consumer coping with print ads using visual metaphors. This finding has strong implications regarding the persuasive power of rhetorical figures used in visual advertising, particularly given how popular the tactic is in practice. Results from both studies suggested that the visual metaphors elicited strong affective reactions. But apparently the exposure duration manipulation in study two was not strong enough to affect the instant impact of visual rhetorical figures on consumer response. Future research should also consider the possibility that the rhetorical "artful deviations" elicit perceptual feelings of familiarity (Whittlesea, 1993). Another possibility worthy of future consideration is that visual processing fluency may moderate more traditional levels of processing effects on visual ads: attention, elaboration, and the formation of new knowledge structures from existing knowledge structures (Petty and Krosnick, 1995).

Using Visual Interference to Establish New Brand-Attribute Linkages

Christina Saenger, Kent State University, USA

Robert Jewell, Kent State University, USA

Jennifer Wiggins Johnson, Kent State University, USA

Memory interference occurs when a memory cue is associated with more than one brand through similar advertisements (Burke and Srull 1988). At retrieval, the cue triggers associations with both brands, yielding response competition and confusion between the brands. Research has found that confusion can interfere with an individual's ability to correctly recall brand-attribute associations, potentially harming the brand (Unnava and Sirdeshmukh 1994). However, research has also suggested that interference can be used for

repositioning when a brand uses an advertisement that communicates similar brand attributes as a competitor's ad (Jewell and Unnava 2003) as recall for new attribute information is enhanced by the common association between the brands.

Most research has focused on text-based interference. However, trends in print advertising show that marketers rely more on images, and use fewer verbal claims (McQuarrie and Phillips 2008), suggesting a new interference problem. An informal content analysis of three fashion magazines revealed ten sets of advertisements for different brands using similar pictures. Research has shown that ads with similar pictures can foster competing associations to the common picture cue at retrieval, leading to the same harmful interference effects (Kumar 2000; Kumar and Krishnan 2004). If similar pictures can lead to interference, then picture similarity may also yield the positive effects observed with text cues when used to reposition a brand. This paper explores whether the repositioning effect of text-based interference also occurs with visual interference.

For a brand to experience the repositioning effect of visual interference, the pictures used need to be similar enough to prompt a common association between two brands and a single picture cue. When consumers view advertising pictures, they extract inferences about the attributes possessed by the brand (Scott and Vargas 2007). This finding is in line with referential processing, where verbal representations of visual stimuli are encoded in memory (Paivio 1971, 1990). Recall for pictorial information relies on this verbal recoding (Walker et al. 1997). Therefore, we propose that when a picture becomes associated with both a target brand and a brand that possesses a new, desirable attribute, response competition during interference may facilitate recall of the desirable attribute for the target brand, effectively repositioning the target brand.

In addition to visual similarity, the use of a picture that communicates the meaning of the repositioning attribute is a second necessary condition in visual interference-based repositioning. If verbal recoding of pictorial information occurs in memory, visual interference-based repositioning is more likely to occur when the picture is communicative of the attribute's meaning. If the picture is similar but not communicative of the intended meaning, it may be verbally-recoded and cause interference, but the desired repositioning is unlikely. If the picture is communicative but not similar to another brand's advertising, interference will not occur and the brand is less likely to reposition due to the lack of competing associations. Therefore, we expect the effectiveness of visual interference in repositioning to depend on the similarity of the picture cue and the meaning extracted from the picture.

We tested this prediction in the context of repositioning a hotel brand. Pretests revealed that our participants were familiar with this product category and the brands Holiday Inn and Hilton. Holiday Inn was perceived to be related to the attribute, "appropriate for vacation," and Hilton was perceived to be related to the attribute, "appropriate for business," with each brand unrelated to the other attribute. The goal of this study was to reposition Holiday Inn as "appropriate for business" using visual interference. Several pictures were pretested, and a briefcase was determined to mean "appropriate for business" while a beach bag meant "appropriate for vacation." We created advertisements for Holiday Inn and Hilton featuring these focal images embedded into images of hotel rooms. The images were accompanied by headlines and text copy that did not make any reference to the focal attributes. Pretesting determined the headlines, text copy, and full ads for each brand were equally persuasive and informative.

We employed a 2 (meaning of target image: conveyed /did not convey the business attribute) x 2 (image similarity: similar/different) design. The meaning and similarity of the ads was manipulated using the focal images in the ads, creating four conditions for the Holiday Inn/Hilton ads: briefcase/briefcase, briefcase/beach bag, beach bag/briefcase, and beach bag/beach bag. 108 business undergraduates viewed a 10-advertisement sequence that included the Holiday Inn and Hilton ads, counterbalanced for order effects, including other competing ads to mask the manipulated ads. The dependent variable, measured via 7-point Likert scale, indicated participants' agreement with the statements, "Holiday Inn is appropriate for business travel" and "Holiday Inn is appropriate for a business conference," which we combined into a single index ($r = .65$).

We found a significant interaction effect between similarity and meaning ($F(1,104) = 4.37, p < .05$). Ratings of Holiday Inn's appropriateness for business were higher when both ads featured the briefcase ($M = 5.65$) than when the Holiday Inn ad featured the briefcase and the Hilton ad featured the beach bag ($M = 4.71, p < .01$), when the Holiday Inn ad featured the beach bag and the Hilton ad featured the briefcase ($M = 4.65, p < .01$), or when both ads featured the beach bag ($M = 4.67, p < .01$). There were no significant differences between the other three conditions.

This suggests that picture meaning or similarity alone are no more effective at repositioning the brand than an advertisement that does not communicate the repositioning attribute at all. We conclude that similarity and meaning are necessary but not sufficient conditions to link a brand to a new attribute using visual interference. Additional studies will investigate how similar the pictures must be when the appropriate meaning is conveyed, how effectively the pictures must communicate the meaning when they are similar, and cross-category effects.

This research contributes to advertising research by demonstrating that visual interference can be an effective repositioning tool. Since visual advertising is dominant and often employs similar imagery, this research demonstrates how advertising's competitive environment can be used to a brand's advantage.

The Bleeding Effect:

How Interference in Advertising Messaging Influences Perceptions and Impacts Behavior

Bryan Greenberg, Elizabethtown College, USA

David Ruggeri, St. Louis University, USA

The question of how advertising effectiveness is influenced by competitive messages, both for similar products as well as for those falling into a different product class, has been an important area of inquiry for researchers. Two areas that researchers have focused on are the impact of messages pertaining to similar types of products and the impact of messages containing similar creative elements. The former, generally referred to as competitive interference, refers to the way that competitive brands, i.e. those brands that represent similar or substitutable products, can interfere with recall measures. Various studies (Burke and Srull, 1988; Keller, 1991) have found that brand recall is significantly lower when an ad for a similar product is present. The second area of research, known as contextual interference, is focused more on the creative decisions that go into the development of an advertisement, such as the use of similar pictures or imagery. Results have shown that contextual interference can diminish recall when multiple products, regardless of their product class, rely on similar executions (Kumar and Krishnan, 2004; Kumar, 2000).

While general brand name and messaging recall has been shown to decrease or become muddled in the face of interference, research into how this may influence consumer perception or interpretation is scarcer. Is interference just problematic for processing and retrieval tasks, or does it alter how consumers view and interpret a product? Some of the research into interference begins to address these questions, including that into contextual interference, which has shown that similarity in executional elements can confuse consumers, leading them to mistake one brand for another when cued with the advertising executional elements both brands shared (Kumar and Krishnan, 2004). Jewell and Unnava (2003) also offered some insight into this issue when they studied the potential positive impact of competitive interference. They found that such interference could be beneficial to established brands attempting to promote a new product attribute.

The primary goal of this research is to further examine how interference influences how and what consumers interpret when faced with such interference effects. This study includes an examination of what specific information consumers recall, and whether that information matches the brand's messaging, the competitive messaging, or is unrelated to both. It also measures consumer intent to purchase, seeking to connect interpretation of messaging to purchasing behavior. In addition, qualitative analysis is also utilized to better understand the link between messaging, processing, interpretation, and behavior.

A secondary goal of this research is to apply what has traditionally been a lab-based approach to studying interference effects to a more natural setting. This project therefore included a field experiment followed by replication in a laboratory setting to compare effects.

To accomplish the above goals, a field experiment was first conducted over the course of one week (Friday through Thursday) at a large multiplex movie theater. Theater management agreed to allow the manipulation of pre-show elements for two prints, both of the same film playing on two of the theater's screens. The messaging tested consisted of movie trailers, what we define as extended commercials. To control for outside variables, each print consisted of only two movie trailers and the film. No additional advertising, theater promotional messaging, or other entertainment content was present. There were three conditions—interference-ad-present, interference-ad-absent, control—with each rotated across screens and dayparts to account for potential bias. The trailer for *Flightplan* served as the target advertisement. The trailer for *Red Eye* version A served as the interference-inducing advertisement (*Red Eye* A contained similar imagery, with both it and *Flightplan* featuring scenes taking place on a plane). *Red Eye* version B was used in the interference-ad-absent condition (this version did not feature any scenes on a plane). A trailer for a romantic comedy, unrelated thematically and executionally to *Flightplan*, was used in the control group.

To test the results from study 1 in a controlled environment, a second study was designed to replicate the first in a laboratory setting. Students, staff, and local residents were invited to attend a free film screening. There were three showings of the film, each representing one of the three conditions found in the first study.

Subjects in both groups were told that a study on the moviegoing experience was being conducted and were asked to complete two surveys. The first was completed prior to entering the theater/screening room, while the second was completed at the completion of the film. Upon completion of survey one, respondents were provided a raffle ticket for free movie tickets and told it would be collected upon completion of survey two. The code on this ticket was used to match both surveys.

The primary measures to understand interference and consumer interpretation in the face of interference were a variety of unaided and aided recall measures. These included three specially-designed thematic recall scores: Correct recall, confused recall, and incorrect recall. For these respondents were asked to list as many themes/elements they could recall from each trailer. These responses were categorized as correct (matched one of a pre-determined set of elements for that trailer), confused (matched a pre-determined set of elements for the alternative trailer the subject viewed), or incorrect (matched neither set of elements). Likelihood to purchase scores, as well as open-ended questions designed to elicit additional details as to why that was the case, were utilized to offer additional insight into the behavioral impact of interference effects.

Results showed a statistically significant difference across all thematic recall measures for those subjects exposed to the trailers featuring similar executions. Those in the interference-ad-absent and control conditions were not significantly different. In addition, those in the interference-ad-present condition were much more likely to interpret the *Flightplan* trailer in a way that did not match its execution or its actual theme. For example, many subjects thought the film included a plane crash when, in fact, it did not (nor did either of the two trailers they saw). Thus consumers were creating alternative interpretations that matched neither the target advertisement nor the test advertisement. Other results include lower unaided recall (of the trailers viewed) and decreased intention to purchase (to see the film advertised).

Is a Diamond Really Forever?

Effects of Lay Theories of Love on Responses to Romance Appeals in Advertising

Li Huang, HKUST, Hong Kong

Anirban Mukhopadhyay, Hong Kong University of Science and Technology, China

Extended Abstract

The theme of romantic love is commonly used in advertising as marketing practitioners strive to generate favorable attitudes towards advertised products (Galician and Merskin 2007; Huang 2004). It is therefore interesting to observe that consumer researchers have paid scarce attention to this theme (choosing instead to focus their efforts on the study of a possibly related area, namely, sex in advertising, cf. Dahl, Sengupta, and Vohs 2009). The aim of this research is to address this gap in the literature, by exploring consumers' responses to romance appeals in advertising and how these may depend on their lay theories.

Lay theories, the basic and often naïve assumptions that people hold about their world, guide many aspects of social behavior (Dweck 1999; Wyer 2004). Consumer researchers have recently begun to uncover some of these diverse effects of lay theories on various aspects of consumer judgment and decision making (e.g., Mukhopadhyay and Yeung 2010; Mukhopadhyay and Johar 2005; Raghunathan, Naylor, and Hoyer 2006; Wang, Keh, and Bolton 2010). Particularly relevant to this research, Hung and Wyer (2008) demonstrated that consumer's responses to advertising may be influenced by their lay theories. Along similar lines, we seek to understand how lay theories that are specific to love might influence consumers' responses to romantic appeals in advertising.

Various literatures have proposed different beliefs regarding love (Lindholm 1998). Some ideally believe that love is forever and eternal; in contrast, some strongly believe that love is transitory and destined to change (Peck 1978). This distinction corresponds to Labroo and Mukhopadhyay's (2009) study of lay theories of emotions, according to which people's beliefs about the transience of emotions range along a continuum from "lasting" to "fleeting". Correspondingly, we too suggest that lay theories of love may vary—from *lasting* to *fleeting*.

What effect might these lay theories have on the appraisals of romantic messages in advertising? Wheeler, Petty and Bizer (2005) demonstrate that self-schemata matching, or presenting individuals with a message that appeals or conforms to some aspect of their self-conception, enhances favorable reactions to that message. Romantic love often entails feelings of attachment and wishes of long-lasting relationships (Hazan and Shaver 1987), which is more consistent with the belief of lasting-theorists. Therefore, our first prediction is that lasting-theorists will have more favorable attitudes towards romance appeals than will fleeting-theorists.

What if the relationship is threatened? Optimism may lead to a false sense of security (Weinstein 1980), and hence lasting-theorists who optimistically believe love is eternal may perceive their relationships to be more secure than they really are. This would make them less inclined to take actions to maintain their relationships. Knee (1998) found that people who held a "destiny" theory of relationship (potential partners are meant for each other) were more likely to engage in avoidance coping in response to a stressful relationship event as compared to "growth" theorists (relationship is cultivated and developed over time). In our context, this would imply that lasting-theorists would have an avoidant reaction to relationship threats, and therefore the presence of a relationship threat would make them less likely to buy products advertised using romantic appeals. In contrast, since fleeting-theorists do not hold such over-optimistic beliefs about perennial love, the presence of threat should not affect their responses to romantic appeals.

Till date, we have tested our hypotheses in two completed experiments. In Study 1a ($N=144$), participants viewed a target ad for chocolates, featuring a romantic appeal, and a filler ad for mobile phones, and reported their attitudes towards both ads ($\alpha=.95$). They then responded to some demographic measures, following which we assessed lay theories of love based on six items including statements such as "Love is forever" and "love is transitory" ($\alpha=.87$). Lower (higher) scores on this scale represent a greater fleeting (lasting) orientation. Regression analyses showed that lay theories of love significantly predicted attitudes towards the romance appeal ad, such that lasting-theorists had more positive attitudes than fleeting-theorists ($\beta=.40$, $t(143)=5.18$, $p<.001$). An analysis using median splits

for ease of explication indicates the difference between the two groups ($M_{\text{lasting}}=5.84$, $M_{\text{fleeting}}=4.94$, $t(143)=4.84$, $p<.001$). There were no significant differences in attitudes for the filler ad. Study 1b ($N=65$) replicated these results on a different sample, with the stimuli consisting only of the target ad and no filler ($\beta=.47$, $M_{\text{lasting}}=6.24$, $M_{\text{fleeting}}=5.04$, $t(64)=4.29$, $p<.001$).

Study 2 assessed whether threat moderates the effect of lay theories of love on the purchase intention for the advertised product. Participants ($N=48$) in a 2 (threat vs. no threat) \times 2 (lasting vs. fleeting) between-subjects design read a scenario in which their romantic relationship was in conflict vs. not. They then saw an ad featuring a romantic appeal for chocolates, and indicated their intention of buying the advertised product as a gift to resolve the conflict ($\alpha=.88$). Participants in the no-threat condition merely indicated how likely they were to buy the chocolates as gifts for their lovers. The analysis reveals a significant interaction between threat and lay theories of love ($F(1, 44)=55.16$, $p<.01$). In the absence of threat, the previous results obtain, such that lasting-theorists had higher purchase intentions than fleeting-theorists ($M_{\text{lasting}}=4.58$, $M_{\text{fleeting}}=3.98$; $F(1, 44)=5.25$, $p<.01$). In contrast, under threat, there was no difference in purchase intentions ($M_{\text{lasting}}=3.94$, $M_{\text{fleeting}}=3.79$, $F(1, 48)=1.78$, ns). As expected, relationship threat does not affect fleeting-theorists' responses to romance appeals, but strongly affect lasting-theorists' behavior.

To summarize, this research investigates romantic appeals in advertising, and our results till date demonstrate that responses to such appeals vary based on consumers' lay theories of love as well as the presence of relationship threat. These results are among the first in consumer research to investigate the effects of romantic appeals, a perennial theme in advertising. Subsequent studies will explore the mechanisms underlying the observed effects.

The Effect of Cultural Orientation on Responses to Comparative Advertising

Ozge Yucel-Aybat, Baruch College, CUNY, USA

Thomas Kramer, Baruch College, CUNY, USA

Nowadays, brands often try to differentiate themselves from competitors, and comparative advertisements are used as traditional tactics to persuade consumers of their superiority over other brands. To that effect, advertisers state that their product is better than the competitor's product or even better than any other product. Many of us are familiar with Subway's advertisement targeting McDonald's and these practices are increasingly used by industry giants such as Pizza Hut, Diet Pepsi and Apple (McArthur and Cuneo, 2007). Extant research has examined the effects of comparative message claims. For example, Grewal et al (1997) found that comparative ads

are more effective than noncomparative ads in terms of brand awareness, attitudes and purchase intentions. Research has also examined the effectiveness of comparative ads by concentrating on valence of framing (Jain et al., 2007), on information processing (Thompson and Hamilton, 2006) and on brand positioning (Pechmann and Ratneshwar, 1991). In this research, we propose that comparative ads may not be universally effective and that individual differences associated with distinct cultural values may affect consumers' perceptions.

We focus on the extent to which consumers accept "inequality" as a legitimate result of their cultural values, which is defined as "power distance" in Hofstede's (1980) cross-cultural studies. It is assumed that cultures are distinguished by the way they are accustomed to deal with inequalities, in other words by how individuals handle inequality in society and hierarchy of powers (Hofstede, 1991). For some cultures (low power distance), inequality and inconsistencies among various areas are often problematic. On contrary, for others (high power distance), unequal power distribution is generally accepted: people do not and should not question the power of others; they should accept the hierarchy as it is. Thus, the more their culture encourages rigid social hierarchy in different positions of power, the more they are expected to be comfortable in accepting this inequality. We argue that this acceptance of inequality may in turn affect how consumers cope with companies' claims of being superior to their competitors in comparative ads. Therefore, the aim of this research is to extend the comparative advertisement literature by investigating potential differences in consumer responses due to the cultural orientation construct of power distance.

One of the first cross-country investigations about comparative advertisement is conducted by Donthu (1998). This research suggests that although consumers recall these ads better, their attitudes toward comparative ads are not very positive in countries where these practices are rarely used. However, Jeon and Beatty (2002) show that in countries where consumers are unfamiliar with direct comparative ad (explicitly naming the well-known competitor), this type of advertisement is more effective than indirect comparative ad (e.g., "our brand is better than any other brand"). Choi and Miracle (2004) on the other hand examine the mediating effect of self-construal on the relationship between national culture and effectiveness of comparative advertisement. Polyorat and Alden (2005) also investigate the effectiveness of indirect comparative ads by using two different samples (US and Thai) and test the effects of self-construal and need for cognition. In this research, we extend Polyorat and Alden's work (2005) by investigating the effects of direct comparison, indirect comparison and noncomparison advertisements by considering cultural differences. Researchers examining comparative advertisement through cross-country investigation conducted studies with participants born in different countries. However, even individuals of the same country may differ in terms of how they are affected by the same culture. Therefore, instead of differentiating based on the country, we try to differentiate among consumers based on their personality traits as Hofstede (1991) suggests.

Study

We manipulated presence of comparison in the ads by using direct, indirect and noncomparative arguments in the ads. Three ad versions of a fictitious brand were used as in Pechmann and Ratneshwar's studies (1991) to control for subjects' familiarity with the ad. 137 undergraduate students enrolled in marketing courses at an East Cost University participated in the study in exchange for course credit. Participants were first presented with brief information about the target fictitious brand (Star) and some of them saw direct comparative version (comparing Star with Ajax), some indirect comparative version (claiming that Star is the best) and some noncomparative version (only stating Star's positive attributes) of the ad. We then measured participants' power distance scores as a second factor. Manipulation checks were conducted to make sure that participants can easily distinguish between the comparative and noncomparative ads.

Data supported our hypothesis that comparative ads may not be universally effective and participants' willingness to accept inequality (power distance) may affect this process. An ANOVA on ad effectiveness revealed a significant interaction ($p < .05$) between the ad type and power distance measures. Direct comparison ads were more effective for participants with lower power distance scores (less willing to accept inequality); whereas indirect comparison ads were more effective for participants with higher power distance scores than those with lower power distance scores.

Discussion

Using power distance as a construct to differentiate between individuals' perceptions of inequality, this research tries to contribute to literature by showing that individual differences caused by cultural differences can moderate the way consumers perceive comparative advertisements. This research also has practical implications for managers, suggesting under which conditions comparative ads are likely to be most effective.

The current stimuli use a fictitious brand name and compare it with a well-known competitor. To increase the external validity and to comply with real-life settings, in the next study we will use familiar brand names. We will also manipulate the credibility of comparative claims (direct and indirect). In direct comparison condition, for the incredible version, the ad will compare an inferior brand with a high quality brand and claim its superiority; whereas for the credible version an equally powerful brand will claim that is superior to its competitor. We will use pretests to make sure we use the appropriate brand names for inferior, equally powerful and best-known competitor brands. In addition, in a follow-up study, we will investigate how cognitive load impacts the effect of power distance on effectiveness of comparative ads.

Effects of Metaphor on Goal-Oriented Appeals in Advertising

Hongmin Ahn, The University of Texas at Austin, USA

Yongjun Sung, The University of Texas at Austin, USA

Jason Crandall, The University of Texas at Austin, USA

Advertising messages influence one's motivations, views, and perceptions in achieving goals. One of the key techniques to encourage consumers to reinforce or alter their goals is the use of rhetorical figures, such as metaphorical expression (McQuarrie and Mick 1996). While metaphorical claim is the most widely used rhetoric in current advertising practice, little is known about the circumstances under which metaphorical claims are most persuasive. Previous studies tend to focus on the advantages of metaphoric claims as compared with literal claims (e.g., McQuarrie and Phillips 2005), and the persuasive nature of metaphorical claims themselves is not fully investigated. In this article, we adopt regulatory focus theory to investigate the effectiveness of metaphor on enhancing one's goal achievement.

Regulatory focus theory (Higgins 1997) suggests two basic motivational orientations that individuals adopt to achieve their goals: prevention-focus and promotion-focus. Prevention-focus oriented individuals seek to avoid negative outcomes; thus, their concerns are about safety, responsibilities, and obligations (Higgins 1997, 2000). Conversely, promotion-focus oriented individuals, seek to achieve positive goals and are concerned with growth, accomplishment, and aspirations. When people adopt the goal pursuit strategies and engage in activities that are consistent with their regulatory orientation, they experience "feels-it-right" sensation and their motivations become heightened (Aaker and Lee 2006).

Researchers of regulatory orientation have also suggested that not only a match between a manner in which a person pursue a goal and his or her goal orientation, but also the types of message framing (i.e., promotion vs. prevention) in a given context determine the persuasiveness of information. That is, prevention-focused messages are most persuasive at a concrete, detail-oriented level because they allow consumers to maximize the accuracy of their decision outcomes (Mogilner, Aaker, and Pennington 2008). Promotion-focused messages, however, are most persuasive when framed at an abstract level because people who are presented with promotion-focused messages would focus more on the ultimate meaning of an event, as opposed to its concrete details. Mogilner et al. (2008) empirically tested this notion by suggesting that prevention-framed products were more favorable when consumers' purchase decisions are imminent while promotion-framed products were preferred when the purchases did not need to be made immediately.

Given the different characteristics of prevention/promotion goal orientations, it is expected that prevention-focused messages would be more effective when the ad employs literal rhetorical techniques to persuade consumers because these messages provide explicit, concrete means to avoid the negative outcomes. On the other hand, it is expected that promotion-focused messages will be more persuasive when the ad uses metaphorical rhetorical technique because promotion-oriented individuals will focus more on the ultimate meaning of an event. The promotion-focused messages should motivate people to achieve positive outcomes rather than emphasizing a concrete focus (Mogilner et al. 2008). Furthermore, metaphorical claims have been shown to be more advantageous in providing positive outcomes as compared to literal claims because they render consumers more receptive to diverse and positive influences about advertised brands while still conveying the main message of the ad (McQuarrie and Phillips 2005). We conducted an experiment to test these expectations.

Method

Stimulus Development. To develop a set of rigorous metaphoric advertising stimuli, stimulus development procedure followed a multiple-step process. First, professional advertising artists initially created 10 sets of ads carrying various themes of metaphorical verbal expressions that emphasize the benefits of eating cereals. The prevention-focused ads conveyed messages such as, "This cereal helps prevent heart disease" whereas the promotion-focused ads had messages such as, "This cereal helps enhance your heart health." Since the quality of metaphorical expression critically influences participants' evaluations of ads, we conducted several pre-tests to screen out dead or inapt metaphors among these ads. Undergraduate students at a large southern American university evaluated whether ads were creative/imaginative or plain/matter-of-fact (McQuarrie and Mick 1996). Participants also rated the levels of implications of these ads on a seven-point scale anchored by "Almost everyone/no reasonable person would draw this conclusion from the ad." (McQuarrie and Phillips 2005). Through these procedures, we selected a final set of metaphorical ads for the preliminary study.

Preliminary Analysis. In order to investigate these hypotheses, we used a 2 (rhetorical styles: metaphorical vs. literal) × 2 (goal orientation: prevention vs. promotion) between-subjects factorial design. The dependent variable was attitude toward the advertised brand (a cereal brand). The results of ANOVA indicated that there was a marginally significant interaction effect of rhetorical styles and

goal orientations ($F= 3.78, p=. 058$). Direction of the effect was consistent with our expectations. That is, the prevention-focused ad was more favorable ($M= 4.92$) than the promotion focused ad ($M= 4.05$) when participants were shown a set of ads containing literal claims. The promotion-focused ads, however, became more appealing ($M= 4.60$) than prevention-focused ads ($M= 4.25$) when participants were presented with metaphorical claims.

Implications and Limitations

McQuarrie and Phillips (2005) argued that, in general, the use of metaphorical claims (vs. literal claims) in ads is more effective to evoke positive attitudes among consumers given its ability to provide diverse references about advertised brands. Our initial phase of the study, however, shows that the goal orientation of the message-framing influences the persuasiveness of metaphors in ads, thus demonstrating a potential limitation on the suitability of metaphorical claims. The results provide useful guidelines for advertising practitioners in effectively utilizing metaphoric techniques in ads. At this stage, we only tested the effectiveness of metaphor in terms of verbal expression (i.e., ad copies) for a routinely purchased commodity. To a better understanding of the nature of persuasiveness in metaphor, future study should incorporate visual metaphors. It may also be worthwhile to investigate if this interaction occurs in other types of purchases.

Do I Really Have to Prove Who I Am? The Impact of Identity Denial and Targeted Ads

Bruno Kocher, HEC Paris, France

Luna David, Baruch College, USA

Extended Abstract

American citizens of foreign origins, who might be born and raised in the United States, frequently have to answer questions such as "do you speak English" or "where are you really from?" (Cheryan and Monin 2005). Since they do not match the prototype of the in-group, their belonging to that group is questioned. This phenomenon has been labeled as "identity denial" (Cheryan and Monin 2005). The purpose of this research is to assess consumers' reaction to such an acceptance threat (Branscombe, Ellemers, Spears, and Doosje 1999).

Past consumer research has assessed the impact of in-groups, out-groups and dissociative groups from different perspectives (e.g. Bearden and Etzel 1982; White and Dahl 2007). Consumption (or abandon) of brands/products was advocated to help individuals build their self-concept (e.g. Escalas and Bettman 2005) or to differentiate them from out-group members adopting these tastes (Berger and Heath 2007, 2008).

However, to the best of our knowledge, no research has assessed the impact of identity denial on consumers' attitudes. Cheryan and Monin (2005) demonstrate that identity denial leads to an increase in respondents' effort to show cultural knowledge and claims to participate in in-group practices. Nevertheless, we currently do not know to which extent this phenomenon affects consumers' consumption decisions, brand/product attitudes and perception of advertisement executions.

Theoretical Background

Ethnic identities. Advertisers frequently use ethnic cues in order to target members of ethnic groups. Past research has shown that, in general, consumers targeted by this tactic respond in a positive manner (Whittler 1989, 1991). According to Deshpandé and Stayman (1994), ethnic minorities (vs. ethnic majorities) evaluate spokespersons from the same ethnic background as more trustworthy. Subsequently, this increased trustworthiness leads to higher brand attitudes. Most of past research has assessed ethnic cues from an in-group versus out-group perspective. Respondents were primed by (or exposed to) ads containing (vs. not containing) a cue specific to their ethnicity. As Deshpandé and Stayman (1994), we are interested in trustworthiness or honesty of advertisers. However, the present study takes a different look at the implementation of ethnic primes. More precisely, we are interested by the impact of a prime which denies membership to a group, even though the person objectively belongs to that group. In other words, the purpose is to assess how consumers react to ethnically targeted ads when they are denied one of their identities and, concomitantly remembered of another one.

Identity denial. As stated by Cheryan and Monin (2005, p. 718) "whereas stereotypes threat (Steele 1997) is the fear of being seen in a negative light because of one's group membership, identity denial is the fear of not being seen as part of the in-group at all". Rejection from an important group may frustrate the basic need of belonging (Baumeister and Leary 1995; Eisenberger, Liberman and Williams 2003). As demonstrated by Schmitt and Branscombe (2001), when people are targeted by a social identity threat, they alter their subsequent behavior. The reaction to an identity denial is to assert one's identity in order to prove to others than one really belongs to that in-group (Cheryan and Monin 2005).

Study

Procedure. Forty-three American citizens from Chinese origins were recruited through flyers on the campus of a major East Coast university. After entering the lab, subjects were asked (or not) about their knowledge of English (do you speak English?). This question represents the identity denial manipulation. As shown by previous researchers (Cheryan and Monin 2005), this interrogation makes respondents think about their membership of the group. After this question, they received a fake magazine directed toward Chinese American or American respondents. The magazine contained the ad for a fictitious brand (Expert Financial Services) as well as some filler ads and articles. In the magazine directed toward Americans, the ad was in English. The magazine directed toward Chinese Americans was exactly the same, except that the brand name in the ads was written in English and in Chinese characters. After having scanned the magazine, respondents were asked to respond to a short survey.

Results. A 2 X 2 ANOVA was conducted with perceived honesty (2 items: dishonest-honest, insincere-sincere) of the magazine and the ad as dependent variables and identity denial (identity denial vs. no identity denial) and type of ad (ad targeted toward Americans vs. ad targeted toward Chinese) as independent variables. The two-way interaction between identity denial and type of ad was significant for the perceived honesty toward the magazine ($F(1, 42)=4.17, p<.05$). Planned contrasts revealed that when the respondents' identity was denied, they rated the magazine directed toward Americans ($M_{\text{american}}=5.75, SD=.84$) as more honest than the magazine directed toward Chinese Americans ($M_{\text{chinese-american}}=4.94, SD=0.85; F(1, 39)=4.03, p=.052$). However, this was not the case when their identity was not denied ($M_{\text{american}}=5.00, SD=.97, M_{\text{chinese-american}}=5.38, SD=1.06; F(1, 39) =.81, p=.375$).

The two-way interaction between identity denial and type of ad was marginally significant for the perceived honesty toward the brand ($F(1, 43)=3.63, p=.06$). Planned contrasts revealed that when the respondents' identity was denied, they rated the brand directed toward Americans ($M_{\text{american}}=5.33, SD=1.02$) as more honest than the brand directed toward Chinese Americans ($M_{\text{chinese-american}}=4.40, SD=1.79; F(1, 40)=3.17, p=.083$). However, this was not the case when their identity was not denied ($M_{\text{american}}=4.55, SD=.86, M_{\text{chinese-american}}=5.04, SD=1.12; F(1, 40) =.85, p=.363$). These results support our proposition that identity denial affects consumers' perception toward the magazines as well as toward brands targeting certain type of consumers.

As a next step, a series of experiments, which are currently executed, are testing the effect of other moderators on this relationship. These moderators include the impact of acculturation and strength of identity. Moreover, we also varied the identity denial manipulation in order to increase its external validity. We hope this research will be a first step in the understanding of the relationship between denial and consumption.

Do Males Endorse Thin Ideal for Women When the Price is High?

Maxim Polonsky, University of Connecticut, USA

Ioannis Kareklas, University of Connecticut, USA

Extended Abstract

Marketers claim that thin models are very efficient in selling products (Gillian, 2000). Research findings show that consumers generally associate thin with happiness, desirability, and status (Tiggemann, 2003). On the other hand, marketers and advertisers have been criticized for using thin models which adversely affect young women's self-esteem and body satisfaction (Martin and Gentry 1997). Hence, marketer's dilemma is evident: images that are most effective in selling products may also harm consumers the most. For example, Dittmar and Howard (2004) have shown that while the exposure to thin ideals in ads may harm an individual's body esteem, there is no difference between thin and average-size models in terms of advertising effectiveness (i.e. product and ad evaluation, and purchase intention).

Further, research indicates that omnipresence of idealized thin models has a cross-gender effect (Lavine, Sweeney, and Wagner 1999). Proliferation of thin-ideal images in male consumed media may lead to males' endorsement of thinness for women. Because men often influence, advice and participate in women's shopping decisions, we focus our investigation on males and ask whether body size of advertising models influences males' perception of product quality, price, and willingness to recommend and/or buy the advertised product for women.

Our experiment employs a between-subject 3 x 2 factorial design, investigating the effect of exposure condition (ads featuring thin models, plus-size models, and average models) and price (low and high) on the following outcomes: 1) advertising effectiveness (ad attitude, perceived product quality, model attitude, and purchase intention and 2) body-esteem and intentions to diet and lose weight. We introduce price variable as an important and potentially powerful moderator of body size effects on aforementioned dependent variables. Furthermore, because thin is associated with status, the absence of research on body size and price interaction is puzzling. We manipulate price in order to investigate whether price interacts with model body size and to determine under which conditions body and price create the perception of quality and elicit generally more favorable attitudes toward advertisements.

One hundred and sixty males participated in the online experiment. Upon login onto the website, participants were randomized into one of the six conditions and told that they are participating in a marketing research study that explores different communication and appeal strategies (print vs. video, reading detailed information versus watching a short ad, etc.) for two product categories—computers and women shoes. After completing pre-test, participants in each condition were referred to CNET.com page "Best 5 desktops" (<http://reviews.cnet.com/best-desktops/?tag=leftColumnArea1.0>) or similar updated page, and asked to read short one-paragraph review for each of the five computers. Next, participants answered filler questions about their liking, preference, and purchase intention for any of the reviewed computers. Upon the completion, study participants saw the experimental ad and filled a post-test questionnaire that consisted of a) questions about advertising effectiveness (e.g. ad evaluation, purchase intention), and b) questions about attitudes toward and behavioral intentions to diet and lose weight. Participants were deceived that the later part of the post-test was an unrelated small scale study that would be used to design local health marketing campaign. Six ads used in the study were separately pre-tested on one hundred and twenty undergraduate students. Our manipulation was successful.

To examine the effects of price and model body size on our dependent variables, we conducted a 2 (price: high and low) x 3 (model body size: thin, average, plus size) MANOVA. Our results showed significant main effects of price [Wilks' $\lambda=.71$, $F(6, 120)=8.13$, $p<.001$], of model body size [Wilks' $\lambda=.81$, $F(12, 240)=2.83$, $p=.013$], and a significant two-way interaction (Wilks' $\lambda=.80$, $F(12, 240)=2.24$, $p=.011$). For two independent variables, there were four significant main effects: the effects of body size on perception of price ($F(2, 147)=3.31$, $p=.04$), and model attitude ($F(2, 147)=4.82$, $p=.01$), and the effect of price on model attitude ($F(1, 148)=4.27$, $p=.04$) and perceived product quality ($F(1, 146)=4.43$, $p=.037$). The interaction of price with model body size was significant for all dependent variables, save body esteem, price perception, and product quality.

We describe main effects that are not complicated by the presence of significant interaction first. We find that price was evaluated least favorably in a plus-size model condition, and there were no statistically significant difference in price evaluations between the ads featuring thin and average models ($p=.18$). Main effect of price on product quality revealed that higher price signaled higher quality ($p=.037$). Follow-up univariate post-hoc comparisons between groups revealed that consumers' attitude toward the ad was the least favorable in a high price average body condition; in a low price condition, however, average model elicited more positive ad attitudes relative to thin and plus-size models. Further, our findings indicate that thin model was evaluated more positively relative to plus size and average models only in a high price condition. In a low price condition average model was preferred. We expected higher values of purchase intention when thin model was paired with high price. Although mean value for purchase intention for this particular condition was the highest, it was not significantly different from plus size model in the same condition. Again, we find that average model had a positive effect on purchase intention in a low price condition and negative effect in a high price condition. In a low price condition, the purchase intention was the lowest for thin model.

Last but not least, although price and body size manipulation did not affect males' body-esteem, there was an interaction effect of two independent variables on intention to diet. Specifically, males exposed to a thin model paired with high price, were more likely to indicate their intention to diet and lose weight. We focus our discussion on these controversial findings while more data is being collected.

Who Said Multitasking is Bad? The Benefits of Doing Two Things at The Same Time

Sydney Chinchachokchai, University of Illinois, USA

Brittany Duff, University of Illinois, USA

Robert S. Wyer, University of Illinois, USA

Consumers are often multitaskers, turning on a TV while flipping through a magazine or talking on a cell phone while browsing through grocery aisles. In everyday life, people often engage in multiple tasks at the same time. Multitasking behavior in consumers is an area underexplored yet important for marketers to understand in its impact on advertising effectiveness.

Although multitasking has been explored in psychology and consumer research, most studies show that when people perform two tasks simultaneously, their performance on one or both tasks decreases (Hembrooke & Gay 2003). In some cases, however, performing a secondary task can actually increase one's attention to a primary task by preventing one's mind from wandering and, therefore, may increase performance on the primary task and memory for the material that is relevant to it (Andrade 2009). This paper presents a preliminary look at why this difference may occur, particularly in an advertising context, and how multitasking affects memory under different levels of involvement.

In the situation where the two tasks are not equally cognitive demanding, the performance of one task may benefit the others. Performance decrements through competition for task-specific resources are moderated when the secondary task reduces the mind-wandering that can be a hidden feature of single task control conditions (Smallwood et al 2007). fMRI studies have also shown that as central executive demands of tasks decrease, stimulus-independent thought (mind-wandering) increases (Mason et al 2007). These stimulus-irrelevant thoughts have been shown to lower performance on memory tasks (Seibert & Ellis 1991), showing that there might not always be straightforward effects of multitasking on consumer memory.

One exception to the lack of research on multitasking and advertising is Shapiro and Krishnan (2001). In this study, attention was divided by playing an audio program at the same time ads were shown on slides. However, this study compared dual-task groups and did not look at possible detrimental effects of a single-task, particularly when the single-task is not involving.

The concept of involvement is an important moderator of the amount and type of information processing elicited by a persuasive communication (Petty & Cacioppo 1981). High-involvement messages have greater personal relevance and consequences or elicit more personal connections than low-involvement messages (Krugman 1965). According to the elaboration likelihood model, as product increases in personal relevance or consequences, people are more motivated to devote cognitive effort required to evaluate it when involvement is high rather than low (Petty et al 1983). High involvement also leads to greater attention and comprehension (Celsi & Olson 1988). When the level of involvement is high, consumers are more motivated to process salient product information in advertisements. They also exert greater cognitive effort during comprehension of the ads, increasingly focusing their attention on the product-related information (Celsi & Olson 1988). Therefore, people who are performing a low cognitive-demand task (such as doodling) while low-involvement ads are presented should recognize product and ad points more than those who are not performing the task. A high-involvement ad may be able to draw attention from the audience by itself, therefore, the low demand task should not help ad memory in this case.

A study was conducted to examine the effect of a low cognitive demand secondary task on memory. In this experiment, we used doodling as a secondary task. Participants ($n = 77$; 2×2 (Task \times Involvement)) were told to listen to a series of monotonous radio commercials as if they were listening to the radio at home and form an impression toward the ads. Participants were randomly assigned into one of the two conditions (dual-task vs. single-task). In the dual-task condition, they performed a "doodling task" while listening to the commercials. Participants were provided paper with shapes on the left hand side and asked to copy the target shapes into the blank spaces. The single-task group only listened to the ads. There were two versions of the target commercial: high and low involvement. Each group heard five radio ads with four ads that were the same for all groups. The target commercial (high or low involvement) was placed at the end in order to generate a boredom effect. After the commercials finished playing, participants wrote down their impression and answered filler questions about the other ads that played and then performed a recognition task on 15 product and ad points (correct and foil).

A separate group ($n = 23$) rated only the high or low involvement ad (no other ads or tasks) confirmed the high-involvement ad was easier to pay attention to, was less boring, and had a more interesting product than the low-involvement ad

The results supported the hypotheses. There was a significant interaction effect between doodle task and the level of involvement on the ad recognition [$F(1,73) = 7.89$, $p < 0.01$]. Participants in the dual-task group scored lower than the single-task group in the recognition task when the target ad was high-involvement. Importantly, the opposite was true for the low-involvement condition. Dual-task participants actually scored higher in the ad recognition task than the single-task participants.

There is a significant main effect of involvement on the target ad [$F(1,73) = 8.65$, $p < 0.01$]. Participants in both groups rated the target ad in the high-involvement condition as more interesting than in the low-involvement condition. As expected, the effect was not significant for other ads ($p > .1$, n.s.), indicating the manipulation worked as intended. There was also a significant interaction in self-reported boredom between two groups $F(1,73) = 6.7$, $p < 0.05$. Specifically, for those that listened to the low-involvement ad, the dual-task condition was less bored than the single-task condition. However, in the high-involvement condition, the difference in boredom was not significant. This indicates that the secondary task keeps participants from being bored especially when they are not interested in the primary task (ads).

