Regarding symbolic consumption our work has contributed by showing that the consumption of sacred vessels such as religious jewelry and candles are symbolic consumption practices, which for the Catholic consumer are consumed at the individual, and private level, not at the conspicuous level but with the aim of drawing closer and building connection with the *Sacred*. Likewise, our findings have demonstrated that the consumption of Mass is not an individually symbolic consumption practice, but a shared one. Focusing upon building personal connection with God, but likewise about building connection with the body of Catholicism in its entirety. Thus, we have shown symbolic consumption practices from the Catholic consumer, which go against the norms of conspicuous symbolic consumption, which have been the forerunners within symbolic consumption theory to date. Additionally, this research points towards the complete antithesis of self-differentiation within sacred consumption as we demonstrate that the consumption of sacred vessels builds communication with God/ the absolute *Sacred*, but simultaneously builds connection and communality with the entire body of Catholicism.

Ger (2005:79) questioned, "How does sacred religion appropriate the profane consumption…how does the spiritual interplay with the material?" We reference St. Paul in answering this query, "the world, life and death, the present and the future are all your servants; but you belong to Christ and Christ belongs to God" (3:16-23). Thus, God gave man the material world to serve their needs, in short it is a playground for man to interact upon, and as such draw closer to Him. The findings from this study agree with St. Paul, as they demonstrate that material goods provide an interactional platform with the *Sacred*, for through consumption of the material world consumers are able to build connection and

draw closer to the *Sacred*. Our research therefore, adds further to research such as Touzani & Hirschman (2008) and Sandikci & Ger (2010) which have proven that the dichotomy existing between religion and consumption is a false one, as consumption does not demean religion, but often has a "symbiotic relationship" with it.

Throughout this study we have discovered that within consumer culture there appear issues regarding terminology. Through our adoption of Plato and Iacobucci's (2001) differentiation between the metaphorical form of the sacred and the absolute idea of the *Sacred*, we have introduced a body of theory addressing such terminological issues, with our *consumption of sacred vessels* concept. Nonetheless, confusion remains within consumer culture whereby words such as sacred, spiritual, and especially transcendent are all used inter-changeably. And as such, we suggest that instead of continuous focus upon secularizations, sacralizations, or even upon the consumption of religiously/spiritually linked goods, which help build connection with the *Sacred*, we need to start questioning and focusing upon terminology. And in doing so we shall be able to further diminish the religion-consumption dichotomy present within consumer culture and society today. We believe a predominant conundrum exists in consumer culture's usage of the word transcendence, and as such we suggest that future research begins with questioning transcendence terminology, by asking and answering: "What is transcendence and in what ways do the transcendental feelings experienced during differing consumption practices resonate or differ?"

A Luxury Perspective on Brands - Characteristics, Value, and the Eye of the Beholder

Renu Emile, AUT School of Business, Auckland, New Zealand
Margaret Craig-Lees, AUT School of Business, Auckland, New Zealand

INTRODUCTION

This paper is part of a wider study that investigates whether and how consumers use products or brands to construct, support or communicate aspects of their self to others. A facet of the study is to ascertain if consumers identify luxury brands. If so, what brands do they speak of? How do they use them in relation to their self? The self is, to a degree, a nebulous concept and difficult to operationalize. Reed (2002) lists six paradigms and also presents a cogent argument for the notion that 'the self, social relationships, and social identity' paradigm should dominate consumer research. The self is "a reflective mirror born out of social interaction with the individual's social milieu, as an object that arises out of social interaction; an outgrowth of people's reactions of appropriate behaviour; as an enacted role for a particular audience; as a universe of potential different identities that may guide behaviour" (Reed 2002: 250-251).

Reed's use of the term social identity accords with that of Tajfel and Turner (1979, 1986). The self, social relationships, and social identity paradigm does not negate the notion that the self comprises of at least two interacting facets - the persona (the self as denoted by characteristics and abilities) and the social self (the self as denoted by roles and status). It recognises that these are interrelated and their formation is a function of social interaction. The consumption of product/brand choice is a social activity - irrespective of a public/ private consumption situation, primarily because the meanings associated with product/brand choice are socially constructed.

CHARACTERISTICS OF THE LUXURY BRAND: THE BRAND MANAGER PERSPECTIVE

Characterising the luxury brand is tricky as luxury is an elusive concept. Phau and Prendergast (2000) note the subjectivity of the term and the consequential difficulty in the differentiation from the ordinary. In other words, the perception of what is or not a luxury brand is context driven and people dependent, and it may be hard indeed to categorise products or brands as luxury or non-luxury. Vigneron and Johnson (2004) contend that even though a brand may be perceived as luxurious, not all luxury brands are deemed equally luxurious. For example, while both a Cadillac and a Rolls-Royce may be perceived as luxury cars, the Rolls-Royce could be considered to be more luxurious than the Cadillac. This being said, the notion of the 'luxury' brand is widely recognised. The decision to position a brand as a luxury brand is of course the province of the brand manager. Once such a decision is made, then specific actions are required in order to create and maintain this position.

Kapferer (1998) lists product aesthetics, quality, uniqueness, sensuality as key attributes that need to be combined with exclusivity - in terms of distribution and permission (i.e., who should be associated with and/or allowed to use). Central to the luxury brand position is a strong brand identity. According to Keller (2009), a luxury position requires actions that will result in a premium image such as a selective (exclusive) channel strategy, premium pricing strategy with strong quality cues and few discounts and mark downs, the use of high status persons as endorsers, attention to logos, symbols, packaging and consistent linking to prestigious communication mediums and events linked to the brand. Similarly, Fionda and Moore (2009), based on interviews with managers of luxury brands found that they advocate attention to quality, and craftsmanship, design signature/

uniqueness, premium price, exclusivity of editions, range and distribution, consistent linking to prestigious communication mediums and the creation of events linked to the brand. Undoubtedly, the intention is for the consumer to see the brand as special in some way at both the personal and public level; the latter of course using the brand as a 'Veblen' good, a means to displaying wealth and status.

CONSUMERS AND LUXURY BRANDS

To date, the handful of studies that investigate consumers' perceptions of luxury brands and/or products examine brands preselected by the researcher and assess responses to predetermined scales (Dubious and Paternault 1995; Dubois, Czellar and Laurent 2005; Christodoulides, Michaelidou and Li 2009; Husic and Cicic 2009; Vickers and Renand 2003; Vigneron and Johnson 2004). To facilitate the identification of luxury brands, Vigneron and Johnson developed a brand luxury index (BLI). The BLI items comprise of attributes - non-personal such as conspicuousness, uniqueness and quality, and personal such as hedonism and extended self - to form an overall index of luxury. The scale was developed using data collected from a student sample in Australia. Christodoulides et al. (2009) tested the scale in the context of Taiwanese students and report concerns with dimensionality and contextual issues. They conclude that more research is necessary to determine the viability of the scale.

Even so, extant studies that examine consumer perceptions of luxury brands suggest that consumers are able to identify characteristics of products or brands they associate with the concept of luxury. For example, the participants in the Dubious and Paternault (1995) study associate luxury goods with the attribute of rarity and by definition exclusivity. Dubois, Czellar and Laurent (2005) found that their 'elitist' segment, i.e., those consumers who acknowledge the luxury concept also identified rarity and exclusivity as luxury attributes. The exclusivity factor is linked to the notion that only people of refinement and good taste appreciate luxury goods. Vickers and Renand (2003) examined how consumers use luxury goods and their findings support the notions of exclusivity, refinement and status, in particular the public conferring of status. Husic and Cicic (2009) also found that the key role of the luxury brand is the communication of prestige and status.

Wiedman, Hennigs and Siebels (2007) developed a framework to study luxury value perception - a framework that could be used across cultures. Similar to Vigneron and Johnson, they suggest that when determining the value of the 'luxury' element, what should be measured is value in relation to price, quality, usability, uniqueness, self-identity, hedonic, materialistic, conspicuousness and prestige. These constructs form the nexus of their proposed conceptual framework.

METHODOLOGY

This study concerns with examining how young adult consumers use brands in the context of managing aspects of their self. One facet of the task is to ascertain if they identify luxury brands. If they do, how they do so. The underlying premise is that if brands are deemed to be luxury, the attributes should be clearly articulated to consumers, and so consumers should have understanding of the explicit and implicit meanings in their decision to use the brand. This study explores the degree of consciousness accorded to the notion of luxury in relation to products or brands by specifically addressing the following questions: Do consumers display a conscious awareness of the luxury element in the products/brands they choose to display

aspects of the 'self'? If so, what brands do they speak of? How do they talk about the concept in general and in relation to their self?

The study focuses on young adults between the ages of 18 and 21 and uses a set of interpretive procedures (Denzin and Lincoln, 2000). The study requires data that is essentially individual interpretations and inferences of phenomena, so is positioned within the interpretivist paradigm and adopts a phenomenological oriented approach to data collection (Husserl 1970; Schutz, 1970; Thompson, Locander and Pollio 1989). Participants were instructed to photograph those products or brands that indicated an aspect of their self such as their personality, characteristics, abilities, attitudes, roles and status. The auto-photography approach allows participants to speak for themselves and reduces researcher bias (e.g., Kjeldgaard 2004; Noland 2006; Ziller 1990). Once the cameras were returned and photographs developed, each participant was interviewed for about an hour.

The transcribed interviews were analyzed as per guidelines suggested by Potter and Wetherell (1987), Wetherell and Potter (1988), Owen (1984) and Carabine (2001). Essentially this meant identifying themes, words and phrases for variability and consistency across interviews. To reduce subjective bias, the transcribed interviews were also analyzed by two independent analyzers. Differences were sorted by mutual discussion and agreement.

FINDINGS & DISCUSSION

The final sample comprised of twenty eight participants. 12 (42 %) were of European ethnicity, 7 (25%) of Maori, 5 (18%) of Indian, 3 (15%) of Chinese, and 1 (3%) of Middle East ethnicity. Participants identified brands across fifteen product categories. These were - shoes, bags, clothes, Mp3 players, mobile phones, cars, computers, cosmetics, food and drink, electronic equipment, sunglasses, perfume, wallet and watches, alcohol and wine, and miscellaneous. Of the fifteen product categories, eight accord with those identified by Fionda and Moore (2009) as luxury i.e., fashion (couture, ready-to-wear and accessories), perfumes and cosmetics, wines and spirits and watches and jewellery (See Table 1).

Table 1: Product categories and brands identified

Products	Brands Identified
Shoes	Witchery, New Balance, Vans, Nike, Converse, Puma, Adidas
Bags	*Lacoste, Louis Vuitton,* Adidas, Rip Curl, Billabong
Clothes	Ksubi, Levis, Diesel, Quick Silver, Billabong, Laura Parker, Witchery, Abercrombie and Fitch, Workshop, Dickies, Horley, Supre, True Religion Jeans, *Ralph Lauren,* Kathmandu, Mossimo,
Cosmetics & Hair products	Elizabeth Arden, Thin Lizzy, Neutrogena, Mac, Revlon, Maybelline, Fantasy cream, Smash Box, Cetaphil
Sunglasses	*Gucci,* Le Specs, *Ray-Ban, Dolce & Gabbana,* Wayfarer
Perfumes	*Lancome, Christian Dior,* Elizabeth Arden, Marc Jacobs (Daisy), *Van Cleef & Arpels, Yves Saint Laurent (YSL), Chanel,* Kylie Minogue, Jo Malone, *Oscar de La Renta*
Wallets and Watches	Ripcurl, Glassons, Guess, Adidas, *Omega,* Baby-G
Alcohol/Wine	Lindauer, Malibu, Barbados Rum, Speights, Tui, 42 Below, Smirnoff Vodka, Villa Maria

Whilst most of the brands selected in the product categories identified in Table 1 are high-end global brands, a few are high-end regional brands, e.g., Billabong and Rip Curl. Thirteen of the high-end, global brands selected (italicised in Table 1) feature on a luxury brands list (Luxury Brands List, 2010). However, participants also speak of some others that do not figure on the luxury brands list. These include Ksubi, Laura Parker, Workshop, True Religion Jeans, Kathmandu, Elizabeth Arden (See Exhibit 1 for sample extracts).

Christodoulides, Michaelidou and Li (2009) suggest that luxury products or brands can be categorised in terms of a hierarchy. At the bottom of the hierarchy is accessible luxury which in terms of socio-economic dimensions refers to luxury products that are attainable by the middle socio-economic class. The mid-level hierarchy relates to product purchases by the professional socio-economic class, while the top of the hierarchy is associated with an elite socio economic class. Though the participants own some high-end luxury brands, the product forms selected, to an extent, accord with the life stage and the socio-economic status of the sample. Christian Dior and YSL perfume and/or sunglasses are more accessible to this group than the haute couture linked to this brand. High-end clothing brands that from the way participants talk about them, are considered luxury.

It is evident that participants have an acute awareness of what selected brands communicate, and use them to clarify who they are to themselves and to communicate some aspects of their self to others. Though not specifically directed to identify brands that could be deemed 'luxury', participants talk about their selections in terms of conspicuousness, exclusivity, quality, refined taste, and status. See, for example, words highlighted in bold in sample extracts - Exhibit 1. By speaking of brands in terms of highlighted characteristics, participants reflect the elements associated with luxury brands in the literature (e.g., Dubious and Paternault, 1995; Dubois et al., 2005; Kapferer, 1998; Phau and Prendergast 2000; Vickers and Renand, 2003; Vigneron and Johnson 2004; Wiedman et al. 2007).

Exhibit 1: Sample Extracts

> *This is an Australian brand called Ksubi…umm…they are quite expensive… it is quite expensive, quite upmarket…the designers…they design for people who want to be different (Quote One - Photograph of Ksubi shorts - Jessica)*
>
> *Because Elizabeth Arden is one of those brands that everybody knows and it is quite esteemed and it is quite high up. It is almost exclusive I suppose (Quote Two - Photograph of Elizabeth Arden Perfume - Sarah)*
>
> *This is an Omega watch. It is a well known brand as well...It is a Swiss watch, and Swiss watch is best so it shows me the right time and it says it is a luxury accessory as well…As I told you before I like expensive things and when I can afford them I buy them (Quote Three - Photograph of Omega - Paul)*
>
> *The reason I took so much pictures of Ralph Lauren is because when people look at Ralph Lauren they see 'he's a high achiever, he is successful' and that 'he is talented and he looks good'…It means they are successful… they are rich (Quote Four - Photograph of Ralph Lauren T-Shirts - Craig)*
>
> *Absolutely, I mean you know a Laura Parker dress has a definite brand standard and social advantages would include like a higher social circle recognising that maybe them going 'hey she looks cool, I could hang out with her' (Quote Five - Photograph of Laura Parker Ball Dress - Melissa)*
>
> *The Yves St Laurent perfume (Baby Doll) is special to me because my mum brought it for me, but I love it, it smells really good and all my friends, every time I wear it, are like "you smell really good". It's just perfume I suppose… it appeals to mostly girls my age (Quote Six - Photograph of Yves St. Laurent perfume - Laura)*

Cornell (2002) notes that luxury is difficult to define but that it involves a strong element of human involvement; that luxury goods represent value to both the individual and their reference groups. The extracts in Exhibit 1 demonstrate that participants are cognizant of the social benefits that luxury goods afford. They are well aware that the message communicated is that they are persons of taste and refinement, successful, and that they are members of an elite group. They are able to clearly articulate what the brands represent to themselves and what they think the brands communicate to others. They value the hedonic and sensory benefits of the brands they identify; whether the sensory pleasure is enhanced by the brand image is not clear, however, there is a distinct link between perceptions of quality and the brand. The central value of the perfume in Quote Six, for example, is the smell and the value accorded by Laura's reference group.

Whilst the brands that the participants link to the attributes that research suggests are associated with luxury brands are global and feature on accredited lists as luxury brands, some do not. The Elizabeth Arden, Kathmandu, Ksubi, Workshop, and True Religion Jeans though high-end brands, their status as luxury brands is debatable. Even so, participants talk about them in terms of luxury attributes suggesting that what is a luxury brand is also contingent on the consumer's frame of reference. This means that future research should take into account variance across groups - in particular socio-economic factors that determine the elite hierarchies. Such research would not only contribute to a better understanding of the relativity of the term 'luxury', but would also provide insightful findings for both academics and practitioners alike.

The study also suggests a strong link between brand management - particularly positioning and communication in the creation of brand value - and thus the directions as to how the brand can be used and what it means. It may well be that the brands spoken of in terms of luxury do give unambiguous information to young adult consumers, and therefore, evoke luxury related associations more readily in comparison to other brands. The implications for practitioners lie in matching up their brand offerings with the potential and needs of various target markets.

CONCLUSION

This paper provides evidence for the notion that luxury as a concept is context dependent and is a function of demographic factors such as age, life stage and income. It identifies a range of fashion brands that young adult consumers speak of in terms of luxury connotations in the literature. Even though some may not be formally classified as luxury either in the scholarly literature or in industry rankings, young adult consumers perceive luxury value in the choices they make. They use the brands to communicate that they are persons of taste and social class. In other words, luxury lies in the eyes of the beholder. Last and importantly, the study emphasizes the connection between brand management, especially communication and positioning, and perceptions of luxury as one of vital significance for branding practitioners.

On the Use of Multi-Unit Auctions in Measuring Consumers' Willingness to Pay for Products

Faical Akaichi, University of Arkansas, USA
Rodolfo M. Nayga, University of Arkansas, USA
Jose M. Gil, CREDA, Polytechnic University of Catalonia, Spain

INTRODUCTION

Experimental auctions have become a popular tool to assess consumers' willingness to pay (WTP) for food products. Their popularity partly stems from their incentive compatibility property where people have the weakly dominant strategy of revealing their true valuation for a good. In experimental auctions, people are put in an active market environment with real economic consequences. Experimental auctions also provide quite a relatively easy way to assess heterogeneity in valuations across people. According to Lusk and Shogren (2007), over 100 academic studies have utilized experimental auctions to examine consumers' valuation of different products. Some of these studies focused on the valuation of food safety and health attributes (e.g., Fox et al., 2002; Dickinson and Bailey, 2002; Shaw et al., 2006) or on willingness to pay for new food products (e.g., Kassardjian et al., 2005; Rousu et al., 2005; Alfnes, 2007). Many other studies have also been carried out to test methodological aspects of auctions such as the comparison between WTP and willingness-to-accept (WTA) (Knetch et al., 2001; Shogren et al., 2001b), the learning effect (List and Shogren, 1999), the endowment effect (Lusk et al., 2004a; Corrigan and Rousu, 2006), the optimum mechanism of auctions (Rustrom, 1998; List and Lucking-Reiley, 2000; Lusk et al., 2004c), and risk preferences (McClelland et al., 1993). In these studies, however, participants were asked to report their WTP only for a single unit of the auctioned product[1].

In real market, however, consumers may be interested in buying multiple units. In fact, while the use of single-unit auctions is useful in assessing consumers' valuation of a single unit of a product, consumers can be interested as well in purchasing not just one but multiple units of a product. Also, due to increasing time constraints, many consumers are becoming increasingly concerned about optimizing shopping efficiency by purchasing multiple units of products (e.g. soda, beer, water, juice etc.) to save several trips to the store. This tendency in consumer behavior has provided an incentive to producers and retailers of food products to adjust their marketing strategies to benefit from these changes in consumer preferences. Considerable effort, for instance, has been devoted to the packaging and the promotion of products that consumers are used to buying in multiple units. In fact, producers and retailers are increasingly marketing food products in bundles of multiple-units (e.g. six-pack: 6 identical units in the same bundle). Also, they are increasingly using multi-unit price promotions such as "buy two and pay one", "buy X units and save $Y" etc. There is however scant literature on assessment of consumer behavior in a multi-unit shopping scenario

The use of single-unit auction to examine consumers' WTP for multiple units of a product is inadequate unless we assume that consumer preferences for subsequent units are similar to the first one (e.g. WTP is independent of the quantity purchased). However it is well known that for a normal good consumer demand is decreasing in price and hence, we would expect a lower WTP for each additional unit purchased beyond the first unit. Also, the assumption that consumers' WTP is in-dependent of the auctioned quantity is unrealistic since it leads to zero price elasticities. Finally, the effects of various factors determining consumers' WTP can be different for different quantities of the purchased product. For example, it is possible that some of the factors that are statistically significant in determining WTP for a single unit may become statistically insignificant for multiple units of purchase.

A modified format of single-unit auction was used by Rousu et al (2008) to measure consumers' WTP for multiple units of the same product with the objective of examining the effect of selling complements and substitutes on consumers' WTP. The modified format involves auctioning different quantities of a product in several rounds. For example, they auctioned one unit in the first round, a bundle of two units in the second round and a bundle of three units in the third round. Then they randomly choose a round to be the binding round. Although this modified format can be a good method to assess consumer behavior in multi-unit shopping scenario, the unfairness of its pricing rule can discourage certain participants from bidding their true valuations. Since a different quantity is auctioned in each round and only one round is chosen as binding, participants who are willing to pay a positive price for large quantity will have a higher probability to win than others. In other words, suppose that we use the second price auction in which the participant with the highest bid wins the auctioned product and pays an amount equal to the second highest bid. Now, suppose that two subjects are participating in a second price auction of three rounds. In the first round one unit is auctioned, two units are auctioned in the second round and three units are auctioned in the third round. Suppose that participant 1 is willing to buy just one unit and bids a value of 10 in the first round and zero in both the second and third rounds. Participant 2 is willing to buy the three units and bids a value of 8 in the first round, a value of 12 in the second round and a value of 14 in the third round. Hence, participant 2 is willing to pay 8 for the first unit, 4 for the second unit and 2 for the third unit. Now if the binding round is the first one, the winner is participant 1. But if the binding round is the second or the third round, participant 2 is declared the winner although s/he reports a lower value for the first unit. That is participant 2 has a chance to win in the three rounds but participant 1 can win only if the first round is selected. Therefore, due the unfairness of this pricing rule, participant 1 cannot win any unit if the binding round is the second or the third round even though his or her WTP for the first unit is the highest. The feeling of unfairness can discourage participant 1 from bidding his or her true value.

Fortunately, auction theory provides an auction mechanism that allows us to measure consumers' WTP for multiple units and avoid the unfairness of the pricing rule of the modified format of single-unit auction. This auction mechanism is called multi-unit auction. Multi-unit auctions can be described as an auction where multiple identical units are auctioned and participants are asked to report their WTP for each unit. Among multi-unit auction formats, the most common mechanisms used in the empirical literature are the uniform-price and the multi-unit Vickrey auctions. The uniform-price auction mechanism has been used frequently in Treasury bill and Federal Communications Commission (FCC) auctions due to its straightforward implementation and, therefore, understandable pricing rule. All winners pay the same price which is equal to the highest rejected bid. In the multi-unit Vickrey auction, which is a generalization of the second price auction (Vickrey), the winner pays an amount corresponding to the sum of the bids (excluding his or her own bids) that are displaced by his or her successful bids (Krishna,

[2] While the participant can be asked to report his/her WTP for different products, at the end of the auction only one product is randomly drawn to be sold to the winner.

2002). In spite of its demand-revealing property, the Vickrey auction, however, is not popularly used in real auctions due to the complexity of its pricing rule that makes it difficult to understand and implement in the real world. Since the main objective of this paper is to show the usefulness of multi-unit auction in assessing consumer behavior in multi-unit shopping scenario, we use the uniform price auction due to the simplicity of its pricing rule.

So how does the uniform price auction eliminate the unfairness of the pricing rule of the modified format of the single-unit auction? In the uniform price auction, each participant reports a separate bid for each auctioned unit in the same round. That is if three units are auctioned, each participant has to report his/her WTP for the first unit, his/her WTP for the second unit and his/her WTP for the third unit. The bids are then sorted and if for example the number of auctioned units is three, the three highest bidders are declared winners and they pay for each unit won an amount equal to the fourth highest bid. Let's revisit the last simple example provided above involving two bidders. Recall that participant 1 bids 10 for the first unit and zero for the second and the third unit (i.e. 10, 0, 0) and participant 2 bids 8 for the first unit, 4 for the second unit and 2 for the third unit (i.e. 8, 4, 2). Sorting the bids we obtain (10, 8, 4, 2, 0, 0). Following the pricing rule of the uniform price auction, participant 1 wins a unit with his/her bid 10 and pays a price equal to 2 and participant 2 wins two units with his/her bids 8 and 4 and also pays a price equal to 2 for each unit. We can see that the pricing rule of uniform price auction is fair since the determination of the winner depends only on his/her bids and not on the binding round like in the modified single-unit auction. As a result, both participants win based on their bids and not on the probability of a round being chosen as the binding round.

Using the uniform price auction in a laboratory experiment, we will show how the multi-unit auction allows us to obtain: 1) consumers' WTP for multiple units of the same product; 2) demand curve; 3) price elasticity; and the factors influencing consumers' WTP for different quantities of a food product. Also, using a multi-unit auction, we will be able to test two hypotheses:

Hypothesis 1   *Consumers' WTP is decreasing in the number of units.*

Hypothesis 2   *The direction and/or the magnitude of the effect of factors determining consumers' WTP can be different for each additional unit auctioned beyond the first unit.*

EXPERIMENTAL DESIGN

Forty undergraduate students took place in the study. To increase the number of observations we carried out the uniform price auction in five rounds. Hence, a total of 200 observations were obtained from the experiment. We did not post the clearing price after each round to avoid the problem of bid affiliation (Corrigan and Rousu, 2006). In each round, participants were asked to report their WTP for small packages (40 grams each) of organic chips. This product type and package size are popularly sold in vending machines in schools[2]. Participants were randomly assigned between two treatments. In the first treatment, participants were grouped in groups of 10 subjects. In the second treatment participants were grouped in groups of 2 subjects. This distribution of participants allows the assessment of the effect of varying the number bidders on consumers' WTP. However, since the objective of the paper is to show the usefulness of multi-unit auctions, the results on the effect of varying the number of bidders are not dis-

cussed in this paper.

The experiment was performed in a room equipped with ten computers. We used the z-tree software (Fischbacher, 2007) to collect bids and to determine the winner and the clearing price. Participants also had to complete a questionnaire on various aspects related to organic products, in general, and organic chips, in particular. The responses were used to characterize the participants and to analyze the main determinants of consumers' WTP for organic chips. The information collected via the questionnaire showed that all participants are regular or occasional consumers of conventional chips. 62.5% of participants characterized themselves as regular or occasional purchasers of organic food and only 17.5% of participants revealed being occasional consumers of organic chips.

The experiment was performed in three steps. In step 1, each subject sat in a table separated from the rest to minimize any possible interactions and allow anonymous bidding. After taking a seat, each participant received an envelope which contained 10€ as compensation for their participation, his or her identification number (to maintain anonymity) and a questionnaire. We then asked participants to complete the questionnaire. In step 2, once the questionnaire was completed, the actual experiment began. One of the main determinants of success in experimental auctions is a good understanding by the participants of the operating procedures used in the auction mechanism. To achieve this goal, we gave each participant a printed material that included an explanation of how the specific auction works and some examples to illustrate the auction. After reading and discussing the instructions, participants were given the opportunity to ask questions to dissipate any doubts about the process. Finally, to permit a better understanding of the auction mechanism and a good familiarity with the software, we carried out a training session, auctioning four identical units of organic chips and informed participants that no actual economic exchange will take place at the end of the training session. In this session, we asked participants to bid the amount they are willing to pay for each item of organic chips. Once all participants reported their bids through the computer, the software determined the identification number of the winner(s) and the price he/she (they) has (have) to pay.

In step 3, once the participants became familiar with the procedure, we announced the start of the real auction of organic chips. Each participant had to submit, again through the computer, how much he or she was willing-to-pay for each unit of organic chips. We made clear that we were asking for the marginal WTP. That is the WTP for the first unit, then the second unit, then the third unit and finally the fourth unit and not the WTP for one unit, two units, three units and four units. The marginal WTP is necessary to estimate the demand function and, hence, the price elasticity. Once all participants finished reporting their bids, the software determined the winner(s) and the clearing price. The same process was repeated four more times (i.e., with four additional rounds of bidding). At the end of the fifth round, one round was chosen randomly to determine the binding round. The winner(s) in the binding round was (were) appointed as the winner(s) of the auction. Once the results were announced, the experiment ended by handing the product to the winner(s) who had to pay the corresponding market-clearing price.

RESULTS

To illustrate the usefulness of multi-unit auctions in assessing consumer behavior in a multi-unit shopping setting of food products, we report in this section the results of the construction of the demand curve, estimation of price elasticity and consumer surplus as well as the determination of the factors that influence consumers' WTP for multiple units of organic chips.

3.1 Demand Curve and consumer surplus

Based on our first hypothesis, our first task was to check if

---

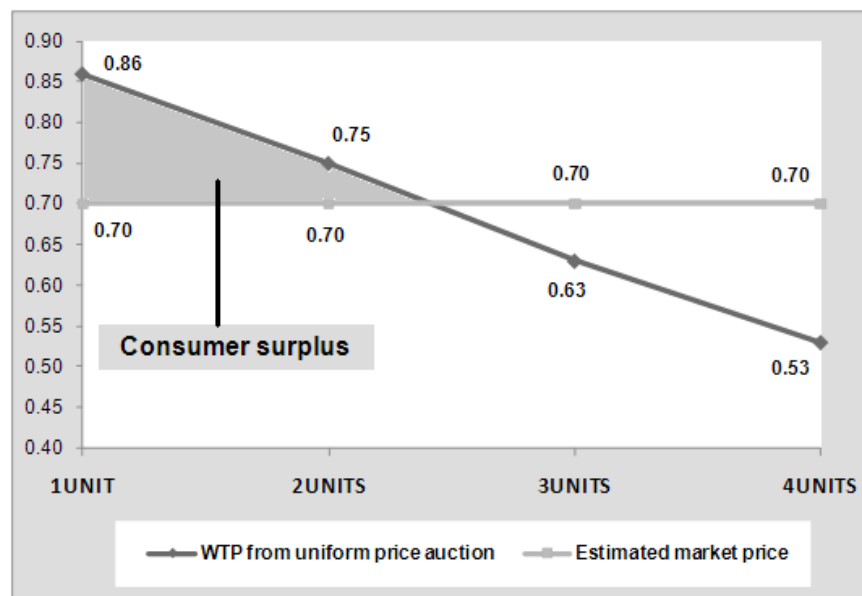
[2] For simplicity, we will use in the rest of the paper the term unit instead of package.

WTP values decrease as the number of units increases. The demand curve exhibited in Figure 1, clearly shows that the means of the WTP for organic chips is decreasing as the number of units being auctioned increases. In fact, results from uniform price auction indicate that the average WTP per unit decreases from 0.86€ when the quantity of organic chips is equal to one unit to 0.53€ when the quantity of organic chips is equal to four units. This result confirms the inadequacy of using the original format of single-unit auctions and the appropriateness of multi-unit auctions in assessing consumers' WTP for multiple units of food products. Also, this finding reflects the importance of switching from a strategy of constant or flat prices to a price-discount strategy to increase sales. In fact, since consumers' WTP is decreasing in the number of units, a price discount - that makes the market price decreasing as the number of units increases - may motivate buyers to buy more units.

Figure 1: WTP for organic chips
As previously discussed, an advantage of the use of multi-unit auctions is that it allows us to obtain the demand curve, and hence, the calculation of consumer surplus. This information is very useful when we want to investigate consumer welfare effects of the introduction of new products, new food policies/programs, etc. In Figure 2, consumer surplus is shown by the area under the demand curve and above the real market premium price. For illustration purposes, we assume that the real market premium price based on current market estimates is 0.70€[3]. We can see that participants can benefit from purchasing two units of the auctioned organic chips in the market since their average WTP for these units is higher than the market price (i.e., the consumer surplus is positive).

---

[3] There was an attempt by a retailer of high quality foods in Barcelona to introduce its own brand of organic chips (small size package) with a market price of 0.70€/unit.

Figure 2: Consumers surplus in the case of organic chips


Consumer surplus information can also help the seller decide the optimal bundle size for the product if s/he decides to sell his/her product in bundles of multiple units. In our case, the producer of the auctioned organic chips can, at most, introduce into the market bundles of two units since our results showed that there are buyers who are willing to purchase two units at a premium price of 0.70€/unit. However, if the producer wants to introduce bundle of more than 2 units, results in figure 2 show the necessity of discounting the market price (e.g. 0.53€/unit) to attract buyers. We can see that obtaining this kind of information would not be possible if we used single-unit auctions to determine consumers' WTP.

3.2 Inverse Price Elasticity

One of the prominent advantages of the use of multi-unit auction is that it allows the derivation of price elasticity which can then be used, among others, in evaluating consumer demand and welfare implications of policy interventions (e.g., product taxes, price ceilings, price floors). In a real shopping setting, consumer faces a fixed market price and has to determine the quantity s/he is willing to buy at that price. In multi-unit auctions, however, participants are offered a determined quantity of a product and s/he has to report his/her WTP for that quantity. Hence what we measure are inverse elasticities rather than elasticities. In other worlds, the inverse elasticity measures the responsiveness of marginal WTP (i.e. the WTP for each additional auctioned unit) to changes in the quantity. To estimate the inverse elasticity of the organic chips, we specify a model that relates the marginal WTP to the auctioned quantity of organic chips. We choose a log-log specification mainly for two reasons: (1) it allows us to interpret the coefficient associated with the quantity as elasticity; and (2) because our data showed that marginal consumers' WTP is decreasing with quantity. The model estimated for the organic chips was:

$$\ln WTP_{ij} = \alpha + \beta \ln Q_j + \delta X_i + \varepsilon_{ij}$$

where WTP_i is participant i's marginal WTP for the quantity j of organic chips, Q_j is the quantity of organic chips that varies from one to four units (i.e. j = 1,2,3,4). The quantity is independent of i since all participants were asked to bid for the same quantity. β is the corresponding coefficient of the quality and represents also the inverse elasticity. X_i is a vector of other explanatory variables and δ s are the corresponding coefficients. ε_{ij} is the random error term. The description of the variables used in the estimation of this model and the model presented in the next section is exhibited in Table 1. Since there are four observations for each participant (i.e. marginal WTP value for each unit), we estimated the demand equation using a random effect model to account for unobserved heterogeneity. Finally, the zero values of marginal WTP were replaced by a very small number (0.0001€) since the natural log of zero is undefined.

Table 1: The independent variables used in the estimations

Label of independent Variables	Name	Description
Log (the quantity of organic chips)	LN(QUANTITY)	Variable that takes the value 1, 2, 3 or 4 if the auctioned quantity is equal to 1, 2, 3 or 4 units.
First round	ROUND1	Dummy variable that takes the value 1 if the round is the first one; and 0 otherwise
Second round	ROUND2	Dummy variable that takes the value 1 if the round is the second one; and 0 otherwise
Third round	ROUND3	Dummy variable that takes the value 1 if the round is the third one; and 0 otherwise
Fourth round	ROUND4	Dummy variable that takes the value 1 if the round is the fourth one; and 0 otherwise
Fifth round	ROUND5	Dummy variable that takes the value 1 if the round is the fifth one; and 0 otherwise
Treatment	TREATMENT10	Dummy variable that takes the value 1 if the participant is grouped in a group of 10 subjects; and 0 otherwise
Price of conventional chips	PRICE	Continue variable: the price at which participant used to buying small size package of conventional chips
Log(Price of conventional chips)	LN(PRICE)	Continue variable: log (the price at which participant used to buying small size package of conventional chips)
Consumption frequency of conventional chips	REG_CONS	Dummy variable that takes the value 1 if the participant is regular consumer of conventional chips; and 0 otherwise
Consumption frequency of conventional chips	OCC_CONS	Dummy variable that takes the value 1 if the participant is occasional consumer of conventional chips; and 0 otherwise
Consumption frequency of organic foods	REGBUY_OF	Dummy variable that takes the value 1 if the participant is regular buyer of organic foods; and 0 otherwise
Consumption frequency of organic foods	NOCONS_OF	Dummy variable that takes the value 1 if the participant is not consumer of organic foods; and 0 otherwise
Taste of organic foods	TASTE	Dummy variable that takes the value 1 if the participant agrees with the statement that organic foods are tastier than conventional foods; and 0 otherwise

Aspect of organic foods	ASPECT	Dummy variable that takes the value 1 if the participant agrees with the statement that organic foods have a worse aspect comparing to conventional foods; and 0 otherwise
Availability of organic foods	UNAVAILABLE	Dummy variable that takes the value 1 if the participant agrees with the statement that organic foods are unavailable in the most frequented supermarkets; and 0 otherwise
Environment	ENVIRONMENT	Dummy variable that takes the value 1 if the participant agrees with the statement that organic farming improve the sustainability of the environment; and 0 otherwise
Gender	GENDER	Dummy variable that takes the value 1 if the participant is male; and 0 otherwise
Household	HOUSEHOLD	Dummy variable that takes the value 1 if the participant lives in household of more than two members; and 0 otherwise
Income	INCOME	Dummy variable that takes the value 1 if the household's income is more than 2500€/month; and 0 otherwise

The results of the estimation of the random effect model are displayed in Table 2. The coefficient of the log of the variable quantity represents the inverse elasticity which is equal to -2.78. This value indicates that an increase of 10% in the quantity of organic chips would decrease consumers' WTP by 27.8%. Since consumers' WTP is highly elastic to an increase in the quantity, producers and retailers of organic chips should consider the introduction of multi-unit price promotions if they want to fit consumer preferences.

3.3 Determining factors of consumers' WTP for multiple units of organic chips

The objective of this section is to show the usefulness of multi-unit auctions in assessing the determinants of consumers' WTP for multiple units. To tackle this objective we test hypothesis 2 which stated that the determining factors of consumers' WTP can be different from one unit to another. Hence, it is inadequate to use single-unit auctions, in its original format, to determine the key factors of consumers' WTP for a single unit and then assume that the consumers' WTP for any additional unit will be influenced by the same determinants of the first unit. To test hypothesis 2, we estimated a random effect Tobit model[4] for each auctioned unit. We estimated separate

[4] We used a random effect Tobit model: 1) to account for the panel nature of our data (five observations from each participant); and 2) participants' WTP are censored at zero.

models to assess the factors influencing the WTP of each auctioned unit. We specified the four models as follows:

$$y_{irj} = \begin{cases} y^*_{irj} & if \quad y^*_{irj} > 0 \\ 0 & if \quad y^*_{irj} \leq 0 \end{cases}$$

$$y^*_{irj} = x_{irj}\beta_j + u_{ij} + \varepsilon_{irj} \qquad \forall i = 1,...N; \ r = 1,...,5; \ and \ j = 1,...,4$$

where i indexes cross-section units such that $i = 1, 2, ..., N$ (N is the number of participants); r indexes the number of rounds (time series units) such that $r = 1, 2, 3, 4, 5$; and j indexes the units auctioned in the experiment ; The matrix X_{irj} contains data on the observable explanatory variables. Y_{irj} is the price consumer i is willing to pay for the jth unit of organic chip in the rth round. $\beta_j = \left(\beta_{j,1}...\beta_{j,k_j}\right) \in R^{k_j}$ are

vectors of parameters to estimate. The effects of relevant unobservable variables and time-invariant factors are captured by the vector u_{ij} and the stochastic disturbances of the model for the six auctioned units are captured by the vector ε_{irj}. Table 1 shows the description of the variables used in the estimation of the four models.

Results from the estimation of the four random effect Tobit models are displayed in Table 3. Among all variables, only the variable ENVIRONMENT is a key determinant of the WTP for all the units. In fact, participants who think that organic farming improves the sustainability of the environment are willing to pay a higher price for all units. In general, our results show that the WTP for the first unit and the second unit of organic chips is affected by the same factors. For example the higher is the price that participant is used to paying for conventional chips, the higher is his/her WTP for the first two units of organic chips. Also, participants who revealed being non consumers of organic foods (NOCONS_OF) reported a significant higher price premium for the first two units of

organic chips, perhaps, because they wanted to try the new product. If we look at the determinants of the WTP for the third and the fourth unit, we can see that three of the significant factors (PRICE, NOCONS_OF and ASPECT) for the first and the second units are no longer statistically significant. Also, the results show that in comparison with female participants, male participants were willing to pay less for the two last units of organic chips. However, this variable is not significant for the first two units. Finally, we found that regular buyers of organic foods have significant higher WTP only for the fourth unit. Therefore, our results confirm the hypothesis that the effect of various variables on the WTP can be different between the first unit and subsequent units. Hence, assuming constant effects of variables across the different units can lead to misleading inferences. In conclusion, our findings showed the necessity of assessing the determinants of consumers' WTP for each auctioned unit and, hence, the adequacy of using multi-unit auctions in measuring the WTP for multiple units of a food product.

CONCLUSIONS

Due to its demand revealing properties, experimental auctions have gained recognition among applied economists and marketers interested in valuing new products and product attributes. Numerous studies have used experimental auctions to elicit consumers' WTP for food products. However, these studies used single-unit experimental auctions in which the participants were asked to report their WTP for a single unit of the auctioned product. The results from these single unit auctions are useful only in cases where consumers are content to purchase only one unit of the product being valued or when the objective of the study is to assess consumers' WTP for a single unit of a food product. However, due to increasing opportunity cost of time and other reasons, consumers nowadays tend to purchase multiple units of the same products per shopping trip. In these

cases, using single-unit auction to study consumers' WTP for a new product can produce limited results. In this paper, we introduced the use of multi-unit auctions in the assessment of consumers' WTP for food products and showed how the implementation of this method permits the user to obtain useful parameters to analyze consumer behavior and consumers' WTP in a multi-unit setting. With multi-unit auctions, one can estimate the demand curve, consumer surplus, the inverse price elasticity, and the determinants of consumers' WTP for various units of a product.

While we showed in this study the promise of the use of multi-unit auctions to assess consumers' WTP for food products, it is important to note that in contrast to single-unit experimental auctions, multi-unit auctions could involve significantly more complicated tasks related to the determination of winners and calculation of

the clearing price especially in cases when both the number of bidders and number of units are high. Since the main objective of this paper was to show the usefulness of the implementation of multi-unit auction in assessing consumer behavior in a shopping setting of multiple units, we only used the uniform price auction due to its simple pricing rule. However, other mechanisms such as multi-unit Vickrey auction and the Ausubel auction - that have a more complicated pricing rule but better theoretical characteristics – can be an interesting alternative to be used in future empirical researches. In addition, multi-unit auctions could be prone to other methodological issues such as demand reduction effects and these should be evaluated and taken into account in the future. Nevertheless, we hope that our study will motivate others to use multi-unit auctions in determining consumers' valuation of multiple units of food products with and without important policy related issues.

Dynamic Ideologies: The Case of Slow Food

Miranda Mirosa, University of Otago, New Zealand
Ben Wooliscroft, University of Otago, New Zealand
Rob Lawson, University of Otago, New Zealand

INTRODUCTION

There is a need for more discussion amongst consumer researchers about what ideology actually is and how it may be used in a consumer context. The concept of ideology remains incomplete on a number of grounds. Most importantly, little consideration has been given to the dynamism of ideologies (Kozinets 2008) even though ideologies do change, as extended goals shift over time. In this article, we investigate the interaction between consumer movements and dynamic ideologies. The Slow Food (SF) movement, a contemporary movement concerned with food quality, taste, environmental/cultural sustainability and social justice (Sassatelli and Davolio 2010) is used as a case study of dynamic ideology. Given that the SF Movement has undergone significant changes in recent years, shifting from a focus on gastronomy (good food), to the environment (clean food), to social justice (fair food) issues (Parkins and Graig 2006), it is an appropriate case study for studying how movement ideologies change overtime.

It is natural to turn to the new social movement literature on movement ideologies for guidance, given that well established and rich theories of movement ideologies are here. Unlike the classical reductionism of Marxism which relied on analyzing social movements in terms of production, new social movement theorists have turned to the spheres of culture, politics and ideologies and often include consumerist elements into analyzes rending their frameworks useful for analyzing contemporary consumer movements such as SF (Cherrier and Murray 2002; Kozinets 2002; Kozinets and Handelman 2004). We use the work of Italian theorist Melucci (1943-2001), one of the key new social movement theorists (Buechler, 1995). Melucci's work (as opposed to work by other key new social movement theorists such as Touraine, Castells and Habermas) takes the dynamic nature of ideology into consideration and is the theoretical basis for this paper.

DEFINING IDEOLOGY

Ideology is most commonly used in political discourse however other types of ideologies exist including social, ethical, environmental and epistemological ideologies. Geuss (1981) suggests that the definitions of the term ideology fall into three categories—descriptive, pejorative and positive. The descriptive definitions of ideology are self-explanatory and discuss ideology in a neutral sense. In this context, ideologies are close to the concept of worldview. The pejorative definitions refer critically or negatively to the relationship between power and maintaining dominance. If the motivation is unconscious, then this is considered self-deception. Here ideology represents ideas which are fundamentally flawed. The positive definitions consider ideology in a more favorable light and it is in this sense that ideology is defined in this article; specifically, an adapted version of Melucci's definition (1996, p. 349). "Ideology is a set of symbolic frames which collective actors use to represent their own actions to themselves and to others within a system of social relationships in the pursuit of interests judged to be desirable."

IDEOLOGY WITHIN THE CONSUMER RESEARCH LITERATURE

Whilst the concept of ideology has been theorized extensively in other social sciences, consumer researchers have not fully considered the various meanings of ideology. The most relevant work is in the literature on consumer movements, especially consumer resistance.

Penaloza and Price (1993) have delineated this area of research which explores the meaning of behaviors such as boycotting (Kozinets and Handelman 1998). However, within consumer resistance literature, ideology has been pushed aside and no mention is made of how consumers' ideologies determine the acts of resistance. The one notable exception is Kozinets and Handelman 2004 who use Touraine's 1981 "identity, opposition and totality" theory to investigate how members of anti-advertising, anti-Nike and anti-GE movements construct ideologies. Their study is important because it highlights that the new social movement paradigm has the potential to be an appropriate framework for the study of ideology in a consumer context.

The socio-historic patterning of consumption research program is also relevant. This literature considers institutional and social structures such as class, gender, ethnicity, community, family and other formal groups and how they influence consumption (Arnould and Thompson 2005). Literature on how consumers' belief structures (or their ideologies) influence consumption includes studies on occupation and values (Rosenberg 1980) and class and conformity (Kohn 1989). More recently, Kozinet's study 2008 looks at how ideological fields influence consumers' technology narratives. Kozinets highlights how researchers have failed to consider the dynamic nature of ideology and have the tendency to "treat particular ideologies as totalized and static categories" (Kozinets 2008, 878). Also of significance is the work of Kilbourne (1995, 1998) who worked alongside others (Kilbourne, Beckmann, and Thelen 2002) on the subject of the dominant social paradigm (DSP). Although it is not explicitly implied in the marketing literature, the notion of a DSP appears to be very similar to the notion of dominant ideology as described by Marx and Engels in their 1845 work *The German Ideology* (translated by Lawrence and Wishart 1970). The DSP seems to function as an ideology that seeks to legitimize and justify dominant social process. The fundamental difference between DSP and ideology lies in the definition of ideology. While DSP literature relies on a more critical Marxist definition of ideology, here we employ a positive definition of the concept and discuss ideology as a representation of set of ideas of those individuals and groups that are in fact counter to the ideas of their dominant culture.

MELUCCI'S FRAMEWORK OF IDEOLOGY

Like Touraine 1981, Melucci (1996) suggests that the three analytical elements that make up the form of an ideology of a movement are: identity (members are able to articulate a self-identity which determines the limits of collective identity and the legitimacy of the movement), opposition (there is identification by movement members of an adversary); and totality (members are able to articulate shared objectives). Developing Touraine's (1981) trichotomy, Melucci (1996) adds a time dimension to this model by proposing the three constituent elements of the ideology take on changed cultural contents and roles as the movement develops from a formative phase into a consolidative phase.

The formative phase occurs during the nascent state of the movement. It is a "moment of the fusion of the various components of a movement into a new form of solidarity in which the expressive dimensions and emotional identification with collective goals prevail" (Melucci 1996, 350). During this phase, ideology legitimizes the movement's goals and identity by referring back to the past. It is also used to overcome the "inadequacy of practice" (Melucci 1996,

350). For example, when a movement does not yet have the capacity for action, leaders may use their movement's ideology to produce symbols.

During the consolidation phase, "the mobilized social group, the adversary, and the collective goals are redefined in a more pertinent manner; ideology becomes a more complex and detailed symbolic system" (Melucci 1996, 352). Two aspects of ideology become important. Integration of the movement as a whole is accomplished by a repeated proposal for values and norms; the control of deviant behavior; and the stabilization of certain rituals. Secondly, ideology fulfills a strategic function. This can take place by widening the margins within which the movement acts in the political system or by expanding the movement's base by encouraging groups which were previously outside the conflict to become involved.

BACKGROUND TO THE SF MOVEMENT

The conceptualization of the SF Movement includes a multiplicity of different organizations, interest groups and individuals. The initiator and main driver of the movement since it officially become an international organization in 1989 is the official SF organization which has attracted over 100,000 subscribed members who belong to 1000 local chapters in over 150 countries (SF.Editore, 2011). Each of the organization's nine national associations (in Italy, France, Germany, Netherlands, Switzerland, UK, Japan, USA and Australia) hosts a range of events. The organization's ideology is nicely summed up by the current marketing slogan that they use: "Good, Clean and Fair". This ideology has evolved since SF began. As the president of the SF Movement Carlo Petrini explains: "[Its] a result of our twenty-year journey.... While respecting our original search for pleasure and taste, it includes the ever more urgent ecological and social issues emerging around the world" (SF.Editoire 2009, online).

METHODOLOGY

Historical method (adopted from Shafer 1974) provides the best research design method for capturing a dynamic evolutionary concept such as change (Kumcu 1987). The data was collected at both the organizational level (a mix of secondary data found in SF archives, documents and publications and primary data obtained by attending a SF organization Meeting of International Councilors in Switzerland in 2008) and at the individual activist level (primary data collected in semi-structured interviews conducted with members from either the SF organization or the wider SF Movement). In interviews, respondents were asked a series of questions pertaining to their own personal life histories (e.g. their own current beliefs and experiences of ideological change). They were also asked to serve as an expert informer on various aspects of the SF Movement. This critical approach to data collection provides a human and subjective account of change and allows insights into aspects of ideology (such as movement identity) that are not otherwise apparent from organizational texts. Interview respondents were selected to achieve diversity and to ensure a rich and more realistic historical data. Thus, different types of SF members (official members of the SF organization as well as unofficial members of the wider SF Movement) were interviewed. Respondents were also selected to have a variety of nationalities in order to acknowledge this aspect of the SF Movement. As with the analysis of the organizational texts, the main aim for the data collection in the interview stage was depth. Thus, when a new respondent's stories added no extra relevant information, the interview process was considered complete The researchers obtained access to impressive wide range of people for this research, including founding leaders of the international SF organization based in Italy as well as grassroots members from seven other countries (see Table 1). In total, 23 respondents were interviewed.

Table 1 An overview of the respondents interviewed.

Pseudonym *	Involvement **	Nationality ***	General interest
Glenn	M	A/N	An academic who founded and leads a SF convivium
Rosa	M	I/N	Owns an Italian cooking school. Founded a SF convivium
Jim	M	E	SF convivium leader. Was owner of a local restaurant
Carmel	M	I	Manager for a SF office at the International headquarters
Agosto	M	I	Academic at the University of Gastronomic Sciences
Raul	M	I	Holds a senior position in the SF Italy organisation
Santo	M	I	Holds a senior position in the SF Italy organisation
Piero	M	I	On the international SF board and is manager of a SF office
Elisa	M	A/S	Director of a geographical area at SF international headquarters
Fiorella	M	I	Works at the SF Study Centre
Pam	S	N	Works for national organic association. A Green Party member
Jane	S	N	Political studies student who organises a campus eco-group
Sam	S	N	Academic teaching global politics of food

John	S	N	Community social justice advocate and an environmentalist
Bianca	S	N	Chairperson of a local farmers' market
Vincent	S	I/N	Owns and manages a fresh pasta making factory
Tibold	S	G	PhD student studying wine
Gilbert	S	E/N	Retired café owner and psychiatric nurse. A home gardener
Ray	S	N	Academic whose research area includes wine and food tourism
Doug	S	E/N	Culinary-tourism academic. Experience in hospitality industry
Ruby	S	N	High school French teacher. A Green Party member
Rob	S	N	High school art teacher who runs adult cooking classes
Kaye	S	N	National spokesperson for a multinational fast food company

* To ensure the promised confidentiality, each respondent has been given a fictional name;
**M=Member S=Supporter;
***A=Australian, N= New Zealander, I=Italian, E=English, G=German S=Spanish.

Given the interpretive stance of the research, the historical materials were contextualized within Melucci's theoretical framework as the primary means to reveal the reality of the historical framework used to structure the analysis. Chronological periodization of this information presents the history of the SF Movement and the changing elements and ideological roles scattered throughout the narrative which are then brought together at the end of the findings section in a summary table.

FINDINGS: THE HISTORY OF THE SF MOVEMENT AND INSIGHTS INTO SF IDEOLOGY

1980 –Mid-1990s. The roots of SF can be traced back to a specific place, person and time. The environment is Bra (a small town in northwest Italy) and the person is Carlo Petrini "the main animator of the town" (Carmel), who along with a number of other friends who were "passionate about local food and local music would organize folk festivals to celebrate traditions and histories" (Raul). Petrini and his friends from Bra became interested in wine and in 1980 "they came up with the idea of founding a club—something like the then trendy gastronomical academies, but with the specific goal of spreading the culture of good food even among ordinary people" (Petrini and Padovani 2006, 12). This club was the nucleus of what would later become Arci Gola—the forerunner of the SF organization. At this time, the Socialist and Communist parties in Italy supported a nationwide network called Arci which organized an array of cultural events. Based on a common interest in food and wine and spurred on by Petrini, an oeno-gastronomic group, Arci Gola started in 1983. Initially the group's main goal was to support local producers by increasing the value and demand for local cuisine and products by creating a market for high quality food and wine products. As the group developed, it also began to advocate the right to material and convivial pleasure for everyone and that the flavor of the food was a serious matter.

In 1986, the Arci Gola group—annoyed by the fact that McDonald's was opening a store at Rome's famous Piazza di Spagna—protested against an invasion of American fast food by handing out bowls of free pasta in front of the fast food restaurant (SF.Editore 2002). In 1987, Arci Gola published its first journal and soon began producing articles and books. On the cover of its first journal, a common snail is introduced as the organization's official logo (chosen because it moves slowly and calmly eats its way through life, SF.Editore 2001). Notable in these early works is "[A]n un-

compromising and tough language that stakes out its opposition to businessmen, bureaucrats and the local church in a single J'accuse" (Petrini and Padovani 2006, 28). The use of war and military terms such as lieutenant, defensive maneuver, self-destruction and enemy (c.f. Petrini and Padovani 2006, 4, 70, 71, 81) provides a case in point. Thanks to the success of these media, the ideas promoted by the group gained wide attention. Later that year, Petrini organized a conference called *At the Table with the Italian Communist Party*, and in his opening speech "he exalted the culture of honesty and authenticity at the table, what he called the slow food approach of eating well and slowly and he spoke out against the effects of fast-food and against the constant rush to make a profit" (Petrini and Padovani 2006, 58).

In 1989, a manifesto of the slow food approach was written and presented in Paris at the inauguration of the international SF Movement. The spirit of the manifesto is summarized nicely by Porta (cited in Petrini and Padovani 2006, 73): "The Slow Food manifesto [1987] is after all the dream of holding the old kitchen stove in our arms, our chest against its knobs, in a slow embrace". At this event, participants celebrated the bicentennial of the French Revolution and the pioneer chefs that became the celebrities during the Revolution. SF was not only applauding the renowned chefs, but the fact that good quality cuisine was available to the masses. This idea is a central tenet of the SF concept and to this day SF fights to liberate the traditional Italian taverns from the threat of a fast food culture.

After the official launch, SF leaders started expanding the conceptual makeup of SF and the range of activities they conducted. In 1990 they launched the SF Editore Publishing House which was initially the main tool used by the organization to build their profile. Reading early SF publications, one is struck by many examples of SF using symbols, cultural models and language from their country's political past. Many terms with strong communist connotations, such as comrades and fraternity, were regularly used by leaders of the organization when addressing or discussing their membership. For example, in the original SF manifesto, Porta writes, "Comrades, enough with these sloppy grilled chops" (1987, cited in Petrini and Padovani 2006, 7). The next pivotal moment in the development of the organization was the SF World Congress which was held in 1990. A significant outcome of this meeting was a statute outlining the main tasks of the organization including the improvement of food culture, the defense of food heritage including culinary practices and the promotion and distribution of quality products. After the con-

gress, "the value of the term *Slow* as a global marketing tool became clear [and] we realized that we had to consolidate our image and build a truly international movement" (Petrini and Padovani 2006, 136). This meant re-positioning the political standpoint of the organization away from the organization's Leftist origins and towards a stance where "we're not aligned with governments" (Elisa) so that the SF organization "could ask for support from left, right, center or whatever" (Peiro) and thus SF increased the political domain within which the organization was able to operate.

In 1992 the first national SF association outside Italy was opened in Germany and one year later, SF opened a national office in Switzerland. Following the success of SF in these two countries, the decision was made at the 1994 SF Italy National Congress to invest in the development of SF internationally. SF also decided to adopt the objective of improving local products, not just in Italy but in the other countries where SF had a presence. This was a significant change, as up until that date, SF's goals were often seen by its members to be largely about promoting the Italian way of life and Italian products both nationally and abroad.

Mid-1990s–Mid-2000s. Along with this new emphasis on improving the quality of local food, SF started branching out into other areas. Raul explains, "So for the first 10 years [the goal] was to promote the food quality… but we started to see there was a great danger of extinction in not only the products but also their producers". In 1996, SF put forward the idea of creating an "Ark" built on the biblical metaphor of Noah's Ark which would save traditional and rare food species from the big flood of industrial foods. The following quote from Petrini (1996, cited in Petrini and Padovani 2006, 93) illustrates how the organization's leaders used symbols, cultural models and language from the bible to help bring this concept to fruition: "Since the flood was imminent… our ark could be the only salvation. The incoming storms threatened to inflict genocide… we had to build an ark… once the flood was over, we would come down from the ark, back to earth, like Noah". The launching of this event was indicative of the changing direction of SF ideology, "Looking back you could say that that moment [1996] was the first great change... it was the moment when we started talking about biodiversity and biodiversity means talking about the environment (Raul).

By the mid-1990s, both the Italian Arci Gola SF organization and the International SF organization had grown significantly and the organization's leaders decided to consolidate their efforts. This merging was important as it symbolized SF's strategic decision to leave behind the strong Italian identity that had characterized the organization up until this time. Given this change in focus, movement leaders espoused new principles that promoted the direction they envisioned for the international movement. Amongst these were the principles of diversity and unity as SF's president Petrini explains, "The importance of the former, the strength of the latter. What we are: different. And what we have to be: united" (Petrini 2003, 10).

Also in the mid-1990s, SF leaders started developing the organization's focus on biodiversity into a more widespread and complex notion of general food environmentalism. This thinking was formalized in 1999 when the organization introduced SF as an eco-gastronomic organization, as explained by Petrini (Petrini and Padovani 2006, 118), "An environmentalist who is not a gastronomist is sad; a gastronomist who is not an environmentalist is silly. We changed our point of view with the idea of defending good food in a healthy environment. This move ratified our transformation into an eco-gastronomic movement". With this new positioning as an eco-gastronomic organization, SF moved away from opposing the culinary aspects of fast food and new adversaries were defined, as Glenn explains, "Its opponents have been much more delineated as

the global trans-national food corporations and agricultural mono-cropping… and in that sense that is now more explicitly identified as what SF is against".

A noteworthy event in 2000 was the founding of the SF USA national association with headquarters in New York City. The growth of SF USA was exponential in the following years adding a new flavor to the organization. In 2001, two new SF websites appeared. As the SF ideology spread around the world facilitated by the creation of an international website, the organisation kept its feet firmly planted in the ground by engaging in two fresh conflicts: (1) The campaign against hygienic norms that the organization leaders believed would jeopardize the production of raw milk cheeses; and (2) the No GMO Wine campaign which was launched against the Europe's commercialization of transgenic vines. Notably, at this time there was "a really conscious effort to build particular types of relationships around eco-green activism in food" (Sam). For example, SF became involved in an alliance of associations (including NGOs such as Greenpeace, farmers associations, organizations of distributors and corporations) by sharing a manifesto saying no to GMO.

Mid-2000s–2010. The year 2004 was a big year in the history of the SF with the high point being a world meeting of food communities; Terra Madre event. This event signified the SF organization's increased awareness of ethical issues surrounding agricultural and gastronomy. Evidence of SF leaders referring to the past to help defend this new focus for their movement can be seen in the ceremonies' closing speech, where one leader made direct reference to a social movement which had come before SF, "the feelings of Terra Madre [were similar] to those that arose during the assembly of Sem Terra, the movement that gave strength and a voice to Brazilian farmers" (SF.Editore 2006, online). This new facet to SF ideology would later be more clearly articulated as fair food, "Thanks to Terra Madre, where we started working with the farmers especially in the South of the world, we understood… the real concept of 'fair' in food today" (Raul). There is evidence SF members used ideology at this event to create symbolic gestures that represent their high hopes for the future in this domain. Petrini explains, "When the Middle Eastern meeting was held, people were a bit stiff to start with, but after a few minutes Israel, Palestine, Iraq and Lebanon understood they were all part of the same family and symbolically dipped bread in salt. The great fraternal gesture of dipping bread in salt!" (SF.Editore 2006, online). The Terra Madre event really consolidated the SF ideology which at present is based on three basic principles: good, clean and fair.

Also in 2004, SF officially opened the world's first University of Gastronomic Sciences in Italy. The university aims to transform gastronomy into a multidisciplinary science and mirroring an important step in the development of the SF ideology. The SF organization has since adopted the term neo-gastronomy to explain their commitment to this multifaceted approach to food which includes giving consideration to a range of production, consumption, sustainability, quality and social justice issues. In 2007, at the fifth International SF Congress, the top priority was increasing the organisation's membership numbers and it was decided that the SF organisation would change their statutes to allow them to become "more flexible, especially in developing countries" (Elisa). As well as aiming to include more members in their movement, SF actively worked to attract the support of a number of groups and organisations that were previously outside their domain. For example, SF and Fair-trade Italia "united to support a three-year project entitled 'Sustainable agriculture, biodiversity protection and fair trade, together against poverty' co-financed by the European Union" (SF.Editoire 2008, online).

In 2008, the third Terra Madre was held and for the first time event organizers invited participants to bring their instruments. Santo

explains the logic behind this addition to the event: "Only our actual lives tend to separate food from music… with Terra Madre we want to defend and promote food communities, music, common interests". This was significant in that it revealed the far reaching extent of the SF organization's ambitions, "We don't want to only preserve the knowledge of food and the knowledge of culture, but also the knowledge about our cultural traditions" (Raul). SF's shared organizational culture was particularly obvious at this event; with many gestural codes (such as using a peasant's horn from the Peruvian Andes to call event participants to a meeting) and cultural rituals (such as wearing traditional costumes throughout the event).

2010 saw local Terra Madre regional meetings held in the Balkans, Brazil, Georgia, Azerbaijan, Kazakhstan and Argentina, indicative of the direction that SF is currently taking. Looking forward, the "future of Slow Food is really difficult to predict" (Agosto) and it seems likely that there will be the continual extension of the SF ideology into other domains with the expansion of the scope of activities by the organization. The SF leaders are, however, quick to point out that "the main focus must remain on food" (Piero). Evidence of the changing content and form of SF ideology has been scattered throughout the above narrative and is now synthesized in Table 2.

DISCUSSION

The top section of Table 2 shows that three elements of ideology (identity, opposition, and totality) are present throughout the history of SF and that the content of these elements of ideology have changed considerably over the years. The bottom section of Table 2 shows examples of how ideology has served different functions throughout the evolution of the SF Movement. While Melucci's model of ideological change predicts that movements pass through just two phases of ideological development throughout the movement lifecycle (a formative and consolidative phase), our study revealed not two but three distinct periods of ideological change. These periods are as follows: (1) 1980s to ~1995, Recreational-gastronomy; (2) ~1995 to ~2005, Ecological- gastronomy; and (3) ~2005 to ~2010, Neo-gastronomy. Furthermore, the SF data revealed that each time the ideology changed, it appears to have passed through a new formative phase of development before becoming consolidated.

Much of the literature on lifecycles in marketing suggests that the lifecycle of a product (or in this case an ideology) may be more complex than the framework proposed by Melucci. Melucci's framework appears stuck in the metaphor of the product lifecycle of 30 or so years ago in marketing (e.g. birth, growth, maturation, death) and the two phases (formative and consolidative) do not capture the richness of the true diffusion process over time. For example, Dhalla and Yuspeh 1976 say that it is possible to restart this cycle again and again. Applying this theory to the context of ideology could inform and strengthen Melucci's framework of ideological development.

Table 2 A historical summary of the elements and role of the SF Movement's ideology

	Elements of Ideology		
	SF self-identity	SF adversaries	SF shared objectives
1980s to ~1995	Italian focused More characteristics of a club or an association (e.g. exclusive, hierarchal structure	Bad food/wine Speed (fast life), fast food Openly oppositional	Recreational or Oeno-gastronomy: Promote '*good*' food (quality gastronomy) and the right to pleasure Celebrate slow and conviviality support small producers and improve food culture
~1995 to ~2005	More internationally focused More characteristics of an organization	Industrial foods and standardization Mono-cropping, GMOs and hygienic norms	Eco-gastronomy: Promote '*clean*' food - 'good' food in a healthy environment Defend biodiversity
~2005 to ~2010	Very internationally focused (local identity in a global world) More movement characteristics (e.g. inclusive, emphasizes networks)	(as above) + fighting against 'cultural' globalization Less oppositional (promoting message "for not against")	Neo-gastronomy: Promote '*fair*' food - social dimension of food Virtuous globalization Extension into new domains

Role of ideology					
Formative	Consolidative	Formative	Consolidative	Formative	Consolidative
1980s to ~1995		~1995 to ~2005		~2005 to ~2010	
Referring to past (ex. Military language and Communist connotations) Producing symbols (ex. French Revolution)	Putting forward proposal for values, norms (ex. SF's Manifesto) Widening the margins of the political system (ex. Moving away from Leftist origins)	Referring to past and producing symbols (ex. Noah's Ark)	Proposal for values, norms (ex. Diversity and unity) Networking (ex. No-GMO alliance)	Referring to past (ex. Sem Terra Movement) Producing symbols (ex. Dipping bread in salt gesture)	Creating rituals (ex. Ways of dressing at Terra Madre event) Networking (ex. SF and Fair- trade Italia Project)

Figure 1 suggests an extended model of ideological change in a consumer movement. The points A, B, and C show the moments where the ideology is re-launched. The problem with applying product life-cycle theory to SF is that it is impossible to predict how the product (in this case SF ideology) will finally be adopted. Furthermore, the product life cycle model has traditionally been used to explain sales and repeat sales, which are arguably quite different from the case at hand. Given these limitations, the proposed model is useful as a metaphor but not as strong predictive model.

Although our findings suggest that the ideology changes over and over again, Melucci's framework still provides significant insights into what happens to an innovation, such as an ideology, as it diffuses over time and thus it complements the diffusion of innovation models (as ex-plained by Rogers 1976). For example, over time "the mobilized social group, the adversary, and the collective goals are redefined in a more pertinent manner [and] ideology becomes a more complex and detailed symbolic system" (Melucci 1996, 352). Furthermore, the framework recognises that it is not only the innovation itself changing as it diffuses over time, but that the purpose for which it is used is also changing. Further research which investigates using product life cycle and diffusion of innovation models to help explain ideological change is warranted. Of particular interest are questions such as 'are the concepts of early adopt-ers and laggards still relevant?' and if so, 'when new ideological stages emerge, is there a period of tension between early adopters and those still consuming previous ideological underpinnings?'.
Figure 1. Ideological development of a consumer movement over time.

CONCLUSION

There are two major contributions that this article makes toward understanding interactions between consumer movements and ideology. Firstly, the research proposes that Melucci's framework as it stands is useful to consumer behavior researchers for understanding ideological change in the context of contemporary consumer activist movements, in particular for conceptualizing the form of an ideology and as such it provides an appropriate definition for the concept of ideology that can be used in the consumer movement context. This will allow consum-er behaviour researchers to differentiate ideology from (and compare ideology to) other similar concepts and theories they are more familiar with such as values, ideas and the dominant social paradigm. Melucci's framework is also useful in that it helps to operationalize ideology by providing a process with which to identify and categorise ideological change.

Secondly, this article highlights that lifecycle literature in market-ing has the potential to add strength and vigor to Melucci's framework. Melucci's framework as it stands has only two simple stages and does not go far enough to capture the dynamics of ideological change, which appears to be re-formed over and over again as the movement develops. To this end, a new model of ideological development is proposed that builds on Melucci's (1996) framework, and provides a comprehensive tool for the analysis of movement ideology.

Challenging the Culture-Free Hypothesis of Cognitive Age among Older Consumers: Evidence from a Cross-National Survey

INTRODUCTION

The current ageing of the world's population is probably the most profound demographic change in the history of humankind. It is a pervasive and truly global phenomenon, without precedent or parallel, largely irreversible, and with the young populations of the past unlikely to occur again. Indeed, at the world level, the number of older persons will exceed the number of children by 2047, which has already occurred in many developed regions. The profundity of this demographic change will impact on economic growth, labor markets, pensions, health care, housing, migration, politics, and of course consumption (United Nations 2007). If the second half of the 20th century focused on the young, the 21st century will have to focus on the mature.

Despite the growing importance of the 50+ population and its perception as an attractive market segment, older consumers are still routinely neglected by many marketing and advertising practitioners (Niemelä-Nyrhinen 2007; Simcock and Sudbury 2006; Uncles and Lee 2006) and what is known about their consumer behavior still lags far behind what is known about other important segments (Williams et al. 2010; Yoon et al. 2005). This is particularly true of research conducted outside the USA, where there is a marked lack of a coherent body of knowledge pertaining to senior consumers which can guide international marketing decisions.

Self-perceived or cognitive age has emerged as a key variable in studying older people and their consumer behavior (Psychology & Marketing 2001; Wilkes 1992). The relatively sparse number of studies that have investigated this type of age identity in cross-national settings have concluded that cognitive age is "culture-free" (cf. also Barak 2009; Van Auken and Barry 2009; Van Auken, Barry, and Bagozzi 2006). Using data from an empirical study in four different countries, we challenge this view of cognitive age as culture free and thus aim to make a contribution to knowledge on older consumers on an international scale.

SELF-PERCEIVED AGE

Chronological age is a constant in daily life, in age related research, and in marketing. The use of chronological age as an objective measure that shapes the lives of individuals can be illustrated by the age restrictions imposed by the government. For example, chronological age dictates the point at which an individual can drive, vote, drink alcohol, marry, and claim a state pension. In research, chronological age is the most commonly used yardstick when studying the ageing process (Cunningham and Brookbank 1988). In marketing, chronological age is the most frequently used of all demographic variables to describe consumer behavior research and to segment consumer markets (Barak and Schiffman 1981).

Despite these numerous uses, the limitations of chronological age have long been acknowledged (Adams 1971; Heron and Chown 1967). Whilst chronological age may be a useful clue to performance during early life (Jarvik 1975), ageing does not perfectly coincide with chronological age (Bell 1972) so homogeneity in individual lifestyles and conditions among age groups cannot be assumed. Indeed, the number of years lived is a poor indicator of a person's attitudes and consumer behavior (Chua, Cote, and Leong 1990; Van Auken, Barry, and Anderson 1993).

Given the limitations of chronological age, the implications of the cliché that a person is as young, or as old, as they feel may be more useful in understanding the behavior of older people. Research shows that the age a person perceives themselves to be, or identifies with, constrains them to recognize changes in themselves and to perceive that attitudes toward them have changed (Peters 1971). Thus, the age a person identifies with gives an insight into the behaviors that the individual thinks society expects from them (Guptill 1969). Likewise, an individual's self-perceived age gives a better understanding of their likely consumer behavior than can chronological age alone (Barak and Schiffman 1981; Cleaver and Muller 2002; Schiffman and Sherman 1991; Stephens 1991). For this reason, self-perceived age has been used in research investigating older consumers and values (Kohlbacher and Chéron 2010; Sudbury and Simcock 2009b), attitudes toward senior sales promotions (Moschis and Mathur 2006; Sudbury and Simcock 2010; Tepper 1994), brand purchasing (Uncles and Lee 2006), innovative purchasing (Sherman, Schiffman, and Dillon 1988; Stephens 1991), information seeking (Barak and Rahtz 1990), interest in fashion (Wilkes 1992), complaining behavior (Dolinsky et al. 1998), media usage (Barak and Gould 1985; Johnson 1993), internet use (Eastman and Iyer 2005; McMellon, Schiffman, and Sherman 1997) and in segmentation studies (Sudbury and Simcock 2009a).

There are many different ways of measuring self-perceived age, and these methods fall into two major groups. The first, and oldest, is age identity (Cavan et al. 1949), concerning the age category (young, middle-aged, old) in which people perceive themselves to be, and is used extensively in gerontology studies. A second type of measure grew in response to the recognition that ageing is multidimensional (Birren 1968), comprising biological, psychological, and sociological dimensions, none of which can be understood without reference to the others (Riley 1985). The cognitive age scale (Barak and Schiffman 1981) is one such multidimensional scale, which incorporates the different dimensions of aging by asking people how old they think they look (biological), how old they feel (psychological and biological), and how old they rate their behavior and interests (social). This typology has its roots in the consensus reached by philosophers concerning the existential stances with regard to the human condition, which are knowing, feeling, and acting (Bengtson, Reedy, and Gordon 1985). The cognitive age scale has become the most popular measure of self-perceived age in marketing research pertaining to seniors. The superiority of the cognitive age scale over other available instruments is due to its ease of administration and understanding by respondents (Stephens 1991), its validity (Van Auken and Barry 1995), and its multidimensionality. As a matter of fact, ease of administration and understanding are crucial issues in scale employment with samples of older people (Flynn Reinecke 1993).

The overwhelming finding from studies of age identity is that the vast majority of older adults do not identify with the age categories 'elderly' or 'old', preferring instead to consider themselves 'middle aged'. This finding holds true even for people past retirement age (when, arguably, they are deemed old by society), and it is not until people are well into their seventies that more and more begin to admit to an old age status (Blau 1956). Those studies that have utilized the multidimensional scales to measure the self-perceived age of older people (for example Barak 1998; Barak and Gould 1985; Clark, Long, and Schiffman 1999; Goldsmith and Heiens 1992; Johnson

1995, 1996; Kastenbaum et al. 1972; Mathur, Sherman, and Schiffman 1998; Sudbury 2004) have found a strong degree of consistency, in that:

- There is little agreement between self-perceived age and chronological age, although the two correlate.
- There is a strong bias towards a more youthful self-perceived age in comparison to chronological age.
- The look age dimension is closest to actual age than any of the other self-perceived age dimensions.

Whilst the majority of studies into self-perceived age, at least from a marketing perspective, have been conducted in the US, the relatively sparse and recent research conducted outside America tentatively suggests that self-perceived age is a universal concept that can be measured globally, in different languages, and in a reliable and valid manner (Barak 2009). Indeed, the cross-cultural research by Barak and associates suggests that the cognitive age scale is reliable and can be used in diverse cultures and that there is a universal nature of the way human beings - irrespective of culture - perceive and feel about cognitive age (Barak et al. 2001; Barak et al. 2003; Mathur et al. 2001). As a result, researchers have suggested that cognitive age is "culture free" (cf. also Barak 2009; Van Auken and Barry 2009; Van Auken et al. 2006).

Nevertheless, in a recent review of the literature Barak (2009: 8) concluded that that cross-cultural global age research is still in an early pioneering stage and that follow up and replication studies are needed. Indeed, validity is a dynamic process that results from the accumulation of evidence over time (Wells 1975) and the aggregation of results (Peter 1981), with Epstein (1980: 796) arguing that "there is no more fundamental requirement in science than that the replicability of findings be established". In fact, replications play a valuable role in ensuring the integrity of a discipline's empirical results and they are considered to be important for the advancement of science and for discovering empirical generalizations (Easley, Madden, and Dunn 2000; Hubbard and Armstrong 1994; Hubbard and Lindsay 2002). This is particularly important when researching consumers by age group as period and cohort effects play a crucial role in addition to age effects (Cole et al. 2008; Fukuda 2010; Palmore 1978; Rentz, Reynolds, and Stout 1983); this means that e.g. findings about older consumers 10 or 20 years ago may no longer hold true today. Given that the few cross-national studies on cognitive age have been conducted at least 10 years ago, our paper makes an important contribution to the literature by checking whether the culture-free assumption of cognitive age also holds true for the current cohorts of older consumers.

In time, it may be possible to acknowledge the phenomenon as a useful marketing tool that is truly global. On this basis, the present study contributes to the small but growing body of knowledge pertaining to self-perceived age outside the USA, and for these reasons four countries which have little or no previous research in this field have been selected.

METHODOLOGY

The study comprised part of a major piece of international research into older consumers across several culturally disparate nations, and utilized questionnaires. The lower age parameter of 50 was selected on the basis that this is the starting point for many age-related services offered to older consumers (for example, SAGA, Age UK, Seniorsurfers.net). Besides, previous research has called for including middle-aged respondents in order to better understand aging mechanisms and their impact on consumer behavior (e.g. Cole et al. 2008). The two self-perceived age instruments, both age identity and cognitive age, were used. Additionally, respondents completed a battery of socio-demographic questions.

The four nations selected are Japan, Germany, UK, and Hungary. Japan is ranked number one in every international league table that considers population ageing, with 28% of its population already age 60 or over and a median age of 43 years (United Nations 2007). Despite the fact that it is the country most severely affected by the megatrend that is population ageing only two previous studies have considered self-perceived age from a marketing perspective, and both found Japan's older population to feel about 8 years younger than their actual age (Kohlbacher and Chéron 2010; Van Auken et al. 2006).

Germany is ranked 3rd in the league tables produced by the United Nations (2007) with 25.3% of its population already 60 or above. Despite this, there has never been a marketing study into the self-perceived ages of German's senior consumers, although a previous gerontological study suggests that Germany's older population feel about 12 years younger than their chronological age (Smith and Baltes 1999). Data from the German Aging Survey in 1996, however, found their age identity about 6.5 years younger than their chronological age (Westerhof and Barrett 2005; Westerhof, Barrett, and Steverink 2003).

The UK is ranked 17th from a total of 192 countries with 22% of its population already 60 or over. The three previous studies conducted in Britain (Sudbury 2004; Sudbury and Simcock 2009b; Szmigin and Carrigan 2000) suggest older British consumers feel about 10 years younger than their actual age. Finally, Hungary is ranked 19th in the league tables and has more than 21% of its population already aged 60 or above. Despite this, and the fact that Hungary is an important market that has made a major transition from communism to a market that has attracted much inward investment, no previous study has been conducted into the self-perceived ages of its older consumers. Overall, our sample thus consists of the following four countries in three regions: 1) Japan, the most aged society in the world, and – in our sample – the representative of Asia, 2) Germany and 3) Hungary as the representatives from continental Europe, one being the largest and oldest of the Western economies on the Continent and the other an a recent member of the European Union with a communist past, 4) the UK as a representative of the Anglo-Saxon European culture.

The questionnaire was translated and back translated by teams in Japan, Germany, and Hungary before being piloted across all four countries. Several changes were made on the basis of the pilot study. Three lists were purchased, one German (n = 6000), one British (n = 5000), and one Japanese (n = 1044) that contained randomly selected names and addresses of people aged 50+, and a questionnaire and pre-paid envelope was posted to them all. Piloting in Hungary demonstrated the difficulties of self-completion among many older Hungarian adults, thus the distribution strategy was adapted in that country, where a team of trained researchers administered the questionnaire face-to-face to 200 adults aged 50+.

A total of 1368 usable questionnaires were received. After removing cases with missing values for the scales used in this paper, 1293 questionnaires remained in the data set. Table 1 details the final sample by age and country.

Table 1: Total Sample by Chronological Age and Country

Country	N	Response Rate (%)	Mean Age	Std. Deviation
UK	456	3.5	66.24	8.21
Germany	211	9.1	63.50	8.41
Japan	426	40.1	64.11	8.56
Hungary	200	N/A	58.66	5.63
Total	**1293**		**63.92**	**8.39**

The reliability of the cognitive age scale was found to be acceptable (Cronbach's alphas ranged from .88 for the UK sample to .91 for the Hungarian and Japanese samples). A confirmatory factor analysis (CFA) using AMOS 18 led to composite reliabilities ranging from .88 for the UK to .91 for Hungary and Japan and average variances extracted ranging from .65 in the UK to .72 in Japan. While we are able to establish partial measurement invariance, the model fit for scalar invariance was only marginally satisfactory, but judged sufficient given the exploratory nature of this research.

Cognitive age was found to be highly correlated with chronological age (ranging from r=.6 in Hungary to r=.81 in Japan, p<.01) and with age identity (ranging from rho=.46 in Germany to rho=.68 in Hungary, p<.01).

FINDINGS

Table 2 details the age identities of the sample by country, where it can be seen that the vast majority of older adults, regardless of their nationality, consider themselves to be middle aged. Conversely, few people still feel young, although these differ slightly between nationalities, with only 2.4% of Germans feeling young, compared to almost 8% of older UK adults. This is despite the fact that the UK sample is older than the German sample by almost 3 years. Nevertheless, particularly noteworthy are the differences in those who admit to an old identity. In the UK and Germany less than 15% of older adults admit to feeling old, in comparison to one quarter of Hungarians and more than 30% of Japanese respondents. Indeed, a Chi-square test for independence indicated that there is a significant association between nationality and age identity (χ^2= 57.315, df = 6, p < .001), with fewer than expected British and Germans, and greater than expected numbers of Japanese and Hungarians, admitting to an old age identity.

Table 2: Age Identity by Country

Country	Age Identity		
	Young (%)	Middle-Aged (%)	Old/Elderly (%)
UK	7.89	77.41	14.69
Germany	2.37	85.31	12.32
Japan	7.04	62.21	30.75
Hungary	5.50	69.00	25.50

χ^2=57.315, df = 6, p < .001

Consistent with previous research, our multi-national sample found little agreement between cognitive and chronological age, although a strong and positive correlation was found between the two (r = 0.71, n = 1293, p <.01). Indeed, across the sample as a whole only 125 (9.7%) respondents had cognitive ages that were greater than their actual age. In contrast, the vast majority (87.2%) perceived themselves to be younger than their actual age. There were, however, comparisons between the nations. Table 3 classifies the differences in actual and cognitive age by country, where it can be seen that greater numbers of Hungarians (28.5%) felt older than their age, while only 3.8% of Germans felt older. Indeed, at least 87% of seniors from the UK, Japan and Germany felt younger than their actual age, while this figure drops to 66.5% for older Hungarians.

Table 3: Cognitive Age Compared to Actual Age, by Country

Country	Cognitive age older than actual age (%)	Cognitive age same as actual age (%)	Cognitive age younger than actual age (%)
UK	5.04	1.75	93.20
Germany	3.79	2.84	93.36
Japan	8.69	3.99	87.32
Hungary	28.50	5.00	66.50

Table 4 details the mean chronological and cognitive ages by country, as well as the youth bias (defined as the difference between chronological and cognitive age) where it is clear that there is a bias towards a more youthful self-perceived age. In all four samples paired-samples t-tests demonstrated that chronological and cognitive age are significantly different.

Table 4: Mean Chronological and Cognitive Age by Country

Country	Mean Chronological Age	Mean Cognitive Age	Youth Bias
UK	66.24	56.00	10.24
Germany	63.50	54.42	9.08
Japan	64.11	57.61	6.51
Hungary	58.66	54.99	3.67
Total	63.92	56.11	7.81

Noticeably, however, the youth bias ranges from less than 4 years for Hungarians to over 10 years for UK seniors. One-way ANOVA showed these differences to be significant (Welch (3, 1289) = 55.596, p < .001). Post-hoc comparisons revealed Hungary to have a significantly lower youth bias than any other country, while the UK has a significantly greater youth bias than Japan. Conversely, no significant differences emerged between Germany and the UK.

Finally, table 5 shows the percentages of seniors by nation who feel younger than their actual age by cognitive age dimension, whilst table 6 provides the mean cognitive age dimensions by country.

Table 5: Youthful Self-perceived Age by Dimensions of Cognitive Age (per cent)

Country	Feel age	Look age	Do age	Interests age
UK	86.84	80.92	89.91	89.25
Germany	85.31	81.52	85.78	86.26
Japan	75.35	78.40	81.22	81.46
Hungary	56.00	59.50	65.50	71.50

Consistent with previous research, for the sample as a whole look age is the dimension closest to chronological age. Once again, however, there are contrasts between the nations, as the difference between look age and the other dimensions are greater in the UK and Germany in comparison to Japan and Hungary. In these latter countries, there is little difference between look age and other dimensions, and indeed in Hungary the mean look age is actually marginally higher than feel age.

Table 6: Mean Actual and Cognitive Age Dimensions

Country	Actual age	Feel age	Look age	Do age	Interests age
UK	66.24	55.09	60.29	54.17	54.45
Germany	63.50	54.95	57.13	53.10	52.49
Japan	64.11	58.36	59.32	57.51	55.23
Hungary	58.66	56.25	56.15	54.55	53.00
Total	**63.92**	**56.32**	**58.81**	**55.15**	**54.16**

DISCUSSION

This research has found the 'young at heart' philosophy to be true for older consumers in all four nations under study. The vast majority of seniors feel middle-aged, and are not yet ready to admit they feel old. Moreover, many of the patterns to emerge have some similarities to American research in that there is little agreement between cognitive and chronological age, with a strong youth bias. Likewise, the expectation that the look age dimension would be closest to actual age than any of the other self-perceived age dimensions emerged in all the samples with the exception of Hungary.

However, despite some similarities to previous research and across countries, the significant differences found between the nations in this study are its most important contribution to knowledge. We thus successfully challenged the view of cognitive age as "culture-free". Clearly, Japanese and Hungarian seniors are more likely to admit to being old than are their British and German counterparts, and this pattern was repeated in the cognitive age results.

Wahl and Kruse (2003) argue that research into older adults should be designed and interpreted with a consideration of the social and cultural contexts in which these adults live.

The tendency for older people to report younger self-perceived ages has been viewed as a form of denial in the United States, where it has long been noted that youth is valued over old age (Guy, Rittenburg, and Hawes 1994). Such an ideology is not limited to American culture: British writing provides overwhelming support for the contention that in the UK old age is associated with negative characteristics; indeed in contrast to some other European countries Britain still has age discrimination built into the fabric of its society, and ageing is often portrayed in negative ways in the media (Joseph Rowntree Foundation 2004; Williams et al. 2010). In a similar vein, Catterall and Maclaran (2001) argue that the underpinning assumptions inherent in the concept of cognitive age reflect a Western preoccupation with youthfulness. However, given that the youth bias also exists in non-western nations, this view is challenged.

While the UK sample demonstrates similarities to American studies which typically report an age bias of between 8 and 12 years (Barak 1998; Sherman, Schiffman, and Mathur 2001), a number of studies conducted outside the US show the bias to be less pronounced. Chua, Cote and Leong (1990) conducted their cognitive age study in Singapore and found that English-speaking respondents were more likely to feel younger than their actual age in comparison to Chinese-speaking respondents. This difference was interpreted as a result of differing cultures, and as such was one of the first known studies to speculate that cultural forces may impact self-perceived age. However, given the much larger body of knowledge that suggests otherwise, this consideration appears to have been forgotten, neglected, or ignored in much subsequent research. Moreover, Chua, Cote and Leong (1990) interpreted their differences as a result of age being more respected in Eastern as opposed to Western cultures. However, it is not just Eastern cultures that have been found to have a less pronounced youth bias, as older Finnish adults have also been found to have a greater acceptance of their actual age in comparison to older Americans (Uotinen 1998). Thus, particularly in view of the significance of the European Union, it would seem that more research is needed across European nations before seniors markets are targeted with a pan-European marketing strategy. A recent meta-analysis, using data from 598 studies conducted over 30 years, into cultural value dimensions found that cultural values were more strongly related to older adults in comparison to younger people (Taras, Kirkman, and Steel 2010). Clearly, then, the life-experiences of individual nations needs to be considered.

The nations selected here are very different with regards to the life-experiences of older adults. Older Germans have experienced re-unification (and before that the separation), migration of younger adults from Eastern to Western Germany which has affected older people's social networks and integration, war guilt and a lack of focus on war veterans that is in stark contrast to the UK and US, and different social welfare arrangements which produce continuity of income in old age (Wahl and Kruse 2003). Language is an important part of culture, and interestingly the Hungarian language belongs to the Finno-Ugric family and is one of the few languages spoken within the European Union that are not of Indo-European origin. Moreover, older Hungarians have lived through the collapse of communism and the transition to a market economy, and a large study into the formulation of a consumer society and on the development of local identities in Central Europe found that a special type of consumer society came into being into these countries, with Hungary being one of them (Wessely 2000). From a consumer values perspective, the socialist system in Hungary which emphasized altruism and concern for the community has been replaced with more materialistic values, but there are still major generational differences (Hofmeister Toth and Neulinger 2009). Finally, older Japanese seniors have – just like their German counterparts – experienced the post-war efforts to rebuild their country and finding a new national identity. American occupation during the post-war years and the subsequent globalization have led to an acculturation process that has had a strong impact on Japanese values, thinking and consumer behavior (cf. also Francks 2009).

In sum, this research has answered a recent call for replication studies to be undertaken in the field of cross-cultural global age research, which is still in an early pioneering stage (Barak 2009). The study also adds to the small but growing amount of empirical evidence pertaining to seniors outside the US. Results lend support for the claim that the concept of cognitive age is reliable and can be used in diverse cultures, and that there is a universal way that human beings perceive and feel about self-perceived age (Barak 2009; Barak

et al. 2001). However, the latter holds only true as far as the general tendency to feel younger than one's actual age is concerned, but not to the degree and magnitude of the youth bias. Indeed, our findings seem to challenge the assumption of cognitive age as culture free. This is actually not all too surprising given the disparate cultures and life-experiences that these seniors have experienced. Some previous studies have also found some indications that culture may play at least some role in the perception of age (Chua et al. 1990; Mathur et al. 2001; Uotinen 1998), but the prevailing view in the cross-national literature on cognitive age saw it as culture free and universal. This view will now have to be changed.

LIMITATIONS AND NEED FOR FURTHER RESEARCH

We cannot know for sure if culture is the (sole) explanation for the differences we have found across the four countries surveyed. Other factors on the individual or sample level may be confounding our results. Indeed, previous research has identified various antecedents and correlates of cognitive age (Barak and Stern 1986; Mathur and Moschis 2005; Ong, Lu, and Abessi 2009) and further research will necessary to disentangle cultural effects from those of other correlates. Besides, subjective age might also be a social phenomenon and in that case the usefulness and applicability of the cognitive age concept could change along with changing social attitudes such as the one towards aging for example (cf. e.g. Catterall and Maclaran 2001). Thus, it is impossible to explain why the young-at-heart bias differs across the nations studied here, but these results do set a clear research agenda, in that further research into the underlying antecedents of cognitive age, particularly across nations outside America (and especially across the European Union) is needed.

It is hoped that the different sampling methods which were needed due to cultural differences did not impact the results, but we note that Hungary, where the administration of the questionnaires was different, has emerged as significantly different to the other nations from a self-perceived age perspective. Future research will have to address data equivalence and measurement issues in greater detail (Barak 2009; Hult et al. 2008; Reynolds, Simintiras, and Diamantopoulos 2003; Singh 1995). Further research needs to delve into the antecedents of the concept of self-perceived age, and consider different life experiences and cultures as potential antecedents. Finally, employing cohort analysis on longitudinal or repeated cross-sectional data may help to shed further light on older consumers (Cole et al. 2008; Fukuda 2010; Rentz et al. 1983).

MANAGERIAL IMPLICATIONS

This study has important implications for marketing practice. In advertising, for example, the use of "cognitive-age congruent" models or spokespersons should prove fertile as a consumer's self-perceived age interacts with the perceived age of the model or spokesperson seen in an ad, and can subsequently influence the response to the advertising message (Chang 2008; Van Auken and Barry 2009). This may also explain why older people are often underrepresented in advertising, a fact that also holds true for TV commercials in the UK (Simcock and Sudbury 2006), Germany (Kessler, Schwender, and Bowen 2010), and Japan (Prieler et al. 2009). Research has also shown the importance of understanding motivational differences that underlie the effects of aging on attitudes toward and recall of advertisements (Drolet, Williams, and Lau-Gesk 2007) and heeding to the cognitive age of the target group will likely be an additional, crucial factor.

From an international marketing perspective, the study lends support to the usefulness of self-perceived age as a way of segment-

ing and targeting senior consumers across the globe. In the same way as a youth segment represents an example of a universal global common segment (Kjeldgaard and Askegaard 2006), there is growing evidence that a 'young at heart' senior global market exists (Barak 2009) and this study lends further support to that. That is not to suggest that older adults can be treated as an undifferentiated monolith. Indeed, the differences between the nations suggest that local differences still need to be considered in advertising and positioning strategies. Nevertheless, it provides a starting point for marketers wishing to target this growing and important global phenomenon that is the senior market.

Measuring Consumers' Emotional Reactions to Company Crises:
Scale Development and Implications

Lynette McDonald, University of Queensland, Australia
A. Ian Glendon, Griffith University, Australia
Beverley Sparks, Griffith University, Australia

INTRODUCTION

Crises negatively impact an organization's financial stability, its relationship with its publics, its image and reputation, as well as its ability to function, and to deliver its products and services (Jin and Cameron 2007). Between 2003 and 2006 almost half of U. S.-based multinationals were affected by major crises that caused catastrophic business impacts (PricewaterhouseCoopers 2006). In 2010, global insurance claims for man-made crises were $5 billion (Swiss Re 2010).

Crises trigger emotions in impacted consumers. These emotions guide the interpretation of an unfolding crisis, shaping attitudes towards the organization (Jin, Pang, and Cameron 2007). Emotions influence stakeholders' future organizational interactions, powerfully influencing post-crisis behavior (Coombs and Holladay 2005) such as product boycotts (Choi and Lin 2009). Yet crisis emotions' influence on behavioral tendencies is little investigated (Coombs and Holladay 2005). A strong need exists to explore the variety of crisis-generated emotions (Choi and Lin 2009) to understand emotions and to develop effective crisis management strategies.

The recently increasing momentum of crisis emotion research suggests the need for psychometrically-validated scales that reflect consumers' experienced crisis emotions. However, no studies that reported significant effects for emotional response to organizational crises used scales that had been tested, not just for reliability and predictive validity, but for content validity, unidimensionality, and convergent and discriminant validity as specified by Churchill (1979), Gerbing and Anderson (1988), and Hair et al. (2009). Measures should incorporate the diversity of most frequently experienced emotions in a particular context, and use readily understood words (Richins 1997), ideally using laypersons' own emotion lexicon (Carpenter and Halberstadt 1996). Across three studies we develop an instrument to measure crisis emotions as a tool for managers and scholars to identify consumers' crisis emotional responses and intensity, predict behavioral outcomes, guide crisis communication strategies, and indicate degree of crisis management success.

CRISIS AND EMOTIONS

Organizational crises trigger consumer emotions which drive behavioral intentions towards a firm and its product. Crisis studies using Weiner's (1986) attribution theory (WAT) or Coombs and Holladay's (2002) Situational Crisis Communication Theory (SCCT) based on WAT, identified that crisis cause attributions determine emotions, with emotions driving behavioral intentions. That is, crisis emotions immediately precede behaviors. Anger directly predicts negative purchase intentions (Coombs and Holladay 2007; Jorgensen 1996), negative word-of-mouth (WOM) behavior (Coombs and Holladay 2007), boycott (Choi and Lin 2009), punitiveness, and indirectly leads to reduced investment intentions (Jorgensen 1996). Fear leads to venting intentions or avoidance, while sadness results in a preference for emotional support and positive thinking as coping strategies (Jin 2009).

Limitations of Existing Crisis Emotion Measures

Consumer emotions are context specific (Richins 1997). Those resulting from service failures (e.g., Folkes 1984) differ from those relating to consumption (e.g., Laros and Steenkamp 2005). As scales should include context-specific emotion words (Carpenter and Halber-

stadt 1996; Richins 1997), crisis emotion scales would benefit from words acquired from consumers' own crisis language. Researchers using modified scales or scale parts still must follow standard scale development and refinement procedures (Ortinau 2011). Scales should be conceptually defined, have content validity, use multiple indicators, be unidimensional, and have convergent, discriminant, and nomological validity (Hair et al. 2009).

Of 11 studies reporting significant effects for emotional response to various organizational crises, none used emotion scales that fulfilled all criteria. Using exploratory factor analysis, Kim and Cameron (2011) adapted emotion scales originally created for public health advertising, to identify four scales (anger, sadness, fear, surprise). Six studies applying multiple-item emotion scales (Coombs and Holladay 2007, 2008, 2009; Jin and Cameron 2007; Jorgensen 1996; Lee 2004) only report reliability scores. Jorgensen's (1996) 4-item scale tests negative affect, rather than any specific emotion, and includes reversed-scored items (e.g., angry, sympathetic). Coombs and Holladay's (2008, 2009) 3-item anger scale uses Jorgensen's (1996) items. Coombs and Holladay's (2007) 3-item anger scale lists only two items and cannot be assessed for content validity. Jin and Cameron's (2007) two 3-item scales do not measure emotion but affect in the form of emotion valence and arousal. Lee's (2004) sympathy scale includes frustration. The 4 remaining crisis emotion scales (Choi and Lin 2009; Coombs and Holladay 2005; Jin 2009; Jorgensen 1994) use 1-item measures. These are psychometrically less reliable than multiple-item measures; highly reliable measures are crucial to statistical analyses to minimize error variance effects (Loo 2001). In sum, no identified studies reported fully-tested crisis emotion scales. We develop and validate multiple-item self-report crisis emotion scales to enable managers and researchers to more comprehensively examine consumers' varied crisis emotions.

CRISIS EMOTION SCALE DEVELOPMENT AND TESTING

Following well-established scale development procedures (Bearden, Netemeyer, and Mobley 1999; Churchill 1979; Gerbing and Anderson 1988), we started with construct specification and domain, allowing an understanding of the theory on which the construct is embedded (Peter 1981). Item generation followed in study 1, trait validation in study 2, and evaluation of convergent, discriminant, and nomological validity in study 3.

Construct Specification and Domain

The emotion concept has no single agreed definition (Izard 1993). Attribution-appraisal theorists (Frijda 1986; Weiner 1986) consider that emotion comprises discrete states generated by cognitive appraisals leading to specific affect, action tendencies and physiological reactions (Scherer 2000). Thus, one distinguishing feature of primary emotions is "action readiness" (Frijda 1986). However, dispute remains about the number of distinct primary emotions (Laros and Steenkamp 2005). Shaver et al. (1987) and Nyer (1997) contended that six primary emotion categories exist: anger, fear, joy, love, sadness, and surprise.

Different emotions call for varied coping strategies, generating distinct behaviors (Nyer 1997; Scherer 2000). Anger functions to

regain control, focusing on obstruction removal (Frijda 1986). Fear acts to protect (Frijda 1986) and motivate escape from danger (Izard 1993). Joy signals readiness for friendly interaction (Izard 1993). Sadness communicates trouble to self and others (Izard 1993), allowing recuperation and disengagement (Frijda 1986). Surprise's function is reorientation (Frijda 1986) and may be either undesirable (shock) or desirable (pleasant surprise) (Ortony, Clore, and Collins 1988). Love creates a desire for continued interaction (Epstein 1984).

Study 1: Item Generation

The second step in scale development is item generation and pool editing (Churchill 1979). As a researcher's meaning for a measure may not accord with respondents' imputed meaning (Gerbing and Anderson 1988), focus groups were conducted to establish consumers' emotion words in an organizational crisis context. The objective was to produce a commonly employed word set, with the most frequently recurring words considered to be valid indicators of importance (Havlena, Holbrook, and Lehmann 1989). Focus group size was congruent with Lunt's (1996) recommendation of six to 10. The 52 participants from a major Australian city, recruited predomi-

nantly via media publicity, were allocated among eight groups. Ages ranged from 19 to 79 years ($M = 43$, $SD = 14$), 58% were males, and 61% had college education or higher. Most had low (48%) to average (35%) incomes assessed according to government-sourced information. Almost all participants had been personally impacted by organizational crises. Crises varied from an airline fleet grounding, three product recalls (two following extortion threats, one following salmonella poisoning), two separate legionella outbreaks, and a two-week shutdown of a city's natural gas supply. As the intention was to later test emotions in a nomological net, discussion of attitudes and behaviors was invited. Videotape transcriptions and whiteboard discussion summaries were content analyzed using an iterative approach. Shaver et al.'s (1987) list of 135 emotion words was used to categorize the 80+ emotion words elicited. Anger category words dominated emotion content (42.6%), followed by fear (20.9%), sadness (20.5%), joy (9.1%), surprise (3.6%), and love (3.3%) (see table 1). The most frequently occurring words in each category were used for scale development (Havlena et al. 1989).

TABLE 1
STUDY 1: MOST COMMONLY-USED EMOTIONS WORDS

Emotion	Emotion words
Anger	angry, annoyed, contempt, disgusted, frustrated, outraged, dislike
Fear	fear, worried, uneasy, apprehensive, scared, concerned, distressed
Sad	disappointed, sympathetic, hopeless, insecure, sorry, unhappy
Joy	relieved, satisfied, enjoyment, contented, glad
Surprise	surprised, shocked, amazed
Love	liking, compassion

Study 2: Scale Dimensionality and Internal Consistency

Study 2 assessed the six emotion scales' internal consistency, dimensionality, and criterion validity (Gerbing and Anderson 1988). As crisis emotions are generated via cognitive appraisal, airline crash vignettes similar to Jorgensen (1996) and Lee's (2004) were created with differing causes to generate differing attributions, eliciting a variety of emotions in a between-subjects factorial design.

Undergraduate students ($N = 316$, 65% female, $M_{age} = 23$ years, $SD = 6$) from an Australian east coast university were randomly assigned to one treatment. Participants were asked to imagine themselves or their families were recent airline customers, then read a mocked-up front-page newspaper story on the crash cause, complete with a large photograph. The self-paced questionnaire asked participants about their feelings towards the company and towards flying with the company using 7-point scales with not at all/very much end points. Adjectival forms of the table 1 words were used where pos-

sible, congruent with other emotion scales.

As there was a minimum of 300 cases (Tabachnik and Fidell 2001), an exploratory factor analysis (EFA) investigated scale item loadings (Churchill 1979; Gerbing and Anderson 1988) using principal axis factoring (PAF) with oblique rotation in SPSS. The correlation matrix indicated neither extreme multicollinearity nor singularity (Hair et al. 2009). Items with low construct loadings (< .4 were deleted and those with high loadings were retained (Churchill 1979). Love did not appear as a separate factor and was excluded from further analysis. As complex items loaded on more than one factor, an oblique rotation was conducted. This yielded a five-factor solution explaining 62.2% of the variance, with only one complex item which, being correlated at .55 with joy, was retained. Sadness was renamed sympathy to reflect its content. Standardized factor loadings and inter-item correlations in table 2 provide evidence of construct validity.

TABLE 2
STUDY 2 EFA: STANDARDIZED SCALE FACTOR LOADINGS

	Factor loading/Item-total correlation				
	Fear	Joy	Sympathy	Surprise	Anger
Emotions towards service use					
Insecure	.89*				
Worried	.88/.81				
Scared	.83/.82				
Fearful	.81/.83				
Uneasy	.78/.80				
Apprehensive	.75/.69				
Concerned	.73/.79				
Distressed	.69/.70				
Unhappy	.62*				
Satisfied		.74/.57			
Glad		.68/.69			
Liking		.68*			
Contented		.65/.66			
Enjoyment	-.32	.55/.58			
Emotion towards the company					
Relieved		.54/.54			
Contented		.52/.54			
Sympathetic			.80/.66		
Sorry			.68/.55		
Compassion			.50/.47		
Shocked				.60/.53	
Amazed				.58/.46	
Surprised				.52/.49	
Annoyed					.62/.68
Outraged					.61/.74
Disgusted					.60/.67
Dislike					.58/.60
Contempt					.56/.52
Unhappy					.56*
Frustrated					.56/.60
Angry					.48/.63
Hopelessness					.46*
% of total variance explained	33.26	10.80	7.17	6.11	4.11

* removed due to being classified as belonging to a different emotion category
NB: Factor loadings < .4 omitted

Study 3: Scale Confirmation

Study 3 refined each emotion scale to increase its internal consistency, maximize reliability, and enhance validity (Churchill 1979; Gerbing and Anderson 1988). Scales were assessed for construct and discriminant validity via confirmatory factor analyses (CFA) (Gerbing and Anderson 1988) to check construct validity, unidimensionality, and to determine factor score weightings. The goal was to retain

items that formed a reliable and valid measure of crisis emotions. Extra items were added to the shorter sympathy and surprise scales to enhance reliability. As the relationship between emotions, attitude and behaviors had been established (Jin 2009; Lee 2004), nomological validity was examined by testing the relationship between the theoretically related measures or constructs (Bearden et al. 1999) of attitude and behaviors in a nomological net. The 6-item attitude scale

(α = .81) by Milliman, Fugate, and Afzalurrahim (1991, in Bruner II and Hensel 1998) was selected for its face validity when applied to company crises. Fifteen items from behavioral intention scales by Zeithhaml, Berry, and Parasuraman (1996) and Singh (1988 in Bruner, James, and Hensel 2001) were selected, as they closely resembled participants' reported behaviors in study 1. All measures were tested using the same procedures and samples as previously described for the emotion measures, evaluating their construct and discriminant validity.

Study 3 followed the same procedures as study 2, generating emotions through a cognitive appraisal process. A randomly-selected general population sample from a recently updated State electoral roll for a major Australian city received a mailed questionnaire. With voting legally compulsory in Australia, this was the best publicly-available sample source as 93% of citizens aged 18+ appear on electoral rolls (Australian Electoral Commission Annual Report 2006-2007). The rolls are commonly used for population surveys. Of 4500 questionnaires posted, 942 responses were received (907 usable responses, 21% response rate), within the 20% to 25% range typically produced by random samples generated through publicly-available sources (Hunsaker et al. 2002). Respondents were aged from 18 to 95 years (M = 46, SD = 16), and 60% were female. Government-sourced data indicated that respondents' demographic profile (age, gender, education, income) closely matched the local population, although respondents were slightly more educated, and females and the 45 to 54 age group were slightly over-represented. Following Byrne's (2001) recommendation, the sample was split in two for EFA (n = 453) and CFA (n = 454).

Exploratory factor analysis (EFA). The study 2 EFA procedures were repeated. No correlations approached 1, indicating neither extreme multicollinearity nor singularity (Hair et al. 2009), although several same-scale items correlated at .8, suggesting convergent validity (Yavus and Babakus 1995). Items with construct loadings below the .4 level at which a variable is normally retained were the joy words felt towards the company of "relieved" and "contented" and the anger word, "frustrated." These were removed from analysis. The emotion scales were tested by requesting a 5-factor solution, which explained 71.7% of the variance, and as part of a nomological net with attitudes and behaviors as a 9-factor solution to determine whether they were correlated with measures of these theoretically-related constructs. Item-total correlation, advocated in constructing unidimensional scales (Gerbing and Anderson 1988), indicated that, except for same-scale items, no emotion items inter-correlated at .7 or above. The emotion scale items were not highly correlated with attitude or behaviors and neither solution had complex items, indicating good discriminant validity.

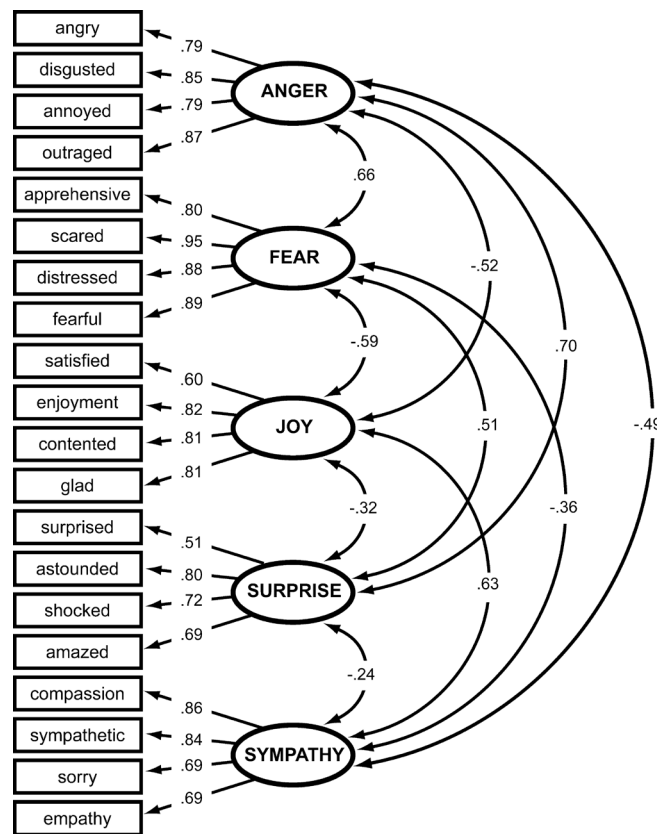
The EFA resulted in a 6-item anger scale (angry, annoyed, contempt, disgusted, outraged, dislike), a 4-item sympathy scale (sympathetic, compassion, empathy, sorry), a 4-item joy scale (glad, enjoyment, contented, satisfied), a 5-item surprise scale (surprised, astounded, astonished, amazed, shocked), and a 7-item fear scale (concerned, worried, apprehensive, uneasy, scared, distressed, fearful). All attitude items were retained, and behavior had three factors (loyalty, complaining, disloyalty).

Confirmatory factor analysis (CFA). Using the other half-sample, a CFA using AMOS with maximum likelihood estimation provided construct and discriminant validity tests (Anderson and Gerbing 1988), testing the model fit and the scales' content validity. Scales were first separately analysed using 1-factor congeneric models representing the regression of each set of observed variables (scale items) on its respective latent variable (Byrne 2001). Items with correlated error terms indicated redundancy (Byrne 2001) and were removed to improve fit indices and internal reliability, with scales reduced to four items for parsimony. Each scale was tested and revised to obtain reasonable fit statistics (see table 3) which ranged from excellent to satisfactory. For the Normed Fit Index (NFI), Comparative Fit Index (CFI), and Adjusted Goodness of Fit (AGFI), values over .90 are satisfactory, over .95 indicate a good fit (Kaplan 2000), and 1.00 indicates that the data fit the model perfectly (Byrne, 2001). Root Mean Square Error of Approximation (RMSEA) values between .05 and .08 are satisfactory, below .05 indicate a good fit (Kaplan 2000), while zero indicates an exact fit (Byrne 2001).

TABLE 3
STUDY 3: 1-FACTOR CONGENERIC MODELS' FIT

	Anger	Fear	Joy	Surprise	Sympathy
χ^2 (df)	0.20 (2)	1.65 (2)	0.70 (1)	0.85 (2)	2.80 (2)
NFI	1.00	1.00	1.00	1.00	.99
CFI	1.00	1.00	1.00	1.00	1.00
AGFI	1.00	.98	.99	.97	.99
SRMR	.01	.02	.01	.04	.06
RMSEA	.00	.04	.00	.00	.06
Alpha	.89	.93	.83	.80	.85
AVE	68%	77%	57%	46%	58%
N items	4	4	4	4	4

After finalizing a suitable CFA structure, factor score weightings were calculated on the entire original sample (Byrne 2001). Scale reliability was tested using Cronbach alpha and by calculating average variance extracted (AVE), which reflects the overall amount of variance in the indicators accounted for by the latent construct, which should exceed 50% (Hair et al. 2009). This occurred for all scales except surprise, which was 46%. The anger, sympathy and surprise scales (see Appendix for items) measured feelings towards the company. The fear scale measured feelings towards product or service use. The joy scale measured feelings towards product or service use, and towards the company in crisis. The final latent variable model showed acceptable fit statistics, χ^2 (160) = 468.50, p < .001, CFI = .94, NFI = .92, AGFI = .88, RMSEA = .07, SRMR = .18, with factor loadings as per figure 1. This model's reliability using AVE calculations was 68%. The fit statistics indicated this model to be preferred to a higher order construct model for positive and negative emotion.

FIGURE 1
STUDY 3: STANDARDIZED ESTIMATES SHOWING DISCRIMINANT VALIDITY OF THE EMOTION SCALES


Predictive validity with other constructs. The final stage involved demonstrating that the emotion scales had nomological validity against attitudes and behaviors of loyalty, disloyalty, and complaining using standard regression analyses. First the attitude and behavior scales' fit indices were examined, resulting in five 4-item scales. All emotions significantly predicted attitude, $F(5, 837) = 151.48, p < .001$. All emotions except sympathy significantly predicted disloyalty, $F(5, 838) = 235.04, p < .001$. Joy, fear, and sympathy significantly predicted loyalty, $F(5, 838) = 153.43, p < .001$. Anger and fear significantly predicted complaining, $F(5, 838) = 74.31, p < .001$.

DISCUSSION

Research on the burgeoning field of emotional reactions to crises is hindered by the absence of scales using words that incorporate consumers' own crisis emotion lexicon and which are psychometrically robust. To extend research in this field, we developed and tested crisis emotion scales, demonstrating their convergent and discriminant validity, internal reliability, and predictive validity. Testing resulted in three negative emotion scales (anger, fear, surprise) and two positive emotion scales (joy, sympathy) suitable for examining emotions felt towards a company and its products or services. The scales, albeit in early testing stages, may stimulate further research aimed at understanding consumer crisis emotions–positive and negative–in particular, the relationship between emotions and attitude and behaviors. This is important in view of concrete evidence of consumers' negative reactions to crises, evidenced in the marketplace in product boycotts and reduced market share. Further, the creation of

a joy measure facilitates tests of this positive crisis emotion, which currently attracts little research attention.

Although an airline crash is considered a severe crisis (Lee, 2004), anger, fear, surprise, sadness, and sympathy felt towards organizations has also been identified in studies examining response to less severe scenarios. These include Kim and Cameron's (2011) product defect scenarios involving burns, and Coombs and Holladay's (2005) 10-scenario study, which included rumor, organizational misdeed and human-error product recalls. This indicates that our scales may apply to less severe, less emotionally-intense crises. Further research is required to examine the stability of the scale across different crisis types and settings.

The study also extends the limited existing research on crisis emotion effects on attitude and behaviors, finding that emotions impacted consumers' attitudes and differentially impacted their reported behaviors. Anger predicted complaining, disloyalty and attitude. Fear predicted disloyalty, complaining and attitude, and negatively predicted loyalty. Joy predicted loyalty and attitude, and negatively predicted disloyalty. Sympathy predicted attitude and loyalty. Surprise predicted disloyalty and negatively predicted attitude. These differing emotion reactions emphasize the need for managers to identify which emotions are likely to arise when a crisis erupts in order to implement intervention measures to minimize damage to the brand and company reputation, and to attenuate loss of customers, sales, and market share.

These short easily administered self-report emotion measures provide managers with a toolkit to assess current consumer emotions–and their strength–in order to predict likely attitudinal and

behavioral consequences of an organizational crisis and to be able to tailor responses. If the dominant emotion is fear, then crisis statements should provide information about specific actions to take (e.g., product return), followed by information to help consumers cope with the crisis (e.g., seek advice from the organization's website) or focus on possible positive outcomes. Surprise (akin to shock) may require both forms of action. If anger is uppermost, crisis communication should incorporate image repair information (e.g., highlighting organizational safety). Finding positive emotions signals that the company does not need to expend major resources dealing with the crisis. These scales may also assist in gauging the success of interventions, including emotion-tailored crisis communication, and assessing the effectiveness of crisis management strategies.

As the scales were developed using an Australian sample and tested using airline crash scenarios, further scale validation using different respondent samples and different crisis types is warranted to examine the scales' robustness and the scope of their application. Investigating emotional responses to actual crises with real implications for consumers is important to capture the dynamic processes occurring during crises.

APPENDIX
CRISIS EMOTION SCALES

1. Emotions towards the company

For *each* word below, please circle the number that best describes the feelings that you have about *X*. When I think about *X*, I feel…

(a) angry[1]	(b) surprised[2]	(c) sympathetic[3]	(d) contented[4]
(e) annoyed[1]	(f) shocked[2]	(g) sorry[3]	(h) enjoyment[4]
(i) disgusted[1]	(j) amazed[2]	(k) compassion[3]	(l) glad[4]
(m) outraged[1]	(n) astounded[2]	(o) empathy[3]	(p) satisfied[4]

[1]Anger scale, [2]Surprise scale, [3]Sympathy scale, [4]Joy scale.

2. Emotions towards using the service/product

For *each* word below, please circle the number that best describes the feelings that you have towards using *X's* product/service. Towards using product/service I feel…

(a) contented[4]	(b) scared[5]
(c) enjoyment[4]	(d) apprehensive[5]
(e) glad[4]	(f) fearful[5]
(g) satisfied[4]	(h) distressed[5]

[4]Joy scale, [5]Fear scale.

NOTE: Responses are based on a 7-point Likert-type scale, anchored by *not at all* (1) and *very much* (7).

Using Self-Perceived Age and the List of Values to Study Older Consumer in 4 Nations

Florian Kohlbacher, German Institute for Japanese Studies (DIJ) Tokyo, Japan
Lynn Sudbury, Liverpool John Moores University, UK
Agnes Hofmeister, Corvinus University of Budapest, Hungary

ABSTRACT

This study is the first one to look into the relationship between personal values and self-perceived age for older consumers in the UK, Germany, Hungary and Japan. Apart from overall cross-national differences, interesting differences in value rankings by self-perceived age groups emerged within countries as well.

Population ageing has emerged as a powerful megatrend affecting a large number of countries around the world. Indeed, the United Nations (2007) suggests that this megatrend is probably the most profound demographic change in the history of humankind. It is a pervasive and truly global phenomenon, without precedent or parallel, largely irreversible, and with the young populations of the past unlikely to occur again. Globally, the number of older persons will exceed the number of children by 2047, which has already occurred in many developed regions. The profundity of this demographic change will impact on economic growth, labour markets, pensions, health care, housing, migration, politics, and of course consumption. It is surprising, therefore, that older consumers are still relatively neglected by both marketing academics and practitioners alike (Niemelä-Nyrhinen, 2007; Simcock and Sudbury, 2006). This situation is particularly true for countries outside the United States of America, where what is known about the consumer behaviour of seniors still lags far behind what is known about other important segments (Kohlbacher and Chéron, 2010; Williams et al., 2010).

Similarly, as Kahle and Kennedy (1988) point out, business has too often neglected the importance of values, despite the prominence given to them by philosophers and social scientists, and the fact that values have been shown to influence a range of consumer behaviours. An understanding of the impact of age and values on the consumer behaviour of a particular cohort can therefore be a powerful tool for market planning, product development, demand forecasting and innovation (Muller, Kahle and Chéron, 1992). With this in mind, this paper aims to make a contribution to knowledge by analysing and comparing the values of older consumers across four nations outside North America.

Theoretical background and previous research

Cognitive age: The significance of a persons' age in wider society is apparent in many walks of life. One's chronological age dictates, for example, the point at which one can legally drive an automobile, marry, consume alcohol, vote, and enlist in the military. Although chronological age is still widely used in both marketing research and segmentation practice, its limitations as an indicator of values, attitudes and behavior have long been known (Adams, 1971; Chua, Cote and Leong, 1990), and are acknowledged in everyday parlance -'he's got an old head on young shoulders', 'she's still very young at heart'- and it may well be that the adage that one is as young or as old as one feels provides more useful insights into the behavior of older people.

Measurement methods for ascertaining how old a person feels, i.e., a person's self-perceived age, fall into two major groups. The first, and oldest, is age identity (Cavan *et al*., 1949), concerning the age category (young, middle-aged, old) in which people perceive themselves to be. A second type of measure grew in response to the recognition that ageing is multidimensional (Birren, 1968), comprising biological, psychological, and sociological dimensions, none of which can be understood without reference to the others (Riley, 1985). The cognitive age scale (Barak and Schiffman, 1981) is one such multidimensional scale, which incorporates the different dimensions of aging by asking people how old they think they look (biological), how old they feel (psychological and biological), and how old they rate their behavior and interests (social). Cognitive age has been shown to be useful in order to better understand consumer behavior in later life across a variety of marketing studies from Internet usage and senior innovators to use of senior promotions and segmentation (Eastman and Iyer 2005; Moschis and Mathur 2006; Sherman, Schiffman, and Dillon 1988; Sudbury and Simcock 2010), and is now well established in the marketing literature.

Personal Values: Research pertaining to personal values agrees that they are an integral influence upon human behaviour, with their impact being recognised across social science disciplines (Vinson et al., 1977; Clawson and Vinson, 1978). Whilst there is some debate on how values are created, evolve, and impact human behaviour, and indeed there is a lack of agreement on a 'formal' definition of values, many researchers adopt Rokeach's (1968) contention that values are "enduring beliefs that a specific mode of conduct or end-state of existence is personally or socially preferable to an opposite or converse mode of conduct or end state" (p. 550). Thus, values appear to be ideal states for which an individual strives.

Values not only have hierarchical primacy over attitudes (Homer and Kahle, 1988; Kahle, Liu and Watkins, 1992), but influence a variety of consumer behaviours, including reactions to products (Batra, Homer and Kahle, 2001; Kahle, 1986), media preferences (Beatty et al., 1985), positioning (Kennedy, Best and Kahle, 1988), advertising, packaging, personal selling, and retailing (Beatty, Homer and Kahle, 1988). Moreover, age differences in the importance placed on different values have been identified (Kahle, Beatty and Homer, 1986; Kahle, Poulos and Sukhdial, 1988), with a recent American study (Gurel-Atay et al. 2010) finding older Americans to have significantly different rankings of values than other age groups. Conversely, the same study found no differences between the several younger age groupings, suggesting that value systems do indeed change at different life stages. Indeed, the literature devoted to older consumers clearly suggests that older people have different values to younger people (Wolfe 1988; Yovovich 1983), and suggests that the older generation may value trustworthiness and being responsible and sensible above other values (De Jonquieres, 1993), while several authors cite security, safety, social connectedness and spirituality as key (Dychtwald and Flower, 1989; Schewe, 1990, 1991; Wolfe 1994).

While a body of research suggests that the most important values are handed down from generation to generation (Kahle, Liu and Watkins, 1992; Kahle, Poulous, and Sukdial, 1988), one explanation for generational differences was proffered by Crosby, Gill and Lee (1984) who suggested that economic conditions, historical and political events, and the specific deprivations experienced by different cohorts may be the antecedents for age differences. Clearly, this argument gives rise to the need for a cross national investigation into the differing values of adults of the same generation who have experienced very different economic conditions and historical and political events. On this basis, the current study aims to fill a significant gap in the literature by studying the value bases of an important cohort of older consumers, drawn from four nations that have experienced very different political and economic conditions during the life-times of these older adults.

Cognitive Age and Personal Values: There are only a few previous studies into older adults and values, and none of these are multinational. The first, an Australian study (Cleaver and Muller 2002), found 'fun and enjoyment' to be associated with feeling younger than one's actual age, while those who felt older valued 'security'. However, only one previous study (Sudbury and Simcock 2009) has used cognitive age to study the values of older consumers. Conducted in the UK, these authors found that significant differences did emerge between cognitive age and value rankings. A major gap in current knowledge is a cross-national comparison of older consumers and values, in order to provide marketing practitioners with some insight into this important area of consumer behavior, which can help guide their international marketing strategies.

METHODOLOGY

The study comprised part of a major piece of international research into older consumers across several culturally disparate nations, and utilized questionnaires. The lower age parameter of 50 was selected on the basis that this is the starting point for many age-related services offered to older consumers (for example, SAGA, Age UK, Seniorsurfers.net). Besides, previous research has called for including middle-aged respondents in order to better understand aging mechanisms and their impact on consumer behavior (e.g. Cole et al. 2008). Barak and Schiffman's (1981) cognitive age scale was used. As for personal values, the LOV scale developed by Kahle (1983) was employed and requested respondents to read all eight statements shown in Table 2 carefully before giving their answer on a scale of importance from 1 to9. Additionally, respondents completed a battery of socio-demographic questions.

The four nations selected are Japan, Germany, UK, and Hungary. Japan is ranked number one in every international league table that considers population ageing, with 28% of its population already age 60 or over and a median age of 43 years (United Nations 2007). Older Japanese adults have experienced US occupation of post-war Japan (1945-1952), and then the remarkable post-war economic recovery which continued through the 1970s and 1980s which even-

tually made Japan the world's second-largest economy, before succumbing to the Asian economic crisis in 1998. Germany is ranked 3rd in the league tables produced by the United Nations (2007) with 25.3% of its population already 60 or above. Irrespective of whether these people lived in East or West Germany before reunification, all have experienced dramatic political and economic upheavals. The UK is ranked 17th from a total of 192 countries with 22% of its population already 60 or over. Despite its membership of the European Union, its close relations with the Untied States reflects a common language and ideals, and it is therefor possible that the values of older UK adults are influenced to a greater extent by America than its European neighbors. Finally, Hungary is ranked 19th in the league tables and has more than 21% of its population already aged 60 or above. Older Hungarians have lived through forty-seven years of military presence, many have experienced economic hardship, and all have experienced the transition to a market economy. Overall, our sample thus consists of the following four countries in three regions: 1) Japan, the most aged society in the world, and – in our sample – the representative of Asia, 2) Germany and 3) Hungary as the representatives from continental Europe, one being the largest and oldest of the Western economies on the Continent and the other an a recent member of the European Union with a communist past, 4) the UK as a representative of the Anglo-Saxon European culture.

The questionnaire was translated and back translated by teams in Japan, Germany, and Hungary before being piloted across all four countries. Several changes were made on the basis of the pilot study. Three lists were purchased, one German (n = 6000), one British (n = 5000), and one Japanese (n = 1044) that contained randomly selected names and addresses of people aged 50+, and a questionnaire and pre-paid envelope was posted to them all. Piloting in Hungary demonstrated the difficulties of self-completion among many older Hungarian adults, thus the distribution strategy was adapted in that country, where a team of trained researchers administered the questionnaire face-to-face to 200 adults aged 50+. A total of 1368 usable questionnaires were received.

Results
Table 1 details the final sample by age and country.

Table 1: Total Sample by Chronological Age and Country

Country	N	Mean Age	Std. Deviation
UK	502	66.6	8.57
Germany	227	63.3	8.42
Japan	439	64.31	8.66
Hungary	200	58.66	5.64
Total	**1368**	**64.16**	**8.60**

The reliability of the cognitive age scale was found to be acceptable (Cronbach's alphas were .88 for the UK sample, .89 for the German sample, and .91 for both the Japanese and the Hungarian samples).

LOV Scale by Score and Rank: Mean scores (measured from 1 = not at all important to 9 = very important) and values by rank (1 = most valued, 8 = least valued) for each nation appear in Table 2.

Table 2: List of Values Average Scores and Rank in the 4 Countries

Value	UK		Germany		Japan		Hungary	
	Mean	Rank	Mean	Rank	Mean	Rank	Mean	Rank
Self-Respect	8.26	1	8.08	1	6.54	6	8.44	4
Security	7.93	2	7.77	3	7.86	2	8.76	1
Accomplishment	7.82	3	7.50	5	7.17	5	7.68	6
Warm Relationships	7.78	4	7.63	4	7.95	1	8.48	3
Fun and Enjoyment	7.59	5	8.02	2	7.63	3	6.21	8
Self-Fulfillment	7.46	6	6.71	8	7.48	4	7.74	5
Being Well Respected	7.43	7	6.97	7	6.40	7	7.65	7
Sense of Belonging	7.35	8	7.18	6	4.98	8	8.22	2

The sample of UK older respondents ranked "self-respect" followed by "security" as their highest values. In Germany, "self-respect" was the top score, too, with "Fun and enjoyment" being second. The Japanese respondents gave a top mean score to "Warm relationships with others", followed by "security". In Hungary, "security" was highest and "Sense of belonging" was the second highest. The least important values were: "Sense of belonging" in the UK and Japan,, "Self-fulfillment" in Germany, and "Fun and enjoyment" in Hungary.

LOV by Cognitive Age Decade: The LOV scores are further investigated in relation to four cognitive age groups. The four groups were formed along cognitive age decades (cognitive age in e.g. the 50s), comprising of cognitive ages lower than 50 (<50s), cognitive ages in the 50s, 60s, and finally cognitive ages equal to 70 or greater (>=70s). The ranking/ mean scores of values for our respondents slightly fluctuates with cognitive age. In Germany for example, "Security" and "Fun and enjoyment" switch ranks in higher cognitive age, thus as the cognitive age of older Germans increases, security appears to become more important and "Fun and Enjoyment becomes less important. Similarly, the lower the cognitive age, the greater the importance placed on "Being Well Respected". In Japan, "Fun and enjoyment" is more important for those with a younger cognitive age, but becomes less important for older cohorts, who then place more importance on "Warm relationships with others". Cognitively younger UK adults value "Fun and Enjoyment" to a greater extent than do their cognitively older counterparts, while a sense of belonging becomes more important the older one feels. Finally, in Hungary cognitive age appears to affect the importance placed on "security", which has a positive relationship with cognitive age, while a "sense of belonging" becomes less important.

A Kruskal Wallis nonparametric test was calculated to check if there was an overall significant statistical rank difference between cognitive age groups for each value. A significant difference was found for "Warm relationships" in Germany (Chi-square = 10.109; df = 3; p = .018), "Self-fulfillment" in the UK (Chi-square = 7.577; df = 3; p = .056) – even though only on the 10% level – in Germany (Chi-square = 9.902; df = 3; p = .019), and Japan (Chi-square = 9.725; df = 3; p = .021), "Being well respected" in Germany (Chi-square = 7.753; df = 3; p = .051) and Japan (Chi-square = 8.587; df = 3; p = .035), "Fun and enjoyment" in the UK (Chi-square = 8.919; df = 3; p = .030) and Germany (Chi-square = 8.508; df = 3; p = .037), "Security" in the UK (Chi-square = 6.367; df = 3; p = .095), and finally "Self-respect" in Germany (Chi-square = 8.998; df = 3; p = .029).

Bivariate Kendall's tau b correlations between cognitive age groups and "Self-fulfillment", Being well respected" and "Fun and enjoyment" were computed and found negative and significant (Respectively: -.106, -.085, and -.036) in the UK. In Germany, significances were only found for "Self-fulfillment" (tau-b=-.127) and "Fun and enjoyment" (tau-b= -.150), while in Japan all three were significant (tau-bs: -.113, -.110, and -.083). This confirms the lower importance of the above three personal values with higher cognitive age. In Hungary, a significance was only found for security (tau-b = .131), with a positive relationship between cognitive age and this value.

DISCUSSION

In terms of cognitive age, the results for the mature markets in our sample countries reveal an average difference between actual age and cognitive age of 7 years in the UK and Germany and 5.5 years in Japan and 6.5 years in Hungary. I.e. in all countries studied, respondents felt younger than their actual biological by at least 5 years. Although a difference of 5-7 years is substantial, it is smaller than the difference of 10.3 years found by Szmigin and Carrigan (2000) and that of 10.3 and 9.7 years found by Sudbury and Simcock (2009) in the UK, or of 8.4 years found by Van Auken et al. (2006) for their Japanese sample. This is also lower than a difference of 11.97 years found in France by Guiot (2001) and of 10.2 years in Australia (Cleaver and Muller 2002). This may be due to the recent tendency for the youth bias – i.e. the difference between chronological age and cognitive age – to become smaller as the images of age and aging change. E.g. age 60 used to be perceived as old until recently, but with rising life expectancy and longevity it is nowadays not perceived as old, but rather middle-aged. It is as the saying goes, "50 is the new 40" or even the "new 30", i.e. people considered 'old' in previous generations are much younger now in outlook and appearance as well as attitude. Thus, there is no more need to adjust ones cognitive age downward so strongly as it used to be the case. Also, as life spans increase, the old '3 decades plus 10' i.e. 70 is the expected life span, is changing – so perhaps old is now measured on how long people expect to live. This is only speculation, but other researchers seem to back up this assumption. Catterall and Maclaran e.g. (2001) have argued that subjective age might also be a social phenomenon and that thus the usefulness and applicability of the cognitive age concept could change along with changing social attitudes such as the one towards aging. Indeed, the meaning of individual age categories is dependent on the given culture and social environment in which they are used (Maddox and Campbell 1985). Thus, it is to be expected that the meanings of distinct categories will differ between cultures, but a degree of consensus would be found among people in the same culture, with only minor variation from one person to another (Fry 1988).

In the Asian context, Chua et al. (1990) advanced the hypothesis that those identifying with the Chinese culture in Singapore have a higher cognitive age than those identifying with the English culture. In Malaysia, Ong et al. (2009) found the differences between chronological and cognitive age to be 10.8 years for a convenience sample of people aged 40 and older. Although preliminary, the results for the Japanese context tend to confirm a slightly lower age difference than in Europe. Overall, the results with respect to the applicability of the cognitive age concept and scale to both Western and non-Western context seem to confirm the findings from previous research (cf. e.g. Barak 2009). In a similar vein, the cross-cultural research by Barak and associates suggests that the cognitive age scale is reliable and can be used in diverse cultures and that there is a universal nature of the way human beings – irrespective of culture – perceive and feel about cognitive age (Barak et al. 2001; Barak et al. 2003; Mathur et al. 2001). However, these studies also found that the cognitive age scale exhibits only partial measurement invariance across the three countries, which implies that culture may play at least some role in the perception of age (Mathur et al. 2001). This is partly supported by Uotinen's (1998) study which showed differences between residents of Finland and those in the northeastern United States in terms of cognitive age, with the former expressing a greater acceptance of their present age status. Nevertheless, despite some cultural differences in subjective age perceptions, the empirical evidence collected so far in various countries rather indicates that cognitive age is a universal characteristic, irrespective of the cultural background. Our study seems to confirm this for the overall tendency to feel younger than one's biological age, but there are still differences in terms of the magnitude of the difference between actual age and cognitive age.

Cognitive Age and LOV Differences: Any cross-cultural comparison of our data is difficult since perfect equivalence of meaning and measurement is not guaranteed. However, preliminary data analysis suggests at least partial measurement invariance for our samples. A tentative interpretation of the ranking similarities and differences between older respondents in the four countries seems to point to a strong importance of "Security" but to a substantial ranking difference of the importance of "Self-respect", ranked first by British and German respondents, but sixth by Japanese and fourth by Hungarian respondents. In addition, Japanese respondents give top ranking to "Warm relationships with others" while it comes third for Hungarians and fourth for both British and German respondents. This finding suggests the overall importance of this value for older consumers. "Fun and enjoyment" seems to be fairly important to Germans and Japanese (ranked second and third respectively), but not so important for British (ranked fifth) and rather unimportant for Hungarians (ranked last). Finally, while British, German and Japanese older consumers do not perceive "Sense of belonging" as particularly important (ranked eighth, sixth, eighth, respectively), it is the second most important value for Hungarians. Cultural and historical effects may be at play here, but further research is necessary to establish whether this is really the case or not.

Even though probably quite problematic to compare due to time differences and the nature of the study, it may be interesting to mention some results on older US consumers from the study by Kahle et al. (1988) to which Sudbury and Simcock (2009) also compared their results. Kahle et al. (1988) found that the three most important values to those US consumers aged 60 and older in 1976 were ""Security", "Self-respect" and "Warm relationships", while in 1986 the order was "Warm relationships", "Security", and "Self-respect" (Kahle et al. 1988). They also found substantial changes between their data from 1976 and 1986 and then further changes in 2007 in a follow-up study (Gurel-Atay et al. 2010). Indeed, comparing rank-order cor-

relations between 1976 and 2007 revealed that only Americans age 60 and older showed a significantly different ranking of values than those in 2007 in terms of the relative importance of the nine values (Gurel-Atay et al. 2010: 60). This means that values changes mainly occurred among older cohorts. In 2007, the most important values to consumers age 60 and older were "Self-respect", "Self-fulfillment", and "Warm relationships" (Gurel-Atay et al. 2010).

An additional study by Muller et al. (1992) compared LOV data for younger and older baby boomers from the US and Canada at three points in time (1976, 1986 and 1989). Results tended to show not only cross-sectional differences at the same period but also sequential shift over time. Overall, the following cultural differences were found: "Warm relationships" and "Self-fulfillment" were found to be more important for Americans than for Canadians, who valued "Security" more than Americans. In relation to age group, a drop in importance of "Fun and enjoyment" was noted between the younger and the older group in Canada but not in the US. However, the importance of "Self-respect" and "Sense of accomplishment" tended to increase with age for both groups. These results confirm that age has an impact on value importance but that additional underlying cultural factors and time are also influencing the value system of consumers.

CONCLUSION AND PRACTICAL IMPLICATIONS

Findings showed that mature consumers in the UK, Germany, Japan and Hungary feel on average 5-7 years younger than their actual age. This is in line with research from other countries, lending support to the assumption of cognitive age as a self-concept being – at least to a certain extent – culture free or universal. Specifically, it seems that the phenomenon of older people having age identities different from their chronological age as well as the direction of the differences (and the factors influencing it) may be universal, while the detailed characteristics of cognitive age and the magnitude of the age difference may be influenced by individual, social as well as cultural factors.

Our results indicate that Sudbury and Simcock's (2009) approach of combining cognitive age and personal values to better understand older consumers is a viable one and also applicable to other countries such as Germany, Japan, and Hungary. Using subjective age measures and personal values will help to change the traditional way of viewing the mature market as a monolith and to open the path for breaking it up into different segments. Companies following this approach should become able to better cater to the needs of older consumers, thus increasing business opportunities while at the same time contributing to the well-being of the fastest growing age group in the world.

Indeed, this study has important implications for marketing practice. In advertising, for example, the use of "cognitive-age congruent" models or spokespersons should prove fertile as a consumer's self-perceived age interacts with the perceived age of the model or spokesperson seen in an ad, and can subsequently influence the response to the advertising message (Chang 2008; Van Auken and Barry 2009). This may also explain why older people are often underrepresented in advertising, a fact that also holds true for TV commercials in the UK (Simcock and Sudbury 2006), Germany (Kessler, Schwender, and Bowen 2010), and Japan (Prieler et al. 2009). Research has also shown the importance of understanding motivational differences that underlie the effects of aging on attitudes toward and recall of advertisements (Drolet, Williams, and Lau-Gesk 2007) and heeding to the cognitive age as well as the values of the target group will likely be an additional, crucial factor.

From an international marketing perspective, the study lends support to the usefulness of self-perceived age together with per-

sonal values as a way of segmenting and targeting senior consumers across the globe. In the same way as a youth segment represents an example of a universal global common segment (Kjeldgaard and Askegaard 2006), there is growing evidence that a 'young at heart' senior global market exists (Barak 2009) and this study lends further support to that. That is not to suggest that older adults can be treated as an undifferentiated monolith. Indeed, the differences between the nations suggest that local differences still need to be considered in advertising and positioning strategies. Nevertheless, it provides a starting point for marketers wishing to target this growing and important global phenomenon that is the senior market.

Seeking the Opinions of Others Online:
Evidence of Evaluation Overshoot

Brent Coker, University of Melbourne, Australia

The internet has evolved into a social tool whereby people share their life experiences with the world. This sharing of information provides opportunities to seek the opinions of others about products to aid purchase decision making. Product review sites, blog comments, star rating systems, and discussion forums are some of the sources commonly referenced before actual purchase.

Consumers sharing information about their experiences with brands is of course not new. Past research identified early on that purchase decisions may be influenced by conversations with friends or family, or from reading consumer reports (e.g., Dichter 1966). What is new however is the amount of information available from people who are unknown to the purchaser. Most product reviews have been written by strangers, which may dilute the credibility of the review to some extent. Traditional word-of-mouth is more likely to be between trusted sources such as friends and family, or endorsed third party organizations (Brown and Reingen 1987). However, with online sources there is more chance of reviews being inaccurate as a result of contamination such as dishonesty or rumor (Dellarocas 2003). For example, in early 2009, a cosmetic surgery company was ordered to pay $300,000 in penalties and costs for writing false positive customer reviews about the quality of their service (Miller 2009). In another example, false rumors about Kryptonite bicycle locks cost the company significantly from a false instructional movie posted on uTube explaining how easy the locks were to pick. Actual estimates of how authentic most product reviews are online are difficult to determine, though exploratory studies in some product categories suggest a significant number of positive product reviews are false (Shay and Pinch 2005).

In order to form a balanced judgment, and mitigate the chances of forming a positive evaluation form false positive review, consumers are motivated to process both negative and positive information about a brand. Reading positive reviews about a hotel on tripadvisor.com for example is often accompanied by reading negative reviews in order to identify what could go wrong, no matter how rosy the positive reviews may be. Thus, the development of a brand judgment from review information may involve online processing of both negative and positive information. In fact, it is rare to find a product that has attracted entirely positive or negative reviews; there are always some consumers who appear to have had a better, or worse, experience with a product or service than the majority. Reviews on a five-star rating system for example typically resemble a negative skewed distribution for popular products, and a positive skew for unpopular products.

Although the effects of negative WOM vis-à-vis positive negative WOM have been explored (Richins 1983), there is little understanding of how consumers form attitudes and judgments when exposed to both positive and negative information. It is important for Marketers to understand how consumer judgments are formed in this context given the internet is now a main source of information for product evaluations (Anderson et al. 2010) .Before the emergence of the internet, WOM networks were much smaller, characterized by single valenced information (Brown and Reingen 1987). Since the emergence of the internet as a social channel, consumers have more opportunity to evaluate a product using both positive and negative information than in the past.

Against this background, this study is the first to understand how consumers form brand judgments when word-of-mouth (WOM) information is mixed in valence. An individual's attitude towards the brand will take shape in a positive or negative direction as information of each valence is processed. (Blanc et al. 2008; Blanc and Tapiero 2001; Feldman and Lynch 1988; Schwarz and Bless 1992; Wilson and Hodges 1992; Wilson et al. 2000). Using asymmetric affective perseverance theory to explain judgments in these conditions, we document in two experiments evidence of judgment overshoot whereby the participants make overly positive judgments towards a product after processing mixed valenced information. The findings of this research contribute to the literature in several ways. First, this study is the first to investigate how consumers form judgments when exposed to mixed WOM information about a product Second, this is the first study to find evidence of judgment overshoot in the context of product attitude formation. Third, this study is the first to apply asymmetric affective perseverance theory to explain consumer behavior. In Sum, the goal of this research is to understand how judgments towards products and services are formed when information given about a product or service is a mixture of both positive and negative.

Asymmetric Affective Perseverance

Conventional wisdom suggests that the order in which oppositely valenced information is presented will have no bearing on final judgment. For example, a negative review about a hotel after reading a positive review should result in the same end judgment as when the same reviews were read in the opposite order. Asymmetric Affective Perseverance holds however that the order in which oppositely valenced information is processed does impact end judgments. Specifically, a shift from positive evaluation to negative evaluation is more difficult than a shift from negative to positive, consumers are less successful at adjusting their attitudes in a positive to negative direction than they are at adjusting their attitudes in a negative to positive direction. This results in a more positive attitude when information is presented from positive to negative, than when presented from negative to positive order. Related theories have also posited that invalidated information may continue to contaminate future judgments (Bekerian and Bowers 1983; Greenwald and Banaji 1995; Lindsay and Johnson 1989).

The phenomenon of asymmetric affective perseverance is attributed to people's relative difficulty in shifting their attitude in a positive to negative direction, than in a negative to positive direction. Anecdotally, a person given bad news when in a positive state of mind will find it the shift in ill often experience disbelief, deferral, and dismissal before a relatively negative affective state sinks in (Lubinsky 1994). In contrast, the shift from relative despair to happiness is often instantaneous, and has a stronger effect on imagined outcomes than negative factors. In general, human beings prefer to remain optimistic and are more willing and hopeful towards adopting a positive outlook than remaining in a relative state of negativity (Greenwald 1980).

People tend to prefer the positive side of things rather than the negative side (Greenwald 1980; Taylor 1988). This bias towards positivity is rooted in self serving attributions. Much research has documented evidence of people being over positive in their self evaluation. Tests have shown that people generally believe that they are better than they actually are on a number of factors (Alicke and Govorun 2005). For example, people's evaluation of other people, places, and things which they are associated with is often positively skewed (Pelham, Mirenberg, and Jones 2002). People believe they have improved more than their counterparts on a task (Wilson and Ross 2001), and tend to describe themselves in ways that cast them

in a more positive light (Dunning and Cohen 1992).

Wilson et al (2000), argued that oftentimes a person's attitude does not get completely replaced when it is overridden by a new attitude, and might continue to influence judgments even though the valence of judgment is opposite. To demonstrate, Wilson et al. showed participants photos of a sex offender, alongside the prosecutor responsible for convicting the sex offender. Participants also listened to taped descriptions describing each person. The aim was to evoke a strong negative attitude towards the sex offender, and a positive attitude towards the prosecutor. In the experimental condition, the photos were shown the wrong way around –the photo of the prosecutor was actually the sex offender. Participants' attitudes towards the sex offender were then measured and compared against the control group. The results found that attitudes towards the sex offender were significantly more positive in the experimental group than in the control group, suggesting the positive attitude that was evoked when it was thought the prosecutor was the good guy continued to contaminate judgments when replaced.

Wilson et al's (2000) experiment demonstrated contamination of positive attitude on negative attitude. Golding, Fowler, Long, and Latta (1990) on the other hand tested the contaminating effect of negative information on positive information, and found no effect. Participants were given facts about a person, with the experimental group receiving some negative facts. The group given negative facts were then told the negative facts were untrue. When measured, their attitudes were no different from the control group who were given no negative information. This seeming ability for people to better control the contaminating effects of negative information have been reported in other studies. For example, efforts to understand how inadmissible evidence given during a trial have contaminated judgments generally not found that negative information was easily discounted when jurors were told the information was inadmissible (Pickel 1995; Schul and Manzury 1990; Sommers and Kassin 2001).

Other literature documents evidence of asymmetric effect of affective contamination. Petty and Wegener (1994) found that rating the desirability of vacations in desirable holiday destinations lowered evaluations of taking a vacation in non-holiday destination city. After participants were made aware of the manipulation, their desires towards visiting the non-holiday destination cities were still less than the control group who were not told about the desirable holiday destinations. This experiment suggested the participants under-corrected their evaluations, and were unsuccessful at completely correcting for the mental contamination from the holiday destination priming. Effects of imperfect memory replacement have been reported in at least two other studies (Bekerian and Bowers 1983; Lindsay and Johnson 1989)

One explanation for asymmetry in attitude adjustment might be because negative attitudes are easier to retrieve than positive attitudes, and therefore are held more salient and therefore more easily updated than positive attitudes. Eiser et al (2003) for example demonstrated asymmetry in the acquisition of positive and negative evaluations, suggesting positive experiences tended to predominate over negative ones. People might be more reluctant to change their attitude from good to bad than they would be to change their attitude from bad to good, because shifting from positive to negative results in a loss of mental positivity.

Experiment 1

The purpose of Experiment 1 was to assess attitudes towards a product after the information shaping the attitude was invalidated. Specifically, the design of experiment one simulated the scenario of processing information about a product online that turned out later on to be untrue. Such a situation might occur for instance if a consumer reads a review about a product online, reads a rumor, or reads some information about a brand on a social networking which they later find to be false. Consistent with the theory of asymmetric affective perseverance, we should be positive attitude contaminating judgments towards the brand after positive information is invalidated, and negative information having a non-contaminating effect.

Participants, Design, and Procedure. By email, 229 undergraduate students were invited to participate, of which 128 accepted. Respondents were randomly assigned into a control or experimental group. Both groups were told about two new apparel fashion brands who sold a wide range of formal and casual clothing for men and women that were soon to start selling in the local market. Both brands, Rokit and Rokout, were described by six neutral facts each to illicit ambivalent and equal attitudes between each brand.

Although the aim was to illicit neutral attitudes, it was understood that respondents would likely form at least mild attitudes even if the information given was neutral (Bargh et al. 1996; Fazio 1995). The aim was to minimize attitude strength. After evaluating each brand from the information given, respondents were asked to rate their attitudes towards each brand on three items (-3 = bad, negative, undesirable; +3 = good, positive, desirable). Intentions to purchase each brand were also measured on four items measuring likelihood (seven-points: 1= very low, 7 = very high), probability (seven-points: 1= very low, 7 = very high), willingness (seven-points: 1= very low, 7 = very high), and agreement with the statement "I would consider purchasing Rokit/Rokout clothing" (seven-points: 1= strongly disagree, 7 = strongly agree).

The experimental group was told that talk of these two brands coming to the local market had stirred considerable discussion on social networking sites such as Facebook, MySpace, Bebo, and Twitter. Then, a summary of topics discussed about each brand was listed. The Rokit brand had six negative topics, designed to evoke a negative attitude towards the brand. The Rokout brands also had six topics, but were all positive, designed to evoke positive attitudes towards the brand. Then, respondents were told that expert investigators were hired to scrutinize the facts about each brand and determine if they were true. The investigators discovered the facts were all untrue, except for the original neutral facts. The aim was to motivate respondents to re-evaluate each brand, discounting the false information they had heard. Once again, attitudes and intentions to purchase were measured, and respondents were asked to choose which brand they preferred. The experiment was conducted on a web survey.

Results. Before the manipulation, mean attitude for the Rokit brand in the control group was 0.56 (*SD* = 1.10), and mean attitude for the Rokout brand in the control group was 0.56 (*SD* = 1.28). Mean attitude for the Rokit brand in the experimental group was 0.87 (*SD* = 1.01), and mean attitude for the Rokout brand in the experimental group was 0.91 (*SD* = .88). These preliminary tests suggested perceptions of the brands were similar, providing a good base for comparison.

After manipulation, a paired samples t-test suggested the manipulations were successful. Attitudes towards the Rokit brand were significantly lower (*M* = -1.63; *SD* = 1.47) $t(55)$ = 12.66, $p < .0001$, and attitudes towards the Rokout brand were significantly higher (*M* = 1.96; *SD* = .86) $t(55)$ = 8.50, $p < .0001$ than before the negative and positive rumors were given. Furthermore, likelihood of purchase was lower after reading the negative rumors about the Rokit brand (*M* = 2.72; *SD* = 1.58), $t(55)$ = 8.27, $p < .0001$, and higher after reading the positive rumors about the Rokout brand (*M* = 5.31; *SD* = 1.09), $t(55)$ = -7.95, $p < .0001$. When asked to choose a brand, 93% chose the positively evaluated Rokout brand.

The experiment predicted that consumers' should be successful at reverting attitudes towards a brand back to the same state of indifference when negative information is discredited. In contrast, positive information should continue to contaminate judgments after invalidated. After respondents were told the positive facts about Rokout were rumors and were untrue, attitudes remained significantly higher in the experimental group ($M = 1.05$; $SD = .99$) than in the control group ($M = 0.56$; $SD = 1.28$), $F(1, 127) = 5.48$, $p < .05$. Furthermore, likelihood of purchase continued to be higher in the experimental group ($M = 4.57$; $SD = 1.09$) than in the control group ($M = 4.09$; $SD = 1.36$), $F(1, 127) = 4.75$, $p < .05$.

Contrasted against the positive rumor manipulation, after participants were told the negative information was untrue there was no difference in attitude towards the Rokit brand in the experimental group ($M = 0.58$; $SD = 1.15$) than in the control group ($M = 0.56$; $SD = 1.10$), $F(1, 127) = .02$, NS. Likelihood of purchase was also not significantly different in the experimental group ($M = 4.23$; $SD = 1.18$) compared to the control group ($M = 3.91$; $SD = 1.36$), $F(1, 127) = 1.94$, NS.

Twenty percent of participants who originally chose the Rockit brand (before the manipulation) ended up choosing the Rockout brand after they were told the rumored facts were false. Two percent who originally chose the Rokout brand ended up choosing the Rokit brand.
Figure 1: Attitudes towards Rokit and Rokout apparel brands as a function of rumored information manipulations.

Experiment 1 Discussion

The results in experiment 1 found evidence of an enduring effect of positive attitude after invalidating positive information. The results suggested that participants were relatively successful at removing encoded negative information, but are unsuccessful at readjusting their attitude back to a state of relative indifference when removing encoded positive information. Those who were exposed to the discredited negative information had similar mild attitudes as those who were not exposed to any misinformation. In contrast, those who were exposed to discredited positive misinformation had significantly higher attitudes towards the brand than those who were not exposed. The results add evidence to the prediction that re-encoding of attitudes occurs asymmetrically, with negative to positive re-encoding being more complete than positive to negative re-encoding.

Experiment 2

The aim of experiment three was to test asymmetrical affective perseverance in the context of reading product reviews. Specifically, the contaminating effect of positive attitude on evaluation was tested in a hotel review exercise whereby positive and negative hotel reviews were presented in opposite order. To assess how time moderates affective perseverance, an additional variable of "length of time between reviews" was included. The aim was to assess how time trend information given about positive-to-negative or negative-to-positive ordered reviews might moderate asymmetrical affective adjustment. Earlier negative reviews followed by more recent positive reviews should be perceived as improvement and less likelihood of having a bad experience than if reviews are ordered from earlier positive reviews to more recent negative reviews. When time trend information is absent, such as when reviews about a hotel are taken from the same holiday weekend, we should observe a more positive skew in hotel rating when reviews are ordered from positive to negative because of positive contamination. In contrast, if trend information over time is available for reviews ordered from positive to

negative, then we should not observe a positively skewed evaluation of the hotel from positive contamination, because the reviews should suggest a decline in quality over time.

Participants, Design, and Procedure. Two-hundred and eighty undergraduate and graduate students were invited to participate by email. One hundred and thirty one responded. Participants were randomly split into four groups. All participants were asked to imagine they were planning a trip to Los Angeles with two of their closest friends. They were then shown five mixed reviews of a hotel taken from tripadvisor.com, and asked to imagine they were considering this hotel to book for their holiday. For consistency, all reviews contained references to staff service quality, room comfort, and hotel cleanliness. Actual location in LA and price information were not given. In addition to comments, each review had a graphic one, two, three, four, or five star rating from the reviewer. Two groups had the reviews ordered in descending order from five star to one star—positive to negative, and the other two groups had the reviews ascending from one star to five star—negative to positive. Two groups were told the reviews were taken in order over the previous year. The other two groups were told the reviews were taken from last weekend. This resulted in a 2 (review trend/no review trend) x 2 (positive-to-negative order/negative to positive order review) between subjects design.

Respondents were shown the reviews one-by-one, and given adequate time to read and consider each review. Then, respondents were asked to rate their attitudes towards booking the hotel on three items (-3 = bad, negative, undesirable; +3 = good, positive, desirable). Intentions to book the hotel were also measured on four items measuring likelihood (seven-points: 1= very low, 7 = very high), probability (seven-points: 1= very low, 7 = very high), willingness (seven-points: 1= very low, 7 = very high), and agreement with the statement "I would consider booking this hotel for our trip to LA" (seven-points: 1= strongly disagree, 7 = strongly agree).

Results. In the no trend information groups, attitudes towards booking the hotel when the reviews were ordered in a positive to negative order were higher (M = 4.06; SD = 0.98) than when the same hotel reviews were ordered in a negative to positive order (M = 3.55; SD = 1.14), $F(1, 55)$ = 3.19, p = .08. The difference was marginally significant. Intentions to book the hotel when the reviews were ordered in a positive to negative order were also higher (M = 3.55; SD = 1.29) than when the same hotel reviews were ordered in a negative to positive order (M = 2.83; SD = 1.39), $F(1, 55)$ = 4.00, p = .05. These results suggested positive contamination, consistent with the findings in study one.

When trend information was available, we expected to observe no positive contamination. Attitudes towards booking the hotel when the reviews were ordered in a positive to negative order were lower (M = 4.04; SD = 1.26) than when the same hotel reviews were ordered in a negative to positive order (M = 4.79; SD = 1.26), $F(1, 74)$ = 6.69, p < .05. Intentions to book the hotel when the reviews were ordered in a positive to negative order were also lower (M = 4.29; SD = 1.55) than when the same hotel reviews were ordered in a negative to positive order (M = 5.30; SD = 1.24), $F(1, 74)$ = 10.07, p < .01. However, this result does not disprove our assumption that trend information when reviews were ordered from positive to negative would attenuate positive contamination, leading participants to believe that the hotel was decreasing in quality over time. It does not eliminate the possibility that participants actually thought reviews ordered from negative to positive meant the hotel was improving over time, which would also explain the significant difference in attitudes towards booking when trend information was available. A test for interaction between trend information and order of review valance clarified what was happening.

The interaction was significant $F(1, 127)$ = 9.14, p < .01. Unexpectedly, the results suggested attitudes towards booking the hotel when reviews were ordered from positive to negative were the same whether trend information was given or not. In contrast, attitudes towards booking the hotel with trend information was significantly higher when reviews were ordered negative to positive than when no trend information was given (figure 3).

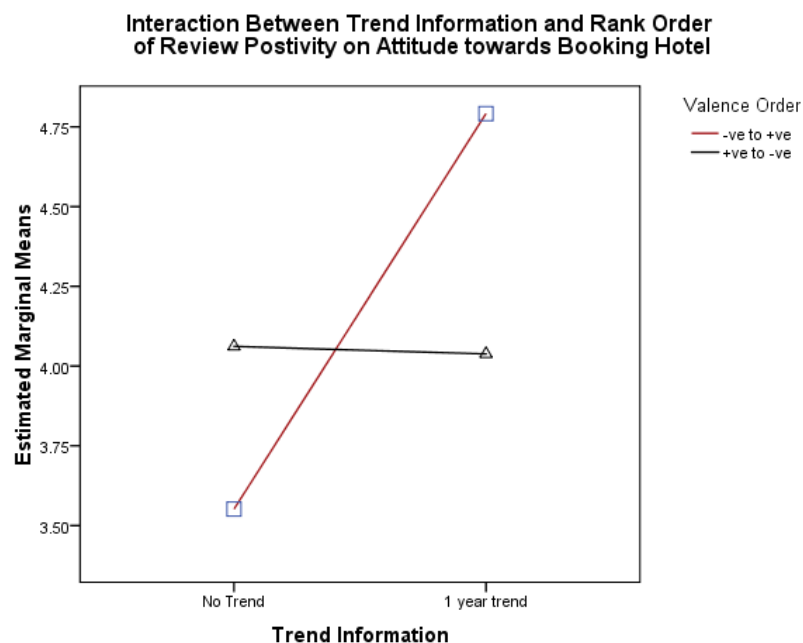
Interaction Between Trend Information and Rank Order of Review Postivity on Attitude towards Booking Hotel


Figure 2: Interaction between trend information and rank order of reviews

Discussion. The results were consistent with those found in study one. When the reviews were ranked from positive first to nega-

tive last, participants rated the hotel more favorably than when the reviews were ranked from negative to positive. This suggests participants were less successful at adjusting their attitudes from a positive to negative valence, than they were adjusting their attitudes from a negative to positive valance as attitudes were updated when reading the reviews. In other words, the positive reviews read earlier on appeared to have continued to contaminate judgments even after reading negative reviews.

The surprising result was that evaluations towards the hotel were the same between trend and no trend groups, when reviews were ordered from positive to negative. This suggested that participants did not perceive reviews ordered from negative to positive over time as evidence that the establishment was worsening in quality, and would therefore lead to greater chance of having a bad experience. One reason for this result may be due to design—just five reviews might not have been enough for participants to believe the trend over time was consistent, and therefore would not have reached the conclusion of worsening quality over time. In contrast however, there was a significant difference in trend for those presented with the reviews in a negative to positive order; they rated the hotel significantly higher when given trend information. Presumably, participants believed this was evidence the hotel was improving over time, a good sign they would enjoy a quality stay. This might have been an easier conclusion to reach with only five reviews than the other conclusion in the other group of worsening quality, and appears consistent with past research that people have a bias to prefer the positive side of things and hope for the best rather than focus on the negative side (Greenwald 1980; Taylor 1988).

General Discussion

This research documented evidence of asymmetrical affective perseverance when consumers form attitudes towards brands from information that is of opposite valence. Two experiments provide converging evidence that consumers may overshoot their judgments towards brands when positive information is found to be untrue, or is invalidated. In the first experiment, evidence of positive contamination was demonstrated after positive information was invalidated. Despite the information being discounted, participants continued to have significantly higher attitudes and intentions to purchase the brand than those who were not exposed to the manipulation. This research sheds light on the continued influence effect which suggests that discredited information on judgments is contingent on how the misinformation is replaced (Johnson and Seifert 1994, 1998), by showing that positive attitudes towards a brand are replaced less easily, and often incompletely, compared to negative attitudes.

The implications of this research for marketers are interesting. Consumers increasingly base their decisions to purchase from online review systems, and online communities are full of queries for advice on products and services to aid decision making. But although consumers have more information to aid their decision making than ever before, there is also more chance of hearing a wider gamut of evaluation, making evaluation more difficult as negative information must be weighed against the positive. The results of this research are encouraging to marketers by suggesting that consumers do not forget a good deed easily—good service given early on has at least some positive flow on to future judgments, even if the more recent information is comparatively negative. On the other hand, the results suggest consumers are relatively forgiving, being relatively successful at controlling previously encoded negative information from contaminating judgments when the information is replaced by more recent, or more accurate positive information. There is certainly power to the positivity of brands.

There are certain limitations to the findings of this research, which offer direction for future investigation in this area. In both studies, hypothetical brands were introduced. Thus, the asymmetrical replacement affect demonstrated in this research was not tested on existing brands. It was assumed that attitudes are context sensitive constructions, which easily change as new information is encoded. Attitudes were constructed on the spot, rather than formed slowly over time. Accordingly, one could argue that some negative attitudes could be more enduring, and therefore more difficult to replace. For example, research into aversive racism has found that people may hold strong implicit attitudes towards other people which are very difficult to change (Gaertner and McLaughlin 1983).

MANIPULATIONS

Experiment 1

Rokit Apparel Company Neutral Facts

- Rokit was founded by Peter Thompson in 2002
- Rokit's offices are located in Holmby Hills in Los Angeles
- Rokit currently has 40 employees
- Annual revenue of Rokit clothing is 16 million
- Rokit has plans to expand and open new stores in Arazona and New Mexico
- the corporate colors of Rokit are blue and yellow

Rokout Apparel Company Neutral Facts

- Rokout was founded by John Watson in 2002
- Rokout's offices are located in Palos Verdes in Los Angeles
- Rockout currently has 39 employees
- Annual revenue of Rokout clothing is 15 million
- Rokout has plans to expand and open new stores in Oregon and Washington
- The corporate colors of Rokout are red and black

Rokit Apparel Company Negative Facts

- Rokit were recently fined by local authorities for false advertising
- Rokit were recently under investigation for exploiting foreign workers in their factories
- Two factories owned by Rokit continue to pump industrial run off into nearby rivers without regard for the local ecosystem
- Rokit is known for being a difficult place to work, underpaying employees and offering few benefits to employment
- Rokit is known for taking immediate legal action against retailers who do not pay on time
- Rokit factories are known for producing higher than average carbon emissions

Rokout Apparel Company Positive Facts

- Rokout performs routine checks on the working environment and conditions in their factories
- Rokout uses biodegradable packaging to package all their apparel before shipping.
- Rokout donates 1% of all revenue made on apparel sales to support cancer research
- Rokout cares about small clothing stores who sell their apparel, and offers generous payment terms and does not take court action against non-payment until all other options have been explored
- Rokout offers generous working conditions to employees including subsidized medical insurance and paid annual leave
- Rokout has invested in research to reduce carbon emissions from their factories

Experiment 2

The asymmetric effect moderated by temporal distance

2 (review valence order) x 2 (long/short timeframe) between subjects design

[Temporal manipulation –Short timeframe]:

The following reviews were all submitted to a well known online Hotel Review website. The Reviews are all from the second weekend in February 2010.

[Temporal manipulation – Long timeframe]:

The following reviews were all submitted to a well known online Hotel Review website. The Reviews, in order they were taken, span January 2009 through to January 2010.

Imagine you are planning a trip to Los Angeles with two of your closest friends. In planning your trip, you consider the following hotel which is within your budget. Please read the reviews from people who have stayed in this hotel, and answer the questions that follow.

[For consistency, all reviews contained references to: staff service quality, room comfort, and cleanliness.]

HOTEL A

REVIEW ONE

Staff on the front desk gave us the key to our room, and were rude. Upon arriving at the front door we wanted to leave, the carpets were filthy, plaster was peeling off the walls and when we opened the door we could have cried. The room was terrible. The furniture looked extremely dated and the shower area was disgusting. The bed was hard and uncomfortable. Went down to the front desk and asked if we could change rooms, the new room was even worse. With this in mind we checked out and booked into a different hotel across the road. In all honesty this was the worst hotel that we have ever stayed in (albeit very short)

★☆☆☆☆

REVIEW TWO

The air-con is in the corner alcove so air circulation to the bedding area is next to nonexistent. Bed is crammed in there so you can barely get out of it on 1 side and the TV credenza at the foot of the bed also blocks egress. The Kitchen and living area were great with lots of space. The carpet baseboard was coming off in 1 corner. Bathroom had previous guest's hair in the tub and on the floor, but room service were able to remedy that when we called down to the desk. Sink made a horrible noise when you turned the water on. You cannot have the closet and the bathroom door open at the same time as they block each other. Some plaster issues in the bath. Staff were reasonably courteous, but could have been better.

★★☆☆☆

REVIEW Three

This hotel is merely ok to me. The rooms are kinda smallish, but they are pretty nice. They have nice LCD type TV's, and a nice little kitchen. They are pretty small, however, for this kinda hotel. It is average overall, but staff were quite helpful recommending some nice restaurants down the street.

★★★☆☆

REVIEW FOUR

Room was fine, bed very comfy! Bathroom is on the small side, but was fine for a hotel bathroom. We had no problems with the staff. Breakfast was *very* busy, food was great, but it was difficult to get a seat. We took our breakfasts back to our room. Room servcie were on time, and did quite a good job cleaning up. Good experience overall.

★★★★☆

REVIEW FIVE

I have to say from start to finish this has been one of the better stays I have experienced at a hotel. The staff at the hotel was probably the most polite and attentive people I have come across. Whenever we needed something, they were all very engaged and very helpful. The room itself was better than I expected. With very clean and nicely done bedrooms, separate bathroom, and rather big kitchen area - complete with most everything you would need. The free breakfast buffet each morning was awesome and was changed up daily. I can't say enough how impressed I was with everything. All in All... this is the place to stay when going to L.A.

★★★★★

The Processing of Threat Appeals in the Prevention of Obesity: Weighing the Weight Issue

Birgit Wauters, Vrije Universiteit Brussel, Belgium
Malaika Brengman, Vrije Universiteit Brussel, Belgium
Wim Janssens, Universiteit Hasselt, Belgium

OBESITY AND USING THREAT APPEALS TO PREVENT OBESITY

According to the estimations of the World Health Organization a quarter of the worldwide population is overweight and 6.13% have a BMI higher than 30, indicating obesity. While mass media campaigns have an important responsibility in raising awareness about obesity and other unhealthy behaviors (Lewis, Watson, and Tay 2007; Miles, Rapoport, Wardle, Afuape, and Duman 2001), the effectiveness of such campaigns is not always clear (Brengman, Wauters, Macharis, and Mairesse 2010) and therefore questioned by some researchers (Berry 2006; Hillsdon, Thorogood, White, and Foster 2002). One frequently used message tactic in campaigns promoting health behavior change is a threat or fear appeal (Wong and Cappella 2009). By describing the negative consequences of certain riskful actions, e.g., lung cancer for smokers, social marketers try to convince the receiver of the message to adopt the change in behavior or lifestyle that the message prescribes (Witte 1992). While numerous academics have proposed different theories to explain the process through which threat appeals motivate behavioral change (Janis 1967; Leventhal 1971; Rogers 1975), the underlying theoretical framework for our study is the '*Extended Parallel Process Model'* (EPPM) presented by Witte (1992), as it integrates various previous theories in order to explain when and why threat appeals are effective and why they sometimes fail. According to the EPPM, which integrates Leventhal's (1971) '*Parallel Process Model*' and Rogers' (1975) '*Protection Motivation Theory*', two parallel message appraisals occur when someone is exposed to a threat appeal message: (1) '*threat appraisal*' and (2) '*efficacy appraisal*'. '*Threat appraisal*' involves the assessment of (i) the '*severity*' of the threat (i.e., how severe are the negative consequences) and (ii) the '*susceptibility*' to the threat (i.e., how vulnerable am I to this threat). Someone has to perceive the threat as severe and to be at risk in order for the threat appeal to produce the necessary fear to motivate action. '*Efficacy appraisal*' or coping appraisal involves the assessment of (i) '*response efficacy*' (i.e., the belief that the recommended behavior is actually effective to avert the threat) and (ii) '*self-efficacy*' (i.e., the belief to be able to perform the recommended behavior). According to the EPPM (Witte 1992), threat appeals can have three different effects based on these two message appraisals: a null effect, an intended effect (i.e., '*danger control*') or an unintended effect (i.e., '*fear control*'). When perceived threat is low, threat appeals are assumed to have no effect on behavioral change. In this case people are not motivated to perform the recommended behavior because they do not feel the health risk is serious or personally relevant. If the message fails to evoke at least some moderate threat, Witte (1992) argues that it will not motivate people to consider the '*efficacy appraisal*'. On the other hand, when perceived threat is high, the ultimate response to the threat appeal will depend on the '*assessment of efficacy*'. In case perceived efficacy is high, people will engage in '*danger control*' (i.e., attempting to control the threat by performing the recommended behavior as intended by the sender of the message). If the perceived efficacy is low, however, people may try to manage their fear by engaging in an unintended maladaptive response: '*fear control*' (i.e., alleviating the fear by denial of the threat). Hence, as fear causes a negative emotional state, the person experiencing this emotion wants to neutralize this feeling by either coping with the risk and following the recommended behavior (i.e., cognitive reaction / danger control) or by reacting defensively and denying the potential problem (i.e., emotional reaction / fear control) (Tanner, James, Hunt,

and Eppright 1991). The proposed danger has to be experienced as relevant and the recommended behavior will only reduce the threat if it is seen as effective (Das, de Wit, and Stroebe 2003). Thus far not many studies have been conducted with the threat of overweight and obesity as a specific topic. In a study about the effects of threatening communication towards mothers on their health beliefs and the weight of their obese children, Kirscht et al. (1975) investigated the role of different levels of threat on the weight of obese children. Results showed that the threatening communication had a positive effect on the weight status of the children: the most threatening communication caused the most weight loss, followed by the low level threat appeal and the control group.

RESEARCH OBJECTIVE

This article investigates the processing of threat appeal messages against obesity, and more specifically the possible differences in processing between people who think they experience overweight or obesity and persons who do not think they are overweight or obese. The hypotheses will be based on the threat appeal framework of Witte. A meta-analysis indicates that the stronger the evoked fear, the more persuasive the threat appeal is (Witte and Allen 2000). Therefore we claim that a threat appeal which evokes fear will have a positive relation with behavioral intention.

Hypothesis 1:   *Evoked fear has a positive effect on behavioral intention.*

Finding the problem of overweight and obesity severe, one of the elements of the threat appraisal, will probably result in feeling fear and wanting to overcome the overweight issue.

Hypothesis 2a: *Perceived severity has a positive effect on evoked fear.*

Hypothesis 2b: *Perceived severity has a positive effect on behavioral intention.*

Since '*perceived susceptibility*' is conceptualized as 'an individual's beliefs about his or her chances of experiencing a threat' (Witte 1992, 332), people who find themselves highly susceptible to overweight or obesity are expected to indicate feeling emotions of '*fear*'. They probably will also be motivated to do something about their problem and will most likely have the intention to change their current lifestyle and behavior.

Hypothesis 3a: *Perceived susceptibility has a positive effect on evoked fear.*

Hypothesis 3b: *Perceived susceptibility has a positive effect on behavioral intention.*

Having a threat appeal message with strong arguments and a good recommended response to avert the threat (in our case: talk to your GP about overweight or obesity) will enhance the '*response efficacy*'. If the recommendation is seen by the respondent as effective, this will have a positive effect on the behavioral intention. The perceived response efficacy of the message will, on the other hand, have

a negative impact on the evoked fear. If the respondent positively evaluates the response efficacy, he or she will feel less fear.

Hypothesis 4a: *Response efficacy has a negative effect on evoked fear.*

Hypothesis 4b: *Response efficacy has a positive effect on behavioral intention.*

'*Self efficacy*' refers to the perceived ability of a person to act on the recommendation. In this study self-efficacy captures a person's perceived ability to keep his or her weight under control. If one finds him/herself easily capable of keeping his/her weight under control and not sliding off to overweight or obesity, the threat appeal will most likely not evoke any emotions of fear. The effect of self efficacy on behavioral intention and evoked fear is expected to be negative in this context.

Hypothesis 5a: *Self efficacy has a negative effect on evoked fear.*

Hypothesis 5b: *Self efficacy has a negative effect on behavioral intention.*

If the receiver finds the message of personal relevance, he or she will process the information carefully (Ajzen, Brown, and Rosenthal 1996). In this case the person can make a thorough judgment of the quality and effectiveness of the threat appeal. A more thorough, systematic and further elaboration of the message content is made, if people are highly involved with the message topic (Petty and Cacioppo 1986). When the threat of being obese or overweight does not attract the receiver's attention, he or she will not be motivated to process the message in depth and hence, this will influence the effectiveness of the appeal negatively. When people report not feeling overweight or obese, the threat message will be less relevant since they already perceive to successfully keep control of their health and weight. Pritchard, King, and Czajka-Narins (1997) stated in a study on body mass indices and self perception that someone's perception of his or her weight is more important than the actual BMI category regarding his or her reception of health programs. If someone feels overweight or obese, this person will be more likely to respond to health programs, regardless of actually belonging to the overweight or obese BMI categories. Therefore we hypothesize that respondents with feelings of overweight will be more motivated to process the threat appeal and thus will have stronger relations between the elements of the coping and threat appraisals and behavioral intention.

Hypothesis 6: *People perceiving themselves as obese or overweight will display stronger relations between perceived severity, susceptibility, response efficacy and self efficacy and behavioral intention than respondents who do not think they are overweight or obese.*

METHODOLOGY

The respondents were asked to participate in the study and were given a paper and pencil-based questionnaire consisting of two parts; the first part had to be filled in before the respondents were confronted with the threat appeal message and gauged for the participants' health behavior. After exposure to the appeal they were asked to fill in the second part containing questions about the threat appeal, such as the level of '*evoked fear*', '*self efficacy*' and '*response efficacy*', '*severity*', '*behavioral intention*' and '*susceptibility*'. Their perceived weight status

and body mass index (BMI) was also asked in the questionnaire. 169 participants were found, 87 females and 82 males, with a mean age of 27 years (min. 17, max. 60, SD= 10). Two threat appeals with different levels of fear were developed with respect to the issue of obesity and its consequences. The high threat message presented severe consequences of being overweight, e.g., high blood pressure, a stroke and cancer. The stimulus with the low level of threat had as consequences among others: skin problems, high cholesterol and back problems. The illustration in the advertisement for the low threat was: a white background with 6 rulers indicating a fictive percentage of the mentioned consequences and next to the rulers the different consequences cited in the text was labeled. The high threat had a black background with a noose made of a measuring cord, stipulating that one with obesity is condemned to be hanged by the threat.

The choice was made not to work with the BMI due to several reasons. First of all, the respondents were asked to fill in their own weight and height what could lead to a wrongful estimation of these parameters (Kuczmarski, Kuczmarski, and Najjar 2001). A second restraint against using the BMI is that it does not take into consideration the amount of body fat (Kuczmarski and Flegal 2000), nor does it take into account the skeletal size, amount of body water, muscle mass and gender. Kuczmarski and Flegal (2000) gave the example of a very athletic and muscled person who may be heavy but does not have excessive body fat. Seeing that relative weight and the body mass index do not quantify total body adiposity (Gray and Fujioka 1991) it cannot be concluded that everybody who is overweight also has too much fat nor can we say that people who are not obese will not have obese levels of body fat (Frankenfield 2001). Furthermore, studies have indicated that ethnic differences also play an important role in percentage of fat and BMI (Bell, Adair, and Popkin 2002; Deurenberg, Deurenberg-Yap, and Guricci 2002). Another reason for not using the BMI is that its categories are static, meaning that a person weighing 63,7kg and measuring 1,60m has a BMI of 24,88 is labeled as having a normal weight and somebody with a weight of 64kg and the same height is labeled overweight, although those two persons differ only 300grams in weight. Add to this the differences of cut offs between health organizations and the changes of these cut offs during the years (Kuczlarski and Flegal 2000). When applying the cut offs of the *Third National Health and Nutrition Examination Survey* data, the USA counts 61.7 million overweight people. When using the BMI categories of the WHO this number increases with more than 20 million, leading towards 97.1 million overweight citizens in the United States (Kuczmarski and Flegal 2000). The current weight status is also very important in regard to own perceptions of normal and overweight classification. Crawford and Campbell (1999) found differences between the health authorities' definitions of ideal and overweight and the people's definitions. On top of this, lay definitions also varied across sex, ages and current weight status. Men and women, who were not overweight by the BMI classification but considered themselves to be overweight, engaged in actions towards weight loss and prevention to gain weight. These own perceptions of weight status are very important seeing that it is unlikely that somebody who does not believe having a weight problem will be susceptible for weight control promotion (Crawford and Campbell 1999; Pritchard et al. 1997). Given above mentioned reasons we expect that the respondents' own opinion about their body and weight/height ratio will be more suitable for this study. These findings are supported by the study of Rahman and Berenson (2010). They examined whether low-income multiethnic women of a reproductive age perceive their weight correctly. The investigated population included both overweight and normal weight women. Rahman et al (2010) concluded that weight misperception, perceiving oneself as overweight but not being overweight according to authorities' measurement and the other way around, is common for women with overweight as well as for women without

overweight. An important recommendation is thus to take the person's own perception into account which is done in this study. The hypothesis that there might be discrepancies between being categorized in a certain BMI-category and a person's own judgment about being overweight or not was tested. A cross tabulation was conducted between (no) perceived overweight and the BMI categories and found significant differences between the 2 variables (χ^2= 65,184 df=4, p<.000). 10.3% of the respondents who were categorized in the overweight category according to the WHO did not perceive themselves as being overweight Also 25% of the respondents who fell under the cut-off of the overweight limit (BMI $\leq$ 24.9) consider themselves at risk of being overweight. These findings along with the reasons mentioned below, have led to working with the personal indication of being overweight.