Multitasking is not always inefficient and sometimes can actually help memory, particularly in low-involvement conditions. Future studies will examine in more depth the role of mind-wandering and stimulus independent thought as well as the limits of the effect in terms of task load, the role of goals in multitasking, as well as individual differences such as attentional control.

Increasing Persuasion While Decreasing Recognition: Exploring the Interactive Effects of Product Placements on Consumers in a State of Ego-Depletion

Brian Gillespie, Washington State University, USA

Jeff Joireman, Washington State University, USA

The majority of people who watch television, watch during evening "primetime" hours. While they watch, they are frequently exposed to product placements stemming from a \$3.36 billion dollar industry (PQ Media 2007). Importantly, before people sit down to watch primetime television, most spend their day regulating their behavior (e.g. being at work when they would rather be golfing, or working to put their kids to bed when it would be easier to just let them stay up). Past research suggests that engaging in such tasks is likely to lead to a state of "ego-depletion" (Baumeister 2002). This is important because past research shows that ego-depletion interferes with cognitive functioning on challenging intellectual tasks (Schmeichel, Vohs and Baumeister 2003). Furthermore, past research has shown when cognitive resources are limited and individuals have no motivation to process a message, the message is processed peripherally and persuasiveness (positive impact on attitudes) increases (Petty, Cacioppo and Schumann 1983).

This suggests two hypotheses. First, when viewers are in a state of ego-depletion, they may be more positively influenced by lower plot connection (LPC) product placements—products that are subtle and not connected to the plot in a meaningful manner—because LPC placements offering no motivation for the viewer to process the placement. Motivation to process higher plot connection (HPC) product placements—products that are blatant and connected to the plot in a meaningful manner—does exist, so no differences between conditions are expected. Second, the lack of cognitive resources available will interfere with ego-depleted viewers' ability to recognize LPC placements. HPC placements, however, are so blatant that all individuals will recognize them. This reasoning led to the following two hypotheses:

H1: For LPC product placements, individuals in an ego-depleted condition will experience a significant increase in brand attitudes. There will be no difference for HPC product placements.

H2: For LPC product placements, individuals in an ego-depleted condition will experience a significant decrease in brand recognition. There will be no difference for HPC product placements.

Method

Participants were 50 undergraduate students participating for course credit. Two participants' results were dropped due to their inability to follow instructions. Participants arrived and participated in the study individually. The experimenter was blind to participants' condition.

Upon arrival, half the participants were given instructions designed to result in ego-depletion. We used a standard attention regulation based ego-depletion manipulation (Schmeichel et al. 2003). Following the ego-depletion manipulation, participants watched an episode of a popular 30 minute primetime comedy television show from a major television network. The episode used in this study was chosen because pilot testing—on a different group of participants—indicated that participants liked the show, recognized the brands involved

in the product placements, and had neutral brand attitudes toward those products. After participants watched the show, they reported their attitudes toward brands that were and were not placed in the show using a 7-point likert scale (1=strongly dislike to 7=strongly like). After participants evaluated the brands, they completed a recognition task in which they indicated the brands they recognized seeing in the show.

Major Findings

Manipulation Checks. After the ego-depletion manipulation, participants rated the difficulty of the video-viewing task. As expected, participants in the ego-depletion condition reported that the task was significantly more difficult than participants in the control condition ($p=.001$). To rule out mood as an alternative explanation, participants also completed a mood scale. Results showed no significant difference between the conditions in negative or positive mood ($p>.58$). These results suggest a successful ego-depletion manipulation that is not confounded with mood.

Hypothesis Tests. To begin the analysis, we first standardized the participant's reported brand attitudes and recognition using z-scores. We did this for two reasons. First, in standardizing scores, we were able to control for previous participant attitudes toward products. Second, in standardizing the data, we were able to compare brand recognition and brand attitudes on the same scale.

A 2 x 2 x 3 (Control vs. Ego-depletion, Attitudes vs. Recognition, LPC vs. HPC vs. Not placed) mixed model ANOVA, revealed a significant three way interaction, $F(2,45)=6.14$, $p<.01$. We followed this up by examining the simple 2 x 2 (Control vs. Ego-depletion, Attitudes vs. Recognition) interaction within each level of "plot connection" (low, high, not placed).

The 2 x 2 interaction was not significant within either the not placed or the high plot connection conditions. However, in the LPC condition, there was a significant interaction between conditions, $F(1,46)=7.42$, $p<.01$. We further explored the simple effect of ego depletion on attitudes and recognition. Consistent with hypothesis 1, brand attitudes were higher among those in the ego depletion condition ($M=.24$) than those in the control condition ($M=-.24$), $F(1,46)=2.77$, $p=.05$ (one-tailed). Also, consistent with hypothesis 2, recognition was higher among those in the control condition ($M=.29$) than those in the ego depletion condition ($M=-.29$), $F(1,46)=4.18$, $p<.05$ (one-tailed).

Conclusion

To date, most product placement research has focused on either the nature of the placement, such as its connection to the plot (Russell 2002), or pre-existing differences between viewers such as viewers' connection to the show (Cowley and Barron 2008) or its actors (Russell and Stern 2006). The current paper expands product placement research by exploring whether the effectiveness of product placements depends on temporary variations in viewers' self-regulatory strength. Assuming that there is little motivation for individuals to process LPC product placements, we hypothesized (and found) that ego-depletion increased brand attitudes toward LPC product placements while at the same time decreasing recognition of those same brands. These effects suggest that while ego-depleted individuals are less aware of LPC placements than non ego-depleted individuals, they are more positively persuaded by those placements. The present results underscore the importance of ego-depletion for research on product placement.

True Lies in Online Research: How to Determine Accuracy in Web Surveys

Boris Toma, University of Mannheim, Germany

Daniel Heinrich, University of Mannheim, Germany

Hans H. Bauer, University of Mannheim, Germany

Extended Abstract

The growth and diffusion of the Internet have led to a rapid development of surveys on the World Wide Web (WWW) by opening new opportunities for collecting and disseminating research information. Existing research on web surveys has mainly focused on comparing internet-based and traditional mail surveys or on combining existing evidence into a meta-analysis (Cook, Heath, and Thompson 2000; Ilieva, Baron, and Healey 2002; Sheehan 2001; Shermis and Lombard 1999). Main focus has thereby been placed on response rates. While methodological research around response quality in online surveys is still limited (O'Neil and Penrod 2001; Deutskens et al.

2004), past research has mainly determined data quality by strictly quantitative measures such as the number of omitted items (item-nonresponse) or dropouts (Goeritz 2004; O'Neil and Penrod 2001; Tuten, Galesic, and Bosnjak 2004; Frick, Baechtiger, and Reips 2001). Little or no attention has been paid to the motivation and attitude of respondents, and the question whether respondents give accurate answers to survey questions.

In two experimental studies, we propose mechanisms, which are appropriate to identify inaccurate response behavior. In our first survey, we provide an incentive and examine three groups, which have been recruited by (1) email, (2) online panel and (3) virtual communities. By determining the data quality of the three experimental groups, we are able to draw conclusions on effective indicators for accurate response behavior in online surveys. In order to explore whether results will vary when no incentives are given, we conduct a second study replicating our first one.

In the context of surveys, data quality is merely a function of the amount of error in the data. The more accurate the data (or: the less erroneous the data), the higher is the quality of the data (Biemer and Lyberg 2003). An approach that focuses on accuracy and that is often used for analyzing the several different sources of error in surveys is the total survey error (Groves et al. 2009). Following Assael and Keon (1982, 115), total survey error is "a function of the difference between the overall population's mean true value and the mean observed value obtained from the respondents of a particular sample" and can be measured by the mean squared error. But even though Weisberg (2005) elaborates the importance of response behavior within the concept of total survey error, existing literature mostly examines data quality on the basis of indicators such as item-nonresponse or dropouts and gives recommendations on how to design questionnaires in order to minimize error (MacElroy 2000; Deutskens et al. 2004). However, even a perfect questionnaire does not necessarily prevent respondents from giving inaccurate answers.

Thus, it is imperative to broaden the scope on the response process when determining data quality. An accurate response requires going through all of the four stages of the response process (Tourangeau 1984), but not all of the respondents do so. In fact, this depends on the respondent's motivation and other factors (Tourangeau, Rips, and Rasinski 2000). Incentives are a widely spread means of motivating people (Manfreda and Vehovar 2008). Past research shows that incentives do raise response rates and motivate respondents to finish surveys (Tuten, Bosnjak and Bandilla 2000). Nevertheless, the impact of the incentive depends on the whole context of the web survey, especially on the way of recruiting and the population targeted (Manfreda and Vehovar 2008).

Hence, in study 1 we conducted an experimental web survey by using a 1x3 design, with the form of recruiting (email, online panel, and virtual community) as the independent variable and the data quality as the dependent variable. Respondents in the first group were invited by an email that was sent from their e-mail hosting service. The second group was made up of online panelists, who regularly participate in online surveys. Respondents from group three were acquired by web banners in virtual communities such as facebook. The three groups (n=532) were exposed to the same questionnaire, which consisted of several questions and items. These mechanisms allow us to check the respondent's motivation and manipulation attempts and thus the response accuracy. For instance, we asked the same question on different scales (semantic differential versus Likert scaling). We also checked the length of answers in an open question as well as the misspelling. Altogether we developed more than 15 of these mechanisms. The three groups in our first study were promised an incentive for completing the questionnaire. As the panelists were paid in bonus points, we set a voucher for an online music store as incentive for the email and virtual community group. To ensure comparability, the voucher amounted to the cash equivalent of the bonus points (€ 1). In order to determine data quality we used the total survey error approach. The empirical values for each group were externally validated so that the mean squared error could be computed. By this means, the mean squared error compared empirical and true values and alluded to accuracy of data within the three groups. By using this measure, we were able to determine data quality.

In study 2 the experiment was replicated with the same parameters but without an incentive for the respondents. We ought to examine whether intrinsic motivation, such as altruistic or issue-oriented factors, results in higher data quality than extrinsic motivation, and if yes whether different mechanisms of response behavior account for that.

Our research shows that the respondents who were acquired in virtual communities give the most accurate answers. This is in accordance with prior research, as people in virtual communities tend to be more faithful and talkative (Williams 2001). In opposition to the academic literature, the virtual community group that received an incentive features higher data quality than the non-incentive group, but still the quality of the group without incentive is high. Moreover, first results show that we identified several mechanisms (questions and items) with focus on the respondent's motivation that effectively determine data quality. We therefore propose to implement these mechanisms into future studies and surveys in order to revise our findings.

Attitudes and Behaviors Assessment: The Impact of the Hypothetical Bias

Caroline Roux, McGill University, Canada

Ulf Böckenholt, McGill University, Canada and Northwestern University, USA

Extended Abstract

Surveys consistently show that people are voicing strong support for environmental protection, but they seem to be paying lip service when an investigator asks whether they are taking actions to save the planet from climate change (Dolliver 2008). But why do environmentally conscious consumers tend to express recurrent equivocal or "aspirational" commitment to the environment (Dolliver 2008)? According to Cotte and Trudel (2009), we should not be surprised that consumers state to hold very positive attitudes toward the environment when surveyed about their environmental opinions, since survey researchers seem to rarely try to find subtle ways of eliciting more "true" responding. This suggests that the way consumers are surveyed about their pro-environmental attitudes and behavioral intentions can hinder their "true" reporting, and the goal of this paper is to better understand how survey formats can influence attitudinal and behavioral assessments.

Background

The hypothetical bias is an overestimation of willingness to pay in hypothetical or contingent markets, when compared to actual payments in otherwise identical real cash markets (Ajzen, Brown, and Carvajal 2004). This bias also applies to contingent valuation in the context of a referendum, where individuals that are confronted with a real referendum about contributing money to a worthy goal express less favorable reactions with respect to voting yes than individuals who are confronted with a hypothetical referendum (Ajzen, Brown, and Carvajal 2004). This suggests that hypothetical and real contexts are construed in very different ways, that they are qualitatively different, and that questions posed in such contexts can elicit very different responses (Ajzen, Brown, and Carvajal 2004). Moreover, according to Ajzen, Brown and Carvajal (2004), statements of willingness to pay in a hypothetical situation can be equated to behavioral intentions and the hypothetical bias to a discrepancy between intentions and behavior. We thus hypothesize that people should express different levels of attitudes in different contexts:

H1: People express stronger attitudes and behavioral intentions in a hypothetical context than in a real one.

Different ways to adjust for the bias have been demonstrated, but they mainly apply to contingent valuation studies (e.g., asking participants to respond as if they were really spending their money; Ajzen, Brown, and Carvajal 2004). However, it seems that for contingent valuation survey to elicit useful information about willingness-to-pay, respondents must understand exactly what they are being asked to value (Johnston 2006). Hence, familiarity may lead to closer correspondence between intentions and behavior, and thus reduce or even eliminate the hypothetical bias (Johnston 2006). We thus hypothesize that familiarity could moderate the effect:

H2: People express similar attitudes and behavioral intentions in both concrete and hypothetical conditions when surveyed about familiar behaviors.

Furthermore, when people are asked to report an attitude, they often infer this attitude from the implications of a past behavior that happens to be salient to them at the time of the reporting (Albarracín and Wyer 2000). In fact, subjective judgments of attitude certainty, intensity, and importance are affected by the subjective ease of retrieval of experiences that accompany the recollection of attitude-relevant information (Haddock et al. 1999). In addition, construal level theory states that people represent hypothetical tasks in a more

abstract, high-level terms, and real tasks in a more concrete, low-level terms (Armor and Sackett 2006; Trope, Liberman, and Wakslak 2007). Consequently, we hypothesize that reporting behavioral intentions could have the same effect as making salient past behavior on people's attitude assessment, and that the hypothetical bias should moderate the informational value of behavioral intentions:

H3: Behavioral intentions are used as more abstract information in a hypothetical context and as more concrete information in a real context in further assessments.

Study

These propositions were tested within the realm of environmental protection. Respondents (114 undergraduate students) pledged to perform behaviors from statements (Roberts 1996) that were formulated either in a hypothetical or a concrete way. Results from the study provided support for our hypotheses.

When asked to pledge to perform hypothetical behaviors (e.g., I pledge that I would buy), participants expressed greater behavioral intentions than when asked to pledge to perform actual behaviors (e.g., I pledge to buy; 4.26 vs. 3.31, $p < 0.001$), which supports H1. Moreover, familiarity seems to moderate this effect, since there is no significant difference between the hypothetical and the concrete conditions (4.15 vs. 3.98, $p > 0.1$) for what appears to be more familiar behaviors (i.e., behaviors that are performed inside the home—e.g., recycle, save energy and water), while there is a significant effect (4.03 vs. 3.54, $p < 0.05$) on less familiar, and maybe less concrete behaviors (i.e., behaviors that are performed outside the home or related to social activities in support of the cause—e.g., buying fair-trade or organic products, convincing friends to be more eco-friendly), thus supporting H2.

Furthermore, when in a hypothetical condition, participants expressed stronger attitudinal self-relevance with the environment than in the concrete condition (3.97 vs. 3.76). On the other hand, when in a concrete condition, participants stated that they perform more actual behaviors that in the hypothetical condition (3.48 vs. 3.81). The interaction effect is significant ($p = 0.05$). People thus seem to be inferring their attitudes from the actions that they are willing to do and their level of hypotheticality, since there is a match between “would-behavior” and self-relevance and between “do-behavior” and reported behaviors, providing support for H3.

Discussion

Our study shows that there is a hypothetical bias in the pro-environmental domain, that this bias affects how people assess their attitudes and behaviors, and that it is moderated by familiarity. Moreover, making people think more abstractly or more concretely about their behaviors affects their self-relevance perception or their retrieval memory of past behaviors, respectively.

The next step is to try to better understand the process underlying the hypothetical bias, and to establish a link with actual behavior, in order to determine whether the hypothetical bias results in more or less actual behavioral consistency.

The Abstractness of Luxury

Jochim Hansen, New York University, USA
 Michaela Wänke, University of Basel, Switzerland

Almost everyday, consumers buy and use commodities such as food, clothing, or other necessities. Sometimes, however, they may indulge in luxurious goods (Kivetz and Simonson, 2002). Yet, luxury purchases are exceptions to the rule as they occur rather seldom and often are merely hypothetical.

Moreover, luxury cannot be purchased everywhere; it is usually limited and for most people difficult to attain (Miyazaki, Grewal, and Goodstein, 2005; Nuemo and Quelch, 1998; Silverstein and Fiske, 2003). As such, luxury is something that only a few people can

afford; and luxurious goods are usually consumed especially by the higher upper-class society, which implies a connection between luxury and exclusiveness. Since luxurious goods are relatively exclusive and their acquisition is limited and often only hypothetical, they generally are perceived as more psychologically distant than ordinary objects.

Construal Level Theory (Trope and Liberman, 2000, 2003) assumes that psychologically distant objects are construed abstractly, whereas proximal objects are construed concretely. An abstract representation of an object consists of its high-level features which capture the central and stable aspects of an object. A concrete representation, on the other hand, includes more low-level aspects such as incidental details that are peripheral to the object's core representation.

Because luxury appears to be psychologically distant, and because psychologically distant objects are mentally represented more abstractly than psychologically proximal objects, we propose that luxury is mentally construed abstractly instead of concretely. In three studies, we investigated the bi-directional relationship between luxury and abstractness of mental representations. Study 1 tested whether consumers describe situations that involve luxury objects in a more abstract language than situations that involve comparably mundane objects. Study 2 tested the converse relationship and showed that products that are described in abstract language are perceived as more luxurious than products that are described in concrete language. Finally, study 3 showed that actual product descriptions of luxury goods are more abstract than descriptions of ordinary goods.

In study 1 which was framed as a creativity study, we asked participants to write a short story by using 12 specific words that should appear in their text at least once. For half of the participants, the list included 6 words that are associated with luxury (i.e., mansion, gourmet restaurant, limousine, 5-stars hotel, candelabra, and gemstone). For the other half of the participants, the target words were exchanged with their ordinary counterpart (i.e., house, canteen, car, hostel, lamp, and stone). The stories were analyzed with the Linguistic Category Model (Semin and Fiedler, 1988, 1991). This model distinguishes between several classes of word (descriptive action verbs, interpretive action verbs, state verbs, and adjectives) that can be located on the concreteness–abstractness continuum. The relative proportions of words of the different classes were determined by two coders who were unaware of the hypothesis, in order to measure the abstractness of the texts. As hypothesized, the findings indicated that stories that included luxurious objects were linguistically more abstract than stories that included ordinary objects.

In study 2, we tested the converse relationship and hypothesized that abstract descriptions of products cause consumers to perceive them as more luxurious than concrete descriptions. Participants were presented with short descriptions of six product types (i.e., yacht trips, dog food, cars, TV sets, vacuum cleaners, and watches). For each product type, we presented two descriptions—one abstract and one concrete. For the vacuum cleaners, for instance, one feature of the abstract description reads "...this unit has a very good vacuum pump, a low sound level, and a clever filtration." The more concrete counterpart reads "...this unit vacuums very well, does not make much sound, and filtrates dust cleverly." The content of the descriptions was counterbalanced in such way that specific features appeared either only in an abstract language or only in a concrete language. Participants were asked to judge for each product type on an 8-point scale which of two descriptions (concrete vs. abstract) they perceived as more luxurious, more expensive, and more exclusive. As expected, the findings indicated that the abstract descriptions were judged as more luxurious for these items.

Finally, in study 3, we were interested in the link between luxury and abstractness in real-world product descriptions. Forty-six descriptions of diverse products (23 luxury, 23 mundane products) were located on the Internet and analyzed regarding their linguistic abstractness. In line with the results of studies 1 and 2, we found that luxurious goods were described with more abstract language than mundane objects. This effect emerged (1) when comparing luxurious products with mundane products (e.g., fragrances vs. detergents), (2) when comparing two instances of the same product type (e.g., luxury cars vs. cheap cars), and (3) when comparing products within specific brands (e.g., the most expensive razor vs. the cheapest razor of the same brand). These findings give a first indication that advertisers may intuitively use the abstractness-luxury link in promoting their products.

In summary, the findings of the present research document that luxury is associated with an abstract representation: Luxury caused a more abstract language (both in study participants and in advertisers), and abstract language caused perceptions of luxury. The findings have important implication for advertising: An abstract presentation may lead consumers to perceive products as more exclusive, more luxurious, but also as more expensive.

When Closer is Better: The Influence of Physical Distance on Consumer Judgment of Product Effectiveness

Xiuping Li, National University of Singapore, Singapore
Boyoun (Grace) Chae, University of British Columbia, Canada
Rui (Juliet) Zhu, University of British Columbia, Canada

Extended Abstract

This study was motivated by new drug-failure cases in real life. The most prominent case is Pfizer's \$2.8 billion withdraw of its needle-free insulin inhaler when it failed to convince the patients about the effectiveness of the new format of the medicine (Johnson, 2007). This case makes us wonder what influences people's judgment of the efficacy of a drug, or in a broader sense, the effectiveness of a product on addressing a particular problem. This research will investigate the effect of spatial distance on perception of product effectiveness.

It has been found that spatial distance (i.e., "near-far") influences individuals' judgment. For example, people who were primed with spatial closeness (versus distance) showed an increase in emotional intensity toward stimuli (Williams & Bargh, 2008). People also use spatial distance to avoid influence from unfamiliar (Patterson & Sechrest, 1970) and undesirable objects (Kim, Ellen, & Margaret, 1992). Based on these observations about the relationship between spatial distance and intensity, we predict that people will judge a product to be more effective when it is physically close to the focal problem. Moreover, we also posit that the effect of spatial distance on effectiveness judgment is moderated by how long it takes the product to become effective. Last, we argue that people's lay theories about distance and effectiveness will moderate the demonstrated impact of spatial distance. These predictions are tested and supported by 4 studies we have conducted in our labs.

In Study 1, participants were asked to judge how effective a new over the counter (OTC) drug was at treating allergies with nasal symptoms. The perceived spatial distance was manipulated by different drug types: nasal spray versus tablet that people take orally. Since spray works closer to the affected area (nose) than the tablet, we predicted that people would judge the product in the spray format to be more effective than that in the tablet format. Participants read similar product information and the only differences were drug formats and corresponding images of the new drug. As anticipated, we found that people evaluated the drug to be more effective when the product was in closer contact to the symptomatic problem areas (i.e., nasal spray vs. table). The aim of study 2 was to replicate experiment 1 results and to further test how people's belief of the relationship between the spatial distance and efficacy of the product in general might moderate the observed effect. The procedure of Study 2 was similar to that of Study 1 except that participants indicated the extent to which they believed that closer (vs. farther) distance between a solution (e.g., product) and a problem would imply greater effectiveness. As anticipated, regression analysis revealed that the belief strength moderated the main effect of spatial distance. Specifically, people who strongly believed there was a relationship between closeness and efficacy judged the nasal spray format as more effective than the tablet format. However, such a pattern was absent among participants who did not hold such strong beliefs.

Study 3 aimed to demonstrate another boundary condition for the effect of spatial distance on efficacy judgment. We predicted that the closeness is more related to immediate effectiveness. When a drug was intended to solve a problem gradually, over the long term, the closeness would not impact the efficacy judgment to the same extent. A 2 (nasal spray vs. tablet) X 2 (immediate solution vs. gradual solution) factorial design was applied. Consistent with our prediction, the results revealed a significant interaction. In particular, when the drug claimed to have immediate relief, consumers judged the drug in nasal spray format to be more effective than in a tablet format. However, no effect was found when the drug was introduced as a gradual relief to the problem.

Study 4 further investigated our theorizing by manipulating spatial distance in a different manner. Here, we manipulated the perceived spatial distance by varying the distance between a drug image and an agent image (e.g., a picture of patient) in the advertisement. In the spatially close condition, the product was placed next to problem agent; whereas in the remote condition, the two images were put relatively far away from each other on the same page. Participants were assigned in a 2 (spatial distance close vs. far) X 2 (immediate relief vs. long term relief) between-subjects design study. In order to test the role of lay theory (i.e., general belief about the relationship between distance and effectiveness), we also measured the strength of each participant's belief in this relationship. Regression analyses revealed a significant three-way interaction. Only those people who had relatively strong belief in the relationship between distance and effectiveness judged the drug to be more effective when the images of the drug and the agent were proximal rather than distant to each other.

In sum, across four studies and using different methods to manipulate spatial distance, we showed the role of spatial-distance on judgment of product effectiveness. We also demonstrated that the lay beliefs about the distance-effectiveness relationship moderated the effect.

Does Bodily Feedback Signal Differential Psychological Distance? The Effect of Approach and Avoidance Motor Action Signals on the Level of Construal for Mental Representation

Fang-Chi Lu, University of Iowa, USA

Dhananjay Nayakankuppam, University of Iowa, USA

Extended Abstract

A body of literature has suggested that the chronic-built association between isometric arm flexion/extension contraction and approach/avoidance motivational orientations influences people's judgment and attitude formation (Cacioppo, Priester, & Berntson, 1993; Peiester, Cacioppo, & Petty, 1996). Arm flexion (by pressing upward on a table) produces bodily feedback which is associated with approaching positive stimuli; while arm extension (by pressing downward on a table) provides the association with avoiding negative stimuli (Forster, 1998; Forster, & Strack, 1997). This motor action effect is bidirectional. Performing arm flexion vs. extension makes people evaluate a neutral object more positively or negatively; presenting people with positive vs. negative valenced stimuli also automatically activates an approach vs. avoidance motor tendency (Bargh, 1997).

Construal level theory was recently suggested by Liberman and Trope (1998) as a framework linking psychological distance and abstraction. According to their theory, the chronic association between psychological distance (temporal, social, spatial or hypothetical) and abstraction in cognition leads to the tendency to mentally represent a distant object with higher-level (abstract) construals, while represent a near object with lower-level (concrete) construals.

We propose that the approach vs. avoidance motor actions, bringing things toward or away from oneself, might signal differential psychological distance. That is, the arm flexion contraction is associated with near psychological distance and arm extension is associated with far psychological distance. Therefore, performing arm flexion might lead to the tendency of construing objects with more concrete, subordinate terms; while performing arm extension leads to a more high-level construal mental representation of objects. Two studies were conducted to test this proposition.

In Study 1, participants were presented with a series of pictures of objects from four different categories (vehicle, clothing, furniture, and fruit) on the computers. The choice of exemplars for each category is following Rosch's (1975) norms, with exemplars having differential typicality to their corresponding categories. The presentation order of the objects was randomized. After seeing each picture, participants were asked to assign the item to a superordinate or a subordinate category (i.e. a picture of apple followed by two categorization choices: apple and fruit). Response time on categorization decision was also measured. While performing the categorization task, participants were asked to either place their palm on the bottom (flexion) or on the top (extension) of the table. We predict that when an objects is presented under arm flexion, less psychological distance of the object is perceived, thus people are more likely to represent it at more concrete construals, which in turn leads to a more subordinate categorization. On the other hand, arm extension will lead to a more superordinate categorization. Repeated measure ANOVA was performed with isometric exercise (flexion vs. extension) as between-subjects variable, and we looked at the isometric exercise effect on both binary categorization choice and response time. Results from the vehicle category support our hypothesis. A significant categorization by motor action interaction effect was shown on the response time ($P=.01$). When performing arm flexion, people were faster at assigning items to a subordinate category (i.e. car) ($RT_{\text{superordinate}}=2087$; $RT_{\text{subordinate}}=1449$ mini sec.); while performing arm extension, people were faster at assigning items to a superordinate category (vehicle) ($RT_{\text{superordinate}}=1393$; $RT_{\text{subordinate}}=1567$ mini sec.).

In Study 2, Vallacher and Wegner's Behavioral Identification Form (BIF) (1989) was used as the test stimuli to measure the construal level of people's action identification under different motor action conditions. Specifically, while performing isometric exercise, participants were asked to choose between a high-level and a low-level identity on the 25 action items from the BIF scale (i.e. Reading: a. following lines of print; b. gaining knowledge). The presentation order of the two alternatives was counterbalanced. We predict that people under arm flexion are more likely to choose low-level identity of the actions; while people in the arm extension are more likely to choose high-level identity of the actions. Results of analyses support our prediction ($p=.06$).

Taken these two studies together, we found the effects of bodily feedback on the level of construals being used to represent objects or events. When people are performing arm extension contraction, they tend to form a mental representation in higher-level, more abstract terms, and categorize things at a superordinate category; while performing arm flexion contraction leads to a lower-level, more concrete mental representation and a more subordinate categorization.

Previous research has suggested that effect between construal and psychological distance is bidirectional. Manipulations of construal would affect distance perceptions in the same way as the distance of an event influences its construal. Therefore, one of the future research directions will be to test the direct effect of approach/avoidance motor actions on the perception of various dimensions of psychological distance. For example, in the temporal distance dimension, while performing arm flexion vs. extension contraction, participants will be presented with descriptions of a series of events (i.e. imagine that you're considering "opening a bank account", "enrolling in a fitness program"), and then be asked to answer how much time from now the activity would be performed (Liberman et al., 2007). It will be interesting to know if people's perception of psychological distance shifts with the motor actions being performed.

A Regulatory Focus–Reactance Perspective of Consumer Reward Preferences in Loyalty Programs

Meltem Tugut, Saint Louis University, USA

Mark J. Arnold, Saint Louis University, USA

Extended Abstract

Regulatory focus theory (Higgins 1997) suggests that individuals differ in how they approach pleasure and avoid pain. These differences are manifested in two distinct regulatory systems which govern how people pursue goals: promotion focus and prevention focus (Higgins 1997). When it comes to consumption, different product attributes help individuals fulfill different regulatory focus goals. It has been shown that hedonic products allow consumers to reach their promotion-focus goals whereas utilitarian products permit them to realize their prevention-focus goals (Chernev 2004; Dhar and Wertenbroch 2000). In this research, we explore whether the “fit” between hedonic products and promotion-focus and that between utilitarian products and prevention-focus holds true in the context of loyalty rewards programs. Specifically, we propose that psychological reactance aroused by loyalty programs may result in reward preferences that do not necessarily match individuals’ regulatory goals.

Regulatory focus can be a chronic individual trait or situationally induced (Aaker and Lee 2001; Higgins et al. 2001). Promotion-focused individuals are concerned with the presence and absence of positive outcomes (gains and non-gains) to pursue maximal goals of advancement, growth, and accomplishment (Camacho, Higgins, and Lugar 2003; Higgins 2000). On the other hand, prevention-focused individuals are interested in the presence and absence of negative outcomes (losses and non-losses) to attain minimal goals of protection, safety, and responsibility (Brendl and Higgins 1996; Idson, Liberman, and Higgins 2000).

Hedonic goods provide individuals with an affect-based consumption experience that delivers benefits of sensual fun, pleasure, and excitement (Hirschman and Holbrook 1982). Since individuals with promotion goals are inclined to maximize their potential gains, they place more emphasis on products that provide hedonic benefits in order to realize their “maximal” goals (Chernev 2004; Chitturi, Raghunathan, and Mahajan 2007). On the other hand, consumption of utilitarian goods is often cognition-based and driven by a need to acquire functional, practical, and instrumental benefits (Strahilevitz and Myers 1998). As individuals with prevention goals are concerned with minimizing their losses, they show a tendency toward products that present utilitarian benefits in order to fulfill their “minimal” goals (Kivetz and Simonson 2002).

However, this regulatory focus–product fit may not hold for consumers who choose between loyalty programs offering a hedonic vs. a utilitarian reward of equal monetary value. Loyalty programs are known to activate reactance among consumers (Kivetz 2005). Since loyalty programs demand commitment over a period of time in order to prevent switching behavior, consumers may perceive these programs as a restriction to their future freedom of choice and express reactance toward them (Kivetz 2005). The situational reactance experienced by individuals is partly driven by their level of chronic reactance (Hong and Faedda 1996).

We expect promotion-focused individuals to experience higher levels of chronic reactance than prevention-focused individuals. While promotion-focused individuals often adopt a more risky bias and consider various alternatives in consumption choice contexts, prevention-focused consumers usually follow a more risk-averse strategy and limit themselves to fewer alternatives. “Variety-seeking” people tend to express intense reactance toward threats to their freedom of choice.

When an extrinsic reward becomes salient as a potential reason for a particular behavior, people attribute their behavior to this outside influence (Kivetz 2005). Utilitarian rewards do not provide a strong extrinsic reason for consumers to exhibit specific consumption behaviors. Therefore, consumers believe that their behavior is not influenced by utilitarian rewards and do not perceive them as a threat. In contrast, hedonic rewards present a salient extrinsic explanation for particular consumption behaviors. Hence, consumers usually attribute their behavior to these incentives and see them as a threat to their freedom.

Since promotion-focused consumers are expected to have higher levels of chronic reactance, they are more likely to prefer loyalty programs that offer utilitarian rewards in order to alleviate their reactance toward such programs. On the other hand, as prevention-focused consumers are expected to have lower levels of chronic reactance and do not face the need to alleviate their reactance, they are expected to be indifferent toward loyalty programs that offer hedonic or utilitarian rewards.

We tested the present predictions in two studies. In Study 1, we used a regulatory focus (promotion vs. prevention) x loyalty reward (hedonic vs. utilitarian) two-factor design where the reward was manipulated as a between-subject factor through loyalty program scenarios and the regulatory focus was measured as an individual difference factor (N=236). Wine and a gasoline coupon (equal monetary value) were used as hedonic and utilitarian rewards respectively. The dependent variables were preference toward the loyalty program and the likelihood of joining the program. A MANOVA revealed that promotion-focused consumers are more likely to prefer and join loyalty programs offering utilitarian rewards compared to those offering hedonic rewards. Prevention-consumers were indifferent toward either type of loyalty program. Participants' chronic reactance was also measured and an ANOVA indicated that promotion-focused consumers were indeed higher in chronic reactance compared to prevention-focused consumers.

Study 2 utilized a regulatory focus (promotion vs. prevention) x loyalty reward (hedonic vs. utilitarian) two-factor design where both the reward and the regulatory focus were manipulated as between-subject factors through loyalty program scenarios (N=143). A restaurant certificate and a grocery coupon (equal monetary value) were used as hedonic and utilitarian rewards respectively. The dependent variables were the same as in Study 1. The MANOVA replicated Study 1 results. When individuals' promotion goals were made accessible, they showed a tendency to prefer and join loyalty programs offering utilitarian rewards vs. hedonic rewards. When prevention goals were induced, individuals were indifferent toward either type of loyalty program. An ANOVA indicated that promotion-primed consumers exhibited higher reactance compared to prevention-primed consumers.

The present research showed that consumers' preferences toward hedonic and utilitarian rewards in the context of loyalty programs may not necessarily fit their regulatory goals. The differences in the level of reactance experienced seem to influence consumers' reward preferences. Promotion-focused consumers, for whom reactance becomes a salient factor, tend to prefer utilitarian loyalty rewards to alleviate the resulting unpleasant state. Prevention-focused consumers, who are less concerned with reactance, are indifferent toward either loyalty reward.

The Impact of Counterfactual Mindset on Consumer Information Processing

Guangzhi Zhao, University of Kansas, USA

Kai-Yu Wang, Brock University, Canada

Extended Abstract

Counterfactual thinking is the process of looking back at events and thinking how things could have turned out differently. Whenever individuals consider how the past might have turned out differently, they are engaging in counterfactual thinking. For example, in consumption context, imagine that one consumer finds her HDTV needs repair just after the warranty expires. This consumer may think to herself: "If only I had purchased a TV with an extended warranty, I would not have to incur so much cost on this repair."

A large body of research has documented a wide variety of psychological (e.g., emotional and judgmental) consequences of engaging in counterfactual thinking. Two basic routes through which counterfactual thinking influences individuals have been differentiated in the literature: the content-specific route and the content-neutral route (Epstude and Roese 2008). Through the content-specific route, counterfactual thinking influences the same behavior specified by the counterfactual. In contrast, through the content-neutral route, counterfactual thinking influences individuals' behavior in domains that are independent of the counterfactual context. That is, independent of the meaning contained in a counterfactual thought, the process of counterfactual thinking can ignite attentional, cognitive, or motivational processes that will linger after counterfactual thinking and alter individuals' subsequent behavior in another domain. For example, counterfactual thinking in one domain (e.g., missing a flight) can influence behavior in a different domain (e.g., buying a book, ordering meal in the airport).

Recently, an emerging stream of research starts to study the content-neutral route, especially, the influence of counterfactual mindset (or cognition orientations) that results from constructing counterfactual thoughts (Galinsky and Moskowitz 2000). A counterfactual mind-set may involve a range of cognitive operations, including attention shifts to specific classes of information and the use of specific inferential strategies (Galinsky and Kray 2004; Krishnamurthy and Sivaraman 2002). In this research we explored how counterfactual thinking might activate another cognition orientation and influence consumers' preferences. Specifically, we propose that counterfactual thinking can activate a process/procedure-focused (i.e., "how to") cognition orientation, which leads consumers to construe activities

more often as “how to,” overweight product feasibility attributes in choice, and be persuaded more by ad messages promoting ease-of-use product features.

Counterfactual thinking often takes the form of a conditional proposition, in which individuals identify alternative routes or processes to mutate factual events. For example, Krishnamurthy and Sivaraman (2002) view counterfactual thinking as a problem-solving process which involves generating alternatives, steps, and solutions to solve problems. That is, counterfactual thinking involves mentally mutating a past event by re-running the sequence of the event and also simulating the necessary alternative steps or procedures needed to alter what has happened. In this way, counterfactual thinking may activate a process-focused information processing mentality and sensitize individuals to procedural information. This is especially true for counterfactual thinking involving a sequence of actions (e.g., one missed an important meeting because of first alarm clock failure, then being caught in traffic jams, and also getting lost the building) instead of single event (e.g., one missed the chance to win a trip to Hawaii because of seat switching) (Roese 1997).

In consumption context, the mindset of focusing on processes or procedural relationships created through counterfactual thinking will increase consumers' ability to perceive, understand, and value product ease-of-use or product feasibility in judgment and choice. Product feasibility, in addition to desirability, is a prominent consideration of consumer choices. Many times consumer decision making involves a trade-off between these two product attributes (Zhao, Hoeffler, Zaubermaier 2007). Several moderating conditions for consumers' preference for product feasibility and desirability have been identified in the literature, e.g., product trial experience, decision time distance, decision stage, etc. (Hamilton and Thompson 2007; Rothman 2000; Trope and Liberman 2000).

We propose that consumers' preference for product feasibility and desirability will be moderated by counterfactual thinking (vs. control). Specifically, consumers' preference for product feasibility will be boosted after going through counterfactual thinking in an unrelated domain. We conducted three experiments to test our hypotheses.

In Study 1, we examined how counterfactual thinking (vs. control) impacts the way in which individuals construe activities. 124 participants were randomly assigned to either a control condition or a counterfactual thinking group. Participants in the counterfactual thinking group were instructed to engage in counterfactual thinking with a standard procedure borrowed from the literature. Then, all the participants completed the Behavior Identification Form (BIF). The BIF, a 25-item, dichotomous-response questionnaire, assesses individual differences in level of action identification. For each item, participants read about an action (e.g., “voting”) and circled which of two identifications more appropriately described it. The choices corresponded to “how to” (i.e., procedural) identifications (e.g., “marking a ballot”) and ends identifications (e.g., “influencing the election”). A one-way ANOVA on the total number of “how to” identifications revealed a significant main effect for counterfactual thinking such that individuals gone through counterfactual thinking had a higher total number of “how to” identifications ($M=5.75$) than the control group ($M=4.70$, $F(1, 122)=6.52$, $p<.05$).

In Study 2, we employed a 2 (counterfactual thinking vs. control) x 2 (high-desirability and low-feasibility product vs. low-desirability and high-feasibility product) between subject factorial design to study how counterfactual thinking will impact consumer choices of product that are presented either in terms of product feasibility or desirability. A total 171 students participated in the study. The counterfactual scenario was modeled after the literature (Roese 1997). The scenario asked the participants to imagine that they experienced a broken camera on a beach during a vacation and later found out that the camera was broken because the camera was left on the beach too long and the battery was damaged. After reading the scenario, participants were asked to complete a series of “If only _____” counterfactual thinking sentences. The control group read the same scenario without going through counterfactual thinking and only wrote down their thoughts that went through their minds as they read the story. Then, participants read a product review from the CNET about MP3 voice recorder. The high-desirability and low-feasibility product was rated high on desirability attributes (e.g., recording quality, overall rating); whereas the high-feasibility and low-desirability product was rated high on feasibility (e.g., ease of use, quick to set up). Two-way ANOVAs revealed a significant two-way interaction between the two factors ($F(1, 167)=5.30$, $p<.05$). Further analyses showed that individuals gone through counterfactual thinking indicated higher intentions to choose the high-feasibility and low-desirability option ($M=4.79$) than the high-desirability and low-feasibility option ($M=4.09$, $t=2.43$, $p<.05$). There was no difference in the control condition. Similar results were found on other dependent measures including likelihood to buy and product attitude.

In Study 3, we seek to replicate the findings in Study 2 in persuasion context to further explore the role of counterfactual thinking on consumer information processing. It was a two-factor between subject factorial: 2 (counterfactual thinking vs. control) x 2 (ad promoting feasibility attributes vs. ad promoting desirability attributes). A total of 136 students participated in the study. A similar procedure was used to manipulated counterfactual thinking, but with a scenario about missing an important interview. Then participants were shown two digital camera ads promoting a pseudo brand. One ad had a headline of “An Easy Way to Capture Important Moments!” and highlighted the feasibility attributes of the camera (e.g., easy to frame and shoot pictures and videos, automatic face detection, etc.); the other ad had a headline of “An Perfect Camera for Important Moments!” and highlighted the desirability attributes of the camera (e.g., large LCD, true HD quality, etc). Two-way ANOVAs revealed a significant two-way interaction between the two factors on intention to use ($F(1, 132)=5.60$, $p<.05$). Further analyses showed that, for individuals gone through counterfactual thinking, they indicated higher intentions to use the camera after reading the ad promoting feasibility attributes ($M=5.02$) than the ad promoting desirability attributes ($M=3.84$, $t=2.68$, $p<.01$). The two ads were equally persuasive in the control condition ($t=.67$, $p=.51$). Similar results were found on other dependent measures including likelihood to buy and product attitude.