MODEL CONSTRUCTS

The amount of fear evoked by the threat appeal, hereunder labeled as '*evoked fear*' (translated into Dutch from Madden, Allen, and Twibble 1988) was measured with 3-items (α =.79; "The advertisement is fearful, repulsing and upseting/distrubing"). All variables were measured on a five-point Likert type scale. '*Severity*' (3-items, α =.82; "How important do you find the problem of overweight and obesity", "How important do you find the possible consequences of overweight or obesity", "To what degree do you find overweight and obesity to be a societal problem"); '*susceptibility*' (3-items, α =.86; "The chance that one day I will suffer from overweight or obesity is very large", "I find it hard not to get overweight", "I often diet to keep my weight under control"); '*response efficacy*' (2-items, α =.74; "Somebody who suffers from overweight or obesity, can easily overcome this", "Keeping your weight under control is easy") and '*self efficacy*' (1-item; "If I would suffer from overweight or obesity, I would be able to easily overcome this"). The respondents'

behavioral intention was the dependent variable by Cronin et al., 2000 but translated (2-items, α =.86; "After seeing the advertisement, I will devote more attention to keep my weight under control"; "After seeing the advertisement, I will, if necessary, consult my family doctor to keep my weight under control"). The respondents were divided based on a median split between persons who think that they suffer from overweight or obesity, labeled as *(no) perceived overweight* ("I think I'm suffering from overweight or obesity").

RESULTS

Student's t-tests were conducted on perceived susceptibility and severity, response and self efficacy, evoked fear and behavioral intention for two groups of respondents based on their own perception of their weight status. The results (see table 1) reveal significant differences in the '*perceived susceptibility*' experienced by the two groups. Respondents who indicated that they think to suffer from overweight perceived themselves more susceptible (3.38 vs. 1.76, p <.001). The '*severity*' of obesity is not perceived differently by the two groups (p=.818). Also the '*amount of fear*' generated by the threat appeals led to no significant differences (p=.539). Respondents with no perceived overweight have a significant higher '*response efficacy*' (2.31 vs. 1.96, p=.009) and '*self efficacy*' (2.71 vs. 2.07, p <.001) than the respondents who feel overweight or obese. A significant difference in '*behavioral intention*' between people with no perceived overweight and those with overweight issues is also found. The results show that respondents who perceive themselves as overweight will have a significantly higher intention to change their behavior than people with no perceived overweight (2.66 vs. 1.90, p <.001).

	Perceiving no overweight [n=99]		Perceiving overweight [n=70]		
	M	SD	M	SD	p-value [c]
Perceived Susceptibility	1,76	0,778	3,38	0,953	<.001
Perceived Severity	3,96	0,734	3,93	0,818	.818
Response Efficacy	2,31	0,930	1,96	0,797	.009
Self Efficacy	2,71	1,052	2,07	0,89	<.001
Evoked Fear	2,77	1,015	2,87	1,039	.539
Behavioural Intention	1,90	0,884	2,66	0,923	<.001

Table 1: Two Tailed Student's t-test

To discover how the respondents processed the threat appeal message Partial Least Squares (PLS) path analysis, a variance-based technique, was used (statistical software application: SmartPLS 2.0 by Ringle et al. 2005). This method was preferred because of the small amount of respondents in each group. Chin and Newsted (1999) claim PLS to be a good estimator of path models when sample sizes are small. The recommended rule of thumb by Chin (1998) prescribes that the overall sample size should be at least 10 times the number of receiving causal arrows of the dependent variable with the largest number those incoming arrows. In our study, this dependent variable is '*behavioral intention*' which receives 5 incoming arrows; meaning that we need at least 50 cases to fulfill Chins (1998) rule of thumb. Given our number of participants, respectively 99 in the group of no perceived overweight and 70 in the group of people with perceived overweight, this sample size can be seen as sufficient "for obtaining stable estimates" (Chin 1998, 311).

Before looking at results, an evaluation of the quality criteria needs to be done. Hereby the used measures are tested on their reliability and validity (see table 2). The communalities reflecting the average percentage of variance explained by a row factor for this row factor, need to exceed the value of .5 according to Höck and Ringel (2006, 15) and this is accomplished in this model. The next measures of quality are the composite reliability and Cronbachs alpha (α). The composite reliability values are acceptable for both models as they all exceed .60 (Höck and Ringel 2006). The Cronbach alpha values are deemed good when $\alpha \geq$ .80, acceptable when $\alpha \geq$ .70 and for exploratory purposes when $\alpha \geq$ .60 (Chin, 1998). The scale reliability for behavioral intention on both models is below .70 (α= .67 for no perceived overweight and α= .64 for perceived overweight). Given an acceptable value for the composite reliability and the known underestimation of reliability by Cronbachs alpha (Chin 1998) these scales will also be considered as acceptable. The R^2 explains the overall effect size. In the model for people with perceived overweight, 28% of their behavioral intention and 20% of their evoked

fear is explained by the model. The percentages for people with no perceived overweight are somewhat lower; namely 22% for behavioral intention and 19% for evoked fear. All four R^2 values can be considered as ranging between moderate and low (Chin, 1998). Nevertheless, sufficient criteria for quality are met by both models, indicating these models as good and their results adequate for interpretation.

The next step is testing and interpreting the structural model, as displayed in table 3. The average variance extracted (AVE) reflecting the average communality for each latent factor and indicating convergent validity, needs to exceed the value of .5 according to Höck and Ringel (2006, 15). The two models fulfill this criterion. When looking at the two groups separately, the results reveal different processing patterns for people perceiving themselves as having overweight than for those who do not. Similar for both groups are the impacts of perceived severity on evoked fear (β= .326, p <.001 for no perceived overweight, β= .396, p= .003 for perceived overweight) and the significant relations between evoked fear and behavioral intention (β= .207, p= .042 for no perceived overweight, β= .324, p= .008 for perceived overweight). For respondents with perceived overweight, the perceived severity generated through the threat leads to feelings of fear and this evoked fear is the only motivation by which the respondents with perceived overweight process the threat appeal leading towards an intention to change their current behavior. No significant relations could be revealed either between the efficacy variables and behavioral intention or between the threat appraisal variables and behavioral intention for people with perceived overweight.

For people who do not find themselves overweight or obesity, a different way of processing is found. Here, significant relations are found for perceived severity (β= .251, p= .005), response efficacy (β= .443, p< .001), self efficacy (β= -.268, p= .015), and evoked fear (β= .207, p= .042) and behavioral intention, and also between the threat appraisal and evoked fear. Besides the afore mentioned similar relationships revealed among both groups, perceived severity also has a positive significant impact on evoked fear among respondents who perceive themselves as not overweight. Feeling vulnerable to the threat of overweight; '*perceived susceptibility*', will also lead to feelings of fear and shock (β= .179, p= .037). For people with no perceived overweight, response efficacy has the strongest impact on behavioral intention, followed by self efficacy. Taking a closer look, this last relation between self efficacy and behavioral intention is a negative one, what could be odd at first sight. However, looking at the content of the variables, the negative relation is explainable when following the reasoning of the respondents: '*I could easily overcome overweight or obesity, if I would suffer from it*' (self efficacy). '*But I do not think I'm overweight or obese*' (perceiving no overweight). '*So I will not pay extra attention to keep my weight under control*' (behavioral intention). The strongest influence on evoking fear comes from the supposed severity of obesity or overweight. In the overall model only one relation, namely between response efficacy and behavioral intention, is significant (β= .443 for no perceived overweight, β= -.019 for perceived overweight, *t-value*= 2.278 and p= .026). For people with no perceived overweight the evaluation of the response efficacy in the threat appeal had a significant higher impact on behavioral intention than for people with perceived overweight.

Perceived overweight (* p<.05 ** p<.01 ***p<.001)

	1	2	3	4	5	6

DISCUSSION

In this study we investigated the processing of threat appeal message against obesity. We were specifically interested in two different groups, namely people who feel overweight or obese and people who indicate that they do not perceive themselves as overweight. By making this distinction we get a better view on how people for whom the health message is intended, process this appeal, since those are the people who we want to inform about the negative consequences of having too much weight. However, the inclusion in the investigation of the other group: those who have no perceived overweight, is of equal importance. Seeing that the number of people with overweight grows every year (Wyatt et al. 2006), healthcare practitioners need to inform not only people who are already perceived themselves as overweight, but also those who may become and feel overweight in the future. Confronting them with the consequences of overweight like high blood pressure, diabetes, strokes and worse will hopefully help them keeping their weight under control. As the saying goes: '*prevention is better than cure*' (in this case it may be

easier as well). The results of the Students t-tests tell us that there are significant group differences for perceived susceptibility, the two variables of the coping appraisal and behavioral intention. As for the last variable the respondents who perceive to be overweight intended significantly more to keep their weight under control in the future than those without perceived overweight. These results are in line with previous research, as Kirscht et al. (1975) also found a positive effect on the effective weight status of children after the exposure to threatening communication. The respondents with perceived overweight also felt themselves to be significantly more susceptible to the threats of obesity displayed in the message. This may seem logical, but a high perceived susceptibility is nonetheless an important factor in the threat appeal framework. If a person does not think he or she is in danger of the threat, the person will not be motivated to perform a mental assessment of efficacy and ultimately will not perform the recommended behavior (Witte 1992). The significant discrepancies in our sample between being categorized in a BMI-category and a person's own judgment about being overweight or not, have led us to work with the respondents' indication of being overweight. Previous literature (Crawford and Campbell 1999; Deurenberg et al. 2002) has also indicated that weight misperception is common due to several reasons. The recommendation of using the respondents' perception instead of the BMI-categories is thus taking into account in this study. Concerning the dimensions of the efficacy appraisal, there were significant differences between the two groups: people with no perceived overweight indicate a higher response and self efficacy than the members of the other group.

The people with no perceived overweight thus find the recommendation to avert obesity significantly better and also find themselves more capable of doing something about these weight issues. For people with perceived overweight, having mean scores which are too low on the efficacy appraisal traits, may have negative consequences. Witte (1992) indicates that after assessing the threat, people confronted with a threatening message will assess their and the recommendations' efficacy. If those are insufficient, this will lead to a controlling of the fear instead of the danger of the threat. Therefore it is necessary to create a decent amount of response and self efficacy (in our case: mean scores respectively 1.96 and 2.07 on a 5 point Likert scale going for '*Strongly disagree'* until,*'Strongly agree'*) to avert a fear control reaction. Given the lower mean scores but the fact that the behavioral intention of the respondents with perceived overweight is tolerable, we may conclude that the threat appeal message will lead towards a controlling of the threat of overweight and obesity as opposed to the denial of the warning among this group of respondents.

The processing patterns were exposed with Partial Least Squares path modeling. The results indicated differences in processing between the two groups, but not in the way that we predicted. For people who perceive themselves to be overweight, significant relations were found between perceived severity and evoked fear (confirming hypothesis 2a) and evoked fear and behavioral intention (confirming hypothesis 1). The respondents for whom the threat appeal should be relevant experience emotions of fear due to the perceived severity of the threat. The results also confirm the theory of Witte (1992) who restored the value of the emotion of fear back into the health messages after it got on a sidetrack due to the Protection Motivation Theory of Rogers (Tanner, 2006). For people with perceived overweight, the relation between evoked fear and behavioral intention was the only significant one by which they processed the appeal (disconfirming hypotheses 2b, 3b, 4b and 5b) and therefore we must underline the importance of evoking fear emotions linked to the magnitude of the threat appeal (Boster and Mongeau (1984); Sutton (1982), Witte and Allen (2000)). Hypotheses 4a and 5a claiming a negative effect of response and self efficacy on evoked fear cannot be confirmed. This may be due to the fact that those

two constructs are aspects of the efficacy appraisal and thus may be less influencing personal feelings and more cognitive processes, like behavioral intention. As for the full model only the relation between response efficacy and behavioral intention was significant. It was expected that people with perceived overweight would display stronger relations than the respondents who did not think they were overweight or obese. Nevertheless, the only significant relation pointed toward a higher impact of response efficacy on behavioral intention for people with no perceived overweight, although it was thought that this message and its content would be less relevant for the latter and thus would be processed less carefully by people with perceived overweight (Ajzen et al. 1996). As mentioned above, it is not only interesting to know how people with perceived overweight process such threat appeals, also the processing pattern of people without overweight can be very interesting for healthcare workers. Here, three significant relations were discovered, namely one between perceived severity and behavioral intention (confirming hypothesis 2b), one negative relation between self efficacy and behavioral intention (confirming hypothesis 5b) and the strongest one between response efficacy and behavioral intention (confirming hypothesis 4b). Only perceived susceptibility did not seem to have any effect on behavioral intention (disconfirming hypothesis 3b). For a person with no perceived overweight his or her perceived vulnerability did have a significant relation with evoked fear, through which behavioral intention can be reached (confirming hypothesis 3a). Although the relation between perceived susceptibility and behavioral intention is not direct, as it is mediated by evoked fear, all 5 components of Witte's theory (1992) have significant relations with the intention of a person to keep his/her weight under control in the future. This study thus underlines the importance of having threat appraisals and efficacy appraisals in a threat appeal in order to, on the one hand evoke fear and on the other hand have a direct impact on the behavioral intention of the receiver.

CONCLUSION

The two different processing patterns in which evoked fear is central for people with perceived overweight and on the other hand perception of severity and the coping appraisals are important for people who do not feel overweight is a new finding in threat appeal research. If the aim of the health messages is to prevent people getting overweight or worse there should be a focus on the coping and threat appraisals rather than on fear only as these are the significant factors by which those respondents assess an appeal. If the goal is to diminish the number of overweight people the focal point should be on evoking the right amount of fear.

Images of Identity in Consumer Research:
A Study of the Worship, Experimentation, Community and Domination of Signs

Lauren Gurrieri, Griffith Univesity, Australia
Helene Cherrier, Griffith Univesity, Australia

ABSTRACT

This paper seeks to understand how consumers negotiate contested symbolic meanings 'permanently' marked on the body. It offers four images of identity – assumed, trialled, tribal and trapped. In doing so, the research aims to provide a metaphorical understanding of identity work in consumer research.

The Discursive Construction of the Consuming Subject

In contemporary consumer culture, consumption is considered a key site from which one discursively constructs their identity, whereby 'we are what we consume' (Bauman 2007). Accordingly, Arnould and Thompson (2005) identify consumer identity projects as a research program of consumer culture theory. This focus on consumption is the consequence of the fragmented consumer of postmodernity, whose sense of self is no longer conceived as a unified construction driven by well-defined, purposeful and rational needs, instead comprising fragmented patterns of consumption and engagement in multiple experiences (Benwell and Stokoe 2006). As identity is constantly changing and emergent, it is through consumption and its symbolic meanings, as constituted through enduring socio-historic discourses, that consumers are able to construct identities (Thompson and Hirschman 1995).

Two views of this postmodern condition exist (Goulding, Shankar and Elliott 2002). First, a more pessimistic view of society as dystopian and alienating, conceives fragmented consumers fraught with identity confusion and struggling with sign domination (e.g. Baudrillard 1981; Jameson 1984). In the absence of overarching narratives, the self is placed in a position of vulnerability and dominant discourses create normalising or disciplinary effects, with various social and historical forces affecting identity work and constraining individuals in ways that attempt to inscribe what can be said and who can be what. Second, a more liberatory account presents subjects embracing fragmentation as a force that frees them from conformity. In the place of traditional institutions, consumption becomes a means of constructing and expressing multiple identities (e.g. Firat and Venkatesh 1995). Under this perspective, the self becomes a symbolic project and consumers express accounts of who they are from available symbolic materials, which also provide a means of participating in social life (Elliott and Wattanasuwan 1998; Featherstone 1991).

In addition to these two conceptualisations, consumer identity construction can be read as a dialogical or dialectical process emerging from a tension between 'sign experimentation' and 'sign domination' (Murray 2002), namely interplay between agency and structure. In this perspective, mass consumption, social categories and normative discourses influence consumption patterns yet still allow for a form of creative identity play. For example, Holt and Thompson's (2004, 439) study of masculinity in America conceives social categories as a frame of reference that "encourage and constrain particular kinds of consumer creativity". Similarly, Murray (2002) shows consumers' construction of style resulting from a tension between sign experimentation and sign domination. On the one hand consumers draw on the meanings of signs to construct symbolic statements about themselves and on the other they respond to normalising and disciplinary discourses ascribing what can be said and what can be worn.

Whilst understanding the dialectical interplay between agency and structure has been a preoccupation in studies on non-permanent consumption behaviour, very few studies have discussed the agency/

structure interplay in permanent forms of body alteration such as body sculpting, piercing, scarification and tattoo. For example, Askergaard, Gertsen and Langer's (2002) study on plastic surgery adopts an agentic approach to an individual's reflexive construction of identity. Similarly, Sanders' (1985) study on tattoo consumption accepts the agentic power of deviant consumers who manoeuvre the risks of consuming marginal products. In contrast to this view of consumption as an expressive movement taking place in open discursive systems, Patterson and Schroeder (2010) consider tattoo consumption resulting from a dialectical interplay between agency/sign experimentation and structure/sign domination. For the authors, the skin "reflects the dynamic relationship between inside and outside, self and society, between personal identity projects and marketplace cultures. It represents the meeting place of structure and agency; a primary site for the inscription of ideology and a text upon which individuals write their own stories" (Patterson and Schroeder 2010, 254). Under this perspective, identity becomes something worked on by multiple actors, bridging the individual and the social (Patterson and Schroeder 2010). For embodied identity statements such as tattoos, the interpretations that take place between actors can be diverse, contested and complex. Patterson and Schroeder (2010) note that tattooing brings with it a set of competing and contested understandings between the individual and group, deviant and mainstream, public and private, personal and social and subject and object. It is this instability and ambiguity of both the skin and tattooing which make them rich sites for examinations of consumer identity construction as a dialogical process between agency and structure.

Taking a dialectical and multifaceted view of identity construction, this paper seeks to understand how consumers navigate across contested symbolic meanings 'permanently' marked on the body, shifting the focus from meaning to action. In contrast to Patterson and Schroeder's (2010) study on tattoo consumption amongst heavily tattooed women we consider one particular tattoo, the Southern Cross tattoo, which symbolises heavily contested meanings in Australia. Our objectives are threefold. First, we contribute to the consumer culture theory debate on the agency/structure dialectic in the consumption of permanent bodily modification. Second, we offer insights on what consumers do with the multiplicity of symbolic meanings available to them, shifting the focus from meaning to action. Finally, we propose four images of consumer identity – assumed, trialled, tribal and trapped – to provide a metaphorical understanding of identity work in consumer research.

Methodological Overview

Discourse analysis was conducted on texts derived from a combination of data collection procedures. Firstly, netnographic data on the Southern Cross tattoo was collected from weblogs, online tattoo discussion forums and news reports to provide a genealogical understanding of the symbol. Secondly, interviews of 60 to 120 minutes in length were conducted with five Australian informants based in Melbourne, Sydney and Brisbane who have the Southern Cross tattoo. Finally, memos and reflections written at various stages of the empirical process were documented and collected to facilitate reflexivity. The analysis sought to identify the ways identity was constructed and worked upon. Informed by grounded analysis procedures (Locke 2001), the interview data was coded using a three-stage process of open coding, identification of mid-level themes, and then broader conceptual categories. During this process we frequently returned to the literature to make sense of emerging

themes and to sharpen our interpretations as guided by constructionist sensitivities and assumptions about language. Collaborative readings of the data were also undertaken by the authors in order to bring multiple perspectives to the data, its coding and subsequent interpretations.

The Southern Cross Symbol and its Contested Meanings

The Southern Cross is a symbol fundamental to the Australian cultural psyche, providing an observable way for people to be recognised as belonging to the Australian 'tribe' (Maffesoli 1996). The Crux constellation is dominated by a cross-shaped asterism of four bright stars, commonly known as the Southern Cross. The Southern Cross has great significance in many cultures of the Southern Hemisphere where it is visible at any time of the year, unlike in the Northern Hemisphere where it is only occasionally seen by those south of latitude 30 degrees. For thousands of years, the Southern Cross has been an object of reverence around the world, such as for Christians who claim it was last visible from Jerusalem at the time of the crucifixion of Jesus Christ. Over time, the Southern Cross has become most closely associated with the Australian identity.

The Southern Cross is an important element of Aboriginal Dreamtime, the Cross conceived as a stingray being pursued throughout the southern sky by a shark (the pointers). The Crux itself is mythologised as a possum sitting in a tree that represents the sky deity Mirrabooka, a clever man immortalised into the night sky by Biami, the creator, to assist in watching over people on earth. Since the colonial era, the Southern Cross has been used as a national symbol in Australia, residing on various state and territory flags as well as the national flag, where the four stars are said to represent the moral virtues of justice, prudence, temperance and fortitude. A stylised Southern Cross dominates the 'Eureka flag', first used in Victoria in 1854 as the battle flag of the Eureka Stockade – a key event in the development of Australian democracy where goldfield workers protested against Government sanctioned mining licenses. The Eureka flag has since continued as a symbol of protest, egalitarianism, liberty and revolution, particularly pertaining to class as reflected in its adoption by numerous trade unions. The Eureka flag has been proposed by the republican movement as an alternative national flag, as first suggested by the iconic poet Banjo Patterson in his poem 'Our Own Flag'. Finally, the Southern Cross is referenced in the lyrics of the Australian national anthem, the title of the victory song of the Australian national cricket team whilst numerous institutions such as hospitals, universities and railway stations also bear the name 'Southern Cross', illustrating its deep cultural embedment.

In recent times, two phenomena have resulted in the Southern Cross symbol taking on different and highly contested sets of meanings. Firstly, a growing trend towards 'marketplace patriotism' has emerged, whereby Australian symbols – overwhelmingly the Southern Cross – are emblazoned on every product imaginable. Consuming patriotism also extends to embodied practices, such as body modification. This can be observed in the ever-increasing number of Australians, including Australian athletes at the Sydney Olympics in 2000, showing the emblem of the Southern Cross tattooed on their skin. Secondly, a nationalist, xenophobic 'Aussie Pride' movement that developed out of the racially motivated Cronulla riots have latched on to the Southern Cross symbol as emblematic of their 'cause'. This is most clearly apparent in the 'Southern Cross Soldiers', a group who band together around the belief that "there is only one ethnicity in Australia: Australian" (SCS website, 2010). The Southern Cross Soldiers are the largest organised group aligned to the 'Aussie pride' movement with chapters throughout Australia. Members are tattooed with the Southern Cross as a way of alleging their membership to the group, which adopts a US 'gangsta' style through the appropriation of cultural expressions, such as rap music. As a consequence, the Southern Cross has taken on connotations of racial

vilification, leading some to brand it the 'Aussie Swazie'.

Whilst we may think of national symbols as sacred, non-contested, coherent, untouchable and ever present, the case of the Southern Cross illustrates the deep contestation of its meanings within contemporary Australian society, partially the consequence of these various appropriations. What does this mean for people who have chosen to 'permanently' etch their skin with the symbol of the Southern Cross as a part of their own personal narrative? We explore this question in the ensuing sections, which provide insights into how consuming subjects engage with contested symbolic meanings in the process of identity construction. We begin by outlining the findings from the research study, which demonstrate that four discourses were drawn on in processes of identity construction for those engaging with the embodied experience of consuming the Southern Cross symbol as a tattoo, namely worship, experimentation, community and domination.

Discourses of Worship

Our informants drew on discourses of worship in talk about tattooing their skin with the Southern Cross. By imprinting their skin with the symbol, our informants performed an act of devotion that adoringly acknowledged their love for their country: Australia. They spoke about how they considered the Southern Cross to be a quintessentially Australian symbol, and by laying claim to it in this way the informants were able to demonstrate their avowal. Demi, a nurse aged 36, considers herself a "*proud Australian*" and inked her allegiance as an act of praise to the country in which she has lived her entire life:

> There was no question of anything else. I wanted the Southern Cross and that was it. It shows I'm an Aussie ¼ The Southern Cross, it's unique. There's no explanation needed. You just know.

The strong emotions that were raised in speaking about her tattoo gave Demi goose bumps. She believed her tattoo provided her with "*proof of my patriotism*", using her body as a text to "*mark my territory*" and "*show how this means so much to me*". As Demi mentions in the excerpt above, the symbol is "*unique*" and does not need an explanation, it "*shows I'm an Aussie.*" Demi and all of our informants did not consider expressing their commitment to 'being Australian' through any other symbol. They considered the Southern Cross to be the most highly recognisable symbol associated with Australia, thus best enabling them to communicate their national pride and "*prove*" (Demi) their heritage. Moreover, other national symbols, such as the flag, were "*tainted*" (Jack) by their association with Britain. In contrast, the Southern Cross was a sacred symbol (Belk, Wallendorf and Sherry 1989). Our informants celebrate their deep connection to their country using the Southern Cross as a value-expressive symbol to being "*an Aussie*" (Demi) and a "*proud Australian*" (Leon). For example, below Josh explains how the symbol is a sacred artefact that provides "social cohesion and societal integration" (Belk et al. 1989, 31):

> It's over my heart and they say things like you're wearing your country over your heart that was why I got it there. It's something that belongs to all of us whether you're born here or not. If you choose to live here then I believe you choose to live under the Southern Cross, you choose to live our way – and then you're entitled to have a tattoo of the Southern Cross.

For Josh, a construction worker aged 44, his Southern Cross tattoo signified his adherence to the '*Australian way of life*', it was a mark that demonstrated he was committed to his country and maintaining its cultural traditions. Tattooing the Southern Cross is clearly not for the mass but is reserved to the "*entitled*" individuals who belong to Australia. Josh and all of our informants constructed their experience of being tattooed

as affirming their devotion and being emblematic of a spiritual pledge taken for their country. The informants uncritically spoke about the Southern Cross as something greater than themselves. This was strongly reflective and nostalgic, with informants constructing their tattoo as a "*tribute*" (Josh) or mark of respect to cultural heroes who have passed on but are forever remembered for the ways they shaped the nation. As Leon, an electrician aged 19, reflects:

> I'm proud of our ancestry, it makes us who we are and what we will be. I've got a grandfather that served in World War II, two of my uncles who served over in Timor and Afghanistan and so I'm proud of people who serve our country and make it a safe place to be. That makes me proud of who I am and where I've come from and what my country's done. Yeah, what our country is and what it stands for and what it's got to offer. When I was young I marched in the Anzac Day marches and wore his medals, I've just grown up with a pride knowing he served the country and served so that I can be here today. Yes, just made me proud at the end of the day, not just me but for everyone that's here now.

Leon describes his Southern Cross tattoo as a psychic bridge to "*our ancestry*" and his "*grandfather*." Wearing the Southern Cross denotes the bearer's status of being Australian and descending from Australians. For many of our informants, this patriotic worship had far reaching consequences for their other consumption choices. For Josh, who was suffering from terminal cancer, various sacrifices were personally made in order to ensure he was duly "*living under the Southern Cross*", always placing the country before himself:

> I've got absolutely no desire to travel anywhere in the world until I've seen all of Australia and that's never going to happen. There's just too much to see here. So I'm never going to leave our shores because there's nothing else I want to see first ¼ I was a farmer for about 16 years. I lost thousands and thousands of dollars worth of crops with hail storms and what have you. When I did have a good crop so did every other bugger and you couldn't sell it. The idea of importing food into Australia is just absolute bullshit. I hate going into a supermarket in the middle of winter and finding cherries for sale. I mean you can't, it's just not right. We should not be importing food. We can produce everything that we need here. That's what I believe anyway. So I only buy what we produce.

When pressed about what the Southern Cross symbol personally meant to them, most of the informants felt they were unable to answer. They considered the decision to get the tattoo not to be a rational, conscious one. Rather, the informants spoke of a kind of divine imperative or epiphany that drove them to ink their skins. As Leon noted, "*I don't think it's something I wanted to do, it's something I needed to do*". They constructed the Southern Cross as a sacred symbol, something extraordinary that was not to be tampered with but treated with respect and awe. This sacralisation of the Southern Cross further fuelled its construction as a symbol of reverence. For the informants, the tattoo provided them with an enduring expression of worship, its materiality functioning as a kind of sacrament. For Leon, undertaking the rite of tattooing the cross conferred upon him permanent sanctity. It provided a transcendent experience, and he was proud to be able to display the scars that signified the physical agony he made the sacrifice for:

> It's going to stay with me forever. It's not something that will just go away, it's pretty much there for good. It's something I chose for everyone to see at all times. It's a clear way of doing it. I wanted to express that I am proud of being Australian, whether it be the bearing of the cross or showing I went through the pain.

For other informants, the tattoo became so intimately connected with their being they came to regard it as a natural part of their body. As Demi noted, the tattoo became "*an identity: it's a mark, a stamp, a birthmark*". This naturally occurring state was reinforced through references to the cosmic connection of the symbol, namely the Southern Cross in the sky, the seemingly eternal nature of which was constructed as reflecting their permanent undertaking of tattooing. For Jack, a retail worker aged 26, both the constellation and his tattoo provided "*a constant reminder of who I am and what it is to be Australian*". As many of the informants noted, both were "*always there*". In this way, the Southern Cross symbol came to be emblematic of a kind of everlasting life, something to be worshipped and sacralised.

Discourses of Experimentation

In talk about their tattoo, the informants also drew on discourses of experimentation. The act of inking their skin enabled them to construct a narrative about who they were and facilitated a way of communicating their identity work to those around them. For Demi, her tattoo represented the trying of personal circumstances she had weathered and overcome to be the person she is today:

> I think tattoos are an individual thing, because you choose what you want to have so it's a personal thing. There's always a story behind it. The taxi driver the other day had a black rose on his arm with the names of his parents who had passed, his brother and his cousin who are passed and that was his family memorial. He'll continue to get names added. That was him whereas for me this is the Southern Cross ¼ your past and your history shapes who you are today, those mistakes and errors and outbursts and whatever in your past that has made you who you are ¼ about my ex-husband and about what he has done, that's made me who I am ¼ it changed my life to move on and now I've got the confidence to show who I am.

Our informants felt that the act of imprinting their skin enabled them to draw on meanings of the symbol and rework them as part of their identity. For example, Jack tattooed his shoulder with the Southern Cross as a rite of passage to mark the end of his youth. For him, the meanings of rebellion associated with the symbol resonated with his personal narrative and he considered the tattoo to function as forever telling that story:

> I guess it would be along the lines of the Eureka Flag, being the rebel thing to do. It's probably become the younger generations' Eureka Flag. It's just something to do to rebel against modern society and everything else. It's probably just to be different, in a way and not be stereotyped into one dimension type of stuff. Because probably at the time it was a rebellious thing that my parents weren't huge tattoo fans. Then because I moved out of home for more independence it was another step towards that ¼ Just the choice to live how I want to live and do what I want to live. Just the freedom aspect to it. It's just a part of me and it's something that I have to show who I am.

The process of being tattooed with the Southern Cross allowed our informants to both appropriate its cultural meanings and construct their own personalised meanings. In this way, the informants engaged in acts of bricolage (De Certeau 1984), adopting and adapting symbolic resources to build their own stories. For Kate, a photographer in her mid 20s, her Southern Cross tattoo was a means of creatively expressing her personal myth – something fundamental about her life (Velliquette, Murray and Evers 2006). For Kate, the tattoo functioned as a way of remembering her home, family and friends

when she was living overseas. In this way, the tattoo embodied her myth and enabled her to meaningfully interpret her life experiences:

> I went to England and I was going to live there for two years and work and be away from home. I'm very attached to my family; we're very, very close. I lived at home for quite a while and it was very hard moving out for the first time. I guess being an only child and being close to my parents, it was hard. So being over in England it was just being away from everything that I've known. No friends, family, no nothing. I didn't know anybody in England ¼ there was nothing home about it over there. I wanted something that I could have with me wherever I was, I'd know I was home.

Yet, some informants struggled with the symbol being "*public property*" (Jack), perceiving its collective appropriation as hampering the interpretation of their embodied self-narrative. In response, some sought to modify the symbol as an act of self-expression. Leon personalised the symbol by placing it amongst others he believed collectively elaborated his identity. In doing so, he attempted to take control of its meanings, moving it from the public sphere to the private. Interestingly, Leon chose to augment his Southern Cross tattoo with other shared symbols commonly associated with the Australian national identity, signalling he still felt bound to observe an existing identity script.

Discourses of Community

For some informants, the Southern Cross tattoo provided a sense of belonging, functioning as an identity marker that signalled a shared consciousness with others. The informants divulged how strangers would approach them upon seeing the symbol, interested to hear their story, compare tattoos or communicate feelings of camaraderie. In this way the informants drew on discourses of community, constructing the tattoo as creating a dialogue with others that conferred social benefits. For Josh, his tattoo became a "uniform", an identity badge that linked him to others connected to the symbol:

> I like the way when you're at the beach and you haven't got a shirt on people notice it. Obviously they may have different opinions and different ideas as to why someone might get it. But to me it's like they realise that I'm Australian ¼ It's good to know that I'm a part of all of that. Like I belong. It's a little stamp of being here, like part of Australia I guess. It's just knowing that you're part of a team.

Having branded themselves with the Southern Cross, the informants claimed they felt more connected to the legends, traditions and values commonly associated with being an Australian. In doing so, many of the informants came to perform an identity that slipped into typecasting of what a 'typical' Australian was considered to be. For instance, Jack emphasised how his '*ockerisms*' or Australian clichés reinforced his belonging to the community accessible through his tattoo:

> Out of what I've been told from my group of friends, I'm more Australian than anyone else. Just the way I act and a few of my sayings ¼ like the 'no worries' and 'she'll be right mate', pretty much your stock standard Australian sayings will just come out naturally to me ¼ I guess it [the tattoo] may have appeared to have an effect on me to my friends and outsiders.

The communality of the tattoo also provided some informants with an understanding of the types of people to whom they felt akin.

Leon noted his tattoo provided him entry to a group called 'Aussie Patriotism Ink', an online community who bond over patriotic symbols tattooed on the skin. Leon considered the people within the group to be likeminded in ways beyond the mere act of inking the skin:

> It's just a group of people like myself ¼ A lot of the blokes on the site I know are tradesmen. A lot of them go camping, love the outdoors, love sports, go 4WD and whatnot. Most of them are Caucasian, Australian, Christian ... I suppose you say they fit.

In a subcultural sense (Hebdige 1981), Leon shared how members of the group sought out a minority style interpreted in accordance with subversive values that were critical of dominant societal standards. Members embraced casual tradesperson attire such as 'wifebeater' singlets, stubby shorts and thongs and espoused nationalistic, xenophobic values that ran counter to the prevailing climate of political correctness:

> When you try to express your love for your country and you see so many people that aren't Australian it can be frustrating. There was more Australians living here than there is now and it's more frustrating than anything seeing a country that you love and having so many other people moving into it ¼ you do want it for yourself. When I'm going camping I rarely see someone who is Asian or Indian ¼ I don't think they share the same sort of beliefs and enjoy the same activities that we do.

Leon noted how having a Southern Cross tattoo brought together and identified members of the group empowering them to feel "*more Australian*", however this also spilled over into understandings of who they were unlike and othered and excluded:

Discourses of Domination

Finally, informants drew on discourses of domination in talk about themselves and their tattoo. Some informants claimed they felt stereotyped as a result of their Southern Cross tattoo. For Kate, who was "*ashamed*" of her working class background and experienced considerable obstacles in coming out as gay, being classed as a 'bogan' or racist was a highly fraught identity struggle:

> Even though to me it means something else, no one else knows that. So everyone thinks you're that demographic. I know a few people who have it and they're the typical tradies. I'm still centred around that fear - V8 supercars, Bathurst, football, tradie - because to me they're all the people who have it. They're all the people I've come across who have it or really just bogan people. That's kind of the category I've been lumped in now. That's what I see now that I've been pigeonholed ¼ it's horrible.

For Kate, this stereotyping resulted in feelings of social exclusion, whereby the symbol came to dominate her identity and shape perceptions of what others thought of her. Describing it being "*like a gang tattoo*", Kate felt branded as a deviant and outcast by the symbol. This created a sense of cultural anxiety, with Kate feeling the need to constantly reconstruct her identity to others to mitigate the undermining power of the Southern Cross upon her identity work. She claimed that the tattoo even attracted physical violence, to the extent that she was often concerned for her physical safety in public spaces. In this way, Kate ascribed considerable agency to the tattoo, constructing it as overpowering all other visible symbolic cues on her body that could be read to interpret her identity:

I just don't feel the same with it. I always feel that sense of somebody looking at me, somebody judging me. It feels like it's going to consume you and then you're going to become that, you have to become that symbol that everybody thinks you are ¼ it attracts a lot of anger and hate, others pick people out for having it. I feel that. If you go to a pub or a bar you don't know if you're going to be standing there and someone's going to come up and have a go at you.

In an attempt to counter these feelings of categorisation, the informants employed various coping strategies and made particular sacrifices. Jack was always concerned about being approached by the "*wrong type of people*" because of his tattoo. For this reason, he kept his tattoo covered and hidden the vast majority of the time, only revealing it when in front of people he trusted such as family and friends. For Leon, who feels he has been unfairly treated and labelled as unintelligent as a result of his tattoo, his coping strategy was to "*remember the reasons why I got it*" in an attempt to reassert control over the symbol's interpretation. Yet for Kate, it has reached the point where she feels she must dispose of the symbol by getting the tattoo covered up to disidentify herself from what she considers to be its negatively connoted meanings:

A lot of people, when I tell them I'm getting it covered over, a lot of my closer friends are like 'oh it's a part of who you are and we all know you for it'. It's like yeah but it's kind of not me anymore, I don't want it. If I could scratch it off I would. If I could just get rid of it today I would. If I had the money right now I'd be gone down there and get her to do a design and get

it right and get it done ¼ I don't want to get angry over it. It's something that's meant to make me feel good, it's not meant to make me feel unhappy.

Kate tried growing her hair longer, wearing scarves and high collared shirts to cover the tattoo on her neck, but felt that its meanings still haunted her. By letting go of the symbol and its visibility entirely, Kate believes she can gain a sense of control over her identity construction, enabling her to "*be myself again*". For her, this comes at the cost of needing to defend her identity and letting go of part of her personal history:

Images of Identity: A Consumer Research Agenda

We contend that the discourses outlined provide a useful lens for examining how identity has been constructed in consumer research. Extant research emphasises the interplay between agentic and structural forces in identity construction, whereby tensions arise in dialectical interactions between individuals acting in self-interest and social structures that seek to control their actions (e.g. Holt 2002). To Murray's (2002) framework on the juxtaposition between sign experimentation and sign domination we add two forces that play critical roles in identity work, namely sign worship and sign community. Further, we propose that each sign discourse relates to an 'image' of identity. Image refers to the "overall idea or conceptualisation, capturing how researchers relate to — and shape — a phenomenon" (Alvesson 2010, 194). We offer four images of identity – assumed, trialled, tribal and trapped – to provide a metaphorical understanding of conceptualisations of identity work in consumer research. These are outlined in Table 1 below.

Discourses	Images of identity	Key characteristics of identity work	Examples
Worship	Assumed	• Uncritical appropriation of symbolic meanings • Identity construction is driven by a spiritual-like quest to be associated with something 'greater than oneself'	Muniz and Schau (2005) O'Guinn and Belk (1989)
Experimentation	Trialled	• Bricolage of symbolic meanings • Identity construction is motivated by the desire for self-expression	Arnould and Price (1993) Murray (2002)
Community	Tribal	• Sharing of symbolic meanings • Identity construction is directed by being situated in a specific social space	Kozinets (2001) Schouten and McAlexander (1995)
Domination	Trapped	• Inscription of symbolic meanings • Identity construction is regulated and controlled by social structures	Holt (1998) Murray (2002)

Table 1: Sign Discourses and Images Of Identities

In providing these images of identity, we seek to extend Arnould and Thompson's (2005) framework of consumer culture theory, which identifies identity projects as a key research agenda for consumer researchers. By specifying four areas of research pertaining to consumer identity, we aim to provide a platform from which future researchers can navigate the diverse work that is currently undertaken in the field of identity. It is important to note that studies may simultaneously address multiple images of identity, which har-

bour slippage and overlap. Consequently, this framework does not purport to offer static 'categories' of identity, but rather function for the purpose of analytic explanation. Finally, as discursive approaches to identity represent a growing area of interest in marketing research (e.g. Ellis and Ybema 2010), this research seeks to offer a starting point for future investigations of the role that discourses play in constructing and legitimising relations, meanings and identities in the field of consumer research.

How Best to Get their Own Way? Children's Influence Strategies within Families

Ben Kerrane, Bradford University, UK
Margaret Hogg, Lancaster University, UK

ABSTRACT

How do children decide how best to try and get their own way? Despite extensive studies of children's influence strategies there has been little research into understanding *why* children utilise given influence strategies i.e. *"the underlying motivations of strategy usage"* (Palan and Wilkes 1997, p.167). The motivations that drive the choice of different influence strategies result from a combination of personal goals and environmental factors. The family environment provides children with some of their most important experiences about how best to compete for limited resources (e.g. time, attention, money). Choices about the allocation of income across family members' preferences are central to children's consumer socialization. In order to throw more light on the motivations for children's choice of particular strategies in their family environment (Cotte and Wood 2004), we investigate the family environments in which the influence strategies are played out; and how far the family environment has a moderating effect on the types of influence strategies that children use.

Our contribution is thus twofold. Firstly we seek to better understand the family environments in which children reside; and secondly, to identify the implications that the different family environments may have in relation to each child's choice of influence strategies within their family setting. Our study responds to Cotte and Wood's (2004) and Flurry's (2007) call for research that explores further the purchase influence of children in families, specifically by exploring how the family environment affects the influence strategies that children employ.

Child Influence Strategies: The Research Context

Research over the past forty years has established that *"purchase decisions within the family are not always the outcome of individual choice, but rather, family members influence each other"* (Hamilton and Catterall 2006, p.1032). Examinations of children's influence strategies began with a study of cereal choices which identified that both the child's assertiveness and the mother's child-centeredness were central to mother's susceptibility to their child's requests (Berey and Pollay 1968). In another cereal choice supermarket setting, children were more successful if they told their mothers to buy their preferred cereal, or if they demanded their choice, rather than if they simply asked their mother for it, or requested the item (Atkin 1978).

Another study specifically asked adolescents to write a series of essays entitled "How I get my way with my mother … father … best friend". Fifteen influence strategies were identified, sub divided by whether the strategies used were direct or indirect (Cowan, Drinkard and MacGavin 1984). Direct strategies included the use of more overt behaviours (asking, begging and pleading, telling or asserting, reasoning, demanding or arguing, stating importance, bargaining and persistence), whereas indirect strategies are believed to occur when *"the influencer acts as if the person on the receiving end is not aware of the influence"* (Johnson 1976, p. 100). Indirect influence strategies included the use of negative affect (such as the use of crying, sadness and anger), positive affect (including the use of sweetness and innocence), verbal manipulation (often involving telling lies), eliciting reciprocity, using an advocate, evasion and laissez-faire (taking independent action, regardless) (Cowan *et al.* 1984). Adolescents directed more influence strategies towards their mothers than their fathers, and of those strategies directed towards mothers most involved the use of negative affect.

Examining explicitly the mother-child dyad, twelve child influence strategies were identified by Cowan and Avants (1988) which included: ask, bargain, show positive feelings, do as I please, show negative affect, persistence, beg and plead, perform good deeds, reason, cry and get angry. What is significant from this study is that strategies were related to the level of parental resistance that the children expected to encounter: high (anticipating non-compliance strategies e.g. beg and plead, cry) or low (autonomous strategies e.g. tell), and whether or not an equal power relationship existed between the parent and child (egalitarian strategies e.g. bargain and reason).

A study of the power strategies of popular and rejected black South African children identified four dimensions of influence strategies: direct and indirect influence strategies (as identified by Cowan *et al.* 1984), and bilateral and unilateral strategies (Bonn 1995). Falbo and Peplau (1980) had earlier identified the concept of bilateral and unilateral dimensions within influence strategies in their study of intimate relationships. Whereas bilateral strategies require the co-operation and responsiveness of the target (e.g. bargaining), unilateral strategies do not. Bonn (1995), through interviews with children involving hypothetical situations, identified a range of strategies, including persuasion, bargaining and compromise (bilateral, direct strategies); suggesting, ingratiating, and deception (bilateral, indirect strategies); sadness, crying and anger (unilateral, indirect strategies); and asking, threatening and coercion (unilateral, direct influence strategies). Rejected children often used unilateral influence strategies, frequently involving the use of aggression (Bonn 1995).

More recent work on adolescents and their parents identified four classes of influence strategies[1]: bargaining, persuasion, emotional, and request strategies (Palan and Wilkes 1997). In a diary study which applied Palan and Wilkes' (1997) influence strategy framework focussing on children's impact on innovative decision-making, children were subsequently found to employ persuasion strategies most often, followed by request and bargaining strategies (Götze, Prange and Uhrovska 2009). In only a few cases were children found to utilise emotion based strategies (Götze *et al.* 2009).

Lee and Collins (2000) and Lee and Beatty (2002), through videotaped recordings of family interactions during a simulated decision-making situation, recognised the potential for coalitions to form within families. Five main influence strategy types were identified: experience strategies (using experience and knowledge as a source of information to influence the outcome of a decision), legitimate strategies (which emphasise positional power and stereotypes), emotion strategies, bargaining strategies and coalition strategies (Lee and Collins 2000). Seven dimensions of children's direct influence strategies, ask nicely, bargain, show affection, just ask, beg and plead, show anger and con, have also been identified (Williams and Burns 2000). More recently the child influence strategies of justifying and highlighting the benefits of purchases, forming coalitions, compromising and remaining persistent, have also been documented (Thompson, Laing and McKee 2007).

Ultimately although we do have a solid understanding of the repertoire of influence strategies that children are believed to use, we do not have an adequate understanding as to *why* children utilise given influence strategies – or indeed whether every child has access to every type

---

[1] It should be noted that Palan and Wilkes (1997) identified seven influence strategies, although the latter three (expert, legitimate and directive) were strategies solely utilised by parents in response to their adolescent's use of an influence strategy.

of influence strategy identified.

In addition to child influence strategies, a number of studies have also assessed children's influence on family decision processes i.e. their level of ability, and the type of situations in which children employ their influence strategies. The influence of children has been found to vary along the stages of decision-making. Results across studies were consistent in that children's influence was reported to be highest in the problem recognition stage, and significantly lower in the decision-making stage (Szybillo and Sosanie 1977; Belch *et al.* 1985; Lee and Beatty 2002). Recent research, however, particularly in studies involving innovative or technically complex products, suggests that children have much greater influence than previously acknowledged across *each* stage of the buying decision process (Götze *et al.* 2009; Wang, Holloway, Beatty and Hill 2007). Similarly children are believed to exert more influence for products they will use themselves (Beatty and Talpade 1994; Belch *et al.* 1985; Darley and Lim 1986; Shoham and Dalakas 2003).

Demographic factors are also suggested to affect the child's level of influence. Older children are suggested to exert more influence than younger children in family decisions (Jenkins 1979; John 1999), and past research indicated that female children were more influential than were male children in family decision-making (Atkin 1978; Moschis and Mitchell 1986). Recently, however, the moderating effect of a child's gender in relation to influence on decision-making has been called into question (Flurry 2007; Wang et al 2007). A child's birth position has also been related to their ability to influence family decisions, with first born children exerting greatest purchase decision influence (Churchill and Moschis 1979; Flurry 2007). Children who earn income have also been found to have more influence in purchase decisions than those children who do not (Moschis and Mitchell 1986; Flurry 2007).

Other family related factors are also suggested to affect a child's involvement in family decision-making. Children are suggested to have greater influence: in larger families which contain lots of children (Jenkins 1979; Ahuja and Stinson 1993), although debate does surround the link between child influence potential and family size (Ward, Wackman and Wartella 1977); as the number of years their parents have been married increases (Jenkins 1979); when both parents have an income of their own (Foxman, Tansuhaj and Ekström 1989; Hall, Shaw, Johnson and Oppenheim 1995), with parents in dual income families characterised as being busier and feeling guiltier and softer when it comes to their children's requests (Beatty and Talpade 1994; Geuens, Mast and De Pelsmacker 2002); in higher income families (Ekström 2007; Jenkins 1979), although one study did find that children in poor families exert considerable influence on family consumption, to the extent that consumption is often organised around their needs (Hamilton and Catterall 2006); as the education of their parents increases (Ahuja and Stinson 1993); as the family's social class increases (Atkin 1978; Moschis and Mitchell 1986), although Lee and Beatty (2002) question this relationship; and in relation to family type, with children of single parent or stem families suggested to exert considerable influence over family decisions (Ahuja and Stinson 1993; Bates and Gentry 1994; Hall *et al.* 1995; Mangleburg and Grewal 1999).

In terms of the family environment, *family communication pattern* (Carlson, Walsh, Laczniak and Grossbart 1994) and *parental socialization style* (Carlson and Grossbart 1988) have been linked to child influence. Five general parental socialization styles have been identified, *authoritarian*, *rigid controlling*, *neglecting*, *authoritative* and *permissive* (Carlson and Grossbart 1988), which we argue directly relates to both the extent of a child's influence in family purchase decisions and the types of influence strategy that they can employ.

For example, a child of authoritarian parents, who expect unquestioned obedience and who discourage parent-child communication (Johnson, McPhail and Yau 1994), is not expected to influence family decisions (Hall *et al* 1995; Ward and Wackman 1972). Authoritarian parents are also likely to view, for example, the use of persuasion or bargaining tactics in a negative light (Johnson *et al* 1994).

Family communication pattern, *"the frequency, type and quality of communication that takes place amongst family members"* (Carlson *et al.* 1994, p.29), also affects a child's influence in family purchase decisions. Four family communication patterns are identified; *laissez-faire*, *protective*, *pluralistic* and *consensual* (see Carlson *et al.* 1994 for a review). Children within families characterised as having a laissez-faire family communication pattern, involving limited parent-child communication of any kind (Moschis and Moore 1979; John 1999), are less likely to participate in shaping the family decision-making process, whereas children within pluralistic families are more likely to.

Children appear to make informed choices about which influence strategy they will employ (Williams and Burns 2000). Their decisions are informed by the historical success or failure of utilizing such strategies in previous decision-making situations (Bao *et al.* 2007; Götze *et al.* 2009; Thompson *et al.* 2007). However, relatively little is known about children's choice processes. This study explores how far the family environment has a moderating effect on the types of influence strategies that children choose to use, throwing light on the underlying motivations which children have in relation to strategy employment. Within consumer research, the family environment has been characterised as being a homogenous environment for each child. This assumption about the homogeneous nature of the family environment underpins current work on family communication pattern and parental socialization style studies. However Cotte and Wood (2004) called for further investigation of the "shared" nature of the family environment. This study therefore seeks to explore how children's varying experiences of their family environment facilitates or hinders children's choices of different influence strategies.

Methodology

Phenomenological interviews (Thompson, Locander and Pollio 1989) were conducted with six families living in the North West of England. Following calls for family research which captures the dynamics of family purchase decision-making (Hamilton and Catterall 2006; Tinson and Nancarrow 2005) interviews were conducted with both children and their parents. As many family members as possible were included in the data collection process. In line with other interpretivist studies (see for instance Thompson and Troester 2002) purposive sampling (Miles and Huberman 1984) was used to identify and recruit a range of family types and not just nuclear family forms.

In view of changing family configurations, we explored child influence strategies across a range of family forms (Thompson *et al.* 2007), including a lesbian headed family with both adopted and biological children; a family headed by a cohabiting couple; a family headed by a single mother; and a blended family.[2] All these family forms represent types identified by Harrison and Gentry (2007a, 2007b) as receiving inadequate research attention. Two nuclear families were also recruited from different socio-economic groups. An emphasis on studying consumers in-depth necessitated a smaller sample size to be used to allow thick descriptions to emerge (Carrigan and Szmigin 2006) which is common for interpretivist consumer research.

---

[2] A blended family has been described by Belch and Willis (2001) as a step family; however, Schultz et al. (1991) state that blended families have to be complex stepfamilies in which both spouses were parents before the current marriage

The families were recruited partly through personal contacts; partly through placing online appeals for participants in family newspapers and publications; and partly by contacting relevant family organisations in the North West region. The interviews were largely conducted in the family home, usually in the kitchen at the dining table, although one interview was conducted at one respondent's place of work. Each family was visited between three and five times and interviews were conducted over a period ranging from four to twelve months. Respondents were first asked for their consent to participate in the research process, assured of anonymity, told about the purpose of the research and then asked for permission to record the conversations.

Consent was sought from parents and guardians to approach their children in order to then seek the children's consent to be involved in the data collection process (Mandell 1991). Methods by which valid consent can be obtained from children were adhered to (Mason 2004). Recognising that children are potentially vulnerable research participants (Morrow and Richards 1996) the children were interviewed within the family home where an adult was always present, although not necessarily within earshot.

Interviews were tape recorded in full, lasted between 60 and 130 minutes, and were transcribed verbatim. The interviews with family members were conducted over three stages and explored themes such as family history and how family members got their own way. In stage one an interview was conducted with the parents/guardians, although two points are worth highlighting at this stage. In two of the families the fathers chose not to participate in any part of the data collection, and fathers generally had much less involvement than mothers in the interview process as a whole (although every attempt was made to capture their voices, principally by utilizing a male researcher to seek their views). Following this initial interview, stage two involved interviews with the children. Given that children, particularly younger children, may feel uncomfortable in a one-on-one interview situation (Mayall 2001) the children were given the option to have another sibling present during their interview.

Indeed in the second stage of the interviewing process the membership of the interviews was very fluid. Some children preferred to be interviewed individually, whereas in other families the children freely left and returned to the interview as other siblings joined and departed. Accordingly with some of the families one longer style visit was conducted with the children (comprising several shorter interviews with single and multiple children, often with overlapping attendance), whereas in other families the children preferred to have a much more contained interview. A semi participatory researcher role was adopted with the children (Mandell, 1991). Following this stage of interviewing, a final family group interview was conducted at stage three with as many family members as possible present. As with Hamilton and Catterall (2006) a financial incentive was offered to the families to thank them for their participation.

The interpretation of the interview texts was undertaken using a hermeneutical process (Thompson 1991; Thompson, Locander and Pollio 1990) which involved moving iteratively, back and forth between interview texts (within and across family cases) and the literature. Emerging themes in the data drove subsequent reading in the literature (Thompson 1996). Following hermeneutical principles (at the methodological level) a constant shift when reading between individual transcripts and the entire data set enabled a greater emergent understanding to develop in which elements of the part gave further meaning to the whole. Each family case was analysed on an idiographic basis which allowed for categorization of data from which larger conceptual classes emerged. These concepts were then compared across family cases, following Spiggle's (1994) initial steps for qualitative data analysis.

Findings

Across all six family cases, the family stories highlight the significant differences which exist *within* the families studied, and of the different treatment of family members by other family members. Each child did not have the same level of access to influence strategies, particularly in relation to his or her ability to form a coalition with other family members. Similarly the level of resistance to an influence strategy also varied depending on the child's characteristics and unique position within their family's environment. Our presentation, in a similar vein to Thompson (2005), highlights two family cases which illuminate the global themes found across all the families in this study. The family stories of the Baldwin and Jones families are introduced because these family stories emphasise the significant differences in children's experiences within the family environment, and highlight how these different family environments affect the influence strategies which the children employ.

The Baldwin Family Story

Carole and Ray Baldwin have been married for two years, having met following the death of Carole's first husband, Greg, and the unrelated breakdown of Ray's marriage to his first wife, Paula. Both Carole and Ray have children from their previous marriages, and so the Baldwin family is considered to be a blended family (Belch and Willis, 2001). Carole has four children from her first marriage: three grown up non-resident children, George, Kathy and Marie; and one resident child, Jessica (14), who lives with Carole and Ray in their new family home. Ray also has two non-resident children, Jamie and Anthony, who live with their mother. Ray tries to see his sons whenever he can. Carole and Ray have also had a biological child together, Nina (5).

The relationship that Carole and Ray have with Nina and Jessica is markedly different for each child. Whereas Nina is considered to be a good child, Jessica is not, with sibling comparison within families suggested to be common (Schachter and Stone 1985). Whilst Ray spends a great deal of time with Nina he spends little time with Jessica, with stepfathers often finding greater satisfaction in rearing their biological vs. step-children (Thoits 1992). Indeed, it is common for stepfathers to spend little time, and adopt a disengaged parenting style, with their step-children (Coleman, Ganong and Fine 2000). As a result Ray and Jessica do not have a strong relationship, and despite Ray's marriage to Carole, Ray has no intention of adopting Jessica as his own child:

> *Carole:* I said to [interviewer's name] before, that's why we ignore her [Jessica] (..) all of the time that she [Jessica] was sat there rabbitting on, Nina was sat there (.) and, and, she just wrote that [passing Ray a piece of paper that Nina had written on]
> *Ray:* I need a hug?
> *Carole:* That's what she's [Nina] like (..) it's like good child [Nina], bad child [Jessica]
> *Ray:* It's not bad child, it's pain in the arse child
> *Jessica:* But I got good grades
> *Ray:* I'm very pleased that you got good grades (.) but that's for your science, not for your maths
> *Jessica:* Yeah, but if I get another sticker I get a credit card, and then after that (.) after that, if I do good, I get a certificate
> *Ray:* If you do well, not if you do good
> *Jessica:* And then I do a certificate
> *Ray:* So you're not doing very well at English, then, are you?

Jessica is very aware that her parents treat her step-sister in a much more positive manner. Whereas Carole and Ray describe Jes-

sica respectively as *"crafty"* and *"stupid"*, Nina is described by Carole as *"innocent and sweet"*, much to Jessica's annoyance:

> *Interviewer:* Do you think that Nina gets more [things] than you?
> *Jessica:* I guess so (.) but then she gets little stuff. But they make me pay for my own things now; I have to pay money towards them
> *Interviewer:* Do you think your Mum and Ray give in more to Nina than you?
> *Jessica:* Yes! She's their little angel (..) I get treated like a right skivvy

The different treatment of the girls affects both the manner in which they attempt to influence the decisions of their parents and their success in doing so. Whereas Carole and Ray believe that Nina doesn't ask for things, and is happy with what she has, Jessica suggests otherwise. As the following extract suggests, which describes how the girls asked for Christmas presents, Carole believes that Nina hasn't directly asked for any presents:

> *Carole:* This one [Nina] doesn't ask (.) you haven't asked for anything yet
> *Jessica:* Yes she has (..) she's asked for, she's about circled all the Argos catalogue
> *Carole:* She's ticked things; she's ticked things (.) she's not actually asked
> *Jessica:* Yeah, but Ray said I can have
> *Carole:* At her age
> *Jessica:* She was asking for things before the Christmas disco
> *Carole:* At her age, they just watch the telly and everything that comes up it's I want one of them, I want one of them, I want one of them, without particularly realising what it is (..) so I don't think you've actually decided properly, have you, what you want? You're quite happy with anything (.) aren't you?
> *Nina:* I'm happy with anything

In the individual interview with Nina she commented *"I want lots and lots of stuff"* and she is aware that she doesn't have to try too hard to get what she wants. Nina directs emotion based strategies towards her parents, and utilizes her affection to get the things that she wants, most often from her father, as Carole and Ray comment:

> *Carole:* Ray and Nina have a very close bond (.) more so than Ray and Jessica. Nina's very tactile with Ray, Nina, she's always hugging him and she doesn't ask for anything back, but I think she's building foundations for a big whammy when she's older (…) she gets up in the morning and she'll come down, and the first thing she'll do is, she'll come and get hold of him, she'll come downstairs, and she'll grab his leg and just squeeze him
> *Ray:* She can get away with murder!

Accordingly Nina doesn't have to try too hard to influence her parents, particularly Ray. As a result she utilizes a limited range of influence strategies, largely using unilateral, positive effect, influence strategies. Jessica, on the other hand, coupled with her perceived parental rejection, tries much harder to influence the decisions her parents make. Carole feels that Jessica's persistence has hampered her ability to get things from her parents, and it is suggested that the over employment of child influence strategies may lead to parents becoming immune to their influence (Ekström 2007):

> *Carole:* What Jessica tends to do, she's like a dripping tap (..) and she drip, drip, drip, drips until you get that fed up of it she ends up with nothing (.) and she's not sussed this out yet. If she doesn't mither, and she just (..) all she's got to do is mention it the once … the minute he walks through the door it's, Ray? With her there's a tone (..) it's a definite, you just hear it

Faced with this high level of parental resistance, Jessica does not direct bilateral influence strategies towards her parents as she lacks their support. Accordingly she uses unilateral influence strategies (Bonn 1995), which often involve the use of negative affect (Cowan *et al.* 1984) and violence. What is interesting to note within this family, however, is that Jessica tries to bolster her own influence potential and success. Recognising the power that Nina holds over her mother and step-father, and the expected parental resistance should Jessica act alone in her strategy employment, Jessica forms temporary coalitions with her step-sister in order to utilize Nina's influence potential. This would seem to support the notion that children consider the expected level of parental resistance in their strategy selection (Cowan and Avants 1988). One such occasion involved the purchase of an iToy. Jessica wanted this toy which connected to her PlayStation, but she couldn't afford it by herself. Realising this, and accepting that her mother and step-father were unlikely to purchase it for her, she approached Nina and asked her to contribute some of the money that she had received from Christmas towards the cost of the iToy. Together they could afford the toy, but Jessica was equally aware that she still needed to persuade her parents, as the gatekeepers of her consumption, that this was a sound decision made by both girls:

> *Jessica:* I Knew Mum wouldn't let me have it (..) so I teamed up with Nina, they'd give her anything. I don't think Nina even wanted it
> *Interviewer:* But she still paid for some of it?
> *Jessica:* Yeah, but she's not bothered with it

Carole was concerned about this purchase, and what she considered to be the *"bullying"* that she felt had gone on between Jessica and Nina. Jessica, faced with the conditions of her position within her family's ecology, feels that she has little choice but to collude with Nina in order to get the things that she wants. Such coalitions are often very short lived, with Jessica ending the coalition once she has what she wants. The ability to form a coalition has also been linked to the ability to 'sell' a proposition (Thomson *et al.* 2007); although we suggest that this alone is not enough. The cause needs to be just, *and* the child needs to hold positive relationships with other family members, particularly their siblings, to be able to form a coalition. It is also unlikely that Jessica could form a coalition with her parents, as Lee and Collins (2000) and Lee and Beatty (2002) suggest is possible for some children.

The Jones Family Story

Debbie Smith and Paul Jones have been living together for just under twenty years. They have four children together who live in the family home: Michael (14), Anna (12), Adam (9), and Tina (7). Again, the children in the Jones family are not treated in a similar way by either their parents or their fellow siblings. Whereas Paul sees Michael as his mother's *"golden boy"*, his siblings do not share the same favourable position as Michael in their parents' eyes:

> *Interviewer;* Who do you give in to the most?
> *Debbie;* Paul would probably say my 'golden boy', as he calls him, Michael. I don't know what it is, perhaps it's because he's

my first born, but I suppose he does get away with doing more things. I think partly it's because I feel sorry for him, there's no one around here for him to hang around with, and he's doing well at school and with his drama and with his music (..) he's just a good boy, dead reliable and dependable

In the eyes of his mother at least, Michael's birth position (Lee and Collins 2000) grants him certain privileges in his family. However, this preferential parental treatment is not viewed favourably by his siblings, who are often antagonised by this, as Michael's sister, Anna, comments:

Anna; Michael just gets (.) he gets whatever he wants, just one word with Mum and he's got it. She'll get him anything (…) I don't get anything like he does

Anna in particular feels that there is a great deal of comparison between herself and Michael, with Michael seemingly able to monopolise their mother's time, with Debbie taking an active interest in Michael's leisure pursuits. Michael is a promising young actor, and Debbie pays for him to attend drama classes and often drives him to rehearsals:

Anna; It's always Michael does this, Michael can do that, why don't you be more like Michael? Michael's the one who's doing the best, he can act, he can sing, he's clever at school (..) he's all Mum ever talks about, the rest of us don't get a look in

Such is the tension between Michael and the rest of his siblings, who also view his ability to successfully influence their parents in a detrimental light, that Michael is often excluded and ostracised by his siblings. Although many of the products that Michael owns are relatively expensive and high-tech, purchased through his earnings as a young actor, his siblings do not show a great deal of interest in them. When Anna, however, won an Apple iPod in a supermarket prize draw Adam and Tina were immediately fascinated with it, and wanted one just like Anna's, even though Michael had bought himself one months before:

Michael; Anna's was better (.) better because it was hers, and she's the cool one, so it was just better

Although Michael can, and does, form a coalition with his mother, as the following quote suggests, he would struggle to gain this level of support from other family members (particularly his siblings):

Debbie; He'll [Michael] come round, and he'll put his arms around you (.) and he'll just say you know what I'd really like? … And then it's up to me to break the news to Paul (..) he wants what? My God! Does he realise how many hours I've got to put in to get that? And then I'll say, well I'll give you my family allowance, and we'll cut down on food, and we'll got to ALDI instead of ASDA [supermarkets].

Debbie also suggests that she tries harder to get Michael the things that he wants in relation to her other children, and as a result Michael simply has to use unilateral influence strategies. Faced with minimal parental resistance Michael uses autonomous influence strategies, including telling and asking (Cowan and Avants 1988) to influence his mother, and subsequently his father. The other children, however, employ a range of influence strategies. Anna, deemed to be a boisterous child by her parents, often makes deals with them, or uses laissez-faire influence strategies. Over the Christmas period

Anna also did not ask for any presents, with not asking proving to be a very effective influence strategy for Anna to use. Recognising her non-demands, Debbie and Paul bought her a range of presents, including an expensive video camera. Such an influence strategy, of not asking, has not been fully recognised within existing child influence strategy frameworks:

Paul; Anna did well out of it [Christmas]. She didn't ask for anything, but she had to have something. We ended up buying her a video camera (.) so she did well

Tina, supporting Kipnis's (1976, p.46) assertion that children can only *"beg, ask, plead or whine in order to influence their parents"*, demands items, cries, or plays on their emotions to get what she wants. Adam frequently asks his parents for things.

We also have further empirical evidence from the Jones family story to suggest that the repertoire of influence strategies available to children may be somewhat restricted, dependant on their place within the family environment. As Michael is viewed as being *"dull and boring"* by Tina, and indeed his siblings as a whole, he does not have access to their support. Consequently Michael has little choice but to employ unilateral influence strategies, or form a coalition with his mother. Anna, on the other hand, is well liked by her younger brother and sister, and Anna effectively exploits this. Recognising the high level of parental resistance to her influence strategies, and aware that her mother thinks that Anna *"wants every single week, every single week … it's all year round with Anna"*, Anna encourages Adam and Tina to ask their parents for things on her behalf, or she forms a coalition with them:

Debbie; She's [Anna] quite clever now, she gets the others to put a word in for her so she gets what she wants
Interviewer; So they come to you and say Anna wants this?
Debbie; Adam and Tina, usually (.) she's quite clever, she knows if she really, really wants something that it's no good just asking all the time because I'd get sick of it (.) so what she does is she makes other people ask for the things she wants, you know … she ends up getting things even though she herself hasn't asked for them … to her it might look like she's not asking for much, but she has, even if she's not come out and asked me for things.

DISCUSSION

Michael Jones, unlike his siblings, faces minimal parental resistance to his influence strategies, and he is able to garner considerable support from his mother, and subsequently his father. Mothers have been found to work best with sons in coalitions, particularly when the son is the eldest child (Lee and Collins 2000). Nina Baldwin can also easily influence the decisions of her parents, and both Nina and Michael therefore need to utilize only a limited range of autonomous influence strategies (e.g. tell, ask, positive affect).

Birth order, we suggest, is therefore related to a child's influence strategy choice and the subsequent parental resistance to its employment. First born children within the families studied were found to have a greater influence in the decision-making process. Although birth order has been related to a child's success in employing influence strategies (Cotte and Wood 2004; Dunn and Plomin 1990; Lee and Collins 2000), we suggest that disruption in the family can affect this.

Whilst existing literature suggests that it should be Nina Baldwin who is compared with Jessica, with older children often used as a benchmark for younger children (Buhrmester and Furman 1990; Harris 1995), this is not the case in the Baldwin family. Similarly

Jessica should hold more influence in the decision-making process because of her age (John 1999), but her position within the family has been disturbed because of the changes to her family form. As the Baldwin family has changed, so too has the power distribution amongst the resident children. Jessica's position within her family has been displaced, and Nina (the biological child of both couples) is treated as if she were the first born child who is suggested to hold greater influence. In effect Nina is the first born child of this new coupling, and it appears as if a new, "second" family has been created composed of Carol, Ray and Nina.

A child's ability to influence the decisions made by their parents relates to how that child is situated within the family ecology, and how they are viewed by their parents (as figure 1 suggests). Michael

Jones and Nina Baldwin are viewed in a favourable light by their parents, and need only use *autonomous* influence strategies to get what they want. They also face limited parental resistance. Anna Jones and Jessica Baldwin, for example, are not held in such high regard by their parents. Consequently both girls need to adopt much more aggressive and *confrontational* influence strategies, and need to fight for what they want because of the high level of parental resistance. Accordingly, as shown across each family, a child does not have automatic access to each influence strategy identified earlier; Anna and Jessica, for example, can not form coalitions with their parents, and they would struggle to effectively utilize the influence strategy of positive affect.

Figure 1: Influence Strategy Matrix

Lone Influence		**Strategy Type**		
		Group Influence		
		Autonomous e.g. Emotion; Positive Affect; Ask e.g. Michael; Nina	*Cooperative* e.g. Deals; Bargaining; Positive coalitions e.g. Michael and Debbie; Nina and Ray or Carole	Little Resistance
Child's Position in Family	Favourable			
	Unfavourable	*Confrontational* e.g. Demand; Show aggression; Laissez-faire e.g. Jessica; Anna	*Collaborative* e.g. Coalitions (which involve coercion) e.g. Jessica and Nina	Strong Resistance

With regards to coalition formation, however, both Jessica and Anna recognise their low standing in their parent's eyes. It has been suggested that "weaker" family members can unite to counter the influence or resistance of a "stronger" family member (Pearson 1989), and so in an effort to boost their own influence potential (and to stand a greater chance of getting the things that they want) the girls utilize a sophisticated series of coalition formation strategies.

Although Jessica and Anna could never form a direct coalition with their parents, they both have the potential to begin by forming a coalition with their siblings in order to exert indirect influence on their parents. In the first stage of strategy deployment Jessica and Anna recruit other siblings to work with them to facilitate their influence strategies. Once this sibling-based coalition is formed then the group as a whole attempts to influence the decisions of their parents in the second stage of this coalition-based strategy. Jessica Baldwin often utilizes this strategy, first influencing Nina to work alongside her, and then both Nina and Jessica work together in a coalition to influence their parents. Alone Jessica could never influence her parents in this way, but she cloaks her influence strategy with the presence of her step-sister. Such a strategy has been termed *collaborative*, as although co-operation is needed to form the coalition, such co-operation may not always be granted by a child's free volition. Carole Baldwin, for example, believes that often Jessica bullies Nina into working together in this way (with Carole feeling that many of the things that the two girls ask for together are only really wanted by Jessica), and an element of parental resistance is encountered because of this.

What is interesting to highlight is that whilst individually Jessica Baldwin would utilize confrontational influence strategy types (demanding; showing aggression), when she works in coalition with

Nina the strategy types are much less aggressive. We, therefore, have early findings which suggest that coalition formation can affect the types of influence strategy which the group as a whole employs. It is almost as if Nina's presence, and her success in influencing her parents, dilutes the normally aggressive strategies which Jessica alone employs.

One other form of influence strategy type, termed *cooperative*, was evident which involved the use of less coercion in employing collaborative influence strategies. In such coalitions (such as that of Michael Jones and Debbie Smith; or Nina and Carole or Ray Baldwin) the members freely agreed to work in collaboration with one another to influence others. Due to the coalition membership (which often includes a parent) little parental resistance was encountered.

The familial environments which exist within each family story suggest that it is probably rare for any one family to be composed of a single universal family environment, except possibly in the case of only children. We found little empirical support for the idea of a universal parental socialization style and family communication pattern within a family, although this seems to have been an assumption which has underpinned earlier studies (Carlson and Grossbart 1988; Carlson et al. 1994). Rather, different socialization tendencies exist within the same family. Children therefore appear to have different levels of access to the range of influence strategies identified, principally in relation to their ability to form coalitions with siblings and/or their parents to influence family purchase decisions. A child's family environment does therefore, we suggest, effect the types of influence strategy which they choose to employ.

As Flurry (2007) and Palan and Wilkes (1997) point out, considerable gaps exist in both our understanding of the influence strategies which children use and in terms of understanding the choices

they make when choosing which influence strategy to employ. Our paper has attempted to fill some of these gaps by suggesting that the family environment can restrict a child's choice of influence strategy. Ultimately children experience their family in different ways, and this has implications for the types of strategy which they choose to use and those that they have access to.

Opportunities exist to explore the influence strategies of children across a greater range of family types, and also to explore in further depth whether children direct different types of influence strategies towards different family members (e.g. siblings, grandparents, step-parents). Similarly opportunities exist to explore multiple family consumption sites (e.g. can children switch strategy use in different family settings, or homes), and families of different cultures, to investigate whether such factors also influence the choice processes involved in selecting which influence strategy to employ.

Consuming Buddhism: The Pursuit Of Happiness

Siwarit Pongsakornrungsilp, Walailuk University, Thailand
Theeranuch Pusaksrikit, The University of the Thai Chamber of Commerce, Thailand

INTRODUCTION

Buddhism has been an important part of Thai religion and culture for hundreds of years. In the past few years the emerging trend in Thailand has been the renewal of interest in Buddhism, particularly among younger generations. People now experience Buddhism through new media including YouTube, Facebook, and Twitter. Materials such as CDs, DVDs, and MP3s are full of Buddha's teachings. In addition, there is evidence showing that a dozen Dhamma pocket books have been listed in the 100 top selling pocket books (Se-Ed, 2011). It becomes very common to see many Thai people attending sessions of Dhamma talks, watching Dhamma TV programs, or listening to Dhamma songs. Moreover, on New Year's Eve, instead of going out for partying, thousands of people choose to come to temples for chanting and praying. During New Year celebrations, many of them take temple tours to pay respect to the images of Buddha at various well-known temples. The increase in sales of certain types of religious consumption reaches millions of Thai Buddhists. This indicates that Thai Buddhists are getting religion in many other ways. Religious consumption is very much a part of Thai society whether people consume through print media, electronic media, music, films, clothing, and other sacred objects.

Religious consumption is an activity that covers various parts of life, including the marketplace (Daniels, 2005), identity formation/maintenance (Wattanasuwan and Elliott, 1999), and entertainment (Romanowski, 1996). While religious consumption is a general phenomenon, it is a distinct feature for some more than others. As consumers' economic power increases, choices in material religious consumption grow significantly (Park and Baker, 2007). Along with the increase in consumption of material religious products, there is the growing recognition of practicing religion.

In consumer research, many scholars (e.g., Pongsakornrungsilp, Pusaksrikit, and Schroeder, 2010; Skousgaard, 2006; Veer and Shankar, 2011; Wattnasuwan and Elliott, 1999) have employed spirituality and religion to understand consumer behavior. For example, Wattanasuwan and Elliott (1999) studied the identity consumption among teenage Buddhists in Thailand in order to understanding how these teenagers who are dominated by Western consumer culture construct their selves through Buddhism.

Although religious consumption is not a recent phenomenon, it is important to understand how religious consumption associates and transforms consumer experience in spirituality. Buddhists consume their religion following the principle of Buddhism. Thus, this paper aims to study through the lens of Buddhist people about why and how Buddhists acquire and consume Buddhism in Thailand.

Furthermore, this study provides an additional perspective of Buddhism consumption by demonstrating that Buddhism is not entirely related to the abandonment of self or no-self as mentioned in many works (e.g. Wattanasuwan and Elliott, 1999). In fact, many studies state that consumers who have the strong belief in spirituality tend to attach themselves with materialism. This study demonstrates the different stages of consuming Buddhism whereby the self and material attachments do gradually dilute when Buddhists have pursued the Buddhism practices such as performing meritorious deeds, praying, and meditation. It is worth noting that only at the nirvana stage, one is no self or emptiness (Buddhadasa Bhikkhu, 2009). In the next section, we employ the concept of spirituality to demonstrate consumer insights related their religious belief.

Thai Buddhist Consumers and Buddhism Consumption

Buddhism plays a key role in Thai people's lives as it is the major religion in Thailand. Approximately 94 per cent of Thais are Buddhists (National Statistical Office, 2010). Buddhism is seen by Thai people as a way of living, a national identity, and the characteristics of being Thai (Wattanasuwan and Elliott, 1999). 'Wat' or temple has become the center of mind for Thai Buddhists. It is mentioned by the Office of National Buddhism (2009) that there are 35,773 temples in Thailand. Moreover, Buddhist temples are the center of Thai communities in foreign countries. For many Thais, experiencing or connecting with Buddhism often occurs through consuming the sacred material objects or religious goods. These sacred objects are highly personal and accessible to a large number of consumers (Park and Baker, 2007). The distribution of popular religious goods has been an integral part of Buddhist culture in Thailand since the 19th century. With the development of production and technology, more religious products are now available than ever before.

However, it is accepted that consuming religious material objects does not make you a good Buddhists (Punyanantaphikku, 2007). Doing so is seen as having only a superficial adherence to the tenets of Buddhism (Wattanasuwan and Elliott, 1999). In fact, Buddhist consumption is not a concept most Thai Buddhists are engaged in, even though most of them declare to be Buddhists themselves. According to Puntasen (2005), there are two main reasons for this occurrence. First, most Thais who claim to be Buddhists do not really understand the core concept of Buddha's teaching due to the dominance of capitalism worldview. Looking outside this economic worldview becomes much more difficult as most economic teaching and training emphasize an appreciation of economic mechanisms. Second, the main objective of Buddhism consumption is not to gain pleasure from material possession, but to maintain physical and mental well-being by being involved in the principle of right thought, action, and livelihood (Zadek, 1993). This principle serves as the fundamental tool to relieve individuals and society from suffering (see also Pongsakornrungsilp et al., 2010).

Consumption is said to be one of the main marketing activities. It is simply defined as the acquisition, usage, and disposition of goods and services to satisfy demand or desire (Kotler and Kwller, 2009). The fundamental concepts in the consumer behavior process are want, choice, consumption, and satisfaction, which describe the basic process of people's lives. Buddhism consumption, however, defines consumption differently. Buddhism consumption is defined as the acquisition, usage and disposition of goods and services to satisfy the desire for true well-being (Payutto, 1994). It considers whether or not physical and mental well-being is adversely affected by that consumption. This consideration is often overlooked by producers and marketers. The main purpose of Buddhism consumption is to form a basis for the further development of human capability (Payutto, 1994).

The key characteristics of Buddhism consumption are that the desires are controlled by moderation and the objective of well-being (Payutto, 1994). Buddhism consumption, therefore, holds on to the middle path. Too little consumption will lead to deficiencies that can be harmful to physical and mental well-being. Too much accumulation of material wealth will bring more pain as a result of cravings (Puntasen, 2005). Today's society encourages consumption that can lead to delusion, intoxication, and health and mental problems. Buddhists recognize that certain demands can be satisfied through mind-

ful consumption (Sheth, Sethia, and Srinivas, 2011). Additionally, refraining from consuming can play a role in satisfying spiritual needs. In this study, Buddhism consumption which is so central to millions of Thais will be understood more holistically by including not only what one believes, but how one exercises such belief. Hence, the questions are raised in relation to how and why Buddhism is consumed, and how religious consumption is associated with Buddhist belief.

SPIRITUALITY

Spirituality is a distinct element that influences people's way of life. It involves either religious or non-religious beliefs and behavior, which people can obtain individually and collectively through acquiring skills, practices, artifacts, or qualifications during their spiritual journey within a social group (Skousgaard, 2006). Spirituality concept is sometimes constructed in a close link with materialist view (Reindfleish, 2005). Gould (2006) identifies this view as spiritual materialism, in which it occurs when consumers consume spirituality in the same way as they consume products. He then illustrates material-spiritual orientation and divides it into four levels: (1) completely materialistically orientated without a spiritual connection, (2) asceticism, (3) spiritualized self-transformation, and (4) spiritualized self-liberation (Gould, 2006, p. 66).

Spirituality and religion are shared constructs that have idiosyncratic characteristics (Miller and Thoresen, 2003). While many empirical studies treat both constructs quite the same, Miller and Thoresen (2003) suggest the way to differentiate these constructs is by viewing religion as a social phenomenon and viewing spirituality on an individual level.

Research regarding the influence of spirituality and religion has been thoroughly studied in the field of psychology. The findings support the notion that individuals who are highly spiritual or religious have fewer physical and mental health problems, recover from illness quickly and experience less stress (Duffy, 2006). In addition, it also shows that highly spiritual individuals can develop a worldview that promotes well-being and an optimistic view on life. This is because spirituality can help transform a negative into a positive perspective. In Pongsakornrungsilp et al.'s (2010) study on co-creation brand through myth-making and spirituality, they found that spiritual experience is the authentic experience that interact, share and co-create power to benefit people's minds and their belief in order to form the consumption process and the meaning of the brands. However, the limited research on spirituality, religion, and consumption restricts the understanding of the dynamics of spirituality in the marketplace (Skousgaard, 2006). It is possible that spirituality can help explain the dynamics between individuals and religious consumption.

METHODS

We employed two main methods for this study. First, we proposed to understand how consumers consume Buddhism from one of the most

visited online Buddhism communities in the world, Palungjit.com. There were around 339,110 members in February 2011 (Palungjit.com, 2011). We conducted the empirical netnographic study by observing, participating, and co-creating (as insiders) the culture of a group within Palungjit.com. This group is co-created by different members who have different backgrounds. In this forum, members have different intentions to collaborate in the collective network such as searching for amulets, donating their resources, and discussing their meditation experience and other Buddhism practices. There have been 3,226 regular members with 42,243 posts and 1,610,796 views since May 2010. We also used personal messaging (PM) to follow up additional data from prominent informants.

Additionally, we also employed ethnographic method to collect data by participating in different Buddhism practices such as attending a meditation retreat, listening to Dhamma talks, and performing meritorious deeds. We conducted participant and non-participant observation during the practices. As mentioned by Kozinets (2010), netnographic study should not require only one data collection technique, but researchers also need additional study to insure that they can get the relevant data. One of the authors also attended a 5-day meditation retreat in the participation observation method, and also interviewed other attendants during February, 2011. Both netnography and ethnography allow authors to understand how and why Buddhists commit to Buddhism practices.

RESULTS

This study provides additional insights of Wattanasuwan and Elliott's (1999) Buddhism consumption. Their data were collected from Thai Buddhists who live in the urban community, especially in Bangkok, where Western culture has dominated consumer culture. Buddhist teenagers domesticate through postmodern activities such as music, films, and western-branded products (Wattanasuwan and Elliott, 1999). These teenagers view Buddhism as the extraordinary way to escape from their complicated lives. On the other hand, this study considers various groups of Buddhists who engage in Buddhist rituals and experience consumer culture in a different manner.

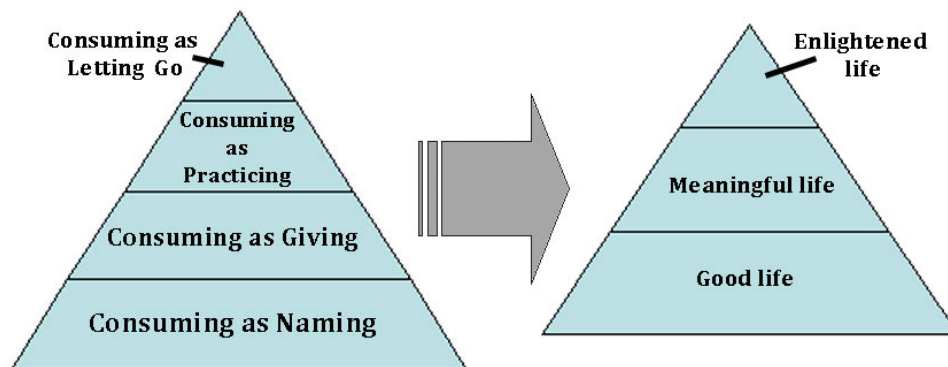
This study found that Thai Buddhists consume Buddhism in various ways with different purposes. Most Thai Buddhists have experienced Buddhism since childhood and gradually adopt additional practices when they grow up (e.g., performing meritorious deeds, praying, and practicing meditation). Learning from family and schools, many Thai Buddhists acculturate Buddhism practices into their everyday lives. Many of them observe five *sila* or precepts and consume some practices as parts of Thai culture. The findings show that many Thai Buddhists go through different stages of Buddhism consumption. Moreover, this study also found the dematerialization among Buddhism practices. As demonstrated in Figure 1, materialism and spirituality are degraded from lower to higher levels.


Figure 1: Buddhism Consumption and Purposes

Consuming as Naming

The first stage of consuming Buddhism is related to accepting oneself as a Buddhist. In general, many Thais become Buddhists following their Buddhist parents. There is no need to participate in any affirmation rituals. This stage is a fundamental level of becoming Buddhist. However, many Buddhists do not acculturate Buddhism in their everyday life, despite the fact that they live in the Buddhist environment. The following posts are examples of consuming as naming:

Dara: "I declare myself as Buddhist, but I never really engage in any kinds of Buddhist practices. I only follow the religion my parents respect."
Ed: "Being a Buddhist is something I've become since I was little. I learned about Buddhism in school, so I know about the historical part but I hardly practice Buddhism."

Like Dara and Ed, many Buddhists do not engage in Buddhist practices, even though they know the importance of Buddhism since their childhood. They understand what is 'good' or 'bad' and 'right' or 'wrong', but they do not embody with Buddhism practices and path. They consume Buddhism merely as a small part of their cultural identity. This is because they consider Buddhism as the morality rather than the religion (Buddhadasa Bhikkhu, 2009). Quite often many Buddhists who touch on a superficial part of Buddhism will consider Buddhism as the sacred religion when they face problems or suffer from their desires. Therefore, spirituality is employed to persuade these Buddhists to engage in Buddhism.

Consuming as Giving

The second stage refers to consuming as giving. Giving away material objects and performing meritorious deeds are very typical types of Buddhism consumption. Many Buddhists engage in this type of consumption since their childhood and continue doing so in their adulthood. However, the concept of giving for Buddhists is defined in various levels. Besides giving away things to people in needs, some Buddhists also view donating their blood, organs, or even their dead bodies as the beginning of eliminating their selfhood. Many also attempt to give the knowledge of Buddha's teaching or Dhamma in the forms of CD, DVD, books, and leaflets to others as they believe giving Dhamma is the best of giving.

Giving is a very important foundation of consuming Buddhism. By performing these giving activities, many Buddhists intend to accumulate 'Boon' or merit that they believe the merit can provide them with good fortune and strengthen them to overcome any obstacles. This spirituality of consumption is one of the main life goals which most Buddhists want to achieve. In addition, many Buddhists believe that the next life and the samsaric circle (birth – death – rebirth) depend on the obtained merit (Payutto, 1994). They expect to gain more merit so that they can have their life after death in heaven. This study found that the more Buddhists engage in giving activities, the more they connect with their religion.

Charlie: "I've given monks foods since I was a little… Accumulating merit would bring good things into my life. So I believe you have to make merits as often as you can."
Patty: "My mum always asks me to join her deeds at the temple. When I was sick or unhappy, I would go to make merits by giving food, money or products to monks. It makes me feel better."
Dorn: "Every week, I go to the temple to give alms. I dedicate the merit to the venerable monks who produced the amulets. Doing this would give them supernatural power which can increase my luck and fortune."

This study shows that Buddhists consider practicing the rituals of giving as the ordinary experience that they participate in their daily life. We found from participating in this practice that most Buddhists feel delightful to participate, socialize, and share in order to make merits. As mentioned by Dorn, spirituality is one of the aspects that some Buddhists would like to gain from engaging in giving. This demonstrates the *intrinsic-active-self oriented value* (Holbrook, 2006) which consumers obtain from Buddhism practices. At this stage, accumulating merits may help these givers/donors learn to give and distribute their wealth to others. For many Buddhists this action, however, does not lessen their desire to occupy material objects. This is because many of them give with the purpose of reciprocity. It is not that they want to receive things back from receivers, but their hope is to gain spirituality in this life or the next life. The second stage represents the accumulation of merits through the means of giving to gain the better life in return. Additionally, these Buddhists still have the desire to consume material objects to satisfy their needs and wants.

Consuming as Practicing

Moving to the third stage, a few Buddhists begin to realize that gaining wealth or becoming rich is not their ultimate life goal. They try to search for other ways to bring them the feeling of true happiness. As mentioned by Jit, she and her husband acquire various material objects, but they feel that this material acquisition cannot provide them the real happiness.

Jit: "My husband and I came from poor family background. We work extremely hard until we now have everything; a big house, a luxurious car, a lot of money to spend. Although I have all those things I want, I still don't feel happy. There is something still missing in my life..."

At this stage, praying and meditating become common practices among some Buddhists in order to make them feel calm and peaceful. They regularly listen to Dhamma talks or read Dhamma books. These Buddhists have more opportunities to learn Dhamma and accumulate knowledge of Buddhism in order to obtain a peaceful mind. They view that performing good deeds or accumulating merit by donating is only a small part of consuming Buddhism. As found in our data, consumers believe that practicing spirituality can create happiness. However, some Buddhists are much more attached with materiality and spirituality. They define the meaning of practices as a symbolic meaning of spirituality and materiality. Some perceive that practicing can give them greater merit than giving. They therefore expect to gain a high level of merits from their practice.

Montri: "I always pray to Lord Buddha every night before going to bed. I chant different Buddha praises. During my pray, I am in peace. I believe that praying would give me more merit than giving alms."
Ton: "Praying is like working. We work to gain some capital (merit). I believe that this capital can have a huge effect to my life. Like doing business, you need enough capital to run your business. So, merit is the capital for you to run your life."

Some Buddhists also choose to commit to meditation retreat as the basic way to obtain an intensive meditation. Practicing religion by participating in meditation retreat currently becomes extremely appealing to both young and adult Buddhists. These meditation retreat courses are held in various places throughout the country. Many of them are fully booked. Some places even have to book a year in advance. Retreat participants have to live with limited consump-

tion following Buddhist's eight precepts. They have to refrain from: killing; stealing; unchaste behavior; lying; using alcohol and drugs; eating after noon; listening to music and entertainments, wearing jewelry and makeup; and using high and luxurious seats and beds.

Pen: "My interest in Dhamma comes from a best-seller pocket book "Khemtid Chevit" (Life Compass). This book creates the interest in Dhamma among young generation. As my interest grows, I then search to read a few more Dhamma books by other authors and start to attend meditation retreats. I used to ask my friends to come along, but they didn't want to. I then realize that it really depends on their past Karma."

Consuming Buddhism is the way to understand the causes of sufferings and find the way to eliminate those sufferings permanently so that they can lead the way to liberate from the samsaric cycle. Some Buddhists, however, merely expect to obtain the peaceful mind from attending meditation retreats. They thus can temporarily escape from their problem. Very few of them continually practice meditation seriously after finishing the retreats. This is an inauthentic Buddhism practice which is not the real objective of attending meditation retreat. In other words, it is similar to what found in brand community study (Muñiz and O'Guinn, 2001) that some community members have used brand in the wrong way.

Buddhists consider their practices in two meanings: peace and spirituality. To obtain the spirituality from the practice, these practitioners tend to focus on materiality of their consumption or what Sheth et al. (2011) use the term as acquisitive consumption. On the other hand, practitioners who search for peace emphasize gaining experience and knowledge of symbolic meaning. This knowledge would activate them to search for an additional level of Buddhism practice. These Buddhists still have demands in consumption, but some of them obtain more mindful mindset than another (see also Sheth et al., 2011).

Consuming as Letting Go

By accumulating and gaining knowledge from performing Buddhist rituals, a few Buddhists are interested in finding the real happiness of Buddhism – Nirvana – liberating from samsaric cycle (birth-death-rebirth) or laws of Karma (see also Wattansuwan and Elliott, 1999). Some Buddhists follow the next stage of Buddha's teaching that the key to provide the real happiness is being mindful in every thought and action. To achieve this stage, contemplating their mind is considered as the way they gain pure and strong mind.

Terk: "The core concept of Buddhism is not the learning process from the outside – that are resources such as books, CDs, or masters – but we should learn from the inside or learning to know ourselves."
Noi: "Mindfulness is the process of mind-aware practice. We have to contemplate our mind until we obtain consciousness and awareness in every moment. This process takes time, and we have to work hard. Then, we will enlighten the laws of karma."

Both Terk and Noi demonstrate an interesting issue about the liberation of samsaric cycle or Nirvana which consumes time and requires practices. However, samsaric cycle or laws of karma is not just about birth-death-rebirth, but it also relates to the awareness of nature around the self. Practicing mindfulness is the way for Buddhists to gain a strong mindset which influences them to concern the nature, and also avoid them to harm others including human beings, animals, and environment.

Dang: "Buddha has taught us to realize or be aware of nature how we can accept or live with the real situation even we don't want to. We have to concern this point during the contemplating session."
Kathy: "Buddhism is about peace and nature. Practicing mindfulness can help us understand this issue. It gradually brings us back to reach the nature. I may not attend the nirvana in this life, but I will never give up."

As mentioned above, although the highest goal of Buddhism consumption is obtaining nirvana, many Buddhists do only expect to gain a peaceful mind. In fact, practicing mindfulness is the process of accumulating mindset which supports consumers to live with nature and community (Sheth et al., 2011). Then, Buddhists who are in this stage still require goods and services as other consumers do, but their consumption would concern to themselves, environment, and community without any cravings. Moreover, Buddhism does not instruct them to abandon everything, but it shows how people can consume or behave with less harmful to environment and other consumers. This is in line with the Buddhist way that consuming Buddhism is the co-creation process of wisdom and insights for understanding "What is truly what?" Selfhood and material attachments are causes of sufferings, and engaging in Buddhist path is the only way to be free from sufferings and samsaric cycle (Buddhadasa Bhikkhu, 2009).

DISCUSSION AND CONCLUSION

This study gives an insight into what the motivations for Buddhism consumption are and contributes the prevalence of religious consumption experienced by non-Christian believers. We have extended Gould's (2006) spiritual materiality in Buddhism by demonstrating the empirical data. The findings show four stages of Buddhism consumption to achieve three main life goals. The first stage refers consuming Buddhism as naming themselves to be Buddhists. This level is the most common for most Buddhists. However, many of them do not practice Buddhism but refer themselves as Buddhists following their parents and ancestors. The second stage refers to consuming as giving. Many Buddhists believe that by giving away from small things to donating their lives, or even giving Buddha's teaching to others will lead them to the good life. Sacrificing their material and non-material objects in order to gain tranquility and spirituality is the first level of obtaining happiness in world view. The third stage refers to consuming as practicing. The main activities for Buddhists to practice are reading Dhamma books, listening to Dhamma talks, chanting, meditating, and attending meditation retreat. It is through these practices that Buddhists can find the way to search for true happiness. These practices will lead them to gain *the meaningful life*. The final stage refers to consuming as letting go. This is the hardest stage for Buddhists as they learn to think and to behave mindfully in every moment and action in order to letting go of their desire and their selfhood. It is through this consumption that Buddhists can find the way to search for true happiness. By maintaining this practice, they hope to reach *the enlightened life*. This life emphasizes the search for happiness from persistence and mindfulness.

This study has highlighted that there are different levels of Buddhism consumption, and each level can pursue through different strategies. The findings from this study provide an additional perspective to the controversial issue in consumer culture (e.g. Kilbourne, 1989). The level of consumption does not influence the level of happiness. Instead it is much more important for people to accept the real situation during the consumption process. In all stages of Buddhism consumption, the materiality has gradually degraded from Buddhists who participate in performing meritorious deeds to attend-

ing meditation retreats. For example, the second stage, consumers are much more attachment with materiality, whereby consumers co-create spirituality as a symbolic meaning through the objects. They attach their self by viewing that the more they give, the more they get merit. This shows the interconnection between spirituality and materiality. Thus, consumers tend to display 'self' in their consumption. Even in the third and fourth stages where some Buddhists intensively focus on practicing and contemplating, Buddhists still require consumption, but their cravings (e.g., prestige, beauty, scent, luxury, and so on) are lower than other Buddhists who are in a lower stage. In other words, Buddhism is not a threat to consumer culture. Buddhism is the way of learning, understanding, and accepting the nature and situation, and it also helps us understanding causes of problems or sufferings in order to search the ways to get rid of them (Payutto, 1994). Therefore, it is arguable that self is not generally prohibited in the Buddhism but reducing the level of selfness can decrease sufferings.

This study shows that religious consumption is an important issue and Buddhism as a spiritual source has much to offer. Consuming Buddhism has formed a nurturing ground for people to discover a method of personal transformation. This study shows that consumption alone may not give people's lives satisfactory meanings. Consuming Buddhism can make them aware of how they should live to gain an ultimate life goal.

Although a collective process in this study can provide an additional perspective on Buddhism consumption, we focus only on an individual process that consumers engage in Buddhism activities. Future research may explore the collective process of Buddhism consumption. Moreover, additional consumption in each stage which provides unique meanings related to materiality, spirituality, and beliefs toward Buddhism need to be explored. Future research should also examine the similarities and differences between preferences in people's selection of religious consumption. In addition, it is interesting to understand non-consumption practice, which may be evidenced by studying how Buddhist monks consume. A sense of monk's religious identity in an era of materialism may take the different form of restraining one's purchases from goods. The knowledge of monk's consumption may help to gain the understanding in creating sustainable consumption. Furthermore, supply side factors that influence religious consumption such as the availability and marketing of religious items also deserve scholarly attention. Further research inquiry into these issues will extend our understanding of religious consumption.

Brands as Resources in Intergenerational Cultural Transfer

Sandy Bulmer, Massey University, New Zealand
Margo Buchanan-Oliver, University of Auckland, New Zealand

ABSTRACT

Brands are part of the backdrop in which everyday family life unfolds. Household product names, games and entertainment systems, advertising jingles, distinctive packaging, branded service experiences, and commercials with familiar narratives and imagery form the reality of many young lives. Children experience brands as an integral part of their lives, much of it influenced by their families. The ways that parents choose and use brands, as trust mechanisms, heuristic frames, and symbols acting as "vessels of meaning and sentiment" (Holt 2006a, p.357), surely affects their children. Certainly, parents train their daughters and sons which brands to buy, and this type of intergenerational influence on brand equity is reported in the literature (see, for example Moore et al. 2002). Yet, despite understanding that brands play an important role in consumer culture, relatively little research has been done to investigate the ways that parents use brands as resources in their parenting.

Previous research generally has studied the socialization of children as consumers and investigated brands in terms of purchase and usage preferences passed on through families. However, consumer culture theory (Arnould and Thompson 2005) suggests that consumers not only consume brands in the traditional sense, they also use and experience them through advertisements and other marketing communications, termed 'mediated experiences' (Elliott and Wattanasuwan 1998). Brand commercials are used by consumers for purposes other than the persuasive and mostly commercial ones intended by brand owners (Arnould and Thompson 2005; Elliott and Wattanasuwan 1998; O'Donohoe 1994; Ritson and Elliott 1999). This paper explores the conceptualization of brands as resources used by parents in the intergenerational transfer of culture. The qualitative study reported analyses interviews with women and narrative accounts of their life histories to extend understanding of the role of brands in the intergenerational transfer of culture. Such an exploration is needed to extend our understanding of the ways brands impact on children over and above purchase and usage preferences imparted by parents.

THEORETICAL BACKGROUND

Brands as Resources

Consumer goods and brands play important roles within a cultural setting. There is a well developed literature on the symbolic role of consumer goods and the use of brands as resources in adult society (Arnould and Thompson 2005; Belk 1988; Bourdieu 1994; Csikszentmihalyi and Rochberg-Halton 1981; Elliott and Wattanasuwan 1998). Brands, partly through their advertisements, have a role to play in the expression of self-identity and in fostering community (Cova 1997; Firat and Dholakia 1998; Muñiz and O'Guinn 2005; Schouten and McAlexander 1995). Certainly, there is ample evidence to suggest that advertising is discussed amongst adults in everyday settings, and studies have reported the social uses of advertising amongst teenagers (Ritson and Elliott 1999). However, the literature does not yet provide much insight into parent/child conversations around brands and their advertisements.

There is a two way link between culture and brands—each impacts on the other. McCracken's (1986) seminal work in cultural anthropology advanced a theoretical account of the structure and movement of cultural meaning, suggesting advertising plays a role in providing representation of the culturally constituted world. More recently, Thompson and Tian (2008) have reported that brands, through their commercial activities, are involved in leveraging culturally rooted identities that provide narrative resources for identity projects. Their study showed that the socio-cultural context affects the way that traditions and particular constructions of the past are mythologized by advertisers and other marketing agents. Brand experiences are also thought to permit and support social connections and the building of community. For example, Cova (1997) has argued for the wider, macro-societal and communal 'linking value' of products and services (and by default the brands that symbolically represent and emblematize them). Marketers are in no doubt that brands and culture are inextricably intertwined (Holt 2006b) and yet this intersection has not been fully explored in order to conceptualize other dimensions to the relationship between culture and brands.

Cultural Transfer

Socialization during infancy and childhood is understood to be the most intense period of cultural learning (Giddens 2001) when families teach their children the information, codes, skills, attitudes, conceptions, beliefs, systems and values that constitute cultural knowledge. According to Bourdieu's (1986) concept of cultural capital, a process of domestic education is responsible for the level of cultural knowledge acquired by children, although Bourdieu "does not report how exactly cultural knowledge is transmitted within the families" (Becker 2010, p.19). Some parental activities that impact on children's cultural knowledge have been identified by education researchers, such as telling stories and reading books to children, playing cards and board games with them, doing jigsaw puzzles, visiting zoos, libraries and museums (Becker 2010). Cultural messages are reportedly embedded in daily parent-child interactions (Dunn and Brown 1991) where cultural knowledge is repeated and re-affirmed, but little is known about exactly how this occurs.

As they mature, children are impacted by other socializing influences in the social environment, particularly schools, peer groups and mass media. Media and cultural studies researchers have shown clear links between television, children and cultural identity—for example, Barker (1997) suggests that television programs become a site for discussion (about relationships and cultural taboos) amongst children and a point of contact between children and adults. Researchers have particularly focused on the globalizing forces of mass media impacting on the world of the child, as young people develop an increasingly cosmopolitan identity (Barker 1999). Much less has been written about the impact of advertising and brand stories on incidental conversations and opportunistic teaching occasions that contribute to cultural transfer and ultimately play a part in parents' attempts to acculturate and socialize their children.

CULTURAL KNOWLEDGE

Cultural knowledge takes many different forms and impacts on all processes of life. At one level culture is concerned with refined and sophisticated society and the visible, overt creative expressions of literature, art, music and architecture. Cultural knowledge in these spheres is necessarily predicated on more fundamental socio-cultural knowledge that is essential for the most basic and mundane operations of society. Within a culture there are ideas which define the things that are "considered important, worthwhile and desirable" (Giddens 2001, p.22). These values are enshrined in the cultural norms of behavior, both of which are actively learned rather than inherited or passively acquired. Social roles, social identities and self-

identity are negotiated by individuals as they interact with others in society and use cultural knowledge as a framework to guide their social interactions. Thus, cultural knowledge is required for both micro and macro aspects of life as individuals negotiate and link their personal and public worlds.

Having a shared sense of the past and a common interpretation of history is one dimension of cultural knowledge. Halbwachs (1992) proposed that social groups actively construct and sustain a sense of unity and cohesion by reproducing collective and cultural memories. Collective forgetting and remembering involves reconstructing histories that serve to unite society and emphasize defining moments of the past, thus creating a 'usable past' (Brooks 1915). Advertisers evoke the shared past using archival materials and recreations of easily recognized scenes, relying on the audience's imagination to complete the story. The way that an individual evaluates the past impacts on how they evaluate the way they are and the way they were. Personal nostalgia (Stern 1992), the content of an individual's memories, what they remember about their personal past and their point of view/perspective on the past, has implications for how the past affects the present (Wilson and Ross 2003) and colors the transmission of cultural knowledge to younger generations.

Cultural knowledge enables familiarity with myths, symbols, codes and meanings that confer insider status within a cultural group. There are many place based myths that are considered foundational in a culture. Desire for attachment to place is evident in the powerful myth New Zealanders tell the outside world, of a kind of unspoiled Garden of Eden at the bottom of the world. The propagators of this myth consider it a great blessing to live in harmony with the wild and sacred natural world of New Zealand (Bell 1996). Scenic representations, buildings, signage, statues and symbolic artifacts link members of society. Thus, distinctive, quintessential cultural knowledge is passed on so that new generations are acculturated and socialized into their own society.

Another specialized form of cultural knowledge is persuasion knowledge (Friestad and Wright 1994, 1995). Part of being socialized into a culture means learning how to negotiate everyday life in places of commerce, to make sense of the media and communications technology, and to how cope with commercial/persuasive messages. The behaviors and skills required are based on particular cultural knowledge that very young children start to learn while accompanying family members as they shop. The literature points to programs in schools that aim to develop what is termed media literacy, knowledge and skills needed to function in contemporary media culture (Potter 2011). Parents also actively teach their children about advertising and marketing, passing on cultural knowledge about how consumers are influenced by commercial messages, how to identify and resist persuasion attempts, and how to perform the role of a wise consumer.

METHOD

The findings reported in our paper are drawn from a study of brands and national identity. Themes of intergenerational national identity transfer were identified in this study. However, other unexpected connections between brands and intergenerational cultural transfer (unrelated to national identity) emerged, and these are discussed in the following section. In summary, the study employed narrative analysis, and utilized a two part interview method using life history and narrative techniques in conjunction with the use of a selection of actual television brand advertisements. Interviews were conducted with middle aged women in a major New Zealand city. Snowball sampling was used to recruit friendship pair participants— ten pairs of friends (twenty individual informants) participated in

the study. The interviews were digitally audio-taped and transcribed, using pseudonyms to preserve participant anonymity. Subsequent thematic analysis and coding was facilitated using NVivo8 qualitative data management software. The entire study utilized a discourse analysis methodology.

Autobiographical narratives, in the form of life histories illustrating national identity, were elicited from each individual participant. These depth interview sessions were designed to focus on issues in terms of the implications and experiences of individual consumers, so that important findings would flow from detailed analyses of particular life histories (Firkin 2004). In the second part of the fieldwork protocol, interviews were conducted with friendship pairs, as reported in studies by Banister and Hogg (2004). Two people, who had related consumption characteristics and similar world views, were interviewed together, providing "an effective means through which to ensure a more natural setting within which to negotiate identity talk" (Banister and Hogg 2004, p.857). During the interviews participants were shown six well known television brand communications. This was used to set the scene for discussing experiences of brands and identity. As the discussion evolved, conversation moved on from the selected brands' advertisements to other occasions of consuming brand narratives and the subsequent experiences of identity. It was during this time that intergenerational themes were revealed.

FINDINGS AND DISCUSSION

Beliefs, Values and Norms

Generally talking to their children about advertising was a theme common amongst the participants. However, it was not just the overarching *concept* of advertising that people talked about; parents used specific, branded stories as a resource in passing on cultural knowledge to their children. Sensitive issues (possibly including relationships, puberty and death) could be introduced (by parent or child) into a discussion as a result of shared ad viewing. Participant comments relating to the U by Kotex *Beaver* tampon ad indicated this. During the interviews both Tess and Belinda noted their relief at not having to answer questions arising from the U by Kotex commercial but were aware of the potential for such parent child discussions.

> I have seen the beaver one once. (Tess)
> *You had to explain it to your* [seven year old] *daughter? (laughter) (Sharon)*
> *No, God no! (Tess)*
> *... you'd take an interest in it, like the beaver ad because it relates to you because you know your daughter* [a teenager] *didn't pick up on that* [vulgar terminology]. *(Belinda)*
> Lana, who had young school-aged children, commented in general:
> ... if there was something that had a bit of an adult theme about it and I wanted to give the kids a kind of bare level thing on it I might say, "Oh yes well," you know, kind of disguise the adult theme in something that's a bit more appropriate for them. (Lana)

While the brand itself (U by Kotex) might not have been discussed, the interviews clearly illustrated the ways that the narratives embedded in brand advertisements act as resources for parents as they interact with their children and transfer cultural knowledge of taboos, socially appropriate language and sexual mores onto the next generation. This occurrence almost certainly was not intended or explicitly considered by the brand owners and their advertising agents, highlighting the polysemy in advertising (Phillips 1997; Puntoni,

Schroeder, and Ritson 2010).

Other types of cultural beliefs and stereotypes were also passed on by parents in this study. Brand advertising provided the script for parents to illustrate strongly held beliefs about being culturally distinct, to a new generation—for example, children were told about the much talked about trans-Tasman (Australia-New Zealand) rivalry, as illustrated in the Mitre 10 *Sandpit* ad.

> Yeah, yeah, saying they're gonna build a wall and they ask the Aussie guy and he says, "Oh you're dreaming mate," when they asked if he would come over and help. (Georgina)
> Spoke to my kids about that. Oh they were laughing, thought it was hilarious. (Helen)
> Yeah? (Researcher)
> Yeah, they thought it was really funny. (Helen)
> "No surprises there!"(Georgina)

The children in the example above were already aware of the practice of making Australians the butt of local New Zealand humor which highlights Australian cultural stereotypes: laziness, stupidity, brashness and boorishness. Both their mothers reinforced this stereotypical belief when the opportunity presented itself, thanks to the Mitre 10 home handyman brand narrative. Furthermore, due to the mothers' singular commentary and discussion about the advertisement they culturally heightened the issue in their children's consciousness and affirmed the cultural lensing the brand advertisement provided. Similarly, Marcia highlighted that she made a point of talking to her children about ads which exemplified beliefs about Australians. A recent trip to Australia with her children had provided much brand advertising material to feed conversations comparing Australians and New Zealanders.

> Do you ever talk about ads with your kids? (Researcher)
> Oh only the Australian stupid dickhead ones, eh? They're so bad. You know, they think they've got a sense of humor but they don't match us at all, have you noticed that? They're bloody shocking. You know they're Australian even if they don't have an accent you think, "That was made in Australia." (Marcia)
> After denigrating Australian people for a while, Marcia continued;
> And their ads are the same, they're really, they're very immature and just stupid. You sort of look at them and think, "What?" You know, yeah. (Marcia)
> So you talked to your kids about those when you were there? (Researcher)
> And when we're here because if we see them here we know they're Australian because of the tone, yeah. (Marcia)

Social Memories

The findings in this study clearly demonstrate the facility of brands to embed collective memories and a shared sense of the past in their narratives. The women in this study used the social memories and the usable past provided by brand stories as conversational resources for use in object lessons re-creating the past. In the following text units, Belinda refers to a famous local soda brand advertisement. The brand narrative tells of a group of carefree children who are enjoying a small community swimming pool during the summer vacation. Cinematographically, it evokes the feel of the 1970s and the advertisement is edited to simulate a nostalgic documentary.

> I saw that on TV and my daughter was with me and I said, "That was what it was like when we were kids." And she just went,

(gagging noise made). (Belinda)
So there, you do. You do talk to people. You talk to your kids. (Researcher)
Yeah, I did say, "Oh that's exactly what it was like when we were kids," and I said, "Me and Meredith used to do that," and I told, she knows Meredith. And I told her and she goes, "Uh. Oh yeah." (Belinda)
She looked really bored? (Researcher)
She looked like I was saying we went to school on a horse and cart basically. Like when we were kids we used to get all about the war and I used to think, "Oh God, here he goes." So, yeah. (Belinda)
So why did you mention it to your daughter? (Researcher)
I think I did say something to her because I just sometimes think that we're just too PC nowadays. Everything has to, you know, the kids are just so molly coddled, now they can't walk the streets, they can't, everything. You know, it's just not the same for safety or, I'm not saying that there was safety in those days 'cause we still had people that were a bit peculiar, if not very peculiar, but you didn't worry about it like you do now, do you? (Belinda)

Belinda used the famous brand soda advertisement to illustrate the simple pleasures of her girlhood, a "golden age" where earlier generations of children were independent, never bored and did not have to worry about contemporary issues such as 24/7 parental supervision, sun protection and swimming pool safety protocols.

> But they'd be thinking, "Where's the lifeguard? Where's the sun screen? Where's the parents?" (Belinda)
> "And can I plug my iPod in somewhere?" (Ann)
> *Yeah. (Belinda)*
> *"And where can I put my* [hair] *straightener for afterwards?" (Ann)*
> *Yeah. Yeah. "And where's the shower block 'cause I don't want to get chlorine in my hair?" You know, it's, they couldn't relate to that at all, no. (Belinda)*

As Ann later mentioned:

> I think we're just trying to make that generational point that this is how life used to be and everybody was happy with it, you know? (Ann)

It was important to the women in the study to teach their children about the past, because collective reaffirmations of identity help individuals within a society to maintain a sense of self-identity and connectedness to others. The patterns of leisure, dress and family life that represent a culture at a certain time were evocatively captured in the commercial brand narrative. These brand nostalgic stories provided an opportunity for parents to teach their children how identities continue to evolve as individuals, as socially constructed concepts of the family and as a culture. These consumers of such historical constructions used them to locate themselves within a long term context by comparing then and now, who we were and who we are now.

Ways of Talking About Place

Findings from this study clearly showed that parents used brand advertising to socialize their children into the accepted ways of talking about the land and important symbolic places valued by society.

> Now you already said the kids ... Did you say you talked about the scenery with them? (Researcher)

> Yeah, like when I saw that Air New Zealand ad for the first time.

(Donna)

So what did you say …? (Researcher)
I just said to them that, "Look how beautiful our country is, you know. That's what our country looks like out of Auckland." (Donna)

In general, the findings showed that brand ads provided commonly available representations of places in the heart (such as holiday homes) and, as such, constitute a widely available conversational resource, as noted by Virginia and Waverley.

[My husband] *might have said "You know that ad? Well that's like the bach* [holiday home] *that we used to go to and we'd, like that, we used to do that too." We'd often use ads as a point of reference when talking about a story, of recreating a story from our childhood or something because everyone knows ads. (Virginia)*
I do the same. (Waverley)

The study provided evidence that brand commercials for products and services ranging from airlines, banks and paint to cheese employed the cultural codes and conventions for representing, visualizing and telling stories about place. This meant that even if families were unable to visit such places, brands put resources at their disposal to facilitate the intergenerational flow of cultural knowledge relating to place, as the previous text units show.

Persuasion Knowledge

The findings of this study showed that at the most basic level, ads provided an opportunity to educate children about the ways of the world. For example, the techniques used in making ads were sometimes a point of discussion between parents and children.

So what would you say if it was your kids and they, if you were having a discussion, what would be the nature of the discussion that you'd have with them? (Researcher)
Just, "How do you think they worked out, how do you think they've done that?" Like the latest Gorilla [she then realizes her mistake—she does not mean the Gorilla ad]*, Cadbury ad has got, they're playing, they're doing a song with their eyebrows, they're raising their eyebrows up and stuff so it's all computer generated. (Georgina)*

In this case above, the brand provided resources and the parents of pre-teens used shared viewing occasions as an opportunity to develop knowledge about how ads are made. This form of cultural knowledge is part of what Friestad and Wright (1994, 1995) termed persuasion knowledge—culturally relevant knowledge about advertisers' goals and tactics. Georgina used Cadbury resources and the Socratic Method to stimulate critical thinking and illuminate particular ideas that she deemed important for her children to know.

While older children may learn to be media savvy through personal interactions with peer groups and at school, parents still play a part in intergenerational cultural transfer and developing persuasion knowledge. Waverley and Virginia revealed that their teenage daughters, who are friends, have had parental discussions and compared notes about ads.

Do you talk with your daughter about it? (Researcher)
Imogen knows the tunes to all the ads and I say, "My God, you know that song off by heart," but we don't really have a conversation about it. (Waverley)

You haven't talked about how they're trying to get you to do something because of the ad? (Virginia)
Oh yeah, we do talk about things like that. (Waverley)
Yeah, yeah, yeah I knew Waverley would. (Virginia)
Yeah, I'm from the perspective of how they're manipulating your mind, we often talk about things like that. (Waverley)
Yeah, 'cause I knew you would. That's because, yeah, because Waverley, sorry Imogen and Jody have talked about that ad so our children have talked about stuff about what it's doing or its suggestiveness. Yeah. (Virginia)
From a persuasiveness marketing angle. We do talk about things like that. (Waverley)

In the previous example a more critical, media studies approach has been used by the mothers in discussing the influence and social impact of ads. Again, the mothers responded to specific brand communications, using them as a launching pad for discussions with their children about commercial motivations, persuasion and how to be an informed consumer, all based on essential cultural knowledge.

CONCLUSIONS

The findings provide support for Elliott and Wattanasuwan's (1998, p.135) claims that mediated experiences of brands can provide resources that, "*interlaced with lived experience,*" are used in imagining the self within a particular socio-cultural and historical context. The intergenerational processes facilitated by brands are an extension of Ritson and Elliott's (1999) concept of the social uses aspect of advertising. With respect to brand narratives, these findings confirm Thompson and Tian's (2008) claim that commercial activities offer views of the past and provide narrative resources for cultural identity projects.

Evidence from this study provides insights into the intergenerational transfer of cultural knowledge. The mothers who participated in our study provided unexpected narratives which demonstrated the process of domestic education referred to by Bourdieu (1986). Usage of television brand advertising for teaching and learning during unscheduled occasions was for them, an unremarkable, everyday type of parenting experience. However, evidence of this has not been reported previously in the consumer research and marketing literature.

Particular forms of cultural knowledge, embedded in brand narratives, were utilized during the ongoing process of socialization. Beliefs, values and norms relating to taboos, socially appropriate language and sexual mores were recognized by the adults as being available in brand ads for use in acculturation. Culturally based stereotypes were provided by advertisements and acted as a resource for affirming cultural beliefs and reinforcing appropriate responses to culturally referenced humor. Collective memories and a shared sense of the past was made available in nostalgic advertisements, assisting parents to reaffirm the connections between society, parents and their children and to maintain a sense of self-identity in relation to others. Cultural knowledge relating to accepted ways of talking about the land and important symbolic places was utilized by parents in response to certain brand narratives. Finally, cultural knowledge pertaining to the role of wise consumer was leveraged by parents as a result of shared consumption of particular brand narratives

This study enlarges what is known about what consumers do with brand advertisements. Even though society may have a slight sense that brands *should* not be part of the cultural land-

scape (Bengtsson and Ostberg 2006), the evidence is clear that, in the New Zealand setting at least, brands are significant cultural markers. A key message for brand owners from this study is that consumers can derive value from brands in ways that were previously unknown, that is, as resources in intergenerational cultural transfer. The findings underscore the important role and significance of brand marcoms as a widely accessible cultural resource used by parents in socializing their children.

We are suggesting that brand experiences and brand resources such as advertisements, play a broader socially contributive role in establishing and reinforcing elements of culture at the macro level within society in general and within families at the micro level. Brand commercials could function as one of the ties that bind generations together, enabling intergenerational knowledge transfer and memorial reconstruction at the national, the familial and individual levels. Brand advertisements are, by their ubiquity and their emotionally and symbolically infused brand narratives, pervasive meaning vessels which encapsulate cultural attitudes and values, deploying myths, popular memory and culturally relevant icons, and act as creators of nostalgic reverie. The nature of advertising scheduling on television generates serendipitous occasions for young and old to consume together, creating opportunities for cultural teaching and learning. In essence, the transfer of cultural knowledge that contributes to the socialization of children into a culture might be facilitated by brands.

Movement, Knowledge and Consumption within Elderly Care Environments

Tim Stone, University of Aberdeen, Scotland
Paul Hewer, University of Strathclyde, Scotland
Douglas Brownlie, University of Stirling, Scotland

INTRODUCTION

Everyday life within care homes has been the focus of much media interest within Europe and the United States of America over recent years. This interest has taken the form of reports that focus on the lack of a dignified existence (Parkinson 2010), the financial implications of care for the elderly (Morris; 2004; Duffy 2003; Carvel and Meikle 2002), profit over care (Duhigg 2007), maladministration (BBC 2007), inaccurate reporting of problems (Copple 2008), the stress associated with relocating groups of elderly people from one care home to another (Grant 2004; Portlock 2003; Sapsted 2002), nutritional standards (BBC 2009) government legislation (Butler 2003; Cunningham 2002), physical, mental and/or racial abuse of elderly people in care homes (Fackelmann 2007; Smith 2007; Gonzales 2004; Marsh 2003) and the spread of infection (BBC 2009). In the light of these mass media representations the notion emerges whereby these accounts have focussed on a range of problematic issues associated with elderly consumers who live in such institutions. However, as Thompson (1998) suggests, this problem centred approach can be critiqued for not explicitly considering the living arrangements of elderly consumers (Kim et al. 2003; Gibler et al. 1998; Gibler et al. 1997) as meaningful human situations in their own right. Moreover, elderly consumers' voices are often muted within gerontological studies of consumption within care environment (Stone 2009; Wilson 1997; Wilson 1991).

Theoretical Positioning

Consumer research examines how identities are carefully forged through co-constituted, co-produced market generated materials (Arnould & Thompson 2005). Within the tradition of consumer culture theory (henceforth, CCT), consumers, more often than not, are seen to adopt a pro-active role in constructing desirable and expressive identities. In the light of such scholarly revelations, researchers' have directed their attention toward and throughout marketplace cultures in order to reflect upon how "consumer culture is instantiated in a particular cultural milieu and the implications of this process for people experiencing it...through the pursuit of common consumption interests" (ibid: 871 in line with Epp and Price 2010; Schau, Gilly & Wolfinbarger 2009; Kates 2002; Kozinets 2002; Kozinets 2001; Thompson and Tambyah 1999; Belk and Costa 1998; Thompson 1996; Holt 1995; Schouten and McAlexander 1995).

Tim Ingold (forthcoming), reflecting upon contemporary thought within social anthropology, art and architecture, calls for a "profound understanding of the lived world and for enquiries into what the possibilities for human life might be." Ingold forwards a vision of culture as a textured meshwork of interwoven threads. This Ingoldian characterisation of context is based on fundamental understandings of the role of movement and bodily knowledge in bringing the meshwork of culture back to life. Our study is positioned in such a way as to cast new rays of light upon Ingold's theory by investigating accounts of movement and bodily knowledge within institutional spaces where bodily movement and subsequent knowledge is subject to careful calculation and strategization. Principally, our work investigates how elderly consumers in care produce affectual meaning. With the discipline of consumer research in mind, this study has implications for the way in which CCT is utilised as a theoretical point of reflection, challenging us to reconsider the terms we use within gerontological studies of consumption.

Within discussions of CCT it has become relatively commonplace to draw upon the symbolic, interpretive anthropology of Geertz (1973),

and/or the deconstructionalist philosophy of Bourdieu (1990), and/or pioneering consumer research (Belk, Wallendorf, and Sherry 1989; Belk 1988; Belk 1987; Holbrook 1987; McCracken 1986; Mick 1986 Hirschman and Holbrook 1982) to explore various aspects of consumption within the dominant social paradigm of market capitalism. Such scholarly endeavour either explicitly or implicitly acknowledges that studies of "consumer culture" tend to fall in line with an anthropological tradition that views "culture" as "a system of inherited conceptions expressed in symbolic forms by means of which [wo]men communicate, perpetuate, and develop their knowledge about and attitudes toward life" (Geertz 1973: 89). Following on from this, culture, not forgetting the promptings of genetic predisposition (Ingold forthcoming), can be seen to play an important role in continually enabling a coherent, intelligible, public system of symbols (Erickson & Murphy 2008) to emerge, develop, structure and transform shared everyday experiences and belief systems throughout the life course.

Such a proposition might enable a question to appear in the reader's mind: How do people inherit symbolic cultural conceptions? Geertz (1973) suggests that when human beings are very young; a gap exists between emerging bodily knowledge and meaningful day-to-day functioning. Commenting on this gap, Ingold (forthcoming) forwards the proposition that such a lacuna is filled by essential guidelines for a certain way to live that is passed from one generation to the next. From this perspective, culture is acquired through observation learning and replication rather than being innate. "Equipped with these representations, freshly encultured individuals can go forth into the world where they will encounter diverse environmental conditions, causing their knowledge to be 'expressed' in one way or another, in the subtle variations and idiosyncrasies of observed behaviour" (ibid.). Reflecting upon such a proposition, the notion emerges whereby culture can be either be thought of as a subtle "system of inherited conceptions" (Geertz 1973) or an acquired diverse "blueprint of activity" (McCracken 1986) or a "framed horizon of conceivable action, feeling and thought" (Arnould and Thompson 2005) that organises a wide range of individual and shared symbolic experiences and knowledge generation practices (Martin et al. 2006; Bengtsson et al. 2005; Goulding and Shankar 2004; Maxwell 2003; Fung 2002; Goulding et al. 2002; Kates 2002; Kozinets 2001; Schouten and McAlexander 1995).

However, current thought within anthropology, suggests that such a conceptualisation of culture that is based on an assumed, coherent and static cultural boundary is problematic (Ingold forthcoming; Kottak 2008; Rapport and Overing 2007). Such cultural models are based on the premise that, over time, involvement within the world is converted into an internal schema which becomes manifest in outward appearance and behaviour. Moreover, from such a perspective, people become closed off from the outer world of interactions with their surroundings. By virtue, cultural actors are framed in such a way that suggests that communal meaningful activities come into being within inverted, closed and static boundaries (Ingold 2008). Rather as Ingold (1998: 330 his italics) stresses, "what we do *not* find are neatly bounded and mutually exclusive bodies of thought and custom, perfectly shared by all who subscribe to them, and in which their lives and works are fully encapsulated". Along similar lines, Rapport and Overing (2007: 298) state, "[t]here is no longer traditional, bounded cultural worlds in which to live – pure, integrated, cohesive, place rooted – from which to depart and which to return, for all is situated and all is moving". From this we argue that cultural life "does not begin here or end there, or connect a point of origin with a final des-

tination, but rather it keeps on going, finding a way through the myriad of things that form, persist and break up its currents. Life, in short, is a movement of opening, not of closure" (Ingold forthcoming).

With such a perspective in mind, human-beings do not propel themselves across a carefully constructed "blueprint of human activity" (McCracken, 1986) nor should they be thought of as being enclosed within "framed horizons of conceivable action, feeling and thought" (Arnould and Thompson 2005). Rather, we argue, along with Ingold (forthcoming; 2008), that there is significant value in trying to recover that original openness to the world to probe the complexities and nuances of context and environment in the deepest possible sense. Such an epistemological and ontological perspective embraces the notion that human-beings issue forth through a world-in-formation along a tangled mesh of continuous and never-ending interweaving lines of genetics, life experiences, growth and movement. Or, to stick more closely to Ingold's (ibid.) lines of argument, this world-in-formation can be thought of as a dynamic, transformative, relational meshwork of continued flux (or becoming), never the same from one moment to the next.

From this perspective, human beings become meaningful as a consequence of their "patterns of activity and movement signatures" (ibid.) that can be found inscribed into particular identities, relationships, people, communities, things and so on (Rapport and Overing 2007). "As walking, talking and gesticulating creatures, human beings generate lines [of movement] wherever they go" (Ingold 2007: 1). With such nomothetic practices in mind, every person can be thought of as being instantiated in the world as an unfolding, tangled mesh of movement along ways of life (Ingold forthcoming). Thus movement becomes a critical vista for enabling the world (or the meshwork) to endlessly renew itself (ibid.; Ingold 2007); movement thus becomes a fundamental precursor for all socio-cultural experience within and throughout the meshwork of life.

Developing the emerging discussion still further, the authors argue that meshwork movement is responsible for the becoming, growth and reproduction of inter-place cultural knowledge. For example, the development of a knowledge system within science is attributed to "the work that goes into moving its diverse components – including practitioners, their know-how and skills, technical devices and standards of evaluation – from one local site of knowledge production to another" (Turnbull 1993: 30 in Ingold 2000: 229). Ingold (2000: 227) further suggests that knowledge "comes from a history of previous flights, of take-offs and landings, and of incidents and encounters en-route. In other words it is forged in movement, in the passage from place-to-place and the changing horizons along the way". Thus far from being copied, ready-made, into the mind in advance of its encounter with the world, knowledge is perpetually becoming within the open field of relations established through the immersion of the actor-in-the-world. Knowledge, in this view, is not transmitted as a complex structure but is the ever emergent product of a complex process of movement; put simply, "movement is itself the inhabitant's way of knowing" (Ingold forthcoming).

Part of CCT's allure resides in the call to encourage consumer researchers to reflect upon the contextual, productive, symbolic and experiential aspects of consumption and how these interact with lifestyle goals, and personal & social circumstances (Arnould and Thompson 2005). However, in an attempt to open up gerontological cultural discourse within consumer research, this paper will place emphasis on meshwork "movement" and "knowledge" in order to better understand how elderly consumers construct their lives within care home environments.

METHODOLOGY

A major factor in selecting qualitative, unstructured, in-depth interviews is because the outlined approach enables the researchers to engage with the elderly in such a way that enables them to reflect upon the flux of their experiences. Viewed in this way, in-depth interviews enable deep understandings of the nature of what it *feels* to be a consumer within a care home to emerge. Furthermore, such a methodological approach also enables the researcher to gain in-depth first person understandings of how participants define their own lives (Aberg et al. 2005). In this case, the researchers invited participants to give relatively unrestricted account of their lives within their respective care homes. By virtue, each participant was invited to talk about some of the things in their room with the goal of obtaining first person descriptions of these things.

The identification of suitable care homes that could enable the initialization of the fieldwork depended on practical considerations such as the type of care home and the number of people who were fit enough to be interviewed. Following on from this, letters were written to several care homes within the United Kingdom containing information about the nature of the research project, enquiring whether it would be possible to conduct interviews with elderly people within that particular institution. By virtue, the managers of St. Augustine's and Cedar View (names changed) provided the lead researcher with access to their respective institutions and suggested potential participants. As such, it was necessary to work around the routines of daily living, such as meal times, visiting professional carers (such as physiotherapists, vicars, chiropodists etc.) or social activities (such as trips to the theatre, tea dances, visiting friends etc.), in an attempt to ensure that any interview would not disrupt the social and/or care needs of the potential participants. In light of this, sixteen potentially suitable participants were approached and informed of the research objectives in the hope that they would agree to participate. Of this group, eight participants happily gave their consent to be interviewed at a mutually agreeable time. These are identified within the following table:

Case.	Name.	Care Home	Brief Description of the Care Home
1.	Violet.	St. Augustine's.	St. Augustine's (name changed) is located within Stirlingshire (Scotland) and is nestled in a quiet, leafy residential street in an affluent area with picture postcard views of the surrounding countryside. The original building was a large house that has been extended so that it can meet the needs of 22 residents.
2.	Lottie.	St. Augustine's.	
3.	Doreen.	St. Augustine's.	
4.	Harry.	St. Augustine's.	
5.	Rita.	St. Augustine's.	
6.	George.	Cedar View.	*Cedar View* (name changed) is located within Norfolk (England) and is in close proximity to the Norfolk Boards, the East of England coastline and the historic city of Norwich. The building has been constructed in such a way that reflects modern (but sensitive) design principles. The building can comfortably accommodate 44 residents.
7.	Anne.	Cedar View.	
8.	Bill	Cedar View.	

Findings

We examine, with no framed apriori expectations, the lives and movements of elderly people within care environments through discussion of a small selection of vignettes around the central theme of movement.

Movement: *George and his Correspondence*

George suggested that he had attempted to personalise his room with moveable items of furniture and correspondence aids in such a way as to feel more flexible, organised and comfortable:

> **George**: *"I put this extra furniture in and this large wooden hostess style trolley that can be used as a portable table is wonderful because it's on casters and I can swing it round and use it as a table."*

To this end, the wonderful, multifunctional, flexible nature of the objects within George's room (such as a hostess trolley that can be used as a table and a word processor that can be used as a typewriter) seemed to compensate, at least to some extent, for his lack of mobility:

> **George**: *"Of course, now I've got my word processor so that I can write letters because I couldn't write letters because I've got arthritis in both hands. When I'm writing anything in the diary I have to be very careful so that I can read it [laughing]. I haven't used it as a word processor for years. I just use it as a typewriter."*

As the preceding text reveals, George did not primarily navigate his life-world with his legs and feet (he was wheelchair bound), but rather with his arms, hands and fingers. Set within this context, George indicated that he often experienced problems moving his arthritic hands and fingers to the extent that he had been forced to adopt a more careful, considered and restricted approach to daily living within Cedar View. Such kinaesthetic knowledge (Ingold forthcoming) could be seen to affect his attempts to use his word processor/typewriter to correspond with friends and family and to make entries into his diary. With such an interpretation in mind, Ingold (ibid.) suggests that it seemed as if George's life-world, at least to some extent, had been kept intact by the presumably painful tuning of relatively small horizontal and vertical movements of his arthritic hands over the keyboard in order to maintain his social ties. Such a finding appears to suggest that George's frail arms, hands and fingers were crucial elements in enabling him to carry out such manual operations (ibid.). At the time of the interview, such fragile lines of movement could be seen to revive and enhance his sense of well being and improve the quality of his life. However, the text seems to suggest, George was finding it harder to control his hands, especially when he attempted to write legibly in his diary. Whilst such a task was still feasible at the time of the interview, the proposition emerges whereby this manual activity could cease if the pain in George's hands becomes too great. Furthermore, by extension, it would also seem reasonable to propose that a time will come when George is also unable to use his word-processor and independently maintain his social connections.

Perhaps with similar thoughts in mind, George subsequently suggested that such activities appeared to be consuming more (and more) of his time and energy. Such a process, in more general terms, seemed to create restrictions in the nature and scope of bodily movements that were available to him in the latter phase of his life. The implications of this would seem to suggest that lines of movement, slowly but surely, lose agency in old age and that such potentially reviving undercurrents (Kirkby 2009) are only capable of improving feelings of well-being when the body (or in the case of Bill, mostly his arms, hands and fingers) are capable of movement and relatively free from pain.

Movement: *Lottie and the Need for Physiotherapy*

Lottie's vignette begins by revealing lines of movement that have come into being as a result of a period of serious illness and the subsequent extended need for medical care within a hospital. Such a figural experience seemed to leave a lasting impression on Lottie's diminishing sense of independence and overall quality of life. Moving to the time of the interview, it seemed as if Lottie had come to terms with her life within St. Augustine's House as the following text suggests:

> **Lottie**: *"I am here and here I stay [sad laughter]. You find yourself in a position that you just have to do as things will do with you. I hope I can stay here because I have been here a long time now. I've been here four years and it feels like home."*

Within this period of time, Lottie suggested that she had come to reluctantly accept that she was no longer in a position where she could physically respond to the flux of a world in-formation (Ingold forthcoming). Such a relatively passive world-view seemed to be based on the notion that Lottie was no longer capable of physically responding to or resisting any dynamic changes in relation to the conditions of being-in-the-world (ibid.). As such, Lottie was crucially dependent on the carers within St. Augustine's House to meet such basic needs as getting out of bed, going to the toilet, getting dressed, being taken to the dining room, being taken to her room, sitting in her chair, getting undressed, taking medication, going to bed etc. Such extensive physical limitations, for example, had a negative impact on Lottie's sense of communal identity (Bauman 2004) as she could no longer visit friends in other rooms without the occasional assistance of a carer.

Furthermore, Lottie also noted that many of her friends within St. Augustine's House had become immersed within the ebb and flow of the untimely and inescapable eddies of death. Having encountered such, dark, depressing and unsettling experiences, it would seem reasonable to suggest that Lottie's sense of being embedded within an institutional community had been eroded on several occasions. No doubt, repeatedly experiencing such an unpleasant and upsetting phenomena as bereavement would seem to suggest that, at the very least, lines of social interaction (Ingold 2007) can subside over a relatively short period of time. This could also be attributed to the rather depressing notion that as fellow residents become frailer they become less capable of extended periods of physical activity and/or verbal communication the longer they stay within the care home. Or, to use Lottie's words:

> **Lottie**: *"They are well when they come in and they get frailer as they go on. They don't get stronger. They go downhill. There was a man up above called George something. He has gone downhill very much this last while."*

Set within such a physically degenerative context, Lottie revealed that, despite being in her nineties, she tried to ensure that she could continue to move such limbs as her arms and legs by visiting the physiotherapist on a regular basis. However, such bio-mechanical movements seemed to exact an uncomfortable toll, in the sense that Lottie's muscles were sore for a least a day or so after visiting the health professional. Knowledge of life, in this context, seemed to be derived through feeling muscular pain. Whilst reflecting upon such

experiences, Lottie stated such movements produce the knowledge that she "*would be no use at doing exercises.*" Subsequently, Lottie stated that she was more than happy to sit and enjoy the peace and quiet as these aspects provided her with warmth, comfort and an improved sense of well-being. Movement, for Lottie, as Ingold (forthcoming) suggests, may not be independent or regular but a pattern is nevertheless established through the unfolding of her everyday lived experiences.

Movement: *Bill's Experiences of Feeling Cold*

Bill discussed the various procedures that had been put in place within Cedar View to facilitate care:

> **Bill**: *"Everything is wired up here. If I want something, I just pull this cord which operates a buzzer down there. They come up and turn it off in here and see what the trouble is."*

When asked if he used the Tele-care System regularly, Bill seemed to suggest that he was comforted by the knowledge that he could easily use this device (there was a very long cord that hung within easy reach of his bed). This was a particularly important aid to living as such a device not only enhanced Bill's safety, it presumably also functioned in such a way as to maintain his dignity and, perhaps to a lesser extent, his sense of independence. Such benefits could be seen to be important to Bill as he could not sit up without the assistance of a carer. However, despite such physical limitations, he claimed that he rarely used the Tele-care System. Whenever he felt the need to call for help, via focussed and emplaced hand movements, more often than not, he tended to use the device when he was in his innermost peaceful sanctum – his bed:

> **Bill**: "*I actually used it earlier this or was it yesterday morning? I can't tell which. They came in and said, "What's the matter?" "Cor," I said, "I think I am getting cold. Of course everyone here sleeps with their windows and doors shut. I can't sleep with the window shut. I must have it open.*"

Following on from this, Bill indicated the carers quickly responded to the call for help by placing more blankets on his bed. Subsequently, he drifted back into a restful sleep. Reflecting upon such an experience would seem to suggest that temperate experience, movement, bodily knowledge (Ingold 2010) and sleep are the very roots of being. As such, and with Bill's experiences of care in mind, bodily knowledge comes into being through the very air that Bill breathes and feels (ibid.) when he is in bed and, as a consequence, depending on the temperature, he either experiences a good or a bad night's sleep. In the latter case, as illustrated within the interview text, Bill woke up, realised he was cold and uncomfortable and felt the need to reach for, grasp and pull the help cord. This would seem to suggest that both Bill's and his carer's movements and bodily knowledge are generated within collective fields of practice (Valtonen & Veijola 2010; Ingold 2000 in line with Turnbull 1989). Such collective practice, in an institutional sense, implies that Bill's bodily knowledge is generated by motional thought along particular temperate pathways (Ingold forthcoming) that lead to the natural, non-institutionalised world at large. From Bill's perspective, such institutionalised practices suggest that falling asleep and being asleep are highly meaningful collectively enacted bodily experiences (Valtonen and Veijola, 2010) that tend to occur when both Bill's body and mind recognise that his room and bed are to his liking and that help is, quite literally, to hand at any time during the night.

In addition to the insights revealed within the previous three sections, it also emerged that several participants found it very dif-ficult to move from one place to another without the aid of a wheel-chair. Such a crucial aid to living enables residents' to maintain a certain amount of physical and social independence. Indeed, as Ingold (forthcoming) comments, "locomotion is the start point for perceptual activity." For those elderly people who find it difficult to manoeuvre themselves throughout the home it was not un-common to find such people in either electric or manual wheelchairs. Such manoeuvrable, relatively high-tech objects could, perhaps, be seen as a source of empowerment and facilitate communal links within the home. However, whilst such a scenario would seem to be welcomed by most, it should be noted that such things require the user to have good eyesight – something that is not the norm within a care home. As Violet commented, "*I don't go into the sitting room so much because they are all elderly and I don't see so well anymore. I would hate to run into someone's feet.*"

REFLECTIONS

By way of a contribution to CCT we argue that elderly people in care homes do not find themselves in a position whereby they are at liberty to "make and re-make their identities over the courses of their lifetimes & choose to what degree the new identities are consistent with the old" (Schau et al. 2009: 256). Such a proposition would seem to add a note of caution and nuance to the CCT tradition and its consideration of the way consumers' use symbolic resources to enact personal and collective identities (Arnould and Thompson 2005). To this end, we offer a bespoke set of terms to the CCT community (see Glossary of Terms) to appreciate how the burden of identity work is negotiated in such institutions as care homes for the elderly.

As previously intimated, our findings suggest that elderly consumers in care environments are engaged in relations of deep dependency which leave their imprint within multiple and diverse trails of becoming (Ingold forthcoming) that embrace relatively frail social and material movements (such as those within a wheelchair) and personalised (and institutionalised) bodily knowledge. For example, and reflecting upon the empirical part of this paper, the reader could think of *George* and the primary need to navigate point-to-point lived experiences with frail arms, hands and fingers; or *Lottie* and her reliance on carers to get out of bed, go to the toilet, get dressed and undressed; or *Bill's* reliance on carers to sit him up in bed or to provide him with warmth whilst sleeping as illustrative experiential examples that reveal how the elderly engage with their surroundings in order to dwell within and understand care environments.

In order to navigate these fragile lines of immersed dwelling and becoming (ibid.) consumer researchers need to appreciate how the elderly within care environments bring (meshwork) form into being (ibid.) through the continued movements and interactions that are also associated with friends and family, professional carers, material artefacts and the institution as a whole. By virtue, physical and emotional pain, fear, sadness, debilitation, depression, restriction, un-happiness and, perhaps most importantly, loss of independence emerge and have significant agency within such environments. Moreover, let's not forget that such deep, dark and distressing feelings are negotiated and processed without the luxury of choice or independent access to market mechanisms.

Therefore, we argue, elderly care environments are incredibly demanding social, individual and material spaces within which consumption (of care services) is alive, active and constantly becoming. It involves levels of penetration, inscription, dependency and movement where simple notions of exchange and use, symbolic display and service delivery are insufficient to capture the emotional investments involved as a matter of routine. As Bauman (2004) suggests, in a society of consumers, such elderly people are 'flawed consumers'

but consumers nonetheless, who, through no fault of their own, find themselves dwelling in unyielding currents, without the continued close support of their local community, friends and immediate family, within institutions that, more often than not, only strive to meet residents' basic care needs...if they are lucky. Such fragile and elderly consumers, to put in bluntly, would not survive on their own (ibid.). Within such restricted contexts, the notion of loving care remains just that, a notion that is rarely articulated within institutional care strategies.

APPENDIX ONE:
INGOLDIAN GLOSSARY OF TERMS

Please note; the following terms are all derived from Ingold (forthcoming) unless otherwise stated.

Becoming – "In a world of becoming even the ordinary, the mundane or the intuitive gives cause for astonishment – the kind of astonishment that comes from treasuring every moment, as if, in that moment, we are encountering the world for the first time, sensing its pulse, marvelling at its beauty, and wondering how such a world is possible."

Being-in-the-world – "A condition of being alive to the world, characterised by a heightened sensitivity and responsiveness, in perception and action, to an environment that is always in flux, never the same from one moment to the next."

Bodily knowledge – "Far from being copied, ready-made, into the mind in advance of its encounter with the world, knowledge is perpetually under construction within the field of relations established through the immersion of the actor-perceiver in a certain context. Knowledge, in this view, is not transmitted as a complex structure but is the ever emergent product of a complex process. It is not so much replicated as reproduced."

Ingoldian anthropology – "A sustained and disciplined inquiry into the essence of the conditions and potentials of human life that is located [at the nexus between] art, architecture and anthropology."

Life – "The essence of life is that it does not begin here or end there, or connect to a point of origin with a final destination, but rather it keeps on going, finding a way through the myriad of things that form, persist and break up its currents. Life, in short, is a movement of opening not of closure."

Lines- "Individual or group, we are composed of lines...or rather, bundles of lines...There are lines of life, lines of writing... lines of luck or misfortune, lines of flight, lines of becoming and so on" (Ingold, forthcoming. In line with Deleuze and Guattari, 2004: 215 – 223).

Meshwork – "The world we inhabit. What is commonly known as the 'web of life' is precisely that: not a network of connected points but a meshwork of interwoven lines."

Movement – "Different beings, whether or not they qualify as persons, have characteristic patterns of movement – which reveal them for what they are" (Ingold, 2000: 98).

'Land of History and Romance': Consuming Nostalgia through the British Italian Cookbook

Elizabeth Parsons, Keele University, UK
Benedetta Cappellini, University of London, UK

INTRODUCTION

In this paper we explore the role of nostalgia in the production and consumption of British Italian cookbooks. We provide an interpretive analysis of British Italian cookbooks from across the 51 year period 1954-2005 exploring the ways in which their authors evoke past times, people and places in their promotion of Italian cuisine. Undeniably food as an ultimately sensual product which we engage with on an intimate level 'may be particularly effective in transporting consumers back in time' (Baker, Karrer and Veeck 2005, 402). Through examining the nostalgic rendering of Italian food culture in British Italian cookbooks, we explore some of the ways in which these books might transport the consumer back in time.

Although there is a growing interest in understanding food consumption, the majority of consumer studies dedicate their attention to looking at people's practices and discourses (Marshall 2005). What we know much less about is how such everyday food consumption practices, and the market mythologies attached to them, are *reconstructed* in texts such as cookbooks. Although there is a growing interest amongst consumer researchers in looking at 'symbolic meanings, cultural ideals, and inducements encoded in popular culture texts' (Arnould and Thompson 2005, 875), little has been said about culinary representations. Despite some recent exceptions (Brownlie, Hewer and Horne 2005; Schneider and Davis 2010) the written world of food remains an understudied topic of investigation in the consumer research community. In addition consumer researchers have long been interested in the role of nostalgia in the consumption process (Baker and Kennedy 1994; Havlena and Holak 1996; Holbrook and Schindler 2003). However, as yet little work has explored the role of nostalgia in relation to the written word. This focus on the written text is particularly apposite because it embraces both the author and reader in the production and consumption of nostalgic discourse. Such a focus then blurs the boundaries between production and consumption given the dialetic relationship between author and reader. Within this relationship nostalgic discourses are co-produced, reinterpreted and mobilized by both parties for specific ends (which we explore in the course of the paper).

With the above absences in mind in this paper we explore the British-Italian cookbook as consumption text but also on a wider level as a cultural artefact. Cookbooks offer us insights into the axis of political, cultural and social context of their making. They have been seen by a range of scholars as important historical – cultural resources, examined as cultural artefacts to be studied in relation to their cultural and social contexts (McDonagh and Prothero 2005). Considered not simply a collection of food recipes, they have been studied as a privileged source in representing 'unusual cultural tales' and 'revealing artefacts of culture in the making' (Appadurai 1988, 22). Most recently, consumer researchers have identified cookbooks 'as constructed social forms which are amenable to textual analysis' (Brownlie et al. 2005, 7). We similarly explore British Italian cookbooks through this lens using a socio-historical approach. The paper begins with a review of relevant literature and outline of the interpretive approach to textual analysis pursued. This is followed by a socio-historical analysis of cookbooks as cultural artefacts. In closing we observe our contributions to existing theorisation of nostalgia and culinary representations within consumer research.

CULINARY CULTURE, CONSUMPTION AND NOSTALGIA

In this paper we use two specific strands of literature to aid us in our project of exploring representations of Italian culinary culture. The first is work within consumer research which explores the role of nostalgia in structuring consumer meanings and experiences. The second includes work from cultural geographers which explores the evocation of place through what might be termed 'nostalgic food cultures'.

Consumer researchers have long found the idea of nostalgia useful in understanding consumer motivations and behaviours (Baker and Kennedy 1994; Havlena and Holak 1996; Holbrook and Schindler 2003). The nostalgia concept is useful here in that it not only encompasses memories and imaginings of the past, but idealised versions of these memories with their negative elements largely stripped away (Goulding 1999). A second vital component of nostalgia is that it generally acts as a counterpoint to a less attractive, and most often undesirable, present. Another element of nostalgia, according to Davis (1979), includes a longing for past experiences. However, as we are at pains to illustrate in this paper, nostalgic consumption does not have to rely on individual experience, rather what we have seen in recent years is an increased and deliberate commodification of nostalgic experience (Brown 2001), in product design (Weaving 2008), retail environments (Maclaran and Brown 2005) and historical theme parks and leisure environments (Goulding 1999) and of course (cook)books. The impetus behind this marketing drive, and the attendant consumption of these products, is undoubtedly increasing consumer anxiety in the face of a fragmented global postmodern consumer culture wherein consumers struggle for stable reference points for their sense of identification and belonging (Strauth and Turner 1988). In Western affluent contexts the market reaction is a plundering of the past in attempts to reclaim, and repackage for sale to the consumer, a sense of place, belonging and authenticity. However, while we observe that there has certainly been a recent resurgence of market interest in past times, and this is where our socio-historical approach becomes significant, our analysis shows nostalgic consumption has much earlier roots and is likely to be part of a more deep seated human condition (Davis 1979).

Baker and Kennedy (1994) delineate three levels of nostalgia: real, simulated and collective; they argue that each level has a different degree of attendant emotional intensity. While we observe that these levels are perhaps a little discrete they do usefully identify the nuances in individual experience (real), the role of the media and other objects in simulating nostalgia (simulated) and the role of collectivities in nostalgic experience (collective) such as culture, generation or nation. Our analysis identifies elements of all three of these levels of nostalgia. Often cookbook narratives rely on the author's individual experiences, but equally, and simultaneously they evoke collective nostalgia surrounding Italian landscape, people and food cultures, in addition these cookbooks in themselves might be seen as simulating (and indeed stimulating) nostalgic experiences in the consumer.

In their interpretive exploration of nostalgia as a driver of consumption Holbrook and Schindler (2003), similarly identify the collective dimension of nostalgia. They attribute this collective dimension of nostalgia in the UK and US to the Baby Boomer generation. However, in this paper they relate nostalgia very closely to individu-

al consumer experience drawing on earlier work in this respect (Holbrook and Hirschman 1982). In our examination of British Italian cookbooks while we do explore the experiences of the authors in framing nostalgia we also emphasise the commodification of nostalgia on a more general and collective level. The stories and images of Italy that emerge from our reading do not necessarily always rely on the reader/consumers past experiences for their meaning.

Both consumer researchers (Brownlie et al. 2005; Hewer and Brownlie 2007) and others (Appadurai 1988; Cinotto 2005) have explored the ways in which cookbooks represent and reproduce national cultures and identities. Geographers have also been interested in nostalgia and its links to food in helping them to understand the ways in which places are imagined and become meaningful. Duruz's (2005) evocative interweaving of participants food stories, everyday practices and memories to explore the themes of identity, place, ethnicity and belonging in London and Sydney really emphasises the strength of links between imagined food cultures and a sense of place. She finds in these stories a 'nostalgia for 'traditional' country cooking and the 'past', she also observes the 'catalogues of the effort these women make towards maintaining their culinary heritage' (2005, 67). As such we should also recognise the significance of cookbooks in maintaining culinary heritage. This is particularly the case for cookbooks at the beginning of the period we study where there is no doubt that the authors were keen to both promote and preserve a particular version of Italian culinary heritage. As such the stories that we will be exploring below are attempts at preserving a slice of Italian history as much as they are instructions in Italian cooking.

However, we want to acknowledge the potential pitfalls and misrepresentations of talking about a definitive Italian food culture. In our globalised world it can be argued that all cuisines are necessarily 'hybrid' (Cook, Crang and Thorpe 2000; Duruz 2005). As Cook et al. observe: 'ingredients, knowledges, technologies and practices – culinary and otherwise – cannot have any straightforward 'origins'' instead they identify the 'messy boundary crossings of ingredients, cuisines, people and their histories' (2000, 113). It is in this spirit that we explore the narratives within British Italian cookbooks as hybrid and contested.

METHODOLOGY

This paper emerges from a wider study looking at the representation and consumption of Italian food in the UK. In this paper we provide an interpretive reading of continuities and discontinuities of discourses surrounding nostalgia as they emerged in representations of Italian food in cookbooks. Our approach follows previous interpretive consumer studies providing a critical reading of media discourses in popular magazines (Martens and Scott 2005; Schneider and Davis 2010) and cookbooks (Brownlie et al. 2005). As Brewis and Jack (2005, 51) point out providing a critical reading implies that we do not assert that what we understand from the cookbooks is what

authors intended to communicate, or even what consumers would see in these texts. Our interpretive reading would offer 'a think piece, a broad-brush polemic' (Brewis and Jack 2005, 51) and as such it provides one understanding of how discourses about nostalgia have been reconstructed in the examined cookbooks. Our reading focused on Italian culinary culture, the authors' travel stories and anecdotes about Italy as well as recipes, products, cooking and shopping practices. In the current paper we have focused on the nostalgic representation of Italy and its culinary culture and the way consumers are encouraged to reconstruct a nostalgic food experience in their homes.

A multicultural team iterated the analysis and as such a 'triangulation across co-authors led to new insights and resolved differences in interpretation' (Askegaard, Arnould and Kjeldgaard 2005, 163). The triangulation across authors does not simply increase the validity of our analysis, but most importantly enriches our interpretive reading by combining two understandings of the examined discourses. One author is Italian, and thus familiar with Italian food culture, Italian ingredients, dishes, domestic consumption practices, and mealtime conventions; and one author is English and thus familiar with similar elements of British food culture. Data analysis and interpretation followed the general form used in interpretive research and hence a continuous interaction between data and theoretical frameworks has been privileged as a crucial part of the hermeneutical process (Spiggle, 1994; Thompson, 1997).

Following previous research looking at food discourses in a socio-historical perspective (Martens and Scott 2005; Schneider and Davis 2010) our sample has been selected using a chronological criteria. 8 cookbooks have been selected from 1954 to 1974, 22 cookbooks from 1975 to 1995 and 14 cookbooks from 1996 to 2005. The first period is relatively has underrepresented because of the scarcity of published cookbooks, rather the second period is overrepresented because of the explosion of cookbooks published in the late seventies (see Cinotto, 2005). Another sampling criterion was based on the popularity of the writer. Celebrity chefs, such as Elizabeth Davis (1954), Jamie Oliver (2005) were selected together with less popular cookbooks recommended by these celebrities. This criterion was applied because, as scholars have shown (Brownlie et al. 2005), celebrity chefs have had a significant impact on British food culture.

ANALYSIS: THREE PERIODS OF NOSTALGIA

From our analysis we have identified three distinct periods wherein discourses around nostalgia have been reconstructed in different ways (see table 1). Each of these periods is not a discrete stage with a clear beginning and end, rather periods overlap and continuities and discontinuities with the previous and subsequent phases are evident. Given this, it is still possible to identify a broad set of features which characterise each period as distinct.

Table 1 Changing Representations of Nostalgia in British Italian Cookbooks 1954-2005

	1954-1970 **An Exotic and Rich Culinary Heritage**	1971-1986 **A Romanticised, Pre-modern Past**	1990-2005 **The Simple and Authentic Life**
Intended readership	Affluent housewife	Working mother	Male or female cook
Discourses of Nostalgia	Real nostalgia: escaping post-war food rationalisation	Simulated nostalgia: escaping the juggling lifestyle	Collective nostalgia: escaping a collective and frenetic lifestyle
Consuming Nostalgia	Shopping and cooking exotic products	Cooking convenient dishes	Following culinary gurus's shopping recommendations

1954- 1970 An Exotic and Rich Culinary Heritage

This period is characterised by the production of books written by women with a direct link to Italy. These authors frequently refer to their own past travel experiences in evoking a very personalized nostalgic view of Italy's glorious culinary past. Some of these authors were British middleclass female authors with a taste for travel such as Elizabeth Davis (1954) and others were middle class Italian immigrant women such as Taglienti (1956). The autobiographical notes, which appear in the introduction as well as in the presentation of the recipes, illustrate the writer's privileged consumption experiences, such as dinner with diplomats and Italian aristocrats or adventurous lunches at village festivals.

The intended readership consists of housewives who need to be "educated" and guided in their new consumption experiences of dealing with exotic Italian products.

> There is, I know, a school of writers who seem to believe that English housewives are weak in the head and must not be exposed to the truth about the cooking of other countries; must not shocked by the idea of making a yeast dough, cleaning an ink-fish, adding nutritive value to a soup with olive oil [...] (David 1963, 25n6).

While cookbooks of this period are addressed to a female readership, it is not the case that women from all walks of life are targeted. Indeed authors seem to address women who share similar privileged and nostalgic consumption experiences, or at least those who aspire to share in such privilege (and the associated cultural capital) through the acquisition of knowledge of foreign cuisines.

> Do you remember your first meal on the Rome Express after you left Modena? Or your first fettuccini at Alfredo's in Rome? Or the café granita at Doney's in Florence? If your tongue still quivers at the thought of the succulent scaloppine con olive, the pasta golden and its sugo di formaggio e burro, the icy block coffee crystals melting on your tongue on a hot day, this book will fill you with nostalgia as well as nourishments. If, on the other hand, you are as yet unacquainted with these joys of Italian cooking, it will introduce you to many new gastronomic delights (Taglienti, 1956, 1)

This complicity between reader and writer rooted in the cultural capital of the privileged leisured class is illustrated in recalling nostalgic memories of exclusive cafes in Florence, luxurious train rides but also ingredients and dishes. The author entreats the reader to recreate her own sense of nostalgia through buying familiar products and transforming them into dishes which are familiar from their pasts. Also the author invites readers who have not experienced this culinary past to invent these memories in their kitchen, through consuming new products and transforming them into evocative dishes.

The nostalgic tone of this period seems particularly acute in some cookbooks, like Elizabeth Davis's (1950) *Mediterranean Food* wherein the author's adventures in the South of Europe are compared with 'icy and hungry weeks' in London (David 1950, X). As she describes, recalling food experiences from the past is an enjoyable way to escape the present. In a passage that is particularly evocative of Murcott's (1995, 225) observation that cookbooks are a 'representation of imaginary experiences remote from everyday life'; David's descriptions of the food as 'richly flavoured' and 'brightly coloured' must have contrasted sharply with the food available in the rather drab post war years of early 1950s England:

> But even if people could not very often make the dishes here described, it was stimulating to think about them; to escape from the deadly boredom of queuing and frustration of buying the weekly rations: to read about real food cooked with wine and olive oil, eggs and butter and cream, and dishes richly flavoured with onions, garlic, herbs, and brightly coloured Southern vegetables [...] I took refuge from reality writing down memories of the food I had cooked and eaten during my Mediterranean years. (David 1950, X)

In describing the disappointing present in England these cookbooks seem to talk to a leisured class who is encouraged to take refuge in their past through exotic products and challenging consumption practices. Also these books seem to deliberately play upon aspiration through the mobilization of nostalgic discourse. Readers who have not had these privileged travel experiences are encouraged to imagine and recreate them through learning new food consumption skills and practices at home.

1971-1986 A Romanticised, Pre-modern Past

At the end of the Seventies and during the Eighties the numbers of cookbooks really took off (Cinotto 2005). Cookbooks written by writers with no evident links with Italian culture started to appear. Although there are still cookbooks written by Italian immigrants (Hazan, 1980) or British travellers, many publications are written by authors not claiming any travel experiences in Italy or childhood memories about Italian food. Also cookbooks written by supermarket chains, like Sainsbury's (Reynolds 1981), appeared. The increased numbers of publications generate a heterogeneous representation in terms of advised ingredients, recipes and cooking techniques. In fact there are cookbooks only for vegetarians, for single people, for fast cooking, for low fat cooking, but also for cooking only one dish like pasta or pizza. This fragmentation of Italian food representations seems to reflect a more general trend inolving the fragmentation and increasing incoherence of food discourses during this period, inparticular those surrounding food choice which commentators have termed gastronomy (Fischler 1993).

While cookbooks from this period re-present Italian food in contradictory terms regarding shopping and cooking advice, they are very homogenous in presenting a nostalgic idea of Italy and its gastronomic culture. The author's biographic notes about Italy and its food gradually disappear but descriptions of villages and small communities immersed in a fairyland become very popular.

> To buy food at the market you have to get up early, because by eight o'clock the best has already gone. Peasants from villages near and far will not miss coming to town on market day. They used to either walk from miles away, or come in donkey and horse carts, but motorcycles and cars are now the more usual transport. But the market atmosphere remains unchanged. (Birch 1985, 17)

This new nostalgic tone is used to describe an Italian society immersed in a past without time and space coordinates. The same tone is also adopted in illustrating Italian food. Italian cuisine is described as 'authentic', a term used to underline how the food is a product of a society bypassed by modernity and thus uncorrupted by modern life. As this author points out 'a typical Italian meal is still very much as it was in the eighteenth century' (Barker 1979, 6).

Another new element of this nostalgic representation is the emphasis on the Italian family, especially Italian women as mothers. Introduced as the centre of Italian society, the family is also depicted as the centre of gastronomic activity. As Marcella Hazan observes

'eating in Italy is essentially a family art, practised for and by the family' (1980, 4). The everyday work surrounding family meals is depicted solely as the preserve of women (in particular mothers). Represented as housewives devoted to their husbands and children, women are usually illustrated in the act of serving a meal, cooking or preparing food.

> *For although the legal position of women in Italy has improved greatly over the last two decades, it is still rare, though known, for babbo to turn his hand to cooking- never the washing up of course!- and in the family it is still basically mamma who runs the show. She forms her children's taste in food so firmly that it remains with them all their lives.* (Spike-Huges and Charmain1986, 7)

The emphasis on Italian mothers as housewives "enjoying" feeding their family, is particularly relevant if we consider that cookbooks of this period are not aimed at upper and middle class housewives, but at working women who, as studies suggest, juggle their domestic practices with restricted budgets and inflexible time schedules (Thompson 1996). In fact cookbooks "talking" to working mothers emphasise the convenience of Italian recipes which can be prepared quickly and easily with locally available products.

> *The above traditional technique still stands and works wonderfully with imported Italian rice. If we have time we prefer the traditional, grand method. If we do not have the time, there are still ways to make risotto in the modern kitchen. There are two ways to go, depending on the cook ware as well as the rice in the market.* (Romagnoli and Romagnoli, 1980:135)

We notice a contradiction in the representation of Italian food in this period. On the one hand Italy and its culinary culture are represented through the apparently "relaxed" lifestyle of Italian mothers who not having a job outside the home, have time to leisurely shop in local markets and generally enjoy the work of feeding their family. On the other hand the recipes and consumption practices are addressed to British working women and therefore highlight the economy, both in terms of time and effort, of Italian cooking. We interpret this contradiction as a simulated nostalgia (Baker and Kennedy 1994) where consumers are not required to revisit their own past in order to reconstruct their nostalgia, they can access their simulated nostalgic experience through mass produced items, and convenient recipes saving time and effort in their kitchens. In other words British readers could aspire to live in this "once upon a time" dreamland, with very little effort. Mothers in full time employment with juggling lifestyles can, in part, buy into the figure of the time rich Italian mother who unproblematically places family first by consuming convenient Italian recipes.

1990-2005 The Simple and Authentic Life

In this period the production of cookbooks increases further and the representation of Italian culinary culture becomes even more fragmented than in the previous period (Cinotto 2005). While there is a very heterogeneous representations of recipes, advice and recommendations, images and ideas of Italy as a country are resonant with the representation of the previous period. Descriptions of a harmonic country which remains untouched by modernity are frequently illustrated through images of children wearing traditional dresses, crowded little markets, and devoted housewives preparing family meals.

> *Despite the advent of industrialization and mass-marketing, traditional foods are still central to the cultural identity of each re-*

gion. This is partly due to the way in which recipes are learned: orally passed from generation to generation, and rarely written down in cookbooks, they survive in families for years with little or no changes made to them. (Capalbo 2001, 6)

Italy is depicted as a country firmly rooted in tradition, a place where globalisation has yet to impact on people's food habits, where recipes are orally passed from generation to generation. In some cases these descriptions are explicitly political in tone, the below extract depicts Italian culinary culture as actively resistant to the forces of globalisation:

> *The Common market may eventually impose American uniformity on Europe, in generations to come the food may become uniformly tasteless [...] If the forces of mediocrity are gathering, Italy will be the last centre of resistance.* (Barrett 1993, VII)

In this period references to Italian mothers and British working mothers seem to disappear. This is probably due to fact that many male culinary gurus (Cinotto 2005), such as TV chefs like Jamie Oliver and famous restaurateurs like Antonio Carluccio, dominate the production of cookbooks. Although their representations of Italian food vary, their intended audience is very similar. As the restaurateur Aldo Zilli emphasises, his intended audience consists of 'working people', regardless of their gender, social class or household composition.

> *My main aim is to give you an insight into Italian cooking, showing you how easy it is to create delicious dishes. Forget the fuss! Simplicity is the key....some of them (recipes) are so quick and easy that they are great for working people who do not have much time to cook.* (Zilli 1998, VIII)

Stressing the idea that Italian food is a convenient option, in terms of saving time and effort, the intended audience becomes defined in terms of lifestyle. There are explicit references to people who cannot afford to spend time (and effort) in the kitchen, but that would like to cook their own meals.

As with the authors from the fifties, celebrities emphasise their Italian origins or their travels in Italy as a guarantee of their competence in reproducing an "authentic" Italian food experience. This is especially the case with Jamie Oliver who's book: Jamie's Italy (2005) is a description of his gastronomic tour of the country. This book is noteworthy as in many respects it epitomises the way in which Italy and its gastronomic culture are currently represented in the UK. In the book Jamie celebrates the pre-modern, slow pace of Italian life, which he describes in these terms:

> *I've witnessed so many young people and teenagers in Italy living a 'modern-day-life' which we would have seen in Britain seventy years ago- yes, they have mobile phones and computers but they're not seen as an essential part of everyday life and not as many people have them as here.* (2005, XI)

This nostalgic representation of Italy, as a country still in the past and unaffected by modernity, does not require a particular understanding. Indeed Italian cooking know-how is presented as thoroughly embodied by the culinary subject. Italian cooking skills are tacit in nature, absorbed in the course of everyday life in the family kitchen. As such Italian cooking is presented as accessible to all, as Oliver observes:

> *The truth is, when I'm in Italy I feel Italian—even with my very basic grasp of the language I manage to get by, and you know*

why? Because, like all Italians, I love my family for better or for worse and because food has been something I've grown up around. (Oliver 2005, X)

This accessibility of old world Italian culture is extended to British consumers and offered as an antidote to British living, lost as it has been to the forces of modernity and globalisation. Here Italian culture is presented as offering readers an opportunity to revisit a nostalgic past, a past grounded in authenticity, where readers might escape from the anxieties of contemporary British life.

The "authentic" and nostalgic Italian experience is reconstructed with elements of continuity and discontinuities in relation to the cookbooks of the 1980s. As in previous cookbooks, in this period the nostalgic past is reconstructed through the concept of convenience. However, here convenience becomes even more specific, for example the required time is measured in minutes, and the required work is evaluated in more detail by the author. Saving time probably receives greatest emphasis, calculated for the entire process, from the preparation to the cooking. In addition the level of required cooking skills is also identified in many books, and there are suggestions as to how to reduce the amount of time and effort required (for example by using electronic devices such as food processors and microwaves).

CONCLUSION

In this paper we have identified three different phases of nostalgic representation of Italy and its food. From this analysis we have three key observations to make about nostalgia and its role in the consumption experience. First we acknowledge the commodification of nostalgia, and second (drawing from Baker and Kennedy's 1994 earlier work) we observe that its form and intensity varies according to socio-historical context, finally we suggest that nostalgic food cultures and their representations are central to consumers' sense of identity and belonging.

Each of the periods analysed encompasses different modes of nostalgia, but all of them present nostalgia as a consumption experience that consumers can access through the shopping, cooking and display of Italian food. As such, our study highlights the commodification of nostalgia, which is portrayed as an "object" that can be consumed by following the author's shopping recommendations and cooking advice.

Our socio-historical approach to the analysis of these texts has also underlined the role of nostalgic consumption in escaping an undesirable present (Davis 1979). In each period the features of this undesirable present and its socio-economic underpinnings differs. The promotion of an exotic and rich food culture in the fifties is an antidote to a post-war country with a strict rationing of such foods. The promotion of a pre-modern, traditional food culture in the eighties is in response to the time poor "juggling lifestyle" required by the increased presence of women in the workplace during this period. In the most recent phase a simple and authentic food culture is emphasised in response to an increasingly fragmented, post-modern, inauthentic lifestyle.

In addition we see Baker and Kennedy's (1994) three levels of nostalgia (*real, simulated and collective*) reflected in each of these three periods with different emphases in each. In the first period the emphasis is on '*real*' nostalgic experience. Here authors rely on their own past experience and the text emerges as an intimate dialogue between the female author and imputed middle class female reader through remembered holidays and travels to Italy. This form of nostalgia represents a personal past which is shared with people who have had (or have aspired to have) the same experiences. Nostalgia is reconstructed through products and dishes from an individual past,

and as such the reader is invited to discover specific products in local shops and delicatessens, as well as "learn" new cooking skills. In the second period nostalgia is not a class based experience any longer, but rather a '*simulated*' experience wherein women can imagine (aspire to) a vaguely "better" reality, wherein life is suspended in a "once upon a time" atmosphere. Consumers are not required to revisit their own past in order to reconstruct their nostalgia, they can access their simulated nostalgic experience through mass produced items, and convenient recipes saving time and effort in the kitchen. In the last period nostalgia seems to have been democratized. It is not an experience reserved for women, but it is a '*collective*' dialogue wherein also men are admitted as authors and readers. Because it is not gender and class bound any longer, nostalgia is represented as a collective experience an escape from the current lifestyle available to everybody. However it is also an individual experience as cookbooks represent the celebrity gurus "own" version of nostalgia, which consumers can access through consumption. As in the first period nostalgia is consumable through shopping more than through other consumption practices. Indeed consumers are invited to recreate their nostalgic experience by rehearsing their cultural capital in their shopping trips to delicatessens and markets.

Finally, we'd like to make some comments about the consumption of these texts, in particular their context of consumption. In a contemporary Western consumer context where home cooking and dining and the traditional rituals, knowledges and practices associated with them are in decline, it is perhaps not surprising that the values of tradition, family and home are recurrent in the British Italian cookbooks we analysed. In fact evidence suggests that narratives of the kitchen table, the smells and sounds of home cooked food and the central role of the maternal figure are typical in remembrances of home across a range of cultural contexts (Duruz 2001). Cutting across all three periods we see nostalgia operating to invoke a sense of authenticity and belonging through consumption. In an increasingly globalised context where boundaries become increasingly blurred 'the discomforts of fragmentation, disruption and "placelessness" have produced nostalgic longings for a secure world and for secure positionings within it' (Duruz 2001, 22). Our socio-historical analysis of cookbooks has identified the centrality of food, food cultures and the representation of these as important antidotes to feelings of placelessness and alienation.

Beyond Enemy Lines: Sociality in Consumer Activism

Leah Carter Schneider, York University, Canada
Robert Kozinets, York University, Canada

INTRODUCTION

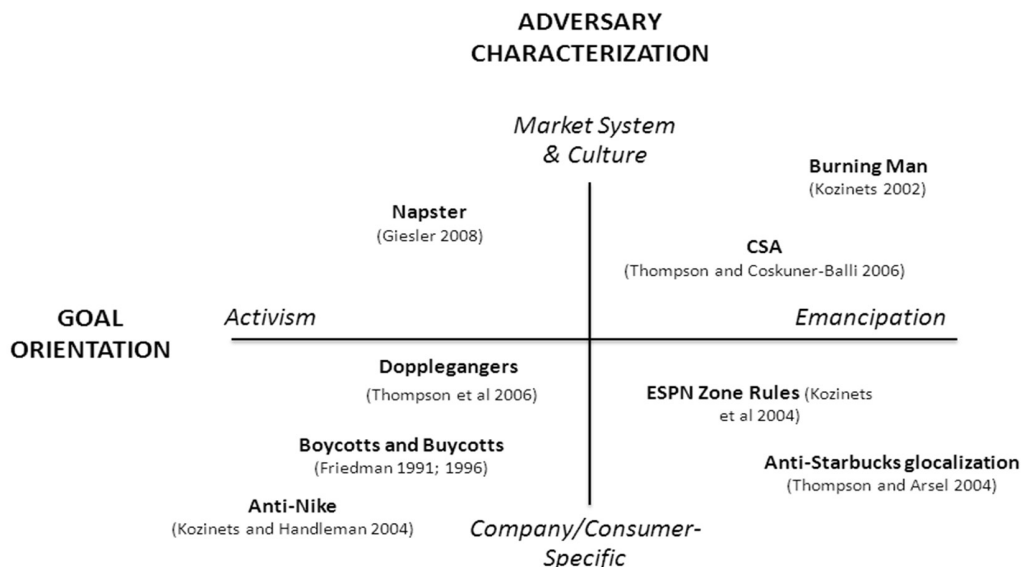
Consumers and market entities clash in the marketplace over competing values, goals, and practices (Kozinets and Handleman 2004). Drawing on battle myths and discourses, consumers give meaning to and narrate market conflicts (Giesler 2008). In particular, the identification and characterization of an enemy is a fundamental component of consumer activists' ideology (Kozinets and Handleman 2004). Specific firms (e.g., Thompson, Rindfleisch, and Arsel 2006; Friedman 1991; Friedman 1996), hegemonic market discourses and movements (e.g., Thompson and Coskuner-Balli 2007; Kozinets 2002a), and "unenlightened" consumers (e.g., Kozinets and Handleman 2004; Luedicke, Thompson, and Giesler 2010) alike have been cast as adversarial foes in various market conflicts. Consumer activists, contrastingly, characterize themselves as heroic, wise rebels (Giesler 2008; Kozinets and Handleman 2004). Extant research on counter-market activities and movements appears to focus primarily on describing and exploring activism in dyadic terms between adversary and activist in market conflicts, including organized boycotts, doppelganger image creations, and escapist retreats (e.g., Kozinets 2002a; Giesler 2008; Kozinets and Handleman 2004; Holt 2002; Thompson et al. 2006; Friedman 1991; Friedman 1996).

Although marketplace conflicts center on adversarial relationships between a focal consumer hero and corporate/market antagonist, "supporting" relationships can arise or transform in ways that contribute to the enactment of activist initiatives and the development of market interactions. Relationships outside of the hero-adversary dyad, such as alliances between unlikely partners or friends who rally together with the hero to fight a common enemy, may be necessary for desired goal achievement and create a lasting effect on long-term market interactions. We therefore propose that consumer activism is more complex than consumers fighting against market foes, and by extension, more socially dynamic than linear models of consumer resistance (e.g., Giesler 2008) have suggested.

In this paper, we explore consumer activism to extend theoretical and practical understanding of the underlying complexity of market relationships that underpin resistance activities. Integrating consumer resistance, consumer community, and business alliance literatures, we address questions regarding the interplay between consumer relationships and activism: how and why consumer campaigns, a specific site of consumer activism, create a space for influencing market-based relationships, the role of alliances during campaigns, and how consumer community relationships are internally transformed as a result of campaigning.

CONSUMER RESISTANCE AND ACTIVISM

Consumer resistance colors marketplace dynamics. Rather than passively accepting hegemonic producer domination, consumers exert their individual and collective power by opposing market structures and discourses through innovative, nonconformist activities (Holt 2002). In order to begin to understand the importance of relationships in activism, we first address what is meant by activism. From past research, it appears that the actualization of consumer resistance varies in the marketplace (Figure 1).

FIGURE 1: CONSUMER RESISTANCE FRAMEWORK


First, the goal orientation of resistance activities can range from goals centered on resistance *within* the market system that seek changes to the system, companies, or practices, to goals of emancipation *from* a market entity or system's rules, constraints, or hegemony. Some consumer projects have attempted to bring about desired changes to specific practices, policies, decisions, or behaviors to market-based entities. On the opposing side of the goal orientation dimension, consumer resistance efforts focus on breaking free from market rules, constraints, or hegemonic discourses. By so doing, these movements and activities create new systems of exchange and values that run counter to the dominant market system (e.g., counter-cultural movements, hypercommunities, and so on; Thompson and Coskuner-Balli 2007; Kozinets 2002a).

The second dimension organizes consumer resistance according to an identified adversary against whom consumers fight. Some resistance efforts primarily focus on micro-level resistance against a specific opponent, such as Starbucks, Wal-Mart, and Nike corporations (Thompson et al. 2006). Resistance activities can also challenge macro-level adversaries that include the capitalist market system (Giesler 2008) and dominant exchange discourses or norms (Kozinets 2002a; Thompson and Coskuner-Balli 2007). Rather than focusing resistance efforts on a specific company, these movements or behaviors attempt to resist an established and pervasive structure or discourse (e.g., the Napster rebellion against the market's music system).

Activism, from this resistance mapping, appears to be a subset of market resistance movements and behaviors. Consumer activists attempt to change an external entity (organization, business, and so on) or marketing norms, practices, and policies (Kozinets and Handleman 2004) in order to protect consumers from amoral, destructive, or undesirable corporate/marketer actions (Trentmann 2001). Consumer campaigns represent an organized, communal effort of activism. Campaigns are visible and vocal manifestations of a breach between consumers and producers, and can include campaigns that arise within pre-existing communities and communities that arise with particular campaign causes. As campaigns are a type of consumer resistance, it is likely that they arise in markets and exchange relationships marked by transitions and instability. In campaigning, activists group together and engage in deliberate activities oriented to achieve specific goals, often one primary goal, during a condensed time frame. Because campaigns are primarily goal driven, leveraging or forming new relationships may be necessary and beneficial tactics for consumers to pursue in order to attain desired goals.

CONSUMER SOCIALITY & ALLIANCES

Consumer activism is a social endeavor that is facilitated by communities formed by like-minded consumers (Muñiz and O'Guinn 2001). Consumer communities, though gathering spaces both online and offline for consumers who exhibit similar interests, values, goals, tastes, lifestyles, skills, and consumption preferences (Muñiz and O'Guinn 2001; Schouten and McAlexander 2002; Kozinets, Hemetsberger, and Schau 2008; Muñiz and Schau 2005), are not homogenous. Rather, collectives vary in purpose, participation, relationships, and core practices of the community (Kozinets, Hemetsberger, and Schau 2008; Schau, Muñiz, Arnould 2009). Kozinets, Hemetsberger, and Schau (2008) distinguished different consumer collectives, classifying them according to their goal orientation (i.e., telo-specific and communo-ludic) and contributor distribution (i.e., high and low), with activist communities engaged in campaigning exhibiting telo-specific qualities. Boundaries between community types are considered fluid, allowing for the possibility that communities may shift between one "type" to another over time due to new goals or contributor distribution, though the transformation process over time has been little discussed in the existing literature.

Changes in the environment and market uncertainty experienced in a consumer community may provide a catalyst for mobilizing a community to action, thereby transforming a community's goals in ways that simultaneously facilitates the formation of new alliances and propels a community from its previous orientation. In an organizational context, firms respond to external threats, such as likely losses, by altering internal and external practices, structures, and goals (Chattopadhyay, Glick, and Huber 2001) and exploring opportunities for alliances with other companies to control or mitigate market uncertainty (e.g., Thompson 1967; Pfeffer and Salancik 1978). Alliances between businesses can generate various benefits such as resource pooling (Das and Teng 2000), risk sharing (Ohmae 1989), and competency development (Hamel, Doz, and Prahalad

1989). The concept of alliances and the potential benefits derived from business-to-business alliances may be extended to explain and analyze relationships between consumer groups and other market entities that emerge in response to market instability.