Taken together, these three experiments support our proposed theorizing that consumers' preference for product feasibility will be boosted after going through counterfactual thinking in an unrelated domain.

Counterfactual Priming Effects on Advertising Persuasion

Kai-Yu Wang, Brock University, Canada

Xiaojing Yang, University of Wisconsin-Milwaukee, USA

Extended Abstract

Counterfactual thinking (CFT) refers to the process of reflecting on past events and simulating alternative possible outcomes. CFT impacts consumers in many ways, including their emotions, judgments, and decision making. Consumers engage in CFT, either upward or downward, after experiencing purchase events. For example, imagine that your new plasma TV needs to be repaired immediately after the warranty expires. As you consider this repair, you might engage in upward counterfactual thinking, generating alternatives that are better than actuality, when you think, if only I had purchased a TV with an extended warranty, I would not have to spend so much money on this repair. Conversely, if you engage in downward counterfactual thinking as you contemplate the repair, you would generate alternatives that are worse than actuality. You might think, at least I did not purchase the model with the longer warranty and smaller screen, because I enjoy my large screen TV. CFT occurs in a variety of consumer contexts, regardless of the valence, positive or negative, of purchase outcomes.

In consumer contexts, it is important to understand how CFT affects consumers' future decision making. Such understanding will help marketers develop effective marketing strategies. Little consumer research has investigated related issues on this topic. Given that CFT may influence information processing (Krishnamurthy and Sivaraman 2002), it is important to determine how and when such effects occur. This research investigates how cognitive activities (i.e., CFT) initiated by previously encountered events (e.g., a negative purchase experience) impact consumers' subsequent processing of ad messages. Such motivational priming processes are only beginning to be understood in social psychology (Roese, Hur, and Pennington 1999, Galinsky and Moskowitz 2000), and have not received much attention in the consumer behavior literature.

After experiencing a purchase event, particularly following a negative outcome, consumers engage in either upward or downward CFT (Walchli and Landman 2003). Recent research has indicated that upward CFT impacts consumers' processing of subsequently encountered ad messages (Krishnamurthy and Sivaraman 2002). Consumers who engage in upward CFT scrutinize ad claims, and thus they are more persuaded by strong arguments than by weak arguments. Roese (1994) indicates that upward counterfactuals serve a preparative function and help to improve performance in the future. Following this logic, after a negative purchase outcome, consumers who engage in upward CFT should seek improvements over their previous experience. Thus, these consumers should process subsequent information via a central route, while those who do not engage in upward CFT via peripheral route, according to the elaboration-likelihood model, ELM (Petty, Cacioppo, and Schumann 1983). We argue that this mentality primed should affect consumers' preference for comparative appeals vs. noncomparative appeals.

Specifically, we conducted two experiments demonstrating the impact of CFT in response to previous consumption experience on the effectiveness of comparative advertising appeals that consumers subsequently get exposed to. In experiment 1, we show the effect of CFT on consumers' processing of subsequently encountered ad messages (comparative vs. noncomparative) that is relevant to prior consumption experience. In experiment 2, the effects observed in experiment 1 are replicated when subsequently encountered ad information is unrelated to the previous consumption experience, providing an extension of experiment 1 and establishing the robustness of the documented findings.

In experiment 1, counterfactual thinking (CFT and control) and ad format (comparative and noncomparative) were manipulated. We hypothesized that when presented with a comparative ad, respondents who receive instructions (vs. those who do not receive instructions) to think counterfactually generate higher ad evaluations, brand evaluations, and purchase intentions than in a subsequent related context. In contrast, when presented with a noncomparative ad, respondents who do not receive instructions (vs. those who receive instructions) to think counterfactually generate higher ad evaluations, brand evaluations, and purchase intentions in a subsequent related context. The results were consistent with our predictions. Examination of thought measures provided additional support for the hypotheses.

Experiment 2 replicated findings in experiment 1 in a subsequent unrelated context. All of our predictions were supported. Examination of thought measures also provided additional support for the predictions.

Taken together, these two studies support most of our proposed theorizing regarding the effect of CFT on consumers' processing of subsequently encountered ad messages (comparative vs. noncomparative) that is relevant/irrelevant to prior consumption experience. The studies reveal that respondents who engage in upward CFT process ad information via a central route whereas those who do not engage in upward CFT process ad information via a peripheral route and consequently, they prefer different ad formats. This is the first attempt to apply CFT to comparative advertising contexts and advances our current knowledge by identifying the importance of understanding the impact of CFT on comparative advertising persuasion. This research also extends CFT priming effects to subsequent information processing in unrelated consumption contexts.

Avoiding Poor Health or Approaching Good Health: Does it Matter? Conceptualization, Measurement and Consequences of Health Regulatory Focus

Pierrick Gomez, Reims Management School and Université Paris Dauphine, France

Adilson Borges, Reims Management School, France

Extended Abstract

The motivational underpinnings of health behavior have been largely ignored in the marketing literature (Briley and Aaker, 2006). The regulatory focus theory (Higgins, 1997) offers a relevant theoretical framework to understand how basic motivations influence health behaviors. In this regard, some researchers have proposed that hoped selves or feared selves could act as motivational incentives (Hooker et Kaus, 1994). However, although regulatory focus theory has already been applied to health message persuasion and health behavior (e.g.: Keller, 2006; Fuglestad, Rothman and Jeffery, 2008), no effort has been made until now to adapt it to the health domain. The present research proposes that individuals could vary in their spontaneous tendency to represent their health in terms of desired state or undesired state and that this individual difference influence their health beliefs and behaviors. Because other variables has been successfully adapted to the health domain (e.g.: Wallston *et alii*, 1978 ; Schwarzer and Renner, 2000) and because past researches using general measure of regulatory focus has lead to mitigated results (e.g.: Vartanian, Herman, and Polivy 2006), conceptualize health regulatory focus and build a specific tool of measurement seem to be an important step to engage.

Development and Validation of the Health Regulatory Focus Scale

To generate items our initial set of 50 items for the HRFS, we first closely examined instruments used to measure general regulatory focus and second conducted in-depth discussions with 8 consumers. 31 items were finally selected by four expert judges and administered to a sample of 187 consumers. The factorial analysis with oblimin rotation was used to check the factorial structure of the measure. A two factors solution is obtained and explained 58% of the variance. Moreover, the correlation between the two dimensions is low ($r=.16$, $p<.001$). The final version of the HRFS includes 8 items (five items for promotion dimension and three for prevention dimension). To assess the relationship between, general regulatory focus and health regulatory focus, the RFQ (Higgins, 2001) has also been administered to the sample: no significant correlation exists between these two constructs.

To validate the HRFS, the items were administered to a sample of 1600 consumers. After checking for the items multinormality, we adopted the maximum likelihood and the bootstrap procedures to conduct the analysis. All the indicators have confirmed that the model fits the data well ($\chi^2=151.67$; GFI=.98 AGFI=.95, CFI=.97, TLI=.97, RMSEA<.08). The model shows that the correlation between the latent constructs and its items are always over .5, and that the error terms variance is bellow the acceptable threshold of 2.58 (Hu and Bentler 1998). However, the correlation between the two latent constructs is much higher than in study 2 ($r=.79$, $p<.001$). This result

threatens our two dimensions solution. To avoid any doubt about this issue, we conducted a model comparison using the chi-square difference tests recommended by Anderson and Gerbing (1988). The results argue that a two constructs model solution fits the data better. The increase in chi square is 283.37, which is significant at $p < 0.01$. These results support the discriminant validity of the HRFS. Each of the resulting scales exhibits good internal reliability: Cronbach alpha and Joreskog's Rhô were superior to recommended thresholds.

Nomological Studies: Consequences of Health Regulatory Focus on Health Beliefs, Health Behaviors and Subjective Health State

Using the data described earlier ($n=1600$), the goal of the study 2 is to test the ability of the HRFS to predict health beliefs, health behavior and subjective health state. To test our hypothesis, we create an HRF index by subtracting participants' promotion scores from their prevention scores. We then perform a tertiary split on this index, creating a predominant promotion group and a predominant prevention group (Camacho, Luger and Higgins, 2003). Concerning health beliefs, based on prior existing research, we expect a relationship between health regulatory focus and health locus of control (Pham and Higgins, 2005) and health risk (Leikas *et alii*, 2006). Confirming our expectations, the results showed that people with higher prevention score have a stronger external locus of control (doctors and chance). However, no significant relationship is found between internal locus of control and promotion orientation contrary to what we expected. To test the influence of health regulatory focus on health risk assessment, two scenarios manipulating health risk due to a *decrease in immune system* function were presented to respondents. There was a significant relationship between health risk perception and health regulatory focus. In comparison to promotion oriented respondents, prevention oriented respondents have higher scores of perceived severity and susceptibility. Promotion oriented consumers were also more likely to adopt approach health behaviors (e.g. sport practice, eat 5 fruits and veggies). We have also found that promotion oriented consumers initiate a larger number of health behavior. This result is consistent with the fact that promotion-oriented consumers exhibit a greater need for variety in their self-regulation strategies (Pham and Higgins, 2005). It appears also clearly that promotion-oriented consumers demonstrate greater ability to maintain these health behaviors. It could be explained by the fact that promotion orientation influences positively the motivation to persist on a complex task (Crowe and Higgins, 1997). Finally, consumers who are promotion-oriented have higher score of subjective health state. This result supports the idea that under prevention, consumers are more likely to perceive their current health state as a source of potential problem. Additionally, a significant relationship between promotion orientation and optimism and between prevention orientation and neuroticism provide further evidence of the good validity of the HRFS.

To conclude, health regulatory focus seems to be an important concept to understand consumers' health motivation and especially how this motivation influence health outcomes. More research is needed to assess the additional contribution of the HRFS versus more domain-general alternative and explore its impact on consumers' health status and health information processing.

The Effect of Self-Construal and Regulatory Focus on Persuasion:

The Moderating Role of Perceived Risk

Ying-Ching Lin, National Dong Hwa University, Taiwan

Chiu-Chi Angela Chang, Shippensburg University, USA

Yu-Fang Lin, National Dong Hwa University, Taiwan

Extended Abstract

Consider an example regarding marketing nutritional supplements. Advertising for supplements may evoke the importance of good health for oneself or for loved ones. The advertisements may focus on either attaining a positive outcome (e.g., boosting energy) for your health, or preventing a negative outcome (e.g., preventing fatigue). The risk perception of a consumer is often influenced by information presented in the ads (e.g., a significant number of people died from heart diseases every year). Different combinations of self-construal

(independent versus interdependent), regulatory focus (promotion-focused versus prevention-focused), and risk perceptions are likely in any given communication. It begs the question: what kind of combination would be the most persuasive? It is the motivation for the present research to investigate the persuasion effect of the interplay of self-construal, regulatory focus, and perceived risk.

Considerable research has been done on self construal and regulatory focus. The independent self is defined by unique attributes and independence from others. This is a dominant self-view in cultures where independence and achievement are emphasized. In contrast, the interdependent self is defined by others and appreciates fitting in and being harmoniously interdependent with each other. This self-view is predominant in cultures where obligations and responsibilities are emphasized (e.g., Fiske et al. 1998). In addition, according to regulatory focus theory (Higgins 2002), individuals with a promotion focus regulate their attitudes and behaviors to attain advancement, growth, and accomplishment. These individuals are inclined against committing errors of omission and are associated with eagerness strategies and openness to change. In contrast, individuals with a prevention focus regulate their attitudes and behaviors to attain safety and security. They are inclined against making errors of commission and prefer vigilance strategies and stability.

Self-construal and regulatory focus have been found to interact to influence consumer behavior. Lee, Aaker, and Gardner (2000) found that individuals with an accessible independent self perceive promotion-focused information as being more important than prevention-focused information, and that the converse is true for individuals with an accessible interdependent self. Aaker and Lee (2001) further showed that a promotion-focused message is considered more persuasive than a prevention-focused message for individuals with an independent self-view, and that the converse is true for individuals with an interdependent self-view. The present research extends the above mentioned literature by proposing a situational factor, perceived risk, to moderate the aforementioned persuasion effects.

As noted earlier, risk perceptions may be manipulated in a communication in order to attract consumers' attention. It is conceivable that consumers may react differently in a high versus low risk context to promotions (e.g., Bolton et al. 2008). The present research hypothesizes that when perceived risk is high, a prevention- (versus promotion-) focused message is more persuasive, no matter the individual's self-view. The reason for this is that a risk that is perceived to be high will sensitize consumers to focus on the possible negative outcomes and on vigilance (Lee and Aaker 2004), which is consistent with a prevention focus. Conversely, when perceived risk is low, the findings by Aaker and Lee (2001) should be replicated.

Three studies tested the proposition that perceived risk moderates the interaction effect of self-construal and regulatory focus on persuasion. Study 1 replicated the original findings in Aaker and Lee (2001) and Studies 2 and 3 manipulated the perceived risk in different ways and obtained results that were in agreement with our premise. Specifically, Study 1 asked participants to think about either themselves or their family (i.e., an independent versus interdependent self-construal; self-construal was manipulated this way across the three studies). The advertisement for the target product, cranberry juice, focused on the belief that it enhanced youthfulness and energy or that it could prevent heart disease (i.e., a promotion versus prevention focus). In Study 2 where a yogurt drink was the target product, the promotion-focused message mentioned that the product could benefit and strengthen the immune system as well as the digestive system, while the prevention-focused message mentioned the drink's ability to prevent digestive system diseases and reduce cholesterol and cancer-causing toxins. To manipulate perceived risk, half of the participants in Study 2 were told that "six people died of colon cancer *every day* in this country," while the other half learned that "two thousand people died of colon cancer *every year* in this country." This manipulation was based on Chandran and Menon (2004), whose findings showed that risk estimates are higher on a per day versus a per year basis. Finally, Study 3 used another target product, Essence of Golden Clam, which was advertised to either enhance the health of one's liver and boost energy, or prevent liver disease (promotion versus prevention focus). Perceived risk was manipulated based on the frequency of engaging in risk behavior (Menon, Block, & Ramanathan, 2002). Participants were told by the advertisement that hepatitis B could be contracted either by not bandaging a cut (a frequent risk behavior; high perceived risk) or by getting a tattoo (an infrequent behavior; low perceived risk). Consistent with our proposition, both Studies 2 and 3 found that in a high (versus low) perceived risk situation, a prevention-focused message led to more favorable brand attitudes and purchase intentions for both independent- and interdependent-self construal groups.

In summary, the present research proposes that perceived risk moderates the effect of self-construal and regulatory focus on persuasion. In particular, when perceived risk is high, a prevention-focused message should be considered more persuasive, no matter the type of self-construal. Empirical findings from three studies support our proposition, where perceived risk was manipulated by using a day versus year frame, and by highlighting a frequent versus infrequent risk behavior. The theoretical contribution of this research is that it clarifies the moderating role of perceived risk in the findings of Aaker and Lee (2001). From a practical perspective, advertising strategies targeting consumers who are likely to perceive the message in the advertisement as a high risk issue should utilize a prevention-focused appeal to enhance persuasion, irrespective of the consumers' self-views.

Self-control and the Differential Weighting of the Components of Risk

Shi Jia, Stanford University, USA

Ab Litt, Stanford University, USA

Uzma Khan, Stanford University, USA

Tatiana Andreyeva, Yale University, USA

Extended Abstract

Harmful consumption decisions like smoking, overeating, and drinking are commonly blamed on self-control problems. Rather than assume that people with low self-control simply fail to rein in their impulses, this work explores whether such people view the fundamental nature of risks differently.

Risk perception is often divided into two distinct components: probability and consequences of negative outcomes. In this work we show systematic differences in the weighting of these basic risk components by individuals varying in self-control. In particular, we find that low-self-control leads to heightened focus on probability, but relative neglect of consequences. This divergent construction of perceived risk may be influenced by motivating factors and defensive mechanisms. When faced with threatening information, people often engage in defensive or motivated reasoning, even if such processes make a person objectively worse off (Kunda 1987, 1990, Sherman, Nelson, and Steele 2000).

By disentangling the individual components of risk from an overall conception of risk, our approach yields deeper insight into self-control and systematic patterns of risk underestimation and relative focus on distinct components during threat assessment.

In consumer behavior research, perceived risk been modeled as a function of uncertainty and consequences dimensions (Bauer 1960, Cunningham, 1967, Cox 1967):

$$R = v(x)^a p(x)^b \quad (1)$$

where R is the overall perceived risk of x , $v(x)$ represents the negative consequences of x , $p(x)$ is the probability of x occurring, and a and b are the relative weights of probability and consequences. We apply a log-linear transformation for regression analyses to obtain

$$\ln(R) = \ln c + a \ln v(x) + b \ln p(x) \quad (2)$$

By measuring overall threat, R , the probability of x occurring, $p(x)$, and the value of the negative consequence of x , $v(x)$, we will be able to derive the relative weighting of consequence and probability (a and b , respectively). One may think of the weighting coefficient as telling us how much one's overall sense of risk increases with a one unit increase in consequence or probability

We may add two interaction terms, the interaction between self-control (S) and consequence and the interaction between self-control and probability, to see how people with different levels of self-control differentially weight the components of risk;

$$\ln(R) = \ln c + a \ln v(x) + b \ln p(x) + c \ln[v(x) * S] + d \ln[p(x) * S] \quad (3)$$

Study 1: Dietary Disinhibition and Overeating-related Risk Perception

After completing a measure for self-control in eating habits (Karlsson et al., 2000), participants ($n=76$) completed a three-stage rating of perceived risk for heart attack and diabetes due to overeating. Participants rated their perceptions of the consequences, probability, and overall threat for each risk.

In within group analysis using our estimated log-linear model (3), both interaction terms are significant in different directions. For both heart attack and diabetes from overeating, the interaction between consequence and self-control was positive and significant ($p<0.05$), while the interaction between probability and self-control was negative and significant ($p<0.05$). The results show that the negative consequences of diet-related health problems appeared to be a more important component of perceived risk among high-self-control eaters than high-self-control eaters. In contrast, the perceived probability proved relatively more important for low-self-control eaters.

Study 2: General Perceived Risks and Self-Control

Study 2 explores whether study 1's results can be generalized into other domains or risky behavior outside of overeating-related diseases. Subjects ($n=124$) complete the same risk elicitation procedures and perceived risk model as in study 1. However, we now use a general self-control scale that measures Cognitive Restraint (Karlsson et al 2000).

Results indicated a pattern analogous with the results of Study 1—low-self-control leading to relative probability-focus, high-self-control to relative consequences-focus—was observed in non-overeating-related domains characterized by a *high self-agency for*

control. We find this pattern for overeating related diseases ($p < 0.05$), speeding-related car crashes ($p < 0.$), smoking-related lung cancer ($p < 0.01$), food hygiene issues ($p < 0.05$), and MSG poisoning ($p < 0.01$ for c and d).

In contrast, risks with *low potential-for-control* (e.g., genetic-related cancer, avian flu, hard drive crash) did not show similar results. None of the low self-agency risks had any statistically significant interaction terms between self-control and probability or consequence. The necessity of self-agency for differential weighting to occur hints at some motivational process: when adverse consequences are not attributable to self-control failings, low-self-control individuals need not underweight consequences when formulating overall risk.

Study 3: Manipulating Felt Self-Control

Study 3 shows that manipulating one's sense of self-control can cause the differential weighting of the components of risk. In this study, we induce different levels of felt self-control through an ease of retrieval paradigm (Schwarz et al 1991). Participants ($n = 133$) are asked to recall two or ten instances in which they were able to 'exercise self-control, discipline, or willpower in the face of temptation' (2 instances=easy, 10 instances=difficult). The difficulty of the task is supposed to cause participants to infer that they are not very good at that particular action or behavior. After the recall task, subjects' risk attitudes are elicited in the same manner as studies 1 and 2. There is also a control condition against which we compare the recall conditions.

Our results once again show that people with lower felt-self-control focus more on probabilities and less on consequences. In the 'hard recall' condition, where subjects feel lower self-control, our regression analyses finds significant interaction terms between self-control level (now a dummy variable) and risk components. We find that compared to the control condition, subjects who are induced to feel lower self-control weight consequence less and weight probability more (predictors sig. $p < 0.05$ for heart attack and hypertension from overeating, speeding, drinking, smoking, and job loss from shirking).

None of these interactions are significant for people induced to feel 'high control', suggesting that 'high self-control' people do not engage in differential weighting of the risk components.

Conclusions

Differential weighting of the components of perceived risk, probability and consequences, may differentially contribute to the estimation of risk for people with low versus high self-control. This is especially prevalent when defensive and motivated reasoning strategies are both possible and desirable. Such motivated processing may lead to the persistence of both risky and non-risky behavioral patterns, and also to irrational and counter-intuitive underestimations of overall threat by those individuals most at risk of being affected by specific negative outcomes.

Risk Acculturation Through Marketplace and Technology

Gulnur Tumbat, San Francisco State University, USA

Markus Giesler, York University, Canada

Extended Abstract

The theory of risk acculturation explains the process of normalization of risk through socialization and experience. According to Celsi, Rose, and Leigh's (1993) great account of skydiving, risk perceptions become normalized with socialization to a subculture and through gaining experience and the participant achieves an insider status and thus accepted by the skydiving community. For an outsider, the risky activity is deviant and it requires learning and adaptation process to see it as normal. The risk becomes normalized through the process of socialization and thus gradually assuming/adapting the ideology of the subculture. The high-risk subculture is considered as a tight community that places properties of high-risk behavior within the realm of normal. With full acculturation to this community, high-risk performers *learn* to be risk managers and the differences among insiders and outsiders are limited to the stages of their socialization into the high-risk subculture and to the stages of their risk perception evolution trajectories. Furthermore, participants acculturated to risk also become able to attend higher-level transcendent motives such as flow, *communitas*, and phatic communion (Celsi, Rose, and Leigh's 1993).

Yet risk acculturation theory as it currently stands falls short of explaining the implications of the easier access to and participation into high-risk performances by an increasing number of people with various levels of experience in today's marketplace. The availability

of the high-risk performance stages, service providers, and technological developments in the marketplace help novices to become high-risk performers. In order to illustrate, personal GPS tracker devices provide location-based communication and notifies friends, families, or professional services such as rescue coordination services “all with the push of a button.” These devices are designed for backpackers, boaters, campers, cyclists, climbers, hikers, kayakers/canoists, off-road enthusiasts, sailors, snowmobilers, and many others. This is an example of a case that enables people to rely on a technological tool to manage the risk of getting lost or being hurt. In other words, in this case, one can argue that risk is normalized through the help of a tool available in the marketplace. Furthermore, relying on such tools while lacking the necessary understanding and experience may create tensions within the (sub)culture. When people, with a variety of experience and skill levels and physical conditions, end up in situations that would require outside help, discussions arise as to who should pay for their rescue costs. Taxpayers raise their concerns over those rescues of inexperienced people who get lost in the wilderness due to their inexperience. After exploring the relevant consumer behavior literature including the more general acculturation studies (we don’t list the extensive review here due to space limitations), we came to realize that risk acculturation theory ascribes little or no potential for the increasingly commercial nature of such performances and its effects on the interactions among (insider or outsider) participants and non-participants. The aim of this study is thus to address this theoretical gap.

The context of our study is commercially guided climbing expeditions on big mountains as part of the growing adventure industry. It provides a suitable area to explore marketplace dynamics of risk acculturation process. People with different backgrounds and various levels of experience hire professional mountain guides and use high-tech gear and tools to improve their chances to climb mountains and claim a mountaineer identity. We collected data through extensive participant observation and in-depth interviews within various mountaineering communities. Active participant observation for over five years took place at several high-altitude mountains in the world, including Elbrus in Russia, Everest in Nepal, McKinley in the US, and Aconcagua in Argentina. Our data set includes 17 on-site interviews with climbers who pay for guide services on the mountains and their guides. These on-site in-depth interviews were followed by 20 more off-site in-depth interviews with some of the same participants along with the new ones after their climbs. We focused on the commercial nature of the activity as a general topic in our conversations. Standard IRB procedures were followed to gather consent from the participants. The interviews lasted on average 50 minutes and were transcribed verbatim. We analyzed the field notes and in-depth interviews that are close to 1,000 single spaced pages as a whole with the help of the Atlas data analysis software and through a hermeneutic and iterative process. We also incorporated extensive secondary data from sources including but not limited to mountaineering books, adventure magazines, and web blogs.

We found that participants in this high-risk leisure activity do not necessarily follow the path identified by Celsi *et al.* (1993) on their way to claim a high-risk identity. For many, marketplace provides a stage and an opportunity to experience such an identity with the help of high-tech tools, gear, and guide services. Thus, although they lack experience and never truly socialize into a mountaineering subculture, they normalize risk through the marketplace—the missing path in the prior risk acculturation conceptualization. Socialization and gaining experience are not very convenient since they both take time and effort. They instead take an alternate path which allows them to normalize risk and claim a mountaineer identity. Thus, we contend that risk acculturation occurs not only through experience and socialization but also through commercialization of services and tools (Figure 1). This is seen as an illegitimate short cut for some aficionados and results in conflicts and tensions rather than *communitas*. Furthermore, these participants never fully experience flow since they lack the necessary skills and delegate dealing with challenges to guides as commercial service providers.

Figure 1. Marketplace and Risk Acculturation

The theoretical contribution of this study is therefore twofold. First, it unpacks the underappreciated commercial dimension in high-risk performances. Second, it explicates how marketplace dynamics in terms of commercialization and technology significantly shapes the risk acculturation process which is theorized as related only with experience and socialization to a high-risk consumption community. We further argue that this updated risk acculturation process does not necessarily result in higher end states such as flow, *communitas*, or phatic communion (Celsi, Rose, and Leigh 1993). Expanding the theory by accounting the commercialization and marketplace availability has significant implications to a variety of different areas not only for leisure activities (hiring a guide service to climb a mountain, using a GPS tracking device in wilderness, signing up for a rescue service before stepping to the outdoors) but also bigger picture items as encouraged by this ACR’s organizers, such as various financial investments through hiring a financial advisor or signing on a loan from a financial institution that is believed to manage the risk in an uncertain economic environment. Thus, we

believe the extended conceptualization of risk acculturation within marketplace will generate great interest and discussion within the ACR audience which help us improve this study significantly.

An Identity Approach to Prosumption- A Case of Bacalhau Prosumption in Brazil

Lúcia Fátima Martins Guilhoto, Fundação Instituto de Administração, Brazil

Chunyan Xie, Stord/Haugesund University College, Norway

Kjell Gronhaug, Norwegian School of Economics and Business Administration, Norway

Jens Ostli, Nofima marked, Norway

Extended Abstract

The phenomenon of "prosumption" has attracted substantial interest both among researchers and practitioners since this term was first coined by Toffler (1980). In existent research literature, the phenomenon has been addressed from different perspectives. Here we explore the phenomenon of prosumption from the perspectives of role-based identity (Burke 1991) and social identity (Turner et al. 1987), which is a rather novel approach to gain insight into the phenomenon.

Prosumption can be defined as "value creation activities undertaken by the consumer that result in the production of products they eventually consume and that become their consumption experiences" (Xie, Bagozzi and Troye 2008). Furthermore, prosumption can be conceived as a process consisting of two phases: production and consumption. All the activities before the beginning point of consumption are included in the production process, and those after the point are included in the consumption process. Both phases consist of a flow of behaviors, appraisal of those behaviors and emotional experiences. The inputs to the prosumption process are time, effort and monetary resources. The outputs are experiences and values created through the prosumption process.

The prosumption process is embedded in a social world that is constituted not only by formal rules, but also by the wide variety of conventions, habits and styles from different people. That is why our theoretical perspectives of role-based identity and social identity are so relevant to a deeper understanding of the whole process. Key aspects of these theories are people's self-views emerging from the reflexive activity of self-categorization or identification in terms of roles (role-based identity) or membership in particular groups (social identity).

For instance, from the perspective of role-based identity, a prosumer categorizes herself as an occupant of a role (i.e. a hostess), and incorporates into herself of the meanings and expectations associated with that role and its performance. A prosumption process can be, then, conceived as an identity control system that consists of a feedback loop (Burke 1991). The loop has four components: a standard (the set of self-meaning, a prosumer's standard, e.g., to be a good hostess); an input from the social situation (including one's reflected appraisal); a process that compares the input with the standard (a comparator); and an output to the environment (meaningful behavior) that is a results of the comparison. The system works by modifying output to the social situation in attempts to change the input (reflected appraisals) to match the internal standard. Prosumers increase their self-esteem and self-efficacy by performing a role well, because they go through a self-verification process by comparing the what a person perceives in the situation (reflected appraisal) and the self-meaning held by the individual (standard) (Burke and Stets 1999).

A social identity is a person's knowledge that he or she belongs to a social category or group. Such a group-based knowledge may account for the closeness of the social relations among persons who are involved in the prosumption process. Our empirical context is bacalhau prosumption in Brazil. Bacalhau is a Portuguese word for a particular preparation of cod fish and is synonymous with salted and dried cod. It is the tradition that bacalhau meal is served as a centerpiece of family celebrations and social solidarity during important holidays such as Easter and Christmas. Great part of such kind of social gathering relies on symbolic interactive activities that show mutual appreciation, respect, and esteem among the members, helping shaping social identities. To sum up, one way to understand such a prosumption process can be to conceive it as a process where prosumers carry out various production and consumption activities in order to create, maintain and regulate their identities.

We approached this empirical context in an explorative, discovery-oriented basis. Our paper draws upon 13 qualitative focus groups interviews that were developed with 104 consumers from different social classes, genders and geographic locations in Brazil. The guiding heuristic principle is that the informal discussion of all the phases of the prosumption process (namely, planning, shopping, desalting, cooking and serving) can bring to surface several aspects of role-based identity and social identity such as environments, perceived self-meaning, reflected appraisals from others and shared experiences and provide insights on how people interact in order to reinforce social identity in their groups assuming specific roles supported by rituals, behaviors and social connections.

We found empirical evidence on role identity for every phase of the bacalhau prosumption. We verified that for each phase several quality standards are established by a person when she assumes the role of host of the dinner. These standards are controlled once different tasks are performed; if consistency is found between what was established and what was observed the role identity loop is closed and the person experiences feelings of self-accomplishment, pride and satisfaction. For instance, we have found out that for the shopping phase of the bacalhau prosumption the most common standards established are size of the piece of bacalhau, color, kind of package and expiration date. These pre-established standards are checked during the purchase of bacalhau and if this purchase meets all the standards established the host feels that the loop is closed, reinforces her self-accomplishment feeling and passes to the following phase. We also found empirical evidence that the prosumption of bacalhau involves meanings and interactive processes that are deeply

based on the reinforcement of the social identity. For instance, we found that although much of the presumption of bacalhau is done by one person that assumes the role of the host of the dinner everything is done having in mind the rules and expectations of the group; if these rules and expectations are not met ingredients and attitudes are rearranged in order to conform to the groups' social identity.

In sum, we develop and apply a model that integrates the presumption process and the theoretical perspectives on role-based identity and social identity to better understand presumption. It provides novel understanding of the presumption process-especially related to food-related presumption. Both theoretical and managerial implications are highlighted, and avenues for future research indicated.

I Show You Only Who I Am If Needed: Identity Signaling as a Result of the Interaction Between Personal Motives and Situational Factors

Hendrik Slabbinck, Ghent University, Belgium

Patrick Van Kenhove, Ghent University, Belgium

Consumers often make choices that diverge from those of others to ensure that they effectively communicate desired identities. Teens, for instance, regularly want to distinguish themselves from their parents and therefore choose for music styles, clothes, ... their parents dislike. Previous studies demonstrate this drive to differentiate from others through product choices to vary across individuals (Snyder and Fromkin 1977) and situations (Byrne and Griffitt 1969). Further, research shows that for product categories symbolizing one's identity, individuals abandon product options which the majority prefers (Berger and Heath 2007).

In addition, identity signaling is partially driven by price and explicitness of brand logos. Consumers, for instance, who strive for broader public recognition like to show others they can afford expensive products. Therefore, they choose expensive products that are well know by a broad range of consumers. They further prefer loud or large brand logos because it helps them broadcasting their desired identity. Very expensive top-class products that are only recognizable by connoisseurs are for these consumers less suitable for identity signaling.(Berger and Ward 2009).

The data of our three studies, however, display a more nuanced pattern. In Study 1, we asked 56 undergraduate students to enumerate brands that are typically bought or avoided by students who strive for broader recognition by showing their possessions to others. When analyzing the product categories, product categories that are seen as symbolic of identity were, as expected, most frequently listed (i.e. clothes (n= 36) and cars (n=30)). When analyzing brands, results were also straightforward. In general, the rather expensive well known brands that are still affordable by a rather broad range of consumers were top listed as typical signaling brands. These were BMW (n=16) and Mercedes Benz (n=15) for cars and Tommy Hilfiger (n=11) and Armani (n=6) for clothing. Further and in line with our expectations, lower priced well known brands were enumerated as brands these people rather avoid. For cars, these were Volkswagen (n=5) and Opel (n=5), and for clothing, Esprit (n=9) and H&M (n=5). So far, all results were in line with the existing literature.

In study 2 (n=137), we measured the degree to which undergraduate students strive for broader recognition by showing his/her personal wealth to others. The focal product category was clothing because it was top listed as identity signaling product category in Study1. Surprisingly, we could not find any relation between the degree for striving for broader public recognition and the percentage of the clothes of signaling brands that the participant had in his wardrobe ($r=.07$; $p>.05$). Based on previous studies as well as the results of our first study, we expected people high (low) in need for public recognition to own relatively more (less) clothes of signaling brands.

These unexpected results indicated that the activation of signaling related behavior is more complex than just the straightforward relationship between need for public recognition and an individual's number of signaling brands. According to McClelland et al. (1989), behavior is the result of the interaction between motives and the environment. In brief, a person with a certain motive or need will only engage in motive relevant behavior under the presence of appropriate environmental stimuli. Without the presence of these environmental stimuli, motive relevant behavior is less likely to occur. In terms of identity signaling, this means that a consumer high in need for public recognition should be more likely to buy an expensive shirt with a large and loud imprint of a brand logo in a multi-brand store than in a mono-brand store. This because the presence of unwanted, cheap brands in the multi-brand store could act as an environmental stimulus that activates the consumer's need for public recognition. Once this need is activated, the consumer's purchase behavior should be channeled towards signaling brands with large brand logos. If this explanation is true, then the relationship between need for public recognition and intended purchase behavior of signaling brands must be higher in the presence of unwanted brands, certainly if the brands have explicit brand logos. To test this hypothesis, we set up a third study (n=131) in which we measured need for public recognition and intended purchase behaviour of two brands (within subjects): a signaling brand (Tommy Hilfiger) and an unwanted brand (Esprit). Signal explicitness was manipulated between subjects. We created two conditions for each brand. In the first condition, all t-shirts had large brand logos. In the second condition, we showed exactly the same t-shirts, but with brand logos erased. Each picture was tagged with a short description and brand name. To assess intended purchase behavior, each participant (all females) got virtually 100 Euros

which they needed to spend in our online t-shirt shop. Difference tests on Fisher r-to-z transformations fully supported our hypothesis. The correlation, for instance, between need for public recognition and intended purchase behavior for the signaling brand was .41 ($p < .05$) when both the signaling and unwanted brand had explicit brand logos. This correlation was significantly higher than when both brands had no brand logos ($r = .08$, $p > .1$; $z_{\text{diff}} = 1.98$, $p < .05$).

The results of these three studies add important insights to identity signaling theory. We clearly showed that individual differences and situational factors must be studied jointly instead of separately. As shown in our third study, the effect of individual differences on identity signaling is only activated in a specific situation. In future research, we will incorporate additional situational factors and individual difference variables (e.g. self-esteem). Another interesting avenue for further research concerns the question how identity signaling works for symbolic products that are less visible for the general public (e.g. pajamas, bathroom accessories, ...).

Who Determines the Ideal Self?: A Comparative Analysis of Non-Verbal Communication

Junko Kimura, Hosei University, Japan
Mototaka Sakashita, Keio Business School, Japan

Extended Abstract

Self-concept must be treated as having two components; the actual self-concept and the ideal self-concept. Ideal self-concept is defined as the image of oneself as one would like to be. The ideal self-concept has been referred to as the "ideal self," "idealized image," and "desired self" (Sirgy 1982). Consumers hold their own ideal self images, and often try to alter their appearance by changing their outfits, in order to get closer to those images. Ideal self is the self-concept where an individual puts the highest value (Rogers 1959). Consumers use purchasing in order to approach their ideal self (Belk 1988; McCracken 1988). A desirable self-concept can be created through consumption, and it can also be extended into products. (Belk 1988; Schouten 1991). Most scholars seem to agree that the term "self-concept" denotes the "totality of the individual's thoughts and feelings having reference to him as an object" (Rosenberg 1979). Actual self refers to how a person perceives herself. Ideal self refers to how a person would like to perceive herself. Social self refers to how a person presents herself to others.

Since the concept of ideal self is highly important to the consumers, they independently search for their ideal self-image, and often decide on it. When they decide on their ideal self, their significant others approve it. Significant others are specific others who influence the self-formation of consumers. Parents and teachers can be significant others; also, friends, classmates, and mass media can become such influential people (Mead 1934). They have long proposed that parents are the most influential socializing agents for their children (Cooley 1902; Sullivan 1947; Turner 1962).

Mothers might be significant socializers for their daughters and control them by using social power. Social power consists of reward power, coercive power, legitimate power, referent power, and expert power (French and Raven 1959). Significant others may not only approve of the ideal self that the consumers decided on, but also occasionally decide on the consumers' ideal self itself. It seems reasonable to look at mothers as primary socializing agents for the formation of their daughters' attitudes (Bohannon and Blanton 1999). The ideal self determination process under mother-daughter situation can be described as "coercive," since the mother has already formed a clear idea of her daughter's ideal self image prior to the shopping experience. Here, the mother tries to force her daughter to accept whatever ideal self image she has. According to Nobuta and Ueno (2008), in contemporary Japan, identification with mothers does not simply mean identifying with the actual existing mothers. Mothers try to get their daughters to identify with their ideal self.

Female friendship is affective. Women expect their female friends to feel and react in the same manner as they do (Wheeler & Nezlek 1977). Female friends mutually request sympathy from the other party. Sympathy can be created by self-monitoring. Self-monitoring is to observe whether one's expression, action or self-presentation of one's self is socially appropriate. In female friendship context, one's behavior is modified according to the other's reaction (Snyder 1974). The ideal self determination process under friend-daughter situation can be described as "collaborative," since the daughter and her female friend are both engaged in the daughter's ideal self determination process.

We set our proposition: a different nature of relationship results in a different ideal self determination process. Specifically, in a mother-daughter relationship, the mother has already decided on the daughter's ideal self before the actual process starts. The mother then forces her daughter to accept her own idea. This is called a "coercive process", and the entire process is often omitted. In the friend-daughter relationship, the friend and the daughter act as if they mutually sympathize to the other, and cooperatively decide on the daughter's ideal self. This is called a "collaborative process", where they even enjoy spending time together until they reach to the daughter's desirable ideal self.

We use interpretive approach and directly observe actions at catalogue shopping of mother-daughter pair and friend-daughter pair. We conducted a unique comparative analysis of the collected quantity data; using three types of Non Verbal Communication (NVC), we compared frequencies of those NVC in each pair and interpret them with supplemental verbal data. The study consists of [STUDY 1] and [STUDY 2], and there were twelve sets of pair altogether. Six daughters participated in both studies. The daughters brought her mothers for [STUDY 1] to form M-D relationship condition. Under this context, they performed the daughter's ideal self decision process. Not only verbal data but also nonverbal data were collected because the Japanese people tend to use many subtle body language cues in daily conversation.

Results of the comparative analysis were consistent with the proposition. Important future research directions were addressed.

Narcissists as Consumers: Using Scarce Products to Validate Excessively Positive Self-View

Seung Yun Lee, McGill University, Canada

Sung Hoon Park, Yonsei University, Korea

Extended Abstract

Narcissists can be defined as people who can be characterized as self-centered, self-aggrandizing, dominant, and manipulative^{1,2}. Recently, narcissism as an individual difference dimension has been operationalized as a higher scorer on the Narcissistic Personality Inventory (NPI)^{3,4}. Several researchers have shown interest in the characteristic and behavior patterns of narcissists as consumers^{5,6}. They proposed that narcissists as consumers are likely to purchase prestigious and exclusive products to sustain and elevate their self-positivity. That is to say, narcissism can drive people to purchase highly exclusive and luxurious products because the consumptions of such products potentially serve as a means of validating excessively positive self-views. As a result, narcissists may, in order to validate their excessively positive self-views, try to purchase prestigious and exclusive products which are believed to have higher symbolic values than other products. In so doing, they try to regulate their own self-esteem by increasing their apparent status, hence obtaining others' admiration and envy^{5,6}. Past research suggests that when narcissistic consumers make a choice, they may have much higher tendency to sacrifice utilitarian aspects for attaining symbolic ones, compared to non-narcissistic consumers⁶. That is, for narcissists as consumers, it may not be important whether a product will serve their own practical needs or not. The utilitarian value of a product is likely to be of lesser importance to them, whereas a product's symbolic value is of greater importance.