Consumer communities, like organizations, must navigate problematic market changes utilizing a myriad of tactics and resources in order to survive and thrive in the marketplace. Organizing and enacting a consumer campaign represents a site of destabilized market conditions in which consumers' communal actions address a breakdown between consumers and producers. The act of campaigning may transform consumer communities in systematic ways, and incorporate the strategic use of consumer-generated alliances in order to actualize campaign and community goals. Breaking out of the hero-enemy myopia that has previously characterized consumer resistance research may therefore bring to light previously neglected phenomena occurring at the intersection of consumer relationships and activism.

METHOD

We investigated the social relationships associated with the three consumer-generated campaigns that emerged in pre-existing communities: "Save Polaroid," "Nuts for Jericho," and "Save Chuck." Each campaign arose as a result of the core production company either discontinuing or threatening to discontinue production of the community's central product. We selected these sites as prime candidates for exploring the sociality of consumer activism, as these communities negotiated past and present goals, relationships, and market tensions, and thus were more suitable for the purpose of this study than campaigns that did not originate in a pre-existing community.

To begin unpacking the complex system of relationships in consumer activism, we first conducted an historical analysis of fan campaigns. By so doing, we identified previous activities and relationships noted in the accounts as formed during the consumer campaigns, which in turn guided protocol formation. In order to capture a more inclusive picture of the social relationships impacted by the campaigns, we then conducted ten in-depth interviews with campaign leaders/organizers. Following McCracken (1988), the primary author elicited a "grand tour" overview of each informant's experience and probed for further detail about relationship formation and transformation using emergent prompts and pre-determined questions. The interviews lasted approximately 90 minutes each, with interview times ranging from 45 minutes to 150 minutes, and were transcribed verbatim by the author.

We triangulated the interview data with netnographic data (Kozinets 2002b; Kozinets 2010) obtained through group message boards, media articles, and websites devoted to the activist campaigns. The primary gathering place for the consumer communities and organizing space for campaigns occurs online. By investigating the consumer-generated content and conversations on the websites, we were able to examine the members' negotiation of relationships and initiative enactment throughout the campaigns.

Following the hermeneutic method of data analysis (Thompson 1997), we analyzed each interview separately, noting themes that both arose within the data and aligned with themes pre-determined from the literature. We then compared interviews and related themes in order to identify commonalities across the interviews within each campaign, and then across all three campaigns. It is significant to note that the initial impetus for data collection was to probe consumer campaigns from a strategy perspective. However, through the data collection process and analysis over subsequent rounds, a resounding theme of sociality appeared as a central component coloring much of the leaders' discussion of their experiences with the campaign. The focus on internal and external sociality is therefore an emergent theme from the data.

FINDINGS

From the data set, three interrelated themes emerged that explored the complexity of consumer campaign relationships. As the consumer communities faced potentially community-threatening discontinuation of their core products, the communities experienced a shift in goals, identities, and focus that created transitory, liminal spaces for altering relationships within and external to the community. The fluidity of relationships experienced during the campaign periods not only facilitated the coordination of the strategic campaign efforts, but also impacted community relationships in the short and long term.

Communal Liminality

Consumer campaigns appear to be sites of communal liminality in which a consumer collective underwent transformations as they encountered and negotiated market threats. The campaigns represented liminal playspaces for the campaigners in which they could create new actions beyond their traditional methods and resources. Occurring during times of market unrest and change, the campaigns were organized in response to external threats, with the communities fighting to save their products and by extension, ensure their survival as vibrant, living communities. By organizing goal-oriented campaigns, the communities experienced a state of transition and flux, attempting to negotiate not only their community membership, but also their new identity as rallied troops armed for battle and the corresponding activities.

Before the discontinuations and subsequent campaigning, members identified the communities as predominantly fan collectives. Members gathered at their leisure to share consumption experiences, stories, opinions, knowledge, critiques, innovative ideas with one another. Community activities, such as the Polaroid Nerd-Outs (day gatherings of Polaroid users to go on Polaroid-taking excursions), enhanced the anti-digital and consumerism group identity of the Polaroid community. Both "Jericho" and "Chuck" communities were considered to be "fanatic" communities prior to their respective campaigns: actively debating storyline developments, dissecting plot twists, and judging episode quality as the respective seasons progressed. Informants noted that the core of active members were a relatively small group of contributors, although the communities were frequented by numerous lurkers who did not actively join in the community (Kozinets 1999).

Product discontinuation threatened the core reason for the groups' existing. Informants responded by leading the community to shift the primary orientation of the community. In place of central interactions and activities that focused on the consumption experiences with the products, members adopted an overarching, task-oriented goal to rescue their beloved products. Succinctly stated by Christian, "Here's the goal. The goal is to get the show back." Additional campaign goals, such as spreading the word about the campaign, recruiting new members, and so on, supported the overarching, primary motivational goal of rescuing the products in question. The primary goals served as the rallying cry and unifying point for the consumers to exert a common, shared effort during the campaign periods that effectively mobilized communities to new, Telo-specific orientations.

As the campaigners enacted the campaigns, the identities of the overall communities also shifted. Previously loose collectives of individuals, informants described the communities no longer as just fan communities, but as troops, armies, and soldiers ready for the ensuing conflict. As Steve noted, "it was like a war we were in, and we were taking on CBS trying to bring the show back." As armies of devoted, action-ready combatants, the communities and their leaders were positioned to enter into battle as a unified collective, focusing efforts and energies on rescuing the beloved products, though some individuals resisted the change in orientation.

However, the shift between states was not seamlessly accomplished. Steve described that in the "Jericho" community, "some pockets were still talking about the episodes, which was fine. Most of the rest of us were busy caught up in saving the show. During the show, fans…everybody was great in talking about the episodes. During the campaign, obviously people were fighting to save the show. Everybody was together and everything else to save it." It therefore appears that shifting orientations is not without difficulty, as some consumers may resist the change. As a result, the communities experienced relative hybrid states of both fan and activist orientations that most likely further contributes to the feeling of instability and liminality.

Fluidity of Relationships & External Relationships

The relatively short time frame for coordinated action, as well as the specific and singularly focused goals of the campaigns, positioned community members to fluidly engage in or dissolve relationships both externally and internally. We define the construct of relationship fluidity as the mobility of individuals or organizations to form/reform relationship constellations or characterizations. Capitalizing on the changeable nature of relationships opened the door for campaigning consumers to incorporate desirable allies into their folds – allies who could provide resources such as bargaining power with the networks, distribution and communication channels, and so on. Relationship fluidity also created an opportunity for communities to adjust course and manage emergent issues throughout the campaigns when faced with external opposition or change. Consequently, relationship fluidity played a key role in the management and negotiation of communal instability during the campaign periods.

The formation of short-term alliances generated needed resources for the enactment of novel consumer initiatives. Potential market allies were targeted by community members as those market entities whose sentiments and sympathies aligned with the product or community, or those who would benefit from participating in the campaign. Alliances were explored both with previously affiliated market players and third-party companies. Zoey, in conceptualizing the "Finale and a Footlong" initiative of having consumers purchase Subway sandwiches on the day of the "Chuck" season finale, described: "it turned out to be a very easy way that…shows this advertiser, 'We noticed. We noticed your product, and we're going to buy it, because you were on the show.' I was hoping that Subway would see it and they might want to be further involved." As a result, Greg related that "we heard that the VP of marketing at Subway had called Ben Silverman, who was the head of NBC at the time, and talked to him about Chuck. And that's all the info we got at that point. And then we heard more and more from our sources that NBC was talking with Subway and that actually, Subway had initiated the conversation because of the fan campaign." Based on the spike in sales and immensely positive public relations, Subway entered the conflict as an ally to the consumers. By so doing, Subway was able to provide the communities with vicarious bargaining power in negotiations with the network, offering themselves as a more visible and involved sponsor in the show, and providing an added monetary incentive for NBC to renew "Chuck."

Alliances were also formed with third-party companies that provided capabilities and resources unavailable to the individual consumer or community. During the "Nuts for Jericho" campaign, campaign leaders suggested using an online nut company as a way to revolutionize the campaign:"Most campaigns, people send their individual purchase in. This vendor agreed to pull funds. So you

could put in however much you could afford, and at the end of the day, he would tally it and he shipped every couple of days." (Gina) Congregating the orders served to motivate fans to continue their efforts, as the daily and weekly tallies of nuts delivered were published on the nut distributor's website, through his personal videos of delivering the nuts to the network, and on the community's discussion boards. The formation and utilization of an external, third-party ally in this case therefore served a strategic purpose in providing additional pools of resources previously unneeded by the community. However, once the need was fulfilled, the momentary alliance between the third-party producer and the community dissolved, leaving good memories and a ton of nuts at CBS' studios. Thus, in this case, forming alliances represented a fluid resource that was rooted in the transitory nature of the campaign and the goals needing to be achieved at that point in time.

Relationship fluidity not only contributed needed resources to the campaigns for strategic purposes, but also allowed for the communities to adjust to the changing external environment by characterizing new players as potential allies or foes, as seeming fit by the circumstances. For example, for the Polaroid community, as it became evident that Polaroid was no longer going to be producing instant film, community members sought alternative avenues for production so that they could achieve their goal of saving instant film. Fuji film was targeted by leaders for community appeals, as a producer of instant film, though the products would not work directly with Polaroid cameras. Although petitions and letters were sent to the company, the members were disappointed in the non-realization of their potential ally. "We never really got any response from anyone at Fuji. And it's only through like third hand that [we learned] they were not interested… we were sad that they kind of ignored us and our request that they make something the looked like Polaroids and could work with Polaroid cameras." (Dean) The possibility of forming an alliance with Fuji, diffused by the lack of cooperation and interest on the part of the company, resulted in dissolving the hopes and abandoning the ally characterization of the company. The Polaroid community moved on to identifying other possible allies in the market and extending their efforts to encourage an alliance.

Therefore, it appears that the communities exhibited movement in their characterization of and allegiance with market players. Relationship fluidity provided communities with the ability to identify and engage in short-term alliances with external companies that increased pool of needed resources for specific campaign initiatives. The characterization and supplication for involvement seems to be influenced by the goal orientation, external conditions, and novelty of desired initiatives.

Community Transformation

Community relationship transformations. During and after the campaigns, internal community relationships also underwent significant transformations. Consumer-community, consumer-consumer, consumer-brand, and consumer-market relationships were affected as consumers engaged in their activist efforts. First, community leaders sought to revolutionize member overall focused on "rallying the troops," (Marcus) sending out calls to arms to transform lurkers into active members, recruit new members, and motivate members into action. "The activities we designed were really to get people out of their seats, away from their computers, and into the real world to take action." (Dean) Current members worked to recruit new members to the community, as Sam noted in the "Save Polaroid" plan: "Phase 1 was create a lot of noise. Get people interested in what's going on. The choir kind of already knew, but it brought new members into the choir." New recruits cited exposure to the campaigns through the

media and active networking by members as primary causes for their participation. In addition to the stream of new members, community leadership structures emerged and transformed during the campaign periods. In order to coordinate and direct widespread action, leadership groups were formed within the larger community in order to act as gatekeepers, motivators, and strategists for the campaigns:

"But we had a very tight-knit group of maybe 20 people. These are all people we had all communicated with each other on the boards. We knew each other at least in cyberspace. And Sarah [main leader] basically pulled everybody together, and, you know, we held meetings on Skype. Kind of strategy meetings, saying, okay, what are we going to do this next week, and how are we going to do it, and what's the most effective thing to do." (Christian)

New leaders also rose up in the ranks of the community by their active campaigning, innovative ideas for campaign initiatives, visibility through frequent communications, or by the expertise offered from prior campaign activities. Thus, the combination of the influx of new participants and the restructuration of the community leadership contributed to the redistribution of contributors from a small nucleus of contributors to a more diverse set of active participants, with distinctive leadership groups propelling the campaign forward. The overall orientation of the communities therefore shifted in response to the active mobilization of the communities through the campaign process.

Market player transformation. The campaigning communities shifted their focus from primarily enjoying the products as consumers to seeking and incorporation of market logics within the community, thus evolving the consumer-market relationship. Campaign leaders educated themselves to the behind-the-scene business structure that contributed to the production of the products, key decisions makers, and ways of "speaking" to the companies in ways that would be impactful. When organizing the "Finale and a Footlong" initiative for the "Save Chuck" campaign, Greg discussed the importance of communicating to the network in a way that would garner legitimate attention:

"This was a very similar idea, except that I wanted it to be a little more cohesive with the marketing strategy, and for the show itself, because they care if we send them a bunch of nerd candy? I'm like..yeah. It's cute and it's funny. But what are they going to do with it? So instead of sending them candy and nuts, which sounds like Valentine's Day, but instead of sending them a product, if we can coordinate and show an actual purchase to a key sponsor or advertiser, I think a happy advertiser is always going to be welcome at a network."

Moving beyond buzz-worthy gimmicks, such as sending large quantities of products that represent the show, Chuck's leaders leveraged experiences from previous consumer campaigns and knowledge of the television advertising system to elevate their campaign to fight using the logic that would appeal to the network as a business. "It's based upon ratings and whether or not it's going to be profitable. Because at the end of the day, NBC, Warner Brothers, and other advertisers like Subway are businesses. They need to sell a product and make a profit. And you know, by doing this, we were playing the game." (Mindy) The leaders used their understanding of the market system for their particular as a way to strategically tailor their initiatives to have the greatest impact on a business level.

"Save Polaroid" members considered the competitive landscape and product line alignment of potential producers in a bid to find

an appropriate producer-product fit for instant film, "that a company like Fuji and a company like Ilford who had a strong focus on analog film might be interested in buying some of the film from Polaroid and really moving forward, adding one more product to their list of products and sort of shoring up their analog base." (Dean) Campaigning consumers did not campaigning simply based on the platform of passionate fan support, as had been touted in prior campaigns. Rather, the informants entered into the market dialogue by employing research, market analyses, and business knowledge as tools for strategy development and campaign initiatives. Thus, the act of campaigning appears to create a catalyst for members to adopt a more market-oriented sensibility that incorporated business knowledge within the community. Individual members led the way for the community, strengthening and leveraging market-oriented relationships based on the adoption and application of market logics.

Long-term community relationship transformations. The respective battles fought during the campaigns continued to affect consumer-brand and consumer-consumer relationships within the communities. Some informants were unable to go back to the "good 'ole days," continuing to act in a mobilized state as a result of feeling an increased and vested interest in the community-brand relationship. These stalwart campaigns continued to discuss new ways to promote the product, garner new community members, and so on, long after the immediate threats had been resolved. "I knew from what Jericho had done, you know, their failure really. I mean, they got the show back, but then it failed. And I knew from their failure that our work had just begun. That we had to do something bigger. We had to motivate the fan base even more." (Mark) Ardent members acknowledged that they felt an increased burden of responsibility for the success of their products in later incarnations, and that they would be held accountable for both failures and successes by both other members and producers. The relationship between some community members and the product was strengthened through this increased responsibility and residual sense that the consumers were partly responsible for their successful campaigns in bringing back the desired products.

The relationships within the communities between individual consumers after the campaigns were tested and in some cases, dissolved. Some members, exhausted from the intense campaigning period or disillusioned with other community members, effectively "resigned" their status within the communities. It appears that without the guiding and unifying goal to save the product, conversations descended into bickering and argumentation as individuals fought over the direction of the community, leading some consumers exiting the main community and forming exclusive segments. Gina, who assumed a new role in the overall "Jericho" community as an emissary and middleman, mentioned that "there's some people that still won't talk to each other. And there's probably some people in my other group that I don't talk to. There's not too many people in the Jericho group I don't talk to, because it just seems so silly." Acting as a go-between, Gina had to forge new connections between the divergent groups in order to continue sharing information in the overall group. The vacuum of post-campaign directive goals and attitudes appears to have contributed to the destabilization of previously strengthened relationships, and altered the structure of community networks. Campaigning thus appears to have exerted more than a momentary transformative power on internal relationships. Organizing and fighting to save a product seems to have shifted communities in ways that led to new relationships forming or changing over time within the community.

DISCUSSION

Beyond the front lines of consumer hero and market foe lies a complex system of relationships that arise and shift in relation to the response of rising to resist market decisions. Based on the transformations of communities to new orientations and the liminal space in which consumers function as both consumers and activists aiming to achieve particular goals, fluid alliances provided access to needed skills and capabilities of useful market players, represented a method for dealing with the ever-changing external environment, and transformed a community both during and after the campaign period.

Consumer campaigns, like other forms of consumer resistance (e.g., Thompson et al 2006; Giesler 2008), are of strategic importance for companies. Not only can unaffiliated companies develop alternative streams of revenue when collaborating with consumer communities during campaign periods, but also targeted companies can improve consumer relations by actively working with communities to facilitate the mobilization and reorientation of consumer groups into viable promotion and production collaborators. Activists, as part of their goals, work to recruit members through word-of-mouth marketing, testimonials, product trial offers, and so on. As emissaries and ambassadors of the products, companies can benefit from the mobilization and involvement of activists in the marketplace. Further, because consumers utilize the campaigns as opportunities to learn more about and engage with the market on a business level, companies have the chance to cultivate co-creative relationships with market savvy individuals after campaign periods. Thus, we recommend that companies expand their perspective of consumer campaigners: though some many seem to be fanatic extremists, they have the potential to greatly contribute to the future of the product.

Our contributions to consumer literature are five fold. First, contrary to Giesler's (2008) linear, dramatic model of consumer resistance, we find that activism is more fluid and multidimensional in terms of the social structures and actors involved in consumer-generated campaigns. Relationship fluidity appears to be a necessary and useful construct when discussing consumer activism, and by extension, the strategic use of and characterizations of external partnerships. Second, we also note the strategic importance of emergent campaign goals in enabling and guiding relationship formations in activism. New goals fostered the transformation from community orientations, provided a standard under which consumers could gather, and acted as a key criterion for engaging in external alliances. Third, we extend beyond Muniz and Schau's (2005; 2007) findings to suggest that through activism, consumer communities are motivated to engage with market discourses and practices to become strategically minded consumer organizations who are further integrated into the market system. Fourth, we contribute a conceptualization of consumer resistance behaviors that identifies the nuanced differences of consumer resistance as exhibited in the marketplace. Finally, we address longitudinal community transformations, a hitherto neglected area of consumer research, and suggest that the transformations resulting from consumer activism create both short-term adjustments, and long-term shifts in community activities, foci, and networks.

We suggest that corporations take a broader perspective when confronting consumer campaigns. Not only can unaffiliated companies develop alternative streams of revenue when collaborating with consumer communities during campaign periods, but also targeted companies can improve consumer relations by actively working with communities to facilitate the mobilization and reorientation of consumer groups into viable promotion and production collaborators.

Learning to Resist: The Challenges Faced by Beginner Voluntary Simplifiers

Paul Ballantine, University of Canterbury, New Zealand
Paula Arbouw, University of Canterbury, New Zealand
Lucie Ozanne, University of Canterbury, New Zealand

INTRODUCTION

As a form of resistance against the dominant marketing system, anti-consumption has existed since the start of consumerism (Kozinets and Handelman 2004), with anti-consumption being defined as a "resistance to, distaste of, or even resentment or rejection of, consumption more generally" (Zavestoski 2002a, 121). This definition suggests that the concepts of anti-consumption and consumer resistance are inextricably linked, and this paper seeks to explore how these concepts can be used to understand the challenges faced by beginner voluntary simplifiers (a category of anti-consumers) when they try to remove themselves from (or resist) the market.

The idea of voluntary simplicity was first introduced by Gregg (1936), who took his inspiration from the great spiritual leaders of history who he believed practiced the lifestyle. When describing the term, Gregg (1936) identifies concepts such as 'singleness of purpose', 'sincerity and honesty within', and the 'avoidance of exterior clutter', as being the central tenets of voluntary simplification. More recently, Etzioni (1998, 620) defines voluntary simplicity as "the choice out of free will … to limit expenditures on consumer goods and services, and to cultivate non-materialistic sources of satisfaction and meaning". This definition also emphasizes the voluntary nature of the lifestyle, in that it should not occur through either coercion by authorities or as a means of budgeting through tough economic times (Leonard-Barton 1981). To date, the literature on voluntary simplicity has largely focused on either defining or operationalising the term (e.g., Etzioni 1998; Iyer and Muncy 2009; Leonard-Barton 1981), exploring the motivations behind the lifestyle (e.g., Shaw and Newholm 2002; Zavestoski 2002b), or examining the practices of experienced voluntary simplifiers (e.g., Craig-Lees and Hill 2002; Huneke 2005).

To counter the problem that much of the extant literature focuses on those people who have fully adopted the voluntary simplifier lifestyle, McDonald et al. (2006) recognize the importance of a large consumer segment that displays voluntary simplifier behavior, but are not committed or fully converted to the voluntary simplifier lifestyle, terming these people beginner voluntary simplifiers. Within the beginner voluntary simplifier segment, they distinguish between three types of simplifiers: *apprentice simplifiers*, who are voluntary simplifiers in the making; *partial simplifiers*, people that settle for lifestyles with some beginner simplifier features; and *accidental simplifiers*, people that simplify involuntarily because of economic reasons and are often not concerned with the ethical or environmental aspects of consumption.

The focus of this study is on those people who exhibit many of the characteristics of apprentice simplifiers (i.e., they have decided to adopt the voluntary simplifier lifestyle, but are in the early stages of doing so), but for the purpose of this paper, they will still be referred to as beginner voluntary simplifiers. Although not explicitly focusing on this group, Ballantine and Creery (2010) explore the disposition activities of voluntary simplifiers, noting the difficulty associated with the early stages of adopting the lifestyle, and its role in identity construction. The authors also suggest a vague endpoint to the journey of becoming a voluntary simplifier, with some of their participants professing a desire to live 'off the grid', and others indicating that they will always have some reliance on the market for what they need. In this respect, the journey of becoming a voluntary simplifier can be viewed as a liminal transition (Noble and Walker 1997; Turner 1969),

where an individual separates themselves from an existing role (i.e., a mainstream consumer) and undergoes a transitional process (the liminal period) before fully incorporating their new role as a voluntary simplifier into their daily lives.

Such a perspective is consistent with the idea that consumption and anti-consumption, and the attitudes individuals hold about their choices, can act as a form of identity creation and expression (Zavestoski 2002b). For example, attitudes about consumption can be linked to the undesired self, which serves as a reference point for judging overall life satisfaction (Hogg, Banister, and Stephenson 2009). Moreover, consumption is no longer always related to a positive self-concept, with anti-consumption increasingly becoming important in this area (Zavestoski 2002b). Furthermore, anti-consumption can be practiced in several ways, and does not necessarily have to mean non-consumption; it ranges from resistance to the rejection of consumption, and has varying degrees of visibility (Hogg et al. 2009). However, irrespective of what form of anti-consumption behavior occurs, the literature suggests that these behaviors are context dependent, and that the behaviors, challenges and attitudes associated with anti-consumption are highly affected by social, cultural and market influences (Zavestoski 2002b). In many instances, anti-consumption behaviors go against social norms, and therefore, can be stressful (Iyer and Muncy 2009), with Cherrier and Murray (2007) also noting the emotional costs associated with resisting consumption.

Although Bekin, Carrigan, and Szmigin (2005) note that market resistance is a reason why people adopt the voluntary simplifier lifestyle, the literature suggests that not everyone is able to successfully adopt the lifestyle and escape the consumer society. Arnould (2007) argues that the whole idea of anti-consumption reinforces social classes, because only the wealthy can afford to resist the market by adopting voluntary simplicity lifestyles. Similarly, Taylor-Gooby (1998) suggests that voluntary simplicity is a luxury for rich and secure minorities, arguing that the 'greening' of capitalism should be a worldwide project. For both Arnould (2007) and Taylor-Gooby (1998), the notion of being able to escape the market is a romanticized idea, with Arnould providing the example of an African community that is deprived of consumption to support his point-of-view. To counter this, some authors (e.g., McDonald et al. 2006) have highlighted how voluntary simplicity does not necessarily have to be practiced away from the market. Even though voluntary simplifiers can stay within the market, Taylor-Gooby (1998) would criticize them for doing so, arguing that they often keep much of their wealth, and that their approach is too silent; ignoring the possibility of a more activist approach.

Taken together, the literature indicates that market resistance is a reason why many people adopt the voluntary simplifier lifestyle, that consumer resistance is often a difficult act to undertake, and that little is known about individuals early in their transition into becoming a voluntary simplifier, so it is of interest to explore the challenges beginner voluntary simplifiers experience when they try to remove themselves from the market. Thus, a key contribution of this paper is to address the following research question: what challenges do beginner voluntary simplifiers face when trying to resist the market from which they are trying to escape?

Given the above focus, this study will not explore the reasons for adopting the lifestyle, nor will it examine the activities undertaken while adopting the lifestyle; the focus is instead on the challenges en-

countered when adopting the lifestyle, and the reasons it may be difficult to do so. This study also explores resistance to the market as a whole, as opposed to resistance to a specific brand (e.g., Lee, Motion, and Conroy 2009) or specific marketplace behavior (e.g., Close and Zinkhan 2009), which has often been the focus of the literature to date.

METHODOLOGY

This study was interested in the challenges faced by beginner voluntary simplifiers as they adopt their new lifestyle. Since these experiences are subjective, and full of emotional and symbolic content (e.g., Holbrook and Hirschman 1982), rich exploratory qualitative data was gathered from participants. Moreover, given the purpose of this study was to understand the experiences of participants in their own words, an interpretivist methodological approach (e.g., Lincoln and Guba 1985) was taken.

Fourteen beginner voluntary simplifiers were interviewed for this study using a series of in-depth semi-structured interviews. Each interview was approximately one hour in length. The participants ranged in age from 22 to 58, and they were all in the early stages of adopting the voluntary simplifier lifestyle (i.e., they had made the decision to adopt the lifestyle within the previous six month period). Six participants were male and eight were female. To recruit participants, both purposive and snowball sampling were used. Purposive sampling allowed participants to be selected on the basis of specific criteria (i.e., they were beginner voluntary simplifiers), and also allowed diversity to be built into the sample (Lincoln and Guba 1985). These participants were contacted through a sustainability network based in Christchurch, New Zealand. The members of this network were interested in learning about and practicing behaviors consistent with voluntary simplifier behavior. Snowball sampling then meant that those people interested in participating in this study could act as a link, where they identified other potential participants (Miles and Huberman 1994) with similar values, but who were not members of the sustainability network. Based upon a series of questions asked during the recruitment process, the participants in this study perceived themselves as wanting to achieve a lifestyle consistent with the definition of voluntary simplicity provided by Etzioni (1998).

The interviews had a phenomenological focus (i.e., they were from the perspective of the participants). Although an interview guide was followed, the interviews had the nature of a conversation, allowing the researcher to follow the interviewees lead and adjust the course of the interview to the topics that emerged. This approach allowed participants to provide thick descriptions, where they were able to articulate their experiences as they perceived them. To analyze the challenges faced by participants when adopting the voluntary simplifier lifestyle, a within case analysis (Miles and Huberman 1994) was used to gain insight, and was undertaken in the form of coding and sorting, which Tesch (1990) describes as decontextualising as the data are separated from their original cases. The data were then recontextualised through the identification of themes present across cases. The themes were constructed from reoccurring statements or concepts described by the participants (Miles and Huberman 1994). Given the potential for multiple interpretations of the data, two independent judges were used to authenticate the findings.

ANALYSIS AND RESULTS

Six main themes emerged from the interviews, which allow us to understand the challenges faced by beginner voluntary simplifiers as they adopt their new lifestyle and try to resist the pressures of the market. These themes were: habitual consumption, nongenerosity, planning and organizing, substituting experiences, money as an enabler, and balancing social activities and reducing consumption.

Habitual Consumption

All participants found adopting the lifestyle most difficult at the start, but easier later on, as they were able to break their habits and change their mindset. Many also felt frustrated and deprived while doing so. Kayla (aged 22) typified many participants when she reflected "I was tired and working heaps and kind of over it, and I think that was mainly because I was needing to change my ways, my routines, and changing all of that is quite hard. It takes a lot of energy and thought, and you are constantly nagging with yourself".

After a period of adjustment, participants frequently noticed that they did not miss the things they had previously been used to. Moreover, participants often formed new habits which they were happy about. Andrea (aged 27), for example, created the habit of bringing her own lunch to work rather than buying it, stating "It's really good getting into that habit and it's not that hard. Once I got a routine, for example the lunches, it kind of got easier. So originally I had to change my bad habits, but once I had a routine and I could stick to that it got easier I think".

Of all behavior, habits are often the hardest to break because they are ingrained and automatic (Verplanken and Wood 2006), so it was not surprising that participants experienced some difficulty while trying to alter their habitual consumption behavior. It was also evident that after a period of adjustment, behaviors consistent with the voluntary simplifier lifestyle became the norm. However, the short-term difficulty associated with changing habitual consumption behavior could act as a barrier for any individual undertaking the lifestyle.

Nongenerosity

Another challenge faced by participants was nongenerosity, or the unwillingness to share or give possessions to others (Belk 1984). This often manifested itself in not spending money on others, but also included the reduced giving of material items like gifts, as participants felt they needed to look after their own needs first. For Thomas (aged 31), needing to be careful with money in social situations was a negative experience, but he suggested that self-awareness was a way of overcoming this, saying "It does make you a little bit more stingy, which has the potential for impacting either your quality of life or your social interaction … but simply being aware of that reflex seems to do enough to counterbalance it".

Other participants found that being more frugal did not have to result in nongenerosity as they made personal gifts, supporting the idea that a positive outcome of frugality is increased creativity, especially when using and re-using resources (e.g., Lastovicka et al. 1999).

Planning and Organizing

Reducing consumption often required a substantial effort to plan and organize. Homemade lunches, supermarket shopping, homemade gifts, and alternative social activities were common areas where advanced planning was needed. Many participants, when adopting the lifestyle, found planning and organizing difficult due to the time and effort involved. For example, Harry (aged 31) observed "I had to be more organized which I wasn't used to and was very difficult. I wasn't used to planning and thinking ahead. I normally buy as I go".

Participants also realized that consumption was a form of buying time. For example, when buying fast food, the extra money spent was seen as payment for the time saved. Voluntary simplicity can be viewed as the luxury consumption of time (Arnould 2007), and when first adopting the lifestyle, participants reflected that they needed to find a balance between time and money.

Substituting Experiences

Participants found that reducing their consumption via substitution did not have a major effect on their well-being, although the process of finding alternative solutions for their previous consumption behavior was often challenging. The substitution of previous consumption behaviors by voluntary simplifiers is discussed in the literature (e.g., Bekin et al. 2005), and participants in this study found alternatives such as watching movies at home instead of going out, or in the instance of Daniel (aged 44): "I bought fake maple syrup instead of real maple syrup … In a lot of cases I ended up compromising on quantity or cost…".

As exemplified by this quote, the participants came across the dilemma of whether to reduce their consumption in terms of quality or quantity. Another participant decided to buy more expensive beer, because he found he gained the same satisfaction from consuming less. Ahuvia (2008) recognizes a tension in anti-consumption known as the *Rolex Dilemma*, which indicates that anti-consumption requires people to choose between items that are better quality and will last longer versus items that are cheaper but of poorer quality, and this trade-off was found to affect all participants.

Money as an Enabler

When adopting the lifestyle, participants encountered the realization that money was acting as an enabler for activities that made them happy. With this, they often struggled to balance their reducing consumption while still participating in the activities they loved. However, reducing consumption could sometimes go too far, with Dylan (aged 23) stating "There is obviously under consumption, so you've got to find a range which is comfortable for you. Spending that much and getting all the emotional, physical, mental and spiritual fulfillment that you need … Money isn't really going to get you happiness … It's not an end in itself, it is a means to an end, so if you get what you want without spending any money you are fine".

Thus, while participants recognized the role of money in facilitating consumption, they also realized that money was often only a means to an end. Moreover, many activities undertaken by participants had little monetary cost (e.g., going for walks, picnics),

while others did require a level of financial commitment (e.g., outdoor sports such as kayaking and rock climbing, or activities such as dance lessons). With these activities often being linked to a sense of well-being, participants reported that their expectations about what activities they could still participate in as part of the voluntary simplicity lifestyle played a role in how they maintained their quality of life, while still decreasing their consumption in a manner consistent with the lifestyle they had adopted.

Balancing Social Activities and Reducing Consumption

Another challenge for participants was balancing social activities while reducing consumption, as much of their social interaction was based around consumption activities like going out for coffee, movies, or drinks. Thus, they often struggled to find a balance between reducing their consumption and maintaining their social network as the following reflection by Monique (aged 31) suggests: "Sometimes I found it a bit socially isolating as well for the reason that I want to go to a café and be around other people and want to go out with friends".

To address these issues, participants tried to find social activities that were either based on cheaper/reduced consumption (e.g., buying coffee instead of lunch), or free consumption. Free activities included going for walks, picnics and home gatherings, which are considered by Etzioni (1998) as typical downshifter behaviors. However, some participants found it easier to stop participating in social activities, which led them to feeling unhappy and deprived, as the interaction of their social group was facilitated by material or service consumption. Monique (aged 31) exemplified this problem, stating "It was demoralizing. I stopped participating in social activities because the interaction of my social group is based on material or service consumption. I felt rude going around to peoples' houses without bringing anything for example, because it's something I have always done. You take something".

Proposed Conceptual Model

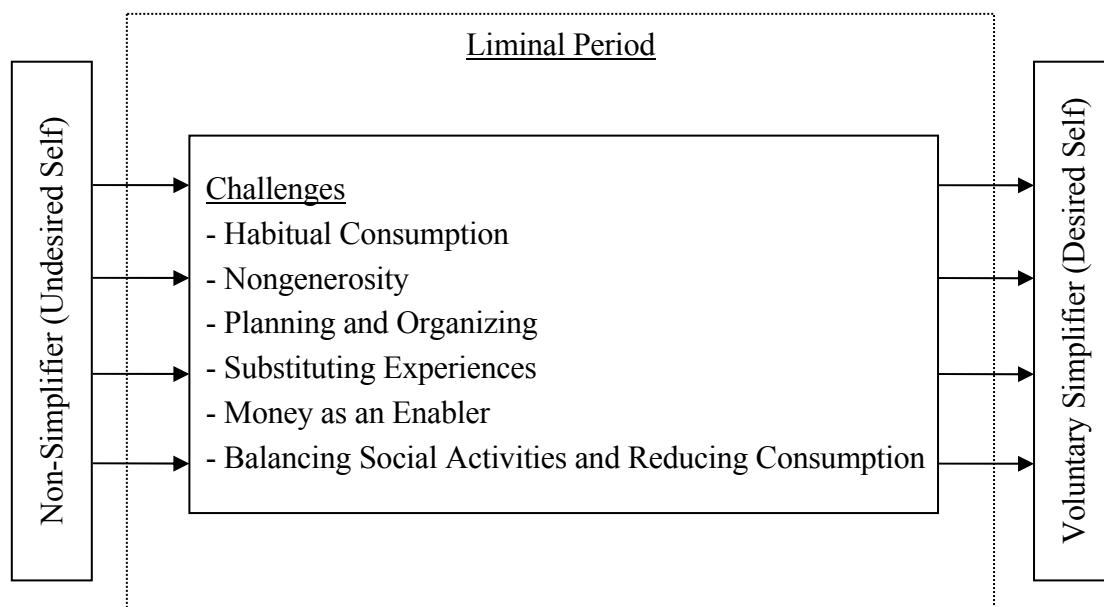
Figure 1 highlights how these six themes can be used to depict the journey of becoming a voluntary simplifier.


FIGURE 1: CHALLENGES FACED WHILE BECOMING A VOLUNTARY SIMPLIFIER

At the start of the journey, a non-simplifier (i.e., a mainstream consumer) may experience a sense of an undesired self, which leads them to consider adopting a lifestyle of lessened consumption, such as that provided by voluntary simplification. After making the decision to change their marketplace behavior, an individual enters a liminal period (Noble and Walker 1997; Turner 1969), where they start the transition towards becoming their desired extension of self (Belk 1988); that of becoming a voluntary simplifier, and the anti-consumption practices which are inherent with that lifestyle. Between these two states, this study has highlighted the challenges an individual may encounter during the transition period, where they are a beginner voluntary simplifier trying to resist the market.

DISCUSSION

While choosing to embrace the anti-consumption ethos of the lifestyle, the participants in this study faced many challenges in the journey of becoming a voluntary simplifier. Perhaps the most challenging aspect of adopting the lifestyle for participants was reducing consumption while still maintaining social ties that were often centered around consumption. In this regard, even though the participants in this study held values around lessened consumption, their social network made it difficult for them to resist their previous market behaviors. This perspective is echoed in the liminality literature, in that the detachment from prior relationships and social roles, which is part of the liminal period, is often an uncomfortable experience for those people who are in between their previous role and the one they wish to assume (Noble and Walker 1997). Many participants were also found to reflect upon the challenges they experienced by incorporating the dimension of financial cost in their discourse. For all participants, this was often reflective of their expectations about voluntary simplification, in that by choosing an anti-consumption lifestyle, their lessened focus on consumption was considered together with the financial costs associated with their previous consumption practices, thus making money a surrogate measure of their progress.

The literature suggests that beyond basic levels of consumption, one can increase their well-being more with social interaction than with further consumption (Cummins 2000). However, if one's social interaction is based on consumption activities, and the values of a social group are not open to alternative consumption, then consumption acts as an enabler for social interaction and long-term well-being. A common motivation for voluntary simplification is social influence (McDonald et al. 2006), and if beginner voluntary simplifiers experience social resistance (e.g., social norms that support consumption), then the transition to adopting the lifestyle is made more difficult.

There are many ways anti-consumption attitudes may manifest themselves, and the voluntary simplifier lifestyle is but one of these. Synonymous with this lifestyle is the idea of consumer resistance, although in the case of voluntary simplifiers, the focus of their resistance is the entire market, and the consumption values and practices of that market. Building upon the conceptual model introduced earlier, while anti-consumption is a dominant discourse for beginner voluntary simplifiers, their resistance to the marketplace can be seen as changing in focus, depending on where they are in the journey of adopting their new lifestyle. Moreover, while voluntary simplifiers are often perceived as a distinct social group, this study suggests their resistance of the market exists at the individual level, and the challenges faced when adopting the lifestyle are often idiosyncratic to each person. In this respect, this paper highlights the transitory nature of resistance; while anti-consumption may be a prevailing discourse for beginner voluntary simplifiers, how they resist the market (and the challenges they have doing so) is continually evolving.

CONCLUSION

The study suggests that beginner voluntary simplifiers encounter several challenges while in the early stages of adopting their new lifestyle. In his 2002 paper, Kozinets asked whether it is possible to evade the market, finding that if it is possible, it is most likely to be temporary and local. Extending this, Cherrier (2009) suggests that whether anti-consumption is a resistance to dominant powers or one's own domination, it depends on a sense of identity grounded in social positions, empowerment, and a vision of society. Overall, this study highlights that while beginner voluntary simplifiers hold a strong anti-consumption ethic, the way this manifests itself is influenced by both themselves and their existing social network. In this respect, the true challenge for beginner voluntary simplifiers is how to resist the influence of the market in which their daily activities and social ties are so firmly imbedded.

What Happens When Consumers Acculturate to Multiple Cultural Contexts?

Bernardo Figueiredo, University of New South Wales, Australia
Julien Cayla, Australian School of Business University of New South Wales, Australia

EXTENDED ABSTRACT

Movement is a key process in global consumer culture. Globalization and advances in technology, communication and transportation have intensified the circulation of goods, services, and people (Appadurai 1990; Ger and Belk 1996; Sherry 1998). Flows of information and ideas "from one culture enter another culture, and create individuals who exhibit elements of multiple cultures" (Craig and Douglas 2006,330). As a consequence, exposure to multiple cultural contexts (through media, through extensive travelling, or by living in large multicultural cities) is an everyday reality for millions of consumers (Klugman 2009).

Despite this, the consumer acculturation literature, i.e. the body of literature concerned with the behavior of consumers and other marketplace actors in their movement from one cultural context to another, has not yet examined the case of very mobile consumers, professionals who frequently shift locations and cultural contexts, people we call circulating consumers. The goal of this article is to bridge this gap by examining this process of circulation as "more than simply the movement of people, ideas, and commodities from one culture to another", but also as "a cultural process with its own forms of abstraction, evaluation, and constraints" (Lee and LiPuma 2002,6).

The consumer acculturation literature has made important contributions to understanding consumer behavior of migrants. Studies from the assimilationist phase have shown that ethnic groups have particular patterns of consumption and that understanding them is important for organizations as they try to develop advertising and sales promotions targeting these communities (Deshpande, Hoyer, and Donthu 1986; O'Guinn and Faber 1985).

Later, works from the post-assimilationist phase (Askegaard, Arnould, and Kjeldgaard 2005; Oswald 1999; Penaloza 1994; Thompson and Tambyah 1999; Üstüner and Holt 2007) challenged the idea of assimilation - i.e. the idea that immigrants are eventually assimilated into the mainstream culture, and advanced the theory on consumer acculturation in three main ways: 1) They have demonstrated that consumer acculturation processes are complex phenomena that involve processes of movement, adaptation and translation, diverse agents from home and host cultures, diverse identity outcomes and elements from the marketplace (Askegaard et al. 2005; Oswald 1999; Penaloza 1994); 2) They have shown how marketers, retailers, middleman, products, services, brands shape and are shaped by consumers' efforts to acculturate (Peñaloza 2000); 3) They have explained how cultural and social structures (e.g.: social class positions, ideological compatibility, consumer culture) can lead to differing patterns of consumer acculturation (Üstüner and Holt 2007).

However, the consumer acculturation literature has tended to focus on movement from one place to another. As noticed by Üstüner and Holt (2007,41) acculturation has been treated as "what happens when peoples socialized in one (minority) culture migrate and so come into continuous first-hand contact with a new (dominant) culture". They have not addressed cases of consumers having to adapt and acculturate more than once. Nor has it considered the cumulative effect of acculturation on consumers' subsequent experiences.

Given that to multiple cultural contexts – or multi-acculturation - has become a much more common phenomenon, especially among employees of multinational corporations (Black, Mendenhall, and Oddou 1991; Nowicka 2006; Sklair 2001), the need to address this gap becomes crucial. In short, the purpose of this paper is to examine how consumers acculturate to multiple cultural contexts. More specifically, what is particular to consumer multi-acculturation? How is it different from single acculturation processes? How does it help us to expand current understanding about consumer behavior?

We interviewed 38 expatriates, from 20 different countries of origins, ranging from 25-55 years old, 19 having a partner and 19 single or divorced. They were all professionals with a tertiary degrees, diverse occupations and diverse geographic mobility paths. Informants were asked to describe their life trajectories and explain their motivations for living in different countries (McCracken 1988). The identification of major life themes and life projects (Mick and Buhl 1992) together with iterative processes of comparison, dimensionalization, and integration (Spiggle 1994) created the necessary conditions to compare and contrast consumers` histories of living in different countries and find the most relevant categories which allowed researchers to group findings by themes

We contribute to the expansion of consumer acculturation literature in three different ways. First, by looking at circulating consumers, we identify a specific type of consumer behavior characterized by very pronounced cultural reflexivity. This reflexivity is expressed through four different aspects: 1) Awareness that one's own cultural identity may vary and that it can even be multiple; 2) Awareness that different cultural identities are perceived differently by different people or in different contexts; 3) Realization that cultural identities may be learned; 4) Indexicality based on first-hand experiences.

Second, we show that multiple acculturation affects consumers notions' of time. It is suggested that reflexive time of multi-acculturated consumes can be represented by a spiral shape, as it cyclical and progressive at the same time. We detail the effects of such notions on consumption practices.

Finally, our research advances the understanding of what it means to live in a global and multicultural marketplace, especially as it deals with consumers' adaptation to multiple cultural contexts. Through our circulating consumers we show that multi-acculturation (i.e. multiple processes of acculturation) may lead to metacculturation (i.e. a higher order of acculturation characterized by high cultural reflexivity). We also show that consumer metacculturation (Askegaard, Kjeldgaard, and Arnould 2010) is a level of acculturation with its own dynamics. Metacculturated consumers are aware of different aspects of their cultural identities and they will try to monitor and manage these aspects in order produce diverse identity outcomes. The consumption of cultures (Firat 1995) becomes a way of managing the self.

Psychological and Neurophysiological Investigations
of Close Consumer-Brand Relationships

Martin Reimann, University of Southern California, USA
Raquel Castaño, Tecnológico de Monterrey, México
Judith Zaichkowsky, Copenhagen Business School, Denmark
Antoine Bechara, University of Southern California, USA

EXTENDED ABSTRACT

Consumer researchers have become increasingly interested in the concept of consumer-brand relationships. Myriad consumer-brand relationship constructs have been offered in the extant literature, including brand attachment (Thomson, MacInnis, and Park 2005), brand commitment (Wang 2002; Warrington and Shim 2000), brand connectedness (Winterich 2007), brand devotion (Pichler and Hemetsberger 2007), and brand love (Ahuvia 2005; Albert, Merunka, and Valette-Florence 2008; Carroll and Ahuvia 2006; Fournier 1998). Research on these concepts has improved our understanding of the consequences of close consumer-brand relationships for various consumer behaviors, such as loyalty and positive word-of-mouth.

Little research, however, has focused on the underlying mechanisms that may explain consumer behaviors related to close brands. In particular, the motivational-emotional aspects associated with close brand relationships have not been fully explored. In general, why do people desire to enter and maintain relationships? And what is the emotional significance of such close relationships? Such questions are at the heart of the social-psychological self-expansion theory (Aron and Aron 1986), which has been applied extensively to human relationships (e.g., Aron, Aron, and Smollan 1992; Aron et al. 1991; Aron et al. 2000; Aron, Paris, and Aron 1995), but not yet to brand relationships. In brief, self-expansion theory suggests that in early stages, close relationships are motivated by rapid self-expansion—the acquisition of resources, perspectives, and identities that enhance one's ability to accomplish goals—whereas in later stages, close relationships are associated with the inclusion of others in the self, i.e., people tend to consider the close other as part of themselves.

Conceptualization

Recently, Reimann and Aron (2009) suggested that these ideas may not only be relevant to interpersonal relationships, but also to consumers' close relationships with brands. It is well known that in addition to close relationships with persons, people also form a similar type of relationship with objects (Belk 1988). More than not, these objects are specific brands, which consumers relate to and use to identify their "selves" (Ahuvia 2005). Similar to loved others, brands can create a "warm feeling" among consumers, form a pleasurable experience of being cared for, and ultimately bond consumer in a close connection (Fournier 1998). Brands can give consumers "ideal selves" to aspire to, as the presentation of self through possessions allows consumers to differ from what may be their "real selves" (Goffman 1959). Given this resemblance, it seems feasible to apply theories on close interpersonal relationships to consumer-brand relationship. As mentioned above, the specific appeal of self-expansion theory for brand research lies in its motivational-emotional account. Additionally, it emphasizes the dynamic character of close relationships and allows for predictions on changes in motivations and emotions as the relationship matures. Thus, self-expansion theory promises a richer understanding of brand relationships at various points of the brand lifecycle and, thus, the development of relevant practical implications for brand image management.

In an effort to test self-expansion theory in the context of brand relationships, the contribution of this paper is to determine (1) whether rapid self-expansion and inclusion in self are greater for close versus neutral brands and (2) whether levels of self-expansion and inclusion of close brands change over time. Using a multi-method approach, the present research adds both to knowledge of psychological and neurophysiological responses to brands as well as brain areas associated with close brand relationships.

Methods

The present research builds on self-expansion theory and applies the framework's key elements—rapid self-expansion and inclusion in the self—to consumers' close relationships with brands. To test self-expansion theory empirically in the context of consumer-brand relationships, a variety of psychological and neurophysiological methodologies, including self-reports, skin conductance recording, and functional magnetic resonance imaging, are drawn upon. Specifically, consumers' skin conductance responses (SCR), which measure the arousal dimension of emotion (Boucsein 1992), have the potential to shed new light on how consumers expand their "selves." A process tracing methodology, the recording of SCR helps provide novel insights on otherwise hidden processes in consumer judgments (Figner and Murphy 2010). For example, Damasio et al. (2000) were able to detect subtle differences in self-generated emotions by recording SCR, which would otherwise be hard to obtain. Additionally, by utilizing functional magnetic resonance imaging (fMRI), the analysis of neurophysiological mechanisms in the brain at the point in time when they take place, not in retrospective, becomes feasible (Shiv 2007; Shiv et al. 2005) because fMRI is not subject to cognitive processes overlapping actual emotional processes (Reimann et al. 2010). Participants do not have to remember how they relate to a brand as they do when they provide self-reports, so the fMRI process helps clarify how consumers include brands in their "selves."

Major Findings

In three experiments, this research provides novel insights into branding by studying the psychological and neurophysiological mechanisms of how consumers relate to their beloved brands. Building on self-expansion theory, the authors propose that self-expansion for a brand, operationalized in terms of emotional arousal, decreases over the brand relationship span, while inclusion of the brand in the self increases over time. In experiment 1, results indicate greater self-reported emotional arousal and inclusion for close versus neutral brands, as well as a decrease in emotional arousal and an increase in inclusion of close brands over time. Experiment 2 measures skin conductance responses to reveal increased emotional arousal, corroborating the results based on self-reported data. In experiment 3, a functional magnetic resonance imaging study reveals an association between long-term close consumer-brand relationships and activation of the insula, a brain area previously found to be a crucial mechanism in diverse, yet related psychological phenomena such as urging, addiction, loss aversion, and interpersonal love.

Complaining When You Are To Blame:
The Role of Impression Management on the Impact of Complaining on Product Attitudes

Lea Dunn, University of British Columbia, Canada
Darren Dahl, University of British Columbia, Canada

EXTENDED ABSTRACT

Complaining in consumer research has commonly been defined as "a means of making one's feelings known when unfair seller practices are encountered [and] when disappointment with a product arises" (Fornell and Westbrook 1979, p.105). Complaining research has historically only examined the impact of consumer complaining in situations in which the product is to blame for the product failure. Researchers in this area have found that complaining (versus not complaining) typically leads to increased product satisfaction. It is hypothesized that the cathartic release of negative emotion brought on by complaining allows consumers to feel better about the situation than if they had held onto the negative comments by not complaining (Bearden and Oliver 1985; Nyer 2000). Companies, therefore, are encouraged to elicit complaints from consumers to create a beneficial company-consumer relationship (Prim and Pras 1999).

According to attribution theory (Weiner 1985; Folkes 1988), however, complaining behavior and outcomes can be determined by whether the consumer attributes the blame to external sources (i.e., the product) or internal sources (i.e., the consumer). Most research, if not all, (dis)satisfaction and complaining research has focused on only the external attribution side, ignoring those consumers with internal attributions of blame. The current paper focuses on the under-represented side of internal attributions and how internal attributions of blame impact the outcomes of complaint behavior. Specifically, we propose that for consumers with internal attributions of blame, complaining is actually detrimental to the product satisfaction and evaluations.

In study 1, we manipulated whether the participant believed the failure was their fault or the products and whether they complained or not. We predicted that consumers who attributed the failure to the product itself would rate the product more favorably after complaining than before complaining. On the other hand, consumers who attributed the failure to their use of the product would rate the product less favorably after complaining than before complaining. We tested these predictions by running a 2(attribution: fault v. no fault) x 2(complaint: no complain v. complain) factorial design. Participants were told that they would assemble, use, and evaluate a "new product". Specifically, they asked to assemble a food processor and make a smoothie to test how well the product worked. Unbeknownst to the participants, the product and ingredients were insufficient to create the expected final product. In the fault condition, participants were told that no other participant was having trouble with the product and therefore, the participant themselves must be to blame for the product failure. In the no fault condition, participants were told that the product was having problems and they were not to blame for the product failure. After using the product, the complaint condition was manipulated by either having the participants complain (complain condition) or not complain (no complain condition). The main dependent variables were product and brand evaluations as well as purchase intentions. The results revealed that, as predicted, consumers who were to blame for the product failure rated the product lower after complaining while the consumers who blamed the product rated the product higher after complaining.

In study 2, we tested the hypothesis that impression management was the underlying mechanism for the previous study's results. In this study, we examined impression management in two ways.

First, we manipulated social presence, an indicator of impression management. Second, we took a measurement of an individual difference of impression management, self-monitoring. In a 2(social presence: friend present v. no friend present) x 2(impression management: high self-monitoring v. low self-monitoring) design, participants read a scenario wherein they failed several times to assemble a home entertainment system correctly. Social presence was manipulated by either having friends present during the assembly and evaluation of the product or simply present during the assembly of the product. Regression analysis revealed main effects for social presence and self-monitoring as well as an interaction of the two. High self-monitors rated the product less favorably in the presence of others than when alone, while low self-monitors rated the product more favorably in the presence of others than when alone. These results provide support for the idea that consumers with internal attributions of blame are using complaining to impression manage by shifting the blame from themselves to the product, thus lower their product satisfaction ratings.

Finally, in study 3 we found that having the consumer take accountability for the complaint mitigate the effects shown in the previous studies. Specifically, we manipulate accountability through both the accountability to the company (signed their name v. didn't sign their name) and to the social audience (friend present v. no friend present). In this study, participants read a scenario that they failed to use a website to correctly order a product. To manipulate the social audience, a friend was either present or not present during the whole experience. Accountability to the company was manipulated by having the participants either sign their complaint or not sign their complaint. Results found that when asked to take accountability for their complaint in the presence of others, participants rated the product higher when they complained than those consumers that that did not take accountability for their actions or when the participants were not in the presence of others. Thus, taking accountability for their complaint led consumers to be more honest in their attributions of blame by not shifting the blame for the failure from themselves to the product.

Taken together, these studies demonstrate that there is an important distinction between external and internal attributions of blame when it comes to the outcomes of complaining. In particular, asking consumers with internal attributions of blame to complain may actually be detrimental to subsequent product evaluations. This pattern of results is due to consumers attempting to maintain an impression of competence by shifting the blame from themselves to the product. Finally, these results can be alleviated by having consumers take accountability for the veracity of their complaint. These results represent the first empirical evidence of the impact of complaining on consumers with internal attributions of blame and have several important implications for companies consumer complaint policies.

Resources Running Out:
How Arbitrary Resource Fragmentation Decreases Consumer Spending

Bert Weemaes, K.U. Leuven, Belgium
Siegfried Dewitte, K.U. Leuven, Belgium
Luk Warlop, K.U. Leuven, Belgium

EXTENDED ABSTRACT

In recent years, consumers' liquid assets have become increasingly fragmented. The money that consumers can use to pay for a purchase tends to be distributed across a multitude of carriers of value including cash, bank accounts, electronic purse smart cards, stored value cards and certificates, prepaid cell phone credit, online wallets, and so on. Given this evolution, the primary objective of this research was to explore if and when such incidental budget divisions influence consumers' decisions.

This manuscript suggests that people are particularly averse to seeing a resource, like the money in their wallet, the funds on their electronic purse, or their PayPal account, run out. Using a variety of operationalizations, five studies show that when decision situations are structured such that a decision to spend would result in a resource running out, consumers' propensity to spend decreases. The first study demonstrates the effect by showing that cueing an incidental resource amount reduces the propensity to spend, but only when the cued amount would largely run out when it would be used to pay the item under consideration. Further studies show that the effect continues to occur when consumers are well aware that they have access to more resources, for example when they are also carrying a debit card that allows them to pay purchases directly from their bank account (study 2) or when they are carrying more cash money (study 3). The effect is also observed when the boundaries that separate a resource from the remainder of a consumer's resource pool are manifestly arbitrary (study 4), and when spending merely creates the illusion of a resource running out (study 5). The effect is shown to be independent of perceived total wealth and of the accessible account effect (Morewedge, Holtzman, and Epley 2007) in study 2, of source effects (Shefrin and Thaler 1988) in study 3, and of perceived resource availability in study 4.

We offer an explanation based on the idea that different cognitive perspectives lead to different valuations (Ariely, Huber, and Wertenbroch 2005; Carmon and Ariely 2000; Heath, Larrick, and Wu 1999; Novemsky and Kahneman 2005). Specifically, we suggest that seeing a resource run out causes a shift in the cognitive perspective that is used to evaluate transactions. Imagining a specific resource running out makes the loss of resources associated with spending money very salient. We propose that this leads consumers to evaluate the money that would be given up in the transaction in the loss domain, which consequently reduces the propensity to spend.

We provide evidence for the process (loss frame activation) through three different routes. The first approach focuses on demonstrating the mediating role of anticipated pain of paying (Prelec and Loewenstein 1998; Rick, Cryder, and Loewenstein 2008) as phenomenological reflection of loss aversion for money. Consistent with the prediction that anticipated pain of paying mediates the effect, all five studies show that the effect of seeing a resource running out on the propensity to spend is moderated by Rick et al.'s (2008) spendthrift-tightwads scale. The effect was strongest for spendthrifts and weakest among tightwads, who already feel pain of paying spontaneously. In addition, anticipated pain of paying is shown to statistically mediate the effect of seeing a resource running out on consumers' spending intentions in studies 2 and 3. The process that underlies our explanation is more directly tested in studies 4 and 5 which provide evidence of shifts in cognitive perspective as measured by written protocols (study 4), and by proportionality judgments (study 5).

From a consumer welfare perspective, our results are particularly relevant to consumers who identify themselves as chronic over-spenders (i.e. spendthrifts). These consumers may benefit from compartmentalizing their funds into relatively small parts. Ironically, consumers who want to reduce their spending may benefit from carrying a larger array of payment modes. Merely carrying different payment modes that typically contain small amounts, like cash and electronic purse smart cards rather than relying only on credit or debit cards, may help to reduce spending. Our research also has implications for marketers who promote the use of stored value cards to facilitate or encourage spending (e.g. cell phone carriers, public transit authorities, retail chains; Raghubir and Srivastava 2008). Our research implies that such cards may sometimes backfire by discouraging consumers from spending when spending would imply that the card would (largely) run out.

Moderating Shelf-Based Scarcity

Jeffrey Parker, Columbia University, USA
Don Lehmann, Columbia University, USA

EXTENDED ABSTRACT

Shelf-based scarcity is said to occur when one product on a shelf is less stocked (more depleted) than its competitor(s). Recent research has documented the strong impact that shelf-based scarcity can have on consumer preferences. Specifically, van Herpen, Pieters, and Zeelenberg (2009) showed that consumers tend to infer that scarcer products are more popular and of higher quality, and that they prefer scarcer products significantly more than abundant products. Building on these findings, Parker and Lehmann (forthcoming) identified the process through which shelf-based scarcity impacts choice. These authors found that, while both popularity and quality inferences are made based on shelf-based scarcity, it is popularity inferences that are the primary driver of shelf-based scarcity effects.

The results of these papers suggest that shelf-based scarcity is a robust phenomenon. For example, shelf-based scarcity is found to have a significant and positive impact on choices made from a wide variety of product categories (e.g., from wine to motor oil to clothing to household cleaners), and Parker and Lehmann (forthcoming) demonstrate that shelf-based scarcity effects occur even when consumers are making real choices (i.e., choosing products which they will pay for and keep) from branded products in well-known product categories. Further, consumers are still found to prefer scarcer products even when they are given explicit popularity and quality information about the available alternatives.

These papers also made the first inroads into identifying the boundary conditions of shelf-based scarcity effects. First, van Herpen, Pieters, and Zeelenberg (2009) found that consumers tend to not prefer scarcer alternatives when they are shopping in an identity-relevant category (e.g., clothing) and the store is frequented by local customers (i.e., people they are likely to encounter). Adopting a different focus, Parker and Lehmann examined the impact of shelf-based scarcity in the presence of other ubiquitous retail cues (including the aforementioned popularity and quality information), and found that shelf-based scarcity effects are overwhelmed when a price promotion is available in the product category. Additionally, these authors determined that consumers with strong prior preferences were largely unaffected by shelf-based scarcity (i.e., they did not prefer scarcer products more). While some very important boundary conditions of shelf-based scarcity effects have been identified by the aforementioned work, there is still much to learn about this phenomenon.

This project picks up where these papers left off and more deeply investigates the conditions under which shelf-based scarcity does not have a positive (and may have a negative) impact on preferences. First, we conceptually replicate the van Herpen, Pieters, and Zeelenberg (2009) findings regarding identity-relevant goods in a subtler manner. Specifically, we ask participants to choose from two winter jackets (an identity-relevant product category), one of which is scarcer than the other. The jackets are manipulated to differ either in a conspicuous manner (i.e., in a way which others could identify) or in an inconspicuous manner (i.e., in a way that others would not notice). Measuring the participants' need for uniqueness (Fromkin and Snyder 1980), we find that high need-for-uniqueness participants prefer the scarcer jacket significantly less than low need-for-uniqueness participants, but only when the jackets differ conspicuously (i.e., could be used to signal one's identity).

Next, we turn our attention to a crucial link in the process underlying shelf-based scarcity effects that was identified by Parker and Lehmann (forthcoming); the link between shelf-based scarcity and popularity inferences. The literature to this point seems to suggest that this link is universally strong and positive. However, if true, this would suggest that shelf-based scarcity effects could only be attenuated by either making popularity a negative characteristic or by introducing an overwhelming cue (e.g., a price promotion) into the choice context.

We argue that consumers will not always believe that scarcer alternatives a more popular and present two studies supporting our contention. First, building on the shelf-location effects literature (see, e.g., Valenzuela and Raghubir 2009), we posit that shelf-based scarcity effects will be moderated by the location of the scarcer product. Specifically, we hypothesize and demonstrate that the relative advantage of being a scarcer alternative is reduced when the scarcer alternative is located on the bottom (vs. an upper) shelf. We show that, because consumers do not expect scarcer products to be on bottom shelves, scarcer products are neither (i) believed to be relatively more popular nor (ii) more preferred when they are located on the bottom (vs. an upper) shelf.

Second, we investigate whether consumers' persuasion knowledge (Friestad and Wright 1994) impacts their responses to shelf-based scarcity by manipulating the salience of retailers' persuasion motives and tactics. If consumers believe that retailers are attempting to manipulate their choices, they are likely to discount cues which the retailer is able to manipulate (e.g., shelf-based scarcity). This is exactly what we find. When retailers' persuasion motives and tactics are made salient there is no longer a strong and positive impact of shelf-based scarcity on choice.

Taken together, these studies add to our understanding of how and when shelf-based scarcity impacts consumers' preferences. Both the theoretical and managerial implications are discussed.

The Instrumental and Detrimental Role of Materialism in the Development of Networks

Seung Hwan (Mark) Lee, University of Western Ontario, Canada

EXTENDED ABSTRACT

Materialism is the dispositional view towards consumption of objects and possessions as an important part of achieving higher goals, such as self-definition and self-enhancement (Chaplin and John 2007). For example, Richins and Dawson (1992, p. 304) state that "it is the pursuit of happiness through acquisition rather than through other means (such as personal relationships, experiences, or achievements) that distinguishes materialism." In other words, materialism is the importance that people place on consumption relative to other values, such as relationships, as a means by which to achieve certain goals (Richins and Dawson 1992).

Research has shown that there are positive and negative consequences of materialism (Burroughs and Rindfleisch 2002; Chaplin and John 2007; Dittmar, Long, and Bond 2007; Fitzmaurice 2008; Van Boven and Gilovich 2003). Overall, research in marketing, for the most part, has depicted materialism as a destructive trait; Hirschman (1991) refers to materialism as one of the "dark sides" of consumer behavior. For example, materialism has been associated with negative personal outcomes, such as social ineptitude (Richins 1987) and narcissistic behavior (Cohen and Cohen 1996), which can hinder an individual's motivation and ability to effectively form social relationships and networks. If materialism is, in fact, negative and destructive, why are we witnessing the rising levels of materialism among consumers (Goldberg et al. 2003; Chaplin and John 2010)?

Perhaps there is a brighter side to materialism. Past researchers have shown that materialistic behavior is associated with positive personal outcomes, such as attaining a higher standard living (Richins and Rudmin 1994) and attaining desirable characteristics (e.g., cultured, sophisticated) (Christopher and Schlenker 2004). This debate about the nature of materialism leads to the main research question: Is materialism *instrumental* or *detrimental* to an individual's social network development?

Findings from a longitudinal field study from an emerging social network (Study 1) reveal that materialism is instrumental to an individual's social network development (i.e., more materialistic people made more social connections over time). However, a caveat is that this benefit is perceptual, not actual. That is, there appears to be a discrepancy between consumers' perceptual social network versus their actual social network, a phenomenon coined here as the *perceptual network fallacy*. Materialistic individuals overestimated the number of friends they had in their social network in two separate time-periods (early and later stages of network development). This finding is important to consumers because materialistic individuals are accustomed to acquiring material goods in response to their belief that possessions will enhance their social standing (i.e., they will become more popular/central in a network). However, the findings of this research suggest that this belief is merely perceptual.

Moreover, in support of this theory, the findings from Study 2 reveal that conversing about product possessions is what primes materialistic individuals to overestimate their friendship desirability. While previous research has noted the negative impact of discussing possessions with others (Van Boven et al. 2010), the current research goes one step further to show that this effect is even stronger for materialistic individuals. In support, the data show that materialistic individuals were rated less desirable by others when they were first given the opportunity to converse about product possessions. Interestingly, the data also show that materialistic individuals rated themselves higher on friendship desirability. Thus, materialistic individuals perceive that conversing about product possessions enhances their self-value, although this was clearly not the case. Materialistic individuals continue to purchase and talk about products that elevate their social image because they mistakenly perceive that doing so will benefit them socially (Bagwell and Bernheim 1996). Unfortunately, they are oblivious to the detrimental effects, a condition that explains why the magnitude of perceptual network fallacy grows over time. As networks mature, materialistic individuals gain more opportunities to talk about their product possessions with others. As a result, such conversations continue to contribute to the growing gap between these individuals' out-degree and in-degree ties over time, thus magnifying their erroneous perception of their position within the network.

In conclusion, this research provides another lesson to consumers regarding the dangers of materialistic consumption. Growing levels of materialism among teenagers have raised concerns among parents and educators alike (Chaplin and John 2010; Goldberg et al. 2003). Adolescents purchase certain objects (e.g., cell phones, MP3 players, brand-name clothing) because they perceive that material possessions will help them gain a desirable status (e.g., popularity) in their social network. However, it must be recognized that these are erroneous perceptions. Indeed, materialistic individuals do not gain more friends over time. They only believe that they will. Therefore, consumers could be warned that their efforts to use material consumption in order to gain favorable network positions may not be successful.

Effects of Family Structure on Compulsive Buying: A Life Course Perspective

Andrew Baker, Georgia State University, USA
George Moschis, Georgia State University, USA
Edward Rigdon, Georgia State University, USA
Anil Mathur, Hofstra University, USA

EXTENDED ABSTRACT

Compulsive buying has been a topic of great interest to researchers and policy makers for decades because it is believed to affect the well-being of millions of U.S. consumers. It can be viewed as form of maladaptive behavior, as it correlates strongly with other forms of compulsive behaviors, such as alcoholism and eating disorders (Faber et al. 1995), which are considered maladaptive phenomena (e.g., Simmons et al. 2002). Although it is recognized that compulsive behavior is rooted (at least partly) in early-life experiences (e.g., Rindfleisch et al.1997), little is known about the processes that link early-life experiences to this form of consumer behavior (Rindfleisch et al. 1997).

The life course paradigm offers a viable framework for studying childhood-adulthood links because it suggests that behavior is embedded with circumstances one has experienced at earlier stages in life. It has been used to study similar phenomena of maladaptive behavior such as binge eating and drinking (e.g., Simmons et al. 2002). This paper uses the life course framework as a blueprint for organizing, integrating, and developing a theory-driven model to explain compulsive buying. A model of compulsive buying that has appeared in leading scientific journals (Rindfleisch et al. 1997) is also tested and compared to the life course model, using a sample and measures similar to those used by its builders. The results suggest that previous efforts to study this consumption phenomenon could be better understood in the context of the broader multi-theoretical life course paradigm.

The life course paradigm suggests that biological and psychological changes during an individual's life and social demands across the life course that are defined by typical life events and social roles create physical, social, and emotional demands and circumstances to which one must adapt. This adaptation entails the processes of socialization, stress and coping, and development and growth or decline. These processes are the underlying change mechanisms of the three most widely-accepted life-course perspectives: normative (socialization), stress, and human capital, respectively (Moschis 2007).

Previous research finds that young consumers from disrupted homes have higher compulsive buying tendencies than those from intact homes (e.g., Rindfleisch et al. 1997), viewing stress as the mechanism or process that links family disruption to compulsive buying. In contrast, the life course paradigm suggests a number of causal mechanisms relating family structure to the child's problem behavior in general and compulsive buying in particular. According to this paradigm, compulsive buying tendencies may be the result of not only stressful experiences of disruptive family events (as suggested by the stress perspective); they may also be attributed to negative consequences these family events have on the child's socialization experiences (as suggested by the normative perspective) and his or her psychological development (as suggested by the human capital perspective). Because the various disciplinary approaches to life course research are complementary, the life course paradigm provides a framework for integrating diverse theoretical perspectives into a multi-theoretical model, which is consistent with recent efforts of life course researchers to develop models that include variables derived from diverse theories (e.g., Mortimer and Shanahan 2003). Thus, based on the power of the life course paradigm to integrate multiple theoretical perspectives, we draw from each of the three theoretical perspectives to provide an integrated model to explain compulsive buying.

The results generally support the life course model, helping us see the contributions of each perspective to our understanding of compulsive buying tendencies. They highlight the mechanisms that may link family disruptions to compulsive buying, beyond those suggested by previous research that has assume stress as an explanation. Specifically, our data suggest that family disruption events experienced in formative years leads to the depletion of socioeconomic resources that interfere with socialization practices and deter human capital development due to ineffective parent-child communications. The youth's experience of stressors from living in disrupted family settings and their experience of socioeconomic deprivation appear to be responsible for the social processes—interactions with peers and parents who stress conformity rather than self-direction and attempt to exercise a greater control over their child's activities, which are fostered in such family settings. These processes appear to put the child at risk of developing compulsive buying tendencies.

Although earlier research has suggested the possibility of mechanisms (other than stress) for the development of compulsive consumer behaviors, such as family socialization practices (e.g., Rindfleisch et al. 1997), research along these suggested directions has been hampered due to a lack of theoretical frameworks. The present study shows how earlier research on compulsive buying can be examined within the broader life course paradigm.

"When Knowing is Better than Expecting"
Resolving Different Types of Ambivalence by (Biased) Information Processing and Spreading Word-Of-Mouth

Nico Heuvinck, Ghent University & University College Ghent, Belgium
Iris Vermeir, Ghent University, Belgium
Maggie Geuens, Ghent University & Vlerick Leuven Gent Management School, Belgium

EXTENDED ABSTRACT

When consumers simultaneously evaluate an attitude object as positive and negative, they are said to experience attitudinal ambivalence (Kaplan 1972). As ambivalence is generally experienced as aversive and unpleasant (Newby-Clark et al. 2002; Nordgren et al. 2006; van Harreveld et al. 2009a), it is assumed to induce ambivalent people to thoroughly scrutinize any information that enables them to resolve their ambivalence (Jonas et al., 1997; Nordgren et al. 2006; van Harreveld et al. 2009b). However, ambivalence can also be resolved through biased information processing (Nordgren et al. 2006; van Harreveld et al. 2009b). Clark et al. (2008), for example, found that ambivalent individuals increase processing of proattitudinal information and avoid processing of counterattitudinal information. The direction of the bias is thus in line with the initial valence of the attitude (Nordgren et al. 2006; van Harreveld et al. 2009b).

This paper builds on and refines these findings in two major ways. First, we distinguish between two different types of subjective ambivalence: *manifest ambivalence* (knowing conflicting information) versus *univalent ambivalence* (expecting conflicting information). Second, next to information processing, we also investigate word-of-mouth (WOM) as a potential coping mechanism. The objective of this paper is then to investigate different types of subjective ambivalence, and information processing and spreading WOM as ways to deal with this ambivalence.

In Study 1, we manipulated univalence, univalent ambivalence, and manifest ambivalence by varying the amount of positive and negative features respondents received about an MP3-player (cf. Priester et al. 2007), and by varying the opinion of one's best friend. Ambivalence was measured by capturing the degree to which respondents' reactions toward this MP3-player are conflicted, mixed, and indecisive. The extent of information processing was measured by means of a thought-listing procedure (cf. Nordgren et al. 2006). Thoughts were coded on valence and total number of arguments listed. Results show that manifest and univalent ambivalent individuals experience the same level of subjective ambivalence and generate the same number of thoughts, but the valence of their thoughts significantly differs. Univalent respondents seem to focus more on positive thoughts than univalent ambivalent respondents who in turn generate more positive thoughts compared to manifest ambivalent individuals. Hence, the type of ambivalence induces a different information processing.

Study 2 addresses whether people in the univalent ambivalent condition attempt and/or succeed in resolving their ambivalence through generating especially positive thoughts and individuals in the manifest ambivalent condition through mainly negative thoughts. This study is similar to Study 1, except for two modifications. First, we now also measured ambivalence aversion (by means of the items irritation, frustration and discontentment, cf. Nordgren et al. 2006). Second, a repeated measure of subjective ambivalence was obtained at the end of the questionnaire. Study 2 replicates the findings of Study 1. In addition, manifest ambivalent respondents report more intense negative emotions than participants in the univalent ambivalent and univalent condition. This higher ambivalence aversion seems to motivate manifest ambivalent consumers to process information that can resolve their conflict. Results confirm that for manifest ambivalent respondents the biased (negative) information processing helps to reduce the discomfort of ambivalence. That is, ratings of subsequent ambivalence were lower than ratings of initial ambivalence. For univalent and univalent ambivalent people, there was no difference between initial and subsequent ambivalence.

WOM has been shown to be one of the most employed strategies for reducing cognitive dissonance (Festinger, 1957). By spreading WOM to others, consumers try to convince themselves of their opinion by convincing others of the same opinion. Therefore, we believe that WOM can also be an effective coping mechanism to reduce subjective ambivalence. To the best of our knowledge, this has only been discussed in the cognitive dissonance literature (e.g. Festinger, 1957) and the service literature (e.g. von Wangenheim, 2005) to cope with evaluative incongruence, but has not yet been investigated in relation with ambivalence.

Study 3 was similar to Study 1 except for one modification. Measures of positive and negative WOM replaced the thought-listing task. Positive WOM captured the degree to which respondents would recommend/ tell others to buy the MP3-player whereas negative WOM covered the extent to which respondents would warn/tell others not to buy it. Results indicate that, although they experience the same extent of ambivalence, manifest ambivalent people spread more negative and less positive WOM than univalent ambivalent and univalent people. This could be due to the awareness of these conflicting (negative) features and/or to the fact that negative features weigh more heavily in the evaluation of an attitude object than positive ones (Ito et al., 1998).

Study 4 investigates whether spreading negative WOM could also account as an effective coping mechanism to resolve the agony of ambivalence for manifest ambivalent individuals. Study 4 was similar to Study 2, except for one modification. That is, instead of a thought-listing task, WOM was assessed using an open-ended question, the answers of which were coded for valence and number of arguments. This study replicated the effects found in Study 3. That is, manifest ambivalent people spread more negative and less positive WOM compared to univalent ambivalent individuals as well as univalent attitude holders. Similar to Study 2, we show that manifest ambivalence is experienced as more aversive than univalent ambivalence and univalence. In addition, manifest ambivalent attitude holders generate more negative WOM (motivated by the aversion) which reduced their feelings of ambivalence.

Taken together, our findings show the relevance of distinguishing between the types of ambivalence (univalent versus manifest ambivalence). They also shed light on the difference of the underlying structure of feelings of ambivalence and how people cope with these different types of ambivalence in terms of information processing and WOM as a means to reduce the aversion caused by the type of ambivalence. It seems that both biased (negative) information processing and negative WOM helps manifest ambivalent people to resolve their subjective ambivalence level. A possible explanation for this finding may reside in the fact that manifest ambivalence is experienced as more aversive compared to univalent ambivalence.

"The Good, the Bad and the Certain"
When Ambivalent Attitudes Affect Intention Differently

Maggie Geuens, Ghent University & Vlerick Leuven Gent Management School, Belgium
Iris Vermeir, Ghent University, Belgium

EXTENDED ABSTRACT

When consumers simultaneously evaluate an attitude object as positive and negative, they are said to experience attitudinal ambivalence (Kaplan 1972; Priester and Petty 1996). Although attitudinal ambivalence is usually treated as a general construct (Kaplan 1972), the underlying structure of the feelings of ambivalence may lead to very different consumer responses. Building on Priester et al. (2007), we distinguish two different types of subjective ambivalence: *manifest ambivalence* (knowing conflicting information) versus *univalent ambivalence* (anticipating/expecting conflicting information). The objective of this paper is to investigate the impact of these different types of subjective ambivalence on attitude certainty (conceptualized by attitude clarity and attitude correctness) and attitude-intention correspondence.

Ambivalence is generally associated with uncertainty as the conflict between positive and negative reactions attenuates the certainty of holding an attitude (e.g. Jonas et al. 1997; Petrocelli et al. 2007; Petty et al. 2006; Tormala and Rucker 2007). However, we suggest that attitude certainty associated with an ambivalent attitude will be influenced by the type of conflicting reactions that underlie subjective ambivalence. When conflicting reactions are anticipated (i.e., univalent ambivalence), people will be less certain of their ambivalent attitude compared to when conflicting reactions are known (i.e., manifest ambivalence) or rather absent (i.e., univalence).

In Study 1, we manipulated attitudinal ambivalence (univalence, univalent ambivalence, and manifest ambivalence) by varying the amount of positive and negative features respondents received about an MP3-player (cf. Priester et al. 2007), and by varying the opinion of one's best friend. Respondents indicated their attitudes, attitude certainty (Clarkson et al. 2008; Petrocelli et al. 2007; Tormala and Petty 2002), type of conflicting reactions, and subjective ambivalence toward the MP3-player (Priester et al. 2007). The results show that although manifest and univalent ambivalent individuals experience the same level of subjective ambivalence, univalent ambivalent attitudes are held with less certainty compared to manifest ambivalent and univalent attitudes. Hence, the type of ambivalence, fed by different conflicting reactions, indeed induces different levels of attitude certainty.

According to Petrocelli et al. (2007), attitude certainty is composed of (1) attitude correctness and (2) attitude clarity. Attitude correctness refers to the extent to which one feels confident that his/her attitude is correct, valid, or justified. Individuals with high attitude correctness not only believe that their attitude is correct, but also think that other people should have the same attitude. Attitude clarity is the extent to which people know what their true attitude toward a topic is and to what extent this attitude is clear to them. We argue that univalent ambivalent people are less likely to know their true attitude (cf. attitude clarity) toward a focal product because they anticipate, but are not really aware of any conflicting information. In contrast, manifest ambivalent individuals are well aware of conflicting information. Therefore, we believe that they perceive their attitude to be clearer compared to univalent ambivalent individuals. In contrast, concerning attitude correctness, we do not expect any differences between manifest and univalent ambivalent individuals. Univalent ambivalent individuals can be as convinced as manifest

ambivalent individuals that their attitude is correct/valid given the available information.

Study 2 was identical to Study 1, except for one modification; at the end of the questionnaire, we assessed attitude clarity and attitude correctness (cf. Petrocelli et al. 2007). Besides replicating the findings of Study 1, Study 2 shows that univalent ambivalent respondents indeed feel that their attitude toward the MP3-player is less clear as compared to manifest ambivalent and univalent participants. Also in line with expectations, univalent ambivalent individuals feel equally confident as manifest ambivalent and univalent individuals that their attitude is correct, valid or justified. Hence, it seems that the lower attitude certainty experienced by univalent ambivalence (versus manifest ambivalence and univalence), is driven by a difference in attitude clarity rather than a difference in attitude correctness.

Several studies have shown that attitudinal ambivalence results in lower attitude-behavior consistency (e.g. Armitage and Conner 2000; Conner et al. 2002; Costarelli and Colloca 2004; Thompson et al. 1995). In contrast, Jonas et al. (2007) and Sengupta and Johar (2002) found that ambivalent attitudes lead to higher attitude-behavior consistency. We argue that the type of conflicting reactions underlying attitudinal ambivalence could help explain these different results. People are spontaneously motivated to make sense of inconsistencies in order to arrive at an integrated evaluation (Srull and Wyer 1989). Accordingly, exposure to inconsistencies stimulates information processing, increasing the strength and the predictive ability of the attitude (Jonas et al. 1997; Petty et al. 1995). Since manifest ambivalent people are confronted with positive and negative information, they will probably consider both in an effort to create an integrated judgment that is predictive of behavior (i.e., a strong attitude). Univalent ambivalent people are aware of only positive items and merely *anticipate* on negative information. As an outcome, judgments can be expected to be less integrated and hence less predictive of behavior. Moreover, attitudes held with high, rather than low, certainty yield greater attitude-behavior consistency (e.g. Rucker and Petty 2004, Tormala et al. 2006; Tormala and Petty, 2004a, 2004b; Tormala and Rucker 2007). The results of Study 1 and 2 show that manifest ambivalent people indicate higher attitude certainty compared to univalent ambivalent people. Hence, manifest ambivalent people can be expected to also display higher attitude-intention correspondence.

Study 3 was similar to Study 2, except for one modification. At the end of the questionnaire we assessed respondents' intention to buy the MP3-player (cf. Costarelli and Colloca 2007; Jonas et al. 1996). Study 3 replicated the results of Studies 1 and 2. Moreover, we show that attitudes are more predictive of behavioral intentions in the manifest ambivalent and univalent condition compared to the univalent ambivalent condition which is not mediated by attitude certainty.

Taken together, the findings of our three studies shed light on the difference of the underlying structure of feelings of ambivalence and how the type of attitudinal ambivalence (manifest versus univalent) influences attitude certainty (conceptualized as attitude clarity and attitude correctness) and attitude-intention consistency. These findings have important implications for both theorists as practitioners.

The Sacred and the Profane in Islamic Consumption

Aliakbar Jafari, University of Strathclyde, UK
Ahmet Suerdem, Istanbul Bilgi University, Turkey

EXTENDED ABSTRACT

The majority of existing literature on consumption in Islamic societies is based on the premises of reductionist conventional theories that make general assumptions about Islamic ideation with little attention and relevance to Moslems' daily life practices. Such conventional theories – that come from two camps outside and inside of the Moslem world – make superficial analogies between the West and Islam. The former is epitomized in Weber's (1958, 1965) trivial analysis of Islam, economy and society in which whilst protestant ethic is driven by value-based rationality, Moslems' value systems are based on militant (*jihad*) instrumental-rationality (short term self-interest and pillaging) and emotional (martyrdom) motivations. Therefore, neither capital accumulation is possible nor worldly pleasures are pursued. As a result, Moslems essentially wash their hands off the worldly blessings. Generated from within the Moslem world, the latter stream of theories also adopts a reductionist approach. Consumption in this perspective is largely analyzed within the rigid framework of *Halal* (lawful) and *Haram* (unlawful), the *Mustahabb* (favored) and *Makruh* (disliked). Such dichotomous categorizations – which legitimize some deeds and demonize others (Soroush, 2000) – prevail in the Islamic discourse as Moslem scholars barely transgress these rigid boundaries to study consumption from other possible angles (e.g., social, cultural, aesthetic). Typically, trenched in an 'ideologized Islam' (Soroush, 2000), consumption culture is viewed (see, for example, Khan 1984; Kahf 1996; Kalantari 2008; Ormanlar 1999; Razzaghi 1996) as the essence of Western capitalism (and, of course, its subsequent Modernity) which seeks to impose its value systems (socio-cultural and economic) on Islamic societies.

Both of these perspectives have encouraged narrow binary oppositions of 'Islam versus the West', 'the Occident versus the Orient', and 'Modernity versus religion'. Whilst the first stream has adopted an 'Orientalist' (Said 1978) approach to define Western Modernity in relation to an anti-Modern Islam, the second perspective has, in a self-Orientalist manner, responded to the superficial assumptions of the first camp in a superficial way. The above-mentioned Moslem scholars have failed to analyze the ever-changing conditions of contemporary life in Moslem societies and overlooked the context-dependency of consumption (Hasan 2005) and the historical trajectories that have traditionally shaped foundations of the private and public lives of Moslems (Jafari 2009). Therefore, there is a need to transgress these clichéd assumptions that are not capable of explaining Moslems' complicated and often paradoxical everyday life consumption practices in contemporary society.

On the other hand, due to the cultural turn's emphasis on identity issues, the culture of consumption in contemporary Moslem societies has been predominantly analyzed from the lens of Consumer Culture Theory (Arnould and Thompson 2005). The existing studies of consumption culture in Islamic societies have examined this subject mainly with reference to the global expansion of consumer culture and multiple discourses associated with globalization (Pink 2009; Sandikci and Ger 2002), issues of resistance or ideological/political identity formation and negotiation (Kiliçbay and Binark 2002; Jafari and Goulding 2008; Fischer 2008), and formation of modern identities in new national and international geographies (Wong 2007; Üstüner and Holt 2007; Sandikci and Ger 2010). These studies have all extended our knowledge of consumption practices within the Moslem world. For instance, they have proposed 'multiple roots to modernity' (Sandikci and Ger 2002); hence, contesting the clichéd perceptions of a hegemonic Western Modernity. They have also opposed the puritan views which portray consumption culture in Islamic societies "as a threat, harmful to religion as it privileges hedonism, pleasure, individualism and an excessive lifestyle" (Wong 2007, 451).

Whilst we acknowledge that the expansion of consumption culture in Moslem societies is associated with pervasive globalization (Kiliçbay and Binark 2002; Sandikci and Ger 2010) and that Moslems practice multiple modernities and Islams (Wong 2007), we argue, as the core of our theoretical contribution, that the popularization of material consumption in the Moslem world is largely stimulated by the embeddedness of this culture within the everyday practices of Islam. We draw on Soroush (2000) and contend that Islam is both secular and plural and it is these characteristics that pave the way for Moslems' multiple interpretations of Islam as a source of constituting their lives.

In our argument, we are not apologetic. We do not seek to defend Islam as a Modern religion juxtaposed with the West. On the contrary, we emphasize that such binary oppositions are political/ideological concepts that are often augmented by biased media in populistic ways. Therefore, we contest the portrayal of Islam as a rigid ideological system and demonstrate that in their everyday life consumption activities (the profane), Moslems constantly (re)interpret religious guidelines of Islam (the sacred) as cultural codes rather than rigid doxas. With reference to Haddorff's (2000) typology of the market-religion interactions, we discuss that in Islam's view, there is a close symbiotic relationship between the sacred and the profane to the extent that abandoning either one to the benefit of the other is reproached (Naraghi 2009/1771-1829). Transgressing the boundaries between the two, peoples' cultural understanding of Islam (Soroush 2000) plays a crucial role in constituting localized cultural forms of Islam. For instance, popular religious activities such as rituals and feasts are all socio-cultural sites where the boundaries between the sacred and profane are transgressed as cultural sense making activities. In such situations, not only are the 'sacred' and the 'profane' symbiotically present (Belk et al., 1989; Wuthnow, 1994a, 1994b, 1996; Muñiz and Schau, 2005), but also the Halal (lawful) and Haram (unlawful), the Mustahabb (favored) and Makruh (disliked), and the Islamic and un-Islamic may all be juxtaposed to shape Moslems' mundane consumption practices.

Therefore, we propose the term 'authorized selection' to denote the fact that with reference to religion, individuals authorize themselves to selectively interpret Islam and justify their own choices (lifestyles and consumption practices). Based on the premises of this paper, we humbly invite our fellow scholars to forsake the clichéd binary oppositions (e.g., the West vs. Islam) and apologetic approaches and embark on fresh investigation of very exciting and paradoxical consumption practices that prevail not only in the Moslem world but also in the population of other creeds.

I Want It Now! Query Theory Explains Discounting Anomalies for Gains and Losses

Kirstin Appelt, Columbia University, USA
David Hardisty, Columbia University, USA
Elke Weber, Columbia University, USA

EXTENDED ABSTRACT

Imagine a consumer expecting to receive $100 now, but being given the option to receive $110 in 3 months instead. Now imagine the consumer expects to receive $110 in three months, but is given the option to receive $100 now. Although in both scenarios consumers often prefer the sooner amount despite it being smaller, they tend to prefer it more strongly in the first scenario than in the second. Initial expectations influence consumer preferences such that they are more impatient when faced with a delay (when the default is to receive a smaller, sooner gain, but there is an option to receive a larger, later gain instead) than with an acceleration (when the default is to receive a larger, later gain, but there is an option to receive a smaller, sooner gain instead). This is the classic "direction effect": people discount delayed gains more than accelerated gains (Loewenstein 1988). For losses, however, this direction effect is reversed and people discount delayed losses *less* than accelerated losses (Benzion, Rapoport, and Yagil 1989; Shelley 1993).

We use Query Theory as a process account to explain the effect of direction (delay vs. acceleration) on intertemporal choice. Query Theory suggests that decision makers construct their preferences by asking internal queries about the available choice options (e.g., $100 now or $110 later; Johnson, Haubl, and Keinan 2007; Weber et al. 2007). Query Theory posits that queries are asked sequentially and that arguments for the default choice option are generated first. In other words, when presented with a delay scenario, people first query their episodic knowledge base for arguments in favor of the default (i.e., "What argues for choosing $100 now?"), before considering arguments in favor of the alternative (i.e., "What argues for choosing $110 later?"). Due to output interference, retrieval for later queries is less successful and, thus, the balance of support tends to favor the default option (Johnson et al. 2007). Weber et al. (2007) successfully used Query Theory to explain the direction effect within gains, but it has not yet been applied to discounting of losses.