Scarcity can be defined as insufficiency of product supply or time of availability⁷. Past research suggests that consumers can use scarcity as a cue (i.e. "What is rare is good") for good value, whereby they infer that a highly scarce product must be more valuable than a less scarce product^{8,9}. The underlying mechanism for this inference of scarcity as value is based on the assumption that people tend to desire uniqueness¹⁰. In this case, people evaluate scarce products as being more valuable because they believe that possessing something scarce can produce positive feelings of personal uniqueness. In the present research, we show that narcissistic individuals are more likely to strive to purchase a scarce product in order to obtain others' admiration and envy, albeit at the cost of utilitarian aspects, compared to non-narcissistic counterparts, because they believe that the possession of a scarce product can show their own exclusive uniqueness, hence validating their excessively self-positive view through such consumption.

In study 1, we propose that for consumers with high narcissism (HN), scarcity will have strong positive effect on product evaluation, while consumers with low narcissism (LN) are less unaffected by scarcity (H1). One hundred participants were randomly assigned to a 2 (Scarcity: High versus Low) between-subject design. Participants were asked to complete the forty-item ($\alpha=.92$) questionnaire from Narcissistic Personality Inventory (NPI), with the purpose of assessing the participants' propensity for self-narcissism. Consistent with other studies in this area¹¹, participants scoring in the top third of the NPI were considered as having high narcissism and those who scored in the bottom third of the NPI were considered as having low narcissism. After then, participants were presented with a hypothetical retail scenario, which included an ad for a wristwatch. The ad manipulated scarcity, in terms of limited quantities. The dependent variable of product evaluation was measured by an item assessing willingness to pay (WTP). We predicted and found that participants with HN reported higher WTP toward the product promoted with scarcity claim than that without scarcity claim ($M=\$163.73$ vs. $\$80.91$, $t(35)=2.63$, $p=.012$). However, this effect did not happen for LN participants ($M=\$90.26$ vs. $\$83.12$, $t(33)=.355$, $p=.725$). This result indicates that HN consumers have a stronger desire for a scarce product, compared to LN counterparts.

The literatures on scarcity have shown that an increase in arousal due to scarcity tends to motivate consumers to pay more attention to task relevant cues, resulting in a systematic processing of relevant information^{12,13}. In study 2, we argue that narcissistic consumers are likely to have a stronger propensity to purchase the scarce product without scrutinizing information because they want to validate their excessively positive self-views by purchasing a scarce product and can sacrifice utilitarian needs for attaining symbolic ones. Therefore, we predict that for consumers with high narcissism (HN), increasing scarcity will reduce depth of processing (H2a). On the other hand, for consumers with low narcissism (LN), consistent with past scarcity research, increasing scarcity will increase depth of processing (H2b). These different effects of scarcity on depth of processing outlined in H2a and H2b, in turn, have consequences for product evaluation, depending on argument quality. We hypothesize that for consumers with HN, the effect of scarcity on product evaluation will not be affected by argument quality (H3a). In contrast, for consumers with LN, scarcity will have a stronger positive effect on product evaluation when argument quality is strong than when argument quality is weak (H3b). The study 2 was designed as a 2 (High Scarcity versus Low Scarcity) x 2 (Strong product argument versus Weak product argument) between-subjects ANOVA, with one hundred fifty participants recruited. The high and low narcissistic Participants were chosen by the same procedure as in study 1. Two-level Narcissism (Low or High) was the third between-subjects factor in the analysis. As study 1, participants were presented with a hypothetical retail scenario, which included an ad for a wristwatch. The ad manipulated scarcity and argument quality using methods validated in past research^{14,15}. Finally, participants responded to the dependent variables, and listed their thoughts while reading the ad. The dependent variable of product evaluation was measured by a single item, nine point scale for purchase intent and a three item, nine-point scale for product attitude. Participants' thoughts were coded into message-related thoughts and irrelevant thoughts by two judges blind to experimental conditions. The number of message-related thoughts served as one measure of depth of processing. A second measure of depth of processing was a two-item scale for cognitive effort anchored by effortful/thought validated in past research¹⁶. We predicted and found that HN participants in the high scarcity condition reported less message-related thoughts than did LN participants in the low scarcity condition ($M=2.96$ vs. 4.11 , $t(44)=-2.02$, $p=.049$). However, as predicted by H2b, this effect was reversed for LN participant ($M=5.04$ vs. 3.76 , $t(52)=1.158$, $p=.02$). The cognitive effort scale showed the same pattern of results. Consistent with H3a, the effect of scarcity on purchase intent for HN participants was not affected by argument quality ($M=4.15$ vs. $M=3.47$, $t(26)=1.051$, $p=.30$). In contrast, as predicted by H3b, for LN participants, scarcity increased purchase intent when argument quality was strong, but not when argument quality was weak ($M=3.57$ vs. 2.18 , $t(23)=2.152$, $p=.04$). The effect of scarcity on attitude toward the target product showed the same pattern of results.

This research makes a theoretical contribution by identifying how narcissistic consumers are motivated to validate their excessively positive self-view by obtaining a scarce product which can give a unique value.

Because I'm Worth It (And You're Not): Separating The Effects Of Narcissism And Self-Esteem On Prestige Purchases

Mary Ann Cunningham-Kim, York University, Canada

Peter Darke, York University, Canada

Extended Abstract

Consumer researchers typically assume that higher self-regard indicates greater benefits to the individual than lower self-regard. High self-regard is associated with ability to resist high calorie treats following mortality salience (Mandel and Smeesters 2008), lower materialism in adolescents (Chaplin and John 2007), and lower proclivity toward compulsive buying (O'Guinn and Faber 1989). However, evidence in the psychology literature suggests that high self-regard is not simply a de facto "good thing;" for example, it has been implicated as a predictor of violence and aggression (Baumeister et al. 1996); perceived invulnerability to health threats, resulting in lower levels of compliance (Lin et al. 2003), and self-protection at the cost of interpersonal relationships (Heatherton and Vohs 2000). Overall, there seem to be two somewhat contradictory patterns of behavior: one suggesting high regard leads to better decision making or more functional behavior, and another pattern suggesting it leads to negative or less functional behavior.

These somewhat contradictory findings may relate to whether self-regard reflects a stable, "true" sense of self, or an attempt to create an overly positive identity by inflating feelings of self-worth. In order to better understand the relationship between self-regard and consumption choices, the current research compares the effects of self-regard in terms of both self-esteem and narcissism under varying conditions of ego-threat. While these measures are typically correlated, the construct of self-esteem is concerned with an individual's feelings about the self in terms of worthiness, likeableness and acceptance (Kernis 2003), whereas narcissism is concerned more with a chronic tendency to inflate or exaggerate self-regard (Raskin, Novacek, and Hogan 1991).

Galinsky and Rucker (2008) suggest consumption of luxury items serves as a method of regaining equilibrium following ego-threat. Since narcissism involves the goal of protecting fragile self-image from threat, it is proposed that narcissists will tend to use consumption of prestige products to reinforce high self-regard more than non-narcissists. The chronic nature of their self-esteem goals should lead narcissists to prefer prestige items even in the absence of any obvious external ego-threats.

In contrast, self-esteem is thought to function in part to help consumers make better decisions (Baumeister 2002), which might be expected to lead to a preference for value based options rather than items that provide prestige without corresponding performance. Also, since low self-esteem indicates a tendency to experience global changes in feelings of self-worth in response to changing circumstances (Deci and Ryan 1985; Kernis 2003), it is predicted that low esteem individuals will be more reactive to external sources of threat, leading to a greater need to choose prestige products. In contrast, high self-esteem individuals should show greater ego-strength in the face of threat (Steele 1988), and should therefore be in a position to stay focused on making better, value-based decisions (Baumeister et al. 2000). The theoretical contribution of this research is that it helps broaden our understanding of the different ways in which self-regard can relate to consumer choice, as well as identifying a new subset of consumers who are particularly vulnerable to self-esteem or prestige based marketing.

Study 1 tested the relationship between narcissism, self-esteem, and the choice of prestige products. Participants completed the Narcissistic Personality Inventory (NPI) and the Rosenberg Self-Esteem Scale (RSE). They were randomly assigned to either an ego-threat condition, where they were provided with unsolvable puzzles and informed that most college students could complete them within 5 minutes and that the results would be displayed publicly; or a non-threat condition with solvable puzzles and no display threat. Under the guise of a separate study, participants were asked for feedback on a new consumer guide that rated products according to whether they provided fair performance at a lower price, superior performance at a reasonable price, or provided prestige to owners. The reviews for the prestige products contained information suggesting that performance was similar to the lower cost items. For the dependent measure, participants were asked which item they would select for purchase in each of 4 product categories. As expected, narcissism predicted a greater number of prestige items chosen ($\beta=.436, p<.001$), and this effect was not moderated by ego-threat. A spotlight analysis on the interaction between threat and self-esteem indicated that low self-esteem participants in the threat condition increased their preference for prestige items ($\beta=.645, p=.05$) while high self-esteem participants were unlikely to choose the prestige products regardless of threat.

For study 2, advertisement based ego-threats were used to examine the more subtle forms of ego-threat that occur in marketing settings. After completing the NPI and RSE, participants received 4 advertisements, which provided either threats to self-image associated with the product (e.g. an ad for The Economist stated "I never read The Economist: 42-year old management trainee") or non-threatening messages (e.g. "The Economist: Turning Average Joe into Mr. Joe.") Dependent measures were attitudes to the ads and the products, as well as purchase intentions toward the products. As predicted, narcissism was marginally associated with higher purchase intentions regardless of the condition ($\beta=.176, p=.07$). Spotlight analysis showed an interaction between threat and self-esteem, with low self-esteem participants more likely to express interest in purchasing the products in the threat condition ($\beta=.411, p=.07$). The effects here show that the basic pattern of ego threat replicated when this took the form of threatening advertising messages, although the significance levels of these results were more marginal in strength. We attribute the latter to more subtle forms of threat in marketing versus the achievement related contexts used in study 1.

Both studies showed narcissists were vulnerable to marketing tactics/options that suggested a means for creating a positive self-image. Consumers with low self-esteem were similarly vulnerable following a threat. In contrast, high self-esteem consumers made better choices in the sense that they tended to disregard the highly expensive prestige items, regardless of threat. These findings suggest that some of the mixed conclusions concerning the relation of self-regard to purchase decisions may be explainable in terms of the manner in which this construct is operationalized.

Self-Construal And Socially Responsible Consumer Behavior

Irina Cojuharenco, Universidade Católica Portuguesa, Portugal

Gert Cornelissen, Pompeu Fabra University, Spain

Natalia Karelaia, INSEAD, France

Current ecological and economical upheaval demonstrates the need for individuals to rethink their consumption pattern and its impact on their social, ideological and ecological environment. Public and private initiatives undertaken with this goal have been proven to be of limited success. Therefore, further research on the factors associated with socially responsible behavior is warranted. In the current paper, we investigate the potential role of the individual's self-construal (e.g., Sedikides & Brewer, 2001) on the shaping of ethical consumer behavior (e.g., choosing fair trade and locally produced products, or boycotting firms with poor ethical standards). From a public policy perspective, an interesting aspect of self-construal is that individualism and collectivism represent separate dimensions within the individual (Triandis & Gelfand, 1998). In other words, a person possesses both individualistic and collectivistic tendencies to a smaller or larger extent (Sinha & Tripathi, 1994). This implies that if, as hypothesized, collective selfconstrual is associated with socially responsible behavior, such behavior can be promoted by emphasizing or activating the collective self.

Self-construal refers to different ways of defining one's identity. Sedikides and Brewer (2001) distinguish between three types of self-construal: the individual self, the relational self, and the collective self. Defining the self by emphasizing unique traits and independence from others is characteristic for the independent self. The relational and collective self are typically defined in terms of relationships with other individuals and group membership, respectively. At the individual level, multiple tendencies can exist within the same person (Trafimow, Triandis, & Goto, 1991). Recent research has demonstrated that socially conscious consumer behavior, like its ecological counterpart, appears to be an expression of prosocial values, like universalism and benevolence (Pepper, Jackson, & Uzzell, 2009). These are the values that are typically associated with collectivism, as opposed to individualism (Triandis, 1995). For example, people with an interdependent self construal (i.e., relational or collective) emphasize group goals over personal goals (e.g., Utz, 2004). Therefore we expect selfconstrual to be related to socially responsible consumer behavior. Rather than to merely ascertain this relationship, we are interested in uncovering the process which connects both constructs. Additionally, we intend to test whether it is possible to temporarily alter one's dominant selfconstrual through a priming procedure and thus influence the likelihood of engaging in socially responsible consumption.

Using data from a large scale survey we verified the relation between selfconstrual and the tendency to engage in socially responsible consumer behavior. A representative sample of 754 US citizens completed a number of measures related to selfconstrual (Selenta & Lord, 2005), socially responsible consumer behavior (Vitell & Muncy, 2005; Webb, Mohr, & Harris, 2008), and Perceived Consumer Effectiveness (PCE; Roberts, 1996), among others.

As expected, we found a strong relationship between relational and collective selfconstrual on the one hand and ethical consumption on the other. The more the individual describes him/herself in interdependent terms, the more s/he is inclined to make ethical consumer decisions. Relations between ethical consumption and the independent self were smaller or non-significant. More interestingly, we found that PCE mediated the relationship between selfconstrual and ethical consumption using a bootstrapping procedure (Preacher & Hayes, 2008). We used this method because it offers a number of advantages compared to other procedures based on multiple regressions (e.g., Baron and Kenny's procedure). Bootstrapping allows for examining all hypotheses in one statistical model, it does not rely on the assumption of normal distribution, and it provides a direct evaluation of the size and significance of the indirect effect. The analysis

suggested that the relational self ($Z=8.43, p<0.01$) and the collective self ($Z=8.65, p<0.01$) have an indirect effect on ethical consumption, mediated by PCE. The independent self does not have such an indirect effect ($Z=-0.58, p=0.56$)¹, because there is no relationship between independent selfconstrual and PCE ($r=-0.02, p=0.56$).

Footnote 1

¹The results of only one DV are reported on here, due to space restrictions. Results were consistent over all DV's.

In follow-up research, which is ongoing and will be completed by the date of the conference, we are further testing the role of PCE and other constructs as mediators of the relationship between selfconstrual and ethical consumption experimentally. PCE refers to the fact that people believe, to a larger or smaller extent, that their actions can make a difference on the large scale. Previous research has demonstrated that PCE is the single largest predictor of socially responsible consumer behaviour (Roberts, 1996). We propose that selfconstrual is linked to PCE through projected expectations. Collectivists (as opposed to individualists), who think in terms of collective rationality, expect others to do so as well (Iedema & Poppe, 1995). As a result, collectivists assume that a larger proportion of the population pursues societal interests and therefore it is more likely that the individual (as part of an aggregate) can make a difference. We are testing this hypothesis against a number of alternatives (differences in levels of trust in others, care for others, and a different judgment of the relevance of socially responsible behavior). Additionally, we are testing whether a priming procedure can temporarily override trait selfconstrual and can successfully activate or emphasize one's relational or collective self. Using behavioral measures, we subsequently test whether such manipulation is successful at influencing an individual's level of socially responsible consumption. If this is the case, and if a subtle priming procedure is successful at manipulating PCE, this idea could be developed into an interesting social marketing tool.

How Self-View Influences Consumers' Propensity to Adopt New Products: Role of Product Newness and Risk-Relieving Information

Zhenfeng Ma, University of Ontario Institute of Technology, Canada

Zhiyong Yang, University of Texas at Arlington, USA

Prior research has shown that certain national cultural traits influence consumers' propensity to adopt new products. The examination of the relationships between collectivism/individualism and innovation adoption across different nations consistently shows that collectivism is negatively associated with innovation adoption, whereas individualism is positively associated with it (Steenkamp, Hofstede, and Wedel 1999; Tellis, Stremersch, and Yin 2003). However, how situationally activated cultural orientations may affect individuals' innovation adoption *within a nation* has not been examined by previous studies.

According to Markus and Kitayama (1991), within a cultural environment, multiple cultural values coexist in an individual's memory. A person in any cultural environment has both an individualist orientation (i.e., an independent self-view), perceiving the self as unique and different from others, and a collectivist orientation (i.e., an interdependent self-view), perceiving the self as part of a group and connected with others. In addition, a self-view can be made more salient by situational cues: consumers in a predominantly individualistic cultural environment can be temporarily primed with a collectivist orientation, or vice versa (Aaker and Lee 2001; Gardner, Gabriel, and Lee 1999).

Following this dynamic view of culture, we posit that situationally activated self-views would influence an individual's new product adoption decision. This proposition is grounded in the differences in regulatory focus between individuals with a situationally activated independent self-view (the 'independents') and those with a situationally activated interdependent self-view (the 'interdependents'). The independents are promotion-oriented, focusing on seeking benefits and gains. In contrast, the interdependents are prevention-oriented, focusing on avoiding mistakes and losses. Prior research on innovation classified products along a spectrum of innovation newness, ranging from really new products (RNP), incrementally new product (INP), to existing products (EP) (Herzenstein, Posavac, and Brakus 2007; Hoeffler 2003). The different regulatory foci between the independents and the interdependents could result in differential responses toward RNP. As a one-of-its-kind product, RNP offers unique benefits, but is associated with high risk and uncertainty (Hoeffler 2003). Because of their promotion focus, the independents would attend more to the unique benefits than the potential risks of RNP. Conversely, given their prevention focus, the interdependents would attend more to the potential risks than the benefits of RNP. Thus, the independents would be more likely to adopt RNP than the interdependents. However, the independents and the interdependents would not differ in their adoption propensity toward INP or EP, because the low to moderate benefits and risks associated with those products are not sufficient to induce differential responses between the two groups.

H1: The independents exhibit higher adoption propensity than the interdependents toward RNP, whereas these two groups do not differ in the adoption propensity toward INP or EP. This is because:

H2: The independents perceive higher benefits and lower risks than the interdependents when the product is a RNP, whereas they do not differ in perceived benefits/risks when the product is an INP/EP.

It is further expected that the independents and the interdependents would react differently to risk-reduction information (e.g., product warranty) about RNP versus INP/EP. Because the interdependents are more inclined to avoid risks and uncertainty than the independents when the product is a RNP, risk-relieving information would be more effective in enhancing the adoption propensity of the interdependents than the independents when the product is a RNP. However, the two groups would not differ in response to risk-relieving information about INP/EP, given the relatively low risk associated with those products.

H3: The interdependents react more favourably toward the risk-relieving information than the independents when the product is a RNP, whereas the two groups do not differ in their reactions toward the risk-relieving information about an INP/EP.

We tested hypotheses H1 through H3 using two experimental studies. In Experiment 1, we examined how situationally activated self-views influence adoption propensity toward products that vary in innovation newness (H1) and the psychological processes underlying such effects (H2). Ninety-eight undergraduate students were primed with either an independent or an interdependent self-view, using a sports-related scenario (Aaker and Lee 2001). Afterwards, each participant read the descriptions of three different cars (the order of presentation was counterbalanced), whose innovation newness was pretested to be high (RNP), moderate (INP), or low (EP). We measured participants' perceived benefits, perceived risks, and adoption propensity toward each car. Consistent with H1, a repeated-measure ANOVA indicated that the independents reported higher adoption propensity than the interdependents toward RNP. In contrast, the two groups did not differ in adoption propensity toward INP or EP. Further, repeated-measure ANOVAs of perceived benefits and risks indicated that when the product was a RNP, the independents reported higher perceived benefits but lower perceived risks than the interdependents. When the product was an INP or EP, however, perceived benefits/risks did not differ between the two groups. Thus, H2 was also supported. Moreover, a follow-up mediation analysis shows that the observed effect of self-view and innovation newness on adoption propensity was mediated by perceived benefits and risks.

In Experiment 2, we examined how risk-relieving information (i.e., product warranty) influences the adoption propensity of the independents versus the interdependents toward RNP and INP/EP (H3). Eighty undergraduate students were primed with either an independent or an interdependent self-view through a life-event recounting task (Trafimow et al. 1991; Zhu and Myers-Lev 2009). Participants were then presented with a description of a TV, which was pretested to be either an EP or RNP. After reporting their baseline adoption propensity, the participants were informed that the manufacturer of the TV offers a 90-day money-back guarantee, compared with a 30-day limited guarantee commonly offered by TV manufacturers. After reading the product warranty, participants then indicated their adoption propensity again. The increment in adoption propensity, measured by the change score of adoption propensity from its baseline, was used as the dependent variable. A two-way ANOVA indicated that when the product was a RNP, the interdependents exhibited larger increment in adoption propensity than the independents. In contrast, when the product was an INP, the two groups did not differ in their increment of adoption propensity. These results supported H3.

Overall, our findings suggest that situationally activated self-views influence consumers' new product adoption decisions, and that such influences were contingent on the newness of the products. The effects of self-view and innovation newness on adoption decisions was mediated by perceived benefits and risks. Moreover, situationally activated self-views also influence consumers' reactions toward risk-relieving information, and such reactions were again contingent on the newness of the products.

Defensive Reactions to Self Threat in Consumption: The Moderating Role of Affirmation

Pingping Qiu, Monash University, Australia

Fang Wan, University of Manitoba, Canada

Darren W. Dahl, University of British Columbia, Canada

Extended Abstract

Consumers often receive information posing threats to self in advertising and consumption contexts. For example, the exposure to idealized images in advertising media poses a threat to one's own physical attractiveness (Richins 1991). In these cases, we could expect two competing outcomes of self threat. On the one hand, consumers who are made insecure about their positive self views could engage in a defensive reaction toward the threat (Baumeister, Dale, and Sommer 1998) and dismiss products and brands that claim to boost their self images in the threatened domain. We label it as a *defensive consumption strategy*. On the other hand, consumers could perceive the same products and brands to be an important means of self improvement (Eisenstadt, Leippe, and Rivers 2002), therefore, would be more likely to welcome and adopt these products and brands. We label it as a *compliant consumption strategy*.

Surprisingly, scanty consumer research has been done to address the conditions in which a defensive (vs. compliant) consumption mode can be activated and how defensive or compliant reactions toward self threat would affect subsequent consumption behaviors. Recent consumer research on this topic demonstrated a compliant consumption mode resulting from self threat. That is, consumers who experience self threat would resort to products that can directly repair and bolster the threatened self domain (Gao, Wheeler, and Shiv 2009). What is missing from this stream of research is the lack of identification of those factors in consumer contexts activating a defensive consumption mode.

Our research addresses this issue by first uncover consumer contexts where self threat can activate a defensive consumption mode. We then investigate that consumers who experience self threat would be more likely to reject products that offer low affirmation value or signal self deficiency (i.e., self improvement products) (Study 1). Furthermore, we address the relationship between the two competing coping mechanisms of self threat: compliance and defense. We argue that there are two key factors in modulating whether a defensive or a compliant strategy takes place: 1) opportunities for self affirmation (including general affirmation opportunities and affirmation value offered by products or brands) and 2) the mode of threat (blatant vs. subtle). Specifically, when there are external opportunities for self affirmation, consumers who experience self threat are less likely to engage in defensive consumption (Study 2). This effect is exacerbated when self threat is activated in blatant manner than in a subtle manner (Study 3). We test these propositions in three experiments.

Study 1 explored a consumer context where a defensive reaction to self threat leads to the dismissal of self improvement products. Specifically, we examined consumers' evaluations of a body enhancement product after a prior exposure to idealized images in a preceding and seemingly unrelated advertisement evaluation task. We expected to find that subjects whose self views on physical appearance are threatened by the exposure to idealized images are more likely to show less favorable attitude toward the product. In addition, we considered the self domain importance as a moderator of the proposed relationship. That is, defensive consumption is only evident when the threatening source is in an important self domain. We used gender as a proxy of domain importance, since physical appearance has been identified to be important for females but not males. ANOVA results of a 2 (self threat: idealized image vs. no image) \times 2 (gender) between-subjects experiment yielded a significant interaction ($F(1,104)=4.89, p<.05$). Planned contrast revealed that females who viewed idealized images (vs. no images) devaluated the product ($M=2.99$ vs. 4.04; $F=8.26, p<.01$), whereas no such effect emerged among males ($F<1$).

Study 2 addresses opportunities for self affirmation as the underlying mechanism of a defensive consumption mode. We argue that the reason for consumers to dismiss self improvement products when their self images were threatened is that these products focus on the domain where self image is threatened, therefore providing no opportunities for self affirmation. We test this proposition by adopting affirmation tasks from Sherman and Cohen (2006). We employed the same research context as in Study 1. We expected that for threatened consumers, when self can be affirmed immediately after the threat (i.e., receiving bogus positive feedback in intelligence

domain), the overall self-worth will be maintained and the subsequent defensive reactions toward self improvement products will be mitigated. We also argue that self esteem can moderate the relationship between self affirmation and defensive consumption strategy. High self-esteem individuals are more likely to utilize external opportunities to replenish self worth when threatened than low self-esteem individuals (Vohs and Heatherton 2004). Results of a 2 (self affirmation: affirming vs. control) by 2 (measured trait self-esteem, high vs. low) between-subjects experiment confirmed our hypothesis, showing that the affirmation task (vs. no affirmation) reduced defensive consumption among high self-esteem individuals ($A_{\text{product}} M=3.59$ vs. 2.97 ; $F=2.87$, $p<.10$) but not low self-esteem individuals ($F<1$).

Study 3 intends to reconcile the discrepancy between the present research and prior research on compliant consumption. We propose that a defensive (vs. compliant) consumption mode is activated by available (vs. absent) opportunities to affirm and blatant (vs. subtle) self threat. In this study, participants' self views were threatened either blatantly (receiving bogus negative feedback) or subtly (performing a difficult task) in intelligence domain. Subsequently, they evaluated products with high affirmation value (products signaling high intelligence of the user) or products with low affirmation value (intelligence improving products signaling low intelligence of the user). Results revealed that defensive consumption mode emerged only in the blatant threat and low-affirmation-value product condition. That is, when participants were threatened blatantly, they held significantly less favorable attitude toward products with low (vs. high) affirmation value ($M=3.38$ vs. 4.21 ; $F(1,54)=5.22$, $p<.05$). Moreover, even if the product offers low affirmation value, participants receiving subtle (vs. blatant) threat held more positive attitude toward the products, signaling a compliant consumption strategy ($M=4.13$ vs. 3.38 ; $F(1,54)=4.09$, $p<.05$).

Taken together, our research echoes with the recent calls from consumer researchers (Dunning 2007) that we need to understand more about the relationship between consumers' self views and their consumption behaviors. Whereas previous research has painted a rosy picture of how products and brands are empowering consumers by providing important symbolic values, this research deviates and presents a darker side of the story. That is, when there is a mismatch between products symbolic value and consumers' fluid self views, consumers would reject these choices as a way to defend their self views. In addition, by delineating how consumers switch between compliant and defensive consumption on the basis of contextual factors (such as the way self is threatened, or affirmation value of products), this research enriches our understanding of the nature of adaptive consumer behaviors.

Co-Branding with an Emotional Brand: Identity Threat and Coping Strategies among Loyal Consumers

Na Xiao, Queen's University, Canada
Fang Wan, University of Manitoba, Canada

Extended Abstract

Emotional branding is heralded as a key strategy to build stronger consumer-brand relationships compared to functional brand strategies (e.g., Thompson, Rindfleisch, and Arsel, 2006). For example, the success of Apple speaks largely to this type of brand strategy. That is, emotional branding strategy involves crafting brands' visions and values in lieu of consumers' deep-seated emotional needs, dreams, and goals, which allows such brands become spokesperson or substitute of consumers' identity (e.g., Gobe, 2001). In spite its success, in a competitive brand world, a well-crafted emotional brand alone can hardly maintain its success without working together with brands with complementary strength to reach broader consumer segments (co-branding, Leuthesser et al. 2003). For example,

Apple aligned co-branded with HP to release its iPod products to reach out to HP's Windows users of PCs and notebooks. As a result, HP Windows users will have a pre-installed Apple's iTunes jukebox software and an easy-reference desktop icon to access the iTunes Music Store (Mahr 2004). However, will this type of brand alliance be successful?

Whereas previous research on co-branding tend to focus on issues such as the perceived fit of brand partners (Taylor and Bearden 2002), we take the perspectives of loyal consumers of an emotional brand and investigate whether or not they perceive co-branding to be an identity threat and how they defend for their identity and reconcile with the incongruence between brand partners. We propose that a co-branding strategy can pose an identity threat to loyal consumers of an emotional brand when the co-brand is perceived to provide an incongruent value. Specifically, loyal consumers would view the co-brand to be a transgressor of their brand's culture, value, promises and a threat to their own identity. We employ qualitative depth interviews to uncover the whether loyal consumers of an emotional brand perceive co-branding as an identity threat and how they cope with such threat (Pretest), and test how two coping strategies affect their evaluation of the brand alliance (Study 1) and how co-branding with different partners can affect consumers attitude and loyalty toward the original brand (Study 2).

Pretest. The goal of Study 1 is to understand whether loyal consumers of an emotional brand perceive its alliance with an incongruent brand to be an identity threat and how they cope with such threat. To do this, we conducted depth interviews with six loyal Apple Mac users. We asked the informants about their views on the release of new Mac computers (i.e., emotional brand, Belk and Tumbat 2002) which uses Intel hardware (a functional brand, Ritson 2006).

Results revealed that informants felt humiliated by the brand alliance between Apple and Intel and were concerned that Apple users' identity was impaired by Intel, strongly associated with PCs. In addition, we discovered two coping strategies informants employed to buttress their support of Apple brand vis-à-vis the incongruent co-branding efforts: 1) "decoupling", the efforts of some informants to single out Intel and dismissing its impact on Apple brand (e.g., "Intel is just an ingredient and will not affect the myth, easiness, and openness that Apple represents" (Informant G)) and 2) "biased assimilation," intending to boost the evaluation of Intel so that it can be assimilated into positive associations of Apple brand. For example, "Apple and Intel are both to make money and to create passion" (Informant F).

Study 1. The goal of Study 1 is to uncover in an experiment setting which coping strategy is more effective in what context. We propose that the perceived fit between brand partners is low, *decoupling* is more effective than *biased assimilation* because the latter requires relatively positive associations with the co-brand to be activated. When the perceived fit is high, this perceived congruence between brand partners itself can trigger positive evaluations of the brand alliance, which makes coping strategies unnecessary and ineffective. We test this argument in Study 2.

A 2 (coping strategy: decoupling vs. biased assimilation) by 2 (fit: low vs. high, measured factor) between-subject design was adopted. Eighty six Apple users (based on screening questions) participated in the study. Coping strategies were manipulated by exposing subjects to difference versions of consumers reviews (elaborating on either decoupling or biased assimilation) preceding brand evaluations. Perceived fit between Apple and Intel (Taylor and Bearden 2002) was measured, split based on its median value and used as a between-subject factor.

ANOVA yielded a significant interaction between coping strategies and fit on attitude towards the brand alliance ($F(1, 82)=8.94, p<.05$). Specifically, when the perceived fit was low, attitude towards brand alliance was more positive when a decoupling strategy (vs. biased assimilation) is activated ($M=5.08$ v.s. 4.22 ; $F(1, 81)=3.64, p=.05$). However, when the perceived fit was high, coping strategy has no impact ($M_{\text{decoupling}}=5.19$ vs. $M_{\text{biased}}=5.47, F<1, p>.05$). The results supported our hypothesis.

Study 2. Study 2 addresses two issues. First, it addresses the fit between brand partners by manipulating the types of co-branding partners (emotional and emotional vs. emotional and functional). Two, it investigates consumers with varying degrees of identification with the original brand can respond to co-brand differently. For loyal consumers with high identification with an emotional brand, they are motivated to buttress their support for their brand, and the brand alliance regardless of the types of brand alliance (e.g., Einwiller et al., 2006). However, for consumers with low identification with an emotional brand, they would evaluate emotional brand-functional brand alliance more positively because the functional benefits (vs. cultural meanings) of resulting co-brand are more intuitive to them.

A 2 (co-branding type: emotional-emotional versus emotional-functional) X 2 (identification with emotional brand, measured: high versus low) between-subject design was adopted. Eighty four current Apple users participated in the study. Co-branding types were manipulated as co-branding between either Apple with Intel or Apple with Nintendo based on pretest results (Nintendo was chosen as pretest subjects perceived it to be cool, active and trendy). Identification with Apple was measured on 5 items (Bhattacharya et al., 1995) first and was entered as between-subject factor based on a median split. Participants read one of the two co-branding scenarios (Apple with Intel, or Nintendo co-launched a new product, Intel's chip or Nintendo's game software in Apple's computers). They lastly responded to questions with regard to the fit between brands (manipulation check questions) and their attitudes toward the brand alliance.

ANOVA analyses revealed that manipulations were successful. Results indicated that there were significant interactions between co-branding types and identification on attitude toward the brand alliance ($F(1, 80)=6.31, p<.05$). Specifically, when consumers' identification with Apple is low, they rated emotional-functional brand alliance (Apple+Intel) to be more positive than emotional-emotional brand alliance (Apple+Nintendo) ($M=5.93$ vs $4.72, F(1, 80)=6.86 p<.05$). However, when brand identification is high, consumers prefer emotional and emotional brand alliance over emotional and functional one ($M=5.56$ vs. $5.50; F<1$).

Put together, our findings help us understand that for brand alliance such as Apple and HP (incongruent co-branding), it will be perceived positively among HP users who may not have a strong identification with Apple users. At the same time, Apple users with high identification with the brand are not sensitive to brand alliances that Apple is striking as they already have a very strong emotional and identity buy-in with the brand.

Do I Remember More When I Feel More Knowledgeable?

Charles Lebar, HEC Paris, France

Sandor Czellar, University of Lausanne, Switzerland

Extended Abstract

"Familiar with sustainable developmental issues, are you? But did you actually notice the picture was upside down?" To their surprise, most of the readers of this humanitarian ad probably did not. We can indeed wonder what reactions will result from situations in which consumers are induced to feel more or less ignorant than initially believed. Will they become more attentive to subsequent information or, on the contrary, give up to process any related incoming information? Answers to this question may have important implications not only for brand marketers willing to enhance consumer brand knowledge but also for consumers who wish to optimize the way they select information from the marketplace.

Subjective knowledge (SK) is consumers' degree of confidence in their knowledge, as opposed to objective knowledge (OK) that refers to what an individual actually knows in a specific domain (Carlson et al. 2009). Whereas the impact of OK on information search (Bettman and Park 1980; Brucks 1985; Radecki and Jaccard 1995; Swasy and Rethans 1986) and processing strategies (Maheswaran, and Sternthal 1990; Suján 1985) has been extensively studied, extant research on the impact of SK remains scarce and leads to inconclusive results (Moorman et al. 2004; Park, Gardner, and Thurkal 1988; Park and Lessig 1981; Raju, Lonia, and Mangold 1995; See 2009).

The present research focuses on a potential effect of SK manipulation that has not yet been investigated: the mechanisms through which SK manipulations may impact actual memory for information. Are consumers who are given the illusion that they know more (less) than they actually do will be able to retain more (v. less) information when exposed to a message?

We assess the extent of SK change as a result of experimental manipulation using two measurements: SK before the manipulation and after the manipulation. Extant research has so far typically used self-reported assessments of SK after false feedback on a task, showing that participants in high (vs. low) SK conditions indeed provide higher SK scores (Moorman et al. 2004). Such procedures, however, do not allow to evaluate the directionality and extent of SK change compared to an initial baseline. This can only be done if SK perceptions are assessed both before and after the critical knowledge manipulations.

We also argue that moderating personality traits as well as mediating variables need to be taken into account to explain contradictory evidence found in the literature. Building upon the ego protection and self-esteem literatures (Baumeister 1993; Brockner and Chen 1996; Rosenberg 1965; Wiener 1973), we propose that a manipulation of SK may have a different impact on information processing depending on the initial level of consumer self-esteem. Chronic low self-esteem individuals tend to be doubtful about their capacities. Following self-consistency theory, a decrease in their SK may increase the negative perception they have of their capacities and discourage them to process any additional information. Opposed to this, positive feedback may increase their confidence in their capacity and motivate them to further process domain-related information. On the other hand, high self-esteem individuals are generally confident in their capacities. Increasing confidence in their capacity may drive them to become over-confident, rest on their laurel and possibly retain less information. However, decreasing their perceptions of knowledge may actually boost their motivation to search for additional information.

We conducted a pilot study to gain initial insights about the feasibility of this research. After reporting their SK on different domains including our focal topic (computer knowledge), 34 undergraduate marketing students took part in a moderately difficult quiz about computers. Subjective knowledge was manipulated via false feedback on the quiz using two conditions (low vs. high score compared to a school average), following which SK was re-assessed. Finally, participants were asked to complete a domain-related information processing task. The manipulation of perceived knowledge occurred as predicted, as individuals in the low (vs. high) SK condition reported lower levels of perceived domain-related knowledge. However, no main effect of SK manipulation on memory for information was found, thus supporting the need to investigate possible moderating variables.

One-hundred and twenty undergraduate students participated in our first experiment, which differed from the pilot in the following way. We included a measure of trait self-esteem (Rosenberg 1965) in an unrelated survey and used four memorization measures: recall (answer to open ended-questions); recognition (choosing the correct answer in multiple-choice items); discrimination task (ability to recognize whether a piece of information was present or not in the message); and the number of items left unanswered. In line with our

pilot study, we found no main effect of SK on any of our memory measures. However, the analysis of the interaction between self-esteem and SK manipulation revealed insightful results. Converging patterns were found for each of our four measures of memory for low SE consumers: an increase (decrease) of SK was associated with higher (lower) scores on recall, recognition, and discrimination tasks and with higher number of unanswered items. The opposite pattern of results was found for high SE consumers.

The next steps of this research involve experiments identifying possible extensions of our findings. The first area we investigate is the possible mediating effect of state (vs. trait) self-esteem on the relation between subjective knowledge change and information processing. A key challenge is to overcome a potential demand effect induced by a repeated explicit measure of self-esteem. To do so, a study-in-progress measures self-esteem using the IAT procedure (Greenwald 1995; Greenwald and Farnham 2000) right after the SK manipulation. In addition, we measure General Self-Efficacy to test whether other personality traits might moderate the relationship between SK change and memory for information. We also test whether our SK manipulation, in addition to memory for information, also impacts attitude change and normative quality of decision-making.

The present research promises important insights for our understanding of the underlying mechanisms of the relationship between SK manipulation and information processing strategies. Our research may also have important applied implications as the findings will likely prove useful in improving information retention in public policy and health-related communications.

When Does National Identity Matter?

Two Contrasting Symbolic Meaning of Brands in Emerging Countries

Man Ching Kwan, Hong Kong Baptist University, Hong Kong

Extended Abstract

Under increasing globalization, cultural convergence occurs and people are exposed to multiple cultures simultaneously. Living in such a multiplex atmosphere, people risk an identity crisis in every aspect of their lives, even during consumption. One of the most

salient incongruence lies between identities and brand perceptions. This has merited much attention in marketing literature. For example, a research stream on nationalism and patriotism highlighted some potential hazardous outcomes, like anti-consumption movement (Varman & Belk, 2009) and repulsion to foreign brands (Wang and Wang, 2007), are resulted from the infringement of nationhood or ethnic identity. However, some research suggested “foreignness” is not essentially bad. For many occasions, global appeal is more valued by consumers due to its connotation of cosmopolitanism, modernity and high quality (Zhou & Belk, 2004; Steenkamp, Batra & Alden, 2001). Dong & Tian (2009) even suggested consumers might use foreign brands to assert a desired national identity.

Apparently, there exists the ambiguity in consumer choice between the protection of embraced ideology and the pursuit of social development. In light of this, this research investigated how this would impact on brand perceptions, especially in the emerging countries like China. More specifically, it was suggested that the congruity of brand personality with people’s beliefs held for their nation (i.e. national identity), either actual or ideal, impacts on brand favorability.

Based on self-concept theories (Levy, 1959; Rogers, 1951; Sirgy, 1986), consumers purchase and use goods that have a user image consistent with their own self-image in order to express and communicate their “self”. This process is known as self-congruity (or “self-image congruence”), which is driven by the two twin motives, the self-esteem motive (the tendency to seek experiences that enhances self-concepts) and the self-consistency motive (the tendency for an individual to behave consistently with her view of herself) (Malhotra, 1981, 1988; Sirgy, 1982a, 1982b, 1982c). This research tried to tease out their effects on different dimensions of a “self”, i.e. actual (referring to how a person perceive herself) and ideal (refers to how a person would like to perceive herself) (Rogers, 1951). It is suggested the relatively more salient the actual self (vs. ideal self) strives the decision making process, the stronger impact the self-esteem motive (vs. self-enhancement motive) exerts.

To operationalize the self-congruity conditions, an important pair of ideology related to national identity (i.e. traditionalism and modernism) was identified. In the research, “Traditional” referred to the values of respecting the past, customs and conventions, and venerating the quality of being historical, time-honored and legendary; whereas “Modern” represented a notion of being new, contemporary, up-to-date, and ahead of times (Pollay, 1983; Zhang & Shavitt, 2003). While many traditional values might have been deeply rooted in consumers’ mind over decades, the influence of modern values has been intensifying and challenging the status quo of the existing ideology in commercial world. The trade-off among them perfectly illustrates the conflicts between the actual self (i.e. what the Chinese believe they are) and the ideal self (i.e. what they desire to become).

On the other hand, recognized as an important symbolic brand attribute through which consumers are enabled to express different dimensions of the self, such as the personal-self (Belk, 1988), the ideal self (Malhotra, 1988) and etc., brand personality is another important variable considered in the research. Two personalities, sincerity and excitement, are selected from the Big-five brand personality model (Aaker, 1997), in regarded to their robustness across cultures (Aaker, 2004) and prominence in variance explanation (Aaker, 1997). Embedding a pursuit of harmony, true sentiment and collective goals, sincere traits are found consistently across the East countries (e.g. Sung and Tinkham, 2005; Aaker, Benet-Martinez & Garolera, 2001; Huang and Lu, 2003). Alternatively, excitement connotes imaginativeness, innovativeness, independence and youthfulness (Aaker, 1997), which are not prevalent and accepted in these traditional societies. Consequently, congruence occurs when sincerity (vs. excitement) matches with traditionalism (vs. modernism) whereas incongruence occurs when reversing the match. In this sense, self-congruity was operationalized in a 2 (brand personality: sincerity vs. excitement) x 2 (national identity: traditional vs. modern) between-subject design and four conditions (i.e. actual/ideal vs. congruent/incongruent) were resulted.