The present research was designed to replicate the sign (gains vs. losses) by direction (delay vs. acceleration) interaction using a between-subjects design and to confirm and extend Query Theory to the discounting of losses.

Method

In a 2 (sign: gain vs. loss) x 2 (direction: delay vs. acceleration) between-subjects design, U.S. residents (N = 607) were randomly assigned to read one of four hypothetical decision scenarios: delayed gain, accelerated gain, delayed loss, or accelerated loss. Participants used a type-aloud protocol to record their thoughts before making their decisions (Johnson et al. 2007; Weber et al. 2007). Participants subsequently coded their own previously recorded thoughts as favoring receiving [paying] now, favoring receiving [paying] later, or favoring neither.

Results

Replicating the sign effect, participants discounted gains more than losses. Replicating the sign by direction interaction, participants discounted delayed gains *more* than accelerated gains, but delayed losses *less* than accelerated losses.

As predicted by Query Theory, across sign, thoughts favoring receiving/paying now (i.e., now thoughts) clustered earlier in the delay conditions (when now was the default) than in the acceleration conditions (when later was the default), the proportion of now thoughts was greater in the delay conditions than in the acceleration conditions, and the effect of direction (delay vs. acceleration) on the proportion of now thoughts was fully mediated by thought clustering. In other words, when the default was to receive [pay] now, thoughts favoring receiving [paying] now were clustered earlier, which led to a greater proportion of these thoughts.

As predicted, a greater prominence of now thoughts (i.e., earlier and more now thoughts) translated to *greater* discounting of gains and to *lower* discounting of losses. In fact, the prominence of now thoughts significantly mediated the relationship between direction and discounting for gains *and* for losses. As predicted by Query Theory, now thoughts were more prominent for delayed outcomes than accelerated outcomes and this led to increased discounting of gains and reduced discounting of losses.

Discussion

Using a between-subject design, our study replicated the sign effect and the sign by direction interaction effect (i.e., the direction effect for gains and the reverse direction effect for losses). More importantly, we provide a process-level causal account for the sign by direction interaction. Confirming a Query Theory process account, the overall prominence of now thoughts mediated the effect of direction on discounting for gains *and* losses.

Because our study is the first to compare the processes underlying discounting of gains and losses, our results can uniquely inform interventions to help consumers make intertemporal choices they are less likely to regret, whether it's the dieter who succumbs to the dessert tray (Metcalfe and Mischel 1999), the worker who retires with insufficient savings (Thaler and Benartzi 2004), or the community that overfishes their lake (Hendrickx, Poortinga, and van der Kooij 2001). Because the intertemporal choice literature studies mostly gain decisions, a naïve choice architect might assume that acceleration frames are a panacea to reduce discounting. Our study confirms that the story is more nuanced. For gains, impatience (i.e., the desire to have the gain now) increases discounting. To decrease the discounting of gains, we need to *decrease* impatience. For losses, however, impatience (i.e., the desire to get the loss over with now) translates to lower discounting. Therefore, to decrease discounting of losses we need to *increase* impatience. Whether with changes to how decisions are presented (e.g., with different default options or with different framings) or how options are considered (i.e., training people to consider the alternative option before the default option), giving consumers the tools to change the prominence of their impatient "act now" thoughts when faced with intertemporal decisions will arm them against making decisions they will later regret.

When Loyalty and Habit Collide

Leona Tam, Old Dominion University, USA
Liu-Thompkins Yuping, Old Dominion University, USA

EXTENDED ABSTRACT

When shoppers repeatedly buy from a business, it is often driven by two very distinct forces: loyalty and habit. The former refers to a deeply held, enduring commitment to rebuy from a business, and may encompass beliefs of product superiority, positive and accessible brand reactions, and a strong intention to continue buying from the business (Oliver 1999). As a key concept in relationship marketing, loyalty has been studied extensively in the marketing discipline. In contrast, the other driver of repeat purchase, habit, has received scant attention from marketing researchers. Most research on habit has arisen from behavioral, social, and health psychology. In these disciplines, habit is defined as a behavioral disposition in which past responses are triggered directly by associated contextual cues (Beatty and Kahle 1988). One important characteristic of habit is that contexts (e.g., time, location, etc.) function outside of awareness to cue performance of repeated responses or preference towards such responses.

Because of the parallel development of loyalty and habit research in different disciplines, few existing studies have examined loyalty and habit simultaneously, although both of these two forces can exert an influence on a shopper's repeat buying decisions. One particularly important question missing from the literature is how loyalty and habit may interact with each other. In other words, when both loyalty and habit are present, what is the combined outcome of these forces? Do the two effects add up and reinforce each other, or is the mechanism more complicated? These are the questions we would like to answer in this paper.

Specifically, we examine the interplay between loyal and habitual forces in determining shoppers' reaction to marketing actions. Although models of brand switching have long incorporated inertia into the study of brand loyalty (e.g., Jeuland 1979), it is largely a reflection of shoppers' tendency to make the same brand choice across transactions without considering the theoretical origin of such inertia. Our paper represents one of the few efforts at integrating the habit literature into loyalty research, thereby offering a theoretical ground for the diverse responses repeat shoppers may exhibit toward marketing actions. Furthermore, by examining the interaction between loyalty and habit, this paper will represent an initial step toward recognizing and understanding the complex ways in which these two forces can affect shopper behavior. This will be a valuable addition to loyalty research and will deepen our understanding of the psychology behind shoppers' repeat purchase behavior.

Considering loyalty and habit together could generate one of two possible and equally plausible effects on consumer responses. On one hand, loyalty and habit could have an additive effect, that is, positive consumer response to marketing actions such as sales promotion could be stronger when both loyalty and habit are present. This is because attitudinal loyalty and habit can lead to similar purchase behaviors, despite the different ways in which they work. For instance, both attitudinally loyal consumers and habitual consumers may repeatedly purchase a brand, and that brand may claim a high share of wallet for both groups of consumers. Furthermore, as a consumer's loyalty evolves from the early more effortful cognitive and affective stages to more behaviorally oriented conative and action stages, the consumer's purchase behavior will become increasingly driven by habitual forces that are characterized by action inertia and high resistance to change (Oliver 1999). Given these close ties between attitudinal loyalty and habit, it is reasonable to expect that the two can reinforce each other or at least complement each other's effects. Reflecting this view, the marketing science literature has often considered both idiosyncratic loyalty and inertia as additive forces in predicting consumers' brand choice (e.g., Jeuland 1979; Roy, Chintagunta, and Haldar 1996). This literature shows that including an inertia effect in a brand choice model outperforms a model that only considers long-term loyalty effects (Jeuland 1979).

On the other hand, loyalty and habit could interfere with each other, that is, the positive effect of loyalty on consumer responses could be diminished when habit is strong. Studies of the habit-goal interface suggest this possibility. These studies show that habitual behavior is triggered via contextual cues in an automatic and effortless fashion (Wood and Neal 2007). Therefore, when a situation does not encourage or allow effortful processing, habitual responses are more likely to result than more conscious and effortful goal fulfillment. This explains the loyalty-habit interference because behavior as a result of loyalty rises through a chain of cognitive, affective, and conative processes (Oliver 1999). Feeling loyal does not necessarily translate into loyal behavior, but rather it requires an effortful implementation of loyalty intention into actual behavior. As a result, it is likely to be dominated by responses from habitual forces when such efforts are not made.

We conducted three studies to explore these two possible interaction patterns between loyalty and habit. Our results showed consistent interference between loyalty and habit over a variety of consumer responses, including reaction to brand-related marketing offers, resistance to alternatives in a stock-out situation, and tendency to engage in word-of-mouth. A fourth study is currently being conducted to examine the mechanism underlying such interference.

Say "I Don't," not "I Can't":
How Verbal Frames Provide Psychological Empowerment

Vanessa Patrick, University of Houston, USA
Henrik Hagtvedt, Boston College, USA

EXTENDED ABSTRACT

In this research, we propose that the language used to communicate self-regulatory efforts serves as a feedback mechanism that signals to oneself either a sense of empowerment or a lack thereof, thus influencing goal achievement. Specifically, with five studies we demonstrate that using the word "don't" (vs. "can't") has a favorable influence on feelings of empowerment and perceived effectiveness of the refusal strategy, as well as on actual behavior.

A stream of research in the judgment and decision-making literature has focused on the influence of different types of framing that are logically equivalent (e.g., ½ vs. 50%; 3% fat versus 97% fat-free). More recently, research in linguistics and persuasion has focused on the influence of words that are not entirely equivalent but nonetheless quite similar and often used interchangeably (e.g., think vs. feel; anytime between vs. only between).

The focus of the current research falls into this latter category of verbal framing. We investigate how the decision not to veer away from one's goal may be framed in terms of a determined (don't) versus deprived (can't) refusal. We theorize that utilizing a determined (don't) versus deprived (can't) verbal framing signals the level of empowerment and control one has in achieving one's self-regulatory goal, resulting in a differential influence on the likelihood that we will engage in goal-directed behavior. Saying "I don't do X" connotes a firmly entrenched attitude rather than a temporary situation, and it emphasizes the personal will that drives the refusal. Thus, using the word "don't" serves as a self-affirmation of one's personal willpower and control in the relevant self-regulatory goal pursuit, leading to a favorable influence on feelings of empowerment, as well as on actual behavior. Saying "I can't do X" emphasizes an external cause, resulting in less feelings of empowerment and thus also hindering the self-regulatory goal pursuit in question.

In Study 1, 47 undergraduates participated in an experiment based on a dieting scenario. Participants were told that they had come up with a strategy "about how to respond when you see a food item that you want to eat, but is not good for your weight loss goal." Every time they saw a tempting food item, they would tell themselves either "*I don't eat X*" or "I *can't eat X*," depending on the experimental condition. An ANOVA with perceived effectiveness as the DV revealed the expected main effect ($M_{don't}$ = 4.91 vs. $M_{can't}$ = 3.50, $F(1, 44)$ = 8.36, $p < .01$). A similar ANOVA on perceived empowerment also revealed the expected main effect ($M_{don't}$ = 5.91 vs. $M_{can't}$ = 4.79, $F(1, 45)$ = 6.73, $p < .05$). Mediation analysis supported full mediation by the empowerment index of the influence of verbal framing on the effectiveness index.

In studies 2a and 2b, we replicate these results and also demonstrate a boundary condition: the results are reversed when an external cause for the goal pursuit is made salient. This is consistent with Deci and Ryan's (1987, 1025) characterization of autonomy and empowerment as that which is "an inner endorsement of one's actions, the sense that they emanate from oneself and are one's own." Thus, when the cause or motivation for refusal is externally driven or derived, a deprived (can't) framing, which better emphasizes and aligns with the external cause, is more effective.

In Study 2a, 179 adults first read a scenario in which they imagined that they had decided to work out at the gym on a regular basis. They were given the "don't" or "can't" framing, and those in the internal (external) condition were told to imagine that they did this for their own (a friend's) sake. A two-way ANOVA with perceived effectiveness as the DV revealed the expected framing x focus interaction ($M_{don't, internal}$ = 5.98 vs. $M_{don't, external}$ = 4.60 vs. $M_{can't, internal}$ = 4.79 vs. $M_{can't, external}$ = 5.81, $F(1, 174)$ = 16.59, $p < .001$). Further, mediation analysis supported full mediation by the empowerment index of the influence of verbal framing on the effectiveness index in the internal focus condition.

In Study 2b, 120 undergraduates read a scenario in which they imagined that they had a goal to lose weight. A two-way ANOVA with perceived effectiveness as the DV revealed a main effect of focus ($M_{internal}$ = 3.30 vs. $M_{external}$ = 4.88, $F(1, 116)$ = 20.66, $p < .001$) and the expected framing x focus interaction ($M_{don't, internal}$ = 4.09 vs. $M_{don't, external}$ = 4.08 vs. $M_{can't, internal}$ = 2.52 vs. $M_{can't, external}$ = 5.63, $F(1, 116)$ = 20.74, $p < .001$). Further, mediation analysis supported full mediation by the empowerment index of the influence of verbal framing on the effectiveness index in the internal focus condition.

Study 3 provided further support for empowerment as the process mechanism underlying the effectiveness of the "don't" strategy by using a priming task to induce an increased (vs. decreased) reliance on empowerment via the priming of autonomous (vs. controlled) motivation. A two-way ANOVA with perceived effectiveness as the DV revealed a main effect of verbal frame ($M_{don't}$ = 5.25 vs. $M_{can't}$ = 4.27, $F(1, 79)$ = 4.49, $p < .05$) and the hypothesized interaction ($M_{don't, autonomous}$ = 5.74 vs. $M_{can't, autonomous}$ = 3.76, $M_{don't, controlled}$ = 4.65 vs. $M_{can't, controlled}$ = 4.63, $F(1, 79)$ = 4.20, $p < .05$).

In Study 4, 30 working women participated in an intervention exercise in which they adopted a new strategy for healthy living and reported how the strategy was working for them every day for a 10-day period. Participants were assigned to either a "don't" or a "can't" framing condition, or a non-specific control condition. Results revealed that 8 (of 10) participants in the "don't" condition persisted the full ten days, whereas only 1 (of 10) participant in the "can't" condition and 3 (of 10) participants in the control condition did so. An ANOVA with number of days of persistence as the DV revealed the expected main effect ($M_{don't}$ = 9.20 vs. $M_{can't}$ = 2.90 vs. $M_{control}$ = 5.20, $F(2, 27)$ = 11.82, $p < .001$).

Benign Marketing Violations: How and When Humorous Marketing Hurts Brands

Caleb Warren, Bocconi University, Italy
Peter McGraw, University of Colorado, USA

EXTENDED ABSTRACT

Humor is generally enjoyed by consumers and assumed to benefit marketers (Beard 2005; Eisend 2009). Although humor is pervasive in marketing, we highlight a potential risk of pursuing humor: humor attempts risk harming brand attitudes. In accordance with the benign violation theory (BVT; McGraw and Warren 2010; Veatch 1998), we propose that humor occurs when a violation is simultaneously interpreted as benign. If a violation is necessary for humor, the presence of a violation may arouse negative affect, which can have a substantial negative effect on brand attitudes. Thus, one reason for the equivocal relationship between humor and brand attitude observed in the literature (Eisend 2009; Weinberger and Gulas 1992) may be that researchers typically do not measure the negative reactions that frequently accompany humor.

Studies 1a and 1b explored the relationship between perceived humor, negative affective reactions, and brand attitude in two samples of print advertisements. Study 1a used 60 print advertisements assembled using three searches on Google Images. Specifically, we took 20 ads identified using each of the following searches: "funny print advertisement," "offensive print advertisement," and "print advertisement." Study 1b used 36 advertisements created by asking marketing students to craft a humorous headline for a fictional online retailer. Participants rated each advertisement on perceived humor, negative affective reactions, or brand attitude. In both studies, negative affect predicted brand attitude better than perceived humor. Regression analyses revealed a strong negative effect of negative affect on brand attitude ($\beta_{Study1a}$ =-.64; $\beta_{Study1b}$ =-.53) and a positive but weaker effect of perceived humor ($\beta_{Study1a}$ =.26; $\beta_{Study1b}$ =.07).

Study 2 tested our predictions across the marketing mix. We contrasted product, distribution, pricing, and promotion tactics depicting benign violations with similar tactics not depicting violations. For example, we compared reactions to a store that institutes a pricing policy that blatantly discriminates against wealthier, monolingual English speakers (i.e., a sign reads: Orange Juice $5; Jugo de Naranja $4) with reactions to a store that charges all customers the same price (the sign reads: Orange Juice $5; Jugo de Naranja $5). Most consumers consider blatant price discrimination unfair (i.e., a violation). However, the discrimination may simultaneously seem benign both because it can be justified by an alternative norm (the monolingual English speakers can probably afford to pay the extra dollar) and because the discrimination is psychologically distant (it is geographically far away and victimizes other people). Participants rated perceived humor, negative affective reactions, and brand attitude in response to one of four marketing tactics (product, distribution, price, promotion). Consistent with the BVT, humor perceptions were greater in response to marketing tactics depicting a benign violation than those not involving a violation. However, benign violations also elicited more negative affect and led to lower brand attitudes. The observed differences were similar for the product, distribution, pricing, and promotion tactics. Regression analyses revealed a strong negative effect of negative affect on brand attitude (β =-.56). The effect of perceived humor was not significant (β =-.11).

Study 3 tested if the relationship between humor and brand attitude depends on whether the absence of humor refers to marketing tactics that do not involve violations (i.e., strictly benign tactics) or to tactics that involve violations that do not seem benign (i.e., malign violations). Although both may lack humor, strictly benign tactics should elicit little negative affect compared to malign violations. Consequently, although humorous benign violations likely hurt brand attitudes relative to purely benign tactics (see study 2), humorous marketing may help brand attitudes relative to tactics depicting malign violations.

Study 3 tested this hypothesis by adding a third condition to the aforementioned pricing stimuli. We added a malign violation condition in which the store charges poorer, monolingual Spanish speakers $5 and wealthier English speakers $4 (i.e., the sign at the store reads: Orange Juice $4; Jugo de Naranja $5). The price discrimination here cannot be justified by an alternative fairness norm so should be seen as less benign than discriminating against wealthier English speakers. As in study 2, comparing a benign pricing tactic to a benign violation revealed a negative relationship between humor and brand attitude. Conversely, comparing a malign violation to one involving a benign violation revealed a positive relationship between humor and brand attitude. The discrepant relationship between perceived humor and brand attitude can be explained by negative affective reactions. Regression analyses revealed a strong negative effect of negative affect on brand attitude (β =-.60), but no detectable effect of perceived humor (β =.03).

In study 4 we explored whether the effect of humor on brand attitude depends on the type of violation used to create humor. Different violations may be equally effective in creating humor, but elicit different emotional and behavioral reactions (Rozin et al. 1999). For example, humor created through purity violations, which tend to elicit disgust and withdrawal (Chapman et al. 2009; Lerner, Small, and Loewenstein 2004), may hurt brands more than humor created through harm violations, which tend to elicit anger and approach (Carver and Harmon-Jones 2009). Participants viewed one of three advertisements for a fictional cola: a control ad not depicting a violation, a humorous ad depicting a purity violation, or a humorous ad depicting a harm violation. Although participants found the two ads depicting a violation equally humorous, they reported lower brand attitudes and less interest in drinking cola when humor was created by depicting a purity violation rather than a harm violation.

Benign violations evoke humor. Arousing humor through marketing tactics, however, is risky because successful and unsuccessful attempts alike may elicit negative affective reactions, and these negative reactions have a powerful effect on brand attitude. Consequently, the relationship between humor and brand attitude depends on the specific benign violation used to create humor and whether this method enhances or reduces negative affective reactions. Collectively, our studies suggest that (1) marketers attempting to use humor should be careful of the strategy they use, and (2) researchers attempting to understand the consequences of humor need to measure negative affective reactions in addition to perceptions of humor.

The Role of Regulatory Fit on the Inclination to Forgive or Seek Revenge Against Sellers Following a Product Failure in the Marketplace

Rajat Roy, Curtin University, Australia
Subimal Chatterjee, SUNY Binghamton, USA

EXTENDED ABSTRACT

In recent times, several companies have found themselves facing the wrath of the marketplace following the failures of their products. For example, Toyota had to recall more than 8 million vehicles worldwide following incidences of sudden unintended acceleration and faulty brakes in their different automobile models that added to an estimated $3 billion loss for the automaker. In the aftermath of product failures, the injured party may wish to forgive the transgressor (if the latter shows repentance), or punish the transgressor (if the victim is encouraged to seek revenge). Santelli, Struthers and Eaton (2009) have found that apologies are more effective when there is a fit or match between the frame of the transgressor's message (emphasizing a gain versus minimizing a loss) and the victim's regulatory orientation (promotion versus prevention focus), relative to when there is a misfit between the two. Our research extends the Santelli et al. (2009) research in understanding how regulatory fit can affect a consumer's desire to forgive (or seek revenge) following a market transgression.

In Study 1 (the forgiveness study), we randomly assigned one hundred eighty five undergraduate students (93 females) from a university in Western Australia to one of the six cells of a 2 (regulatory focus: promotion or prevention focus) by 3 (frame: neutral, promotion-framed apology, prevention-framed apology) between subjects design. We primed promotion (prevention) focus by asking participants to write down their current hopes and aspirations (duties and obligations), and how these may have changed over time. After they had completed their essays, all participants read about a product failure scenario (their car breaks down all of a sudden, and they have missed a very important meeting), and depending upon their experimental conditions, read a promotion-framed apology, prevention-framed apology, or a neutral message from the CEO of the company that made the car. The promotion-framed message contained phrases like "I am hopeful that our relationship with our customers can move forward after this," and "I will strive to do whatever it takes to gain back your trust." The prevention-framed message contained phrases like "I feel it is my duty to repair our relationship with our customers," and "I am obligated to do whatever it takes to not lose your trust."

The two main dependent variables used for this study were "tendency to forgive" (TTF) and "future intentions" (FI). We measured TTF using two 9-point items anchored on "strongly agree" (scale value = 9) and "strongly disagree" (scale value = 1). They were (1) "After listening to the CEO, I am more inclined to forgive the company for my troubles," and (2) "After listening to the CEO, I will forgive the company for my troubles." We measured FI with four 9-point strongly agree / strongly disagree items. They were (1) "I am likely to do business with this company in future," (2) "I am likely to recommend this company to my friends," (3) "I am likely to trust this company in the future," and (4) "I am likely to be satisfied with the future car models of this company." We found that promotion-primed participants were more inclined to forgive the transgressor following a promotion-framed apology ($M = 5.78$) than a prevention-framed apology ($M = 3.82$), and prevention-primed participants were more inclined to forgive the transgressor following a prevention-framed apology ($M = 5.83$) than a promotion-framed apology ($M = 3.61$). Similarly, the promotion-primed participants were more likely to do future business with the transgressor company following a promotion-framed apology ($M = 4.98$) than a prevention-framed apology ($M = 3.14$), and prevention-primed participants were more likely to do future business with the transgressor company following a prevention-framed apology ($M = 4.69$) than a promotion-framed apology ($M = 2.48$).

In Study 2 (the revenge study), we randomly assigned one hundred eighty three undergraduate students (89 females) from a university in Western Australia to one of the six cells of a 2 (regulatory focus: promotion or prevention focus) by 3 (frame: neutral, promotion-framed revenge, prevention-framed revenge) between subjects design. Similar to Study 1, we primed promotion (prevention) focus by asking participants to write down their current hopes and aspirations (duties and obligations), following which all participants proceeded to the next part of the study, wherein they read the same car failure scenario from the first study. However, this time instead of the CEO-seeking-apology scenario, participants read that a lawyer, on television, was inviting victims to join a lawsuit against the company. Depending upon their experimental conditions, the participants read a promotion-framed revenge message, prevention-framed revenge message, or a neutral message. The promotion-framed message contained phrases like "I am sad to note that the company did not do everything possible to ensure your trust," and "join in the lawsuit and help those who have suffered by the actions of this company get what is due to them." The prevention-framed message contained phrases like "I am sad to note that the company did not do what it was obligated to do," and "join in the lawsuit so that those who have suffered do not lose what they are due by the actions of the company."

The two main dependent variables used for this study were "desire to seek revenge" (DSR) and "future intentions" (FI). We measured DSR using a two 9-point items anchored on "strongly agree" (scale value = 9) and "strongly disagree" (scale value = 1). They were (1) "I want to take revenge on the company for my troubles," and (2) "I want to punish this company." We measured FI with three 9-point strongly agree / strongly disagree items. They were (1) "I will not do business with this company in future," (2) "I will not recommend this company to my friends," and (3) "I will not trust this company in the future." We found that the prevention-primed participants were more inclined to seek revenge following a prevention-framed message ($M = 6.39$) than a promotion-framed message ($M = 4.60$), but promotion-primed participants were only directionally more inclined to seek revenge on the transgressor following a promotion-framed revenge message ($M = 5.61$) than a prevention-framed message ($M = 5.05$). Similarly, promotion-primed participants reported more negative future intentions towards the transgressor company following a promotion-framed message ($M = 8.01$) than a prevention-framed message ($M = 5.59$), whereas prevention-primed participants were more inclined to avoid the transgressor following a prevention-framed message ($M = 8.25$) than a promotion-framed message ($M = 5.91$).

Coping with Mixed Emotions: Exploring the Temporal Arousal of Positive Emotion Relative to Negative Emotion

Loraine Lau-Gesk, University of California, Irvine, USA
Thomas Kramer, University of South Carolina, USA
Sayantani Mukherjee, California State University, Long Beach, USA

EXTENDED ABSTRACT

People often rely on their past experiences as guide for their future decisions. Positive experiences are repeated, negative ones avoided. However, rarely are our memories purely positive or purely negative, but instead they are filled with both ups and downs. Rather than feeling pure happiness from a successful negotiation (Thompson, Valley, and Kramer 1995), financial windfall (Levav and Mc-Graw 2009), or visit to "the happiest place on earth" (e.g., Disneyland; Sutton 1992), people often endure mixed emotions from such experiences presumed so clearly positive. Despite their ubiquity, complex experiences comprised of both positive and negative emotions have been studied much less than their single-valenced emotion counterparts, with existing mixed emotions research mostly focused on demonstrating that positive and negative emotions may arise simultaneously or sequentially within the duration of a given experience (Otnes, Lowrey, and Shrum 1997), identifying how and when they may be triggered (Kahneman 1992) and linking them to feelings of discomfort (Priester and Petty 1993; Thompson, Zanna, and Griffin 1995).

More recent research shows that people typically react negatively to mixed emotions unless they acquire the necessary skills to cope with or overcome the discomfort associated with them. For example, those more prone to accepting duality due to their own experiences with conflict accumulated over a lifetime appear better equipped to cope with and thereby respond more favorably to mixed emotions than those with far fewer experiences with facing conflict. The elderly (vs. young), East Asians (vs. westerners) and biculturals (vs. monoculturals) represent such individuals likely associated with higher duality acceptance and thus lower feelings of discomfort with mixed emotions (Kramer, Lau-Gesk, and Chiu 2009; Williams and Aaker 2002).

Beyond examining individual differences, the literature is largely silent about moderators of the relationship between judgment and mixed emotions. Moreover, specific coping processes underlying more favorable reactions to mixed emotions have yet to be pinpointed. Thus, the present research aims to achieve three main objectives. First, it identifies properties that underlie recalled sequential mixed emotional experiences that may bolster or hinder successful coping. Specifically, we explore the temporal arousal of positive emotion relative to negative emotion, and how this property may facilitate coping processes. Varying the temporal arousal of positive, relative to negative, emotion leads us to our second objective of examining sequential patterns of mixed emotional experiences that range in valence and intensity. Most investigations of sequential mixed emotions have focused on two emotion events (i.e., one negative and one positive) and therefore two experiential patterns (negative to positive; positive to negative). In contrast, we focus on far more complex and previously unexamined mixed emotion sequences because of our focus on temporal arousal of positive, relative to negative, emotion. Third, this research pinpoints the specific coping processes involved that lead to more favorable reactions to mixed emotions that arise sequentially.

Specifically, we examine consumers' overall evaluations of mixed emotional experiences varying in temporal arousal of positive versus negative emotion. We argue that relatively close (vs. distant) temporal arousal of positive emotion relative to negative emotion provides cognitive resources necessary to cope with mixed emotions and hence lower the discomfort otherwise associated with it. This in turn leads them to evaluate mixed emotional experiences favorably.

Four studies across a variety of contexts test our main thesis that greater cognitive resources become available to construe mixed experiences in a favorable light with close (vs. distant) temporal arousal of positive emotion relative to negative emotion. In particular, we rely on far more complex sequential mixed emotional experiences than previously investigated, ones that are comprised of multiple emotional events of either valence that vary in emotion intensity levels so that temporal arousal manipulations occur in the middle of the entire experience rather than at the beginning, end or both. This allows us to isolate any effects that may arise from temporal arousal. Indeed, prior studies have used at most three sequential events that vary on valence only (e.g., good and bad events: Linville and Fischer 1991; negative, neutral, and positive events: Lau-Gesk 2005). Specifically, we examine the effect of temporal arousal of the most intense positive emotion relative to the most intense negative emotion, given their robust influence on overall evaluations (Fredrickson and Kahneman 1993).

Study 1 relies on arcade patrons who experience sequentially close (vs. distant) temporal arousal of positive emotion relative to negative emotion, while playing a videogame. Study 2 manipulates temporal arousal of positive emotion relative to negative emotion, through a movie night experience. Results of these two studies show that consumers evaluate sequential mixed emotional experiences more favorably when the temporal arousal of positive emotion is close (vs. distant) to negative emotion. The next two studies examine reappraisal likelihood as the driver of the temporal arousal effect on evaluations of mixed emotional experiences. Study 3 manipulates reappraisal likelihood by imposing cognitive load on half of the study participants and finds differences in evaluations of a mixed romantic relationship experience due to close (vs. distant) temporal arousal of positive emotion relative to negative emotion, eliminated in these conditions. As further support for our theory, we measure reappraisal likelihood in study 4 and show that cognitive load will not moderate the effect of temporal arousal of positive, relative to negative, emotion on evaluation of a mixed emotional experience in a jelly belly sampling context, for those participants high in reappraisal tendencies because of their chronic use of reappraisal as their coping strategy. A suppression coping strategy is ruled out as well (Gross and John 2003).

The Pantomime of Persuasion:
Fit Between Sales-Agent Nonverbal Communication and Influence Strategies

Bob Fennis, University of Groningen, The Netherlands
Marielle Stel, University of Tilburg, The Netherlands

EXTENDED ABSTRACT

We are all frequently approached and sometimes harassed by volunteers, fundraisers, and sales-representatives attempting to get us to say "yes" to their offer. These agents have at their disposal a wide variety of influence strategies aimed at increasing the odds of compliance. Studies have focused on what agents have to say to foster persuasion, but have largely ignored the interplay with nonverbal communication in this process (e.g., Burger 1999; McFarland, Challagalla, & Shervani 2006). Furthermore, the influence of fit (and misfit) between nonverbal communication and influence strategies on the consumers' compliance has not yet received empirical investigation. The present research aims to fill this void by examining the impact of influence strategies when embedded in nonverbal behavior that either fits or misfits the key orientation of the strategy. We propose that nonverbal communication can "boost" the persuasive impact of influence strategies to the extent that it fits the strategy's orientation, and conversely, that a misfit between nonverbal behavior and type of strategy may render it ineffective in fostering compliance.

Previous research on social influence has focused primarily on identifying and testing verbalized scripts that agents may use to induce compliance and persuasion on the part of the recipient (Cialdini & Goldstein 2004). For instance, research on personal selling has identified a host of persuasive techniques that sales representatives use to convince prospective buyers, such as information exchange, the use of recommendations, requests, promises, or ingratiation (McFarland et al., 2006). In addition, studies have focused on several well-defined influence techniques employing heuristic decision making to induce compliance. Well-known examples include the "Door-In-The-Face" technique (DITF; Cialdini et al. 1975), in which the target request is presented as a concession to an unreasonably large initial request, and the "Disrupt-Then-Reframe" technique (DTR; Davis & Knowles 1999; Fennis, Das, & Pruyn 2004, 2006; Kardes, Fennis, Hirt, Tormala, & Bullington, 2007), where an otherwise conventional sales script is interrupted by a subtle, odd element in (i.e., the "disruption", for example stating the price of an offer in pennies before stating it in dollars) followed by a persuasive phrase that concludes the script (i.e., the "reframe", e.g., "it's a bargain!").

Interestingly, Knowles and Linn (2004) have recently argued that the DITF and DTR might operate differently because they rely on different orientations. More specifically, these authors have proposed that some influence strategies may work because they increase an approach orientation, while others are effective because they mobilize an avoidance orientation. More specifically, what they term "alpha strategies" persuade people by activating approach forces, increasing people's motivation toward a goal by making the offer or request more attractive. One of the ways to activate such an approach orientation is to engage a norm of reciprocity in which granting a small favor or concession prompts recipients to reciprocate and return the favor (Knowles & Linn, 2004). As demonstrated by Cialdini et al. (1975), the DITF hinges on the principle of reciprocity (e.g., Cialdini et al., 1975; Fennis, Janssen & Vohs, 2009; Gouldner, 1960): a large request by the agent is typically declined after which the agent presents the smaller request as a clear concession, thus provoking a counter-concession on the part of the recipient (i.e., compliance).

"Omega strategies", on the other hand, attempt to persuade people by minimizing avoidance forces, reducing people's motivation to move away from a goal. One way of minimizing avoidance forces is to reduce the extent of recipient counterargumentation in response to a persuasion attempt (Knowles & Linn, 2004). As shown by Fennis et al. (2004), this process also underlies the impact of the DTR technique where the disruption interferes with the consumer's counterargumentation thus increasing the persuasive impact of the reframe.

There is reason to assume that nonverbal communication may play a role of significance in these settings —by itself and in interplay with these verbal influence strategies. For instance, a study of McGinley, LeFevre, and McGinley (1975) showed that agents with open body positions were evaluated more positively and were more persuasive than agents with closed body positions. In addition, Cesario and Higgins (2008) investigated the influence of fit between the recipient's orientation and the influence agent's nonverbal style. They distinguished between an eager and a vigilant nonverbal style. An eager nonverbal style is approach oriented and involves animated, broad opening movements, hand movements openly projected outward, forward-leaning body positions, fast body movements, and fast speech rate. A vigilant nonverbal style is avoidance oriented and involves gestures showing precision, motions that represent slowing down, backward-leaning positions, slower body movements, and slower speech (Cesario & Higgins, 2008). They showed that when recipients in a promotion focus —who perceive goals as hopes and aspirations and prefer eager, advancement strategies (Higgins, 1998)— viewed a message delivered in an eager nonverbal style, they developed more positive attitudes and also behaved more in accordance with the recommendation than when there was a misfit between nonverbal style and regulatory orientation. Likewise, when recipients in a prevention focus —who perceive goals as duties and obligations and prefer vigilant, cautious strategies (Higgins, 1998)— viewed a message delivered in a vigilant nonverbal style, they too showed more persuasion and advocacy congruent behavior. The experience of regulatory fit underlies these effects, such that a fit between the recipient's focus and the orientation indicated by the nonverbal style can augment persuasion and compliance, whereas a misfit can do the opposite and decrease persuasion and compliance (Cesario & Higgins, 2008).

Importantly, the experience of fit can arise from the interplay between message characteristics and recipient's orientation or it may reside in different features of the persuasive appeal itself (see for example Evans & Petty, 2003; Koenig, Cesario, Molden, Kosloff & Higgins, 2009). Hence, we extend previous research by examining the impact of fit and misfit within one and the same persuasive appeal and assess the effectiveness of (mis)fit of the type of verbal influence strategy and nonverbal style on consumers' behavioral compliance with a sales request.

More specifically, we argue that the impact of alpha (approach) and omega (avoidance) influence strategies will be moderated by the type of nonverbal style. We propose that the effectiveness of these influence strategies will be boosted in situations of fit and attenuated in situations of misfit with the type of nonverbal style. Hence, alpha influence strategies will receive a boost when they are delivered with an eager non-verbal style. Similarly, the impact of omega influence strategies will be increased when delivered with a vigilant nonverbal style. In contrast, the impact of alpha (omega) strategies will be reduced when delivered in a vigilant (eager) nonverbal style influence.

They Say High, I Say Low: The Effect of Power on Consumer Response to Social Influence

Mehdi Mourali, University of Calgary, Canada
Zhiyong Yang, University of Texas at Arlington, USA

EXTENDED ABSTRACT

Consumers regularly experience feelings of being both powerful and powerless. These feelings may be triggered by awareness of socioeconomic status (Henry 2005), bargaining position (Dwyer 1984), or situational contexts. For instance, facing a critical product or service failure such as a canceled flight or a botched medical procedure may induce a psychological state of feeling powerless (Gelbrich 2010), whereas being able to influence an important company decision may evoke a sense of empowerment (Fuchs et al. 2010). In this paper, we examine how consumers' sense of power affects the way they respond to conformity pressure when evaluating a new product.

Prior research (Briñol et al. 2007; Galinsky et al. 2008) suggests that powerful consumers' evaluations should be impervious to others' opinions because powerful consumers either pay no attention to these opinions, or dismiss them entirely when judging a product's attractiveness. We propose an alternative mechanism inspired by research on identity signaling (Berger and Heath 2007). Unlike previous research, which emphasizes powerful individuals' reliance on internal states versus external information, the proposed approach focuses on the social process of communicating one's power and independence to others. The signaling hypothesis suggests that high power consumers often diverge from others' opinions to communicate their independence and power to others, even if doing so contradicts their privately-held attitudes.

We tested the signaling hypothesis in two experimental studies. Study 1 consisted of a 3 (power: control vs. low vs. high) × 3 (peer feedback: control vs. positive vs. negative) between-subjects design. Participants' sense of power was manipulated using a mindset priming technique adapted from Galinsky et al. (2003). Those assigned to the high power condition were instructed to write about a time when they had power over another person, whereas those in the low power condition were instructed to write about a time when someone else had power over them. Respondents in the control group were asked to write about their day yesterday. Next, participants took part in a second, ostensibly unrelated, task, in which they evaluated the attractiveness of a new product. After reading the product description, participants were presented with a feedback sheet and were asked to rate how much they liked the product and how useful they found it (1 = not at all; 11 = extremely). The feedback sheet contained 36 lines, such that many participants could provide their ratings on the same page. In the peer influence conditions, the feedback sheet already contained evaluations from 10 other participants, who apparently (from a respondent's view) completed the product evaluation at an earlier time. One group was given an evaluation sheet containing 10 positive feedbacks, with an average attractiveness rating of 9.9/11. Another group received a sheet containing 10 negative feedbacks, with an average attractiveness rating of 2.15/11. A control group received a blank feedback sheet.

The results indicate that, in the absence of any peer influence (i.e., baseline condition), powerful consumers' attitudes did not differ from the attitudes of those in the low power and control groups. However, in the presence of peer influence, powerless consumers tended to conform to the expressed opinions of others whereas powerful consumers deliberately sought to deviate from the opinion expressed by the majority. Their concern with signaling independence was such that their evaluations diverged even from their own privately-held attitudes, as measured in the baseline condition.

Study 1 provides clear evidence that high power can lead to anti-conformity, as predicted by the signaling hypothesis. Nevertheless, the psychological mechanism underlying the observed effects remains unclear. We do not know whether powerful consumers diverge from others' opinions because they want to signal their power and individuality or because high power simply increases consumers' need to differentiate from other people. Study 2 was conducted to test the psychological process. It featured a 2 (power: high vs. low) × 3 (feedback: negative vs. positive vs. none) × 3 (opportunity to express uniqueness: signal vs. express but not signal vs. control) between-subjects design. In line with the signaling hypothesis, we found that providing powerful consumers with an opportunity to signal their individuality prior to the focal task helps fulfill their signaling goal and results in greater conformity during the later evaluation task. However, providing powerful consumers with an opportunity to express uniqueness but not to signal it does not reduce their tendency to express counter normative attitudes.

Seeing Things in a Different Light: Agent vs. Consumer Responses to Persuasion Attempts

Wenxia Guo, University of Manitoba, Canada
Kelley Main, University of Manitoba, Canada

EXTENDED ABSTRACT

Since the Persuasion Knowledge Model (PKM; Friedtad and Wright 1994) was first introduced, numerous investigations have explored how consumers see an agent's behavior in a different light based on their persuasion knowledge (see for e.g. Campbell and Kirmani 2000). However, there is another set of circumstances in which persuasion attempts might be seen in a different light, when the target of a persuasion attempt has experience as both consumer and agent.

The PKM allows for the situation where individuals have the dual role of agent and consumer (Friestad and Wright 1994), however to date no literature has examined this question. The focus instead has been on consumer reactions (e.g. Sharma and Levy 1995). Utilizing theories of role conflict and salience in addition to the literature on processing motivations, we propose that for dual role consumers, the salience of their role as an agent will lead them to respond to persuasion attempts based more on accuracy motivated processing (Vonk 1999). In contrast, a consumer with no experience as sales agent will respond to a persuasion attempt in line with defense motivated processing (Fisher 1993). These different processing motivations influence whether or not consumers and agents will respond to different cues in the persuasion attempt. We are particularly interested in those cues that are related to ulterior motives: accessibility and acknowledgement.

Ulterior Motive Accessibility

The nature of sales with performance-contingent rewards (Mallin and Pullins 2009) leads to an enduring perception that ulterior motives are guiding the behavior of sales agents. Research has revealed that the accessibility of ulterior motives has a significant impact on consumer responses to persuasion attempts (Campbell and Kirmani 2000). We expect that the accessibility of ulterior motives will moderate agent and consumer responses to the persuasion attempt. In particular, for agents, their accuracy motivation will allow for an adjustment of their perceptions of the other sales agent in the face of information suggesting they are more or less likely to be influenced by ulterior motives. In contrast, consumers who are more likely to process information according to defense motivations will be insensitive to information relating to ulterior motives.

Study 1

This was a 2 (ulterior motive accessibility: high vs. low) × 2 (role: consumer vs. agent) between-subjects design (N=86). Consumer role was a measured variable wherein participants identified whether they had previous working experience in sales. All participants were asked to imagine an interaction with a salesperson where they were going to buy a pair of sunglasses. Half of the participants were told that the store eliminated the commission based reward policies (low ulterior motive accessibility) and the other half were told that the store used commission based reward policies (high ulterior motive accessibility). The persuasion attempt consisted of the salesperson flattering consumers on the sunglasses that they were trying on: "that's a great pair of sunglasses. I think they look good on you".

As expected, results indicated that that agents had significantly higher trustworthiness toward the other salesperson with low as compared to high ulterior motive accessibility $(F(1,82) = 16.21, p < 0.001)$. In contrast, consumers' trustworthiness toward the salesperson were not influenced by the accessibility of the ulterior motives $(F(1,82)=0.13, p=0.53)$.

Ulterior Motive Acknowledgement

Wood and Eagly (1981) found that participants were more likely to trust those individuals who offered information against their own self-interest. Accordingly, we argue that when a sales agent offers information that argues against his/her self-interest during the persuasion attempt or acknowledges the presence of ulterior motives, consumers will be less defensive. This tactic has been referred to as "stealing thunder" and was first studied in the context of trial experts' assertions (Williams et al. 1993). In the current context, the acknowledgement of possible ulterior motives through the use of the stealing thunder tactic should serve to lessen consumer's defensive reactions to persuasion attempts. However, this tactic is unlikely to have an effect for accuracy motivated agents as they tend to evaluate overall information.

Study 2

This was a 2 (ulterior motive acknowledgement: no vs. yes) × 2 (role: consumer vs. agent) between-subjects design (N=72). As in Study 1, participants self-identified whether they had prior sales experience. The ulterior motive acknowledgement manipulation occurred during the persuasion attempt. The no acknowledgement of ulterior motive condition involved the persuasion attempt from the sales agent making the same flattering statement as in Study 1. Those in ulterior motive acknowledged condition were told "You may think that I am just trying to make a sale, but that's a great pair of sunglasses…"

In line with propositions, results showed that for consumers, acknowledging ulterior motives led to higher trustworthiness than not acknowledging ulterior motives $(F(1,68)=4.34, p<0.05)$. However, agent trustworthiness were not influenced by ulterior motive acknowledgement $(F(1,68)=1.89, p>0.1)$. Further, results of a similar study conducted with salesclerks at their place of employment (M = 6.5 years of experience) further confirmed accuracy motivated processing of the acknowledgement of ulterior motives.

Study 3

In the final study, we manipulate accuracy motivations to demonstrate how this may change consumer vs. agent responses. This was a 2 (ulterior motive acknowledgement: yes vs. no) × 2 (role: consumer vs. agent) × 2 (motivation priming: accuracy vs. control) between-subjects design (N=139). All manipulations were the same as in Study 2 with the addition of the accuracy motivation manipulation. Results demonstrated that priming consumer participants with accuracy motivation attenuated the effect of ulterior motive acknowledgement $(F(1,65)=1.03, p=0.3)$. However, priming agent participants' with accuracy motivation, trustworthiness did not change $(F(1,65)=0.53, p=0.47)$.

General Discussion

Through manipulating the accessibility and acknowledgement of ulterior motives, this research demonstrates that when responding to persuasion attempts from salespeople, a single role consumer tends to be defense motivated, whereas an individual with dual roles as both a consumer and an agent is accuracy motivated. The present study contributes to the literature by: (1) comparing different

responses of single vs. dual role consumers thereby extending PKM, (2) introducing role salience as the reason for these differing responses, and (3) demonstrating the impact of different persuasion tactics (i.e. stealing thunder).

Buying the Girlfriend Experience:
An Exploration of Men's Experiences with Escort Workers

Aimee Huff, University of Western Ontario, Canada

EXTENDED ABSTRACT

Cuddling and talking – we shared interests, but most importantly, she made me feel like there was no other place she would rather be in that moment in time. (Lub, Montreal)

The informant who posted this comment is not referring to his wife or girlfriend, but to an encounter with a female sex worker – an escort – with whom he shared a particular type of commercial sex encounter known as the girlfriend experience (GFE). As the focus of this paper, the GFE differs from other types of commercial sex encounters in that it involves more than the exchange of money for sex; in order to derive the true value of the GFE, the male customer must not only pay the sex worker, but must also provide her with sexual pleasure and emotional intimacy. The result is that the encounter feels, to him, more like a romantic encounter with a girlfriend than straight-up sex. For an hour or two, or perhaps an entire evening, the customer indulges in his fantasies of a romantic encounter with a legitimate girlfriend and seeks to be perceived as a nice guy by the escort. This context provides the basis for an examination of the ways in which consumers engage in a form of consumption that has been largely overlooked by consumer researchers, and how consumers experience the blurring of boundaries between purely transactional service encounters and those that entail a deeper connection between provider and consumer. In addition to shedding light on this consumption context in the form of description, I seek to illuminate some aspects of GFE consumption that are theoretically interesting (beyond the context itself) to consumer researchers.

The purpose of this paper is to explore the experiences of male customers of escorts who provide GFE. In doing so, I offer a deeper understanding of the consumption of covert pleasure, consumer fantasies, and the ways in which consumers co-create value in the consumption experience. While different forms of prostitution exist, I am explicitly concerned with indoor prostitution, which encompasses call-girls, escort services, and massage parlor workers. The motivation for this focus is two-fold. First, there is substantially less research on indoor prostitution, in comparison with street prostitution. Second, and more important for this consumer research, "indoor [commercial sex] interactions are typically longer, multifaceted, and more reciprocal" than interactions between street prostitutes and their customers (Weitzer 2009, 220). Therefore, the experiences of male customers of indoor prostitutes are more likely to be characteristic of a romantic, intimate encounter with a partner (Malarek 2009; Sanders 2008), and therefore be of greater curiosity to consumer researchers interested in the blurring of boundaries between commercial transactions and social relationships. Further, I take a rather narrow perspective on sex work. I am explicitly concerned with consumption of prostitution services in a context where use of such services is legal, and I choose to focus on a context where sex workers are more likely to be employed of their own free will (Weitzer 2009).

Using a combination of netnography and depth interviews, I seek to understand how customers (i.e., johns) experience and reflect on GFE. Findings are organized around three central consumption themes: covert pleasure, co-creation of value, and consumer fantasies.

GFE is defined by covert pleasure – a combination of emotional and physical intimacy in a context where consumption is socially contentious and often kept secret. The emotional intimacy compo-

nent is essential to the GFE, and is closely intertwined with the requisite physical intimacy. These two hedonic and highly emotional aspects comprise the pleasure in GFE (Holbrook and Hirschman 1982), and this pleasure is of a covert nature (Frank 2002; Malarek 2009): johns are highly concerned with keeping their dirty little secrets from family and friends, in part due to the socially contentious nature of prostitution usage, and in part due to the physical risks associated with their hobby. The pleasure of GFE is a flow experience, wherein the john's total immersion in the high-risk context provides a cathartic and highly satisfying end state, which he seeks to experience again (Celsi, Rose, and Leigh 1993).

This context also provides an interesting perspective on value co-creation. Deriving value – in the form of pleasure – from the GFE requires the john to give more than money. He is compelled to give a short-term commitment of emotional and physical intimacy, and he becomes accountable for his own level of pleasure in the consumption experience. That is, he derives pleasure from ensuring that the escort has a pleasurable experience, and from adequately performing his role in the GFE such that he can form a temporary emotional connection with her. The escort and the john have roles that require and enable them to create value together (Payne, Storbacka, and Frow 2008), and the john becomes essential as a co-producer of the service (Vargo and Lusch 2004).

Immersion in the fantasy of the girlfriend is critical to the GFE. As he works to perform and co-create value from the experience, the john engages in a temporary escape from reality wherein the norms of everyday life are suspended (Goulding et al. 2009). The fantasy revolves around a romanticized notion of what a girlfriend is, not the reality (Belk and Costa 1998). The more adept the john becomes at immersing himself in the fantasy and performing his role in the GFE, the more value he derives from the experience and the better he performs in subsequent GFEs (Holbrook et al. 1984).

In this study, I seek to establish some preliminary connections between a rather novel research context and three existing streams of consumer research. These connections provide the basis for further developments in our understanding of experiential consumption, the ways that consumers engage in play and fantasy to derive pleasure, how consumers manage and experience consumption in a secretive context, and the ways that consumers can play an active role in value co-creation.

The Effect of Nostalgic Consumption on the Activation of the Interdependent Self and Prosocial Behavior

Jia (Elke) Liu, University of Groningen, The Netherlands
Dirk Smeesters, Erasmus University Rotterdam, The Netherlands

EXTENDED ABSTRACT

Coke and Pepsi have recently introduced "throwback" versions of their soft drinks. The packages and advertising are expected to increase people's preferences for the product in times of anxiety and loneliness (Loveland, Smeesters, and Mandel 2010), because the warm feelings associated with the past generate positive affect and foster social connectedness (Wildschut et al. 2006; Wildschut et al. 2010). This sentimental longing for a period of the past is called nostalgia. Despite its ubiquity, little is known about whether nostalgia can affect overt interpersonal behavior and the process by which that might happen. In the present paper, we want to further advance knowledge about nostalgia in various ways. Specifically, we examine whether nostalgia affects people's view and construal of the self, and the interpersonal behavioral consequences of this shift in self-construal. We test our idea in the context of consumption cues. Whereas past research often activated nostalgia by explicitly asking participants to reflect on a nostalgic event, we want to examine whether emotions of nostalgia can also be triggered by seemingly neutral consumption experiences (i.e., watching a video clip, eating a cookie).

Although negative emotions might be part of nostalgic recollections (e.g., disappointments, losses), nostalgia is a predominantly positive emotion (Wildschut et al. 2006), which involves a strong social component. Most nostalgic recollections contain memories of interactions with close others, such as family members, friends, and partners (Wildschut et al. 2006). The social component of nostalgia is also reflected in the connection between loneliness and feelings of nostalgia (Zhou et al. 2008), because nostalgia can be a source of social connectedness and increase people's perceived interpersonal competence (Wildschut et al. 2010). These findings suggest that nostalgia highlights the association between the self and close others. However, the question remains whether nostalgia also affects one's self-view in relation to others in general.

One of the defining elements in the perception and construal of the self is the interconnectedness with other people. An interdependent self-construal defines the self in relation to others, whereas an independent self-construal perceives the self as a bounded and independent entity with unique personal traits (Markus and Kitayama 1991). Interdependent self-construal reflects the self as socially embedded and emphasizes the connectedness to others. This seems to be consistent with nostalgic themes. Indeed, although people can differ in their chronic inclinations towards interdependent versus independent self-construals, both types of self-construal can coexist within the individual and may be activated in different contexts (Brewer and Gardner, 1996; Gardner, Gabriel, & Lee 1999). Interdependent self-construal is associated with a stronger preference for closeness with others, emotionally, psychologically, and physically (Aron, Aron, and Smollan 1992; Holland et al. 2004). This increased preference for closeness to others is not only limited to significant others, but also to unknown others. This preference for interpersonal closeness is further translated into an other-focused and prosocial orientation. Indeed, interdependent self-construal increases people's inclination to engage in volunteering and probability to donate to charity (Ashton-James et al. 2007).

In three studies, we examined whether a nostalgic experience activates an interdependent self and affects interpersonal behavior. Whereas in past studies nostalgia was activated by either a nega-tive experience (e.g., loneliness) or explicitly asking participants to reflect on a nostalgic event, in the present studies we tested whether seemingly neutral consumption cues related to the past can also activate nostalgia. Specifically, we asked participants to watch a video clip or consume a product that reminds them of the past.

In experiment 1, we asked participants to fill out the Twenty-Statement Test (Kuhn and McPartland, 1954) to assess their self-construal (Gardner et al. 1999; Mandel 2003), after they watched a video clip either from a nostalgic television show or from a non-nostalgic television show. The results indicated that participants who watched a nostalgic video (M = 6.35, SD = 2.34) reported more interdependent self-construals compared to participants who watched a non-nostalgic video (M = 3.80, SD = 2.07, F(1, 38) = 13.71, p < .01). These results provide initial support for the hypothesis that nostalgia increases the interdependence of people's self–construals.

Experiment 2 replicated and corroborated the findings of experiment 1 using a behavioral measure (physical proximity to others) and a different nostalgic manipulation. Specifically, we found that after consuming a nostalgic cookie (M = 1.54, SD = 1.02) (vs. a non-nostalgic cookie, M = 2.19, SD = 1.03, F(1, 59) = 6.77, p < .05), participants sat closer to an unknown person.

The last experiment showed that consumption of nostalgic cookies (vs. consumption of non-nostalgic cookies) rendered participants more helpful. Participants in the nostalgic condition were more likely to help an unknown other to pick up pens from the floor (71%) compared with those in the non-nostalgic condition (37%, χ^2(1, N = 48) = 5.15, p < .05). This effect is mediated by an enhanced interdependent self-construal.

Our findings extend research on nostalgia and nostalgic consumption in several ways. First of all, our studies showed that a nostalgic experience can alter how the self is defined and construed. That is, nostalgia promotes an interdependent self-construal. This construal may have potential implications for cognitive, motivation, and other behavioral correlates. Second, our findings indicate that nostalgia not only makes people feel close to significant others, but also fosters a general preference for interpersonal closeness, even to unknown others. Third, whereas past research activated nostalgic feelings by manipulating negative experiences or explicitly asking people to recall a nostalgic experience (Wildschut et al. 2006, 2010; Zhou et al. 2008), we successfully manipulated nostalgic feelings by presenting participants with ordinary consumption cues related to the past (a video in Experiment 1 and a cookie in Experiments 2-3), things that people encounter frequently in daily life. This seems to suggest that any experience or object that reminds people of the past can induce nostalgia.

On Simple Names and Complex Diseases:
Processing Fluency, not Representativeness, Influences Evaluation of Medications

Simone Dohle, ETH Zurich, Switzerland
Michael Siegrist, ETH Zurich, Switzerland

EXTENDED ABSTRACT

Today's patients play an active role in decisions about which medications to take. This fact is also reflected in the growing market of over-the-counter (OTC) drugs that are available to consumers without a prescription from a health care professional. Since OTC drugs are sold in pharmacies, groceries, or convenience stores, the assumption can be made that recommendations from physicians and other health professionals are one, but not the sole, determinant of a patient's choice of OTC drug purchases. Compared to prescription medications, the decision to buy OTC drugs will also be influenced by factors such as advertisement, recommendations from family and friends, habits, appearance, and the name of a product. In addition, the possibility exists that consumers might apply heuristics, or rules of thumb, when evaluating and choosing health products and medications.

One important heuristic that could play a major role in the evaluation of medications is the representativeness heuristic (Gilovich, Griffin, and Kahneman 2002). Representativeness predicts that consumer evaluations should be more positive for a medication with a complex name, because people believe that complex names more strongly resemble the cause of a disease than do simple names. In contrast, fluency theory suggests that complex names imply hazardousness and thus will negatively influence consumer evaluations (Reber, Schwarz, and Winkielman 2004; Schwarz 2004; Schwarz and Song 2008). Two experiments were conducted to test these conflicting predictions that can be derived from representativeness heuristic and fluency theory.

In experiment 1, participants ($N = 22$) judged ten fictitious medications: five had an easy-to-pronounce name, five had a difficult-to-pronounce name. The medications were presented in two different random orders. Judgments about the medications were made about hazardousness, effectiveness, side effects, and willingness to buy. The easy-to-pronounce medications were perceived as safer than those with the difficult-to-pronounce names. Participants also expected that medications with an easy name had fewer side effects compared with medications with a difficult name. As well, willingness to buy was higher for medications with easy-to-pronounce names than for medications with hard-to-pronounce names. Furthermore, mediation analysis showed that hazardousness fully mediated the relationship between ease of pronunciation and willingness to buy. However, we found no effect of name on the medication's perceived effectiveness; easy-to-pronounce names were perceived as similar in effectiveness to difficult-to-pronounce names. Taken together, experiment 1 revealed a clear support for the fluency hypothesis. We cannot rule out, however, that participants assumed that all of the presented medications were used for the treatment of a rather simple illness. According to this, only simple, easy-to-pronounce names would be representative of the illness, and representativeness could still account for the effect. Thus, a limitation of the first study is that we did not control for the complexity of the disease.

Experiment 2 employed a 2 (simple vs. complex name) $\times$ 2 (simple vs. complex illness) within-subject design. In the first part of the experiment, participants ($N = 28$) were asked to imagine that they were suffering from headaches and that different medications could be considered to treat the headache. Subsequently, respondents judged four medication names on the same dependent variables as used in experiment 1 (hazardousness, effectiveness, side effects, and willingness to buy). Two medication names had an easy-to-pronounce name; two had a difficult-to-pronounce name. In the second part, participants were asked to imagine that they were diagnosed with pancreatic cancer and that different medications could be considered to treat the cancer. Then, two easy- and two difficult-to-pronounce names were presented and participants judged the medication names on the four dependent variables. We controlled for presentation order effects. We also employed a yoked design; the order of the medication names was rotated such that for every medication name encountered by a participant in the simple-illness condition, there was a participant who had encountered the same medication name in the complex-illness condition. Again, experiment 2 provided clear support for the fluency hypothesis: Participants were more inclined to buy medications with simple, easy-to-pronounce names because they perceived these medications to be less harmful. The effect of simple vs. complex names was not qualified by type of illness, which would be expected according to the representativeness heuristic.

Our results have important implications for both health promotion and brand naming. From our research, it can be assumed that consumers believe that a medication with a complex name is more harmful and will lead to more side effects, and thus, they will be less likely to buy the product. This is of particular importance given the evident worldwide trend towards making more drugs available for self-medication. Thus, decisions at the point of purchase of OTC drugs may be influenced by factors other than recommendations from health professionals, and our results suggest that the name of the medication may be an important driver of a consumer's purchasing decisions. This effect might be particularly strong for product innovations, because these products are less likely to be influenced by habits. However, the complexity of a drug's name is not typically part of pharmaceutical brand management strategies (Robins 2006; Schuiling and Moss 2004). Managers should be aware of the fact that a drug's name may raise specific expectations. A medication with side effects and a high potential for misuse should not be branded with a simple name because this may further bolster consumers in their belief that the drug is innocuous. On the other hand, if a consistent and accurate intake of medications is important for therapeutic success, a simple medication name may support compliance with the treatment regimen.

Our research suggests that a medication name is powerful driver of consumers' evaluations and preferences. Whether it is a rather harmless headache or a life threatening disease, a complex drug name raises different expectations compared to a simple drug name. Consideration of these effects is important for assisting patients in the best possible way and for preventing wrong expectations. This, of course, also implies a huge responsibility for all brand managers and health professionals.

EXTENDED ABSTRACT

In this paper we examine how consumers' choices are affected by the interplay between their level of arousal and the valence of their current affective state We are particularly interested in the extent to which the arousal dimension of a consumer's mood affects the choices that s/he will make. We predict that such preferences will be consistent with theories of mood regulation (Larsen 2000; Salovey, Hsee, & Mayer 2001; Thayer, Newman and McClain 1994) – that is, the choices that consumers make will reflect a desire to maintain positive moods and mitigate negative moods. Extending the current literature, we propose that in addition to regulating the valence of their moods – i.e., the extent to which their affective state is positive or negative – consumers will also make choices that allow them to manage their level of arousal. We define arousal as the *subjective experience* of energy mobilization, which can be conceptualized as an affective dimension ranging from sleepy to frantic excitement (Mehrabian and Russell 1974). This is in contrast to objective or physiological arousal, which is defined as the release of energy collected in the tissues (Duffy 1962; Cacioppo, Bernston and Crites 1996) and has been measured using pulse rate (Pham 1996) and systolic blood pressure (Sanbonmatsu and Kardes 1988).

We predict that consumers in a positive mood will tend to prefer products that are *congruent* with both the level of arousal and the valence of their current affective state. For example, people who are feeling relaxed (i.e., a pleasant low-arousal mood) will tend to choose relaxing products and experiences (e.g., lying on the beach or drinking tea); while those who are feeling excited (i.e., a pleasant high-arousal mood) will tend to choose exciting products and experiences (e.g., going surfing or consuming an energy drink). In contrast, we predict that consumers in a negative mood will tend to prefer products that are *incongruent* with both the level of arousal and the valence of their current affective state. For example, people who are depressed (i.e., an unpleasant low-arousal mood) will tend to choose exciting products and experiences (e.g., going surfing or consuming an energy drink); while those who are feeling frustrated (i.e., an unpleasant high-arousal mood) will tend to choose relaxing products and experiences (lying on the beach or drinking tea).

Similar to previous research (Pham 1998; Pham, Cohen, Pracejus & Hughes 2001; Schwarz and Clore 1988), we propose that consumers use the affect they are experiencing as information about their likes and dislikes. However, we propose that it is not only a consumer's current mood that provides preference information; but that affect produced in response to evaluating the congruency between one's current mood and the products or experiences being considered for consumption also influences consumer preferences. For example, imagine a relaxed consumer standing in front of a convenience store cooler, making the decision to purchase either an ice tea or an energy drink. We predict that while considering these two products, she will experience positive affect toward the ice tea (i.e., a product associated with relaxation), which is congruent with her current state of relaxation, but negative affect toward the energy drink (i.e., a product associated with excitement) that is incongruent with her current mood. We contend that it is this product specific affect (PSA) that will inform preferences rather than the consumer's general mood state. More formally, we propose a moderated mediation model (see figure 2 in the paper); which predicts that the interactive effect of arousal and valence on consumer choice is mediated by PSA.

Overall, this paper contributes to the extant literature by demonstrating that consumers make choices that are driven by a desire to regulate *both* the arousal and the valence of their affective states. Moreover, we detail the psychological mechanism through which the interaction of these two dimensions of mood affect consumer choice. In doing so, this research reveals a systematic link between variations in consumers' moods and preferences that can account for dramatic differences in choice shares.

In this paper, we find that consumers' preferences for products and experiences vary with both the level of arousal and the valence of their current mood in a manner that is consistent with mood regulation (Larsen 2000; Salovey, Hsee, & Mayer 2001; Thayer, Newman and McClain 1994). Although prior research has documented similar effects with valence alone, our results demonstrate that arousal also plays a critical role. In addition, as predicted, the choices that consumers make are driven by the product-specific affect they experience, which varies systematically as a function of both the valence *and* arousal dimensions of their current mood. The four experiments reported in this paper provide strong evidence in support of the moderated mediation model of the effect of mood on consumer choice.

The first study used color to manipulate the level of arousal consumers were feeling and examined the impact of arousal on consumer choice when mood valence was positive. The results revealed that consumers made decisions that were congruent with their level of arousal. The second study replicated these findings with a different choice set, and extended the results of the first study by illustrating that PSA mediates the relationship between arousal and consumer choice. To test the full moderated mediation model (figure 2), studies 3a and 3b used scent and sound to manipulate both arousal and valence. These two studies found strong support for the model – that is, the effect of the interaction between level of arousal and mood valence on consumer choice was mediated by PSA.

Salting the Sidewalk In Case the Snowstorm Hits:
Consumption as a Buffer against the Potential for Threat

Soo Kim, Kellogg School of Management, USA
Derek Rucker, Northwestern University, USA

EXTENDED ABSTRACT

Consumers are known to engage in compensatory consumption—the act of purchasing or physically consuming goods to address a threat to the self (Rucker and Galinsky forthcoming). However, we, as consumers, do not seem to react solely to the negativity of the threat after it has been experienced. We are proactive and take actions to mitigate the possibility of potential threat. Based on this idea, the present work focuses on the idea of consumption in response to anticipated threat and its implications for understanding how consumers respond to various forms of threat.

Building on past research that suggests the possibility that people can buffer the self prior to receiving a threat through self-affirmations (e.g., Dalton 2008; Steele, Spencer, and Lynch 1993), we propose that consumers use consumption to buffer themselves against anticipated threat. More importantly, although anticipated and experienced threat can produce compensatory consumption, we propose that anticipated threat and experienced threat are psychologically distinct constructs with differential consequences.

Building on Mandel and Smeesters' (2008) account that threatened consumers increase general consumption because it provides them with the opportunity to be distracted from their self-awareness, we propose that, when consuming products in the heat of threat, consumers will be more likely to increase their overall consumption of both threat-related and threat-unrelated products. However, when consumers are consuming in response to the anticipation of threat the need to distract themselves from the threat may not be as strong as when they are in the heat of threat, as there is no actual experience of threat present. For these consumers, the best consumption strategy may be to consume only products that are presumed to provide protection specifically against the anticipated threat.

To test our hypotheses, we present a pretest and two experiments designed to test whether anticipated threat leads consumers to consume in a manner that will buffer themselves against potential threat and to examine how consumption in response to anticipated threat differs from consumption in response to experienced threat.

Pretest

A pretest was conducted to distinguish anticipated threat from experienced threat. Participants in both the anticipated threat condition and the control condition were asked to first read a brief introduction to a test of their "Perceptual Intelligence" and then were asked on the next screen to indicate either how they currently felt (current feeling of threat) or how scoring low on the test would make them feel (anticipated feeling of threat) on a 7-point scale ranging from "Not Threatened" to "Threatened." Participants in an experienced threat condition reported how much threat they experienced after receiving a bad result from the "Perceptual Intelligence" test. As predicted, the results indicated that consumers do not experience actual threat when they are merely introduced to a potentially threatening test of intelligence. However, consumers seemed to anticipate the potential of threat from the possibility of receiving a disappointing result.

Experiment 1

Experiment 1 tested whether consumers use threat-specific products to buffer themselves against a potential threat to their intelligence, despite no experienced threat.

Participants in the anticipated threat condition were first introduced to a "Virtual Perception Game" that was supposedly designed to assess their "Perceptual Intelligence." However, before they actually played the game or received results they were asked to complete a second, unrelated experiment while the computer program loaded the "Virtual Perception Game." In this "second" experiment, participants' task was to evaluate the cover of a recent music album and they were asked to indicate how long they would like to listen to the music before evaluating the album cover. Participants were randomly presented either threat-related music (i.e., "Music and the Mind") or threat-unrelated music ("Music and Relaxation") and asked how long they would like to listen to it in minutes. Participants in the experienced threat condition, on the other hand, first completed the "Virtual Perception Game" and received disappointing feedback designed to elicit threat. Then they moved on to the "second" study, in which they either indicated how long they would like to listen to the threat-related music or the threat-unrelated music.

As predicted, our findings from the current study and the pretest show that consumers strategically use products to buffer themselves from anticipated threat. Furthermore, we demonstrate that when consumers are engaging in hypothetical consumption (i.e., desired listening time), they strategically value threat-related products more than threat-unrelated products both when actually experiencing threat or merely in the anticipation of threat.

Experiment 2

Experiment 2 investigated how consumers' consumption in response to anticipated threat and experienced threat differ. As noted, for anticipated threat, consumers should only show greater consumption of products that may buffer them specifically against the anticipated threat. However, we predicted that when experiencing actual threat, given an opportunity to distract themselves through actual consumption, consumers would increase consumption more generally as a means to distract themselves.

The overall procedure was similar to Experiment 1. However, unlike Experiment 1 we measured how long participants actually listened to an unfamiliar piece of music that was framed as either threat-related (i.e., enhancing cognitive abilities) or threat-unrelated (i.e., relaxing).

As predicted, we found that when provided with the opportunity to actually consume the product (e.g., actually listen to music), consumers consuming in response to anticipated threat only consumed more (i.e., listened to the music longer) when the product was framed as threat-related, whereas consumers experiencing threat consumed both threat-related and threat-unrelated products more.

Our findings indicate that consumers consume products not only to cope with the experience of threat but that they also strategically consume threat-specific products to protect themselves against anticipated threat. In addition, we find that anticipated threat consumption and experienced threat consumption differ in an important aspect: When consumers consume in response to anticipated threat they only increase consumption of threat-related products, as a buffering strategy. However, once they experience threat they consume both threat-related and threat-unrelated products. It seems that we, as consumers, not only salt the sidewalk in anticipation of the snowstorm but also know exactly what kind of salt to use, at least until the snowstorm hits.

Increasing Attention at What Cost?
Consumer Reactions to Context Sensitive Advertising

Claudiu Dimofte, San Diego State University, USA
Ronald Goodstein, Georgetown University, USA
Ajay Kalra, Rice University, USA

EXTENDED ABSTRACT

This research investigates consumers' reactions to "context sensitive advertising," a strategy used by advertisers across multiple channels to increase consumer attention and improve consumer attitudes. Although advertisers believe in the efficacy of context sensitive ads, there is little empirical evidence to support their beliefs. Furthermore, the academic literature is ambivalent about the role of ad-context congruity on memory and persuasion. We propose and support that while context sensitive advertising may indeed enhance consumers' ad processing, it may do so at the risk of eliciting negative attitudinal reactions. Specifically, we establish a positive main effect of context sensitivity on attention and recall. Attitudes and persuasion, however, are dependent upon how well the context matches the product being advertised. Two competing theoretical accounts for these reactions are tested and the effects are shown to be due to consumers' superior motivation to process context sensitive advertisements as opposed to an ease of processing rationale.

Enhancing consumers' levels of ad processing is vital for companies that aim to make enduring impressions on their target customers. To do so, firms often employ tactics that encourage consumers to process a stimulus in greater detail than they might otherwise. These tactics commonly fall under the rubric of "attention-getting devices" (e.g., Broniarczyk and Gershoff 2003; Gardner 1983). One such tactic that consumers are seeing more often in advertising settings is a practice referred to as "contextual advertising" (e.g., Ciaramita, Murdock, and Plachouras 2008) or "context-sensitive advertising" (e.g., Hristova and O'Hare 2001; hereafter CSA). In general, CSA refers to the practice of placing ads within a contextual environment in which the text and images (i.e., theme) of both tend to be mutually relevant (e.g., Ciaramita et al. 2008). For instance, since 1989 Anheuser Busch has used its "Bud Bowl" series of ads during the NFL season. These TV ads are shown during professional football games and feature animated beer cans playing a championship game where either Bud or Bud Light wins in a dramatic fashion. More recently, news reports on the just completed electoral season were peppered with political campaign-style ads for Toyota Corolla, which supposedly "approved this message." The premise behind CSA is that consumers are more likely to pay attention to the ad if its thematic focus matches the context in which it appears (Lee and Mason 1999).

CSA is increasingly being utilized across a variety media channels including television, print, and the Internet (e.g., Bronner and Neijens 2006; Kenny and Marshall 2000). For example, part of Google's phenomenal success in banner advertising placement (based on a product called AdSense that competes with Yahoo!'s Content Match and Quigo's AdSonar) has been attributed to including context sensitive algorithms in its ad placement system (e.g., Feng, Bhargava, and Pennock 2007), an implicit acknowledgment that even in the web domain control over the consumer-marketer dyad rests with the former and innovative ways to change that are highly valued. Further, several communications companies that create syndicated news stories also offer to place tailored advertisements from firms selling products related to the story. In one illustrative case, a story about dentistry was distributed to TV stations along with an ad from Procter & Gamble for their Crest toothpaste, to be placed immediately after news stations ran that story (Saunders 2001). In Japan, one of the four major broadcasting networks has been recently testing "context-linked ads" that are placed in the middle of various TV dramas and feature actors and storylines straight out of those shows, making it difficult for consumers to separate promotion from entertainment (Chozick 2006). CSA thus refers to two distinct strategies. The first is the well known approach of matching the product category with the editorial context (e.g., the toothpaste ad with the dentistry story). The second is adjusting the ad theme to match the editorial context (e.g., the Budweiser ad featuring animated, football-playing beer cans). As the application of CSA across media outlets continues to expand (e.g., Lee and Jun 2007), consumers' reactions to these tactics seems warranted. .

Our research predicts consumers' cognitive and attitudinal reactions to CSA based on extant theories in the field. We propose that while CSA may enhance consumers' processing, its effect on their attitudes may not always favor the advertised brand. Specifically, we hypothesize that while a high degree of congruity between the ad's theme and its context may indeed increase attention, consumers' attitudes will depend upon the match between the ad's theme and the product category being advertised. This second aspect of congruity has largely been overlooked by those investigating the effects of CSA.

From a more general perspective, the study of context effects in advertising is not new to consumer researchers. For instance, prior research has examined how consumers' involvement with and liking of an ad's context affects message effectiveness (e.g., Dahlén 2005; Pavelchak, Antil, and Munch 1988; Shapiro, MacInnis, and Park 2002) and how context-induced moods affect processing (e.g., Aylesworth and MacKenzie 1998). Context effects have also been studied in terms of how fit between context and advertising might influence message effectiveness (e.g., Dahlén et al. 2008; Russell, Norman, and Heckler 2004). Russell et al. (2004), for example, explore the idea of connectedness (in a television realm) in terms of relatedness between program plot and product placements within that program. Similarly, Moorman, Neijens, and Smit (2002) investigate the effects of congruity between the product advertised and its context. More recent research investigates how one commercial in a larger pod of ads might serve as the context for subsequent ads in that set (Lee and Labroo 2004). Our re-inquiry extends prior research by investigating two levels of fit that remain simultaneously unexplored by analyzing the combined effects of congruity between an advertisement's theme and its media context on the one hand and between the ad's theme and the product being advertised on the other. Across multiple studies, we find that while consumers may pay more attention to CSA, their resulting attitudes depend on the fit between the context and the product being advertised.

Exploring Counterfeit Purchase Behavior – Towards a Unified Conceptual Framework

Piyush Sharma, The Hong Kong Polytechnic University, Hong Kong
Ricky Y. K. Chan, The Hong Kong Polytechnic University, Hong Kong

EXTENDED ABSTRACT

Introduction

Prior research on counterfeit purchase behavior shows mixed findings, possibly because it focuses on the 'direct' and 'independent' effects of attitudes, ethical judgments, and subjective norms, and ignores the role of important constructs such as counterfeit proneness and product evaluations. This paper addresses these gaps with a unified conceptual framework with counterfeit proneness as a focal construct and product evaluation as a key mediator of the process of counterfeit purchase behavior. Using a study with 610 ethnic Chinese shoppers in Hong Kong across four product categories it shows that counterfeit proneness influences the attitudes, ethical judgments, and subjective norms about buying a counterfeit product, which in turn affect the evaluation of a counterfeit product and purchase intentions.

Conceptual Framework

In this paper, we combine the economical, ethical, and socio-psychological perspectives of counterfeit purchase behavior to put forth many hypotheses. First, we propose that counterfeit proneness has a positive effect on the attitude, subjective norms, and ethical judgments about buying a counterfeit product. Next, we posit that the subjective norms and ethical judgments have a positive effect on the attitude towards buying that counterfeit product. Next, we argue that the attitude, subjective norms, and ethical judgments about buying a counterfeit product have a positive effect on the evaluation of that counterfeit product. Finally, we suggest that the evaluation of a counterfeit product has a positive effect on the purchase intentions towards it.

Methodology

We used a field-survey design with a structured questionnaire to collect data from 610 ethnic Chinese shoppers in Hong Kong to test all our hypotheses, across four product categories (luxury watches, anti-virus software, movie DVD, and backpack). We chose these four products based on their varying scores on involvement, consumption context, and purchase motivation. For example, luxury watches scored high on involvement level, public consumption, and hedonic purchase motivation; anti-virus software high on involvement level, private consumption, and utilitarian purchase motivation; movie DVD low on involvement level, and high on private consumption and hedonic purchase motivation; and finally backpack low on involvement level, and high on public consumption and utilitarian purchase motivation.

Data Analysis and Results

We first tested the measurement model using confirmatory factor analysis on all the scales with AMOS 6.0 (Anderson and Gerbing 1988; Byrne 2004), and found a good fit ($\chi2 = 447.11$, p < .001; df = 175, $\chi2$/df = 2.55; CFI = .96, RMSEA = .036, and SRMR = .045). All the fit parameters are better than the cut-off values (RMSEA < .06, SRMR < .08, CFI > .95) advised by Hu and Bentler (1999) and (1 < $\chi2$/df < 3) proposed by Wheaton et al. (1977). The construct reliabilities (.84 to .93) as well as the average variance extracted (AVE) of all the constructs (.54 to .66) are quite high, hence all the constructs appear to be reliable (Bagozzi and Yi 1988). All the parameter estimates (λ) are significantly different from zero at the 5% level, showing convergent validity; and none of the confidence intervals of

the correlation coefficients for each pair of scales includes 1.0, which shows discriminant validity (Anderson and Gerbing 1988).

Next, we tested the overall structural model using the pooled data from all the four product categories. The model provided a good fit to the data ($\chi2 = 495.75$, p < .001, df = 181, $\chi2$/df = 2.74; CFI = .95, RMSEA = .044, SRMR = .059). All the path coefficients were significant and in the expected directions. However, we only found evidence for partial mediation by product evaluation in the influence of subjective norms and attitude, and fully mediation in the influence of ethical judgments on purchase intentions. We also found significant differences in the strength of all the hypothesized relationships between past users and non-users of counterfeit products, as well as across the four product categories.

Discussion

Our findings have several important conceptual and managerial implications. First, we introduce a new conceptual framework that integrates diverse theoretical perspectives to explain mixed and sometimes divergent findings reported in prior research. Our findings show that it is not just individual attitudes, subjective norms, or ethical beliefs, but a combination of all these factors that influences consumers' evaluation and purchase intentions for counterfeit products. We even validate these findings across four different product categories.

Our findings support prior research with ethnic Chinese consumers that show favorable attitudes towards counterfeit products despite strong socio-normative influences due to the collectivistic nature of Chinese societies (Lee and Workman 2009; Wan et al. 2009). Hence, companies planning to market genuine brands to ethnic Chinese consumers should look the ethical or socio-normative aspects of counterfeit purchase in their communication, because these may have minimal impact on their attitudes towards counterfeit products.

Limitations and Future Research

Hong Kong, the setting for this research, is well known for widespread availability and frequent usage of counterfeit goods. Hence, future research in other parts of the world would be useful in order to compare our findings in those markets. We also restricted our sample to ethnic Chinese consumers to ensure high internal validity by controlling the influence of cultural factors, hence it would be useful to explore the influence of culture on counterfeit purchase behavior by including cultural factors such as individualism, uncertainty avoidance etc. Finally, future research may include other variables such as innovativeness, risk taking, and change seeking, to explore their influence on counterfeit purchase behavior and consumption.

Socializing Through Cultural Consumption

Babak Taheri, University of Strathclyde Business School, UK
Aliakbar Jafari, University of Strathclyde Business School, UK

EXTENDED ABSTRACT

Museums are "social constructs, and powerful ones at that, and they need to assume their place in the mainstream of contemporary life, not sit eccentrically on the margins" (Fleming 2005, 1). Throughout history, societies have endeavored to protect their museums as evidence of their dynamism. Yet, despite their crucial role in (re)generation of cultures and civilizations, currently museums are not shielded against the storms of the recent global economic recession. In the UK, for example, in response to state budget cuts, publicly-funded museums (which have traditionally been free to enter) have been reviewing their policies to save money. Under unprecedented pressure, museums are urged to prove their societal worth to avoid possible risks of closure, severe staff redundancy, or the introduction of entrance fees. Although such pressures had already been highlighted by a number of arts enthusiasts (e.g., Fleming, 2005; Hooper-Greenhill 2007; Caru and Cova 2005), the impacts of the current economic downturn seem to go beyond simply economic rehabilitation through budget cuts, and imply significant socio-cultural considerations.

The reactive strategic plans (e.g., introducing entrance fees in order to self-fund museums) signal important policy implications for cultural (re)production and consumption in society. Amongst many critics of the British government's hasty spending review, Mark Serwotka – General Secretary of the British Public and Commercial Services Union – has expressed serious concerns over the impact of budget cuts on society: "It is essential [that] our cultural life is protected and the universal access provided by free admission is maintained to prevent the arts returning to being a privilege only the wealthy can enjoy" (Jury, 2010). Serwotka's statement reminds us of Bourdieu's (1984) analysis of social stratification through consumption of culture that marks distinct social boundaries. If broadly established, these polarizing social distinctions may eventually widen the gap between the less-privileged strata of society and those who have the luxury of re-energizing themselves by 'high' culture.

Drawing upon the importance of museums to contemporary life, in this paper we address the key theme of the conference and seek to communicate our findings primarily with cultural authorities and also with our fellow scholars. Our study, we believe, can remind cultural authorities of the multifaceted role of museums in human society. Also, we modestly believe that our findings refine theory. We use Falk and Dierking's (1997) three salient contexts affecting visitors' experiences of museums (physical, personal, and social) as our departure point in the literature review. We echo the recent calls (Falk and Dierking 1997, 2000; Hein 1998; Hooper-Greenhill 2007; Matarasso 1997; vom Lehn 2006; vom Lehn and Heath 2005; vom Lehn et al. 2001, 2007) for further research into the role of social context in museum visitors' experience. We argue that the social context has not received sufficient attention is the studies of cultural consumers' visiting experience. Addressing this research gap, we then embark to study the social context in more depth. Yet, whilst prior research (Diamond 1986; Blud 1990a and b; Hilke and Balling 1985; vom Lehn et al. 2007) has analyzed the role of social context mainly in terms of fostering learning through social interaction in the physical context of the museum, we demonstrates that people derive high levels of satisfaction from socializing in the museum and extend the social context to the world beyond the museum walls.

Our analysis of interpretive in-depth interviews with seventeen female and male individuals (aged between 25 and 58, educated and from middle-class backgrounds) in Glasgow (the UK) reveals that our informants' socializing experience is confined in neither the learning process (i.e., finding about the contents of the museum) nor the context of the visited sites. Upon their visits to cultural sites (e.g., museums and art galleries), these individuals socialize with others (e.g., family members, friends, and strangers) around the contents of the museum. Our informants draw upon different types of catalysts (e.g., nostalgic feelings, photography, exhibits, etc.) to establish new or strengthen their existing human relations in the social context of the cultural site. Yet, for them, this is not the end of the story. Our findings further reveal that these people not only socialize with others during their visits to the museum, but also continue to socialize with others outside of the museum context. They extend the social context of the museum to the outside world beyond the physical environment of the museum. They take their experience with them to create more conversations and social ties outside the museum. In some cases their individual forms of cultural consumption turn into 'collective forms of consumption' (Cova 1997) through socializing with others. All these instances demonstrate the great potential of museums as 'cultural institutions' in whose context people "can create, share, and connect with each other around content" (Simon 2010, ii).

Based on our findings, therefore, we emphasize the societal dimension of museums as socio-cultural institutions that foster social bonds among different members of contemporary society. In our study, we do not propose that these social ties exclusively rely on conversations around the museums' contents; such socializing practices may occur in other contexts such as Disneyland, theme parks, and theatres and music concerts as well. Yet, we emphasize that in everyday life situations, museums are dynamically present in people's socio-cultural spheres. They constitute an important part of people's socializing agendas. Therefore, we invite our fellow scholars to take this subject further by investigating how these social contexts operate for different people with varying socio-cultural and economic backgrounds. Also, it would be interesting to conduct longitudinal research in order to understand how enduring the museum-embedded social ties are and if they pave the way for the emergence of new social ties and networks. We also sincerely invite policymakers and cultural authorities to rethink their policies and protect museums as significant social contexts that glue human beings together in the age of fragmentation of human relations.

Coping with My Loneliness: The Effects of Social Exclusion
on Consumer Choice of Unique Products

Ying Ding, Peking University, China
Jing Xu, Peking University, China
Echo Wen Wan, University of Hong Kong, Hong Kong

EXTENDED ABSTRACT

The experience of being rejected, excluded, or isolated is quite pervasive in people's social life. Prior literature contends that social exclusion can impair individual's psychological as well as physiological well-beings (Williams 2007), and that people have the motivation to reduce the negative experiences of social exclusion. However, diverging findings has been reported on the behavioral consequences following the experience of social exclusion (Williams 2007). On the one hand, results from some research indicated that social exclusion can lead to prosocial behaviors as an attempt to rebuild social connections (DeWall, Maner and Rouby 2009; Maner et al. 2007). However, other studies suggested a link between social exclusion and antisocial behaviors such as aggression and decreased motivation to help (Twenge et al. 2001; Twenge et al. 2007).

In the current research, we identify dual coping mechanisms toward social exclusion in the domain of consumer choice. Based on the literature of social exclusion (Williams 2007) and need for uniqueness theory (Snyder and Fromkin 1980), we propose that consumers' response to social exclusion depends on how they interpret the experience of being excluded and that consumers may strategically choose to differentiate or assimilate to others as a means to cope with deprivation of social relationships. Two factors are considered which may influence the perception of whether or not it is desirable to regain social acceptance. To begin with, prior work has linked self-affirmation with greater perceived control and personal resources (Schmeichel and Vohs 2009). We expect that excluded individuals with self-affirmation or greater resources are less likely to perceive rebuilding social connection as a way to cope with the exclusion, as they can easily resort to other ways of remedy. For instance, Zhou, Vohs and Baumeister (2009) demonstrated that handling money can reduce distress over social exclusion. Hence, it is plausible that excluded individuals with self-affirmation have a more readily accessible need for uniqueness and in turn tend to choose more unique products. Accordingly, we propose that following the experience of social exclusion, consumers with self-affirmation (or rich resource) are more likely to choose distinctive products, as compared to those without self-affirmation (poor resource).

The second factor is individual's belief about whether things can be changed or fixed. Previous literature differentiated two types of implicit theories people hold about the world around us. Entity theory contends that everything is fixed and can not be changed, whereas incremental theory emphasizes on malleable traits and can be changed (Dweck and Leggett 1988). Hence, following the experience of social exclusion, individuals who hold a belief in incremental theory would consider regaining social acceptance is infeasible and be motivated to seek conformity through choosing less unique options. Conversely, excluded individuals who believe in entity theory would consider rebuilding social relationship to be infeasible. They will be more likely to regard themselves as unique individuals and tend to choose unique options to express their distinctiveness.

Across three experiments, we tested the propositions by using different manipulations of social exclusion and got consistent results. Specifically, experiment 1 documented the moderating role of self-affirmation. We employed a 2 (social exclusion: exclusion vs. inclusion) x 2 (self-affirmation: yes vs. no) between-subjects factorial design and we manipulated social exclusion by Cyberball task. Fol-

lowing the social exclusion and self-affirmation manipulation, participants made a choice between two vacation spots, with one of the options preferred by majority (common option) based on previous survey and another one preferred by minority (unique option). Possessions are extensions of self and prior literatures indicate that distinctive products preferred by a minority of people can signal one's individuality whereas those preferred by majority others convey a sense of belongingness (Ames and Iyengar 2005; Tian, Bearden and Hunter 2001). The results implied that socially excluded participants were more likely to choose the unique option after self-affirmation compared to those without self-affirmation. Based on the mediated moderation analysis, we found the moderation effect of self-affirmation and social exclusion on the choice of unique products was mediated by individuals' need for uniqueness. Furthermore, we showed in experiment 1 that the negative feeling of being socially excluded can be reduced significantly after product choice.

We tested how resource influences the effect of social exclusion on product choice in experiment 2 that employed a 2 (social exclusion: exclusion vs. inclusion) x 2 (resource availability: poor resource vs. rich resource) between-subjects design. After recalling an experience of being socially excluded or included, participants received the scenarios which used to manipulate resource perception. Then participants made choices to donate for one of two endangered animals, one supported by majority (common option) and the other supported by minority (unique option). The results revealed that excluded participants with rich resource chose more unique option than those with poor resource.

In experiment 3, we incorporated a marketing relevant manipulation of social exclusion and tested whether social exclusion interacts with the belief in changeability in affecting product choice. This experiment followed a 2 (social exclusion: exclusion vs. inclusion) x 2 (changeability: entity theory vs. incremental theory) between-subjects design. We found that, following the experience of social exclusion, participants who believe in entity theory would be more likely to choose the unique option than those who believe in incremental theory. In addition, our results indicated that the interaction effect of social exclusion and changeability on the choice of unique products was mediated by consumers' need for uniqueness.

To summarize, our findings suggest that consumers' response to social exclusion depends on the interpretation of whether it is desirable to regaining social connection (self-affirmation and resource) and whether they believe it is possible to change the state of being socially excluded (changeability). As a result, excluded consumers may tend to choose more unique or common products as a strategy to cope with social exclusion.

Surveillance 2.0: Meso Legitimation of Sharing in Healthcare through Social Media

Handan Vicdan, Eastern Kentucky University, USA

EXTENDED ABSTRACT

This research aims to introduce a new marketing system established through social media in healthcare, and how it serve as an enabler of sharing private health data and mutual surveillance among healthcare actors. Through netnographic inquiry of this system called PatientsLikeMe (PLM), I explore how PLM legitimizes the sharing of private health information in the current healthcare market where privacy dominates relations among healthcare actors. PLM is a community organization that gathers patients with diverse health problems (e.g., MS, ALS, Mood, Parkinson, HIV, organ transplant) and other healthcare actors (e.g., pharmaceuticals, caregivers, physicians/researchers). It enables healthcare actors to engage in clinical research in its platform, hence facilitating the acceleration of medical research and generation of medical knowledge by patients. Findings reveal the community (meso) mediated dynamics of surveillance in healthcare through this social media platform.

PLM enables sharing and mutual surveillance in healthcare through intensifying connectedness among diverse healthcare actors and the resulting mobility and flow of health data through this community platform. Sophisticated surveillance tools in PLM enable patients to continuously monitor and watch their and others' disease conditions and treatments, hence intensify sharing and connectedness in healthcare, not only among patients and between patients and physicians, but also among healthcare providers. Constant real-time surveillance of and by healthcare actors in PLM through tracking tools leads to increased disease literacy and support, and connectedness among healthcare actors both inside and outside of the community. Patient ability to create a centralized record of her/his health data also increases connectedness among healthcare providers with increased flow of health data. Transition of data flow among healthcare providers is also less flawed when patients create a centralized record of their conditions in PLM, which also reduces diagnosis and treatment errors. By enabling intra, inter and outer communal sharing and learning, PLM increases patient connectedness to other patients worldwide, their families and caregivers, and their physicians both inside and outside of the community. Multiple ways of learning in the community help patient improve on self-presentation and disease literacy, and as a result, influence relations both inside the community (e.g., increased empathy and tolerance in patient-to-patient connectedness, and increased self-awareness of one's health condition through constant monitoring) and outside of the community (interpretation and presentation of what is learned in the community through surveillance tools to other parties outside of the community).

PLM also intensifies patient-to-physician connectedness. Increased disease literacy and enhanced understanding of the disease by patients and physicians in the community also influence their outside community relations. Physicians/researchers can track specific patients and improve on their treatment methods. Patients can better present their conditions to physicians and engage in proactive dialogues with their physicians. Patients, equipped with more theoretical and experiential knowledge about their diseases, increasingly demand validation of any type of claim made or information presented by other patients and physicians in the community with alternative sources of knowledge and scientific evidence. In addition, research conducted in PLM community serves as a form of validation and a useful check for traditional clinical trials. Patients and physicians can employ a more personalized medicine through constant monitoring of disease progression and the resulting centralized records, which also serves as a form of validation and analysis in physician-patient encounter outside of the community. Physicians, researchers and pharmaceutical firms can also recruit patients from PLM for their own research. Hence, patients are enabled to have increased access to clinical trials both in and outside of PLM, which also intensifies patient-pharmaceutical connectedness. Patient-to-state connectedness is also enabled by PLM. The state cannot interfere with the practice of sharing private health data, since PLM is not a healthcare provider but an opt-in service. Connectedness between patients and the state reflects the acknowledgement of patient license gained through social networking. Patients can directly report drug side effects to FDA, which also serves as a form of validation for the state and influences state intervention in healthcare market regulation (improved state supervision of pharmaceutical industry to eliminate subversion and exploitation by pharmaceutical companies)

PLM also strives to establish 'sharing' as a right versus privacy (a right not to share) for the discovery of new medical knowledge, hence initiates a shift in focus from proprietorship to partnership in sharing of private health data. Patients exhibit increasing willingness to embrace the responsibilization of sharing and getting involved in creating, organizing and distributing medical knowledge in collaboration with other healthcare actors, which will accelerate the medical research process and discovery of new treatments. Discrimination and delayed research process as a result of practices of privacy in healthcare, and the disguised practices of state institutions (e.g., patient non-awareness of her/his inherent rights in data sharing) to protect patient right to privacy seem to be some of the causes of patient turn to alternative sources of knowledge and support.

Consequently, findings articulate how PLM as a social networking platform in the healthcare market is beginning to initiate a shift from state intervention to community intervention in organizing sharing, generation, and distribution of private patient data, and from privacy to sharing as a form of organizing roles and relations in the current healthcare system. The processes of organization, sharing, generation of and access to private health information are also beginning to be controlled by institutions like PLM. Contemporary medicine had long served as a disciplinary entity to maximize our lifespan and normalize our bodies, hence prevent us from death. State institutions and healthcare providers utilized 'security' and 'fear' as discourses of power in this process (Epstein 2006), particularly as a means to protect patient privacy and increase mortality salience among patients. With the increased use of Internet for acquisition, analysis, aggregation, dissemination, deployment and sharing of private health data and information, healthcare industry and the state established policies (HIPAA) to protect patient privacy. These policies strictly set boundaries on the flow of patient health records to third parties (e.g., insurance companies, employers), increase consumer sensitivity and fear about privacy, and serve as a barrier to research and discovery (Brown 2008). Macro institutions' excessive reliance on secrecy and desire to have control over patient health information (Weitzner et al. 2008) are now beginning to be challenged by a meso level institution (PLM), the foundation of which is based on sharing private health data.

Product or Cause? The Impacts of Product Type and Cause Framing in Cause-Related Marketing Advertising

EXTENDED ABSTRACT

Because of increasing public concern over social and environmental matters, many companies have begun to affiliate their products with a range of popular causes related to social and ecological issues. Partnership between product and cause is referred to as cause-related marketing (CRM) (Varadarajan and Menon, 1988). One influential variable that has been identified to determine the success of CRM is its advertising (Chang, 2008 and 2011; Lafferty and Edmondson, 2009). This article contributes to this evolving stream of research by comparing the two execution styles (i.e., product-oriented vs. cause-focused) in promoting CRM campaigns. This research will demonstrate that these two execution styles might not be equally persuasive in all conditions, and could be moderated by two variables: product type and cause framing.

The findings from two experiments raise concerns about the effectiveness of visuals, as well as questions when different visuals (cause or product photo as dominance) are persuasive. The results suggest that selection of cause/product as visual can be an effective tool for influencing consumer behavior, notably in product purchase behaviors. Different from Lafferty and Edmondson (2009) in which the examined cause was low in importance and familiarity (i.e., the Conservancy's efforts to protect the Northern Rocky Mountain Grizzlies' habitat). In current research, World Vision in Study 1 was considered as a non-profit with high credibility and familiarity (Chang, 2008). Using a fictitious non-profit (i.e., Medical Research Charities Association), cause importance was considered as a covariate in Study 2. Extending recent developments in execution style of CRM advertising literature, the present research identifies boundary conditions associated with the roles of product type and cause framing in consumer evaluations of CRM ads. In doing so, the study is capable of providing insight into the important, but previously unanswered questions of "Under what conditions do cause-focused ads facilitate consumer attitudes and purchase intentions? Conversely, when does a cause-focused ad backfire?" The findings presented here establish that the influence of execution style on consumer response is relatively complex and contingent on product type and cause framing. In terms of the relative effects of different product types, this study shows systematic effects on consumer responses by comparing hedonic and utilitarian products/values. Five observations are noteworthy.

First, the beneficial effects of using a cause as a visual focus occur when a hedonic product is promoted or when a product is perceived hedonic. Emotion contagion can be used to explain such a phenomenon. People think with their hearts for hedonic consumption, which arouses emotions including pleasure and guilt. Consistent to charity donation literature (e.g., Chang and Lee, 2009; Small and Verrochi, 2009), visuals of a cause may cause vividness and stimulate sympathy and, thus, more positive attitudes and purchase intentions. The congruence between emotion from hedonic product purchase and emotion evoked by a cause image facilitates people to purchase the promoted with a cause. From a practical point of view, the findings here should be considered encouraging companies who wish to employ cause photos in initiating CRM ads.

Second, a product photo as a visual emphasis is more effective when a utilitarian product is promoted or when a product is perceived utilitarian. Using a product as focal visuals provides precise benefits/attributes. This matches well with the rationality of utilitarian consumption. The finding echoes Lafferty and Edmondson (2009) that the photo of a utilitarian product (i.e., granola bars) had a greater effect on purchase intentions than the cause photo.

Third, investigating impacts of value framing is an important marketing issue because both self-benefit and other-benefit appeals are commonly used as good-faith attempts to communicate why the cause should be supported. However, they may not be equivalent with respect to their ability to enhance CRM effectiveness. An other-benefit appeal facilitates the effects of a cause-focused ad on hedonic product advertising, while a self-benefit appeal enhances the effects of product-oriented ad on utilitarian product promotion. This lends qualified support to the phenomenon of value congruity (Brunel and Nelson, 2000; Chang, Lee, and Chen, 2009) in charity promotion contexts. Altering the frame of a persuasive message is a relatively straightforward task. An appropriately framed message could be incorporated into CRM campaigns to increase its effectiveness.

Fourth, it appears that cause framing could play a similar role as what execution style does in CRM advertising since both influences are contingent on product type. One major difference between cause framing and execution style is the format of presentation: the former is verbal portrayal and the latter is visual display. When comparing each interaction with product type, the experiment results indicate a stronger influence of execution style. The results echo an old saying "a picture is worth a thousand words." Actually, image display is widely used in a charitable communication to boost vividness effects (Chang and Lee, 2009; Perrine and Heather, 2000; Thornton, Kirchner, and Jacobs, 1991). The use of visuals requires more expenses than verbal description, as more talent, artistic skills and digital enhancement are needed for developing impressive images. Meanwhile, good visuals improve advertising persuasion and increase product sales.

Finally, the main effect of product type is consistently found in Study 1 and 2. The results demonstrate the previously observed effects of product type on CRM by comparing utilitarian and hedonic products (Chang, 2008; Strahilevitz, 1999; Strahilevitz and Myers, 1998). The advantage of perceived hedonic value resides in its ability to elicit more favorable consumer attitudes toward the company and toward the sponsoring firm. The current investigation provides guidance for practitioners to frame the nature of the product in CRM campaigns. Perceived hedonic value is an important element in CRM. Transforming a product with perceived utilitarian value into one with clear hedonic value can be an important re-positioning strategy for a company using CRM to successfully promote the product.

To marketers who intend to promote products with charity incentive, this research provides marketing implications into how consumers respond to differently framed CRM messages based on product features. This research suggests that there are specific optimal ways for information presented in an ad that may optimize the effectiveness of cause-related campaigns. The present research should serve a starting point for entry into this under-researched area.

Paying To Be Nice: Consistency and Costly Prosocial Behavior

EXTENDED ABSTRACT

Drawing on self-perception theory and research exploring that theory (e.g., Bem 1970, 1972; Goethals and Reckman 1973), we propose that when recent prosocial behavior was personally *costly*, people would interpret that behavior as a signal of their prosocial identity; we predict, and demonstrate, that having drawn that inference, individuals are more likely to subsequently behave prosocially. Prosocial behavior that comes at lower cost, however, offers a more ambiguous signal: prosocial behavior is clearly positive, yet since it came at no cost, it is less likely to be judged as diagnostic of one's prosocial disposition. Under those circumstances the positive act can serve as a license ("my actions have led to a positive outcome…") without a substantial influence on self-perceptions, resulting in a reduction in subsequent prosocial behavior ("… so I am going to be a bit more greedy now."). Field and lab experiments test our hypothesis.

In the Experiment 1, we sought to test the idea that costly forms of altruism would lead to subsequent increases in prosocial behavior, while costless altruism would result in moral licensing. We further expected costly prosocial behavior to send a signal to the self of one's altruistic preferences, leading to an increase in self-reported prosocial identity; in contrast, because costless altruism does not send a strong signal, we expected no change in prosocial identity. To manipulate the cost of altruism, some participants had part of their payment donated to charity (costly altruism); other participants learned that a donation had been given on their behalf, but that it was not deducted from their payment (costless altruism). Control participants were not exposed to the charitable cause. To measure subsequent prosocial behavior, we created a task in which people could either lie to benefit themselves or tell the truth to benefit an unspecified other. Truth telling and reported self-perceptions of prosociality served as our DVs.

The results show that the three treatments differed in the extent to which people reported feeling prosocial, $F(2, 167) = 8.90$, $p < .001$. Specifically, participants in the Costly treatment reported feeling more prosocial ($M = 3.85$, $SD = .86$) than those in the Control treatment ($M = 3.27$, $SD = .82$), $t(109) = 3.59$, $p < .001$, and those in the Costless treatment ($M = 3.26$, $SD = .75$), $t(104) = 3.74$, $p < .001$. Participants in the Control and Costless treatments did not differ in reported prosocial identity, $t(117) = .08$, $p = .93$. In addition, a comparison of the percentage of participants who told the truth in each treatment revealed a significant difference, $\chi2 (2) = 18.35$, $p < .001$. Consistent with our predictions, participants in the Costly Donation treatment were substantially more likely to send a truthful message (71%) than Control participants (52%), $\chi2 (1) = 4.49$, $p = .04$, and Costless (30%), $\chi2 (1) = 18.35$, $p < .001$. Also, Control participants were more likely to tell the truth than those in the Costless treatment $\chi2 (1) = 5.82$, $p = .02$. A mediation analysis confirmed that individuals' truth telling was mediated by their reported self-perceptions of prosociality; the effect of costliness on truth-telling was reduced (from $\beta = .42$ to $\beta = .36$, $p < .001$) when prosocial identity was included in the equation, and prosocial identity remained a significant predictor of truth-telling ($\beta = .17$, $p = .02$).

Next, we ran a large field experiment to test our predictions in the wild. We conducted the experiment at a ride in a large American amusement park. Visitors were photographed while on the ride and could purchase their photo. To test the effect of prosocial behavior on subsequent behavior, we randomly assigned participants to one of two treatments that differed with respect to whether the photo was sold with a charitable-giving promotion. On some days the photo was sold such that half of the price was donated to a charity (a major patient-support organization); on others, photos were sold without the charitable element. Participants chose whether to buy the photo, and then walked through a retail area that contained other merchandise. Surveyors intercepted a random sample of photo purchasers at the exit, and asked them three questions: "Did you buy a photo?", "Did you buy any other merchandise?", and in reference to the latter, "Are any of those purchases going to be gifts for others?" Responses to the final question served as our primary dependent measure; buying a gift for someone is a prototypical prosocial behavior (Dunn et al 2008).

Neither photo purchasing ($\beta = -.18$, $p = .67$) nor the prosocial promotion ($\beta = -.20$, $p = .62$) influenced subsequent gift buying. However, we observed a marginally significant interaction ($\beta = 1.04$, $p = .05$). When participants were exposed to the prosocial cue, those who purchased a photo were *more* likely than non-purchasers to buy gifts for others ($\beta = .82$, $p = .04$), consistent with our costly altruism account. While all participants were exposed to the prosocial cue, only those engaging in a *costly* prosocial behavior demonstrated subsequent increase in prosocial behavior. When participants were *not* exposed to the prosocial cue, photo purchasers and non-purchasers were equally likely to buy gifts for others ($\beta = -.45$, $p = .43$).

These findings have implications for understanding when and why consistency and licensing may emerge. Furthermore, the current work informs a decades-long dispute across psychology and economics over whether social preferences – selfless behavior toward another – truly exist (Batson et al. 1997; Cialdini et al 1997; Levitt and List 2007). It appears that in part, this debate is rooted in the different orientations toward the study of prosocial behavior, with psychologists generally exploring why people don't help enough and economists exploring why, given a lack of incentives, people help at all (Ariely and Norton 2007; Fehr and Schmidt 1999). By combining both economic and psychological approaches, we show that the two approaches in fact converge: When behavior is costly to the self, that cost serves to make the behavior an informative input in the inference of one's moral disposition, and that changed self-perception also changes one's preferences for future similar behaviors, leading to consistency.

The Number-Location Association and Its Marketing Implications

Fengyan Cai, The Chinese University of Hong Kong, Hong Kong
Hao Shen, The Chinese University of Hong Kong, Hong Kong
King-man Hui, The Chinese University of Hong Kong, China

EXTEND ABSTRACT

Extant literature shows that people spontaneously associate numbers with space: a small number is associated with a left location whereas a large number is associated with a right location (Wood and Fischer 2008).

Perceptual symbols system theory suggests that people often behave like as though perceptual associations are literal (Barsalou 1999; Barsalou 2008). People's judgment and decision are consequently biased by the perceptual factors in those associations (Schuber 2005; Nelson and Simmons 2009). For example, because of the association between cardinal direction and vertical position— "North is up", people feel that heading north is going uphill, and hence expect that northbound travel(vs. southbound) will take longer time. Accordingly, we expect that consumers might treat the association between number and location literally. As a result, once the number-location association is activated, consumers' judgment about the quantifiable attributes of a product could be biased by location.

This research will test the effect of location on consumers' judgment from two different perspectives.

Firstly, location can directly bias the consumers' numerical judgment outcome if people incorrectly take location into consideration when making the judgment. In study1 and study2, we presented the stimulus (circles/squares in study1, product image in study2) either on the left side or on the right side of a display, and found that participants estimated that there are more hollow circles or squares (19.87 vs. 16.22, $F(1,78)=5.72$, $p<.05$) and provided a higher market price (36.59 vs. 34.88; $F(1,58)=4.40$, $p<.05$) if the stimulus is shown on the right (vs. left) side.

After the demonstration of the location effect on numerical estimation, study3 and study4 further showed that the effect of location on consumers' judgment depended on whether the judgment is related to numerical judgment. In study3, participants were exposed to two pictures of wine on a wall and were asked to indicate which wine was more expensive and was of a better quality. The order of questions was counterbalanced such that either price question or quality question was asked first. We found that when participants were asked to consider price first, more participants (94% vs. 74%; p for chi-square test <.05) regarded the wine displayed on the right (vs. left) side as more expensive due to the activation of the number-location association. However, if participants were asked to consider the quality first, the location did not influence quality perception (82% vs. 89%; p for chi-square test >.25), as quality is not typically represented in terms of a number. The interaction above is significant ($Wald=4.73$, $Exp(B)=9.90$, $p<.05$). Study4 follow the same logic of study3, and showed that location could also influence consumers' quality judgment as long as the quality judgment is framed as numerical judgment.

Secondly, location can also influence consumers' judgment by facilitating the judgment process. Dehaene, Bossini and Giraux (1993) demonstrated that showing numerical information in its compatible location (large numbers at right locations and small numbers at left locations) can significantly reduce people's response time, and increase accuracy rate. Reduction of response time and high accuracy rate are typical indicators of processing fluency, and processing fluency can increase people's evaluation (Schwarz 2006).

Therefore, we expect that showing numerical information in its compatible location can make people feel fluent, and that the fluency feeling in turn makes consumers evaluate the target in a more favorable way than otherwise. Study5 and Study6 tested this proposition. In study 5, we manipulate the location of a low price slogan in an advertisement. In one condition, the slogan was located on the left side of the store image; in the other condition, the slogan was located on the right side of the store image. Then, participants were requested to indicate their opinion about their patronage intention to the supermarket along a scale from -3(definitely no) to 3(definitely yes). We found that participants' patronage intention was significantly higher when the low price slogan was on the left side ($M=2.04$) than when it was on the right side ($M=0.92$, $F(1, 48)=21.44$, $p<.001$), and this effect is mediated by processing fluency. In study 6, we manipulated the location of discounted price. For half of participants, the discounted price was left to the original price. For the other half of participants, the discounted price was located right to the original price. Similarly, consumers perceived the discount as more attractive when the discounted price was left to the original price ($M=-0.18$) than when it was on the right to the original price ($M=-1$, $F(1, 59)=6.05$, $p<.05$). Taken together, study 5 and study 6 showed that presenting marketing information related to numerical magnitude such as low price slogan and discounted price in its compatible location can make consumers evaluate the marketing information in a more favorable way, and processing fluency plays a mediating role in this effect.

This paper could contribute to extant literature in several ways. First, it may provide new evidence for the number-location association by demonstrating the effect of location on numerical judgment. Second, this paper adds to the research on consumer behavior by proposing an undocumented factor that influences consumers' judgment. Thirdly, this paper explicitly proposes and demonstrates two different ways that location influences consumers' judgment as well as the underlying mechanism for each effect.

Searching in Choice Mode:
Consumer Decision Processes in Product Search with Recommendations

Benedict Dellaert, Erasmus University Rotterdam, The Netherlands
Gerald Haeubl, University of Alberta, Canada

EXTEND ABSTRACT

Consumers increasingly have easy access to vast numbers of products, and they often engage in an extensive search of the set of available alternatives in order to make a purchase. An effective means of assisting consumer search is to provide them with recommendations that sort alternatives in terms of attractiveness. Such assistance may be provided by human advisors (e.g., realtors), but it is increasingly available in the form of recommendations that are generated automatically by information systems. It has been shown that presenting shoppers with a list of alternatives sorted in line with their preferences substantially increases the quality of their purchase decisions (Häubl and Trifts 2000) and enables them to find lower prices and higher quality items in large retail assortments (Diehl, Kornish, and Lynch 2003).

While prior research has investigated how product recommendations affect decision outcomes, little is known about how such decision assistance influences consumer decision *processes* during product search. The present research seeks to fill this gap. This is particularly important because, despite the generally positive consequences of recommendations for consumer welfare, there are also instances in which providing consumers with sorted lists of alternatives may lead to worse decisions (Diehl 2005). A better understanding of consumer decision processes during search with recommendations can shed light on the underlying mechanisms that might undermine the effectiveness of this type of decision assistance.

Our central thesis is that the presence of recommendations transforms the decision processes consumers use during sequential product search relative to searching without such assistance. In particular, we argue that, when engaging in unassisted search (i.e., without recommendations), consumers naturally have a decision orientation that is characterized by forward-looking considerations directed at determining, at each stage of the search, whether or not an *additional* alternative should be inspected (Adam 2001; Bikhchandani and Sharma 1996; Häubl, Dellaert, and Donkers 2010; Weitzman 1979). By contrast, we propose that, when presented with recommendations, consumers adopt a decision orientation in the search process that incorporates considerations more akin to those used in choosing from a predetermined set of alternatives. Such considerations focus on broader comparisons among alternatives *already inspected* in the course of the search. We refer to this phenomenon as searching in "choice mode."

The proposed shift in decision orientation implies that consumer search behavior in the presence of product recommendations is partly governed by influences that are non-normative and that are commonly observed when consumers choose from small predetermined sets of alternatives – i.e., in settings that do not require search (Payne, Bettman, and Johnson 1988; Simonson 1989; Wright 1975). To test this proposition, we examine how recommendations affect the two key decisions that consumers must make at each stage of their search – determining which of the products already inspected is the most attractive one (product comparison decision) and deciding whether to terminate the search or continue it by inspecting an additional product (stopping decision).

Evidence from two experiments provides strong support for such a transformation of search decisions, which manifests itself in two respects. First, searching with recommendations causes consumers to assess a product they encounter not only by comparing it to the best previously found one (as prescribed by normative models of search), but also by making broader comparisons with other inspected alternatives than in unassisted search. Second, recommendations transform how variability in product attractiveness affects stopping decisions such that greater variability causes consumers to search less, which is opposite to what is commonly observed in search without recommendations. These findings provide evidence in support of the proposed shift towards a choice orientation in consumers' search decisions.

How Goal-Based Labels Drive Choice and Choice Satisfaction

Kristof Geskens, Vlerick Leuven Gent Management School, Belgium
Frank Goedertier, Vlerick Leuven Gent Management School, Belgium
Bert Weijters, Vlerick Leuven Gent Management School, Belgium
Maggie Geuens, Ghent University & Vlerick Leuven Gent Management School, Belgium

EXTENDED ABSTRACT

Increasingly consumers are confronted with an overload of choice. Classic economic theories predict that more choice benefits consumers through better preference matching (Lancaster 1990) and allowing variety seeking (Kahn 1995). Recent research, however, demonstrates that more choice can also lead to confusion, frustration, less satisfaction, and choice paralysis (Iyengar and Lepper 2000; Gourville and Soman 2005; Reutskaja and Hogarth 2009).

To mitigate these negative overchoice effects, previous studies suggest product-based solutions such as creating an alignable assortment (Gourville and Soman 2005) or working with attribute-based categories (Mogilner, Rudnick and Iyengar 2008). In this study we propose a consumer-based solution starting from consumers' ways of processing information. Since the pursuit of goals drives much of consumers' choice behavior (Lawson 1997; Van Osselaer et al. 2005), we advance goal-based labeling as a mechanism to facilitate consumer choice. Goal-based labels (e.g., a "Budget", "Family Trip", or "Professional" camera) may facilitate consumer choice by clearly linking goals with different choice options.

The effect of goal-based labeling on choice is likely to depend on the level of consumer expertise. Because of their extensive category knowledge, experts already have an ideal point (i.e., ideal attribute combination needed to satisfy a goal) in mind (Chernev 2003). Novices, in contrast, lack category knowledge and do not have a readily available ideal point. As a consequence, "translating" a goal into relevant product attributes may be problematic for novices. Goal-based labels can serve as a cue on which novices may rely to facilitate their choice process (Hoeffler and Ariely 1999). Therefore, we expect novices to choose an option with an appropriate goal-based label over an option with a non-meaningful label, even when it is inaccurate (i.e., the choice option does not deliver the benefits needed to satisfy the goal the label suggests). We expect experts to dispose of the cognitive resources to easily process options at a deeper level, which may enable them to make an optimal choice irrespective of the presence of goal-based labels.

Hypothesis 1a   *Goal-based labels will guide the choice alternative selection of novices, but not of experts.*

Hypothesis 1b   *Accurate (vs. inaccurate) goal-based labels increase the likelihood to make an optimal choice for novices, but not for experts.*

Choice satisfaction can be conceptualized as the difference between the perceived costs and perceived benefits of choice (Reutskaja and Hogarth 2009). Because goal-based labels may serve as a cue for choice they can reduce the perceived cost of thinking (Shugan 1980) without reducing the benefits of choice. Since we expect that novices, but not experts, will be guided by goal-based labels, we hypothesize:

Hypothesis 2   *Goal-based labeling has a positive effect on choice satisfaction for novices but not for experts.*

When the number of choice alternatives increases, evaluating and making a well-considered choice becomes more difficult - resulting in lower satisfaction (Iyengar and Lepper 2000, Chernev 2003). Additionally, novices may not know exactly which product attributes enable them to fulfill a specific goal (Brendl, Markman, and Messner 2003), and thus experience uncertainty – which may again result in lower satisfaction. Summarizing, we advance two processes through which goal-based labeling can reduce novices' perceived cognitive costs of choice: (1) a decrease in choice difficulty and (2) a decrease in choice uncertainty. Therefore, we hypothesize:

Hypothesis 3   *The effect of goal-based labeling on choice satisfaction for novice consumers is mediated by perceived choice difficulty.*

Hypothesis 4   *The effect of goal-based labeling on choice satisfaction for novice consumers is mediated by perceived choice uncertainty.*

To test our hypotheses, we conduct an online quasi-experiment with a 2 (expert vs. novice) X 3 (no goal-based labels vs. accurate goal-based labels vs. inaccurate goal-based labels) full-factorial design. We simulate a choice setting using stimuli derived from a sequence of pre-tests. In total, 334 male subjects participated in the main study, grouped into experts ($N = 173$) and novices ($N = 161$). Expertise in the first group was substantially and significantly higher than in the second group, with respective scores on a 20-point scale of $M_1 = 5.89$ (SD = 5.02); $M_2 = 15.28$ (SD = 3.57), t (215) = -15.03, p < .001. Each respondent was randomly assigned to one of three experimental conditions. After being confronted with a scenario prompting a specific goal, each participant was asked to make a choice from the given assortment. Next, respondents had to justify their choice and answer items measuring the mediating and dependent variables.

We first test whether the labeling manipulation affects the proportion of optimal choices. Among novices, the proportion of optimal choices varies significantly across labeling conditions (chi²(2) = 29.9, p < .001), whereas among experts it does not (chi²(2) = .881, p = .644). Among novices, 8.9% of respondents choose the optimal alternative when goal-based labels are absent, whereas in the assortment with accurate goal-based labels significantly more novices make an optimal choice (47.3%; chi²(1)=17.36, p < .001). These findings support H1a.

Next we compare the number of optimal choices for novices versus experts in the accurately and inaccurately labeled conditions. Among novices, in the inaccurately labeled assortment the amount of optimal choices drops to 9.8%, which is significantly lower than in the accurately labeled assortment (where it was 47.3%; chi²(1) = 20.29, p < .001). Among experts the amount of optimal choices does not differ across conditions (chi²(1) = .858, p = .354). These result support H1b.

To study the effect of assortment type and expertise on choice uncertainty, choice difficulty and choice satisfaction, we test a path

model in which the outcomes (uncertainty, difficulty, and satisfaction) are regressed on assortment type.

In line with H2, the total effect of goal-based labeling on choice satisfaction is positive and significant for novices (B=.59, SE=.18, p=.002), but not for experts (B=.05, SE=.15, p=.361). We find that choice difficulty is not a significant mediator, as its impact on choice satisfaction is not significant (and the impact of goal-based labeling on choice difficulty is only marginally significant). Thus, H3 is not supported.

Among novices (but not among experts) choice uncertainty is significantly and negatively affected by goal-based labeling (B = -1.27; SE = .40; t = -3.19; p = .001). Additionally, choice uncertainty has a significant negative effect on choice satisfaction (B= -.48; SE = .05; t = -9.26; p = .000). Hence, in line with H4, among novices (but not among experts) choice uncertainty mediates the positive effect of goal-based labeling on choice satisfaction. Furthermore, content analysis of participants' reasons for choice shows that novices use goal-based labels to make sense of the attributes of the choice options.

On the basis of the obtained results, we conclude that goal-based labels increase the choice satisfaction of novice consumers, by increasing their perceived choice certainty. A possible explanation for the absence of the hypothesized mediating effect of choice difficulty (H3) is that satisfaction relates to the outcome of the choice, not the process.

A Perceived Control-Based Model of the Effects of Co-Production on Satisfaction

Natália Araujo Pacheco, Universidade Federal do Rio Grande do Sul, Brazil
Renaud Lunardo, Troyes Champagne School of Mangement, France
Cristiane Pizzutti, Universidade Federal do Rio Grande do Sul, Brazil

EXTENDED ABSTRACT

Consumer's participation through co-production is increasingly present in marketing literature. Co-production requires consumer participation in production activities, such as product designing, resource aggregating or other processing activities leading to an output that will be used or consumed (Etgar 2008). From the company perspective, co-production can be an effective marketing tool, as the interaction between customer and firm has been pointed as a source of value creation (Prahalad and Ramaswamy 2004) and competitive effectiveness (Bendapudi and Leone 2003). From the consumer perspective, co-production may be of interest for consumers since it allows them to perceive some control over the process of the desired product or service.

The perceived control concept is related to the perceived ability to significantly alter a situation (Burger 1989; Thompson 1981) and has been showed to exert a crucial role in people's life by exhibiting stress-reducing (Glass and Singer 1972) and motivation-inducing (Skinner, 1995) properties. Having made its first appearance in consumer research not until the 1990s, perceived control has been found out to exert some positive influence on pleasure (Hui and Bateson 1991), mood, involvement (Ward and Barnes 2001), satisfaction (Wathieu et al. 2002) and intention to behave (Mathur 1998). However and quite surprisingly when considering the increase of co-production in consumption activities, a clear need to understand the linkage between the control from the co-creation process and the satisfaction toward the related consumption remains (Lusch and Vargo 2006). More specifically, two questions remain unanswered: first, does co-production lead to higher consumers' satisfaction because it makes them feel more in control? Second, does the perception of control induced by the co-production process always lead to higher satisfaction or, on the contrary, may lead in specific circumstances to lower satisfaction?

This article represents an initial effort to analyze the complex linkages between co-production, perceived control and satisfaction. Understanding how the perception of control influences the process of satisfaction is of interest because of the importance of satisfaction to predict future consumer's choices (Woodruff, Cadotte and Jenkins 1983). Within this perspective, understanding how co-production may contribute to enhance perceived control – and consequently satisfaction – is also of importance.

This research draws on Skinner's (1996) conceptualization of perceived control – an extension of Averill's (1973) model which states that behavioral, cognitive, and decisional control are potential antecedents of perceived control - to explain the effects of co-production on satisfaction. Two experimental studies were developed to investigate whether co-production and other two variables, information and consumer choice, affect perceived control and whether the later has an effect on satisfaction moderated by self-efficacy. The first experiment simulates behavioral and cognitive control, respectively, through co-production and information to examine them as two possible sources of perceived control and satisfaction. The second experiment replicates the first by replacing information by choice. Behavioral and decisional controls are simulated, respectively, through co-production and choice.

Therefore three hypotheses about perceived control's antecedents were tested: consumers who co-produce will perceive greater control when compared to those who do not (hypothesis 1); consumers who gain more information will perceive greater control when compared to those who gain less information (hypothesis 2); and consumers who have choice will perceive greater control when compared to those who have no choice (hypothesis 3). As feeling in control of the environment has been strongly related to satisfaction and performance (Greenberger et al. 1989) the hypothesis about perceived control's impact on satisfaction was also tested: the greater the perceived control, the greater the satisfaction (hypothesis 4). A moderation of self-efficacy on the effect of perceived control on satisfaction should be expected since the increase in perceived control may lead to negative reactions (Burger 1989) specially if co-producers are concerned with their own ability (Ertimur 2008), so a last hypothesis was tested on both experiments: consumers with high self-efficacy will experience greater satisfaction when they perceive higher control than consumers with low self-efficacy (hypothesis 5).

Results of both studies supported the five hypotheses, showing that co-production ($F(1, 93) = 57.48$, $p < .001$ on study 1, and ($F(1, 86) = 110.20$, $p < .001$) on study 2), information ($F(1, 93) = 13.53$, $p < .001$) and choice ($F(1, 86) = 23.34$, $p < .001$) affect perceived control which in turn affects satisfaction ($\beta = .809$, $t(95) = 13.39$, $p < .001$ on study 1, and $\beta = .872$, $t(88) = 16.72$, $p < .001$ on study 2). This last relationship depends on self-efficacy such that consumers with high perceived control and high self-efficacy reported greater satisfaction than those with low self-efficacy. These results suggest that perceived control is a powerful concept in explaining satisfaction consequently to co-production and that self-efficacy is a crucial condition for the positive effect of perceived control on satisfaction. Findings of studies 1 and 2 strongly support Skinner's (1996) model of perceived control and confirm the power of perceived control in explaining the effects of co-production, in addition of information and choice, on consumer' satisfaction.

This research may be of interest to marketing practitioners. As co-production leads to more perceived control, marketers can induce consumers' feelings of empowerment by allowing them to participate in the production process. Giving consumers information about the product or service, or giving them choice also represents for marketers means to induce consumer's perceived control. As emphasized by the wide body of literature dealing with control (Skinner, 1996), such consumer's feeling of control may result in a variety of positive outcome, from emotions to behavioral responses, all them being of great interest for practitioners. However, we found self-efficacy as an important variable for the positive effect of perceived control on satisfaction. Thus it may be argued that co-production must engage consumers in simple process or in processes with which the consumers are familiar in order not to jeopardize the consumer's self-efficacy and in turn its satisfaction.

Brands as Product Coordinators: Matching Brands Make Joint Consumption Experiences More Enjoyable

Ryan Rahinel, Unversity of Minnesota, USA
Joseph Redden, Unversity of Minnesota, USA

EXTENDED ABSTRACT

Two product classes are said to be complementary when the utility derived from one good depends on usage of the other good. Such product classes are often jointly consumed as in the case of toothbrushes and toothpaste or tortilla chips and salsa. In the current research, we take the notion of complementarity a level deeper and ask how specific brand combinations within given product classes affect utility during joint consumption (e.g., "Which combination of Tostitos and Old Dutch tortilla chips and salsas would be most enjoyed?"). Previous work suggests that given two brands where one is slightly preferred to the other, one should enjoy as much of the better brand as possible. Contrary to this prediction, we find that consumers experience a bonus in enjoyment from having a single matched brand for both products. We posit that the reason for this "brand matching effect" is that consumers expect a brand to have coordinated its products, through activities like joint product design and testing, to uniquely work well together. The belief that product coordination has taken place is cued when the brands of multiple products match. Four empirical studies support our core prediction that matching brands increases joint consumption.

In the first study, we asked participants to rate the sharpness of pictures said to be created by a printer and ink combination (even though all pictures were actually printed using the same printer and ink cartridge). The design was a 2 (Printer Brand: HP vs. Canon) x 2 (Ink Brand: HP vs. Canon) between-subjects design. Participants rated the pictures as appearing significantly sharper when the printer and ink were labeled as the same brand (vs. different brands) ($p < .03$). A follow-up study in which we did not reveal the brand names but merely told participants that the printer and ink were the same or two different brands replicated this result ($p < .03$).

The second study tested the product coordination explanation against other explanations suggesting general preference for matching on any attribute. We framed labels of tortilla chips and salsa as either brand names (e.g., "Party Time® brand salsa") or general adjectives (e.g., "party time salsa). If our account is correct, then we should observe the brand matching effect in the brand frame case but not in the general adjective frame case. Indeed, tortilla chips and salsa framed as coming from the same brand were enjoyed more than those framed as from different brands ($p < .05$), but there were no differences between the matched and mismatched cases for the adjective frame case ($t < 1$).

The third study sought direct evidence for our product coordination explanation. The design used only the brand frame conditions from Study 2 and asked participants to indicate their perceived coordination (i.e., perceptions of joint research and design) of the two products after the dependent measures. Our core finding that matched brands of tortilla chips and salsa were enjoyed more than mismatched brands was replicated ($p < .02$). In addition, a Sobel test confirmed that perceived coordination mediated the effect of brand matching on rated enjoyment ($p < .03$).

The objective of the fourth study is to provide further process evidence by explicitly manipulating product coordination. We counterbalanced Brand A and Brand B labels that were counterbalanced across the two products. In addition to the brand labels, we also manipulated a line of text participants read before tasting the chips and salsa. In one condition, we told participants that the brand(s) had "coordinated the distribution and coupons for these two products." In the other condition, we told participants that the brand(s) had "coordinated the design of these products and market research on how they tasted together." We expected to replicate the brand matching effect in the former condition but not the latter. In accordance with this prediction, tortilla chips and salsa from the same brand were enjoyed more than those from different brands when participants were told that the brand(s) had coordinated the distributions and coupons for the two products ($p < .04$). This effect was eliminated when we told participants that the brand(s) had coordinated the research and design for the two products ($t < 1$).

The results of these studies contribute to the literature in three important ways. First, we establish brand matching as a way to increase the enjoyment of multiple products consumed jointly without changing what is objectively being consumed. This is in line with previous work, which has shown that the presence of a high quality brand label increases the enjoyment of a single product (Allison and Uhl 1964; Hoegg and Alba 2007). Our finding leads to new insights about how marketers can help consumers enjoy their consumption episodes more without trying to change quality perceptions of the brand. Second, by demonstrating the brand matching effect with unfamiliar brands that have no preexisting associations, our work furthers product coordination as a general role for brands. This contributes to the literature on brand roles, which suggests among other things that brands can serve as a signals of quality and manufacturing competencies (Wernerfelt 1988; Broniarczyk and Alba 1994), figures of attachment (Fournier 1998), and signals of group associations (Belk 1988). Third, by fixing the product categories consumed, our work highlights the role of a product-level fit in consumption enjoyment. This notion of a product-level fit in many ways complements past work on how product extension evaluations are enhanced when they fit with a brand in terms of category-level complementarity (e.g., chips with dip; Aaker and Keller 1990). Our findings demonstrate consumers not only believe that brands that make a specific product can better make products in a complementary category, but also that a brand's complementary extension will work best with existing products from that brand because they were designed and tested together. It is clear that branding is an important question for researchers, made more difficult by the fact that consumers mix brands together quite often. Future research should further our understanding of how brand combinations can ultimately create more enjoyable experiences.

The Influence of Status Differentiation on Vertical Brand Extension: Intercultural and Intracultural Comparisons

Xiang Fang, Oklahoma State University, USA
Shengdong Lin, Xiamen University, China

EXTENDED ABSTRACT

Many companies have employed brand extensions as an effective tool to introduce new products. To date, much emphasis has been placed on horizontal brand extensions and research on vertical extensions is rather limited. In this article, our focus is on price-based line extensions in which an existing brand introduces a higher-price version (upward stretch) or a lower-price version (downward stretch). Past research on vertical extensions has examined numerous factors influencing consumers' responses to line stretches such as parent brand image (prestige vs. nonprestige), stretch direction (upward vs. downward), branding strategy (subbrand vs. direct), ownership status (owner vs. nonowner), consumer goal (browsing vs. buying), and extension distance (far vs. close). In this article, we introduced status differentiation as an important factor influencing consumers' responses to line extension.

Status differentiation is defined as "how people differentiate their behaviors or attribute power to others according to perceived status differences" (Matsumoto 2007, p. 414). Individuals may monitor their behavior accordingly when they interact with their superiors, colleagues, or subordinates. Since brands usually contain important symbolic meanings, consumers purchase certain brands to maintain and/or enhance their self-image (congruence between personal image and brand image). We expect that individuals varying on status differentiation may view upward- and downward-stretch differently because the brand's symbolic meanings to individual consumers may change accordingly. Therefore, we argue that status differentiation may moderate the effect of brand image and stretch direction on the prestige perception of the line extensions and the parent brands after extensions. We conducted two studies to test the moderation effect of status differentiation.

Study one employed a 2 (culture: Chinese vs. American) × 2 (stretch direction: upward vs. downward) × 2 (brand image: prestige vs. functional) mixed design with the first two variables as between-subjects factors and brand image as a within-subject factor. One hundred and sixty-night Chinese students and forty-eight American students participated in the study. Status differentiation scores were measured by the 20-item scale developed by Musumoto (2007). We used BMW and Toyota to represent prestige brand and functional brand, respectively. Stretch direction was manipulated by different price tiers. The results showed a significant three-way interaction of culture, brand image, and stretch direction on the prestige perception of the line extensions. Specifically, for a prestige brand BMW, the difference between upward- and downward-extension was greater for Chinese (high status differentiation) than for Americans (low status differentiation). In addition, planned comparisons showed that when BMW extended upward, Chinese participants perceived it as being more prestigious than American participants. However, when BMW extended downward, Chinese perceived it as being much less prestigious than Americans. This pattern failed to emerge for the functional product Toyota. Furthermore, the results revealed that the downward extension of a prestigious brand caused more parent brand dilution for Chinese than for American. We also conducted intracultural comparisons by using the median-split approach on status differentiation scores for Chinese and American participants, respectively. The similar patterns were observed.

In study two, we attempt to replicate the findings of study one by using the priming technique on status differentiation. To increase the generalizability of our findings, we used two different brands in the watch category, Rolex and Seiko, to represent prestige and functional brands, respectively. The results showed that the difference between upward- and downward-extension was greater for individuals in the high status differentiation condition than for those in the low status differentiation condition. The effect was also transferred to the prestige perception of the parent brand after extension. The patterns were similar to the findings in study one.

Our research makes important contributions to the fields of cross-cultural psychology and consumer research. In cross-cultural psychology, Hong et al.'s (2000) proposed the dynamic constructivist approach suggesting that culture is dynamic and individuals can construct specific cultural meaning systems based on contextual cues. Monga and John (2007) primed analytic thinking in Easterners (chronic holistic thinkers) and holistic thinking in Westerners (chronic analytic thinkers) and found the reverse patterns in the way these cultures influenced brand evaluation. Following this stream of research, we primed status differentiation among Chinese individuals and found that participants indeed shifted their status perceptions according to situational cues although high status differentiation was their chronic tendency. More importantly, the status differentiation beliefs primed temporarily had a significant impact on individuals' responses to line extension.

Our findings also contribute to the growing body of research in cross-cultural consumer behavior (e.g., Aaker 2000; Aaker and Lee 2001; Maheswaran and Shavitt 2000). Most research has focused on the cultural differences along the dimension of individualism/collectivism or independent- and interdependent self construal. We investigate another important concept of status differentiation, which is closely related to power distance (Hofstede 1980). Some research has shown that power distance influences consumers' impulsive purchasing (Zhang et al. 2010) and conspicuous consumption (Rucker and Galinsky 2009). We extend this line of research to the context of brand extensions.

Our research has important managerial implications. In today's highly competitive global environment, it is important for marketers to leverage their brand equity and launch successful brand extensions in foreign markets. Our findings provide some insight into this important strategic decision. Specifically, for a prestige brand entering a culture with high status differentiation, it'd better to use the upward extension due to the enhancement effect. Since the downward extension will hurt the extension evaluation and even the parent brand, companies should avoid it. Instead, companies may use the subbrand strategy or a different brand name to extend downward to prevent the dilution effect.

(In)congruity in the Evaluation of Celebrity Co-Brands

Keith Wilcox, Babson College, USA
William Carroll, Saint John's University, USA

EXTENDED ABSTRACT

Celebrity personalities are ubiquitous. Estimates suggests as much as 25% of U.S. advertising involves celebrities in one form or another (Erdogan 1999), and that figure is higher in many other countries (Crutchfield 2010). While the effect of celebrity endorsements on ad and brand evaluation are well documented (Ohanian 1990), the growing phenomenon of celebrity co-branding has receive little attention. When celebrities co-brand a product, they are not simply endorsing it; instead, they partner with a company to co-create a product that shares the identity of both the celebrity and the company. Celebrity co-brands are present in a diverse set of categories. They are perhaps most prevalent in the fashion and accessories industry. For instance, Scarlett Johansson partnered with Reebok to co-design a new line of clothing and footwear called Scarlett 'Hearts' Rbk. Madonna developed a line of sunglasses with Dolce and Gabbana under the brand MDG.

Recently, Monga and Lau-Gesk (2007) examined how consumers evaluate co-brands with two distinct brand personalities versus one personality. They argue that co-brands with dual personalities are considered to be more complex than single personality co-brands. As a result, when the complex self is activated consumers prefer co-brands that combine the benefits associated with two distinct brand personalities (i.e., glamour and trendiness) to those that combine benefits consistent with a single brand personality (i.e., only glamour).

This current research shows that consumers also prefer celebrity co-brands with dual personalities. However, we identify an additional process through which the evaluation of co-brands can be shaped by dual personalities. We propose that the effectiveness of celebrity co-brands depends on whether the personality of the celebrity is congruent or incongruent with the personality of the parent brand. Consumers are more likely to purchase celebrity co-brands when the personality of the celebrity is incongruent with that of the parent (i.e., there is a dual personality) compared to when the celebrity's personality is congruent with that of the parent. Additionally, we demonstrate that the process underlying these findings is a difference in processing motivation. Specifically, we propose that incongruent personalities increase consumers' processing motivation, which results in more favorable evaluations of the co-branded product.

In study 1, we demonstrate that people prefer a co-brand when the celebrity's personality is incongruent with the parent brand (Kayne West and Louis Vuitton) compared to when it is more congruent with the parent brand (George Clooney and Louis Vuitton). We also show that the effect is unique to co-brands and reverses when the celebrity endorses a product by the same parent brand, which is consistent with previous research on celebrity endorsements (Escalas and Bettman 2011; Kahle and Homer 1985). Additionally, we show that the effect of incongruity on consumers' evaluation of a celebrity co-brand is strongest for those that are low in processing motivation (i.e., those that are low in parent brand involvement).

Study 2 replicates the effects observed in the co-brand conditions of study 1 using a single celebrity. Specifically, we manipulated the personality of Daniel Craig such that his personality would be perceived to be more or less congruent with the parent brand (Louis Vuitton). We find that people evaluate the co-brand more favorably when incongruity is high compared to when it is low and that the effect emerges for consumers that are low in brand involvement.

Additionally, we show that our findings are due to incongruity experienced while integrating existing information about the celebrity and parent brand; the effect does not emerge when consumers do not have existing information about the celebrity to integrate with the parent brand.

Study 3 provides direct evidence that processing motivation underlies our results. Specifically, we show that manipulating participants' motivation to process a celebrity co-brand moderates the effect of incongruity on purchase intent. Specifically, we find that when participants' motivation to process the co-brand is relatively high, participants prefer a co-brand that is incongruent compared to one that is congruent. However, reducing participants' motivation to process the co-brand eliminates the effect.

The present work contributes to extant literature that explores the impact of celebrities on consumer behavior. The findings of Study 1 are consistent with previous research that indicates celebrity endorsers are often seen as a peripheral cue for evaluating a product or brand (Petty, Cacioppo, and Schumann 1983). However, we demonstrate that unlike celebrity endorsements, the use of celebrities in co-branding is not based on peripheral processing, instead the image or personality of the celebrity is a central component of the brand. Our results indicate that celebrity co-branding is not simply an extension of celebrity endorsing, but a unique and yet unexamined area of study.

That was Then, This is Now: Focalism in Temporal Comparisons

Steven Chan, New York University, USA
Justin Kruger, New York University, USA

EXTENDED ABSTRACT

Do people really think things were better "back in the good 'ole days?" Nostalgia as a fond longing for the past would suggest that people often think the past is better than the present. In this research, we demonstrate that this nostalgia is in part a temporal focalism bias driven by polls that ask us to compare the present with the past thereby directing greater focus and weighting of the present relative to the past. Reversing the order in such polls, comparing the past with the present, attenuates (and in some cases reverses) the conclusions of the polls.

A focalism effect based on comparing time has not been previously demonstrated. Previous research on focalism has demonstrated that comparing X with Y focuses attention on the features of X more than Y which leads to biases in comparative judgments (Houston and Sherman 1995). A focalism effect related to time is critical to polls and surveys, which often ask the public to compare the present to a reference point in the past. For example, Gallup polls often ask the public to consider whether there is more or less crime now compared with a year ago.

A temporal focalism bias would suggest that the typical question wording, which asks people to compare the present to the past, causes people to focus on conditions of the present more than that of the past. Differential weighting of the focal point leads to biased judgments. Past research on focalism has highlighted this myopic focus on the focal point in comparative judgments (Chambers, Windschid, and Suls 2003). Using the crime question as an example, having a considerable amount of crime today would lead to a judgment that crime today has become worse over time since the state of crime today is weighted more heavily than crime in the past.

In recent years, noted professor and writer Steven Pinker has often presented his idea of the violent-present illusion (2007). Pinker highlights that "contrary to the popular impression that we are living in extraordinarily violent times, rates of violence at all scales have been in decline over the course of history." Pinker presents psychological explanations based on salience, morality, and motivated reasoning. We contend that the present account of temporal focalism is an additional explanation that contributes to the violent-present illusion as well as other temporal comparisons alike.

Across two studies we demonstrate a temporal focalism effect where differential weight is placed on the present (past) when the present (past) is framed as the focal point of a question. In our first study we demonstrate the main effect of temporal focalism. Using questions drawn from and inspired by previous Gallup Poll research, we demonstrate significant differences in judgment when the focal point of comparison is reversed. For example, the question "Do you think that a year ago, there was more or less crime than there is now?" yields a significantly lower nostalgic "violent-present illusion" than the original "Do you think there is more or less crime in the U.S. than there was a year ago?"

Public opinion can even flip: For instance, when participants are polled about how much Congress has accomplished now as compared to before. In each case, whether for crime or Congress, the magnitude of the pervading opinion in people's consideration will be overweighted for the time frame targeted in the question. So because crime is perpetually common whether in the past or the present, and because Congress is always seemingly in a standstill, the direction of temporal comparison will reflect whether more crime (or less action by Congress) is highlighted for the past or the present.

A second study we conducted shows converging evidence with a context that is personally relevant to respondents while also ruling in our differential weighting explanation. Study 2 showed the effect of comparing judged frequency of both common and rare activities performed currently (undergrad) versus in the past (high school). For example, when asked to compare high school to now, participants (undergrad students in this study) were more likely to indicate that they procrastinated (common) more and watched foreign language films (rare) less in high school than now. A second group asked to compare in the reverse order, now to high school, showed a similar overestimation for common and underestimation for rare activities. In addition to the comparative questions, all participants were also asked absolute questions which rated their frequency for each activity both now and in high school (with order counterbalanced across participants). Path analyses revealed that, as hypothesized, absolute ratings for the focal time frame (present or past) were significantly better predictors for the comparative questions than absolute ratings for the non-focal time frame. This supports the differential weighting account.

When Accepted Inequality Deters Responsibility for Helping Others

Karen Winterich, Pennsylvania State University, USA
Yinlong Zhang, University of Texas at San Antonio, USA

EXTENDED ABSTRACT

Though charitable contributions by individuals exceeded $227 billion in 2009, accounting for nearly 75% of total contributions in 2009 (Giving USA 2010), the need for aid is at an all-time high in many areas, including hunger in America (Fraser 2010). As such, understanding motivations for giving, or perhaps more importantly not giving, is critical. Most of the extant literature tends to focus on individual difference factors in explaining the differences in giving with virtually no attention to cultural orientation (Aquino and Reed 2002; Center on Philanthropy 2009; Piliavin and Charng 1990). In this research, we propose that cultural orientation, more specifically, power-distance belief (PDB) may play a critical role in motivations for charitable giving. By comparing giving differences across countries as well as charitable giving differences among individuals, we show that this effect is independent from factors such as income level, education level, or other cultural orientations such as individualism/collectivism. Further, we test the underlying process and also examine a boundary condition for this effect.

According to Oyserman (2006, p. 353), PDB "involves the extent to which a society accepts and views as inevitable or functional human inequality in power, wealth, or prestige." The acceptance of a power disparity suggests that everyone has a rightful place in the social hierarchy, and this social order should be respected and maintained. As such, people maintain an awareness of the disparity and act according to their place in the social hierarchy, and make sure others' social position is well placed. Consumers who are aware of these social orders are more likely to feel the existing social order should be well respected (*Bourdieu 1984*; Miller et al. 1993). In contrast, in low PDB cultures, the norm is to maintain and respect the equality inherent in social interactions (Hofstede 1984, 2001). Individuals in these cultures do not believe that differences in power, wealth, and prestige are inevitable (Oyserman 2006). As such, people may seek out opportunities to achieve equality. In attempting to achieve equality, individuals should be motivated to aid less fortunate others. That is, low PDB consumers, who expect equality, should feel responsible for helping others if these individuals are to obtain equal resources and opportunities.

Given the expectation and acceptance of (in)equality in (high) low PDB cultures and the corresponding feelings of responsibility to aid less fortunate others in order to (maintain social order) achieve equality, we theorize that PDB influences charitable giving. Specifically, high PDB consumers will donate less to charities for less fortunate others than low PDB consumers. We test this hypothesis with cross-country level secondary data on country-level giving and also at an individual level to examine the effect of PDB as a dispositional trait on charitable giving. In both studies, we found a negative correlation between PDB and charitable giving.

We also propose that it is through decreased responsibility for aiding others that PDB influences charitable giving. In other words, we argue that responsibility will mediate the effect of PDB on charitable giving. We test this hypothesis by directly priming PDB and find that participants in high PDB prime tended to donate less than those in low PDB prime, and this difference was mediated by perceived responsibility.

If the perceived responsibility is underlying the PDB effect on charitable giving, then this effect of PDB will be more pronounced if the recipient is perceived based on an exchange norm rather than a communal relationship (Aggarwal and Law 2005). We test this hypothesis by a (Relationship Norms: Communal vs. Exchange) between-subjects design with PDB measured as a continuous variable. We found that when primed with exchange norms, PDB negatively influenced donation likelihood, such that those with higher PDB had a lower donation likelihood, consistent with the results of the first three studies. In contrast, when primed with communal norms, PDB did not influence donation likelihood. Further, the effect of PDB was again mediated by perceived responsibility.

Through a series of five studies we obtained convergent results of PDB on charitable giving. Results from the first two studies (1A and1B) provide correlational evidence for the relationship between PDB and charitable donations at the country level and the individual level. In study 2, we establish the impact of PDB on charitable donations experimentally by manipulating PDB and examine the underlying role of perceived responsibility. The final study considers relationship norms as a boundary condition for the effect of PDB on charitable donations, demonstrating that high PDB can be influenced to give when primed with communal relationship norms due to the increase in perceived responsibility under communal norms.

With the increasing living standard of consumers from developing countries such as BRIC, it is important to understand the role of cultural orientation in affecting charitable giving from these countries, as these countries have strikingly different cultures from U.S. Our results provide managerial implications for charitable organizations to manage their donation efforts in high and low PDB cultures, as our moderating results suggest ways to enhance consumers' donation intention in high PDB cultures.

Our results also shed light on the theoretical debate on key drivers for charitable giving: both dispositional thesis such as empathy and situational thesis such as responsibly have received empirical support. Our cross-cultural results indicate that both dispositional and situational factors are important in explaining the donation behavior, emphasizing either one too extensively will only lead to misleading conclusions.

Reimagining Charity: Kiva's Ideology of Entrepreneurial Charity

Domen Bajde, University of Ljubljana, Slovenia

EXTENDED ABSTRACT

The often encountered physical and cultural distance between givers and recipients of charity and the complex intermingling of social, political, economic and moral dimensions of charity, accentuate the role of imagination and ideology in charitable giving (Godelier 1999). Yet, surprisingly little attention has been afforded to the imaginary and ideological dimensions of charitable giving in consumer research (Bajde 2009). We believe this to be a serious deficit in light of the cultural turmoil surrounding charitable giving recently. The charitable sector has witnessed considerable experimentation with new ideas and practices, in particularly those adopted from the entrepreneurial sphere (Wagner 2002, Moody 2008). In our preliminary study, we focus on a specific example of such experimentation, by exploring the imaginary and ideological contour of Kiva, a charitable nonprofit that combines microfinancing and internet technology to enable individuals to lend (without interest) small amounts of money to impoverished entrepreneurs.

The imaginary of charitable giving subsumes both how individuals imagine (envision) the world and their role in it, as well as the more specific aims, means and consequences of human activities on society and nature (Godelier 1986). Taylor (2002, 106) describes it as "the ways in which people imagine their social existence, how they fit together with others, how things go on between them and their fellows, the expectations that are normally met, and the deeper normative notions and images that underlie these expectations." One of the vital ways in which imaginary conceptions become articulated, is through ideologies, or more explicit systems of interrelated ideas and beliefs, which mediate all aspects of the reality lived and produced by groups and individuals (Geertz 1973). While certain frictions and contradictions within incumbent ideologies are likely, it is when orthodox ideologies are exposed to more radical utopian ideologies (Langdridge 2006) that significant cultural innovation is likely to occur (Holt and Cameron 2010).

The cultural dynamics surrounding Kiva represent fertile ground for the exploration of the imaginary and ideological elements of charitable giving. The imaginary conceptions that make lending through Kiva meaningful to its creators and supporters were surveyed by combining the analysis of consumer narratives (Kozinets 2008) with the analysis of Kiva's brand genealogy (Holt 2004). Consumer narratives pertaining to Kiva were collected on KivaFriends.org, an active forum and community of Kiva lenders. The brand genealogy of Kiva was conducted by analyzing a set of publicly accessible texts originated by Kiva's founders and the media throughout Kiva's six year history. The subsequent sets of data were analyzed through an iterative process of grounded interpretation (Muniz and Schau, 2007). We present our findings by outlining three complementary strands of Kiva's imaginary and ideological underpinnings. Our analysis reveals how these seemingly separate strands form into a unified utopian ideology of *entrepreneurial charity*, which challenges the orthodox view(s) of charitable giving and poverty alleviation.

The first strand encompasses the mythology surrounding Kiva's creators, who join forces with the media to incessantly dramatize and aestheticise the role of entrepreneurialism in Kiva's success. Second, Kiva's supporters partake in the entrepreneurial ideology through building up their Kiva "portfolios" and actively assuming the entrepreneurial role of "angel investors". The traditional "hands off" charitable giving is replaced by inspiring visions of "hands on" entrepreneurial charity (i.e., increased level of control, the use of market mechanisms as safety valves). Lastly, Kiva's ideology of entrepreneurial charity revamps the established conceptions of impoverished beneficiaries of charity by celebrating "the working poor" as entrepreneurs waiting to be unleashed by micro-loans. The patronizing handout of traditional charity is replaced with a dignified "handup" partnership between entrepreneurial investors and borrowers.

We see the contribution of our preliminary study in demonstrating that Kiva represents not only a technological innovation or a viable extension of existent services, but more fundamentally a "cultural innovation" (Holt and Cameron 2010). The cultural innovation of Kiva results in a utopian ideology of entrepreneurial charity that draws upon fresh imaginary conceptions. Our analysis shows how Kiva's triple glorification of entrepreneurialism supports and legitimizes an alternative approach to running a charity, giving to charity and receiving charity. This is achieved by aestheticising and dramatizing the role of entrepreneurialism in ensuring social progress, by invoking the mythic figure of the heroic entrepreneur and by reaffirming a set of entrepreneurial values that morally legitimize Kiva's rejection of orthodox conceptions of poverty and charitable giving.

The Rebound of the Forgone Alternative

Zachary Arens, University of Maryland, USA
Rebecca Hamilton, University of Maryland, USA

EXTENDED ABSTRACT

Consider the case of Robert and Jenny, who are deciding whether to choose Costa Rica or Italy for their upcoming vacation. They find both destinations attractive but because they only have a week off, they have to choose one. After a long discussion, they decide to go to Italy and forgo Costa Rica. Consumers constantly make decisions like this, in which they must forgo alternatives. Thus, it is important to understand what happens to these forgone alternatives. Does forgoing Costa Rica for this vacation make Robert and Jenny more or less likely to visit in the future?

Two theories offer conflicting predictions as to the fate of these forgone alternatives. Cognitive dissonance theory suggests that the consumer's desire for a forgone alternative decreases after a difficult choice because consumers derogate its attractiveness to eliminate cognitive inconsistencies (Brehm 1956; Festinger 1957). In contrast, goal theory suggests that the desire for the forgone alternative should increase over time – consistent with temporal escalation – as long as the goal associated with it remains unfulfilled (Atkinson and Birch 1970; Chartrand et al. 2008).

We resolve this discrepancy by introducing stage of consumption and the substitutability of the chosen and forgone alternatives as key moderators. After making a choice, consumers shift from a deliberative to an implemental mindset (Gollwitzer 1990) and they derogate the forgone alternative to remove doubt and hesitation while pursuing the chosen alternative (Harmon-Jones and Harmon-Jones 2002; Jones and Gerard 1967). After consuming the chosen alternative, though, it is no longer necessary to derogate the forgone alternative. Goal theory suggests that if the goal associated with the forgone alternative is still unfulfilled, its attractiveness should rebound.

Thus, we predict that the attractiveness of the forgone alternative should exhibit a U-shaped pattern, decreasing after choice but increasing after consumption. This rebound effect will be moderated by the degree of substitutability between the chosen and forgone alternatives. When the forgone alternative is perceived to be a weak substitute for the chosen, its goal will be unfulfilled and its value should rebound after consumption. However, when the forgone is perceived to be a strong substitute for the chosen alternative, they share a common goal; therefore, consuming the chosen alternative will satiate the forgone, and its value will not rebound.

Our first study demonstrates the rebound effect by measuring the attractiveness of the forgone alternative at different stages of consumption. Participant rated a set of fun activities and chose between two. This study ruled out regression to the mean as an alternative explanation by controlling for the duration required to complete the chosen activity. The attractiveness of a forgone activity remained low even after a consumption-length delay, but the forgone alternative rebounded after consumption as long as the forgone activity was a weak substitute for the chosen activity. This study also ruled out regret as an alternative explanation.

The second study uses the temporal escalation criterion to demonstrate that the rebound effect is created by a reactivation of the goal associated with the forgone alternative. Participants chose between viewing kangaroo or penguin photographs. After watching the chosen slideshow, the value of the forgone slideshow was greater after a delay than in the absence of a delay, indicating temporal escalation. In contrast, the value of the forgone was unaffected by a delay prior to watching the chosen slideshow.

The third study provides additional evidence that the rebound effect is a goal-driven process by showing that the forgone alternative does not rebound when its goal has been fulfilled. This was accomplished by characterizing both the chosen and forgone alternatives as means or as an end in itself. Participants choose between two animal slideshows. In the means condition, participants believed the purpose of the slideshow was to help them perform better on a verbal test; in the end condition, no connection was made between the slideshow and the test. When characterized as an end, the forgone slideshow became more attractive after watching the chosen slideshow, replicating the rebound effect. However, when characterized as a means, the forgone slideshow become less attractive after watching the chosen slideshow, indicating that the goal has been fulfilled by the chosen slideshow.

Our results reconcile the predictions made by cognitive dissonance and goal theory by demonstrating that stage of consumption and the substitutability between the alternatives moderate the value of the forgone alternative. By revealing the dynamic processes of how consumers value the alternatives that they chose as well as those they forgo, this research offers insights into the interaction between consumers' goals and choices and provides a richer understanding of consumer behavior. Moreover, based on these results, managers might consider systematically reoffering forgone alternatives to customers at the appropriate time. For instance, the Costa Rican tourism board could contact Robert and Jenny next year with a targeted offer that clearly distinguishes Costa Rica from Italy.

Self-Positivity versus Self-Negativity:
Consumers' Reliance on Base Rate and Case Risk in Perceptions of Health Risk

Dengfeng Yan, HKUST
Jaideep Sengupta, HKUST, Hong Kong

EXTENDED ABSTRACT

Previous literature (Keller, Lipkus, and Rimer 2002; Lin et al. 2003) suggests that consumers' health risk perceptions may be influenced by two types of information. One of these is *base rate,* which reflects the ubiquity of disease in the target population (Lin et al. 2003; Raghubir 2008). Alternately, people may form health risk assessments based on idiosyncratic *case risk information*, which reflects the unique aspects of the target person such as their likelihood of engaging in risky behaviors (e.g., Raghubir and Menon 1998), or possessing certain symptoms of an illness (e.g., Dunning, Heath, and Suls 2004; Menon et al. 2002).

Construal theory literature (e.g., Liberman and Trope 1998; Forster, Friedman and Liberman 2004) suggest that abstract information, compared with concrete information that tends to be relatively more specific and vivid, exerts more impact on representations and judgments of psychologically distant events, while the reverse holds when the focal judgment is about psychologically near events. We argue that this premise contains direct implications for the current research question regarding the relative influence of base rate vs. case risk on health risk assessments. Base rates, by definition, consist of abstracted information about a target category rather than about a specific exemplar of that category (i.e., unconditioned on featural evidence) (e.g., seasonal flu or human flu in the U.S. results in approximately 36,000 deaths each year). On the other hand, case risk provides idiosyncratic, vivid information at a much greater level of specificity. In light of this distinction, and given the preceding arguments arising from construal level theory, it follows that:

Hypothesis   *Consumers' reliance on base rate information for making health risk judgment will be enhanced when the judgment is psychologically distant (versus relatively close). Case risk information (e.g., pathogenic behaviors or syndromes), on the contrary, have a greater influence when the judgment is psychologically close (versus distant).*

This hypothesis has direct implications for previous research on self-positivity bias wherein people tend to underestimate their risk vulnerability as compared to others (for a review, see Menon et al. 2008). Because the base rate (case risk) has a greater influence on judgments regarding others (the self), self-positivity should be most likely to be manifested when the base rate of a health risk is relatively high, while the case risk signals low risk. In such cases, individuals will be prone to judging others more at risk than themselves. In contrast, self-negativity is particularly likely to be manifested when the base rate is relatively low, but the case risk signals high risk – in such cases, individuals will be more prone to judging themselves at risk than others.

Results from four studies provide convergent support for our thesis by using multiple operationalizations of construal levels, different health risks, diverse operationalizations of base rate and case risk information, and several dependent measures. All studies tested our basic proposition by examining respondents' reliance on base rate vs. case risk to form health risk assessments, as a function of psychological distance. Experiment 1-2 focused on the interpersonal dimension of psychological distance. Subsequent studies sought to increase confidence in our construal-based conceptualization by generalizing the obtained effects to other dimensions of psychological distance, and by illuminating the underlying process. Thus, to test the process-related argument that psychological distance has its effect on health risk perception by influencing construal levels, experiment 3 directly manipulated construal type (abstract vs. concrete) prior to the assessment of health risks. Lastly, experiment 4 examined how individuals' self risk perceptions differ across time horizon.

This inquiry adds to the health risk literature in several different ways. First, we present a unifying framework of how individuals' health risk estimates are systematically influenced by base rate and case risk under different conditions. This conceptualization presents a new perspective on how individuals arrive at health risk assessments, and delineates conditions under which the underlying process is more likely to be top-down (enhanced influence of base rate) vs. bottom-up (enhanced influence of case details). Second, while past consumer research on health risk perceptions has reliably documented a self-positivity bias, and also demonstrated ways of attenuating such a bias (Chandran and Menon 2004; Raghubir and Menon 1998), the current inquiry complements these findings by documenting conditions under which a reversal (i.e., a self-negativity effect) is manifested. Such an effect has rarely been obtained before (the exception being research by Lin et al. 2003, who found that pessimistic participants exhibit self-negativity). By predicting and demonstrating the symmetric nature of self-positivity and self-negativity in health risk assessments, the current inquiry is thus able to extend current knowledge in this area.

Third, in addition to documenting the self-negativity effect, the key moderator proposed in our work (construal level) has the potential to integrate several past findings relating to the self-positivity bias in health perceptions. For example, in a seminal article, Raghubir and Menon (1998) found that asking participants to recall three (versus five) risky behaviors significantly increased participants' own vulnerability to HIV. However, perception of others' vulnerability was unaffected by this ease of retrieval manipulation. This finding is consistent with the current conceptualization – the perceived likelihood of engaging in risky behaviors is a form of case-specific information and therefore should be utilized more in the psychologically proximal (i.e., self) condition, as was found in that study. Similarly, and as noted earlier, the finding that the self-positivity bias is reduced by increasing the salience of easy-to-visualize behaviors (such as not bandaging a cut; Menon et al. 2002) also fits with a construal level perspective. Such behaviors are more concrete (visualizability being an aspect of concreteness; Chandran and Menon 2004) and therefore are more likely to influence risk assessments for self vs. others.

Visual Aesthetics and Product Design: Who, What, and When, They All Matter.

Amitava Chattopadhyay, INSEAD, Singapore
Antonios Stamatogiannakis, IE Business School, Spain
Gerald Gorn, The University of Hong Kong, Hong Kong

EXTENDED ABSTRACT

The visual appeal of a product is important. It can influence whether a product gets noticed as well as whether it is chosen (Hoegg and Alba 2007). Once purchased, a product's aesthetic appeal can continue to provide sensory pleasure over its lifetime (Bloch 1995).

The literature suggests several possible antecedents of visual appeal. Most of them pertain to properties held by the visual stimulus: symmetry (Reber 2002), contrast (Reber and Schwarz 2001), prototypicality (Martindale and Moore 1988), and unity (Veryzer and Hutchinson 1998).

Other authors suggest that aesthetic appreciation is context dependent. For example, the same picture was liked more when it was primed by a matched contour, versus by a mismatched contour (Reber, Winkielman, and Schwarz 1998). Still other research suggests that characteristics of the perceiver affect aesthetic preference. For example, the familiarity that someone has with the stimulus, (Cho and Schwarz, 2010) seems to increase liking. Despite the extensiveness of this research, evidence on how the characteristics of the product, the observer, and the context interact to affect aesthetic judgments remains scarce.

Reber, Schwarz and Winkielman (2004) reviewed research examining the above effects, suggesting that they all increase visual liking because they facilitate processing fluency. They focus on how the individual effects of each of these factors affects aesthetic response, and suggest that they increase aesthetic preference only when they facilitate processing.

This paper adds to the above research and makes three specific contributions. First, it examines aesthetic judgments from an integrative perspective and and using a perceptual fluency account argues that the person (who), the product (what), and the context (when?\) interact to determine visual preference,.

Second, it shows that objective properties of the stimulus (e.g., unity) affect aesthetic preference by facilitating visual processing, by showing that unity has a positive effect on preference when visual, but not verbal, processing resources are constrained. Third, it provides evidence for the substitutability of the sources of perceptual fluency. That is, effects of perceptual fluency on aesthetic judgments are similar regardless whether fluency is caused by the product, the person, or the context.

Object possessing properties such as symmetry, unity, etc. are easier for our visual system to detect and process, and for this reason they are perceived as pleasant (Reber et al. 2004; Ramachandran and Hirstein 1999). This article focuses on unity.

If unity increases aesthetic preference because it facilitates fluent processing, its effects should be most strongly observed when processing is constrained. Under such circumstances the superior ability of the perceptual system to detect and process unity should lead to fluent processing for unified objects but not for non-unified objects. On the other hand, unconstrained processing should be able by itself to lead to processing fluency, even when unity is violated.

In addition, we predict that the effect of unity on aesthetic evaluations will be more positive when visual, but not verbal, processing capacity (Baddeley 1992) is constrained. That is, unity should increase aesthetic preference by making "perceptual" processing fluent (Reber et al. 2004). Finally, we predict that the above effects should be moderated by the observer's inherent ability (Ekstrom et al. 1976)

and preference (Childers, Houston, and Heckler 1985) for visual processing. When these characteristics are low, visual processing should be even more difficult, and thus the role of unity more important.

In two studies we test the prediction that the extent to which unified designs are preferred to non-unified ones depends on the interaction of the load type (visual vs. verbal) with the individual's inherent ability and willingness to process visually. Both studies use a 2 x 2 x 2 factorial design with unity (satisfied vs. not) and product replicate as within participants factors, and load (verbal vs. visual) as a between participants factor.

Load was manipulated by having participants to remember some abstract information (e.g., price and delivery method) about a table (verbal load) versus concrete and visualizable aspects (e.g., shape and number of legs) of a table (visual load). These were pretested to be equal in difficulty. Then participants were asked to choose based on visual attractiveness between the unified and the non-unified versions of two products. Finally, we measured participants' inherent ability (study 1) and preference (study 2) for visual processing.

In the first study we used phone and refrigerator designs, taken from Veryzer and Hutchinson (1998), either satisfying unity or not. A logit analysis revealed the predicted significant load x visual processing ability interaction effect on choice of unified designs. The unified designs were more likely to be chosen by participants low in visual processing ability, when they were under visual, but not verbal load.

In the second study we used the designs of a clock and a vase, either satisfying unity or not. A logit analysis revealed the predicted significant load x visual processing preference interaction effect on choice of unified designs. The unified designs were more likely to be chosen by participants low in visual processing preference, when they were under visual, but not verbal load.

In conclusion, this article takes an integrative approach and suggests that the product, the person, and the context interact to affect visual preference. From a theoretical perspective, we document the specific role played by visual but not verbal processing resources in how unified and non-unified designs are processed and evaluated.. Moreover, we demonstrate the substitutability of the different sources of perceptual fluency; Perceptual fluency increases aesthetic preference regardless whether it stems from the object, the person, or the context. Finally, the results indicate that focusing on how these three factors in isolation affect visual preference, might be incomplete..

From a managerial perspective, designers and managers who wish to offer aesthetically pleasing products should consider the context and the customer characteristics on top of design properties, such as unity. To paraphrase Confucius: "Everything has beauty, but not everyone sees it." At least not always.

The Impact of Metacognition on Commitment for Attainment versus Maintenance Goals

Antonios Stamatogiannakis, IE Business School, Spain
Haiyang Yang, INSEAD, Singapore
Amitava Chattopadhyay, INSEAD, Singapore

EXTENDED ABSTRACT

Consumers and firms across many domains (e.g., charity, saving, exercising) use goals to regulate behaviour. For example, HSBC offers the "Premier Investor Savings" account, which requires the maintenance of a $25000 minimum balance, but at the same time offers higher interest rates with higher balances.

Depending on the relation between the actual and the desired state of the goal, goals can be classified as either attainment or maintenance goals. Attainment goals are those for which the actual state differs from the desired state (e.g., increase your balance). Maintenance goals are those for which the actual and the desired states match, and need to remain matched (e.g., maintain your balance; Stamatogiannakis, Chattopadhyay, and Chakravarti 2010).

Given the mixed use of these two goal types, it is surprising that we know little on how they compare with each other. Recent research is covering some of this gap. First, people tend to strive for better states when they focus on what they need to do, but they are satisfied with the present state when they consider what they have already done (Koo and Fishbach 2010). Second, modest attainment goals are perceived as easier than objectively easier maintenance goals (Stamatogiannakis et al. 2010). As a result, they are also more attractive (Stamatogiannakis, Chattopadhyay, and Chakravarti 2011). Finally, matching attainment goals with promotion focus and/ or maintenance goals with prevention focus increases outcome evaluations (Brodscholl, Kober, and Higgins 2007).

The current research examines the complex effects of metacognitive experiences (Schwarz 2004) on consumers' commitment to the two types of goals (Kruglaksi et al. 2002). Our findings make several contributions.. First, they show that, as people draw on their subjective experience when making an evaluative judgment (Wänke, Bohner, and Jurkowitsch 1997; Schwarz 2004), perceived goal difficulty, and thereby goal commitment, are affected by how easy or difficult strategies for success are generated. This generation is particularly difficult for maintenance goals (Jiraporn and Desai 2011). Therefore, we predict that a maintenance goal will become more attractive when strategy generation is made easy (e.g., by asking people to generate only one strategy) versus when it is made hard (e.g., by asking people to generate five strategies). Finally, as success strategy generation is relatively easy for attainment goals (Jiraporn and Desai 2011), the attractiveness of these goals will not be affected by the number of strategies that have to be generated, within the range studied in this research (i.e., 1 vs. 5 strategies). We test these predictions in study 1.

After examining the effects of perceived ease of strategies generation, we turn to another metacognitive experience related variable, increased accessibility; Increased accessibility improves processing fluency of related constructs and thus positively impacts preference for such constructs (Schwarz 2004). Specifically, we show that the commitment for the two goal types is dependent on the accessibility of different self-construals. Independent and interdependent orientations coexist within each person (Markus and Kitayama 1991), and they can be primed by contextual cues (Maddux et al. 2010). Independent self-construals emphasize values such as seeking personal achievement, improving individual status, and being distinct and unique (Markus and Kitayama 1991). Thus, they are congruent with attainment goals. Interdependent self-construals, however, emphasize values such as maintaining social relationships, conforming to others, and not standing out (Markus and Kitayama 1991). Thus, they are congruent with maintenance goals. Given that increased accessibility improves processing fluency of related constructs (Schwarz 2004), when independent (interdependent) aspects of self-construals are made more accessible by the situation, people are likely to see attainment (maintenance) goals more favorably. We test these predictions in study 2.

Third, and importantly, the above predictions are tested with goals that are important for the participant, rather than with imaginary goal scenarios.

Experiment one uses a 2 x 3 between participants design. Participants were recruited for two proofreading tasks, lasting three minutes each. After they have completed the first task, some participants were assigned a maintenance goal (i.e., find at least an equal number of mistakes in the second task) and some an attainment goal (i.e., find at least one more mistake in the second task). Further, some participants had to list 1 strategy that would help them achieve their goal, some had to list 5 such strategies, and some did not have to list any strategies. As expected from past research (Stamatogiannakis et al. 2011), attainment goals were more attractive than maintenance goals in the control (0 strategies) condition. In addition, as strategy generation is easy for attainment goals (Jiraporn and Desai 2011) the number of strategies manipulation did not affect attainment goals. However, generating only 1 strategy made maintenance goals more attractive compared to the control condition, and as attractive as attainment goals. However, generating 5 strategies made attractiveness ratings relapse to the control condition levels, and less attractive than attainment goals.

Experiment two uses a 2 x 2 between participants design. Following Gardner, Gabriel, and Lee (1999), we primed independent (interdependent) self-construal by asking participants to read a text and clicking on singular (plural) pronouns such as I and myself (we and ourselves). Then they were asked to think about their favourite charity, and indicate any amount they would like to donate to it. After that, they were asked their willingness to pre-commit to donate exactly the same amount (a maintenance goal), or the same amount plus 1 cent (an attainment goal), a year from now. The priming x goal type interaction was significant. People indicated greater willingness to pre-commit to an attainment (maintenance) goal when primed with an independent (interdependent) self-construal.

To conclude, this paper adds to previous literature comparing attainment with maintenance goals. It demonstrates that at the baseline, and when strategy generation is difficult, attainment goals are more committing than maintenance goals. However, the two goal types are equally committing when strategy generation is easy. Moreover, attainment (maintenance) goals are more committing when an independent (interdependent) self-construal is accessible. Thus, commitment for the two goal types is context dependent, and is affected differently by meta-cognitive experiences.

Small Change: The Subjective Valuation of Coins and Bills

Eric Dolansky, Brock University, Ontario

EXTENDED ABSTRACT

According to the official website of the U.S. Mint, the U.S. treasury would save $500 million per year if individuals used one-dollar coins rather than bills. As a result, on several occasions in the past, the U.S. mint has issued dollar coins, most recently in 2007. None have proven to be very popular (Unser, 2009). So what is preventing Americans from adopting dollar coins?

Individuals tend to exhibit biases when valuing money, despite the explicit denomination of the coin or bill. Mishra, Mishra and Nayakankuppam (2006) found that individuals valued large-denomination bills more highly than an equivalent amount of money presented in smaller bills. Work by Alter and Oppenheimer (2008) indicates that familiarity of the money has an impact on how highly it is valued. A more recent finding ties denomination of money to self-control in spending (Raghubir and Srivistava 2009).

This research aims to extend previous findings by determining if individuals have a bias towards higher valuation of bills as opposed to coins. This topic has been mentioned in the relevant literature (Alter and Oppenheimer 2008; Mishra et al 2006; Raghubir 2006) as worthy of further exploration, however the idea has not been empirically tested. Raghubir and Srivistava (2009) incorporated coins vs. bills as a condition in one of their studies, but it was inconclusive.

In nearly every currency in the world bills are of a higher denomination than coins. This difference in objective valuation could have an impact on subjective valuation, as a representativeness bias (Kahneman and Tversky 1973). As such, coins would tend to be valued less than bills, even when the denominations are the same. It has also been found that people will take an instance and average it to its own category. Thus a coin would be valued to the average value in its category, which would be lower than the average for the bills category (Huttenlocher, Hedges and Bradburn 1990). This leads to the key hypothesis of this paper:

> Hypothesis 1   An amount of money presented in paper form (i.e. bill) will be valued higher than an equivalent amount of money presented in coin form.

To test this prediction, study 1 was conducted. Participants (n = 52) were given either one Trinidad and Tobago dollar bill or one Trinidad and Tobago dollar coin and were asked how much of each of nine inexpensive items (e.g. pencils, paper clips) they could buy with that money. Participants were also asked to estimate how many Canadian dollars they could purchase with the money.

Unfamiliar currency was used to eliminate the possibility that familiarity with the money was a cause for any differences found, as in previous research (Alter and Oppenheimer 2008). Participants were told that the exchange rate was approximately 1:1 (the real exchange rate is $6 TT to $1 CDN and would result in too little purchasing power for useful estimates) and were instructed that the purchase amounts they estimated should reflect costs in Canada. Participants were also asked how familiar they were with the currency prior to the experiment. Four participants were removed from the analysis because they were previously familiar with the currency.

Overall H_1 is supported: when all of the estimates are standardized, there is a difference between the objects purchasable with bills (1.34 standard deviations above the mean) than with coins (1.39 standard deviations below the mean, p = 0.096). The exchange valuation prediction is more conclusive: participants given coins

estimated they could exchange their $1 TT for $0.798 CDN and those given bills estimated $1.192 ($p$ = 0.02), despite being told that both the coins and bills were worth approximately $1 CDN.

Study 2 was planned to refine and extend this effect. Using the same methodology as study one, participants (n = 82) were recruited at Niagara Falls, Ontario with the intention of having nationality (i.e. Canadian vs. American) as a found condition. Because Canadian currency contains coins of higher value (up to $2) than American currency does (only up to 25 cents), it was expected that the difference between the values ascribed to coins and bills would be bigger. Specifically:

> Hypothesis 2   The effect hypothesized in H1 is moderated by country of origin; the higher the value of coins in a country, the smaller the difference in valuation of coins and bills by those living in it.

The results from study two support this hypothesis. There is a significant interaction between form of money (coins vs. bills) and country of origin for both the total items exhibited an interaction (F = 6.45, p = 0.013), as well as the currency exchange question (F = 16.02, p < 0.001).

This work provides insight into how individuals value money and implications for research, management, and policy. Policy implications are the most salient here, as it is possible that a shift from bills to coins for a particular denomination (e.g., one dollar in the U.S.) could have an impact on valuation of money overall, as individuals ascribe less purchasing power to the coin than to the bill.

The Robin Hood Effect: When High-Level Construals Lead to Immoral Behaviors for the Greater Good

Jessica Rixom, University of Utah, USA
Himanshu Mishra, University of Utah, USA

EXTENDED ABSTRACT

Moral principles (e.g., cheating is wrong, donating is good) can help guide decisions throughout life. Recent research on construal-level theory (CLT; Trope and Liberman 2003) in a moral domain has suggested that these general moral principles act as high-level, abstract constructs. When events are construed at high levels (as opposed to low levels), there is an increased reliance on these moral principles for guidance. For instance, with higher construal levels, immoral acts were judged more harshly and moral acts more virtuously, even when presented with mitigating information (Eyal, Liberman, and Trope 2008). Similarly, it has been shown that people are more cooperative (Sanna et al. 2009) and more willing to help by answering a survey (Agerström and Björklund 2009) when a high-level as opposed to low-level construal is activated. In sum, previous research suggests that when faced with a single moral decision, consumers with high-level relative to low-level construals avoid behaviors that violate moral principles and engage in behaviors that support moral principles.

However, not all moral decisions occur in isolation. Consumers sometimes encounter situations in which violating one moral principle directly enables additional support for another moral principle. While past work on CLT explored events favoring a single moral principle, we investigate situations that pit immoral acts against moral acts. In these situations, we find that people with a high-level construal are willing to violate moral principles in order to increase support for a greater cause, but not solely for personal gain. Specifically, when high-level construals are activated, people are uncooperative in order to help a charity (study 1) and while they will not lie for themselves alone, they will lie to help the less fortunate or to withhold help from wrongdoers who threaten the well-being of others (study 2). We also find that when a low-level construal is activated, people are willing to engage in immoral behaviors for personal gain, with less regard for the overall impact. We term the use of immoral acts by people with a high-level construal for the sake of helping the greater good, the Robin Hood effect.

Study 1 demonstrated the basic effect. Participants were primed with either a high or low-level construal (Freitas, Gollwitzer, and Trope 2004). Then, they played a computer-based fishing cooperation game (Bargh et al. 2001; Sanna et al. 2009), purportedly with someone in another room. Real money was earned for each fish kept. Participants earned money for themselves or a charity, depending on the condition to which they were randomly assigned. In all conditions, the "other participant" earned money for themselves. To promote cooperation, if the fish population dropped too low, then all profits were confiscated. Consistent with previous literature, when earning for themselves, high-level relative to low-level construals were more cooperative (kept fewer fish). However, we find that when earning money for a charity, high-level construals were less cooperative (kept more fish). Said differently, a high-level construal led to uncooperative behavior when doing so meant that the greater good would benefit.

In study 2 we used a dishonesty paradigm adopted from work by Mazar, Amir, and Ariely (2008). Participants solved puzzles and were then primed with a high-level or low-level construal (Freitas et al. 2004). Next, they were asked to indicate how many puzzles they solved correctly so they could be paid for their performance (a quarter per correct answer, up to $5). The instructions varied by condition. In one payment condition (the benchmark), lying was not possible because the researcher graded the answers. Lying was possible in the other conditions because participants graded their own answers, destroyed the answer sheets, and indicated the number correct on a separate payment form. When the average that participants claimed to solve correctly was significantly lower or higher than the benchmark, lying was inferred.

Consistent with past work, those with high-level (low-level) construals acted morally (immorally) and did not (did) lie for personal gain. In the other two payment conditions, participants read that $5 was set aside and they would earn a quarter for each correct answer with the remaining, unearned money donated to charity. Thus, claiming few (many) correct answers resulted in larger (smaller) donations. The charity either granted wishes to ill children (good charity) or paid legal expenses for companies charged with environmental damage (bad charity). In both conditions, participants with high-level construals lied about the number of correct answers. When the charity was good, participants with high-level construals underreported the number correct. That is, they acted immorally, lied, and hurt themselves financially to ensure larger donations to the good charity. Donations would be made even without lying but they underreported so more would be donated. Conversely, for the bad charity, participants with high-level construals lied by overreporting the number correct. They were immoral, lied, and gained financially in order to reduce the donation to a charity that harms the greater good. When deception was possible, people with low-level construals consistently lied by overreporting the number correct to the same extent, regardless the decision's impact.

The findings add to the research on construal level's impact on decision-making by demonstrating that activating high-level construals do not always lead to adherence to moral principles. Instead, the Robin Hood effect shows that high-level construals can lead to immoral behaviors when violating moral principles benefits the greater good. This work also provides some insight into the day-to-day acts of dishonesty that one may justify in order to help the greater good to more extreme issues such as eco-terrorism in which environmental extremists attempt to advance their notion of a greater good (protect further environmental damage) by committing immoral acts (vandalism) toward companies and individuals.

Indulging and Proud of it:
Emotional Responses to Reason-Based Indulgent Consumption

Francine Espinoza, European School of Management and Technology, Germany
Heather M. Johnson, University of Maryland, USA
Yuliya Komarova, Fordham University, USA

EXTENDED ABSTRACT

While consumers may feel mixed emotions following indulgent consumption (e.g., feeling the pleasure of indulgence and frustration for having succumbed to temptation; Ramanathan and Williams 2007), previous research has primarily examined the role of negative emotions emerging from indulgent behavior (e.g., guilt and regret; Kivetz and Simonson 2002). Pride is known to be a powerful specific emotion that affects consumer behavior (Griskevicius, Shiota, and Nowlis 2010; Louro, Pieters, and Zeelenberg 2005; Williams and DeSteno 2008) and yet to date, pride has only been examined as an outcome of avoiding indulgence (Mukhopadhyay and Johar 2007). Given that consumption of luxury products is often marketed as a source of positive emotions (Twitchell 2003), it is important to understand conditions under which consumers may also feel pride after indulging and what downstream consequences such positive emotions can have on evaluations of the luxury product itself.