To examine the hypotheses, several experiments would be conducted. Experiment 1 investigated the dynamics of congruity effect. Participants were given one version of the four manipulated advertisements and asked to rate “how much they like about the brand captured in the ads”, and “how much they identify with traditional (vs. modern) national images”. Results revealed that there exists a crossover interaction effect between brand personality and national identity, consistent with our predictions. It was found that consumers who possess stronger traditional (vs. modern) values prefer brands with coherent brand personalities, i.e. sincerity (vs. excitement). Surprisingly, for sincere brands, brand favorability does not differ significantly among the two country image perceptions; whereas there is significant difference among the two incongruent conditions (i.e. sincere/modern vs. exciting/traditional). This implied a prominent persistence of long-lasting cultural values regardless of social transforms and changes, offering insights unique to the transitioning national state. Meanwhile, the result obtained was encouraging. However, stronger evidence and support were sought to confirm the effect of the two motives and rule out other confining factors. Therefore, additional experiments were designing and would be conducted in parallel to Experiment 1.

In sum, this research enriched the understandings about the dynamics of consumer preferences in transforming economy and brought about both valuable theoretical and managerial implications. Particularly, this research applied self congruity theory to a “collective” self-belief about a nation (i.e. national identity). It also extended some interpretative researches on western brand meaning (e.g. Dong & Tian, 2009; Zhou & Belk, 2004; Zhang & Shavitt, 2003). Through conducting experiments, it was illustrated empirically in what circumstances consumers prefer brands reflecting their desired national identity rather than the one reflecting a consistent identity. Moreover, it supplemented the existing self-concept theory (Levy, 1959; Roger, 1951; Grubb & Grathwohl, 1967; Sirgy, 1982) and offered additional insights to the conflicting congruity/incongruity situations. Most importantly, some valuable insights of understanding a transitioning economy are provided, consolidating the foundation for future research.

Mortality Salience and Foreign Product Evaluation: An Important Moderator

Mark Mulder, Washington State University, Australia

Fang Wan, University of Manitoba, Canada

Darren W. Dahl, University of British Columbia, Canada

EXTENDED ABSTRACT

Motivation and Conceptualization

Terror Management Theory (TMT) (Greenberg et al., 1997) assumes that thoughts of death create anxiety, and that people have developed worldviews as a buffer against this anxiety. In 2004, Arndt et al. suggested that much can be learned regarding the relationship between terror management and consumer behavior. Indeed, at least two studies have shown consumers' tendency to prefer domestic products (over foreign products) is magnified under conditions of MS. In one study, for example, Jonas et al. (2005) found Germans in an MS condition showed more support for the German Mark and less support for the Euro. In another related study, Friese and Hofmann (2008) found Swiss consumers in an MS condition showed a stronger preference for Swiss Chocolate over other foreign options. While these studies support the basic propositions of TMT, previous research leaves at least two interesting questions unanswered. First, past research has focused on a somewhat narrow band of products (foreign currency and chocolates). Accordingly, it is relevant to ask whether similar findings will emerge based on more common products such as cameras or MP3 players. Second, past research has not, to our knowledge, examined whether the impact of MS on foreign product evaluation depends on theoretically-meaningful individual differences.

According to TMT, MS enhances the impact of people's worldviews on judgments of in-groups (e.g., domestic products) and out-groups (e.g., foreign products). One relevant individual difference in this regard is consumer ethnocentrism (CE), which Shimp and Sharma (1987) define as "the belief among consumers that it is inappropriate, or even immoral, to purchase foreign products because to do so is damaging to the domestic economy, costs domestic jobs and is unpatriotic" (p. 281). In theory, the impact of MS on foreign product evaluation should be stronger among consumers high in CE. The present study tests that hypothesis by asking consumers to evaluate products produced in the U.S. and Iran. Prior to evaluating the products, consumers complete the CE scale and write down their thoughts about death or dental pain (a commonly used control condition in TMT research).

Overall, we expected that consumers would prefer products made in the U.S. to products made in Iran (i.e., a main effect of country of production; *Hypothesis 1*). We also expected this tendency to be stronger among those high in CE (i.e., a two-way interaction between country of production and CE; *Hypothesis 2*). Finally, we anticipated that the tendency to prefer U.S. products would be the strongest among consumers high in CE who were assigned to the MS condition (i.e., a three-way interaction between CE, country of production and MS condition; *Hypothesis 3*). We chose to compare products made in the U.S. to products made in Iran because prior research has suggested that it is important to look at the impact of MS on foreign product evaluation using a country which is considered antagonistic

(Maheswaran & Agrawal, 2004), and recent research on consumer animosity suggests that consumers hold a high degree of animosity toward Iran (Funk, Arthurs, Trevino, and Joireman, 2010).

Method

American university students completed the survey in exchange for course credit (38 females, 48 males; median age=21). Participants first completed a shortened ethnocentrism scale (6 items; $\alpha=.90$). Next, participants were randomly assigned to a mortality salience (MS) or dental pain (DP) control condition (cf. Jonas, Schimel, Greenberg, and Pyszczynski, 2002). In the *MS condition*, participants were asked to briefly describe the emotions that the thought of their own death aroused in them, and to jot down, as specifically as they could, what they thought would happen to them (personally) as they die and once they are physically dead. In the *DP condition*, participants responded to similar questions about dental pain. After writing down their thoughts about death or dental pain, participants completed a 60-item mood scale (PANAS-X; Watson, Clark, and Tellegen, 1988) as a delay task (cf., Greenberg, Pyszczynski, Solomon, Simon, & Breus, 1994). Following the mood scale, participants received ads of a camera and an MP3 player and evaluated each product, each of which had a suggested retail of \$99.00. One product was said to be made in the U.S. and one product was said to be made in Iran. To avoid confounding product with country, assignment of product to country was counterbalanced. Brand names were based on a pretest (N=16) which indicated that the brand names chosen were viewed as both likable and believable. Participants evaluated each product using a four-item (7-point Likert type) scale ($\alpha>.93$; bad/good; unfavorable/favorable; worthless/valuable; dislike/like).

Major Findings

To test our hypotheses, we conducted a 2 (MS Condition: MS vs. DP) \times 2 (CE: low vs. high) \times 2 (Country of Production: U.S. vs. Iran) mixed-model ANOVA, treating the first two variables as between-subject variables and the latter variable as a within-subject variable. Supporting H1, participants evaluated the U.S. product more favorably than the Iranian product ($p<.001$). Consistent with H2, results also revealed a marginally significant two-way interaction between Country of Production and CE ($p=.07$). This interaction revealed that the tendency to prefer U.S. products was stronger among those high in CE. Finally, in line with H3, results revealed a marginally-significant three-way interaction between Country of Production, CE and MS condition ($p=.11$). The tendency to evaluate U.S. products more favorably was strongest among participants high in CE who had also been assigned to the MS condition.

Conclusion

The present findings suggest that the impact of MS on foreign product evaluations depends on consumer ethnocentrism. By integrating CE into this line of work, we have helped to extend past research which has shown that MS leads to a stronger preference for domestic products. The current study's sample size was relatively small, and some of the findings did not reach conventional levels of statistical significance. Nevertheless, the overall patterns were consistent with hypotheses and suggest future research in this area is warranted.

Family Obligations and Time Management

Therese A. Louie, San Jose State University, USA

Judy Hanh Vo, San Jose State University, USA

Extended Abstract

The core of successful marketing is providing consumers with products and services that help them spend time in the way they find most meaningful. Addressing their needs is becoming more challenging as the population diversifies ethnically (Kennedy, Lawton,

and Walker, 2001). For example, there are disparate cultural norms regarding how much time is spent on family responsibilities such as care-giving, household chores, and financial support. This research explores how ethnic customs influence consumers' time management.

Much research on family responsibilities has focused upon the Latino subculture. Fuligni and Pedersen (2002) found that Latin American and Filipino students had a strong sense of familial duty, and were more likely than their counterparts to help their families financially. Traditional Latinos' partake in high levels of care-giving (Kuperminc, Jurkovic, and Casey, 2009). In addition, historically the Asian subculture--for which there is a norm of relative interdependence (Aaker and Lee, 2001)--has emphasized family-related activities. Tseng (2004) found that Asian respondents provided large levels of assistance at home (e.g., running errands that the family needs done).

Hence, research has established that Latinos and Asians are inclined to be dedicated to family. This paper extends past work by investigating how they manage those responsibilities. In a given month, how much of their schedule is spent focusing on familial obligations versus on other chores characteristic of their age group? Although individuals from all ethnic backgrounds may have such family duties, it is anticipated that Latinos and Asians from traditional backgrounds will have many such tasks on their to-do lists. In addition, when completing the tasks, it is expected that Latinos and Asians will spend more energy on items family members request that they do.

A total of 57 undergraduates (45% male) taking Marketing classes were asked to participate. First, participants were asked to list all the tasks unrelated to school that they planned to complete within a four-week period; the researcher collected these materials. Then, four weeks later the lists were returned. Participants put a plus sign (+) next to each task they had completed. In addition, they noted throughout their initial lists which tasks family members had asked them to do.

Measures were taken to ascertain participant ethnicity. It was important to identify those who were from families that continued to emphasize customs prevalent in the nations from which they emigrated. Therefore, participants were asked if they spoke a language other than English growing up in their household. A total of 23 participants (40% of the sample) learned Spanish or an Asian language at home. The survey responses from these participants were compared to their classmates during the data analysis.

As anticipated, the type of tasks enumerated on participants' to-do lists reveals an ethnic "familial responsibilities" norm. It was predicted that those with Spanish or Asian language skills would list more tasks that were requests from family members. Indeed, they provided a statistically significant higher percentage of family-related tasks on their to-do lists than did the non-Spanish/Asian language group ($t(55)=2.22, p<.05$). In addition, Spanish and Asian language participants focused proportionately more of their task completion on family duties. Of the tasks that were finished, they had a higher percentage of family-related items ($t(55)=2.42, p<.05$).

Marketers targeting ethnic subcultures might do well to recognize scheduling constraints they may face. Latinos' and Asians' purchase decisions may include strong "family" components that are relevant even to young adults who do not yet have children of their own. For example, familial considerations may influence the neighborhoods in which they want to live, the number of seats in their cars, and the type of employment they seek (e.g., in terms of time flexibility). Furthermore, research can outline practices and products that might help Latinos and Asians organize their days. Those whose lives are disrupted by multiple family activities might learn to develop tactics that help them refocus upon returning to professional and student responsibilities. (For example, before errand-running one scheduling expert takes a moment to list three to-do items that help to ease the transition back to the office.) Note that although norms within the Latino and Asian cultures might prompt higher levels of family duties, many participants from both research groups in this study provided such responsibilities on their to-do lists. Therefore, efforts to help consumers successfully schedule their time might be especially relevant to Latinos and Asians, and are more generally applicable to individuals from all backgrounds.

Extensions of this work include a fuller investigation of demographic factors that influence time management. Although Latinos and Asians may have heightened family obligations, there is a risk in generalizing in-depth similarities across, and even within, the subcultures. It is worthwhile to explore cross-nationality differences in how consumers cope with family responsibilities. In addition, with larger cell sizes it will be possible to explore the effect of gender, as this factor may have a heavier influence on time management in some cultures (Sy and Romero, 2008). In the meantime, it is hoped that this research stimulates more investigations into ethnic differences that influence how consumers spend their time.

Male Interpretation of Idealized Model Images in Advertising—A Cross Cultural Study

Hazel H. Huang, Durham Business School
Richard Elliott, Bath School of Management, UK

Extended Abstract

Traditionally, females are seen to take the predominant consumer role and much research has been conducted in this area. Because of the change of social structure, the role of males as consumers has become more and more important. However, the attention to males as consumers is still inadequate. This paper aims to investigate this area by focusing on male interpretation of idealized model images (both females and males) in advertising.

This study explores how males from different cultural backgrounds, i.e. Western versus Far Eastern, define idealized model images. That gender is seen as a cultural construct is a consensus among sociologists (Massé and Rosenblum 1988) and marketers (Costa 1994). Thus, the perception of idealized model images (i.e. physical attractiveness) may differ across cultures. However, little is known regarding how males in different cultures evaluate physical attractiveness of males as well as females. To explore the differences between two distinct cultures, it attempts to understand how males respond to male and female portrayals in various forms. Current research on male portrayals is limited to content analysis (Kolbe and Albanese 1996; Patterson and England 2000; Rohlinger 2002). If content analysis is not used, the studies mainly examine male sexual representations (Elliott and Elliott 2005; Rohlinger 2002), social comparison theory (Gulas and McKeage 2000), or gender identity congruity (Martin and Gnoth 2009). These studies came to the conclusion that realistic masculinity is appealing, but is masculinity the only factor in evaluating male images? These studies overlooked how an idealized image is identified, and more importantly, identified by males with different cultural backgrounds. In addition to male interpretation of male images, focus is also directed towards male interpretation of female portrayals. Studies on female portrayals date back to the beginning of the liberation of women. Traditionally, the female role in adverts is decorative and usually features gender stereotyping. Early studies focusing on objectification of females utilized content analysis to demonstrate how society saw females (Goffman 1976). This view is a predominantly a male view of females (Stern 1999). Later, research started to center around females as audience through social comparison theory (Richins 1991) with an emphasis on female well-being (Martin and Gentry 1997). However, three decades have passed since Goffman's (1976) benchmarking study and the balance of social power between men and women has changed greatly. A renewed male view of female images is in need for an update.

These objectives prompt the research questions: how do males from different cultural backgrounds respond to the male and female representations in advertising? And what are considered to be idealized images? To explore these questions, the study adopts Scott's (1994) reader-response theory, which signifies the negotiation between the meaning of the images and the reader, because *beauty is in the eyes of the beholder*. Twenty interviews were carried out among heterosexual males; ten were Taiwanese (representing a Far-Eastern culture) and ten were British Caucasian (representing a Western culture). Twelve print adverts, each featuring only one sex, were selected from women's and men's lifestyle magazines in Western and Far Eastern countries.

One similarity between Taiwanese and British males has been identified: their views on the idealized levels of femininity/masculinity for females and males. Both British and Taiwanese view a moderately masculine male image and a moderately feminine female image more favorably than the extreme masculine or feminine forms. This finding is consistent with the ideas of new men (Cramer, Cupp, and Kuhn 1993) and new women (Peck and Loken 2004). In spite of this similarity, the cultural differences in male interpretation of idealized model images are overwhelming and can be classified into three categories: (1) judgment of appearances, (2) evaluation of realistically idealized images, and (3) the relationship between the perception of good adverts and good-looking images.

The first difference lies in how British and Taiwanese see an idealized model image. British informants focus on bodies and facial appearances when describing idealized appearances of males and females. On the other hand, Taiwanese males ignore physical appearances. They focus on 'inner beauty', such as charisma for males and 'qi-zhi' (an inner grace put forward by a mixture of behavior and presence) for females. They tend to read facial expression, rather than facial appearances, in discussing the model images. Another variation in their views of realistically idealized images is observed. While images considered as naturally beautiful or handsome are appealing to Taiwanese males, images close to an unachievable perfection interest them even more. Taiwanese believe that an idealized image should be perfect and that a sense of unattainability increases their curiosity (or fantasy) and wish to worship the person. This is not the case from the responses of their British counterparts, who strongly suggest that realistically beautiful/handsome images are idealized. A final deviation on the relationship between model images and adverts is identified. British informants are able to detach their evaluation of the model images from that of the adverts. Similarly, they are able to isolate how good-looking the model images are from how much they like the models presented in the adverts. By contrast, their Taiwanese counterparts do not display such detachment. In other words, if the Taiwanese interviewees like the model images, they see them as good-looking and develop positive attitudes towards the adverts.

The study supports a sociocultural view of physical attractiveness. The findings are in line with Callow and Schiffman's (2003) argument that a high-context culture (i.e. Taiwanese) is inclined to over-read into the meaning of the model images and connect the dots (e.g. the images) to develop a story (e.g. a positive relationship between the images and adverts). Moreover, the worship of idealized model images observed in Taiwan and the appreciation of realistically idealized model images in Britain may be a transformation from Hofstede's power distance: hierarchy does not only exist in social status; it exists in physical attractiveness. These differences in interpreting idealized model images encourage advertising companies to re-evaluate the effectiveness of using idealized model images in different countries.

Sunglasses, Hierarchy, and Negotiations: Gender Differences in Eye Gaze During Interpersonal Communication

Todd Pezzuti, University of California-Irvine, USA
Connie Pechmann, University of California-Irvine, USA
Adilson Borges, Reims Management School, France
Dante Pirouz, University of Western Ontario, Canada

Extended Abstract

Sales negotiations are an important facet of marketing and consumer behavior because many products and services are sold face to face and the terms are negotiated, e.g., on car lots and golf courses. The impact of visual contact during sales negotiations may differ for males and females. This effect was demonstrated in a recent study that found direct eye contact benefited females negotiating with females, but not males negotiating with males (Swaab and Swaab 2009). That direct eye contact impairs negotiation performance for males is surprising in the light of media richness theory which suggests that performance on complex tasks such as negotiations should be enhanced by visual contact since visual contact provides information about ambiguous or equivocal messages and allows people to communicate more quickly (Daft and Lengel 1986).

Swaab and Swaab (2009) draw on several different areas of research to explain the contrasting effects of eye contact for males and females. The authors explain that females are more comfortable with eye contact and use eye contact to understand others (Connelan et al. 2000; Troemel-Ploetz 1991). Moreover, females communicate in order to discuss and understand the perspectives of others (Tannen 2002). Males, on the other hand, are less comfortable with eye contact (Connelan et al. 2000) and focus on winning discussions (Tannen 2002). Consequently, the competitive intentions communicated by the eyes may distract males from the task at hand, and in turn, interfere with communication.

The present study adds a new layer to the understanding of how eye contact influences complex interactions for males and females by studying the behavior of a buyer and seller as they negotiate the terms of a hypothetical automobile purchase while wearing sunglasses. We illustrate that eye contact does not always benefit negotiations between females, nor does eye contact always impair negotiations between males.

An important methodological difference between the present study and previous work leads to very different assumptions and results. Swaab and Swaab (2009) developed a device that allowed participants to see their partners on a computer monitor. The angle of the cameras was manipulated so that the eyes of one's partner were looking straight ahead (direct eye contact) or appeared to be looking down (no direct eye contact). As Swaab and Swaab (2009) explain, the communication of competitive intentions signaled through direct eye contact was attenuated in the no eye contact condition since participants could not look directly into the eyes of their partner. Moreover, because of the placement of the cameras, all of the participants in the no direct eye contact condition appeared to be looking

down towards the ground, which is a nonverbal cue of submission. Therefore, although the participants in the no eye contact condition did not signal competitive intentions with their eyes, participants may have viewed their partners as submissive since participants looked straight ahead at the computer screen, but were perceived by their partners to be looking down.

The present study differs from Swaab and Swaab (2009) in that participants cannot determine the direction of their partner's gaze since the eyes are completely blocked by sunglasses. Gaze, importantly, facilitates the establishment of hierarchies in social interactions (Hall, Coats, and LeBeau 2005). For instance, looking down as someone gazes in one's direction signals submission. Therefore, completely blocking the eyes impedes establishing a hierarchy. This is particularly significant since research indicates that status hierarchies actually enhance interactions and that individuals like and are more comfortable with people who complement their dominant and submissive nonverbal behaviors (Tiedens and Fragale 2003). Additionally, evidence indicates that individuals have an unconscious drive for hierarchy (Tiedens, Unzueta, and Young 2007). Importantly, however, females are generally viewed as less concerned with hierarchy and are less hierarchically organized than males during initial interactions (Mast 2002). With these considerations in mind, a lack of hierarchy-related cues should lead to less satisfying negotiations for males, but not females. This reasoning leads to the following hypotheses:

H1: When the eyes of a negotiation partner are blocked with sunglasses, males, but not females, evaluate their partners less favorably and like their partners less than do participants who can see the eyes of their partner.

H2: For males, but not females, it takes more effort to reach agreements when the eyes of a negotiation partner are blocked by sunglasses than when the eyes are not blocked, which will impair subsequent performance on a cognitive task for males in the sunglass condition.

Participants (92 students) were assigned the role of buyer or seller and paired together to negotiate the terms of a hypothetical automobile sale (for more details see, Thompson 1991). Buyers and sellers were matched on gender. Groups were randomly assigned to negotiate without sunglasses or to negotiate while wearing sunglasses designed to fit over regular eye glasses. Participants were given 25 minutes to agree on the terms of the sales transaction. After the negotiation, participants descrambled as many groups of letters into words (anagram task) as possible to measure cognitive resource depletion. After the anagram task, participants completed a survey.

The results confirm the hypotheses. Males, but not females, in the sunglass condition liked their partners less and reported less interpersonal attraction when compared to the control condition. Males in the sunglass condition also perceived their partners as less intelligent, less competent, less sincere, less trustworthy, and more manipulative. Furthermore, performance on the anagram task was impaired for males in the sunglass condition, indicating that extra effort was needed in order to reach agreements.

The present study demonstrates that eye contact does not always impair negotiations for males and that eye contact does not always benefit females. In line with the literature on social hierarchy, the presence of subtle cues related to status benefit males in face-to-face interactions. Females, on the other hand, are less concerned with hierarchy and are impacted less when their partner's eyes are covered with sunglasses.

The Role of Culture in the Assimilation of Materialistic Values: The Case of South African Society

James M. Hunt, Temple University, USA

Carol Kaufman Scarborough, Rutgers University-Camden, USA

Scott Hoenig, Witwatersrand University, South Africa

Nicola Klein, University of Pretoria, South Africa

Kerry Chip, Witwatersrand University, South Africa

Extended Abstract

The concept of materialism continues to play an enduring role in the consumer literature because it is widely viewed as a driving force in western society as well as a salient expression of an individual's self-concept (see Richins 1999). Anecdotally, materialism appears to be a central concern for social commentators and scholars alike. As Richins (2004) notes, the topic has spawned more than 100 empirical studies in addition to numerous articles in the popular press focusing on materialism's role in contemporary society. However, much of our formal understanding of materialism comes from research conducted to define and measure the concept or studies that attempt to isolate its individual factors and affirm its basis in possessions. Not only has this research produced viable scales with which to measure materialism (Belk 1984; Richins and Dawson 1992), but it also has demonstrated the relationship between consumption decisions and the values the construct rests on (Belk 1985; Burroughs and Rindfleisch 2002; Dittmar and Pepper 1992; Richins 1994).

Surprisingly, little attention has been paid to the process by which materialism is inculcated from a cultural perspective. Although some studies have shed light on factors effecting materialistic values (Belk 1987; Churchill and Moschis 1979; Flouri 1999 Rindfleisch, Burroughs, and Denton 1997 research on the acculturation of materialistic values remains dormant. This is particularly surprising given that materialism is widely viewed as a value orientation (Burroughs and Rindfleisch 2002). In a series of depth interviews in South Africa, we investigate what happens to the personal values associated with materialism when individuals move from one cultural setting to another, particularly when the new environment is considerably more materialistic than that of the original one.

In the case of South Africa, society has been, and continues to be dominated by western culture (Klein 2007; Thomas and Bendixen 2000), although it is far from uniform in its makeup. In fact, South African society has a fairly extensive tribal heritage, which derives from various subgroups such as Xhosa, Vendi, Zulu, Tsonga, and Sotho. Most of these share a patrilineal clan based system of kinship, resulting in strong individual values.

As South Africa, with its western dominance, has become more economically advanced, it might be expected that it also become more materialistic in nature. On the other hand, given the strong set of individual values formed through a socialization process largely tribal in nature, it is possible that many South Africans may resist the self-centered nature of materialism (Cf., Burroughs and Rindfleisch 2002). To investigate this question, we conducted depth interviews with individuals who had migrated, for one reason or another, from the tribal areas to the major city of Johannesburg. We anticipated that these individuals would experience cross pressures from the conflict between materialism and individual values learned in the tribal socialization process. As a result, they would exhibit less receptivity to a materialistic value system.

Our data set regarding this question originates from six long, interviews employing the theme of value confrontation. Informants were individuals who had come from various tribal areas of southern Africa to Johannesburg. Interviews were conducted on the campus of Witwatersrand University and lasted approximately one hour each. They sought to locate individuals' encounter with modern western culture in the context of personal values.

Interviews were conducted in English and taped; transcription followed. Axial coding across transcripts was used to uncover common themes and patterns underlying the interviews. Themes were identified and bracketed, and coded with examples. Further verification, discussion, and file development remain to be completed at this point in time. However, we present our initial findings here from repeated readings to date.

Emergent themes and key differences across informants are best exhibited in the responses of two of our informants—Thandi, from Limpopo, once called Northern Province, or the Transvaal, and Bobby from Botswanan Xhosa society. The first theme attendant to moving from tribal areas to Johannesburg was that of marginalization. All of our informants felt out of place in moving to a large modern western city. For instance, Thandi indicated that the move was "quite a challenge for me, having grown up in a slow paced life where you see a car once a day [and where] it is more bushy like, more homeland like, more opened. Here, you have got more buildings..." This is noteworthy because both Richins (1999) and Belk (1984) suggest that marginalization associated with moving encourages the use of possessions to regain a sense of self. A second theme was that of the use of possessions to define self. While both recognized this tendency in their new society at large, each responded differently. Bobby admitted that, having become more aware of possessions, he conscientiously attempted to change his appearance to that which was "stylish" in western terms—"the guys I wanted to relate to were more into All-Stars, flat shoes, etc, a more Italian style, so I cut my hair short..." On the other hand, Thandi moderated her adoption of western style products, eschewing western makeup and those who used it while at the same time adopting western clothing. We suggest that this difference is due to Thandi's closer ties to family and tribal past, which can be seen in her response to questions about current associations. While she listed friends from the past and the "rurals" as close entities, Bobby was more focused on finding new friends who were class and brand conscious. Our final theme is valued possessions. While Thandi placed primary emphasis on house and yard, which, with its gardens, reminded her of her tribal setting, Bobby fixated on clothing, shoes, and designer glasses.

In sum, our data (of which an abbreviated portion is shown here) suggest that acculturation of materialistic values in advancing societies such as that of South Africa occurs in variable yet systematic fashion. Individuals who have strong anchorage in personal values, learned through earlier socialization are able to resist the full impact of materialism and the cross pressure it brings. Those lacking in such moorings are more apt to absorb the full force of materialism. Although our work here is preliminary, we see little controversy or limitation to this proposition.

Exploring the Relationship between Types of TV Programs, Advertising, and Materialism: A Cultivation Theory Perspective

Eda Gurel-Atay, University of Oregon, USA

Lynn Kahle, University of Oregon, USA

Karen Ring, Universal McCann, USA

Extended Abstract

Because materialism has important negative consequences, it is important to understand what causes materialism. Television viewership is one of the most examined antecedents of materialism. Cultivation theory (Gerbner et al. 1977) suggests that television programs present a distorted reality and heavy exposure to that distorted reality makes people believe that the real world is similar to what they see on television. For instance, television programs tend to portray a more affluent (O'Guinn and Shrum 1997) and violent (Gerbner et al. 1980b) world full of with doctors and lawyers (Lichter, Lichter, and Rothman 1994).

Many television programs also portray a luxurious lifestyle, making heavy viewers have higher estimates of ownership of luxury products by average people (O'Guinn and Shrum 1997). Moreover, those programs show how people in those programs are happy with their expensive clothes, large homes, luxury cars, and other expensive possessions. Because materialism is a belief that acquiring possessions brings happiness and signals status and success (Belk 1984; Richins 2004) and because TV programs portray people with many possessions as being happy and successful, heavy viewers of TV tend to be more materialistic.

According to the cultivation theory, TV viewing leads to distorted perceptions of reality regardless of the TV program types (Shrum, Burroughs, and Rindfleisch 2004). However, it is also suggested that the cultivation effect might be program-specific (Gunter 1994). For instance, crime-related reality programs might affect people's perceptions of crime rates while family dramas might affect people's perceptions of family relationships. Therefore, in order to examine the cultivation effect of TV viewing, it is important to consider the differences between TV program types (Weimann, Broisus, and Wober 1992).

This research proposes that different kinds of TV programs have different effects on materialism. As suggested by Holt (1995, pg. 13), “materialism can be conceptualized as the consumption style that results when consumers perceive that value inheres in consumption objects rather than in experiences or in other people.” Accordingly, it can be argued that TV programs that emphasize acquiring objects over sharing experiences and portray a luxurious, materialistic lifestyle will be more associated to materialism: (H1a) People who generally watch TV programs that portray a luxurious, materialistic lifestyle will be more materialistic than people who do not generally watch those TV programs; (H1b) People who generally watch TV programs that do not portray a luxurious, materialistic lifestyle will not differ from people who do not watch those TV programs in terms of materialism.

It can also be argued that different specials of a certain TV program type are more related to materialism than others. For instance, some sports specials, such as golf or tennis tournaments, might be associated with materialism because those sports are more related to affluent people, thereby implying a luxurious, materialistic lifestyle. However, we believe that a broader definition of a TV program type will be a better determinant of materialism because specials still reflect the nature of certain TV program types: (H2a) People who watch TV specials related to genres that portray a luxurious, materialistic lifestyle will be more materialistic than people who do not watch those TV specials; (H2b) People who watch TV specials related to genres that do not portray a luxurious, materialistic lifestyle will not differ from people who do not watch those TV specials in terms of materialism.

It is also possible that people who watch certain types of programs might report higher levels of materialism because of the commercials that air in those programs. TV commercials might make people believe that possession of products promoted in advertisements is important to obtain desired qualities, such as happiness, beauty, uniqueness, and success (Pollay 1986). Impact of advertising on materialism is also expected to be stronger when people pay more attention to commercials. Accordingly, paying more attention to commercials aired in favorite TV programs might mediate the relationship between TV viewing and materialism. However, this mediation effect will hold only for the TV programs that portray a luxurious, materialistic lifestyle (H3a). Because one of the conditions of mediation (i.e., a significant relationship between the independent variable and dependent variable; Baron and Kenny 1986) is not satisfied for TV programs that do not portray a luxurious, materialistic lifestyle, there will be no relationship to be mediated by paying attention to commercials (H3b).

To test the proposed hypotheses, data from a national survey conducted by Universal McCann-Ericson in 2005 were used. The survey was completed by 5,508 adults aged 18 and over in 2005.

The results of independent samples t-tests showed that people who generally watch TV programs that portray a luxurious, materialistic lifestyle (i.e., awards shows, celebrity interviews, films/movies, financial/stock market analysis, and reality programs) are more materialistic compared to people who do not generally watch those TV programs. In contrast, there is no significant difference between the materialism level of people who generally watch TV programs that do not portray a luxurious, materialistic lifestyle (i.e., biographies, documentary/nature, do-it-yourself shows, history, news, and sports) and the materialism level of people who do not generally watch those TV programs. Both H1a and H1b were confirmed.

Two different TV specials were used to test for H2a and H2b: one portraying a luxurious lifestyle (i.e., awards specials), and one not portraying a luxurious lifestyle (i.e., sports specials). The results demonstrated that people who watched awards specials on TV are more likely to be materialistic than people who did not watch awards specials, regardless of the type of the awards special, supporting H2a. In contrast to what was proposed in H2b, however, significant differences were found for two sports specials. People who watched March Madness basketball and people who watched the US Open Tennis Tournament on TV are more materialistic compared to people who did not watch those specials. Therefore, H2b was partially supported.

To test the mediating effect of paying attention to commercials (“attention”), blocked multiple regression analyses were conducted for each of the independent variables: Watching TV programs that portray a luxurious, materialistic lifestyle (i.e., materialistic TV viewing), and watching TV programs that do not portray a luxurious, materialistic lifestyle (i.e., nonmaterialistic TV viewing). In each of the analyses, TV viewing was entered in the first step and attention was entered in the second step. The results showed that paying attention to commercials in favorite TV programs partially mediates the relationship between materialistic TV viewing and materialism. H3a and H3b were confirmed.

This study, to our knowledge, is the first attempt to reveal the TV program types that are more related to materialism. However, our findings do not contradict with the cultivation theory. Instead, they emphasize that not all TV programs present the same message and heavy viewing of different TV programs or TV specials might lead to different distorted realities. In fact, focusing on program types (as opposed to total amount of time spent in TV viewing) might increase the effectiveness and validity of the cultivation theory by providing more concrete results.

Exploring the Antecedents and Consequences of Physical Appearance Concern

Eda Gurel-Atay, University of Oregon, USA
 Leslie Koppenhafer, University of Oregon, USA
 Jae-Gu Yu, University of Oregon, USA
 Lynn Kahle, University of Oregon, USA
 Karen Ring, Universal McCann, USA

Extended Abstract

In today's Westernized and competitive environment, both women and men experience increasing pressures of physical appearance. For most people, the discrepancy between ideal body image and actual body image enlarges as the media continually endorses "thinner" and "sexier" bodies. For instance, previous studies demonstrated that heavy TV viewers are more likely to perceive unrealistic thin female bodies as a standard (Hendriks 2002) and have biased perceptions of body images (Eisend and Moller 2006).

The idealized images conveyed by media vehicles also create a sense of displeasure in consumers with their current personal appearance (Hirschman and Thompson 1997), which in turn affects their consumption behaviors. For instance, as people become more concerned with their physical appearances, they become more interested in clothes and apparels (Burton, Netemeyer, and Lichtenstein 1994), their likelihood of purchasing apparels online decreases (Rosa, Garbarino, and Malter 2006), their attitudes toward cosmetic surgery becomes more positive (Burton, Netemeyer, and Lichtenstein 1994), their usage of cosmetics increases (Netemeyer, Burton, and Lichtenstein 1995), and their usage of tanning salons increases (Burton, Netemeyer, and Lichtenstein 1994).

Physical appearance concern can also affect health-related behaviors. For instance, excessive physical appearance concern might lead to excessive exercise (Tiggemann and Lynch 2001) or unhealthy eating behaviors (Armstrong and Mallory 1992). However, it can also be argued that some types of healthful behaviors are practiced because people are concerned with their appearance as much as their health (Hayes and Ross 1987). Moreover, people who are highly concerned with their concern might want to be look healthy.

In this study, we explore the relationship between media consumption, physical appearance concern, cloths/apparel consumption, and health-related behaviors. It is hypothesized that people who read certain magazines (e.g. InStyle, People, and Vogue) and watch particular types of TV programs (e.g., awards shows, celebrity interviews, and news magazine shows) will be more likely to be concerned with their physical appearance (*H1*). High physical appearance concern, on the other hand, will be associated with both negative outcomes (related to cloths/apparel consumption—*H2*: amount of money spent on clothes, apparel, and luxury items; and frequency of cloth/apparel shopping) and positive outcomes (health-related behaviors—*H3*: healthy food consumption; consumption of foods that help weight-management; and frequency of exercising).

To test the proposed hypotheses, data from a national survey conducted by Universal McCann-Ericson in 2005 were used. The survey, called *Media in Mind*, is conducted each year and focuses on lifestyles, media consumption, and other consumption related attitudes and opinions. Of 4,990 adults who completed the survey, 40% were male, 50% were older than 50-years-old, 83.5% were White, and 65% were married. Measures related to media consumption (TV programs that portray thin and sexy body images, and favorite magazines that are related to fashion and celebrities), physical appearance concern, amount of money spent on clothes/apparels and luxury items, frequency of cloth/apparel shopping, and consumption of healthy food, consumption of food that help weight-management, and frequency of exercising were used to test proposed hypotheses. Also, because there is a significant difference between men (Mean=3.36) and women (Mean=3.65; $t=-12.830$, $p<.001$) in terms of physical appearance concern, gender was treated as a control variable in all analyses.

To test for the impact of media consumption on physical appearance concern, a blocked multiple regression analysis was conducted by entering gender in the first step and entering media consumption variables in the second step. The inclusion of media consumption variables in the regression model resulted in a significant F change ($F_{\text{increment}}=190.503$; $df=2, 4983$; $p<.001$; $\Delta R^2=.07$). The predictors explained 10% of the variance in physical appearance concern in the second step ($F=186.044$; $df=3, 4983$; $MS_{\text{res}}=.561$; $p<.001$; $R^2=.101$; adjusted $R^2=.100$). Both media consumption variables have positive and significant effects on physical appearance concern, meaning that as people watched more TV programs that portray thin and sexy bodies ($\beta=.184$, $t=12.593$, $p<.001$) and as people read more fashion-related magazines ($\beta=.138$, $t=9.480$, $p<.001$), they become more concerned with their physical appearances. Therefore, H1 was confirmed.

A series of blocked multiple regression analyses were also conducted to examine the impact of physical appearance concern on proposed dependent variables. In all of these analyses, gender was entered in the first step and physical appearance concern was entered in the second step. The inclusion of physical appearance in the second step resulted in significant F changes in all analyses.

The results showed that as physical appearance concern increases, people spend more money on clothes and apparel ($\beta=.193$, $t=12.773$, $p<.001$) and luxury items ($\beta=.208$, $t=14.679$, $p<.001$). Also, they go shopping for clothes and apparel more frequently ($\beta=.222$, $t=16.145$, $p<.001$). These results provided support for H2.

Our results also showed that people who are highly concerned with their physical appearance are more likely to consume healthy foods ($\beta=.196$, $t=13.934$, $p<.001$) and more likely to consume foods that help them manage their weight ($\beta=.192$, $t=13.571$, $p<.001$). However, no significant relationship between physical appearance concern and frequency of exercising was found ($\beta=-.009$, $t=-.443$, $p=.658$). Therefore, H3 was partially supported.

Overall, our study shows that, as the cultivation theory suggested (Gerbner et al. 1977), media consumption affects the level of physical appearance concern. People who consume certain types of TV programs and magazines are more likely to be concerned with their physical appearances. Similar to previous studies, our study shows that physical appearance concern has negative impacts on clothes/apparel-related consumption behaviors. As opposed to previous studies, on the other hand, our study provides some evidence that physical appearance concern might lead to healthy behaviors, such as healthy food consumption. Future studies should examine these issues through experiments and longitudinal studies in order to establish direct cause-effect relationships between media, physical appearance concern, consumption behaviors, and health-related behaviors.

Don't Go to the Grocery Store Hungry?

Christine Ringler, Arizona State University, USA

Andrea Morales, Arizona State University, USA

Steve Nowlis, Arizona State University, USA

The focus of the current research, is to identify whether consumers show preference for hedonic and utilitarian food and non-food items when hungry, explain why such differences exist, and demonstrate the relationship between hunger and self-control (manipulated through cognitive load) on our consumption of hedonic and utilitarian items. Research on palatability and preference ratings (Rolls et al. 1981), the role of external cues (Cornier et al. 2004), and variety seeking behavior (Menon and Kahn 1995) have explored how hunger affects our preferences and choices. This literature shows that consumers are not very good at understanding their body, instead they respond to external cues like time of day or the smell of pizza (Schachter 1968). Additionally, they tend to seek items that will satiate their hunger (Goukens et al. 2007), which results in increased attractiveness of the items when hungry. Only after they have eaten a large amount of one item does the attractiveness of that item decrease (Rolls et al. 1981). However, research does not offer predictions regarding cases of consumption where the most attractive item is not the most consumed. We hypothesize that while self-control does not affect the attractiveness of an item, self-control is in effect when the individual is ready for consumption, thus extending previous work on the effects of hunger in consumption settings and self-control in general. We extend this research by gaining a better understanding of the effects of self-control as a moderator between hunger and consumption. Specifically, we consider the case where consumers report their individual levels of hunger, then participate in consumption of utilitarian and hedonic foods. This leads us to propose a theory of hunger that demonstrates that when hungry, consumers have a tendency to eat more than they should, therefore, they tend to employ self-control tactics, which stop them from eating excessive quantities of the hedonic foods, but allows them to eat the utilitarian foods. Research on self-regulation has investigated cases where consumer impose measures of self-control (restrained eaters), but has not examined cases where consumers are "normal" eaters and impose measures of self-control when presented with hedonic food items in a hunger situation.

Although prior research on hunger has identified reasons why consumers ignore internal signals of hunger (i.e. impulsiveness) and in particular when external cues are present; we extend the research to explain why hungry consumers eat more of the utilitarian product even though the hedonic is more attractive. Research on hedonic versus utilitarian consumption has shown that consumers rate a hedonic alternative higher than a utilitarian alternative when each is presented by itself, but the utilitarian alternative tends to be chosen over the hedonic alternative when the two are presented together (Okada 2005). To the degree that presenting the utilitarian and hedonic products separately but within the same survey constitutes them being looked at singularly, we would expect the preference for hedonic products to be higher than utilitarian products, this effect being magnified when consumers are hungry and the hedonic products are food. The goal of study 1 is to examine whether hedonic items, (food and non-food), are shown more preference when hungry than when not hungry. We are interested in testing whether self-control moderates the relationship between hunger and preference for hedonic food items, specifically we will examine utilitarian food and non-food item preference when hungry and not hungry. As such, in study 1 we assess whether consumers find hedonic items more attractive than utilitarian items by asking them to rate them individually under situations of low and high cognitive load and under feelings of hungry and not hungry. The results of study 1 indicate that consumers view hedonic food items as being more attractive than hedonic non-food items and utilitarian items when hungry compared to not hungry. Participants rated food items as being preferred only when they were hedonic in nature. Additionally, participants did not consider non-food items more attractive when hungry. This demonstrates that hunger impacts consumer choices when evaluating food products, however this is only applicable to hedonic food products and does not appear to extend beyond this category. Previous research indicates that high cognitive load causes us to make choices based on impulse (choosing hedonic items), which might not occur if consumer's choices were free of cognitive load. These findings suggest that cognitive load moderates the relationship between hunger and product preferences in that only under high load and hunger do consumers prefer hedonic food items. Lastly, we identified no differentiation in product preference when participants were under low load. Study 2 attempts to test our second hypothesis by measuring actual consumption, as it relates to hunger using hedonic and utilitarian food items, under conditions of high and low cognitive load. We test consumption by using hedonic and utilitarian food items (M&M's versus Carrots) under conditions of hungry and not hungry. While attempting to replicate the results of study 1 under low load, study 2 shows that when we present the food item to the participant, hunger has no impact on the preference for hedonic food item (M&M's), which is consistent with the results of study 1. Additionally, results indicate that participants are able to employ self-control tactics when hungry that allowed them to avoid eating more of the hedonic food item but allowed them to eat more of the utilitarian food item. To better understand this, study 3 seeks to replicate the results of study 2 and turn off the over consumption of hedonic food items when hungry and under high load by providing participants with calorie or no calorie information. Study 3 finds that under high load with no calorie information present, participants ate significantly more when hungry than when not hungry. Under high load with calorie information present, the difference between hungry and not hungry failed to reach significance. Additionally, when no calorie information is present and participants were not hungry, the difference between low load and high load failed to reach significance. Study 4 seeks to understand the underlying processes associated with these results.

Environmental Cues and Food Consumption

Beth Vallen, Loyola University, USA
 Lauren G. Block, Baruch College, USA
 Chrissy Mitakakis, Baruch College, USA

Extended Abstract

Individuals often face self-control dilemmas, whereby temptations interfere with the pursuit of long term goals (Fishbach and Shah 2006). Choosing between vices, which provide immediate pleasure, and virtues, which are in line with long-term goals, is likely to generate guilt and intrapersonal conflict. Along these lines, individuals often seek justification for indulging in vices to reduce feelings of guilt (Giner-Sorolla 2001). Recent research provides support for the contention that specific occasions or special events (i.e., holidays, birthdays, etc.) engender a sense of entitlement for individuals in terms of their consumption behavior; this justification cue results in a greater likelihood of relaxing self-control and selecting vices (e.g., chocolate cake) over virtues (e.g., fruit salad; Kivetz and Zheng 2006). On the contrary, such cues can also result in a heightened defensive state for people who are particularly guarding against indulgence, such as dieters.

In this research, we explore how individual differences in dieting behavior interact with the presence of an environmental cue, such as a special occasion or holiday, to either justify indulgence or bolster self-control, leading to a choice of more versus less indulgent

food items, respectively. We posit that dieters will exert more self-control when such environmental cues are present (vs. absent). We argue that for these individuals, cues involving a holiday or special event are interpreted as situations that are characteristic of indulging and, therefore, can automatically signal higher efforts at self-control. Instead of acting as justification for indulgence, these cues will act as triggers for guarding against dieters' long-term eating goals (Myrseth, Fishbach, and Trope 2009; Trope and Fishbach 2005). Additionally, we hypothesize that the absence of such cues will lead dieters to be unprepared to bolster their self-control efforts, thus resulting in a self-control failure and indulgence. On the other hand, since non-dieters do not exert the constant attempts at self-control and monitoring that dieters do, we expect that non-dieters will utilize holiday cues as justifications to indulge.

For our first study, we examined the effect of a specific environmental cue (i.e., a birthday) on people's consumption behavior. Participants were given a questionnaire in which they read about a hypothetical scenario where they were going to dinner with some friends. Half of the participants were told that the dinner was held in honor of their own birthday, while the other half were told that it was for a friend's birthday. All participants were then asked to choose the specific dessert they would order at the dinner. Dessert choices ranged from extremely unindulgent (i.e., a healthy fruit salad), to extremely indulgent (chocolate cake à la mode). A series of self-report measures followed, including measures of self-control and dieting behavior. Results support our hypotheses; dieting participants who were told that they were out to dinner in celebration of a friend's birthday chose the most indulgent dessert significantly more than dieting participants who were told that they were out to dinner celebrating their own birthday. By contrast, non-dieting participants chose the most indulgent dessert more when they were told that they were celebrating their own birthday. Additionally, we found that choice for the most indulgent option was significantly higher for dieting participants than non-dieting participants overall.

In our second study, we explored the impact of dieters' defense bolstering in the presence of a holiday justification cue on actual food consumption. We varied the saliency of the holiday cue by administering half our study on Halloween, and the other half on another day the week following the holiday. All participants were given a bag with 50 M&M candies and a questionnaire to complete. Participants were told that they could enjoy the candy as they filled out the questionnaire. Included on the questionnaire were questions assessing participants' self-control and dieting behavior. At the end of the study, participants were asked to count the number of candies remaining in their bag, which we used to calculate the amount consumed. Our results again support the hypothesis that dieters experience a bolstering of self-control when the holiday cue (i.e., Halloween) is available and consequently eat less than dieters who do not have such cues available (i.e., an ordinary day). Moreover, the opposite effects occur for non-dieting participants, who consumed less of the candy on an ordinary day compared to Halloween.

A third study (currently underway) seeks to examine the proposed psychological mechanisms underlying the effects found in our prior studies, with a particular emphasis on the processes involved in the heightened efforts of self-control for dieters when holiday cues are present. As in study 2, in this study we assess participants' actual consumption behavior, this time in the presence or absence of holiday-related food cues (i.e., highlighting the food-related characteristics of Thanksgiving versus the non-food characteristics). In addition to measures of self-control and dieting behavior, we implicitly assess the specific efforts involved in self-control that act to guard against indulgent consumption. It is hypothesized that, in line with our prior results, dieters will exhibit heightened self-control with the presence of a holiday cue, but will relax efforts at self-control when the holiday cue is framed as a non-eating holiday. We predict that these varying levels of self-control will impact actual food consumption.

In sum, our research demonstrates that certain cues in the environment that have been traditionally considered justifications for indulgence can also have the opposite effects for certain individuals, namely dieters. On one hand, this bodes well for dieters, who may be better equipped to handle holiday-related consumption cues (e.g., a big bowl of mashed potatoes and gravy). On the other hand, it also demonstrates that these individuals might be less well equipped to deal with everyday indulgences (e.g., the candy jar on a co-worker's desk). These findings carry implications for dieters as well as those individuals striving for weight maintenance. Future research might explore other factors that contribute to the bolstering versus licensing effects so that individuals might be better equipped to handle environmental cues linked to overconsumption.

Quality and Quantity of Food Consumption: Role of Emotion and Social Capital

Alice Labban, McGill University, Canada
Spencer Moore, Queen's University, Canada
Laurette Dubé, Canada

EXTENDED ABSTRACT

Research Background

In times in which obesity represents a problematic issue in different countries, it is becoming more and more important to understand individuals' food consumption habits¹⁻². The present work provides a clearer picture of what drives or inhibits healthy/unhealthy eating building on regulatory focus theory and temporal construal theory to explain how emotions and social capital predict quantity and quality of individuals' food consumption. Previous research has suggested that both emotions³⁻⁴ and social capital⁵⁻⁶⁻⁷, here measured by social participation⁶⁻⁸ are assumed to play an important role in food consumption, but we need a clearer understanding of the underlying mechanisms that justify the nature of the relationships and its specific outcomes.

Regulatory focus theory posits that individuals approach desired states and avoid undesired states through promotion and prevention respectively⁹. All behaviors could be categorized as either approach or avoidance behaviors¹⁰. Approach behaviors are the all positive behaviors directed towards a certain environment and avoidance behaviors are the opposite¹¹. We use quantity and quality of food consumed compared to individual's perceived eating norm as indicators of approach and avoidance behaviors. Choosing to conform to the eating norm is considered as an avoidance behavior and choosing to consume healthier/unhealthier to the eating norm is considered to be an approach behavior.

Temporal construal theory posits that the value individuals' give to outcomes is time dependant and individuals sometimes put more weight on short-term rewards while other times focus more on the long-term rewards¹²⁻¹³. When it comes to quantity/quality of food consumed, individuals have a short-termed desired state of fulfillment and pleasure when eating more quantities/unhealthy that could lead to long-term undesirable state of gaining weight. However, consuming fewer quantities/healthy have a short-term undesirable state of un-satisfaction and perceived bad taste but a long-term desirable state of maintaining or losing weight¹⁴. Therefore, both healthier and unhealthier food consumption could prompt individuals either to approach or avoid them.

We argue that individuals focusing on short-term rewards are more likely to approach unhealthy items and avoid healthy items. However, those focusing on the long-term rewards are more likely to approach healthy items and avoid unhealthy items. Previous literature found that individuals in a positive state are preoccupied, in the short-term, to maintain that positive state while individuals in a negative state are preoccupied in the short-term to alleviate immediately that negative state¹⁵. Therefore, we hypothesize that when it comes to emotions (calm and depression) individuals focus on the short-term rewards. Positive emotions like calmness lead individuals to approach objects around them¹¹⁻¹⁷ and in this case approach unhealthy behaviors. Negative emotions such as depression lead individuals to avoid objects around them¹¹⁻¹⁷ and in this case avoid healthy behaviors. As for participation, it was found to provide affective support and increase self-esteem¹⁸ and contributes to individuals' health by promoting positive affect¹⁹, by decreasing negative affects²⁰ and by buffering stress²¹. Participation provides individuals with a general sense of contentment and fulfills individuals need to belong and therefore we hypothesize that participation makes individuals less preoccupied by short-term rewards and more focused on the long-term rewards making them more prompt to conform with others and thus avoid unhealthier behaviors. Moreover, as participation could act as buffer to negative emotions²⁰ we hypothesize that participation will help depressed individuals succumb their negative emotions and thus making them avoid unhealthy behaviors.

METHOD

Design and Procedures

Questionnaires administered through a computer assisted telephone interviewing system were used to test our hypotheses. In total 787 participants completed the questionnaire. These participants were randomly selected from census data from the Montreal Metropolitan Area.

Measures

Participants were asked to rate the quantity and quality of food consumed in comparison to their perceived eating norm (what they perceive others like them usually eat). We operationalize approach behaviors in terms of participants choosing either to consume healthier or unhealthier quantity and quality of food compared to the eating norm. As for avoidance behaviors, we operationalize them in terms of consuming the same quantity and quality of food as the perceived eating norm. Choosing to conform to the eating norm is considered to be an avoidance behavior since it fulfills the prevention goals that individuals think should be met. Consuming healthier or unhealthier than the eating norm is considered to be an approach behavior since it meets individuals' promotion goals that are those goals that individuals aspire to meet²². A 5-point Likert scale measured three types of emotion: Calm, Energy and Depression. A dichotomous measure of Participation showed whether individuals participated or not in any of four form of social participation²³.

Results

A multinomial analysis showed that both emotions and social participation play an important role in the quality and quantity consumed. Actually, we found that the calmer participants are the more likely they were to say that they consumed more quantities than the perceived eating norm. Those that have high levels of depression were less likely to say that they consumed fewer quantities than

the perceived eating norm. Those who participate in social activities are less likely to eat less healthy food compared to the perceived eating norm.

Furthermore, social participation played a moderating role on the relationship between depression and the quantity and quality of food consumed. Participation seems to buffer the effect of depression on the quality of the food consumed making depressed individuals less likely to consume less healthy quality than the perceived eating norm. Moreover, it seems that depressed individuals that participate in social activities are better off than non depressed individuals that do not participate in social activities.

Conclusion and Discussion

In conclusion, this research shows that emotion and social capital captured through social participation have a great effect on food consumption and on whether individuals decide to either approach or avoid healthy or unhealthy items. This research also shows that participation could be a good mood restoration management tool aiding depressed people in their health habits. Finally, this research differs from other research on food consumption in that it shows that different predictors could play differential roles in terms of either prompting or preventing individuals from conducting healthy or unhealthy behaviors.

Everything in Moderation? When Moderation Leads to Indulgence

Ashley Rae Arsenau, The University of Texas at San Antonio, USA

David H. Silvera, The University of Texas at San Antonio, USA

Extended Abstract

“Everything in moderation” is often recommended as a way to achieve balance and limit consumption. From chocolate to wine to eating out, acting in moderation is expected to combat many problems that deal with consumption excess (e.g., obesity, binge drinking, impulsive buying, alcoholism). For example, a recent public service announcement aiming to reduce alcohol consumption features a picture of vodka with the slogan “It’s not what you drink. It’s how much you drink that counts. Moderation in all things.” Similarly, another advertisement advocating the practice of moderation illustrates a body builder with unnaturally large grotesque muscles accompanied by the slogan “Too much of a good thing is still too much. Moderation.”

However, although the practice of moderation has been prescribed by many, there is no empirical research investigating whether moderation actually succeeds in promoting healthy behavior. The objective of this research is to provide a much needed understanding of the role moderation plays in consumption behavior.

Past research has shown that individuals license themselves to indulge when they have previously acted in line with a long-term goal (Fishback and Dhar 2005; Khan and Dhar 2006). That is, when individuals feel they have made progress toward a long term goal, they have less motivation to engage in self-control directed at achieving this goal. This phenomenon, called the licensing effect, indicates that when progress toward a long term goal is perceived, individuals often disengage from that goal and act in opposition to it.

The licensing effect has been observed in many domains. For example, dieters’ who felt they made sufficient progress in losing weight were more likely to choose unhealthy options (Fishbach and Dhar 2005). Similarly, individuals who were induced to feel moral showed less inclination to engage in moral action (i.e., by donating blood) compared to people who were not induced to feel moral (Sachdeva, Ilic, and Medin 2009).

The present research applies this logic to the concept of moderation. Thus, we hypothesize that activation of the moderation concept leads to a temporary satisfaction of health goals, which in turn makes the individual feel that they are licensed to indulge. Consequently, the activation of moderation should result in greater preference for more indulgent items in a choice set.

Furthermore, individual differences in self-control should moderate this effect. Specifically, individuals who are high in self-control can more easily access past behaviors or project future behaviors where they will engage in healthy eating (Wilcox et al. 2009), and the resulting increase in activation of past and/or future health behaviors consequently makes these individuals feel more licensed to indulge. Thus, the concept of moderation is likely to lead to greater preference for indulgent items in a choice set for individuals who are high in self-control.

To test this hypothesis, participants were assigned to one of two conditions. Participants in the moderation prime condition were asked to elaborate on the concept “everything in moderation.” In contrast, participants in the neutral prime condition were asked to provide a summary of their favorite movie. Participants were then shown pictures of 5 dessert choices. Based on a pre-test, these choices varied in their degree of perceived healthiness (from least to most healthy: chocolate brownie with 6 scoops of ice cream, chocolate cake, carrot cake, strawberries with whipped cream, and a bowl of fruit). Participants were asked to indicate their dessert preference. After participants completed the prime and the decision task, trait self-control was measured using the 36-item Self-Control Scale (Tangney et al. 2004). A regression analysis showed a significant interaction between trait self-control and the priming manipulation in predicting the healthiness of food choices. Specifically, among low self-control individuals, the moderation prime was associated with healthier choices than the neutral prime, whereas among high self-control individuals the moderation prime was associated with more indulgent choices than the neutral prime. These results suggest that moderation has the desired effect on low self-control individuals, but that moderation can backfire for high self-control individuals and lead them to prefer indulgent options.

This study demonstrates a relatively novel effect: the impact of activation of the moderation concept on consumption. Thus, the present research makes an important contribution by providing empirical evidence addressing the question of how moderation influences consumption decisions. Moreover, these results support the counterintuitive proposition that moderation actually leads to indulgent preferences for high self-control individuals, which has serious implications for the use of moderation in efforts to promote healthy behavior.

Future studies will examine the underlying mechanism for this effect. That is, how does moderation satisfy health goals? Presumably, moderation puts one in a healthy mindset by invoking past instances where one has satisfied a health goal (e.g., I ate healthy last week) or future behavior where one will satisfy a health goal (e.g., I’ll eat healthy tomorrow). This mindset would potentially connect the present findings with research on the effect of future choices on self-control, which indicates that when a decision is presented in the context of sequential future choices, people optimistically believe they will be virtuous in the future and are thus more likely to indulge in the present (Khan and Dhar 2007). In other words, individuals might feel licensed to engage in short-term transgressions because they believe they can make up for them in the future. This suggests that the effect of moderation on indulgence might be attenuated if participants are asked to think about a choice in isolation rather than a choice that is part of a sequence of choices. If this is the case, then (a) high self-control individuals should prefer indulgent items when the choice is made as part of a sequence but not when the choice is made in isolation, and (b) it is possible that priming moderation spontaneously invokes thoughts of sequential choices (i.e., the realization that moderation can be achieved by balancing past, future, and present choices), and that these thoughts mediate the relation between moderation and feeling licensed to indulge.

Overweight and Self-Control Failure: Is There a Way Out?

Thomas Rudolph, University of St. Gallen, Switzerland

Alexandra Glas, University of St. Gallen, Switzerland

Peter Kenning, Zepelin University, Switzerland

Extended Abstract

Persuading people to eat healthier is a major challenge in modern societies. To prevent diet-related diseases, there are to the best of our knowledge two research approaches being discussed. One approach applies powerful economic mechanisms, e.g. higher taxes for unhealthy food products. Studies showed that the demand for sugar-sweetened beverages can be reduced significantly by increasing prices (Epstein et al. 2010; Brownell and Frieden 2009). The other approach under discussion uses instruments that are grounded in psychology (Garg, Wansink, and Inman 2007; Chandon and Wansink 2007). However, both ways are often discussed unrelated to each other. This is astonishing assuming that a combination of both ways might positively affect the power of prevention. This holds particularly true considering that taxes might have serious consequences for markets and competition and are insofar second best. Against this background the aim of our study is to shed light on the interaction between economic and psychological approaches.

Literature both in psychology and economics ties habits and self-control. A pivotal tenet of economics is that incentives promote effort and performance (Gibbons 1997; Lazear 2000). In other words, rewards serve as positive reinforcers for the desired behavior (Bénabou and Tirole 2004). For psychologists, in contrast, the effect of rewards is more controversial (Deci, Koester, and Ryan 1999). They rather argue that self-regulatory strategies promote the initiation of goal-directed behaviors (Gollwitzer 1999; Baumeister and Heatherton 1996).

In this research we test whether implementation intention as a self-regulation mechanism and monetary incentives can be used in combination to overcome the self-control dilemma and to foster healthy eating behavior. Furthermore we aim to examine which of these approaches have a stronger influence and whether interactions might accrue. Thus comparing the two interventions provides insight into the interplay between psychological and economic processes underlying the healthy eating behavior.

To achieve this aim we conducted a controlled field experiment using a 2 (*Implementation Intention: Formed/Not Formed*) x 2 (*Monetary Incentive: Available/Not Available*) between-subjects design.

The study was conducted in three sequences with 176 Swiss consumers. Firstly, participants completed a baseline questionnaire which was combined with the implementation intention manipulation. The second sequence contained the incentive manipulation followed by the redemption of the voucher which measured actual eating behavior. Participants could choose between high-calorie, unhealthy snacks (croissants) and low-calorie, healthy snacks (mandarins/grapes). We counted the number of snacks chosen and converted the amount into calories (kcal). One week later, all participants completed a follow-up questionnaire being asked for the amount of unhealthy snacks they had consumed during the manipulation week.

Following this setup we are able to observe eating behavior before, during, and for one week after the intervention. Our main predictions are strongly confirmed. Firstly, the short-term interventions "implementation intention" and "monetary incentives" foster to choose the healthy snack. Secondly, participants are dynamically inconsistent: they chose more unhealthy snacks for immediate than for advance choice.

Analyses were conducted with SPSS. In a first step, we checked randomization and intercorrelations between all antecedents, as postulated by the theory of planned behavior as well as whether these antecedents predicted behavioral intention. Therefore, a multivariate analysis (MANOVA) was conducted between participants in the experimental and control groups with respect to the antecedent variables. The Levene's test for each variable was not significant ($p > .05$), suggesting that the randomization had been successful.

Secondly, healthy eating behavior correlated significantly ($p < .01$) with all antecedent variables, except subjective norm. As expected, habits correlated negatively ($-.238, p < .01$) with healthy behavior. To test whether the antecedents predicted behavioral intention, we regressed behavioral intention on all antecedents. In the regression analysis ($R^2 = .45$) both the beta weights of attitude and perceived behavioral control were highly significant, $\beta = .56, p < .01$, and $\beta = .19, p < .01$, respectively, demonstrating that both variables contributed uniquely to the prediction of intention.

In a second step, we analyzed the interventions. Overall, 131 of 176 participants redeemed their voucher. As expected, the percentage of participants redeeming their voucher for a healthy snack in the control group was low-only 50%. In the experimental group "implementation intention" this percentage rises to 78.1%. In the experimental group "monetary incentive" 85.3% choose a healthy snack and in the combined experimental group this percentage is 82.9%. A chi-square-test shows high significance among the observed frequencies ($p < .05$).

The relative power of the three experimental manipulations was tested with an ANOVA. The overall F-test of this ANOVA is significant, $F(3,131) = 4.101, p < .05$. The multiple mean comparisons (Student-Newman-Keuls-test) show a significant difference between

the behavioral reaction of the control group and that of all three experimental groups. For the behavioral differences between the three experimental groups the multiple mean comparisons show no statistically significant differences.

To test whether the two interventions reduced the self-reported snack behavior during the follow-up week, we conducted an ANOVA. The main effect of the interventions was not significant $F(3,160)=1.72$. Following a Wilcoxon-test there was a highly significant ($p<.05$) effect of "Time" for the combined experimental group. Thus, those subjects who received both interventions reduced their snack consumption significantly during the follow-up compared to the baseline week ($M_{\text{baseline}}=7.81$; $M_{\text{follow-up}}=6.45$).

To conclude, our study provides first insights about the effect of the combination of economic and psychological interventions on consumers' food choices. Our data reveal that incentives and self-regulation mechanisms encourage consumers to engage in healthy snack behavior. Incentives seem to have the strongest power. Moreover, the result provides evidence that the combined effect is more overlapping than additive. This finding initiates the discussion of how independent psychological and economic processes are. It could be argued that in daily life strong incentives encourage consumers to engage in self-regulation activities. From the food industry's point of view, such a combined approach may be more attractive—in contrast to taxation—because it gives leeway for communication activities rather than just following policies. Further research should determine details about the long-term effects of combined interventions.

The Boomerang Effect of Mandatory Sanitary Messages to Prevent Obesity

Caroline Cuny, Grenoble Ecole de Management, France

Carolina Werle, Grenoble Ecole de Management, France

The prevalence of overweight and obesity increases in a tremendous way in France, especially since the beginning of the 1990s. To counter this problem, French authorities establish new guidelines and, since 2007, companies are obliged to include health sanitary messages on their advertisements for foods and beverages. Four health messages ("For your health, eat at least five fruit and vegetables a day"; "For your health, avoid foods that are too fatty, too salty or too sweet"; "For your health, avoid snacking between meals"; and "For your health, practice a regular physical activity"). These health messages must "be presented in a way they are easily readable and clearly differentiated from the advertising message" and must occupy at least 7 % of the advertising space.

The inclusion of sanitary messages on advertisements is based on the assumption that food advertisements favour obesity among children. Previous studies emphasized the influence of advertisements on the gain of weight among children (Pécheux, Derbaix and Charry, 2006). The objective of the inclusion of sanitary messages in the food advertisements was to prevent obesity and to easily disseminate health messages to the population.

However, the presence of sanitary messages can have a different effect on consumers' perception of a hedonic product. Indeed, the consumption of hedonic products is associated with a need for justification and feelings of guilt (Kivetz and Simonson, 2002). Although hedonic products' consumption generates positive emotions (Chitturi, Raghunathan and Mahajan, 2007), this choice is difficult to justify (Okada, 2005) and may have negative consequences in the long run, increasing guilt (Hoch and Loewenstein, 1991). The policy makers' objective including sanitary messages in advertisements for foods is to increase the guilt associated with the product, reducing its consumption. Nevertheless, the presence of the health message can be a justification for the hedonic choice. Previous research indicates that presenting a justification for the choice of a hedonic product increases its consumption (Kivetz and Simonson, 2002; Lee, Shavitt, 2009). Making a hedonic decision and claiming to do something good for your health just after it reduces the feeling of guilt and finally encourages the hedonic choice (Strahilevitz and Myers, 1998). Here, presenting a hedonic food simultaneously with the solution to face the consequences of its consumption (sanitary message) may have an unexpected opposite effect.

The objective of this article is to verify the effects of the sanitary messages on the explicit and implicit attitudes towards hedonic foods. Following the conceptualisation above, we propose that attitudes towards the product will be more positive when the sanitary message is present in the advertisement than when it is absent, because the message provides a justification for the hedonic consumption.

One-hundred thirty-one students (average age 20 years old) participated in the study. A single health message was tested in the present study: "For your health, eat at least five fruit and vegetables per day". This message was chosen because it is the best recalled

message among the four mandatory messages imposed by the French government (INPES study, 2007). The hedonic food advertisement used was a real advertisement for McDonald's showing the picture of a BigMac. To measure the implicit attitude towards the product, we developed a visuo-semantic priming protocol. In a task unrelated to the test, participants were instructed to determine as quickly as possible if character strings were real French words or not (lexical decision task). The test comprised a total of 96 sequences including 12 test sequences and 84 distractive sequences designed to prevent participants from understanding the real objective of the study. The 12 test sequences were constituted by the presentation of the Big Mac advertisement followed by the presentation of a real French word. The words used as semantic concepts targets were the following: health, nutrition, wellness, pleasure, taste, credibility, obesity, constraint, casual, guilt, weakness, confusion; they represented 6 positive concepts and 6 negative concepts. The Big Mac advertisement was presented alone in half of the trials and including the sanitary message in the other half.

Participants were then asked to fill in a questionnaire. Before answering they were presented the Big Mac picture with or without the sanitary message for 5 seconds. Participants answered questions about their attitudes towards the product (adapted from Voss, Spangenberg & Grohmann, 2003; Homer, 1990) and general questions, such as gender, age, weight and height, and when was their last meal. After finishing the questionnaire participants received a McDonald's coupon as a thank-you gift for their participation in the study. They had the choice between two coupons for a McDonald dessert: a sundae (unhealthy option) or a bag of fruits (healthy option).

Results indicated no effects of the sanitary messages on the explicit attitudes towards the product, neither on the behavioural measure (choice of dessert). However, results of the lexical decision task demonstrated greater reaction times to process the negative concepts when the Big Mac advertisement was presented with a health message that when it was not. Thus, implicit measures showed that participants associated more easily negative concepts to the product when the advertisement was presented without the sanitary message than when it was presented with a health sanitary message. This result is consistent with our conceptualization.

The presence of the health message can automatically activate representations associated to a justification for the product consumption, leading to a less negative perception of the product. Thanks to implicit and explicit data collection protocols, our research shows that the presence of a health sanitary message on an advertisement for a hedonic product made it less negative. These results highlight an unconscious automatic process which could lead to the association of health messages to a justification for an indulgent behaviour, leading therefore to opposite effects than those expected. Further research should replicate these findings using other products and other health messages in order to design new ways to communicate obesity prevention messages.

The Dove Effect: How the Normalization of Obesity Can Influence Food Consumption

Lily Lin, University of British Columbia, Canada
Brent McFerran, University of British Columbia, Canada

Extended Abstract

Several years ago, Dove introduced the "Real Beauty" campaign, which featured "real women with real curves" as the models in its advertisements. While one of the goals of this campaign was to counter the stigma often faced by overweight individuals, the campaign also set out to enhance women's self-esteem by encouraging them to embrace their physical appearance. Although there is no question that finding ways to reduce the stigma many obese individuals face and promoting a healthy body-esteem are laudable and important

goals (e.g., Smeesters et al. 2010), it may be equally important to examine whether such campaigns and advertisements can influence people's food consumption choices. For instance, if one is told that women who are overweight are "normal" or "real", perhaps this *reduces* consumers' motivation to eat healthy and lose weight. Given the problem of obesity, and how it is largely driven by food intake (Young and Nesle 2002), this is a relevant concern.

We examined this research question in two studies. In both studies, we manipulated perceptions about what a plus size and what an average size person looks like. We then investigated how viewing a single advertisement could influence people's decisions during a food selection task, their attitudes toward healthy eating and weight loss, and their actual consumption behavior. While previous research had shown that exposures to certain figures in the media can impact consumers' perceptions about their own appearances (Smeesters and Mandel 2006; Trampe et al. 2007), our research examined if "normalizing" larger body sizes would change consumers' food choices. Furthermore, we examined whether the normalization of obesity would influence people's selections of menu items and their motivation to pursue a healthier lifestyle.

The purpose of Study 1 was to examine how the normalization of obesity would influence people's actual food consumption tendencies. The study was a one factor between-subjects design, where 49 participants were either assigned to a "plus size" or "normal" condition. Following past research (McFerran et al. 2010, Smeesters and Mandel 2006, and Trampe et al. 2007), only females were included in the study. In both conditions, participants were asked to view an advertisement for a new clothing store that had a photo of an obese female model posing in the center of the ad. While the model and ad copy were the same between conditions, the tag line that was shown with the model was different between the two groups. In the "plus size" condition, the tag line that appeared with the model was "For Plus-Size Women". In the "normal" condition, the tag line that appeared with the model was "For Real Women". Participants then completed a number of dummy measures related to the ad copy and brand, as well as studies unrelated to the present experiment that served to disguise the true purposes of the research. To measure how the exposure of the advertisement affected people's consumption choices, ten chocolates were placed on the table where the participants were seated. Participants were told that the chocolates were left over from a previous study, and that they should feel free to eat as many of them as they wished. The number of chocolates consumed during the course of the study served as the behavioral measure. We found that participants in the "normal" condition consumed more chocolates by the end of the session than those in the "plus size" condition.

Study 2 was designed to replicate the effect from study 1 using a different measure containing several food choices as well as caloric information. The second purpose of the study was to increase the generalizability of the previous study by including both genders in our sample. The third purpose was to extend the previous results by measuring one's motivation to engage in a healthier lifestyle, which would provide some process evidence for the effect. The participants were 95 Amazon.com users, and the study employed the identical design and manipulation for the "plus size" and "normal" conditions as the first study. After the participants viewed the advertisement for a few minutes, they were asked to create their ideal meal from a list of 15 food items. Pictures of the food and caloric counts of the items were shown, and participants could select as many or as few items as they wished. Participants also rated their current motivation to exercise more, lose weight, and eat a more healthy diet on 7-point Likert Scales. Results showed that the meals created by those in the "normal" condition contained significantly more calories in total than those in the "plus size" condition. Additionally, those in "normal" condition provided *lower* ratings on questions related to motivation to be in better shape, to get down to one's desired weight, and to eat a more healthy diet. Importantly, in both studies, the participants' own BMI did not have any mediating or moderating effects.

Two studies showed that while presenting obesity as "normal" or more socially acceptable may be intended to increase consumers' feelings towards their own body image, in doing so consumers may have a reduced desire to make healthy lifestyle decisions. Our research dovetails with that of Christakis and Fowler (2007), who showed that obesity can spread through social networks, but provided little evidence for the mechanism. Perhaps if one's social network is made up of a greater percentage of people who are obese, obesity would become increasingly "normal" to a given individual, and the stigma would be attenuated. While reducing the stigma of obesity is important, normalizing it may also have adverse public health effects.

Social Risk Efficacy in Preventing Youth Obesity

Carolina Werle, Grenoble Ecole de Management, France

Extended Abstract

Obesity prevention campaigns highlighting health risks are omnipresent in France nowadays. A content analysis of official prevention messages in use since 2001 revealed the pervasive use of arguments based on health risks or benefits linked to prevention behaviors (eat healthy, exercise, etc). However, these campaigns neglect social risks and adolescents are especially sensitive to social norms and the positive or negative consideration of their peers (Steinberg and Scott 2003).

Previous research on anti-smoking advertisements shows that the use of social arguments can be more efficient in the short term because they address concerns that are important to adolescents (Ho 1998; Pechmann and Knight 2002; Pechmann and Ratneshwar 1994). In an exploratory study, we found that adolescents are especially susceptible to social risks associated with obesity, such as disapproval or rejection from the group. We therefore suggest that arguments focusing on social issues are likely to be more efficient in the short term because they address concerns of importance to adolescents. Therefore, the first objective of this study is to verify the efficacy of using social risks in obesity prevention campaigns targeting youths.

A second objective is to verify if the message regulatory orientation (Higgins 1997; Zhao and Pechmann 2007) can moderate the impact of the type of obesity prevention argument being used (social vs. health). Other prevention campaigns unrelated to obesity, such as anti-smoking or anti-alcohol campaigns, frequently use prevention-oriented messages. They highlight the negative consequences of an undesired behavior, while obesity prevention campaigns in France use the opposite approach. They put forth the benefits of healthy eating and rarely bring up the negative consequences of obesity. We propose that obesity prevention messages using a prevention orientation will be more efficient in changing behaviors and intentions than messages using a promotion approach.

We conducted an experiment with 797 adolescents (mean age=14 years old) from low- income middle schools and high schools in Grenoble, France. The low income population is, in fact, the most affected by obesity. Parental and student consent were obtained prior to the study. Of the subjects, 57% are male and 88% have a normal body-mass-index.

The design was a between-subjects factorial with two factors: obesity prevention argument (health vs. social) and message orientation (prevention vs. promotion), and control. A professional advertisement agency created five advertisements; four obesity prevention advertisements and a control advertisement about ecology. All advertisements had the same design (colors and typo) and they used characters to avoid stigmatization of obese kids. The health prevention oriented message slogan was "Too many forms, not in shape!" and the image showed characters representing fast-foods (hamburger, fries) in the top of a scale that was breaking down. The social promotion oriented message slogan message was "Balanced meals, lots of friends!") and the image showed characters representing fruits and vegetables (carrots, orange, tomato) playing together.

Target advertisements were placed into a brochure with four filler advertisements about unrelated topics (local public transportation system, a videogame, clothes, and recycling), to reproduce a realistic exposition context. The target ad was shown twice to ensure a strong exposure. Participants received the brochure and were asked to look at each advertisement for a given time (15 seconds, controlled by a research assistant) and then turn the page. After seeing all the pages of the brochure, research assistants collected the brochures and distributed questionnaires. In the first part of the questionnaire, participants were asked to indicate their choice for a thank-you snack to be received at the end of the study; there were two options: a cereal bar (healthy) or a chocolate bar (less healthy). Then participants indicated their intentions to watch what they eat in the future on 5-point Likert scale, but also responded to filler questions about their intentions related to the filler ads (i.e., intention to buy clothes, to use the public transportation system). The order of the questions about intentions and choice was counterbalanced among participants. Finally, participants answered a set of manipulation checks, questions about their eating habits, family model (parenting feeding styles and family food environment), and personal questions (age, gender, height, and weight).

Our behavioral results show that 65% of the participants exposed to the messages using a social argument chose the healthy snack option (cereal bar), while only 55% of those exposed to the health argument made the same choice (Chi-square=6.16; $p=.01$). There was no effect of the regulatory orientation of the message on the snack choice. These results indicate that the social message leads participants' to healthier food choices than the health argument.

Concerning their intentions to watch what they eat, we found an interaction between the message argument (social vs. health) and the regulatory orientation (promotion vs. prevention) of the message ($p=.060$). The prevention orientation works better for messages using the health argument, while the promotion orientation generates higher intentions in conjunction with the social argument. Pair-wise comparisons show that intentions of participants exposed to the message using a health argument and a promotion orientation is not different than intentions of the control group. The other three messages elicited intentions higher than control. Thus, a health message using a prevention orientation and both social messages (prevention and promotion oriented) are efficient to prevent obesity among adolescents.

Our results confirm that an argument based on social consequences of obesity is more efficient because it is closer to the current concerns of young people. Public policymakers should consider including social risks and prevention oriented messages when designing obesity prevention campaigns.

Partnership in Healthcare: The Impact of Co-Production on Healthcare Outcomes

Stephanie J. Lawson, Florida State University, USA

Healthcare in the United States is facing a crisis. The United States spends \$6,401 per capita on healthcare which is far greater than other developed economies (in comparison, Switzerland comes in second and spends \$4,177 per person). This crisis stems from the fact that although healthcare spending is high, the United States ranks last among 19 industrialized countries in preventing death from treatable conditions (Ginsburg, Doherty, Ralston, and Senkeeto, 2008). The majority of deaths related to treatable conditions are the result of modifiable behavior choices (e.g. diet, smoking, physical activity). Consumer lifestyle choices contribute to 40% of the deaths in America (McGinnis, Williams-Russo, and Knickman, 2002). Consumers hold responsibility for their lifestyle choices; however, making behavioral changes requires not only self discipline but access to information and resources through healthcare and social systems. How can consumers and healthcare providers work together to improve the quality of life in the United States? The purpose of this research is to explore how consumers and healthcare practitioners, through co-production impact healthcare outcomes. The importance of this research lies in the fact that due to the rising cost of care our current healthcare system is not sustainable (Berry 2008). Berry and Bendapudi (2007) call for more research in healthcare as its problems are, "perennial (mortality and suffering) but also mutable (technology, advances in science, and social mores continually affect the delivery of health care)."

The commitment-trust theory of relationship marketing provides a framework from which to investigate this issue (Morgan and Hunt 1994). Past research suggests shared values positively impact the level of relationship commitment and trust leading to outcomes of improved compliance and cooperation while reducing uncertainty. Social exchange theory suggests shared values with the firm make customers more likely to voluntarily participate in the firm's initiatives (Bettencourt 1997). Healthcare practitioners represent the firm to consumers, thus, it is reasonable to conclude that shared values (i.e. treatment or therapy goals) between practitioner and patient would yield similar outcomes. Successful health outcomes often require patient participation both during (i.e. answering questions) and after (i.e. taking medication) the service encounter (Berry and Bendapudi 2007). Co-production is a growing trend and past research suggests examining the role customers play in the service production process (Lengnick-Hall 1996). However, the impact of co-production on the relationship between shared values and relationship commitment and trust has yet to be illuminated.

Customer participation is defined as, "the degree to which the customer is involved in producing and delivering the service" (Dabholkar 1990). Co-production represents a shift towards active creation of service encounters (Wind and Rangaswamy 2000). Past research suggests consumer cooperation during the service encounter contributes to their own and others' satisfaction and service quality perceptions (Bendapudi and Leone 2003; Bettencourt 1997). Patients are often suffering from an illness and feel a great amount of stress during health encounters (Berry and Bendapudi 2007). By involving consumers in the creation of their health encounter the moderating effect of co-production on the relationships between shared values (i.e. health goals) and relationship commitment and trust should be positively affected.

Shared values are defined as, "the extent to which partners have beliefs in common about what behaviors, goals, and policies are important or unimportant, appropriate or inappropriate, and right or wrong" (Morgan and Hunt 1994). Past research suggests shared values lead to the development of relationship commitment and trust (Dwyer, Schurr, and Oh 1987). Patients and practitioners share a common goal of positive health outcomes. However, many patients suffer from anxiety and engage in avoidance coping strategies due to the fear associated with making behavioral changes or undergoing a medical procedure (Berry and Bendapudi 2007). The introduction of co-production opportunities for consumers creates an opportunity for control which has been found to increase satisfaction (Bendapudi and Leone 2003).

Berry and Parasuraman (1991, p. 139) suggest, "relationships are built on the foundation of mutual commitment." Relationship commitment is defined as, "the exchange partner believing the ongoing relationship with another is worth maintaining" (Morgan and Hunt 1994). Trust exists when one party has confidence in the exchange partner's reliability and integrity (Morgan and Hunt 1994). Healthcare is a service that is unique from many other services in that consumers need it but often do not want it. Health encounters (between practitioners and patients) are of an interpersonal nature owing to the fact that healthcare is one of the most personal and important services consumers purchase. The relationships between healthcare providers and consumers are inherently personal and, aside from acute care, usually persist over an extended period of time and require trust in technical abilities (Berry and Bendapudi 2007). Social exchange theory supports the idea that customers exhibiting cooperative attitudes toward the firm feel the firm values their contributions and cares about their well-being (Eisenberger, Huntington, Hutchison, and Sowa 1986). If patients feel health providers care about their well-being then it is reasonable to conclude that relationship commitment and trust will have an impact on outcomes related to care compliance, cooperation in care, and uncertainty reduction.

An empirical study using scenario-based surveys is planned to investigate the impact of co-creation on healthcare outcomes. Survey respondents will be adults from a large southeastern city with experience in healthcare encounters. The relationships between the constructs will be analyzed using structural equation modeling. Coproduced healthcare experiences are hypothesized to positively impact

relationship commitment and trust. Relationship commitment and trust are hypothesized to positively impact consumer compliance and consumer cooperation while negatively impacting or reducing consumer uncertainty.

In conclusion, the relationships between shared values and relationship commitment and trust have been established in the literature acting as mediating variables between shared values and outcomes (Morgan and Hunt 1994). However, within the healthcare context, the impact to co-production has not been examined. Recent research calls healthcare a “fertile field for services research” (Berry and Bendapudi 2007). This research contributes to understanding the impact of consumer participation on outcomes and offers healthcare practitioners the opportunity to create innovative care programs aimed at reducing the percentage of preventable deaths in the United States.

Can You Say “No” to Being a Sustainable Consumer?

Sangdo Oh, University of Illinois, USA

Sukki Yoon, Bryant University, USA

Patrick Vargas, University of Illinois, USA

Promoting sustainable consumption is a key goal of numerous academic researchers, corporations, government agencies, and non-government organizations. Across the world, various campaigns are being carried out to promote sustainable consumption among various publics (Nisbet, 2009). However, ‘sustainability’ remains a concept that is yet to be clearly understood (Oopen and Hamacher, 2000), indicating a fundamental problem relating to a lack of appropriate communication strategy. A lack of understanding of the meaning of ‘sustainable consumption’ may hinder their interests towards the necessity for change in current consumption behavior, thus it must be explained in carefully framed information-based campaigns to increase public awareness (Kolandai-Matchett, 2009).

A sizeable literature has accumulated testing message framing effect on persuasion, extensively in how self-regulatory goal framing influence the effectiveness of advertising messages. Higgins (2002) used the terminology *regulatory fit* to describe two distinctive processing styles by which goals are pursued: promotion and prevention, and its strategic means during goal pursuits. A promotion focus is geared to motivate to attain advancement and achievement by approaching matches to end-state. A prevention focus, in contrast, is geared to motivate people to achieve protection and security by avoiding mismatches to desired end-state. When the persuasive message serves self-regulatory goal and compatible strategic, message recipients *feel right* during message reception, thus, attitude becomes more favorable (Avnet and Higgins, 2006).

When measuring the effectiveness of environment-related message, the most controversial issue is how to capture the construct of ‘Environmental Attitude’, a crucial construct in environmental psychology. Studies measuring environmental attitudes have generally used direct self-report. However, research has shown a weak link between explicit environmental attitudes and behavior (e.g., Bamberg 2003). As noted by Beckmann (2005), “Who actually would dare to admit disinterest or even anti-environment attitudes?” (p. 281), there is a strong social desirability element with the self-report measures that may systematically increase the mean ratings or decrease the variability of evaluations (e.g., Bruni & Schultz, 2010). Although several researchers developed scales while acknowledging participants’ impression management occurs in survey responses (e.g., Connectedness to Nature Scale, Mayer & Frantz, 2004), these alternative measures may not entirely rule out social desirability effect.

The study outlined in this presentation drew upon the literature on regulatory fit and how to effectively measure attitudes about the environments. Specifically, we tested whether message recipients are affected by goal framing, targeted recipient and pre-existing implicit attitude. Implicit attitude toward sustainable consumption was measured using modified version of the implicit association test (Greenwald, 1998). This modified version of IAT assessed a person's implicit associations between "sustainable product" and "positive affect" by rapid categorization tasks. Participants received regulatory focus priming about positive (or negative) end-state of the self (or the earth), evaluated sustainable product using 7-point affect scales (Crites, et al., 1994). We hypothesized that promotion-primed participants would evaluate a sustainable product more favorably when the usage of product benefits the planet (compatible) than when it benefits the self (incompatible), and the reverse would be true for prevention-primed participants. However, this goal compatibility effect would be observed only among low-IAT participants.

We analyzed the data by means of an analysis of variance as a 2 (IAT: high or low) x 2 (recipient: the planet or self) x 2 (regulatory focus prime: promotion or prevention) between-subjects factorial design. The results showed that high-IAT participants evaluated the sustainable product more favorably than low-IAT participants (5.33 versus 4.88; $F(1, 394)=11.65, p<.00$). Furthermore, regulatory focus prime x recipient interaction was marginally significant ($p=.05$); prevention-primed participants evaluated the sustainable product more favorably when the usage benefits the planet than the individual, whereas promotion-primed does not differ by proposed recipients. More central to our hypothesis, we observed the predicted three-way interaction among regulatory focus, recipient, and implicit attitude ($p<.001$). Subsequent analyses conducted separately for the two implicit attitude groups showed a regulatory focus x recipient interaction in the low-implicit attitude group ($F(1, 199)=9.68, p<.01$), conceptually replicating Aaker and Lee's (2001) findings. The results of planned contrasts showed that prevention-primed participants evaluated a sustainable product benefitting the planet more favorably than did promotion-primed participants ($M=5.74$ versus 5.28 ; $F(1, 103)=5.34, p<.05$). The reverse was true for a self as a recipient ($M=4.58$ versus 5.18 ; $p<.05$). For the high implicit attitude group, participants evaluated a sustainable product more favorably when promotion-primed than prevention-primed ($M=5.51$ versus $M=5.17$; $F(1, 195)=4.00, p<.05$), regardless of a recipient.

After three weeks, 250 participants returned to the lab for the post measures. We asked participants to indicate use of household goods in the past three weeks. These items were selected from the General Ecological Behavior (GEB) scale (Kaiser, & Wilson, 2000); 4 items were measuring sustainable product consumption behavior, and the other half was about instant use products. The results of 2 (compatibility: compatible versus incompatible) x 2 (implicit attitude: high versus low) ANOVA on the recent ecological behavior index yielded a main effect of compatibility. As predicted, frame-recipient compatibility had a significant effect on recent behavioral change; participants who received compatible priming ($M=3.67$) to the recipient of the product use showed higher score in ecological behavior index than the participants who received incompatible priming ($M=3.39$) to the recipient of the action ($F(1, 249)=6.19, p<.05$). In addition, a main effect for implicit attitude emerged revealing that high-IAT participants ($M=3.68$) scored higher in ECCB index than low-IAT participants ($M=3.40$). However, the interaction was marginally significant ($p=.08$).

Consistent with our predictions, we observed the goal compatibility effect, in immediate evaluations and post-exposure behavior, only when participants' implicit attitude toward sustainable product is relatively low; the effect disappeared when participants' implicit attitude toward sustainable product is high. This implies that environmental message should be carefully framed upon the context, and social desirability concerns should be factor in further development in environmental attitude measures.

Examining the Relationship of Locus of Control, Pro-environmental Attitude and Pro-environmental Behavior

Emine Sarigollu, McGill University, Canada

Rong Huang, Shanghai University of Economics and Finance, China

This research examines the role of locus of control in the context of pro-environmental behavior. As a personality characteristic, locus of control is defined as an individual's generalized expectancies regarding the forces that determine reward and punishments (Rotter, 1966). In the realm of responsible environmental behavior studies, plenty of studies explore the relationship of locus of control, attitude and pro-environment behavior/behavior intentions. However, the extant literature provides inconsistent findings regarding the relationship between locus of control, attitude and pro-environmental behavior/behavior intention. In general, three different associations between locus control and the other two constructs are identified in the existing studies, namely, locus of control as direct predictor to pro-environmental behavior/behavior intention (e.g., Allen & Ferrand, 1999; Bamberg & Moser, 2007; Cleveland, Kalamas, & Laroche, 2005; Hamid & Cheng, 1995; e.g., Hines, Hungerford, & Tomera, 1986/87; Kim, 2005), effect of locus of control on pro-environmental behavior being mediated by attitude (e.g., Balderjahn, 1988; McCarty & Shrum, 2001), and locus of control moderating the impact of attitude on pro-environmental behavior/behavior intention (e.g., Berger & Corbin, 1992).

The present research contributes a better understanding of the role of locus of control on ecological behavior. This work studies both the direct impact of locus of control on behavior and the moderating effects of it on attitude-behavior relationship. Moreover, the current study includes a rather comprehensive assessment of ecological attitude and behavior in Turkey. Currently, most researches in environmental domain are taken in developed countries. As locus of control is a stable, general status being influence greatly by culture, Turkey would be a good context for such studies with its mosaic of eastern and western cultures.

Data were gathered from 1000 randomly selected residences of Istanbul via at-home personal interviews using standard surveys. Attitudinal, behavioral, socioeconomic and demographic variables that were frequently employed in previous studies were used in this research. Appropriateness of the attitude and behavior items for the Turkish context was verified by first testing them on a sample of consumers. Attitudes toward the environment were assessed using a number of items adapted from a Roper study (1990). Behavior was measured by asking respondents for self-reports of nine different behaviors, given the opportunity, on a scale from 1 (never) to 5 (always). Similarly a scale of 1 (strongly disagree) to 5 (strongly agree) was used for measuring attitudinal characteristics. Appropriateness of adopting scales (1-5) typically used in the North American context to Turkey was verified with a local market research industry representative who asserted that these scales are commonly used in Turkey as they nicely correspond with the grading system (1-5) of Turkish schools and hence were easily comprehended by anyone who had at least some level of elementary education. Locus of control was assessed via three items selected from Rotter's (1966) I-E scale. Four items from the general control dimension were selected and those of political control ignored since they were not relevant to the current study.

Data were analyzed in three stages. In the first stage, the various dimensions underlying the behavior and attitude toward environment are uncovered by a factor analysis using the principal component method with varimax rotation (Hair et al. 1998). In the second stage, confirmatory factor analysis (CFA) was applied to purify the measurement of attitude and behavior dimensions. In the third stage, structural equation modeling (SEM) is used to explore the relationship between locus of control, attitude dimensions and behavior dimensions. For moderating effects, the most widely used technique to test for moderating effects in structural equation modeling is the multisample approach (Ridgdon et al. 1998). Two groups are created with the dataset; the internal and external locus of control groups in our case. The interaction effect is assessed by comparing parameters from the two groups.

The study finds two dimensions underlying pro-environmental attitude. One dimension named as "general attitude" summarizes the respondents' overall concern regarding environmental protection. The other dimension named as "activity attitude" represents the respondents' attitude about taking activities to protect environment. In addition, two dimensions are also found for pro-environmental behaviour. One dimension named as "EXPRESS" indicates the respondents' behavior to express their concern of attitude and advocate the environmentally behavior. Named as "PROTECT", the second factor summarizes the some specific actions of respondents to protect the environment.

Analyses of the relationship between locus of control, attitude and behavior are conducted for all the four combinations of attitude and behavior dimensions respectively. The current research finds that the locus of control does not moderate the impact of pro-environmental attitude on pro-environmental behavior. In addition, locus of control neither has direct impact on pro-environmental behavior. Rather, locus of control is directly related to pro-environmental attitude. That is, respondents with internal locus of control are more concerned of environment. Hence, they are more likely to conduct activities to protect the environment. On the contrary, respondents who believe fate or luck more are less likely to do something for the environment.

Breaking the Status Quo: Using Ideology and Conviction to Increase Adoption of Green Behaviors

Blair Kidwell, University of Kentucky, USA

Adam Farmer, University of Kentucky, USA

David Hardesty, University of Kentucky, USA

Extended Abstract

Central issues confronting transformative researchers are how to get consumers to adopt consumption (e.g., healthy food choices) and disposition behaviors (e.g., recycling). A better understanding is needed for why adoption of these behaviors has been slow to catch on, and why these behaviors tend to fall along ideological lines. In this research, we explore the psychological mechanisms underlying conviction, the impact of conviction on consumer decision making, and ways to appeal to different ideologies in promoting the adoption of green behaviors and healthy consumption.

In study 1, we develop a conceptual model for how conviction can be altered via mortality salience manipulation to influence consumer decision making, leading to status quo choices and suboptimal decisions. Study 2 examines the theoretical framework underlying these effects and demonstrates how consumers who have lowered conviction can become more open-minded and consider new information. Finally, in study 3, we extend our understanding of conviction and ideology by examining a green behavior (recycling) from 10,000 households relative to our theoretical model. In addition, we develop tailored messages that may appeal to both conservatives and liberals in promoting this green behavior.

Review of the Literature

The subject of ideology has been pervasive in the behavioral literature in recent years. Ideology has been examined across multiple disciplines in many different ways. This area has recently been extended to understanding differences between conservatives and liberals. For example, McAdams et al. (2008) used life-narrative interviews of self-labeled psychological conservatives and liberals. Liberals were found to recall stories of lessons learned regarding openness and empathy while finding the values of harm and fairness as being the most relevant to them. In contrast, conservatives were more likely to recall lessons learned in regards to authority, strict rules, and self discipline while finding the values of purity, authority, and in-group as being the most relevant. Furthermore, Morrison and Miller (2008) describe conservatives as descriptive deviants in that they tend to move toward and conform to the desirable group attitude, while liberals can be referred to as prescriptive deviants who tend to move away from the desirable group attitude. In line with this theorizing, Janoff-Bulman, Sheikh, and Hepp (2009) recently described differences between liberals and conservatives in terms of prescriptive and proscriptive morality. Prescriptive morality involves activating positive behavior, whereas proscriptive morality is defined as inhibiting negative behavior. Conservatives were found to be more proscriptive in that they restrain undesired behaviors to better the overall social order, whereas liberals are more prescriptive in that they focus on desired behaviors to improve the overall social justice (Janoff-Bulman et al., 2009).

Proposed Conceptual Framework

While the characteristics and moral orientations underlying ideology are apparent, it is important to note that one's views can be significantly polarized by incoming information that often leads to significant strengthening of one's ideology. Such polarization is referred to as eliciting closed-mindedness or conviction (Ledgerwood and Chaiken, 2007). While little is actually known about conviction, how it manifests, or how it might influence behavior, research has begun to indicate that self-affirming information may increase openness to information even if the new information conflicts with a salient identity (Cohen et al., 2007).

Conservatives. Recent research suggests that conservatives are likely to exhibit a motivated tendency to construe the status quo as the most desirable and reasonable state of affairs (Kay et al., 2009). This tendency is increased when personal control is threatened (Kay, et al. 2008). Thus, strategies for behavior change that invoke negative emotion that threatens personal control toward a behavior often does not lead to the intended behavior, rather, it potentially leads to the opposite—adhering to the status quo. However, Kay et al. (2008) also found that some reduction in status quo tendencies was exhibited when the system was perceived as being benevolent. Thus, it may be possible to break the status quo tendency with positively primed messages based on self-affirmation of in-group norms to increase openness to information (Cohen et al., 2007).

Liberals. Liberals are likely to engage in green behaviors because they are desirable behaviors for the social good. Moreover, liberals are prescriptive deviants who tend to move away from the desirable group attitude, and thus, may hold positive views of green behaviors because they deem them as the right thing to do regardless of whether others are engaging in these behaviors. While many liberals may currently adhere to green behaviors, it may be possible to elicit further adoption by evoking positive consequences (as opposed to thoughts about their death) by priming that green behaviors are the right thing to do and help society as a whole.

Plan of Studies and Methodology

Study 1. Study 1 was an experimental study with college students at a large eastern university who were administered a survey about their PFC (preference for consistency), followed by either a mortality salience manipulation or a positive consequence (control) condition where they wrote about watching TV, and follow up conviction items. Participants low in PFC (liberals) who received the mortality salience prime vs. a control condition, exhibited increased conviction ($M=4.9$), while those conservatives high in PFC who received the positive consequences prime, exhibited lowered conviction ($M=3.7$), and thus be more likely to adopt green behaviors ($t_{264}=4.26, p<.05$).

Study 2. Study 2 will involve an experimental design to develop tailored messages for both liberals and conservatives. For conservatives, the message will elicit vulnerability but be self-affirming relative to their in-group's participation in green behaviors. For liberals, the tailored message will be positive in tone, illustrating the favorable consequences of engaging in green behaviors and that it is the right thing to do. Several green behaviors will be examined relative to their adoption of these behaviors.

Study 3. Study 3 will examine the implementation of our theoretical framework to better understand adoption of green behaviors in a field setting. Specifically, we will examine the effects of psychological ideology and conviction relative to message priming in on actual recycling behavior across 10,000 households in support of our conceptual framework.

Process Versus Outcome Focus: How to Encourage Consumer to Increase Repayment Amount

Lili Wang, Shanghai Jiao Tong University, China

Wei Lv, Shanghai Jiao Tong University, China

Most decision research on credit cards has focused on understanding why consumers over-spend with credit. In order to solve debt problem, it is necessary to encourage individual to repay more each month to reduce the debt amount. Taylor and Schneider (1989) suggested that mental simulation served problem-solving functions and emotional regulation functions for turning imagined experience into action. So in present paper, we tried to manipulate mental simulation to encourage consumer to increase repayment amount. Meanwhile, we

There are two kinds of mental simulation—process simulation and outcome simulation (Pham and Taylor 1999; Escalas and Luce 2003, 2004). Process simulation help individual to rehearse the process to reach an envisioned end state, so individual can identify and organize the steps involved in the activities needed to get there, which, in turn, yields a plan. At the same time as one is mentally walking through these activities, the emotions that will be involved may be evoked, at least in a modest state, such that one can anticipate what these emotional states will be and develop some degree of control over them. Outcome simulation espouses an “I can do it” effect on goal pursuit. It helps individual to envision the outcome that one wants to achieve may facilitate efforts to achieve the goal or enhance

perception of self-efficacy. Although, previous literature has already shown that process to some extent are more efficient to increase goal achievement because it provide a detail plan (Pham and Taylor 1999). In contrast, outcome simulations may make people feel good in the present without providing a basis for achievement in the future, so it is much easier for individual to fall into planning fallacy (Oettingen 1995). With the reference of credit debt, researchers generally accepted that unrealistic optimism is the main reason to account for credit debt (Yang, Markoczy and Qi 2007). So in present research we propose that process simulation is more efficient to increase repayment amount than outcome simulation. Moreover, we further propose that process simulation decrease individual's optimistic.

Five studies tested the present prediction. Study 1 and 2 tested that process simulation would increase repayment amount. In study 1, we directly manipulated the information related with the repayment using process or outcome simulation. We randomly assigned participants into process, outcome or control groups. Consistent with prior research (Escalas and Luce 2003,2004), process simulation instructions focused on the activities, procedures associated with paying off the debt, whereas outcome simulation instructions focused on the benefits associated with paying off the debt. The dependent variable was the amount of payment. We found that participants under process simulation would have a significantly higher repayment amount than participants in control group. Meanwhile, there are no significant different amount of payment between participants in outcome simulation situation and control group.

In order to generalize the result of study 1, before we provided the repayment information, we first randomly assigned participants to process or outcome simulation situation. For participants under process simulation, we asked them to image that how to plan a trip, meanwhile asked them to write down the basic procedure to plan a trip. For participants under outcome simulation, we asked them to image that the benefits of a trip, meanwhile asked them to write down the happiness and benefits of the trip. We also found that participants under process simulation would have a higher repayment amount than participants under outcome simulation. From study 1 and study 2, we found that process simulation would increase repayment amount regardless of manipulated information related with repayment or not.

Study 3 tested that consumer under process simulation would have a higher repayment amount depended on the amount of the debt. In study 3, we employed a 2 (mental simulation: process simulation vs. outcome simulation) \times 2 (amount of debt: ¥500 vs. ¥5000) between-subject design. Manipulations of process and outcome simulation are similar to study 1. The dependent variable was repayment amount. We found that participants under process simulation would have a higher repayment amount only when they owned more debt rather than less debt.

Study 4 tested that optimistic bias played as a mediator. Latest research indicated that the main reason for consumer falling into debt was unrealistic optimism (Yang, Markoczy and Qi 2007), which means that individual normal have optimistic bias. Taylor et al (1998) also found that a mental simulation of the process of goal pursuit attenuates optimistic bias. So we hypothesized that process simulation induced optimistic bias thus increased repayment amount. We used the same method of study 1 to manipulated process simulation and outcome simulation. After participants read the process simulated information, we used 7-likert scales to measure optimistic bias. In order to rule out that planning played as a mediator. We also measured planning (Pham and Taylor 1999). After analysis, we found that process simulation significantly decreased individual's optimistic bias. Meanwhile, optimistic bias was positively related with repayment amount. But when we control optimistic bias, the relationship between process simulation and repayment amount would not exist. Although planning was negatively related with repayment amount, when we control planning, the relationship between process simulation and repayment amount also existed. So we made the conclusion that optimistic bias played as mediator rather than planning.

In study 5, we tried to find the boundary of our previous results. We found that all of results we received previously were valid for individuals who were high self-efficacy. For consumer with low self-efficacy, process simulation and outcome simulation didn't function significantly different.

In order to help individual escape from credit debt, we try to use mental simulation to encourage repaying more each month. In present research, we documented that due to optimistic bias, individual normally underestimated the ponderance of financial situation. If we asked individual to imagine the process of repayment rather than the outcome of repayment, it would help them to repay more each month. Thus, process simulation would be more efficient to help individual out of debt.

Understanding the Impact of Parents-Provided Financial Education on the Satisfaction with Life: The Moderating and Mediating Role of Consumer Characteristics

Vladimir Pashkevich, Marymount Manhattan College, USA

Extended Abstract

Deregulated and very innovative financial system demands of its users a high level of financial sophistication. Consumers have to choose from among bewildering array of financial products, such as credit cards and mortgages, which grow more complex. In fact, there is a virtual requirement that consumers bear increasing responsibility for their financial and retirement security. Some argue that it's most important to improve government regulation to make financial products more transparent and fair. Others argue that financial-literacy programs aimed at students and other consumers are effective: we cannot expect consumers to make optimal choices if they are not equipped with the personal resources for doing so. Consumers need to be taught how to do so. The fundamental questions I am asking: what is the best way to structure financial education efforts? There is growing evidence that many consumers lack the basic financial literacy necessary to make decisions in their own best interest. Nevertheless, many researchers debate the value of financial-education programs and some researchers admit that we know very little about whether financial literacy programs actually work. Moreover, there is growing evidence that while higher levels of education and cognitive ability cause increased participation in financial markets, that financial-literacy education does not affect individual savings decision. High-school seniors who take personal-finance courses tend to score no better on the personal finance tests than those who don't. What's more, whites have tended to do better than blacks and Hispanics, and students from wealthy families have tended to score better than those from low-income backgrounds. It seems that one factor that differentiates those who do well on the personal finance tests and go on to make optimal financial choices in the future and those who don't when their "formal" financial literacy training is basically the same, is a better understanding of economic and personal finance issues gained in the families. It seems that personal financial skills are well internalized when they are taught starting at an early age and the learning is hands-on, real-time and involves something that belongs to the child's family. High school or college personal finance courses are unlikely to replace family education where children can start getting the training early enough and this training can be repeated often enough in the context of the decision points that are faced on a daily basis. The financial education received at home is more likely to address social and emotional influences, is more likely to change long-term financial behavior and enhance financial well-being than one-semester course in financial literacy.

However, many adults are ill-equipped to teach their children about budgeting and saving, and are not prepared to guide their teenagers on investing. Therefore, social marketers should target parents with future-oriented educational interventions that have real-world applications and motivate parents to reach their children at their most 'teachable' moments. As a result, parents should become less of a financial 'safety-net' and more of strong normative influence with respect to financial planning and taking responsibility for future financial choices.

In this paper, I deal with empirical issues about whether involving parents into teaching financial literacy has a positive effect on their children's future well being and financial literacy. I also focus on the mechanisms that seem promising for explaining the impact of parental normative influence on their children's future financial well being. I also consider the impact of various moderators on the parental financial education- financial well-being relationship.

Based on a survey study using adult consumers, I explore how different levels of acquiring financial decision-making skills at home during a childhood and adolescence affect the satisfaction with life. Based on the data from 200 respondents, I find support for the expectation that the parental financial education leads to higher satisfaction with life. It is shown that the effect of the parental financial education on the satisfaction with life is fully mediated by its effect of financial literacy and economic locus of control. Finally, the hypothesized moderating effect of materialism and social-economic status is also confirmed.

Finally, I will formulate some suggestions for public policy. Given that many consumers lack the basic financial literacy necessary to make decisions in their own best interest and the "formal" financial literacy training is basically not as effective as expected, this research has clear implications for consumer welfare and public policy administrators.

Embiggeners and Ensmalleners: A Scale Measure of Perceived Risk and Benefits in Sharing Resources

Sommer Kapitan, University of Texas at San Antonio, USA

Rajesh Bhargave, University of Texas at San Antonio, USA

Extended Abstract

Sharing has emerged as a "theoretical terra incognita" in consumer behavior research (Belk 2010, 716), an unexplored arena of social life that guides consumer spending at home as well as among those who extend resources beyond the family circle (Widlock 2004). Motivations vary in the sparse literature that documents sharing behavior, from socially desirable attempts to appear nice to maintaining a balance in reciprocity (Staub and Sherk 1970). From Belk's (2010) call for future research to the paucity of information in the literature, it is clear that further investigations in sharing would benefit from empirically established constructs that pinpoint individual differences within this arena. We propose an 18-item measure of individual differences in perceived risk and benefits in sharing resources.

According to Belk (2010), consumers share resources when they desire connection, with co-management of resources cementing social bonds both within and outside the family unit. However, Marcoux (2009) notes that consumers may sometimes prefer social divestment and autonomy due to risks involved in common property, such as obligation and indebtedness. We argue that these different perspectives may characterize consumer types. Embiggeners view mutual resources as a means of establishing social bonds. They enjoy a sense of belonging and caring for others through extending their resources. Ensmalleners emphasize the risk inherent in lending or co-managing ownership of resources. They prefer to maintain a balance in interactions with others to avoid indebtedness. Whereas embiggeners seek to extend themselves through possessions borrowed and shared, ensmalleners seek differentiation and prefer responsibility and control of their domains. We hypothesize that embiggeners will be more agreeable to sharing resources than ensmalleners. Yet, the Embigger/Ensmallener distinction goes beyond just willingness to share: We expect that ensmalleners will be as likely to share if the context diminishes sharing-related risks.

A pilot test (n=113 undergraduate students) examined the validity of an Embigger/Ensmallener scale, tested hypothesized predictions from the scale, and compared predictions from other relevant scales to establish convergent and discriminant validity. We first piloted an initial pool of 29 items expected to tap into the construct. The first 12 items were true/false (0/1) values statements; these were summed, with higher scores associated with embiggeners. The remaining 17 items were subjected to exploratory factor analysis. Eigenvalues indicated five possible factor loadings, though only one factor loading was reliable, at $\alpha=.68$. Our proposed overall Embigger/Ensmallener scale is the sum of the mean of the 12 true/false items and the mean of the six items in the one reliable factor. As a result, the reliable factor gets a heavier weighting in the overall scale. Representative true/false scale items include responses to "Sharing things with someone brings you closer together" and "I always repay someone for a favor, right away" (reverse coded). The six-item factor identified also includes items such as "I always offer a bite of my dessert to friends I'm eating with," and "I never leave my things out where others can use them" (reverse coded).

We also exposed participants to scenarios with two conditions, varying sharing context. Support for the predictive power of Embigger/Ensmallener was found in two main effects and two interactions. As a main effect, we found that willingness to loan luggage to a friend was positively related to Embigger score ($F(1,111)=9.47, p<.01$). A median split of the scale finds that participants classified

as embiggeners were more willing to share than participants classified as ensmalleners ($M_{\text{embiggerer}}=3.47$ vs. $M_{\text{ensmallener}}=2.78$). Results were significant in another scenario that involved sharing gum with a classmate.

Willingness to share also depended on the context, which interacted with Embiggerer score. One interaction showed ensmalleners were more likely to view sharing as fair when reciprocity was in effect ($F(1,104)=4.09, p<.05$). After being handed a tissue by a fellow student, ensmalleners were more likely to see it as fair to offer use of their pen ($M=4.39$) than if the tissue had not been offered ($M=3.79$), whereas embiggereners' perceived fairness did not depend on the scenario ($M_{\text{no-reciprocity}}=4.37$ vs $M_{\text{reciprocity}}=4.19$). In another scenario in which participants were asked to share a textbook, we varied the situation as either splitting usage of the textbook over a semester or lending the textbook after a course was complete. There was an Embiggerer score X context interaction ($F(1, 104)=2.68, p<.05$) when controlling for demographics. Ensmalleners—but not embiggereners—were more likely to view sharing as fair when asked to lend, as opposed to splitting usage time and co-managing the textbook ($M_{\text{co-manage}}=3.82$ vs. $M_{\text{lend}}=4.26$). Together, these results indicate that ensmalleners are more willing to share if the context encourages autonomy and diminishes indebtedness.

A final goal of the pilot study was to establish convergent and discriminant validity of the scale. During the study, responses were gathered for other extant scales. For space, only significant correlations are reported below. Embiggerer/Ensmallener scale was positively and significantly correlated with John, Naumann and Soto's (2008) Big Five Extraversion ($r(113)=.28, p<.01$) and Big Five Agreeableness ($r(113)=.38, p<.001$); Rushton, Chrisjohn and Fekken's (1981) altruism self-report scale ($r(113)=.28, p<.001$); and Mills and Clark's (1994) scale for communal orientation ($r(113)=.36, p<.001$). Some overlap with related constructs shows convergent validity with well-established theoretical ground. However, discriminant validity in predicting responses is necessary to establish that the construct differentially explains variance in consumer sharing practices. A chief concern was the overlap with communal orientation. People high in communal orientation view exchange as grounded in the social market and prefer equality and cooperation. Yet, communal orientation failed to predict responses to the tested scenarios.

Through future research, we expect to pare down the present 18-item scale, validate it across different groups of participants to increase generalizability, and compare it with additional scales to further establish validity. We also plan to examine other factors that influence whether ensmalleners are willing to share. For instance, we will examine the effect of relationship length, predicting that ensmalleners are more likely to share if engaging in a short-term relationship. Likewise, we expect that ensmalleners are more likely to share when property is clearly engraved or marked (i.e., when there is no chance of confusing ownership).

The Influence of the Entertainment Industry on the Perception of Ethics

Arne Baruca, UTPA, USA

Greg Selber, UTPA, USA

Historically, different philosophies presented the perception of what is moral or immoral differently. Utilitarians, represented by Mill, argue that the morality right action is the one that provides the most happiness for all those affected of actions. Kant on the other hand, argues that action have moral worth only when we act from duty (Shaw, 2008). Nowadays, even though some people developed genuine moral principles, they act differently in different occasions. Thus, it is not unusual to encounter an individual that finds it immoral to copy a hard copy of a book, but yet, uses the internet to download a pirate electronic version of the same books. The question is why double moral standards? Why people behave differently when faced with similar phenomena, but yet different occasions? In accordance with the cultivation theory we argue that the entertainment industry helps to shape the moral standards of today's society. The main goal of the present research is to shed the light on the effects that the entertainment industry has on the perception of what is moral or immoral for the consumers of that industry.

People are bombarded with messages daily and as Snyder (2008) noted the advertising industry spends 200 billions annually. That is the industry that practically largely funds our entertainment, and programming and informs consumers about products and services (Snyder, 2008). Therefore through constant mass communication certain truths are seen differently. To be more precise, we believe that in accordance with cultivation theory (Morgan and Shanahan, 1996) the constant exposure to communication of certain fabricated realities, like TV commercials, TV shows, and so forth, people somehow change their moral standards. A possible example of such phenomena is a comparison study of Zimmerman and Dahlberg (2008) where their result suggested that females do agree that female bodies were portrayed as sex objects in advertisement, but females nowadays are less offended about these portrayals than females in 1991.

As explained before, people have double moral standards when it comes to the same ethical dilemmas. Sometimes they see a certain thing as immoral, but on the other time they see it as moral. One of the reasons why this happens can be found in the philosophical literature. Currently, we live in moment where humanity is moving from the modern era into the so called postmodern era.

The modern era is categorized as an ordinate era. An era, where we as humans have better plans for the future. Humans work today, for benefits they would have in the future. Everything must have a plan and everything is under control. On the other hand, the postmodern society wants to have a meaning right away. Nothing is seen as the “best” thing, the difference is appreciated, and pretty much everything goes. Live now, and do not wait for tomorrow. Post-modernity is chaotic, and so are the people who live in it (Firat and Dholakia, 1998). Fragmentation and consequently multiple (fragmented) personalities are one of the most representative descriptions of post-modernity (Firat and Dholakia, 1998). Each person has a different role at different points in time. The fragmentation can also be a reasonable explanation, why certain actions are explained differently in different occasions. The morality of the situation depends from the role people play at a specific moment.

However, the process of the ethics change can be analyzed through the *change equation model*. The Change Equation model borrows from Hegel and McLuhan (1989) along with the Social Change Model of Leadership Development created in 1996 by the Higher Education Research Institute of UCLA in an effort to enhance student learning and facilitate positive social change. Hegel’s notion of the dialectic argues that each action will eventually receive a reaction, creating a new reality. In terms of the Change Equation, public opinion can be seen to be affected by the reception and perception of media messages, whereby the original idea becomes an opinion which is altered by media exposure into a new opinion, often publically mediated and perceived. Institutions such as mass media or government act as mediating devices for the change, and the key here is for everyday citizens to grab ahold of the mechanism themselves through various means such as involvement in public affairs, publication of ideas, or feedback using interactivity offered on the Internet, i.e. message boards.

Change is achieved as a matter of course due to the dialectical process; whoever controls the power of discourse can guide the perceptions that become new public opinion. McLuhan stated that each new communication technology alters the previous ones, but he was less optimistic that citizens would be able to harness the power of electronic technology, mainly due to the constant distraction such innovation visits on its users.

The Change Equation therefore describes the mechanics of how ideas turn into action, through a mediating device. It combines the structure of Hegel’s dialectic with the electronic dimension McLuhan wrote about and adapts the UCLA model to show how normal citizens not connected with media or government can raise awareness, be active manipulators of message reception and perception, and implement social change agendas by getting out in front of the process and becoming active users with a goal in mind. Therefore, the model consists of six parts; *the thought, the idea, the discourse, power, institution and finally the change*. Each part of the model is analyzed for the case of the entertainment industry, and sheds the light on how ethics of its consumers change.

To conclude, people do not generalize their moral standards, but they rather adjust them according to the situation in which they find themselves in. The main point here is that the context matters, not the deontological behavior that teaches us that we can only be right or wrong, no matter where we are. The same thing can be right in one context, but totally wrong in the other one. The dilemma is not the problem, but the context is. And if something is seen on TV, it is even easier to accept it.

Counter-stigma and Achievement of Happiness through the Freegan Ideology

Hieu Nguyen, California State University, Long Beach, USA

Steven Chen, California State, Fullerton, USA

Sayantani Mukherjee, California State University, Long Beach, USA

Introduction and Research Questions

The purpose of this study is to investigate how stigmatized practices that are rooted in anti-consumption ideology are different from other forms of social stigma, such as disease (Goffman 1963), obesity (Hebl and Mannix 2003), and low literacy (Adkins and Ozanne 2005), and to introduce a theory of “counter-stigma,” where anti-consumption ideology is leveraged to invert the stigma into a heroic morality play, while simultaneously redirecting stigma onto mainstream culture. We also look at how voluntary participation in a stigmatized practice brings about happiness.

To investigate these issues, we focused on Freeganism, a form of activism that involves employing strategies for living based on limited participation in the conventional economy and minimized consumption. A signature practice of Freeganism is dumpster diving—reclaiming food, clothes and other basic needs from dumpsters. For mainstream culture, consuming used, disposed goods and food past the date of expiration is associated with dirtiness, health risks and lower class status (Sen and Block 2008)—a stigma. But for freegans, dumpster diving is central to their freeganism beliefs emphasizing the message that much of what mainstream consumers consider “waste” is still usable, edible goods.

Relevant Literature

Stigma, often examined under the guise of a birth defect or medical condition, is a deeply discrediting attribute that makes the stigmatized individual de-valued by others (Goffman 1963). However, stigma could also result from ingrained cultural beliefs about practices and attributes that are unacceptable by mainstream culture (Sandickci and Ger 2010) such as low literacy (Adkins and Ozanne 2005), living in a mobile home (Kusenbach 2009), obesity (Hebl and Mannix 2003) and sexual orientation (Neuberg et al. 1994). Thus, to mitigate or avoid problematic encounters with mainstream culture, stigmatized individuals often adopt stigma management strategies such as avoidance of contact, defensive cowering, hostile bravado, masking, and identity ambivalence (Adkins and Ozanne 2005; Goffman 1963; Kusenbach 2009; Rochlen et al. 2008).

While these studies offer insights into social stigma and stigma management strategies, there is little research that 1) investigates an instance of social stigma where the stigmatized practice is voluntary and ideologically motivated; 2) examines instances where the stigma is redirected to the mainstream culture, thereby cleansing itself of the taint; and 3) studies social stigma that results in subjective positive outcomes.

Methodology

To address these areas of inquiry, we conducted an ethnographic study on the Freegan community. We conducted long interviews with eight freegans in Los Angeles, Chicago, New York City and London. We also engaged in participant observation of freegan dumpster dives, community meetups, and online discussion forums over a one year period. All interview transcripts, photography and ethnographers' notes were converted to text and subjected to the three iterative stages of grounded theory—open, axial, and selective coding.

Findings

Findings revealed that Freeganism practices represent a unique form of social stigma that is voluntary and politically and morally motivated. Specifically, freeganism is founded on three ideological principles: anti-capitalism, spirituality of nature, and the ethic of sharing. These ideological principles inform the unique practices of freegans, which include dumpster diving, dispossession, squatting/rent-free housing, and voluntary joblessness.

Second, we found evidence of “counter stigma,” when freegans leverage their ideology to invert the stigma of waste onto mainstream consumers. While mainstream consumers see *consuming waste* as a tainted practice, Freegans view *being wasteful* as the stigmatized practice. Findings revealed that the stigma of “eating trash” was inverted into a heroic morality play through three important processes germane to the Freegan practice: de-branding marketplace resources, reclaiming and reusing disposed marketplace resources, and sharing reclaimed resources within communities and anyone else who need them.

Finally, by enacting their heroic morality play centered on waste reduction, living on less, and sharing, Freeganism provided its devotees with a vehicle to achieve happiness. In their quest to save Mother Nature from an overconsumption society, freegans become moral saviors who have shredded themselves of the mundane needs often encouraged by marketers. They achieve a heightened sense of self-actualization and self-liberation which leads to a unique sense of happiness, one not based on possession and consumption but moral purity.

Discussion

In this research, we examine social stigma that is voluntarily adopted by consumers within the context of “freeganism”. By doing so, we add to existing research, which has primarily focused on different forms of stigma of which individuals have little locus of control or choice. These are often attached to biological or cultural situations such as disease (Goffman 1963), sexual orientation (Hebl and Mannix 2003), or courtesy stigma (Argo and Main 2008),

Second, we introduce a theory of counter-stigma that is distinct from theories of stigma management and theories of de-stigmatization. Stigma management assumes that the stigmatized individual acknowledges his or her discredited status (Adkins and Ozanne 2005; Henry and Caldwell 2006), and takes actions to reduce problematic encounters with mainstream culture. De-stigmatization occurs when the taint of a stigmatized practice gets naturalized or erased through routine exposure over time (Sandickci and Ger 2010). However, our examination of the freegans revealed that they did not merely “cope” with the stigma, nor did the stigma get naturalized. Indeed, freegans not only acknowledged the stigma associated with practices such as dumpster-diving, but also reframed the stigma into a heroic practice linked to conservation, sharing and saving the world—that is they transformed the stigma into a “heroic morality play” (Luedicke, Thompson and Giesler 2010). Importantly freegans engaged in a form of “counter-stigma”, whereby they redirected the stigma of waste(fullness) onto the mainstream consumer culture.

Third, our findings provide evidence where a stigmatized practice serves as a vehicle to help individuals achieve self-actualization and happiness. This finding is novel, because past research has stressed the negative outcomes of social stigma, which include alienation, shame, self-hate and self-derogation (Goffman 1963). Social stigma also has been shown to negatively impact self-esteem (Brenda 2006; Crocker 1999; Crocker and Quinn 2003; Twenge and Crocker 2002), academic achievement (McCown and Weinstein 2003), and health (American Heart Association 2003).

Finally, our findings provide an ideological perspective as to why people consume past expired goods. Strong sentiments of anti-capitalism, moral responsibility to save the earth from an overconsumption society, and self-liberation underlie Dumpster diving. This

understanding contributes to existing research that posit economic theories (e.g. sunk cost, search cost) and psychological theories (endowment effect) to explain why consumers will consume goods past the date of expiration (Sen and Block 2008).

Anticipate, Go Big, Enjoy, Repeat: Towards an Optimal Consumption Strategy and Well-Being

Michael Lowe, Texas A&M University, USA

Kelly Haws, Texas A&M University, USA

Extended Abstract

"Happiness is the meaning and the purpose of life, the whole aim and end of human existence"—Aristotle

The ultimate "big picture" of understanding consumer behavior is understanding what maximizes well-being of both individual consumers and society. If we accept happiness as the aim of human existence, it is an enduring obligation to examine the role of marketers in either contributing to or detracting from this goal. It should be troublesome to any in the field of marketing that accusations continue to be raised regarding marketing's detraction from happiness through the promoting of a hedonistic and materialistic society. Marketers, in turn, defend their trade by pointing to the other end of the spectrum where sub-optimal happiness prevails because human needs or desires are left unaddressed (Diener 2000; Haws and Poynor 2008). Similarly, while researchers have contributed much to the understanding of how exercising self-control can lead to more positive long-term outcomes, there is also evidence to suggest that becoming overly focused on future outcomes results in lower overall enjoyment of life (Haws and Poynor 2008; Keinan and Kivetz 2006; Rick et al. 2008).

Research has shown that high levels of consumption do not promote happiness, and the two may actually be negatively correlated (Csikszentmihalyi and Schneider 2000; Diener 2000; Myers 2000). However, research has also illustrated the detrimental effects of the inability (or failure) to consume at sufficient levels to ensure happiness (Diener 2000; Haws and Poynor 2008). There are inherent costs and benefits to consumption, and this relationship is apparently quadratic in nature. This realization, supported by further research, led Csikszentmihalyi (2000) to pose the following; "Up to a certain point, material resources add greatly to the quality of life. *But where is*

the point of inflection after which the relationship may no longer exist, or actually become negative?" (Italics added) This is a question we seek to answer in this research.

As such, we build on past research that shows engaging in experiences rather than buying material goods enhances happiness (Van Boven and Gilovich 2003; Mogilner and Aaker 2009), while spending money on others seems to have a more positive boost on happiness than does spending money on ourselves (Dunn et al. 2008, Harbaugh et al. 2007; McGowan 2006).

While our objectives of learning more about what might generally represent optimal patterns of consumption are admittedly lofty, we begin our research by trying to understand what consumers believe will make them the happiest. This investigation into the intuitions of consumers is consistent with recent perspectives in consumer research examining lay theories (Mukhopadhyay and Johar 2005; Labroo and Mukhopadhyay 2009). For our initial investigation, we have focused specifically on understanding the role of frequency and magnitude of indulgent types of consumption. We will briefly report the results of two studies. Further studies are in progress.

In study 1, we examine beliefs about happiness relating to consumption frequency (i.e., often vs. rarely), and magnitude of consumption experience (relatively smaller vs. larger). We also separately examined beliefs about consuming goods and experiences. Respondents who were undergraduate students (n=109) were presented two hypothetical situations (counterbalanced), each of which utilized a projective technique to try to capture beliefs about the relationship between consumption decisions and happiness. The first situation featured two individuals deciding how to spend vacation days (experience) under constrained resources (time). Respondents strongly agreed that the individual who took one larger vacation rather than an equivalent amount of smaller vacations would be happier with the vacation usage itself ($p<.051$), but that the individual using his vacation time in smaller, more frequent increments would be happier with his life overall ($p<.001$). As such, we see evidence for the general predictions of prospect theory (Tversky and Kahneman 1979) when segregating positive experiences increases overall happiness, but the larger vacation may have a more lasting impact in terms of long-term happiness. The second situation examined the use of another constrained resource, money, and the consumption of indulgent material goods. Two hypothetical individuals facing the same constraint decided between saving up for an infrequent, larger indulgence or spreading out indulgences in smaller, more frequent intervals. Results showed that restraint followed by a large, planned indulgence was expected to lead to greater happiness with the expenditure ($p<.001$), lower guilt over the indulgence ($p<.001$) and overall greater life happiness ($p=.01$) than would spending on a series of smaller indulgences. These results highlight the psychological benefits associated with the anticipation of positive consumption experiences (Caplin and Leahy 2001; Loewenstein 1987), as waiting for one larger good enhanced estimates of happiness.

In study 2, we used a critical incidence technique by asking participants (n=122) to recall a recent indulgence of their own by providing instructions between subjects for one of four conditions representing a 2 (size of indulgence: small or large) X 2 (type of indulgence: good or experience). After describing the indulgence, participants were asked about how long their happiness related to the indulgence lasted. Also, we asked participants to indicate the level of planning that had gone into their consumption decision. A 2 X 2 ANOVA indicate an interaction between product type and magnitude of consumption. Mean value suggested that happiness had lasted longest when consumers were asked to consider large purchases of material goods. Further, the level of planning that went into such purchases appeared to be driving these effects, suggesting the benefits associated with anticipating such a purchase may have caused the resulting happiness to last longer. These results provide support consistent with the second part of study 1.

Overall, understanding the factors that enhance consumer happiness and well-being is an important part of understanding the big picture of what we as consumer researchers are seeking to understand. What and who we spend our time and money on, how often and in what amounts, and the amount of planning we put into our decisions can all impact the ultimate enjoyment of consumption, and we present a small step in enhancing this understanding.

Materialism and Affective Forecasting Error: Implications for Subjective Well-Being

Miguel Hernandez, The University of Texas at San Antonio, USA

Ashley Rae Arsenia, The University of Texas at San Antonio, USA

Jaehoon Lee, The University of Texas at San Antonio, USA

L. J. Shrum, The University of Texas at San Antonio, USA

Extended Abstract

Materialism as a construct is an area of interest in consumer research for the simple reason that materialism by definition is consumption, but with a twist. Consumption through the eyes of the materialist differs from the "norm" in that the pursuit of material possessions is more of a value to the consumer than just merely the act of acquisition to satisfy a need. The materialist views their possessions beyond their actual physical properties and designated purposes and attaches meaning to these objects beyond the scope of the non-materialist. Richins and Dawson (1992) provided a comprehensive measurement scale of materialism with three defining factors for the way material objects affect the way materialists perceive their world. In essence, materialists acquire possessions to pursue happiness, define their success and establish self-meaning in their lives.

The materialist appears to have a rigid and streamlined path to the attainment of life satisfaction, but research investigating the relation between materialism and subjective well-being has indicated that the two constructs appear to move in opposite directions (Burroughs and Rindfleisch 2002; Richins and Dawson 1992). Several hypotheses have been purported in the explanation of this inverse relation. Burroughs and Rindfleisch (2002) investigated this negative relation in the context of conflicting values, indicating that the individualistic path of the materialist conflicts with the collectivist-oriented values of family and religion, thus providing a sense of psychological tension that culminates in a reduction in subjective well-being. Richins and Dawson (1992) also indicated that this negative relation might be due in part to a lack of importance placed on interpersonal interaction with more emphasis put toward the

attainment of financial success. Finally, Kasser (2002) materialists may constantly strive for more material goods with the expectation that these goods will bring happiness. However, when these expectations are unfulfilled, happiness and life satisfaction may be reduced.

The research presented here addresses the latter proposition. Specifically, we were interested in determining whether high materialists may be more likely to overestimate the happiness the acquisition of products will bring them. Such an overestimation is known as affective forecasting error (Wilson and Gilbert 2002). More specifically, when an individual makes a purchase of an item they feel will make them happy, they may overestimate how happy this item will continue to make them feel in the future. If high materialists are more prone to affective forecasting error than are low materialists, it may explain why high materialists tend to be less happy with their lives than do low materialists.

Although the affective forecasting error has the potential to explain the negative relation between materialism and life satisfaction, there is also reason to think that high materialists may be more accurate than low materialists. Because products likely play a more central role in the lives of high materialists than low materialists, high materialists may be more involved with their purchases and the benefits that products may bring them. If so, then high materialists should actually be better calibrated than low materialists, and thus exhibit less affective forecasting error.

The current studies test these competing hypotheses. In study 1, participants were given the opportunity to be both predictors and experiencers for a list of several hedonic products and utilitarian products. The difference between the ratings of the predictors and experiencers served as the dependent variable and level of materialism (centrality dimension; Richins and Dawson 1992) was a measured independent variable. Individuals scoring in the top and bottom third of the distribution were used to maximize differentiation on materialism. The results indicate that high materialists showed no significant affective forecasting error, whereas low materialists did, suggesting that high materialists were more accurate in their forecasts. In study 2 (in progress), we further test these results in a within subjects, longitudinal design.

Exposure to Extreme Luxury: Effects of Well-Being

Katrien Meert, Ghent University, Belgium
Mario Pandelaere, Ghent University, Belgium

Extended Abstract

The current paper deals with the (unintended) effect of exposure to extreme luxury on consumer well-being. We use various dependent variables that are in one way or another related to consumer well-being.

Study 1 focuses on goal pursuit, entitlement and individualism. With regard to goal pursuit, we distinguish between *extrinsic* goals (e.g. wealth, fame, image) to *intrinsic* goals (e.g. growth, relationships, community) (Ryan & Deci, 2000). Individualism also comes in two varieties (Sivadas, Bruvold & Nelson, 2008). *Horizontal individualists* do not want to stand out from a group by aiming at status or achievement. By contrast, *vertical individualists* want to be "the best" and always strive for achievement. *Entitlement* is a stable and pervasive sense that one deserves more and is entitled to more than others and is linked to a pattern of selfish and self-serving beliefs and behaviors (Campbell, Bonacci, Shelton, et al., 2004).

Common sense suggests that marketing, like exposure to luxury, can make people somewhat more extrinsically motivated, entitled or vertical individualistic. However, we believe that this common sense does not apply for exposure to *unattainable* luxury. We suggest that, in the face of unattainable luxury, consumers may engage in self-protection and downplay the importance of luxury. This may affect their goal pursuit. In particular, exposure to extreme luxury may lead consumers to attach more importance to intrinsic goals than to extrinsic ones. In addition, we propose that exposure to extreme luxury leads consumers to derogate status differences between people. Hence, we expect that exposure to extreme luxury will not affect *vertical* individualism but rather *horizontal* individualism. Finally, images of extreme luxury may lead to the realization that life does not give you what you want all the time. This may, in turn, lead to a decreased sense of entitlement.

Study 1 was set up as an online survey to provide test of the hypotheses. 194 participants were asked to indicate on a 9-point Likert scale how much they wanted the object depicted. In the 'extreme luxury' condition, participants rated thirty extreme luxury pictures (e.g. master bedroom with spectacular view, private jet, private sauna); in the 'functional' condition, they rated thirty photos depicting functional products (e.g. rolling pin, hammer, ballpoint, calculator). Participants were randomly assigned to one of the two conditions. The order of the pictures (who were all pretested) was counterbalanced across participants. After this manipulation, our dependent measures were administered, namely *motivation* (Vansteenkiste & Lens, 2006), *entitlement* (Campbell et al., 2004) and *individualism* (Sivadas et al., 2008).

First, our manipulation proved to be successful. Respondents' mean scores of how much they wanted the object depicted differed significantly between the two conditions.

Second, results confirmed our predictions and showed that participants who were exposed to extreme luxury received a lower entitlement score and were more intrinsically motivated than participants in the functional condition. Moreover, a significant interaction effect between condition (extreme luxury/functionality) and individualism (vertical/horizontal) showed no difference for horizontal individualism, but a significant lower score for vertical individualism after exposure to extreme luxury.

In study 2, we focus on goal pursuit, materialism, and willingness-to-pay for luxury items. 136 students participated in a lab study. To manipulate 'extreme luxury' versus 'functionality', respondents had to decorate respectively a residence versus a small house. Therefore, they received a paper floor plan and three paper photos with possible interiors per room to choose from (either luxury interiors or not). Participants had to place their choice of interior on the right room of the floor plan to really make them involved in the task. During the experiment, a manipulation boost was used: participants had to choose additional products from a list to use in their newly decorated house (e.g. surround system, 150" plasma TV versus watering can, garbage can). We measured goal pursuit as in Study 1, materialism using Belk's (1985) scale, and willingness-to-pay for a room in a luxury hotel.

Again, our manipulation proved successful. As in study 1, exposure to luxury caused the importance of intrinsic values to increase. Exposure to luxury also affected materialism, albeit in a rather complex fashion. On the one hand, envy increased in the luxury condition compared to the functional condition. This is consistent with the finding that the possession of anything desirable by another person can cause one to feel envy (Schoeck, 1966). After all, the extreme luxury images signals the wealth others may have but is out of reach for the ordinary consumer. On the other hand, exposure to extreme luxury decreased the importance one attached to one's possessions. Possibly, individuals devalue the importance of their own possessions after repeated exposure to extreme luxury. Although possessiveness and envy are typically positively related, the opposing effect of exposure to luxury causes the relation to become nonsignificant. Still, both increased envy and decreased possessiveness may signal a diminished satisfaction with life. Finally, after exposure to extreme luxury, people were willing to pay more for a given luxury room in a hotel. This implies that when people visit a website to book a room in a luxury hotel, they would pay more after seeing luxury pages on the internet.

In two studies we found evidence that exposure to luxury may threaten consumers' well-being. They feel more envy and think their possessions are worth less. The decreased entitlement seems to suggest that they become more accepting of huge differences in wealth and income. To cope, consumers may increase the value they attach to intrinsic goals. Additional research is needed to further investigate the effect of exposure to luxury on well-being. For instance, what will happen when regarding attainable luxury instead of unattainable luxury? Moreover, this research project will be expanded as we intend to include regulatory focus as a potential moderator because luxury aspects receive more attention when in a promotion focus than in a prevention focus (Werth & Foerster, 2007).

The Effects of Desire: Desire as Motivator

Mario Pandelaere, Ghent University, Belgium

Maarten Elen, Ghent University, Belgium

Christophe Lembregts, Ghent University, Belgium

Katrien Meert, Ghent University, Belgium

Tina Tessitore, Ghent University, Belgium

Extended Abstract

The current paper deals with the effect of desire on a person's self-esteem, subjective happiness and satisfaction with life.

Desire is an important determinant of contemporary consumption. Consumer culture constantly exposes people to a stream of advertisements for goods. Consequently, people participating in consumer culture are continuously encouraged to desire goods. Due to this constant promotion of desire in consumer culture, it is useful to examine the consequences. Belk, Ger and Askegaard (2003) found that desire was seen by consumers as a powerful positive affective state that is both uncomfortable and pleasant. Additionally, perceived

discrepancies between a current and a desired state lead to a decrease in satisfaction with life (Michalos, 1985; Solberg, Diener, Wirtz, Lucas & Oishi, 2002). For instance, Brown, Kasser, Ryan, Linley and Orzech (2009) found that a financial desire discrepancy was inversely related to satisfaction with life. In this study we further examine the consequences of desiring goods. First, when confronted with a desire, we predict that self-esteem will rise. This increase is needed for the achievement of a desire. Here, self-esteem works as a functional resource from which one can draw. Hence, we expect a positive effect of desire on self-esteem (Hypothesis 1). Next to an increase in self-esteem, a positive effect of desire on subjective happiness (Lyubomirsky & Lepper, 1999) is expected (Hypothesis 2). When one desires something, this generally generates positive affective feelings. Possibly these positive feelings are transferred to an overall feeling of subjective happiness. Contrary to satisfaction with life, which gauges more to the cognitive component of happiness, subjective happiness assesses the more affective part of happiness. Simultaneously, we expect a decrease in satisfaction with life (Hypothesis 3). Desiring something also means that something is missing in life, so when people realize this, a decrease in satisfaction with life can be foreseen. It has already been shown that the discrepancy between what people actually have and what they want leads to a decrease in satisfaction with life (Larsen & McKibban, 2008; Solberg et al, 2002).

To test these hypotheses, a first online study was set up. A total of 81 respondents participated in an online experiment. First, the participants' feelings of desire were manipulated. One group of subjects (i.e. 'desire condition') were exposed to thirty desirable pictures (e.g. palm tree, cruise ship, etc...), whereas another group of subjects (i.e. 'no desire condition') were shown undesirable pictures (e.g. pen, calculator, etc...). As a manipulation check, respondents reported on a scale from 0 to 100 how much they desired what was shown in each picture. After this manipulation, our dependent measures were administered, namely self-esteem (Rosenberg, 1965), satisfaction with life (Diener, Emmons, Larsen & Griffin, 1985) and subjective happiness (Lyubomirsky & Lepper, 1999).

First, our manipulation proved to be successful. Respondents' mean desire scores differed significantly between the two conditions ($F(1,79)=80.482, p<.001$). Second, results revealed a significant main effect of condition on self-esteem ($F(1,79)=5.711, p=.019$). Subjects who were exposed to desirable pictures scored significantly higher on self-esteem than subjects who were shown undesirable pictures, hence supporting hypothesis 1. Third, also subjective happiness differed significantly across groups ($F(1,79)=3.966, p<.05$). Respondents from the 'desire condition' reported to be significantly happier than respondents from the 'no desire condition'. Thus, the second hypothesis was supported by the data. Fourth, concerning satisfaction with life, no significances were found. Hence, we found no support for the third hypothesis.

Therefore, in study 2, we focused only on satisfaction with life. 75 subjects participated in a lab study. To manipulate desire, one group of participants was asked to imagine themselves organizing a world trip. Each participant had to situate twelve pictures of desirable destinations in order of preference on a world map. The second group of participants was given a similar task, with the exception that it concerned a regional trip. Moreover, the twelve destinations were less desirable (all material was pretested).

Again, our manipulation proved to be successful. Respondents' mean desire scores differed significantly between the two conditions ($F(1,72)=14.403, p<.001$). Furthermore, results revealed a marginal significant effect of desire on satisfaction with life, hence marginally supporting the third hypothesis. People who organized the regional trip were more satisfied with their lives than people who organized the world trip ($F(1,72)=1.178, p=.084$). Probably, organizing (and actually undertaking) a world trip might seem unattainable, which produces a discrepancy between an actual and a desired state, entailing an effect on people's satisfaction with life.

In two studies we found evidence that desire has implications on one's self-esteem, subjective happiness and satisfaction with life. When consumers are confronted with a feeling of desire, they get a higher self-esteem, feel happier, but are less satisfied with their lives.

Additional research is needed to further investigate the effect of desire on previous discussed dependent variables, especially satisfaction with life, because of its marginally significance. Besides, other dependent variables might be considered as well. For instance, what will be the effect of desire on risk-taking behavior? Probably, consumers who are confronted with a higher self-esteem, due to desire, might be more risk-taking than consumers without an induced feeling of desire.

Ovulatory Cycle Effects on Women's Attention to High-Status Products

Inge Lens, K. U. Leuven, Belgium

Karolien Driesmans, K. U. Leuven, Belgium

Luk Warlop, Catholic University Leuven, Belgium

Mario Pandelaere, Ghent University, Belgium

Extended Abstract

An important life-goal of many species, including humans, is to find an appropriate sexual partner. A number of studies have shown that a woman benefits from selecting a mate with strong genes, who is also willing and able to invest in her and her children (Bjorklund and Shackelford 1999; Brase 2006). Consequently, women are attracted to men with social status and sufficient financial resources (e.g., Li et al. 2002). In response to this, men in a mating-mindset show an increased intention to spend money on luxury products (Griskevicius et al. 2007). Various studies found that women's mating motivations change or increase during the most fertile period of their monthly cycle. For instance, near ovulation women are attracted to more masculine, taller and more socially dominant men (Gangestad, Thornhill, and Garver-Apgar 2005) and they are willing to pay more for products that increase their attractiveness (Hill and Durante 2009). These findings suggest that around ovulation women are more receptive to stimuli that highlight the qualities of a potential mate (mate selection) and are more willing to attract a suitable sexual partner (mate attraction). With respect to the mate selection goal, most research focused on menstrual cycle effects on women's interest in physical signs of genetic quality. Only few studies investigated cycle effects on the appreciation of mate values related to investment capacity (e.g., Gangestad et al. 2007). We aim to fill this gap, yet we focus on attention to material signs of status (i.e., high-status products), rather than on the appreciation of males carrying these products. In particular, we test whether ovulating women pay more attention to status products, even in the absence of an explicit mating context (i.e., without potential partner present). In addition, we test whether attention to high-status products is predicted by levels of estrogen (positively) and progesterone (negatively), consistent with previous findings that hormones underlie menstrual cycle effects on mate preferences (e.g., Lukaszewski and Roney 2009; Roney and Simmons 2008). For women using hormonal contraceptives, such as the Pill, no effect of cycle phase is expected as Pill usage suppresses the regular flow of female hormones. Therefore, Pill use is expected to moderate the effect of cycle phase on attention to high-status products.

In a (quasi)experiment, 124 Pill users and 38 normally cycling women ($M_{\text{age}}=22.34$) were exposed to ten computerized, visual displays consisting of six products (cf. Roskos-Ewoldsen and Fazio 1992). One product in each display was a high-status product (expensive car, exclusive watch,...), the remaining five products were low-status products (bucket, umbrella,...). A pretest confirmed that high-status products were perceived to be more prestigious than low-status products, $t(57)=-17.2$, $p<.001$. Exposure to each display lasted one second after which participants had 20 seconds to write down the objects they had noticed. The dependent variable used in further analyses is the absolute number, as well as the proportion of listed high-status products (taking into account the total number of products listed). We also calculated a score indicating the position of each high-status product in the list of recalled items for each display. Higher scores indicate quicker recall/more attention.

Next, participants indicated whether they take a contraceptive Pill or other hormone based medicine. Subsequently, they reported the start of their last menstruation (cycle day 1). We divided participants in three groups: Participants in days 1-5 are in the menstrual phase (9 normally cycling women, 23 Pill users), participants in days 9-15 are in the fertile phase (11 normally cycling women, 25 Pill users) and participants in days 18-28 are in the luteal phase (12 normally cycling women, 47 Pill users). We dropped participants who were in the ambiguous zones between two phases (cf. Miller, Tybur, and Jordan 2007) or who reported an unusual cycle length. Finally, based on the cycle day we estimated levels of estrogen and progesterone in normally cycling participants (cf. Martin and Behbehani 2006).

Empirical evidence confirms our predictions. For normally cycling women cycle phase has a significant effect on the absolute number, $F(2, 29)=7.14$, $p=.003$, and proportion of listed high-status products, $F(2, 29)=8.32$, $p=.001$. Women around ovulation notice more high-status products than women in other phases do, consistent with the notion that the activation of a goal (e.g., mate selection goal) directs attention to goal-consistent stimuli (Moskowitz 2002). In addition, high-status products are recalled quicker during ovulation than during other phases, $F(2, 29)=7.63$, $p=.002$. As expected, Pill use moderates the effect of cycle phase on the absolute number, $F(2, 121)=5.07$, $p=.008$, and proportion of listed high-status products, $F(2, 121)=5.51$, $p=.005$, as well as on the position of the listed high-status products, $F(2, 121)=3.79$, $p=.03$. In all cases, attention to high-status products does not differ across the cycle for Pill users. In addition, estrogen and progesterone levels significantly influence attention to high-status products. Higher levels of estrogen lead to higher absolute, $\beta=.85$, $t(29)=2.03$, $p=.05$, and relative numbers of noticed high-status products, $\beta=.03$, $t(29)=2.31$, $p=.03$, and to quicker recall, $\beta=.06$, $t(29)=2.07$, $p=.047$. Progesterone levels are associated with smaller absolute numbers, $\beta=-.23$, $t(29)=-2.05$, $p=.049$, and proportions of listed high-status products, $\beta=-.008$, $t(29)=-2.22$, $p=.03$, and with slower recall, $\beta=-.02$, $t(29)=-2.57$, $p=.02$.

In sum, our research relates women's attention to status products to the evolutionary principles of mate selection by showing that attention to high-status products increases during days of high fertility. This finding may have interesting implications, as more diverse consumer preferences or behaviours may differ depending on hormonal fluctuations. Future research might, for instance, address whether heightened attention to luxury products during ovulation leads to increased spending intentions or willingness to pay for status products or to greater acceptance of advertising messages for luxuries.

Testosterone and Context-Specific Risk: Digit Ratios as Predictors of Recreational, Financial, and Social Risk-taking

Eric Stanstrom, Concordia University, Canada

Gad Saad, Concordia University, Canada

Marcelo V. Nepomuceno, Concordia University, Canada

Zack Mendenhall, Concordia University, Canada

Consumers frequently make choices between options that entail varying degrees of risk. Whether it is within financial, recreational, or health contexts, consumers differ a great deal in their appetite for risk. While prior research has identified numerous antecedents of risk-taking proclivities (e.g., Baker and Maner 2009; Loewenstein et al. 2001; Levenson 1990), the physiological correlates of risk-taking remain relatively unexplored. We investigate the impact of testosterone on risk preferences across a variety of contexts. Specifically, we examine the association between digit length ratio (a proxy of prenatal testosterone exposure) and risk-taking behavior across financial, recreational, social, health and ethical domains.

Prenatal androgens have significant effects on brain organization and future behavior (Archer 2006; Auyeung et al. 2009; Udry 2000). This exposure also stunts the growth of the second digit relative to the other fingers. As a result, the second (index) to fourth (ring) digit length ratio (2D:4D) has been used as a proxy of exposure to prenatal testosterone (Lutchmaya et al. 2004; Manning et al. 1998). This association has spurred considerable interest in 2D:4D, which has been associated to an array of masculine traits including aggression (Bailey and Hurd 2005), athletic ability (Manning and Hill 2009), and perceived dominance (Neave et al. 2003). Even among females, a lower 2D:4D tends to predict masculine behavioral traits (Csathó et al. 2003; Paul et al. 2006).

Recent research has linked 2D:4D to financial risk-taking (Coates, Gurnell, and Rustichini 2009; Coates and Page 2009; Dreber and Hoffman 2007). However, there is a paucity of research exploring the link between digit ratio and other forms of risk-taking. Risk-taking preferences are typically assessed via a financially-related measure subsequent to which the findings are generalized to all domains of risk (i.e., one index of risk is associated equally to all risk-related contexts). While this operationalization of risk preferences is consistent with the expected utility framework and prospect theory (Kahneman and Tversky 1979), more recent research suggests that risk-taking proclivity is a domain-specific phenomenon in which an individual's risk proclivities are different across domains (Weber et al. 2002; Blais and Weber 2006; Kruger, Wang, and Wilke 2009). In other words, an individual may display a strong appetite for financial risk and a strong aversion to risk in other domains such as recreational activities or social situations. Accordingly, the current paper examines if digit ratio is predictive of risk-taking propensity across recreational, financial, social, ethical, and health domains. We propose that lower, more masculine digit ratios are predictive of riskier behaviors across all five domains among men and women.

A sample of four hundred and thirteen students completed a survey and had the lengths of all right-hand digits measured by a trained experimenter. The 2D:4D and *rel2* (the length of the second finger relative to the sum of the lengths of all four fingers) ratios were computed for each participant. The *rel2* ratio was included because it has recently been shown to be more accurate than 2D:4D in discriminating between males and females (Loehlin, Medland, and Martin 2008). Risk was assessed via a domain-specific risk-taking behavior scale as described in Weber, Blais and Betz (2002). Each of the five domains contained 10 five-point Likert-type items (1 to 5) assessing one's likelihood of engaging in a given risky activity (all alphas above .67). Items include "periodically engaging in a dangerous sports (e.g., mountain climbing or sky diving)" (recreational), "investing 10% of your annual income in a very speculative stock" (financial), "speaking your mind about an unpopular issue at a social occasion" (social), "shoplifting a small item (e.g., a lipstick or pen)" (ethical), and "eating 'expired' food products that still 'look okay'" (health).

To control for the potentially confounding effects of sex and ethnic heterogeneity (Manning et al. 2007), Pearson correlations between digit ratios and risk measures were performed on the following four subsamples: male Caucasians (n=130), female Caucasians (n=109), all males (n=219), and all females (n=194). In the subsample of male Caucasians, lower *rel2* was predictive of greater financial, social, and recreational risk-taking. Lower 2D:4D was predictive of greater risk-taking in two domains (social and recreational) in this group. In the full male sample (ethnically heterogeneous), the only significant correlation was a negative association between 2D:4D and financial risk. In other words, all significant correlations were in the predicted direction. Surprisingly, no significant correlations were found in the female subsamples. Finally, men were more risk-seeking than women across all five contexts.

In sum, our results indicate that prenatal testosterone exposure has organizational effects on a man's recreational, financial, and social risk-taking propensity. Furthermore, our findings suggest that future digit ratio research should account for ethnic heterogeneity and that *rel2* should be considered as a potential alternative proxy of prenatal testosterone exposure. Moreover, our study highlights the potential of using physiological markers to predict individual differences in consumer behavior. Ultimately, the digit ratio might serve as a test case for the applicability of morphological segmentation as a viable marketing strategy. Morphological segmentation might be used by marketers perhaps not to identify singular individuals but rather to create segments of similar consumers (e.g., high testosterone men), all of whom can then be targeted with tailored advertising messages and promotional campaigns.

The Effects of the Menstrual Cycle on Food Appearance-related Consumption

Gad Saad, Concordia University, Canada

Eric Stenstrom, Concordia University, Canada

Consumer behavior is influenced by a wide variety of situational variables (e.g., Argo, Dahl, and Manchanda 2005). We focus on a physiologically-based situational factor unique to women, namely the menstrual cycle. Despite the mounting evidence demonstrating the profound effect that the menstrual cycle has on women's desires, preferences, and behaviors (e.g., Gangestad et al. 2007), its role in the consumption arena remains relatively unexplored. In the current work, we show that a woman's appearance- and food-related desires, product usage, and purchasing behavior are influenced by her menstrual cycle.

The menstrual cycle begins with the menstrual phase (usually days one to four of a 28-day cycle), followed by the follicular phase (days five to 14), and ending with the luteal phase (days 15 to 28). Women can only conceive during a short fertile window of roughly six days during the late follicular phase, typically occurring between days eight and 15 of a 28-day cycle. Given the evidence suggesting a late follicular peak in mating-related drives (Gangestad, Thornhill, and Garver-Apgar 2005) and associated styling behaviors (Haselton et al. 2007; Durante, Li, and Haselton 2008; Roder, Brewer, and Fink 2009), we expect that women will increase their appearance-related consumption on fertile days in order to maximise their attractiveness to potential mates at this time. Specifically, we predict that women's appearance-related desires, purchases, and product usage, will be greater during the fertile phase compared to during the luteal phase. Further, given the evidence indicating a peak in caloric intake during the luteal phase (Buffenstein et al. 1995; Fessler 2003), we expect that women's food-related desires, purchases, and consumption choices will be greater on luteal days compared to fertile days.

Fifty-nine normally cycling women who were not taking any hormonal contraceptives were asked to track their expenditures in a shopping diary and to answer online survey questions every evening for a period of 35 days. Participants were asked to complete a short survey consisting of a number of survey items every evening (denoted as survey 1) and to complete a much longer survey containing many additional items on three specific evenings (denoted as survey 2). The reported food and clothing-related Likert-type items were included in both surveys. Participants were asked to track the exact amounts of money that they had spent on food and clothing in a paper shopping diary and to indicate their totals every evening in survey 1. To assess food and appearance-related desires and product usage, participants provided ratings in surveys 1 and 2. Specifically, on a nine-point Likert-type scale anchored by -4 ("far less than usual"), 0 ("about average"), and +4 ("far more than usual"), they were requested to indicate "Over the last 24 hours, compared to most days in the last 12 months, I..." In survey 1, desire for food was measured by "felt hungry today" and "craved highly caloric foods," whereas actual food consumption was assessed by the items "consumed calories," and "ate highly caloric foods." In survey 2, appearance-related desires were measured by the item "felt a desire to look sexy," while a variety of items assessed appearance-related product usage including

“wore sexy clothes,” “wore clothes that showed lots of skin,” “wore a skirt,” and “went sun tanning.” Of the 59 women who began the 35-day study, 48 women completed survey 1 at least once each during the luteal and fertile phases, while 20 did so for survey 2. After excluding the data from 12 women who did not have regular cycles between 27 and 39 days in length and one who reported taking a hormonal contraceptive during the study, the final sample sizes were 35 participants for survey 1 (the food-related Likert-type items and the expenditures in both categories) and 17 for survey 2 (the appearance-related Likert-type items). Each participant’s follicular and luteal phases were estimated based on menstruation information collected via survey 1 (i.e., “did you menstruate today?”) and on subsequent post-study email correspondences.

As hypothesized, women reported feeling greater appearance-related desires and engaging in greater appearance-related product usage on fertile days than on luteal days. Despite the large mean difference in the predicted direction, there were no significant differences between the daily amount of money spent on clothing on fertile days and the amount spent on luteal days. However, a more granular split of the data revealed that women spent significantly more money during the fertile phase than during the early follicular phase. Recall that we predict the opposite menstrual cycle effect for food, such that consumption will be greater during the luteal phase than during the fertile phase. As expected, women reported feeling hungrier and stronger cravings for highly caloric foods on luteal days than on fertile days. Similarly, women in their luteal phase reported consuming more calories and more highly caloric foods compared to when they were in their fertile phase. The amounts of money that women spent on food were also significantly influenced by menstrual cycle phase, such that women reported spending significantly more money on food on luteal days than on fertile days. Mediation analyses revealed that the menstrual cycle effect on appearance-related product usage was significantly mediated by appearance-related desires. Further, food-related desires significantly mediated the menstrual cycle effects on food consumption and on food expenditures.

The obtained findings relating to actual purchases constitute the first direct economic evidence of a menstrual cycle effect on women’s consumer behavior. Our research is of relevance to consumer welfare in that we are highlighting when women are most vulnerable to succumbing to cyclical temptations for high-calorie foods and appearance-enhancing products. From a managerial perspective, practitioners having access to detailed purchasing data can deduce a particular consumer’s menstrual cycle phase from her food and/or clothing buying patterns and employ direct marketing strategies accordingly (e.g., send food-related promotions to consumers who are likely to be in their luteal phase). Overall, our findings add to the growing body of work at the nexus of physiology and consumer behavior (Miller, Tybur, and Jordan 2007; Plassmann, O’Doherty, Shiv, and Rangel 2008; Saad and Vongas 2009).

Compulsive Buying—Also a Male Problem?

Mirja Hubert, Zeppelin University, Germany
 Marco Hubert, Zeppelin University, Germany
 Oliver B. Büttner, Zeppelin University, Germany
 Arnd Florack, Zeppelin University, Germany
 Peter Kenning, Zeppelin University, Germany

Extended Abstract

Compulsive Buying (CB) is a problem with increasing relevance for individuals and society. Earlier studies show that the fraction of people who exhibit a strong tendency toward CB is between 5% and 8% of the population in Western societies (Faber and O’Guinn 1992; Koran et al. 2006; Reisch, Neuner, and Raab 2004; Ridgway, Kukar-Kinney, and Monroe 2008). However, previous investigations provide evidence that between 80-95% of compulsive buyers are female (Black 2007; Faber and O’Guinn 1992; Müller and de Zwaan 2004). Remarkably, research indicates that men rarely evidence CB tendencies.

In general, compulsive buyers are prone to run into indebtedness because they are characterized by a tendency for repetitive buying with a loss of impulse control over buying (Ridgway et al. 2008). Evidence that overspending and debts are problems that often affect men more seriously than they do women (www.creditreform.de) suggests that CB is a more severe problem among men than is reflected

in the current literature (Dittmar and Drury 2000, Koran et al. 2006). There are two possible reasons why CB is often not reported for men: First, excessive shopping might be more socially accepted among women. Second, the scales for measuring CB seem to be more representative for female types of shopping behavior (e.g., Ridgway et al. 2008). Thus, CB among men might be underreported and, consequently, underestimated (Koran et al. 2006; Müller et al. 2005).

Against this background, we ran two studies with male participants in order to provide new insights about CB in men. In Study 1 we applied the Implicit-Association-Test (IAT; Greenwald, McGhee, and Schwartz 1998) to examine correlations between indicators of overspending and automatically activated evaluative associations of brands of the high-price segment. In Study 2 we used fMRI (functional magnetic resonance imaging) to measure activity changes in brain areas related to reward experiences or anticipation in men with, and without, CB tendencies.

In Study 1, automatically activated evaluative associations of brands were assessed using a single target IAT (Bluemke and Friese 2008). The IAT is a response-time-based measure that can be used to assess the strength of associations between concepts (Lane et al. 2007). Our study included 28 male participants ($M_{\text{age}}=29$ years). The target category was “brands,” which was represented by thirteen brand-logos assumed to be relevant for a male sample. The attribute categories were “positive” and “negative” valences, represented by a mix of pictures. The sequence of the different IAT blocks followed the standard procedure for a single target IAT (Karpinski and Steinmann 2006). After answering a number of questions unrelated to our study, participants were asked about financial problems using two five-point rating items for the two problems of overdrawing a bank account and of settling debts. Both items showed significant correlation ($r=.30, p=.06$). Based on the response times of the IAT, we calculated the D measure (Greenwald, Nosek, and Banaji 2003), with higher values representing more positive associations of the selected brands. As predicted, the more positive the brand associations were, the more problems with overdrawing one’s account ($r=.43, p<.05$), and with settling one’s debts ($r=.32, p<.05$) were reported. This result shows that adverse financial consequences of CB are correlated with positive brand associations that are activated on an automatic level.

In Study 2 we applied fMRI in order to observe these automatic processes during the perception of brands on a neural level. Taking into account that the underlying neural mechanisms of CB are still not known, we wanted to investigate whether men with CB tendencies exhibit different neural activation patterns compared to men without CB tendencies. Ten men participated in the study (age: $M=31.2$) that was executed on a 3T fMRI-scanner. Data processing and statistical analyses were conducted with SPM5 by using the General Linear Model (Huettel, Song, and McCarthy 2008). The stimulus material consisted of the same brands as in Study 1. The participants’ task was to judge the brand as attractive or unattractive. After the scanning session, participants were asked to fill out a questionnaire that included a demographic information section and a 16-item scale to measure CB tendencies (Scherhorn, Reisch, and Raab, 1990). Using this scale, we classified participants as either having a tendency toward CB (TCB group, $N=3$; $M_{\text{CBscale}}=35.67$) or having no tendency toward CB (NTCB group, $N=6$; $M_{\text{CBscale}}=27.00$) (Scherhorn et al., 1990). An ANOVA confirmed significant differences between the two groups ($F(1, 8)=32.19, p<.001$). Based on this classification, the fMRI analysis revealed different neural activation patterns for the TCB and NTCB groups. We observed neural activity changes in, for example, the caudate, the putamen, or the amygdala. These structures are often associated with reward and emotions (Delgado et al. 2003; Haruno and Kawato 2006; O’Doherty 2004). These results suggest that the “reward system” (Dalgleish 2004; Dalgleish, Dunn, and Mobbs 2009; Elliot, Friston, and Dolan 2000; O’Doherty 2004; Phillips and Stanton 2004; Weber and Johnson 2009) might be crucial for the development of CB. The exhibited activations can be explained by increased emotional arousal and reward expectations regarding attractive brands. This is consistent with the satisfaction experience that compulsive buyers report within the buying situation (Boundy 2004, Faber 2004). Furthermore, our study reveals that male consumers who are prone to CB show activity changes within brain regions that are often seen in studies of psychological diseases, that is, impulsive compulsive disorders, addiction, and obsessive compulsive disorders (e.g., Lubman, Yücel, and Pantelis 2004; Maltby et al. 2005; Saxena et al. 1998).

Our studies show that there is a correlation between the adverse financial consequences of CB and the positive brand associations on an automatic level, and that attractive brands lead to activity changes in reward-related brain areas in men with CB tendencies. Thus, if attractive brands act as strong reward stimuli in the brain and evoke positive associations on an automatic level, men are more likely to show CB characteristics. This indication that CB is also a male phenomenon suggests a need for further attention by consumer researchers.

Do Retail Brands Bias Consumer Decision-Making? –An fMRI Study on Retail Brand Frames and the Evaluation of Product Packaging

Mirja Hubert, Zeppelin University, Germany
 Marco Hubert, Zeppelin University, Germany
 Peter Kenning, Zeppelin University, Germany

Extended Abstract

Research in the field of retail marketing is important for manufacturers, in order to select the best marketing strategy, the most appropriate distribution channels, the optimal price policy, and the best retailers (Choi 1991; Lee and Staelin 1997; Pasternack 1985). However, very little is known about optimal strategies of product positioning, or about how different retail brands influence (“frame”) customers’ product perception and evaluation (Martenson 2007).

In contrast, in economic and psychological theory the “framing effect” is a very well-known and important concept for the identification of judgment biases within subjects’ choices (Gonzalez et al. 2005; Tversky and Kahneman 1981). Recent studies provide evidence that the “framing effect” occurs due to the integration of conscious and unconscious implicit and explicit background knowledge in the decision-making process. In addition, recent evidence indicates that specific neural processes play a central role for susceptibility to the manner in which a choice-problem is presented (Deppe et al. 2005a, Deppe et al. 2007).

Against this background, we applied fMRI in order to understand how the product evaluation of consumers is influenced by retail-brand-frames. In this regard, the application of fMRI could offer a new theoretical perspective and may help to reach a higher level of explained variance regarding the susceptibility of consumers to retail brands.

In our study, we investigated the behavioral decision-making and the correlating neural activity pattern of 21 subjects (11 female,

$M_{age} = 25.91$, $SD = .44$; 10 male, $M_{age} = 28.6$, $SD = 5.502$), by comparing individual attractiveness evaluations of 30 packages within an unframed task and a framed task. The unframed task consisted of the attractiveness evaluation of product packages alone, whereas in the

framed task we presented product packages together with selected retail brands. Both tasks were pseudo-randomized, and repeated four times. Because of this structure, the 30 product package images had to be evaluated four times in the unframed task and, respectively, four times--in combination with the retail brand--in the framed task.

The stimulus material for the fMRI-experiment was selected in a pretest. In this pilot study, 51 randomly selected subjects (23 female, 28 male) evaluated, according to their attractiveness, 130 original paper-based packages of current supermarket products. The packages had to be rated on a score ranging from 1="very unattractive" to 10="very attractive." We then selected only the 10 most attractive packages ("P+"), the 10 least attractive packages ("P-"), and 10 neutral packages ("P0") for the neuroimaging experiment (Deppe et al. 2005a; 2007; Stoll, Baecke and Kenning 2008).

The study was executed on a 3T scanner (Magnetom Trio, SIEMENS, Erlangen, Germany). The protocol included a 3D isotropic T1-weighted data set of the entire head, with a measured voxel size of 1.0 mm edge length for anatomical identification and coregistration into the Talairachspace. The data set consisted of 36 transversal slices of 3.6 mm thickness without a gap, FOV 230 mm x 230 mm, acquired matrix 64 x 64, that is, isotropic voxels with 3.6 mm edge length. Contrast parameters were TR=3000 ms, TE=50 ms, flip angle=90°. The stimuli were projected onto a transparent screen with an LCD beamer, and viewed from the other side via a 45° mirror mounted on an element phase array coil.

First, we compared the behavioral data (the attractiveness rating) of the framed task with the behavioral data of the unframed task. For this we used the evaluations of each participant within the scanner. We calculated an individual attractiveness ratio (AR) for the framed (AR [framing]) and the unframed task (AR [packaging]), by subtracting the number of negative evaluations (not attractive) from the number of positive evaluations (attractive) in the scanner, divided by the total number of all evaluations for each participant (Deppe et al. 2007). The Response Bias (RB), a measure of susceptibility toward framing information, was assessed by subtracting the absolute values of the AR (packaging) from the absolute value of the AR (framing). The expected value of the RB for an individual participant should be zero if the framing information has no influence on the participant's decision-making. We identified 15 of 21 participants who were influenced by the framing information with an RB unequal 0 on a range from RB=0.03 to RB=0.45. A paired t-test for AR (packaging) and AR (framing) confirmed these differences to be significant ($t = 2.155$, $p < 0.05$).

Second, results from the fMRI data analysis indicated that people who are susceptible to framing information (RB unequal 0) also show different neural activity changes compared to people who show an RB=0. We found activity changes in the dorsolateral prefrontal cortex (DLPFC) and the ventral anterior cingulate cortex (vACC). The DLPFC is suggested to play a prominent role for cognitive control, working memory, and decision-making (McClure et al. 2004a; Sanfey et al. 2003). The vACC is linked to emotions and to reward-based learning, and seems to play an important role in visual attention, the integration of incoming information with background knowledge, the retrieval of episodic memory, and self-reflection (Bush et al. 2002; Deppe et al. 2005a, 2005b, 2007; Devinsky, Morrell and Vogt 1995; Lamm et al. 2007). Moreover, activity changes in the vACC are also associated with the general susceptibility of a person (Deppe et al. 2007). Our results are in accordance with the study conducted by Deppe et al. (2007) and their findings that the anterior cingulate cortex is associated with the general susceptibility of a person and plays a decisive role in behavioral adjustments and the integration of framing information in the decision-making process.

Our findings suggest that the application of fMRI can offer a new perspective in order to better understand unconscious processes that influence consumer decision-making. We found neural correlates of judgment biases within the DLPFC and the vACC. This confirmed recent findings in other studies regarding the influence of the "framing effect" on marketing-relevant decisions (e.g., Deppe et al. 2007). Because of the strong influence of the psychological "framing-effect," it should be important for manufacturers to implement consumer susceptibility, product positioning, and the biasing effects of retail brands in their product and price strategy portfolios.