Although recent research suggests that, contrary to consumers' intuition, indulging with or without a reason does not affect the level of enjoyment (Xu and Schwarz 2009), most researchers agree that enjoyment (basic emotion) and pride (self-conscious emotion) are not the same. Pride is a self-conscious emotion associated with self-achievement; pride emerges after deliberative processing (Roseman et al. 1996, Giner-Sorolla 2001) and from appraisals of one's behavior vis-à-vis a social standard (Lewis 2004; Mascolo and Fischer 1995). Consumers compare the perceptions they hold about themselves (e.g., I am a controlled and frugal individual; I am spontaneous and impulsive) with the situation (e.g., indulging with or without a reason), and pride elicits when these two aspects are congruent (Tracy and Robins 2004). Because having a reason to indulge (I am indulging because I am rewarding myself) is more likely to be congruent with high self-control personality aspects (e.g., I am a controlled and frugal individual, I think through all the alternatives before acting), we predict that high (vs. low) self-control consumers will experience pride when they have a reason to indulge.

In our first study, 135 females were asked to imagine that they bought an expensive dress. They were either given a reason to indulge (reason condition) or not (no reason condition). In the justified condition, participants read that by buying another item they could get a discount on the total purchase, whereas no such information was provided in the unjustified condition. Participants reported the extent to which they felt proud and how satisfied they were with the purchase, each with two items (all r > .71, p < .05) using 7-point scales. We measured self-control using a short self-control scale (Tangney, Baumeister, and Boone 2004). As predicted, regression results revealed a significant interaction between reason and self-control on pride (β = .31, SE = .11, t = 2.87, p < .01) and on satisfaction (β = .21, SE = .10, t = 2.22, p < .03). A spotlight analysis at 1 standard deviation above the mean suggests that high self-control consumers feel more proud (β = .45, SE = .15, t = 2.92, p < .01) and are more satisfied (β = .30, SE = .14, t = 2.18, p < .03) when they have a reason to indulge versus when they do not. A spotlight analysis at 1 standard deviation below the mean suggests that low self-control consumers do not seem to change their emotional response as a function of having a reason to indulge (all p >.1). Mediation analysis further show that when pride was inserted as a criterion in the hierarchical regression predicting

satisfaction, pride was significant (β = .23, SE = .08, t = 2.94, p < .01) but the interaction became non-significant (β = .01, SE = .08, t = .17, p > .86, Sobel z = 2.05, p < .05).

Study 2 replicated these results (N = 70, 41.4% male) with a different product (jeans), a different measure of self-control (consumer spending self-control, Haws and Bearden 2010), and while asking participants to recall a reason, which increases the validity of the study given that episodic recall is likely to elicit the same emotions experienced in the actual situation (Xu and Schwarz 2009).

Study 3 (N = 111) used a 3 (no reason vs. consolation vs. reward) between-subjects design. We adapted the manipulations developed by Xu and Schwarz (2009) to distinguish between two types of reason to indulge. Consumers may indulge to console themselves (e.g., after getting a very bad grade in a course) or to reward themselves (e.g., after getting a very good grade). Given that pride is linked to appraisal of success in situations (Higgins et al. 2001; Lewis 2004), we predict that participants will feel proud after indulging more so when they are rewarding themselves than when they are consoling themselves. A regression analysis revealed that reward (β = 1.36, SE = .40, t = 3.41, p < .01) and the interaction between reward and self-control (β = .96, SE = .41, t = 2.33, p < .03) predicted pride. We also found an effect of reward (β = 1.64, SE = .47, t = 3.53, p < .01) and an interaction (β = .94, SE = .48, t = 1.96, p < .05) on satisfaction. Spotlight analyses were consistent with studies 1 and 2, suggesting that high self-control consumers feel more proud (β = 2.32, SE = .50, t = 4.69, p < .01) and more satisfied (β = 2.21, SE = .57, t = 3.85, p < .01) when they indulge to reward themselves as opposed to when they indulge without a reason. Further, pride significantly mediates the effect of reward and the effect of the interaction on satisfaction (Sobel z = 2.28, p < .05).

We contribute to research on affect and self-regulation by exploring conditions under which positive, self-conscious emotions such as pride may emerge after indulgence and influence post-purchase judgments. Our findings also qualify previous research by showing that having a reason to indulge produces different emotional experience and post-consumption judgments when we consider how reasons interact with consumers' level of self-control.

Can Imitation by Private-Label Brands Benefit Consumers and National Brands?
A Processing Fluency Perspective

Katie Kelting, University of Arkansas, USA
Adam Duhachek, Indiana University, USA

EXTENDED ABSTRACT

Extremely large assortments are prevalent in today's retail environment, leading to greater choice difficulty among consumers (for a review see Broniarczyk, 2008). While one may predict that the recent surge of private-label brands into the marketplace has seemingly contributed to such an effect, we posit and show the opposite. Specifically, the current research bridges together the assortment, private-label branding, and processing fluency literature to hypothesize how the mere presence of a particular type of private-label brand, specifically *copy-cat private-label brands* (hereafter CCPLBs) or store brands that blatantly imitate the packaging of popular national brands and display the text "compare to [national brand]" directly on their packaging, in a product assortment leads consumers not only to experience greater ease when making a choice from the assortment but also to evaluate their chosen national brand more favorably.

To theoretically support this proposed relationship between CCPLBs in an assortment and choice ease, we examine a specific type of processing fluency called *perceptual processing fluency,* which is defined as the degree of ease with which a target object can be identified on a subsequent encounter and therefore involves the low-level, data driven operations of processing the physical features of the target object (Schwarz, 2004). Being a form of processing fluency, perceptual processing fluency has been shown to affect evaluations. For example, Labroo, Dhar and Lee (2008) showed that when consumers are first primed with a visual identifier for a product (e.g., a dog), they subsequently process a product depicting the visual identifier on its packaging (e.g., a bottle of pet shampoo with a dog on its label) with greater ease and evaluate it more favorably relative to a product not depicting the visual identifier on its packaging (e.g., the same bottle of pet shampoo but without a dog on its label). Therefore, based on these findings and under the assumption that processing a CCPLB and its mimicked national brand is similar to processing the same product twice, we posit that the presence of CCPLBs in an assortment can enhance the perceptual processing fluency of consumers. Specifically, when CCPLBs are present in an assortment, we posit that the high degree of similarity shared between CCPLBs and the national brands that they mimic will not only attract attention as shown by prior research (Sayman, Hoch & Raju., 2002) but also enhance consumers' ability to identify the mimicked national brands in the assortment with greater ease and thus lead consumers to experience greater ease during choice as suggested by perceptual processing fluency theory.

In Study 1, we find support for this hypothesis with a laboratory experiment. In addition to obtaining support for our perceptual processing fluency theoretical perspective, we also examine and statistically eliminate an alternative explanation for the found relationship between CCPLBs in an assortment and choice ease, specifically that the presence of CCPLBs in the assortment may have caused consumers to erroneously see the CCPLBs as additional facings of the national brands in the assortment (e.g., Broniarczyk, Hoyer & McAlister, 1998) or to mentally categorize the various products in the assortment into two groups, such as national versus private-label brands (e.g., Mogliner, Rudnick & Iyengar, 2008). However, to further examine differences between our theoretical perspective and the perspective of this alternative explanation, we examine the moderating role of consumer knowledge and posit how CCPLBs in an assort-

ment may interact with knowledge of a product category to affect the processing fluency of consumers. Specifically, we posit two different effects depending on the theoretical perspective.

First, adopting the perspective alternative explanation which involves CCPLBs causing a perceptual reduction of assortment size/variety, it seems likely that it will be consumers with low (versus high) product category knowledge who will experience greater processing fluency when CCPLBs are present in an assortment due to prior research showing that consumers with low (versus high) knowledge are more prone to visual priming (e.g., Mandel & Johnson, 2002) and to using peripheral cues (e.g., Xu & Wyer, 2010). Therefore, under the assumption that these effects are similar to CCPLBs perceptually reducing the size and/or variety of an assortment, the alternative explanation predicts that it will be consumers with low product category knowledge who will experience greater feelings of ease when they choose a national brand product from an assortment that contains (versus does not contain) CCPLBs.

However, adopting a processing fluency theoretical perspective, we make a different prediction. Specifically, we believe that it will be consumers with high (versus low) product category knowledge who will experience greater processing fluency when CCPLBs are present in an assortment. Support for this notion is provided by considering the definition of consumer knowledge, which suggests that consumers with high (versus low) product category knowledge are more "fluent processors" of national brands in an assortment due to their greater familiarity and expertise (Alba & Hutchinson, 1987). Therefore, when CCPLBs are present (versus absent) in an assortment, we further believe that such brands will activate prior knowledge of the mimicked national brands in the assortment among high knowledge consumers and will help such consumers identify the mimicked national brands in the assortment with greater ease. In addition, due to our adoption of a processing fluency theoretical perspective, we further predict these effects will transfer to their evaluation of a chosen mimicked national brand from the assortment all via a processing fluency mechanism.

In Study 2, we examine and find support for these latter hypotheses via a 2 (assortment type: national brands only versus national brands plus CCPLBs) by 2 (consumer knowledge: low versus high) between-subject laboratory experiment. Specifically, we show that the presence (versus absence) of CCPLBs in an assortment leads high - not low - knowledge consumers to experience greater ease during choice and thus to evaluate their chosen national brand more favorably. Also, via a *LISREL* mediation model, we show that feelings of ease fully mediate the relationship between assortment type and evaluation of the chosen national brand for high knowledge consumers. Thus, the current research theoretically contributes to the processing fluency, private-label branding, and assortment literatures.

Why Exercise Makes Us Fat:
Compensation between Physical Activity and Food Consumption

Carolina O.C. Werle, Grenoble Ecole de Management, CERAG, France
Brian Wansink, Cornell University, USA
Collin Payne, New Mexico State University, USA

EXTENDED ABSTRACT

When people begin exercise programs they often report gaining weight instead of losing it (Time Magazine, 2009). One of the reasons why individuals may overeat after exercising might be related to calorie underestimation. Another reason may be related to rewarding the self through compensation for the hard time spent while exercising. This paper examines whether compensation through food consumption occurs and investigates a potential solution for these effects: being distracted while exercising.

The purpose of this article is to investigate specifically the relationship between exercising and food consumption – an important issue in the actual context of obesity prevention. Previous research suggests that the presence of a distraction alters the perception of the first action (Fillingim, Roth, & Haley, 1989; Karageorghis & Terry, 1997) and can impact subsequent evaluations, and decisions (Lerouge, 2009; Nowlis & Shiv, 2005; Shiv & Nowlis, 2004). Therefore, the presence or absence of distraction could be one of the keys to better understand the relationship between physical activity and food consumption.

We suggest that the presence of distraction in an initial exertion activity helps consumers to subsequently control themselves during food consumption leading to smaller food intake. Previous research shows that being distracted can be positive, increasing motivation and leading to better choices (Dijksterhuis, Bos, Nordgren, & Van Baaren, 2006; Sanders & Baron, 1975). Additionally, in the context of sequential behaviors (exercise – food intake), previous research suggests that when distracted individuals tend to feel less physical symptoms (like fatigue) associated with physical activity and better mood compared to not being distracted. Therefore, we posit that absence of distraction will result in individuals feeling more exertion (Kivetz & Zheng, 2006), thereby feeling more "licensed" (in search for a reward) and may be more prone to compensate (increasing subsequent food intake).

We further examine how people compensate. It is not clear if people will either compensate exercising in an indiscriminate manner (all types of foods) or in more selective manner over-consuming specific types of food (for instance, hedonic food). Research on hedonic versus utilitarian consumption indicate that hedonic food, specifically, serves as reward (Khan, Dhar, & Wertenbroch, 2005). We thus propose that compensation will be selective and directed to hedonic food (and not a generalized overconsumption). Furthermore, we propose that these effects will be stronger for consumers that are highly conscious of what they eat.

Through two experiments using realistic settings we investigate: 1) whether the presence of a distraction during the physical activity (action 1) influences the subsequent amount of food consumed (action 2); 2) whether the compensation is indiscriminate or selective, and 3) which individuals are more vulnerable to such compensation effects

Study 1 used a one factor, three-level between-subjects design with three conditions: distraction while engaging in physical activity, no distraction, and control – no physical activity). Ninety-five (95) female participants (mean age = 44.52 years old and SD=10.59) were randomly assigned to one of the three conditions. The study was divided in two parts: activity and lunch. Participants in the *no distraction* condition were told that the activity was exercising—

walking through a route in the campus—and that this part of the study would take approximately half an hour, and that after that lunch would be served. In the *distraction* condition, participants followed the same walking route, but they did so while performing a fun activity: listening to music. When the participants arrived from their walk, they served themselves lunch out of a buffet composed of pasta with meat, green beans, bread, and a choice of two desserts, apple sauce and chocolate pudding. Portions served were unobtrusively weighed while participants served themselves drinks. When participants finished their lunches, they answered a questionnaire about their lunch experience and were thanked and dismissed.

Results indicate that, in the *no distraction* condition, participants felt more tired ($M_{distraction}$ = 3.48 versus $M_{no\ distraction}$ = 4.79, $F(55,1)$ = 3.85, p=.04) after the physical activity than those in the *distraction* condition. In the same sense, individuals in the *distraction* condition were in a more positive mood after exercising than those in the *no distraction* condition ($M_{distraction}$=7.91 versus $M_{no\ distraction}$ = 7.12, $F(55,1)$ = 7.19, p=.01). Results also indicate that participants in the *no distraction* condition who chose chocolate pudding as a desert served themselves 35% more desert than participants in the *distraction* condition who made the same choice (calories served - chocolate pudding $_{no\ distraction\ condition}$ = 135.30; calories in the chocolate pudding $_{distraction\ condition}$ = 100.10; *p*=.037). Finally, also as expected, there were no statistical differences across conditions in the total amount of calories served or consumed during the experiment. Together, these results indicate that participants in the *no distraction* condition compensated for exercising but this compensation was selective and exclusively directed to hedonic foods.

In Study 2 we used a different kind of distraction—sightseeing—and we also explored individual differences in compensation effects. We used a one factor, two-level between-subjects design, presence versus absence of distraction during physical activity as the manipulated factor. Fifty-six (56) participants were assigned to one of the two conditions. The instructions and the walking route was the same as in study1, except that in the distraction condition, participants were told that the activity was a campus visit (sightseeing). When the participants arrived from their walk, as a thank-you for their participation, we offered them a sweet snack (M&M's) which was to be poured into zip-loc bags. Results show a significant main effect of the manipulated factor on the amount of M&M's served, such that participants in the *no distraction* condition took more M&Ms ($M_{no\ distraction}$ = 372.3 calorie, SD = 391.9) than those who were in the *distraction* condition sightseeing ($M_{distraction}$ = 166.2 calorie, SD = 222.9; $F(1,45)$ = 5.06, p = .029). These effects were stronger for females and for individuals that are highly conscious of what they eat.

While diet and exercise recommendations seem relatively straightforward, many find it extremely difficult to comply. Our results demonstrate that being distracted during the physical activity can have positive consequences in terms of subsequent food decisions. It avoids compensation that is mainly directed towards hedonic foods.

All Metaphors in Advertising are not Created Equal:
Influences of Product Type and Need for Cognition

Chun-Tuan Chang, National Sun Yat-sen University, Taiwan
Ching-Ting Yen, National Sun Yat-sen University, Taiwan
Ting-Ting Chen, National Taiwan University, Taiwan

EXTENDED ABSTRACT

Metaphors, as one of the rhetorical devices, are the very heart of the modern communication form in advertising. Instead of using literal and direct claim that a product possesses some attribute or benefit, metaphors are attention getting, arousing, affect inducing, and memorable. This article focuses on pictorial metaphors and proposes two types of metaphor: explicit vs. implicit. The difference between explicit and implicit metaphors depends on whether or not the product's likeness is incorporated into the metaphoric picture. An explicit metaphor is clear about the subject, and the viewer can clearly see the product for what it is in the pictorial metaphoric display. In an implicit metaphor, the product is not in the metaphoric illustration and may be depicted in a less prominent place in the ad, such as the bottom corner. The viewer must make an inference as to how the product fits into the theme of the metaphor.

This article contributes to the evolving stream of research by comparing the potential impacts of two metaphors and identifies boundary conditions that influence the effectiveness of metaphor advertising. To be specific, this research demonstrates that the selection of explicit and implicit metaphor could be influenced by two variables: product type and need for cognition (NFC). Although these two variables are identified as influential in metaphor advertising in previous research, they were examined separately and were used to compare with a non-metaphor condition. A 3 (ad type: implicit metaphor vs. explicit metaphor vs. non-metaphor) X 2 (product type: hedonic vs. utilitarian) X 2 (NFC: low vs. high) between-subjects experiment was thus designed wherein individual differences in NFC were measured. Participants were randomly assigned to one of the conditions above. After successful manipulation checks, a series of analysis of variance were conducted to examine proposed hypotheses. The results indicate that focusing on the comparison between two types of metaphor without considering other factors may be overly simplistic. Four observations are noteworthy.

First, that the effects of metaphor type are contingent on individual differences in NFC. This construct delineates the boundary conditions for the metaphor on persuasion. Some metaphor types work better on participants with high NFC. However, these differences did not emerge for participants low in NFC. This is consistent with previous advertising research (e.g., Hautvedt, Petty, and Cacioppo, 1992) which indicated that low-NFC individuals' attitudes in response to a persuasive message are less influenced by the message-relevant cues.

Second, in groups of consumers with high NFC, a strong interaction between product type and metaphor type is observed. This study shows systematic effects on consumer responses by comparing two different product types: hedonic vs. utilitarian. The data from the current research lend support for resource-matching theory. Consumers with high NFC show a more positive attitude and higher purchase intentions in response to an explicit metaphor than an implicit metaphor when a product's utilitarian value is highlighted. Ads using explicit metaphors help high NFC recipients to better structure and more easily organize the message information when the advertised product is utilitarian. The explicit execution of the product image fits into the rational appeal while the pleasure of the metaphoric processing provides sufficient interest to arouse emotion.

Third, an advantage of implicit metaphor on hedonic product promotion is found. Ads using implicit metaphors provide more opportunities for imagination, which fit into the nature of hedonic products. Therefore, ads using implicit metaphors are more likely to arouse favorable attitudes toward the advertised brand and higher purchase intention for hedonic products.

Fourth, metaphor type does not matter to low NFC individuals, and only the superior effects of hedonic over utilitarian product are found. This finding is consistent with past research suggesting that low NFC individuals may be more prone to the influences of symbolic cues and avoid elaborative processing (Martin, Sherrard, and Wentzel, 2005).

The obvious implication of the findings for academic researchers is that moderating variables must be considered in the study of the effectiveness of metaphor in advertising. The experiment reported here offers insight for when different types of metaphor work. The findings substantiate the notion that the perceptual difference between explicit and implicit metaphors is significant for certain individuals but not for others, and product type moderates the effects of metaphor type.

The findings also have important implications for the practice of advertising and marketing communication. Consideration of these two types of metaphor will prove valuable to advertisers that use—or are considering using—metaphors. In terms of message strategy, an ad message should, of course, convey product value. The current investigation provides guidance for practitioners to place the metaphor in the right place in the ad once the product type is determined. In addition to product type, another important contribution of this research is the introduction of NFC into the investigation of metaphor advertising and its potential usefulness as a moderator of metaphor advertising, although cognition has been identified as influential in recent literature (Lagerwerf and Meijers, 2008). Clearly, advertisers who would like to employ metaphors in their ads cannot administer NFC scales to members of their target audience. However, such difficulty does not diminish the importance of understanding of how NFC affects metaphor processing. One can argue that the individual differences in NFC is tantamount to unplanned market segmentation, and that advertisers may improve advertising results through judicious ad placement because audiences with different degrees of NFC may have different media habits. For example, certain technical publications and information/news television programs may attract audience groups with NFC more than *cognitively* undemanding *programs (e.g., gossip magazines or* comedy shows). *S*uch de facto market segmentation may offer potential payoffs to advertisers who strive to discover and take advantage of the diversity of audience characteristics.

This research suggests that not all metaphors are created equal, at least in terms of metaphoric type. When seeking the advantages that two types of metaphors (explicit and implicit) provide in obtaining and sustaining attention, advertisers should consider product type and individual differences in NFC. Such knowledge is useful to advertisers who are interested in maximizing the impact of their advertising dollars.

Does Power-Distance Influence Consumers' Preference for Luxury Status Brands?

Youngseon Kim, University of Texas at San Antonio, USA
Yinlong Zhang, University of Texas at San Antonio, USA

EXTENDED ABSTRACT

Consumers' preference for luxury status brands (brands such as Rolex or Louis Vuitton associated with social prestige and status) is a pervasive and growing global phenomenon.   Despite that, few theoretical studies have investigated this topic in cross-cultural contexts (Wiedmann, Hennigs, and Siebels 2009). The current research aims to examine the role of cultural orientation, more specifically, power-distance in consumers' preference for luxury status brands.

Two major views of why consumers prefer luxury status brands have been suggested in the literature. One view proposes that consumers whose social status issues are salient tend to use luxury status brands to ascertain their social status (Mandel, Petrova, and Cialdini 2006; Miller, McIntyre, and Mantrala 1993). Luxury status brands, due to their exclusively high social status, can be used for this purpose (e.g., Amaldoss and Jain 2005). This status salience view suggests that any factors to make consumers aware of their social status will lead them to more likely prefer luxury status brands to standard brands. A second view proposes that consumers use luxury status brands to compensate for their lack of social status. For example, Rucker and Galinsky (2008) found that people with low power status tend to engage in compensatory consumption by preferring products associated with social status to products without such an association. The compensatory consumption hypothesis proposes that any factors to make consumers feel that their social status is relatively low can make consumers prefer luxury status brands to standard brands.

Power distance has been defined as the degree of power disparity that people in a culture regard as normal (Hofstede 1980; Oyserman 2006; Triandis 1995). High power-distance cultures facilitate a norm that everyone should have a defined place within the social order. In contrast, in low power-distance cultures, the norm is to maintain and respect the equality inherent in social interactions. Acceptance of power disparity tends to remind cultural members of their social status constantly to act properly (Triandis 1995). This practice may make the status concept salient to them. Consumers with status-salient mindset may prefer luxury status brands to standard brands, for the former brands can help them to ascertain and enhance their social status. Thus, based on the status salience view, consumers with high power-distance would show a stronger preference for luxury status brands (vs. standard brands) than those with low power-distance. If this individual tendency holds, countries with high-power distance (Hofstede 1980, 2001; Oyserman 2006) should show the similar pattern compared to those with low-power distance. So we hypothesize that:

Hypothesis 1a   *Countries with high power-distance tend to prefer luxury status brands to standard brands more than those with low power-distance.*

It has been well documented that typical Asian cultures have higher power-distance than the American culture (Hofstede 1980, 2001; Oyserman 2006), accordingly:

Hypothesis 1b   *Asian consumers, compared to American consumers, are more likely to prefer luxury status brands to standard brands due to Asians' power-distance being higher than American's power-distance.*

The compensatory consumption view provides a different prediction on the relationship between power-distance and luxury status brands. Based on the very definition of power-distance (Hofstede 1980, 2001; Oyserman 2006; Triandis 1995), when faced with relatively low social status situations, people from high power-distance culture can accommodate these social disparities easily and do not feel the need to compensate for their relatively low social status. In contrast, consumers from low power-distance cultures, when faced with more social disparities, may feel the need to compensate for their low social status through luxury status brand consumption. Accordingly:

Hypothesis 1c   *Countries with low power-distance show a stronger preference for luxury status brands compared to standard brands than countries with high power-distance.*

Study 1a was a correlation study based upon the dataset from a 2007 Nielson study in which we included country scores on power-distance, individualism, annual income growth, Gini-Index. Countries with higher-power distance scores showed stronger intention to buy luxury status brands than those with lower-power distance. This result supported hypothesis 1a, not hypothesis 1c. Study 1b was a survey of consumers in which attitude toward luxury status brands and power-distance were measured. The survey was conducted in the U.S. and an Asian country. Asian consumers showed a more favorable attitude toward luxury status brands than their American counterparts. A mediation test showed that the effect of country difference on preference for luxury status brands was partially mediated by power-distance.

Based on the knowledge applicability principle (Aaker 2000; Higgins 1996), the power-distance effect will be evident only if consumers see the status concept is applicable for their decision on luxury status brands. Therefore, the power-distance effect will be stronger for consumers believing in the efficacy of engaging in luxury status brands (buying status belief). Formally:

Hypothesis 2   *The effect of power-distance on consumers' preference for luxury status brands will be significant for consumers who believe that buying luxury status brands can enhance their social status, but not for those who do not hold such a belief.*

If the effect of power-distance on consumers' preference for luxury status brands is due to the salience of social status, the effect should be moderated by factors affecting consumers' need for social status, self-worth. If consumers' need for self-worth is satisfied, they tend not to enhance their social status through luxury status brands, even if they see the efficacy of buying luxury status brands. Therefore:

Hypothesis 3   *When consumers' self-worth is relatively low, the effect of power-distance on consumers' preference for luxury status brands will be more significant for strong than for weak buying status belief; when consumers' self-worth is relatively high, the effect of power-distance on consumers' preference for luxury status brands will not be influenced by buying status belief.*

Study 2 was a 2 (power-distance prime: high vs. low) 2 (buying status belief: strong vs. weak) between-subjects design. The first factor was manipulated, and the second was measured with the scales from Eastman, Goldsmith, and Flynn (1999). Consistent with hypothesis 2, we found that the effect of power-distance on preference for luxury status brands was significant for strong but not for weak buying status belief.

Study 3 was a 2 (power-distance prime: high vs. low) x 2 (buying status belief: strong vs. weak) x 2 (self-worth: relatively high vs. relatively low) between-subjects design. All factors were manipulated. The difference in preferring luxury status brands between high and low power-distance was contingent on buying status belief. However, this was qualified by self-worth. Specifically, the 2-way interaction between power-distance and buying status belief was significant when self-worth was relatively low, but not significant when self-worth was relatively high. Further, we also tested the mediating role of status salience in the effect of power-distance on preference for luxury status brands. The simple mediation test showed that the effect of power-distance on the preference for luxury status brands was mediated by status salience, not by compensatory need for social status.

Our cross-cultural results show that power-distance has a systematic impact on consumers' preference for luxury status brands and support the status salience thesis but not the compensatory consumption thesis.

Medium Susceptibility: The Role of Implicit Theories in Consumer Choice

Meng-Hua Hsieh, University of Washington, USA
Shailendra P. Jain, University of Washington, USA

EXTENDED ABSTRACT

Chase Freedom credit cardholders receive five points for every dollar spent in quarterly bonus categories and one point for every dollar spent in other categories. The points presumably motivate consumers to opt to use their credit cards for everyday shopping. Research has examined how certain reward program elements, including effort, medium/points structure, and outcome, influence overall program performance (Bagchi and Li 2011; Hsee et al. 2003; Kivetz and Simonson 2002; van Osselaer, Alba, and Manchanda 2004). A well-documented finding is that consumers demonstrate a tendency to make extra effort to acquire more points even when additional points could not be used to acquire anything of substantial incremental value. This phenomenon is referred to as 'medium maximization effect' (Hsee et al. 2003). However, consumers have different dispositions so they may differ in their reliance on the medium when making decisions. Past research have shown that context effects are moderated by consumer level differences (Mourali, Böckenholt, and Laroche 2007; Zhu and Meyers-Levy 2009). This notion raises the prospect that consumer level differences may also moderate the medium maximization effect.

In our paper, we examine a boundary condition to the medium maximization effect relating to consumers' implicit theories. Indeed, while some studies examining reward programs' effectiveness have explored the impact of consumers' price sensitivity and temporal orientation on the type of rewards chosen (Kim, Shi, and Srinivasan 2001; Kopalle and Neslin 2003), no research to date has explored the effect of the interaction between reward points and consumer characteristics on decisions.

The wide-ranging influence of people's implicit theories on a host of phenomenon has been studied extensively in psychology. Those who subscribe to a belief in fixedness are called entity theorists while those who believe in change are termed incremental theorists (Dweck, Chiu, and Hong 1995a, b; Dweck and Leggett 1988). The role of implicit theories is understudied in marketing literature, with only a handful of exceptions. (Jain, Mathur, and Maheswaran 2009; Yorkston, Nunes, and Matta 2010). Dweck and her colleagues have published a substantial body of work in implicit theory domains like personality, intelligence, morality, and general world order. Our research introduces a novel domain extending implicit theory research and providing evidence that people's ideas of fixedness and malleability are extendible to the economic marketplace as well.

The theoretical premise for this paper's propositions is based on several recent works which demonstrate that entity theorists tend to be more outcome-focused and thus tend to make evaluations on the basis of the outcome. In contrast, incremental theorists focus more on the process and thus rely more on contextual information to make evaluations (Jain et al. 2009; Molden and Dweck 2006; Poon and Koehler 2006). Therefore, we expect that incremental theorists are likely to be more susceptible to a medium than entity theorists because a) incremental theorists are context driven and process focused, and b) medium is the contextual cue and captures the process that is inserted between effort and outcome.

Two experiments show that individuals who believe that the marketplace is changeable (incremental theorists) exhibit a reliance on the medium while those who believe that the marketplace is stable (entity theorists) do not. In study 1, we manipulated the implicit theory of economic marketplace by employing two fictitious scientific articles that argued either in support of the notion of the economic marketplace being fixed or being malleable. The results demonstrate that when a medium was present, incremental theorists chose a higher-effort option that garnered more points but a marginally less advantageous outcome over a lower-effort option that garnered fewer points but a superior outcome. In contrast, entity theorists' likelihood of choosing a higher-effort option was the same regardless of the presence or absence of the medium.

In study 2, the experimental design was a 2 (implicit theory: entity versus incremental) x 2 (medium: no points versus points) x 2 (implicit theory consistency: violation versus confirmation) full factorial design. Participants responded to an implicit theory of the economic marketplace scale. Next, we manipulated implicit theory consistency by exposing participants to scenarios about the test performance of a math person required to take a "year-long required course in English and expository writing" (Plaks, Grant, and Dweck 2005). Participants were subsequently asked to choose between two tasks, for which they would be rewarded with an airline ticket to a desired vacation destination. The results show that under theory confirmation, incremental theorists were more likely to choose a long task in the medium condition as compared to the no-medium condition, while entity theorists' likelihood of choosing a long task was invariant across the medium and no-medium conditions. However, under theory violation, entity theorists appeared to be susceptible to a medium.

The present research is the first to show a consumer level moderator of the medium maximization effect. Furthermore, we introduce a new type of implicit theory to literature – in the domain of the economic marketplace that is relevant to business and policy research. This has important implications for reward program design, marketing communications, and financial decision making.

Doing Privacy: Exploring the Nature of Consumer Privacy and Privacy Management Strategies

Jo En Yap, RMIT University, Australia
Michael B. Beverland, University of Bath, UK
Liliana L. Bove, University of Melbourne, Australia

EXTENDED ABSTRACT

"Privacy invasion is to the information economy what pollution is to the industrial economy – a social cost borne not by those who benefit from pollution, but by the rest of society" (Deighton 2005, 144).

In the context of marketing, the privacy debate is dominated by discussions about consumers' ability to control the collection, dissemination and use of their personal information (i.e., information privacy); and to a lesser degree, consumers' ability to control the type and volume of marketing solicitations into their daily lives (i.e., interaction privacy) (Goodwin, 1991; Jones, 1991; Smith, Milberg and Burke 1996). We believe these approaches, although valuable, are limited for a number of reasons. First, other relevant aspects of privacy found outside the domain of marketing have generally been overlooked. Second, the concepts of information and interaction privacy were conceived in the era of direct and database marketing; and focus primarily on top-down, one-way exchanges from organizations to current and/or prospective customers. Third, instead of reflecting what consumers perceive privacy to be, current meaning(s) of consumer privacy are primarily framed by practitioners, researchers and the media. As such, findings may not fully account for and differentiate between the myriad of technologically advanced privacy related issues experienced by consumers as they navigate through the social-interactive environment of the 21st century (Harper and Singleton 2001; Nguyen and Li 2010; Solove 2002). We believe that a bottom-up approach that produces insights into the ways in which consumers view privacy, and its various forms, would provide a more comprehensive understanding of the concept as it applies in contemporary consumer society. Therefore, the first objective of this study is to explore the nature of consumer privacy.

Furthermore, consumers have largely been portrayed as ignorant and passive players in the marketplace that submissively accept privacy violations and are unable to protect their privacy (Acquisti and Grossklags 2004; Milne 2003; Milne, Rohm, and Bahl 2004; Nehf 2007; Norberg, Horne, and Horne 2007; Sayre and Horne 2000; Spiekermann, Grossklags, and Berendt 2001). This portrayal is in contradiction with current findings of consumers actively exerting their influence and participating in the marketplace; as co-creators of value (Vargo and Lusch 2004) and engaged participants (van Doorn, et al. 2010; Verheof, Reinartz, and Kraft 2010). Therefore, the second objective of this study is to explore the ways in which consumers actively defend or "do" privacy.

To address our research objectives, we conducted image-elicited depth interviews on a theoretical sample of 23 informants; 13 women and 10 men aged between 19 and 60 years of age. Each informant was given a sketchbook and asked to collect and/or draw images that presented their thoughts, feelings and experiences about privacy. They were then asked to explain the significance of each image. Then, informants were given a folder that consisted of around 100 privacy-related images. Informants were asked to select images which resonated with their thoughts and stimulated their emotions; and comment on their selected images. The interviews ranged from one hour to two and a half hours in length, were audio taped and later transcribed. Interviews were analyzed in line with open, axial and selective coding.

Our findings highlight the socio-culturally embedded nature of consumer privacy; where the meaning informants ascribe to privacy–a state of sovereignty over one's personal domain–is shaped by the tension between the greater degree of personalization in all aspects of life and its paradoxical effect, feelings of impersonalization. It was found that three socio-cultural forces largely drive the personalization of life. These forces have been labelled: participation; greater good appeals; and shifting public-private boundaries.

Participation reflects the recognition that disclosure of personally identifiable information is fast becoming a prerequisite to gain access to the market, engage in social networks and live as a member of society. Greater good appeals to security, fairness and community welfare focus on the personal benefits derived from the greater good. Last, shifting public-private boundaries reflect the social trend of living one's life on display, the casualization of relations between people and the insistence of businesses wanting to form relationships with consumers.

As previously alluded, the personalization of life paradoxically engenders feelings of impersonalization. This polar opposite condition of impersonalization is reflected in fuzzy boundaries and the denial of the authentic self. For example, the multiple roles informants play in the course of their daily lives are increasingly difficult to keep separate and the relationship marketing practices of some firms exceed what would normally be considered as the commercial boundary. As such informants acknowledge a need to be more mindful of creating a carefully staged public persona, and thus feel that their sense of authentic self is denied.

This dialectic tension arising from an increased emphasis on the personalization of aspects of life and a greater sense of impersonalization experienced by informants drives consumers desires for privacy and results in consumers actively "doing" privacy through the use of several cognitive and behavioural strategies. These strategies are categorized as: withdraw, defend, attack and reconcile. Withdraw represents avoidance tactics that informants engage in to facilitate the goal of removing one's self from situations that may violate their privacy. Defend represents protective tactics that are largely concerned with proactively enacting and strengthening the barriers of informants' respective personal domains, thus 'minimizing damage'. Attack, represents offensive tactics that informants employ when confronted with a privacy related situation. These tactics are more direct and aggressive in nature. Last, reconcile can take the form where informants either convince themselves that privacy will prevail, or actively negotiate the conditions of disclosure with the requesting party.

In summary, by elucidating the 'what', 'when', 'why' and 'how' of privacy from the consumers' perspective, we offer a more comprehensive understanding of this concept as it applies in contemporary consumer society. Our findings highlight that consumers are active participants in the marketplace and engage in a number of strategies to achieve or maintain sovereignty over their personal domain. In doing so, we contribute to growing literature on customer creativity (Beverland and Farrelly 2010; Epp and Price 2008, 2009; Price 2008; van Doorn et al. 2010; Verheof et al. 2010).

Authenticity is in the Eye of the Beholder:
From Changes in Attitudes and Preferences to Placebo Effects

Hang Nguyen, University of Connecticut, USA
Kunter Gunasti, University of Connecticut, USA

EXTENDED ABSTRACT

Products marketed legally and manufactured by the firms owning the production rights of the brand using original ingredients, genuine parts, and raw materials have been referred to as authentic market offerings (Keller 2008). Inauthentic products, on the other hand, are fine copies of the authentic ones (Lai and Zaichkowsky 1999). They may range from compatibles (e.g., IBM compatible battery), imitations (e.g., imitation crab meat), and replicas (e.g., jewelry) to illegal counterfeits. The global market for inauthentic products exceeds $600 billion, eating up revenues of authentic brands and taking away over 750,000 US jobs every year (World Customs Organization 2004; Wilcox, Kim and Sen 2009). Due to extensive application of advanced technology, quality of some inauthentic products has reached the standards of authentic ones (Keller 2008) and for many consumer goods they are almost indistinguishable from originals (Howie 2010). Thus, it is very important to understand how consumers form their perception of product authenticity and how different cues affect consumers' judgments and choices of products.

Past studies on authenticity have focused on various dimensions, definitions, and conceptualizations of the notion (e.g., Beverland and Farrelly 2010; Beverland, Lindgreen, and Vink 2008; Brown, Kozinets and Sherry 2003; Gilmore and Pine 2007; Grayson and Martinec 2004). Recent research has examined consumers' motivations for consuming authentic and inauthentic products (Wilcox et al. 2009; Han, Nunes and Dreze 2010). Although it is widely accepted that consumers value authenticity, there has been no thorough empirical investigation about consumers' authenticity perceptions and to what extent it influences product judgments, purchase decision, and post-consumption behavior.

Consumers may form their perception of product authenticity via intrinsic cues (product exposures/experiences, actual product quality) and/or extrinsic cues (explicit messages, inconspicuous cues) provided by manufacturers and competitors. Using three empirical studies employing different product categories, we investigate the competing effects of authenticity cues on consumer attitudes, willingness to pay, choices, and consumption outcomes. Our studies systematically demonstrate that extrinsic cues play the major role in shaping consumers' authenticity perception, which in turn affects product attitudes, willingness to pay, choices and even consumption outcomes. Study 1 demonstrates that consumers develop lower (higher) attitude favorability and willingness to pay when a product is introduced as an inauthentic (authentic). Study 2 finds that an objectively inferior product with multiple authenticity cues is preferred over a clearly superior compatible counterpart. Finally, study 3 shows that even subtle cues such as packaging can affect perceived authenticity and lead to a placebo effect of product efficacy.

From a theoretical perspective, our research is the first empirical demonstration of the powerful effects of different authenticity cues and the perception of product authenticity on all stages of a consumption process, from product evaluation, purchase intent and decision making to post-consumption behaviors. The effects occur not only for luxury, well-known, but also less-known brands, from conscious to non-conscious levels. We consider this work as an important step toward developing a more comprehensive conceptual framework for consumption of authentic and inauthentic products. From a managerial perspective, our findings have significant implications for marketing managers and public policy makers. We found that even though consumers highly valued authentic products, they were mostly unable to distinguish them. This phenomenon thus creates many difficulties for legitimate manufacturers, especially when manufacturers of imitations may intentionally provide misleading authenticity information for consumers. Firms can evoke consumers' favorable attitudes and responses toward their products by providing authenticity information via extrinsic cues including subtle cues, and they may further elicit post-consumption satisfaction by creating and maintaining the perception of product authenticity.

Practice Consumption and Value Creation:
Advancing the Practice Theoretical Ontology of Consumption Community

Benjamin J. Hartmann, Jönköping University, Sweden
Caroline Wiertz, Cass Business School, City University London, UK
Eric Arnould, University of Wyoming, USA

EXTENDED ABSTRACT

How and in what ways do practices create value? Conceptual blind spots persist when it comes to understanding how value creation operates through practices in consumer behavior (Schau, Muniz, and Arnould 2009; Shove and Pantzar 2005; Warde 2005). Specifically, various forms of consumer collectives are considered sites of value creation that matter both to consumers and marketers (Cova 1997; Giesler 2006; Kozinets 1999; Mathwick, Wiertz, and De Ruyter 2008; Muniz and O'Guinn 2001), and this research suggests that it is through practices that they exert their value-creating effects (Schau et al. 2009). Because consumer researchers have equated practices with their performance, practice consumption and its role in value creation remains under-theorized. Addressing this theoretical gap, we conceptualize and empirically analyze the consumption dimension of practices through multi-method research conducted within an online gardening community. Thus, the aim of this project is to move beyond a purely performance-based theoretical ontology of practices and value creation to develop a framework that conceptualizes and integrates a consumption dimension into this theory.

Building on the conception of individuals as 'carriers of practice' (Reckwitz 2002) and practices as 'carriers of value' (Schau et al. 2009), we propose that the source of value lies not only in the performance of practices, but also in their consumption. This is particularly evident in the context of online community, where due to the archival and online setting, all practices that are performed are visible and in fact, consumers often perform them with an audience in mind. Thus, we argue that community practices must not only be performed, but also consumed in order to create value, that is, there are recipients or beneficiaries of practice performance.

Prior research implicitly addresses the consumption of practices, yet leaves it as an under-theorized element. We develop two families of practices based on their transitivity (Hopper and Thompson 1980): 1) socially *intransitive* practices in which the performance of a practice involves a non-human object; and 2) socially *transitive* practices in which the performance of a practice involves another human subject. The social transitivity of practices advances a definition of practice consumption. In order to develop our theorizations on the consumption of (community) practices, we use this conceptualization to revisit and extend the community practice catalogue by Schau et al. (2009) and study it empirically in the context of a commercially owned online gardening community.

As most qualitative research done within the context of online communities builds on netnographic material, such research tends to overemphasize 'on-stage' performances within the community. Thus, studies that explicitly focus on a consumer-centric 'backstage,' and on the subjective experiences of performance and community membership are rare. Consequently, we gathered qualitative empirical material through a community member diary study.

The collection of quantitative measures of practices is one of the key components of this study. The majority of brand and consumption community research in CCT is based on qualitative data. In this study, quantitative data was obtained through an online survey based on Schau et al.'s (2009) catalogue of community practices. We developed scales measuring respondents' subjective perception of how much s/he performs each practice, directly consumes each socially transitive practice, and vicariously consumes each socially intransitive practice.

Our preliminary analysis of qualitative data reveals that community practices do not create value simply through performance but that their consumption matters to consumers in negotiating community membership, community attachment, and value creation. Furthermore, our findings demonstrate that there is a systematic relationship between the performance and consumption of certain community practices, which is embedded in a system of generalized reciprocity (Giesler 2006; Sahlins 1972) and accumulated cultural capital (Bourdieu 1986).

Our preliminary analysis of quantitative data adds precision to the assertion that practices create value in online communities. Our findings support the claim that in most cases, performing a practice is perceived as distinct and different from consuming the practice, and that each creates different types of value. For example, consuming empathizing, which in our context involves getting answers to gardening related questions, leads to heightened perceptions of the usefulness of the online community as an information resource. Performing empathizing, answering a gardening question, on the other hand, does not have an impact on the perceived use value, but leads to heightened perceptions of social recognition. This fine-grained understanding of how practices create value should be useful not only for community management, but is also conducive to further development of a practice theoretical ontology of community. Thus, blurring the distinction between consumption and production (e.g. Firat and Venkatesh 1995) does not efface differences in effects from a practice theoretical angle.

Making Space: Revealing Hidden Inconsistencies within the Marketplace

Marcus Phipps, University of Melbourne, Australia
Jan Brace-Govan, Monash University, Australia

EXTENDED ABSTRACT

This paper investigates the private nature of household water consumption. Using three innovative water consumers as indicative examples, the study illustrates how a private marketplace can be challenged and hidden inconsistencies brought into public view. Each consumer sought to remove their household from the public mains supply and in the process challenged central assumptions of the marketplace. When severe drought threatened the adequacy of the city's reservoirs, their countervailing behavior became sought after for inspiration and public discussion.

Marketplaces can seek rejuvenation through opposition (Heath and Potter 2005; Holt 2002; Kozinets 2008; Thompson 2004; Thompson and Coskuner-Balli 2007; Thompson and Haytko 1997; Varman and Belk 2009; Zhao and Belk 2008). Over time, previously rebellious ideologies can become sources for innovation and commercial successes. The subcutural non-commercial sphere of tattooing morphed into a profit-maximizing sphere of the commercial world (Bengtsson, Ostberg, and Kjeldgaard 2005). The rebellious nature of the napster file sharing community was a foreshadow to the commercial success of the Apple iTunes music store (Giesler 2008). The resistance of the voluntary simplicity movement has been refashioned into the contemporary consumption phenomenon of simple living (Gopaldas 2008). Furthermore, contradictions in the marketplace provide opportunities for continued marketplace innovations (Heath and Potter 2005; Kozinets 2008; Thompson 2004; Thompson and Coskuner-Balli 2007).

In particular, public spaces provide an opportunity for countervailing ideologies to contribute to marketplace change (Karababa and Ger 2011; Visconti et al. 2010). However, much marketplace resistance occurs at the private and seemingly invisible household level. The private household level of consumption is underexplored from a consumer culture perspective, yet is such an important part of consumers' identity and subsequent behavior. This paper investigates marketplace resistance from the household level and the processes involved in developing ideological change.

The context of this paper is the urban household water marketplace of Melbourne, Australia. In this marketplace, a severe drought led to a reconceptualisation of the meaning of water consumption, and lifted the previously private nature of water use into public discussion. Three indicative consumers, Neil, Veronica and Andrew, are outlined in the findings to illustrate how private consumer resistance can contribute to wider marketplace change. Each consumer challenged dominant assumptions within the marketplace by developing households' independent of the city's mains water supply.

Challenging the marketplace on a private led to hidden inconsistencies within the marketplace being brought to the surface. Rules and regulations around the installation of rainwater tanks, and the use of graywater, were found to be in conclusion and impossible to follow. The consumers adjusted their behavior to circumnavigate these rules and successfully achieve independence from the mains supply.

A countervailing conceptualisation of what is traditionally considered private in Western societies was provided by the consumers. With a shifted emphasis due to drought, any challenges to the dominant assumption of mains water use were eagerly sought after by the public and the media. The consumer made open their house open to the public and conducted tours to discuss their private consumption behaviors. Inconsistencies in the marketplace were given a stronger public focus, enabling for corrections to be made to the system.

Each innovative consumer's sustainable development were the result of deeply held personal values. The concept of a house as mirror of self (Marcus 1997) resonated with the emergent analysis of the these pioneering individuals. Neil, Veronica, and Andrew used metaphor from their backgrounds in science, medicine and activism respectively to describe their commitment to sustainable development. The study provides an illustration of the processes behind privately held values becoming part of the public discourse.

In contrast to the usual Western norms, these activists were so convinced of the need to move individual water consumption to a conserving, re-using and recycling format that they were prepared to make their private (and family) space public. Previous research would appear to suggest that public behavior is a very important part of marketplace change (Karababa and Ger 2011). Furthermore, marketplace intermediaries were an active part of the shift in social practices. The marketplace become a key facilitator of the uptake of new water consuming behaviors in the provision of water storage tanks, types of hoses and other paraphernalia required to store and re-use water.

This research has important implications around public policy, as public behaviors are more likely to be subject to change then private ones. In particular, private household behaviors have important implications around sustainable consumption. Further research is needed to understand the migration of private behavior into the public discourse and the shifting nature of private/public consumption.

The Content of a Brand Scandal
Moderating the Effect of Thinking Style on the Scandal's Spillover

Yun Lee, University of Iowa, USA
Nara Youn, Hongik University, Korea
Dhananjay Nayakankuppam, University of Iowa, USA

EXTENDED ABSTRACT

Product-harm crises, or brand scandals, significantly decrease consumer preferences and purchases for the scandalized brands and their families (Ahluwalia, Unnava, and Burnkrant 2000, Dawar and Pillutla 2000) as well as their competing brands (Roehm and Tybout 2006). Given the devastating effects of product-harm crises and the increasing number of product recalls, we investigate how the nature of a brand scandal moderates the effect of thinking style on the scandal's spillover. We propose that whether the nature of a brand scandal is extrinsic or intrinsic to the scandalized brand's quality determines the degree to which analytic vs. holistic thinkers are affected by the negative information. Extrinsic content is a case where the issues pertinent to a brand scandal are more social and values-related in nature (e.g. socially irresponsible brand misconduct, labor abuses, or environmental contamination), whereas in the case of intrinsic content, the issues are primarily related to product defects (e.g. brand scandals that are directly associated with product quality and performance) (Zeithaml 1988, Huber, Vogel, and Meyer 2009, Pullig, Netemeyer, and Biswas 2006). We argue that there are individual differences in how much to care about socially/ethically related issues and their perceived importance, and these individual differences affect the negative impacts of different types of brand scandals. For this, we propose that different types of scandal content as a moderator of the effect of different styles of thinking on scandal spillover.

Nisbett et al. (2001) have argued that there are two different types of thinking styles (i.e., analytic vs. holistic). According to them, holistic thinkers tend to rely on contextual information and relationships between focal issues and environments. On the other hand, analytic thinkers tend to ignore contextual information, but more focus on focal issues by detaching them from the field. Interestingly, in a recent brand scandal study, Monga and John (2008) demonstrated that analytic thinkers are more susceptible to an intrinsic brand scandal case than analytic thinkers. They explain that this is because analytic thinkers less consider contextual explanations which lead them to more revise their beliefs about the scandalized brand. However, the negative impacts of an extrinsic brand scandal case depending on analytic vs. holistic thinking styles are yet to be investigated. We predict that holistic thinkers' cognitive tendencies focusing on contextual information and relationships may lead them to be more susceptible to extrinsic brand scandal cases. In this line of reasoning, the current research addresses this gab by examining whether the negative impact of extrinsic vs. intrinsic brand scandals will vary depending on holistic vs. analytic thinking style. We conducted a pretest to examine whether holistic vs. analytic thinkers are more likely to consider corporate social/ethical responsibilities, and found that holistic thinkers care more about social/values-related issues than analytic thinkers do ($F(1, 60) = 5.71$, $\beta = .35$, $p = .02$). Given these results, we test our predictions across three experiments.

In Experiment 1a, participants were randomly assigned to either analytic or holistic thinking styles. Half of them were asked to complete sentences in a short story using singular pronouns to activate analytic thinking mode, and the other half under holistic thinking mode were asked to do it using plural pronouns (Monga and John 2008; Kühnen et al. 2001). Then they were given a fictitiously created brand scandal news story about McDonalds unethically mis-leading its customers about the nutritional content of its burgers (i.e., by advertising that they use only "100% pure beef," which has a possibility to be misunderstood as "100% pure protein; Roehm and Tybout, 2006). As expected, the results revealed that holistic thinkers were more susceptible to McDonald's brand scandal on the likelihood of the scandal spillover to a competing brand, Burger King ($F(1,69)=7.39$, $p < .01$, $M_{holistic} = 7.44$, $M_{analytic} =6.46$).

In Experiment 1b, participants were given a picture and randomly asked to describe the scene of the picture to elicit a holistic thinking mode or find objects hidden in picture to elicit an analytic thinking mode (Mong and John 2008). Then they were asked to read a fictitiously created Colgate's intrinsic brand scandal newspaper article (i.e., Antifreeze chemical found in Colgate toothpastes and severe injuries reported). As predicted, replicating the results of Monga and John (2008), one way ANOVA revealed that holistic thinkers were less susceptible to the intrinsic brand scandal spillover than analytic thinkers were.

In Experiment 2, participants were randomly assigned to one of the four conditions composing a 2(thinking styles) × 2(scandal type) between-subjects design. Thinking style manipulation was same as in Experiment 1b. The news story used for intrinsic content is about a product defect of Nike's new shoes that can cause serious ankle and knee injuries. Participants in the extrinsic content condition read a water pollution scandal regarding Nike athletic shoe factories (Roehm and Tybout 2006). A 2(scandal type) × 2(thinking styles) ANOVA yielded a significant interaction ($F(1, 79)=25.86$, $p < .001$). As hypothesized, follow-up contrasts showed that extrinsic scandal was significant for holistic thinkers on the likelihood of the scandal spillover to a competing brand, Adidas ($F(1, 37) = 8.09$, $p=.007$, $M_{extrinsic, analytic} = 3.56$ vs. $M_{extrinsic, holistic} = 4.81$). On the other hand, when the nature of the scandal is intrinsic, the spillover was more likely to occur to analytic (vs. holistic) thinkers ($F(1, 42) = 20.72$, $p<.001$, $M_{intrinsic, analytic} = 4.90$ vs. $M_{intrinsic, holistic} = 3.37$).

Experiment 3 was conducted to increase the robustness of the found effects. Thinking styles manipulation was same as in Experiment 1b. Participants read a fictitiously created Sony's intrinsic (Sony's laptops have battery problems causing severe burns from exploding) vs. extrinsic (Sony's frequent severe violations of environmental protection laws) brand scandal newspaper article. A 2(content: intrinsic vs. extrinsic) × 2(thinking styles: holistic versus analytic) ANOVA yielded a significant content × thinking style interaction. By replicating previous findings, those with analytic tendency revealed a higher likelihood of intrinsic brand scandal spillover, whereas those with holistic tendency showed higher spillover likelihood for extrinsic content.

The findings contribute to a better understanding of how and why consumer attitudes and beliefs can be revised by negative brand publicity depending on thinking styles. Our results also add to a better understanding of how negative brand information can influence consumer beliefs about competing brands. The current research also has managerial implications for marketing managers, suggesting a strategic facilitation of a particular thinking style depending on the contents of brand scandals to mitigate their impacts on consumer attitudes and beliefs.

Rethinking the Schema-Incongruity Effect in Consumer Judgments

Even J. Lanseng, Norwegian School of Management, Norway
Hanne Sivertsen, UC Davis, USA

EXTENDED ABSTRACT

In consumer research the moderate schema-incongruity effect refers to the notion that a product that is moderately incongruent with the schema evoked for it in knowledge is associated with a comparatively positive product evaluation (Mandler 1982). An important result from research on the incongruity effect is that the effect is limited to novices. Based on the argument that experts have elaborate and flexible schema structures that allow them to accommodate a discrepant stimulus, and therefore deter incongruity from being perceived, Perrachio and Tybout (1996) hypothesized and empirically confirmed that the incongruity effect was confined to novices, who have less elaborate and flexible schemata.

Perrachio and Tybout's (1996) hypothesis is nevertheless based on an incomplete argument. It assumes that novices actually possess schemata to employ. Otherwise, there is no basis for incongruity to emerge (i.e. the product has to be incongruent with *something*). However, a well-developed schema structure within a specific domain is what defines the expert, not the novice (Alba and Hutchinson 1987). Experts encode and store information around key functional mechanisms that allow rapid retrieval whenever stored information is relevant. Novices, in contrast, encode and store information around surfaces structures (e.g. physical attributes) that make the retrieval of even their limited relevant knowledge difficult (Chi, Feltovich, and Glaser 1981; Ericsson and Kintsch 1995). Based on this account, the Perrachio and Tybout's (1996) finding would not be predicted. In response, this study discusses that this unexpected finding could be an artifact related to the particular setting (dessert) and operationalization of expertise (gender).

Accordingly, this study predicts the opposite of Perrachio and Tybout's (1996) - that experts, rather than novices, experience incongruity and prefer moderately incongruent stimuli over congruent ones. Novices typically lack a developed schema structure to be used in assessing stimuli, and they will therefore be insensitive to incongruity. Experts typically have well-developed schemata and can therefore perceive incongruity, and respond according to the general prediction of the schema-incongruity theory. Two studies investigated these predictions.

Study 1

The purpose of this study was to observe whether the incongruity effect exists in a stimuli domain where real expertise is allowed for. Wine was deemed an appropriate product category. Several empirical studies suggest that wine experts excel over novices in terms of cognitive and perceptual skills (Hughson and Boakes 2002; Lawless 1984; Lehrer, 1983; Solomon 1990, 1997). A second purpose was to check if the manipulation of congruity versus moderated incongruity worked as planned.

Participants

69 participants were recruited among inhabitants in a small North-Californian university town.

Design and stimuli

The design was a one-factors (Incongruity: Incongruent vs. congruent) between-subject one. Levels of incongruity were manipulated by asking respondents to form expectations about a wine based on a wine label and then let them taste and smell the ostensibly same wine. In the congruent condition the actual wine, which was constant across conditions, was preceded by a label that correctly specified it (Grape: Cabernet Sauvignon, Vintage: 1999, Region: Napa Valley, Barreled: Old oak barrels) whereas in the incongruent condition the same wine was preceded by a label that incorrectly specified it (Grape: Zinfandel, Vintage: 1994, Region: Napa Valley).

To avoid that taste rather than incongruity drives the results, the same physical wine was used in the two conditions. To control that results are not produced by an expectancy bias (i.e. the expected best wine becomes the perceived best wine), participants' expected liking was measured prior to tasting and smelling.

Results

Results from a MANOVA with actual liking and perceive incongruity as dependent measures, the schema-incongruity as a factor and expected liking as a covariate suggested that an incongruity effect was present and that the incongruity manipulation worked as planned.

Study 2

The objective of the second study was to test the prediction that the moderate incongruity effect is limited to experts and to investigate the mediating role of schema-level processing in this regard.

Participants

227 participants were recruited among inhabitants in a small North-Californian university town.

Design and stimuli

The study used a three-factor (Schema incongruity: Incongruent vs. congruent) x (Expertise: Experts vs. novices) x (Information structure: Schema vs. piecemeal) between-subject design. Schema incongruity was manipulated as in Study 1, information structure were manipulated by providing participants with schematic versus piecemeal information, and expertise was a knowledge measure capturing objective wine knowledge through a 20-item quiz-type scale.

Results and discussion

Contrary to previous findings, the results from this study suggest that the moderate incongruity effect is prevalent for experts, but not for novices. The results also supports that the experts' use of established schemata explains this particular moderating effect. Schematic processing of stimuli information mediates the moderating effect of expertise on the incongruity effect. This result strongly suggests that the incongruity effect is a schema-level phenomenon and that this effect should not be expected when piecemeal processing of stimuli information is likely.

General Discussion

An inverted U-shaped relationship between the moderate incongruity effect and expertise may account for the findings in both the Peracchio and Tybout (1996) study and this study. The effect reported in both studies is observed for moderate levels of expertise. For extremely low levels of expertise (i.e. novices) there is no incongruity effect because no schema is developed to assess (in)congruent stimuli. For moderate expertise levels a developed schema to assess (in)congruent stimuli exists and therefore also an accompanying incongruity effect. For extremely high expertise levels the schema structure is so extensively developed that incongruity is resolved without much cognitive effort and with no incongruity effect

as a result. In the domain of desserts, most people have developed at least some schema-structure, hence the Peracchio and Tybout (1996) finding that the incongruity effect occurs for novices. In the wine domain few people have developed schema structures that are extensive enough to automatically resolve incongruity, hence the finding that experts can face incongruity and display the incongruity effect. This inverted-U interpretation is supported by a reanalysis of the data across Study 1 and Study 2.

Sex Matters: The Effect of Brand Gender on Brand Equity

Theo Lieven, University of St. Gallen, Switzerland
Andreas Herrmann, St. Gallen Universität, Switzerland
Jan R. Landwehr, University of St. Gallen, Switzerland
Miriam van Tilburg, University of St. Gallen, Switzerland

EXTENDED ABSTRACT

Brand equity is a key concept in both theoretical and applied studies of marketing (Aaker and Keller 1990; Farquhar 1989; Keller 1993, 2008). This is not surprising, as numerous papers show that a high brand equity contributes decisively to improving consumer satisfaction with and loyalty to the brand and to enabling higher prices for the brand (Aaker 1991, 1996; Park and Srinivasan 1994). Existing research has contributed strongly to the understanding of the determinants of brand equity and identified a brand's personality as one such determinant (Aaker and Biel 1993; Aaker 1997). Like the "big five" model of human personality (Goldberg 1990), brand personality is measured along five dimensions (sincerity, excitement, competence, sophistication, and ruggedness) that apply to consumers' characterization of brands (Aaker 1997). Consumers associate human personality characteristics with brands, because they perceive brands as extensions of their selves (Belk 1988; Gilmore 1919, 2008; Harvey 2005) or because marketers suggest that brands have certain characteristics (Fournier 1998).

Although these personality characteristics certainly impact the perceived attractiveness of a brand, evolutionary psychology papers suggest that the intensity with which an individual expresses his or her gender to other people plays a particularly key role in the perceived attractiveness of this person (Kaplan and Gangestad 2005; Grammer et al. 2003). This is based on the finding that human judgments about the attractiveness of individuals fundamentally represent the result of a process of sexual selection. This selection process favors men who, from the point of view of women, look typically masculine, and women who, from the perspective of men, appear typically feminine. Masculinity and femininity can be linked to very specific physical features, e.g., the waist-to-hip ratio for women and the V-shaped torso for men (Furnham and Radely 1989). According to evolutionary psychological findings, this sexual selection process is so deeply anchored in the decision-making behavior of individuals that one can propose an influence of these principles on the brand choice of consumers (Buss 1994).

Since brands can be equipped with personality characteristics, it should also be possible to equip them with a certain level of masculinity or femininity. An initial paper on this subject (Grohmann 2009) provides insights into the validity of the brand gender construct and the relationship between brand gender and brand perception. However, three key questions have remained unanswered: Whether there is a direct relationship between brand gender perception and brand equity, which features of a brand express its masculinity or femininity, and how these features should be designed to provide an increased expression of an intended brand gender.

The present research is intended to fill these gaps, at least in part. Two studies have been conducted to address these questions. The aim of the first study is to investigate whether the perceived gender of 73 existing brands has an effect on their equity. The inventory developed by Grohmann (2009) serves to detect the gender of a brand. The brand assessment system of a leading market research company can be used as a proxy for brand equity. This analysis provides information on the relative impact of a brand's gender on its equity by showing that a pronounced brand gender is a key driver of brand equity.

The second study aims at investigating the features that characterize masculine and feminine brands. For this purpose, the logos of 73 brands were assessed by individuals with respect to several criteria (e.g., solid versus airy, edged versus curved). These judgments can be connected with the assessments of consumers in study one concerning the perceived brand gender. The results of this study offer concrete information for brand managers concerning which features of a logo should be changed and how, so that the brand conveys the intended degree of masculinity or femininity to consumers. Furthermore, the second study offers theoretical insights regarding the extent to which findings from evolutionary psychology about the significance of individual physical features can be applied to the design of brand logos. Taken together, these two studies serve to show brand managers the repertoire of activities that can be used to intensify perceptions of brand gender and thereby to increase brand equity.

In sum, the findings of the two studies imply that evolutionary based insights about determinants of gender perception in human beings can be applied to brand logo design. This finding stresses the importance of biological shapes and proportions for the design of artifacts in order to achieve an intended perception. In terms of future research, it would be interesting to explore critical boundary conditions and interactions. In this respect, investigating the gender of the product category or of the consumer and their relationship to brand gender would be promising avenues for subsequent research endeavors.

CSR Wins the Cup – How Social Activities Leverage Commercial Sponsorships

Sebastian Uhrich, University of Rostock, Germany
Joerg Koenigstorfer, Pennsylvania State University, USA
Andrea Groeppel-Klein, Saarland University, Germany

EXTENDED ABSTRACT

Sponsors of mega-events are increasingly linking such events to activities in the area corporate social responsibility (IEG 2010). This is because more and more developing countries are hosting mega-events and consumers increasingly expect brands to behave in an ethical manner. CSR-linked sponsorship may positively influence brand perceptions where consumers perceive this engagement to be sincere and the cause worth supporting (Lacey, Close, and Finney 2010; Sen and Bhattacharya 2001). Altruistic motive attribution – a key variable accounting for the success of sponsorships (Rifon et al. 2004) – may mediate this influence and thus leverage the sponsorship. However, it is also possible that the linking of CSR and sponsorship is perceived as thematically incompatible by consumers and causes reactance. It may, for instance, lead to suspicion and skepticism about the reasons why the brand is engaging in social activities (Vlachos et al. 2009), particularly in the case of highly commercialized mega-events such as the Olympic Games, the FIFA World Cup or the Super Bowl.

In this research we examine whether linking the sponsorship of commercial events with CSR activities results in more favorable brand perceptions than commercial sponsorship on its own. We consider the mediating role of altruistic motive attributions for sponsorship and the moderating roles of congruence between sponsors and events, and commitment to CSR. As far as we are aware, this is the first piece of research investigating the effects of a combined CSR/sponsorship strategy from a consumer perspective.

Consumers' perceptions of brands can be influenced positively by social initiatives (Barone, Miyazaki, and Taylor 2000; Ellen, Mohr, and Webb 2000; Sen and Bhattacharya 2001). In a pilot field study looking at the soccer World Cup 2010 in South Africa, we tested the basic proposition that consumers' attitudes to a brand are more positive when they are aware of both the brand's engagement as a sponsor and its parallel social activities, compared to when they are aware of just the sponsorship activities or aware of neither the sponsorship nor the social activities.

A total of 448 individuals participated in the initial field study. Through personal interviews we identified consumers' recognition of the sponsorship activities and CSR, brand attitudes and brand familiarity. We looked at several brands, including both brands belonging to official sponsors of the World Cup and foils. We found that consumers who were aware of both the sponsorship and the CSR activities reported significantly more positive brand attitudes than those who were only aware of the sponsorship activity or aware of neither the sponsorship nor the CSR activities. The brand *adidas* was the only brand for which this relationship did not hold.

We then provide theoretical background for the effects of linking social activities with sponsorship and investigate the role of potential mediators and moderators. We hypothesized that increases in altruistic motive attributions for the sponsorship mediate the effects of CSR-linked sponsorship communication, and perceived sponsor-event congruence moderates these effects. We base these assumptions on schema and attribution theory, applied to sponsorship-linked marketing (Cornwell et al. 2006; Menon and Kahn 2003).

A total of 127 students participated in a first laboratory experiment applying a one-factorial (content of communication: standard sponsorship *versus* CSR-linked sponsorship; control: CSR) between-subjects design. Sponsor-event congruence was measured via an established scale as a continuous variable. We used press releases about several brands, including the target brand *Sony*, as experimental stimuli. Participants were unaware of the purpose of the study.

ANOVA results show that CSR-linked (*versus* standard sponsorship) sponsorship communication had a positive effect on brand attitude shifts and consumers' CSR perceptions of the brand, whereas brand credibility and the general behavioral tendency to recommend the brand as an employer were not directly affected. However, mediation analyses reveal that CSR-linked sponsorship communication increases attributions of altruistic sponsorship motives, and that this effect mediates the positive effects on all dependent variables. In addition, the results of moderated regressions show that the perception of low congruence of the brand with the sponsored event positively affects the linking of sponsorship information with CSR.

In a second laboratory experiment we investigated whether brands engaging in CSR-linked sponsorship communication can benefit from demonstrating a high level of commitment to social activities, and how these effects are moderated by sponsor-event congruence. As in experiment 1, we used press releases for manipulation purposes. Based on the results of several pretests, we selected *adidas* to represent high-congruence brands and *Coca-Cola* to represent low-congruence brands.

Tests of the indirect effects of CSR commitment on the dependent variables through consumers' attributions of altruistic sponsorship motives show that motive attributions account for the positive effects on perceptions of both the brand and the sponsorship. However, a high level of CSR commitment had negative direct effects on CSR perceptions, brand credibility and sponsorship credibility. Furthermore, a tactical decrease in a brand's commitment to CSR when linked to event sponsorship was more harmful to low-congruence brands than to high-congruence brands.

The results imply that a CSR-linked sponsorship strategy is particularly promising for brands with a low natural congruence to the event, where these brands follow a long-term CSR strategy. For such brands, social engagement adds meaning to the brand. If high-congruence sponsors follow such a strategy, they should ensure that the social engagement is not in conflict with consumers' expectations of the brand's behavior in relation to the event, otherwise the unexpectedness of this information may destroy consumers' consistent and harmonious beliefs about the brand.

CSR-linked sponsorship may become more and more important in the future, particularly as consumers from developing countries represent a growing target group. Through CSR-linked sponsorship, such consumers may feel that they benefit directly from the sponsor's engagement. Moreover, consumers in industrialized countries may attribute good corporate citizenship to brands that follow such a combined strategy.

Exploring the Influence of Ambient Temperature on Cognitive Task Performance

Luqiong Tong, Tsinghua University, China
Rui (Juliet) Zhu, University of British Columbia, Canada
Yuhuang Zheng, Tsinghua University, China
Ping Zhao, Tsinghua University, China

EXTENDED ABSTRACT

Although both practitioners and academics agree that temperature is important in affecting human cognition and behavior (Goldman, 2001; Hancock *et al.*, 2007), mixed results have been observed in the literature with regards with which or what range of temperature will facilitate cognitive task performances (Ramsey, 1995). While some research suggests that warmer temperatures enhance performance (Chiles, 1958; Pepler and Warner, 1968), some others suggest the opposite (Coleshaw *et al.*, 1983; Thomas *et al.*, 1989). Further, prior research efforts in this domain are limited in a number of dimensions. For example, they have focused on extreme temperatures (i.e., higher than 30 Celsius or lower than 10 Celsius; note that human's comfortable temperature range is between 16 to 29 Celsius, Baker and Cameron 1996), and have included predominately simple tasks, such as word memory and figure matching.

This research aims to address these limitations and therefore advance our understanding on the impact of temperature on task performance. Specifically, we examine how warm versus cool temperature, both within a comfortable range and are commonly experienced, can affect people's performance on simple as well as complex tasks.

Prior research on temperature suggests that heat, which can induce thermal stress, competes for attentional resource and consequently hurts task performance (e.g., Hancock and Warm 1989). Thus, compared to individuals in the cool temperature condition, those in the warm temperature condition should have less attentional resource towards the focal task (Enander 1984, 1986).

A separate line of research has shown that different amounts of attentional resource allocated to the focal task can prompt alternative thinking modes. While abundant attentional resource to the focal task usually results in primarily conscious thinking, limited attentional resource is likely to prompt more unconscious thinking (Dijksterhuis et al. 2006). Thus, we expect that those in the warm (cool) temperature condition, which leads to limited (abundant) attentional resource to the focal task, would be more likely to engage in unconscious (conscious) thinking.

Finally, extant research has documented beneficial effects of unconscious thinking on complex task performance (Dijksterhuis and Nordgren 2006). Specifically, unlike conscious thoughts, which have limited processing capacity, unconscious thoughts don't suffer from the capacity constrain, so unconscious thinking mode can benefit complex tasks. Combing the preceding notions, we hypothesize that warm versus cool temperature would enhance individuals' performance on complex tasks. However, such an effect should be attenuated for simple tasks.

Two laboratory studies were conducted which provided systematic support to our hypothesis. Study 1A and 1B demonstrated the basic effect of temperature on task performances. Specifically, study 1A used 3 (temperature: warm vs. moderate vs. cool) * 2 (task complexity: simple vs. complex) between-subject design. The task used was a classic choice task, which requires participants to select their preferred lottery from four different options (Payne *et al.*, 2008). Options were defined by payoffs for 12 equiprobable events defined by drawing 1 of 4 numbered balls (simple condition) or 1 of 12 numbered balls (complex condition) from a bingo cage. Among the four options, one option had the highest expected value, which represents the correct answer. The study was run with no more than four people per session. The same lab was used, but the temperature was set to warm (25-26 Celsius), moderate (21-22 Celsius), or cool (16-17 Celsius). These temperature conditions followed the comfortable temperature boundaries in Baker & Cameron (1996). Results confirmed our hypothesis, such that when the task was complex, a significantly higher percentage of individuals in the warm temperature condition selected the correct lottery (thus indicating better task performance) than those in the low or moderate temperature condition. However, we did not observe any treatment effect when the task was simple.

Study 1B was a theoretical replication of study 1A. By using a different task, we again demonstrated that warm versus cool temperature led to better performance on difficult tasks. Furthermore, additional measures taken in both studies ruled out a number of alternative explanations, such as mood, arousal, and involvement.

Study 2 aimed to shed light to the underlying mechanism. If warm temperature leads to more unconscious thinking and consequently enhances performance on complex tasks, then we should observe equally well performance under the cool temperature if we prompt people to enter the unconscious thinking mode in that condition. Prior research has shown that working memory load manipulation can lead to distraction, and thus reduced attentional resource to the focal task (Lavie, Hirst, and Fockert 2004). So, if we encourage individuals in the cool temperature condition to engage in unconscious thinking by a high load manipulation, they should perform on complex tasks equally well as those in the warm temperature condition. Thus, in this study, we first administered a seemingly unrelated task which varied in memory load in a neutral temperature room. Specifically, participants were asked to remember either a 2-digit number (low load) or an 8-digit number (high load, which would encourage unconscious thinking) throughout the entire study. Then they were escorted to the main lab where temperature was set to warm or cool. The focal task involved the same complex lottery task as in study 1A.

Results supported our theorizing. In particular, for those in the low memory load condition (i.e., people are primarily engaging in conscious thinking before entering the main lab which varied in temperature), we replicated earlier results. That is, warm temperature led to better performance. However, for those who were in the high memory load condition, they performed equally well whether they completed the focal task in warm or cool temperature room, presumably because the high memory load manipulation has prompted them to engage in unconscious thinking, which mitigated the effect of temperature.

Findings from this research make several important contributions. Foremost, they advance our understanding of the impact of ambient temperature on human cognition, esp. task performance. Second, we offer explanation as well empirical evidence with regards to the underlying process that drives these effects. Finally, this research offers practical implications in terms of setting up optimal ambient temperatures in various environments.

Enjoy! Hedonic Consumption and Compliance with Assertive Messages

Ann Kronrod, MIT, USA
Amir Grinstein, Ben-Gurion University, Israel
Luc Wathieu, Georgetown University, USA

EXTENDED ABSTRACT

Consumers are often exposed to forceful messages and imperative slogans such as Nike's "Just do it," Sprite's "Obey your thirst," or U.S. Airways' "Fly with US." The frequent use of assertively phrased messages is puzzling, given the mounting research in consumer behavior (e.g., Dillard and Shen 2005; Fitzsimons and Lehman 2004; Lord 1994), communications (e.g., Kellerman and Shea 1996; Quick and Considine 2008; Quick and Stephenson 2007; Wilson and Kunkel 2000), and socio-linguistics (e.g., Levine and Boster 2001; Sanders and Fitch 2001), which suggests that these messages should lower consumer readiness to comply.

To understand the unexpected prevalence of assertive language, we turn to socio-linguistic literature on the language used in compliance-seeking requests. Research has found that people in positive mood tend to use more assertive language in their requests (e.g., Forgas 1997). Correspondingly, people in positive mood expect to be addressed with more direct and assertive language (Bloch 1996; Forgas 1999a, 1999b). This matching pattern appears consistent with language behavior literature which demonstrates that higher compliance occurs when the language of requests fits the receiver's expectations (e.g., Brown and Levinson 1987; Forgas 1998).

Building on this logic, we suggest in this paper that assertive messages are more persuasive than non-assertive messages when they relate to consumption contexts that induce positive mood. In particular, we focus on hedonic consumption, which commonly elicits positive mood (Chaudhuri and Holbrook 2001). We suggest a conceptual model where the effectiveness of assertive messages regarding hedonic products, or products that are framed hedonically, is higher than the effectiveness of non-assertive messages. By contrast, in baseline utilitarian consumption contexts, non-assertive phrasing should yield higher compliance. We explain these effects through the mediation of mood and communication expectations.

Three experimental studies support our hypothesis and its underlying explanation in terms of induced mood and communication expectations. The experiments are preceded by a field data examination of 428 real-life slogans in hedonic and utilitarian product categories. The field data shows that while about 8% of utilitarian product slogans are assertive, a dramatic 24% of hedonic products are assertively phrased. Study 1 tests the conceptual model. We show that compliance depends on the interaction between language (assertive/non-assertive) and communication expectations for assertive/non-assertive language. Such expectations originate from the mood (positive/non-positive) which is induced by different product types (hedonic/utilitarian). Respondents who were thinking about chocolate reported positive mood and higher compliance intentions with an assertive message ("You must try our chocolate!") than with a non-assertive message ("You could try our chocolate"), as well as higher expectations for assertive language. However, respondents who were thinking of opening a bank account did not report positive mood and were more inclined to comply with a non-assertive message ("You could open a bank-account with us"), compared with an assertive one ("You must open a bank account with us!"). Study 2 employs real print ads from business magazines to generalize the findings to contexts involving utilitarian products presented in metaphorically hedonic language and imagery ("hedonic framing"). We find that even when a utilitarian product is merely presented in a hedonic

framing (e.g. consulting services presented as a flight to the moon), an assertive phrasing is more persuasive than a non-assertive one. Study 3 reinforces the notion that assertive language meets communication expectations in hedonic contexts, showing that consumers perceive unknown products advertised using assertive language as more hedonic than the same products promoted with a non-assertive message.

Additional Alternative Explanations

We specifically proposed that hedonic products are likely to prompt a positive mood, which results in the expectation for, and acceptance of, a more direct and assertive communication style. We empirically considered an alternative explanation for the context-dependent effect of message assertiveness, based on the notion that in hedonic product contexts assertiveness could reduce guilt associated with the anticipation of self-indulgence, but this explanation could not account for our findings.

Another alternative explanation may be related to the beneficiary prediction. Specifically, Buller et al. (1992) find that the degree to which the addressee is the beneficiary of a request positively affects compliance with more assertive requests. It is plausible, then, that assertive messages regarding hedonic consumption elicit higher compliance because the consumer is the obvious beneficiary in hedonic consumption contexts. However, this explanation only weakly supports the prediction of the interaction between product type and language, since it mainly predicts that in hedonic consumption contexts *any* request would be effective. More critically, this explanation does not predict why non-assertive phrasing will elicit lower compliance in hedonic product contexts.

Related to the notion of beneficiary, it could be that the assertively phrased messages in hedonic product contexts, such as "You must have this product", are not perceived as commands but rather as advice because the beneficiary in hedonic consumption is more saliently the consumer. This possibility echoes recent findings of Botti and McGill (2011), who relate higher satisfaction with self-made choices in hedonic consumption, compared with utilitarian consumption, to perceptions of hedonic consumption as more self- rather than externally motivated. This explanation is in line with our theorizing of altered communication expectations in hedonic product contexts. However, it suggests an alternative underlying process, where a different phrasing is expected not because the perception of social and communicational rules and borders loosens due to positive mood, but rather because of a different interpretation of the meaning of directive phrases as advice and not as a request. Further, this explanation too does not account for the interaction of language and product type, because it is not clear why assertively phrased advice would be more complied with than non-assertively phrased advice. To account for the possible different interpretations of the word *must* it is possible to use different phrasings in the experimental design. We address this point in Study 2, employing various assertive and non-assertive phrasing variations.

Universality of the Findings

In Study 2, we used English ads, whereas the rest of the studies were in Hebrew. Research suggests English and Hebrew differ in politeness judgment (e.g., Blum-Kulka 1994). Exploring the robust-

ness of the findings across the two languages was important for this work, as it is also important for other works on language behavior.

While additional interesting directions can be proposed, such as that hedonic framing might elicit a promotion focus while a utilitarian framing ad might evoke a prevention focus, the most important conclusion we draw from this work is that assertive messages can be effective, and non-assertive messages can be counter-productive, depending on their meeting consumers' communicational expectations, in ironic application of Burger King's famously assertive slogan *Have it your way!*

A Pounding Heart and a Narrower Mind:
How Images of Attractive Women in Mass Media Influence Man's Pro-Social Behavior

Xiuping Li, National University of Singapore, Singapore
Meng Zhang, Chinese University of Hong Kong, Hong Kong

EXTENDED ABSTRACT

Advertisements frequently use physically attractive females to sell products since it is the easiest way to attract consumers' attention and to increase promotional effectiveness (Baker and Churchill 1977). Visual images of attractive females, which are sexually rewarding to heterosexual males (Aharon et al. 2001), have also been found to be able to prime a mating motive. From an evolutionary perspective, a mating motive will make males behave in a way to maximize their opportunity to attract a mate. In the context of consumer behavior, a mating motive is shown to lead male consumers to engage in more conspicuous consumption in order to signal their high status, and lead them be more likely to choose unique or conspicuous options to stand out from others (Griskvicius et al. 2006; Sundies et al. 2011).

How would these attractive women pictures influence people's consumption behavior in domains unrelated to the mating motive? The current research takes a social orientation perspective, and proposes that the mere exposure to such stimuli, as ubiquitously portrayed in mass media, can change male consumers' behavior significantly in subsequent, unrelated tasks. Specifically, as compared to other visual stimuli (e.g., pleasant landscapes, or average-looking women) and non-picture baseline, exposure to the images of attractive women should lead people view themselves as being more socially distant from others. This increased self-other distance, in turn, lead males become less concerned about others' wellbeing in a number of contexts, like belief endorsement, evaluations towards ads and products, volunteering behavior, and donation.

Our hypothesis draws on two streams of literature. First, prior research has shown that "physical attractiveness" is given far more priority than other cues such as "warmth" or "social status" when men are looking for short-term mates compared to when they are looking for long-term mates (Li and Kenrick 2006). Therefore, when a cue of physical attractiveness is present, it might activate the short-term mating motive to a greater extent rather than a long-term one. This short-term mating motive has been suggested to activate a general mind state which focuses on short-term rewards over a long-term one (Li, 2006; Loewenstein 1996; Metcalfe and Mischel 1999). Recent studies by Van den Bergh, Dewitte, and Warlop (2008) have shown support to this prediction by demonstrating that seeing images of attractive females (e.g., a commercial video featuring women in bikinis) leads men to have a greater preference for smaller, more immediate gratification than for larger, more future rewards.

Second, it has been found that temporal distance and social distance are both dimensions of a possible unified concept of psychological distance (Trope and Liberman 2003). Both "present" and "me" are regarded as within an individual's proximal space in relation to "future" and "other". Further, it has been found that the distance perception along the two dimensions can influence how consumers construe events in the similar fashion and sub-additively (Kim, Zhang, and Li 2008). Therefore, if priming of a short-term mating motive can make people focus on the immediate benefits and discount future rewards along the time horizon, the same orientation shift should hold along the social distance horizon. People may become socially myopic as well, and focus more on self benefits/cost and discount benefits/cost occurring to others.

Formally, we propose that the mere exposure to images of attractive women would shift social orientation and increase men's perceived social distance towards others, which in turn, change their behavior in many kinds of consumption contexts. We report the results of six experiments. Participants in all experiments were heterosexual male students between 18 and 24 years of age from a large university. In the experiments, we compared behavior of those participants who had briefly viewed pictures of attractive women, to those who had briefly viewed other pleasant pictures (landscapes, or average-looking women), or non-picture baseline. Specifically, we found that those who viewed attractive women pictures endorsed less belief statements which showed concerns of others (experiment 1), demonstrated a weaker social value orientation in decomposed games (experiment 2), evaluated a product less favorably when an ad emphasized the wellbeing of others (experiment 3), and less likely to choose a green or ethical product more (experiment 4). Interestingly, consistent with our prediction, we found in experiment 5 that seeing pictures of attractive women might not necessarily reduce helping behavior. In fact, exposure to such stimuli could lead participants to be either more or less likely to sign up for volunteering, depending on whether they perceived this kind of help as benefitting themselves or benefitting others. In other words, when they believed that a helping behavior can serve some egoistic motives, exposures to pictures of attractive women could *increase* their interest in volunteering – eliminating the previous results. Experiment 6 then tested the mediating role of perceived social distance directly. The results showed the increased self-other distance mediated the effect of images of attractive women on pro-social behavior. By adding a condition of gender role priming, this experiment also ruled out gender role activation as an alternative explanation. Moreover, the effects cannot be attributed to any differences in affect.

To the best of our knowledge, our research is the first piece of work to explore how mere exposure to attractive women pictures can influence social distance perception and change unrelated consumer behavior accordingly. Important implications can be drawn from our findings. Decision-makers in various fields such as charity organizations that appeal for donations and marketing managers who sell environmentally friendly products might want to reconsider their decisions to place their messages in media that are rich in visual sexual cues (e.g., popular men's magazines, late night TV shows, etc.). According to our results, strategies based on the use of such stimuli may backfire.

$29 for 70 or 70 for $29: How Presentation Order Affects Perceptions

Rajesh Bagchi, Virginia Tech, USA
Derick Davis, Virginia Tech, USA

EXTENDED ABSTRACT

Typically, firms communicate the price of their goods by advertising the unit price of a single item. However, sometimes pricing, specifically unit pricing, can be presented in different formats. For instance, supermarkets often have $10 for 10 item promotions, wherein each item costs $1, and consumers can buy as many or as few items as they wish. The $10 for 10 item promotion is merely another way of communicating price. But why would a firm decide to communicate price in this manner? Is it advantageous? This research investigates how under certain conditions communicating unit price via multiple item pricing can have positive and negative effects on consumer perceptions of the offering.

One type of product that lends itself nicely to multiple item pricing strategies, is electronic content, such as song and movies. For instance, with Apple's iTunes, a consumer can buy a single song, or a larger amount of content, such as an entire music album. Obviously, few limits exist for how firms offer access to content and files and therefore, different pricing presentation strategies could be easily varied. For instance, Apple's iTunes could change the presentation order by presenting price first, and then number of songs ($29 for 70 songs) or the reverse (70 songs for $29). They could advertise price via larger packages ($29 for 70 songs) or smaller packages ($2.90 for 7 songs). They can also vary how difficult ($29 for 70 songs) or easy ($20 for 50 songs) it is to compute unit prices. How would these varied characteristics affect consumers' perceptions and why? In this research, we investigate the role that three different characteristics of a package (presentation order, package size, and ease of unit price computation) play in consumers' perceptions.

The price information reflects the costs involved, while quantity corresponds to benefits accrued from the exchange. If computations are easier (e.g., $20 for 50), consumers can easily compute unit price ($.40/item). In this case any effect of other package characteristics on perceptions should be attenuated, as unit prices are easily computed and consumers can buy as many or as few items as they wish at the same unit price. But, when unit price computations are harder (e.g., $29 for 70), consumers may not perform calculations necessary and may instead focus on the first piece of information to make inferences.

If price is first, a higher price (e.g., $29) may highlight the costs involved. In contrast, if quantity were first, greater item quantity (e.g., 70 songs) might suggest a larger gain from the exchange. We posit that presentation order may differentially affect consumers' attention and investigate the effects on relevant marketing variables. Furthermore, this "anchoring" effect is likely to be stronger when package size is large as all the numbers are larger.

We predict a three-way interaction of order by package size by computation ease. We expect computation ease to moderate the relationship between order and numerosity on perceptions (e.g., unit price). Formally:

Hypothesis 1 *Calculation Difficulty moderates effects of order and numerosity on perceptions.* High Calculation Difficulty: *High numerosity: Price-item vs. item-price order will lead to a) higher unit price judgments, b) lower value perceptions, and c) lower trying likelihoods.* Low numerosity: *Differences attenuated.* Low Calculation Difficulty: *These differences will be attenuated.*

We report findings from two studies. In study 1, we use an online music context to investigate the effects of the independent variables on unit price judgments. Study 2 uses an online television viewing service to investigate the effects of the independent variables on likelihood of trying the offer and package value perceptions. Both studies are 2 (Order: Price-Item vs. Item-Price) x 2 (Numerosity: High vs. Low) X 2 (Calculation Difficulty: Hard vs. Easy) full factorial between subject designs. Both studies fully support our hypotheses.

Our research thus makes several important theoretical and managerial contributions. We demonstrate how the presentation order of price and quantity information – even when presented simultaneously, as opposed to separately – influences which piece of information is used in judgments via anchoring (Epley and Gilovich 2010; Frederick, Kahneman, and Mochon 2010; Russo 2010; Tversky and Kahneman 1974; Wegener, Petty, Blankenship and Detweiler-Bedell 2010a, 2010b). We find that computation ease influences anchoring, suggesting stronger effects when computations are harder (Thomas and Morwitz 2009). We also show that these effects are most prevalent when packages are large, thus contributing to work on numerosity (Burson, Larrick, and Lynch 2009; Pelham, Sumarta, and Myaskovsky 1994; Wertenbroch, Soman, and Chattopadhyay 2007).

Our findings also have important managerial implications. This research provides insights that can aid in pricing strategies for different objectives, such as decreasing unit price perceptions or increasing trial likelihood. However, our finding that the influence of presentation order is likely to be stronger for larger (vs. smaller) packages is especially relevant for managers.

Are You Really Paying What You Wish?
Interpersonal Influences on Price Decisions

Sae Rom Lee, Pennsylvania State University, USA
Hans Baumgartner, Pennsylvania State University, USA
Rik Pieters, Tilburg University, The Netherlands

EXTENDED ABSTRACT

Although pay-what-you-wish pricing is increasingly being adopted in the market place, little is known about how consumers make price decisions in the context of these schemes. This is surprising, because such pricing schemes may hold significant cost advantages for consumers and sales and margin implications for firms, who expect to trade-off margin for volume. Because pay-what-you-wish pricing enables the consumer to choose the price paid and this often occurs in social situations, consumers' choice of how much to pay can become a socially embedded decision where the role of other consumers becomes crucial. Yet, no previous research has focused on possible social influences on consumers' price decisions in this context. The current research examines this issue. Two experiments indicate that people do take advantage of pay-what-you-wish pricing opportunities by paying a lower price than the regular suggested price, but in unexpected ways that reflect the social embeddedness of the decision. When people are motivated to make a good impression on certain others, they offer a higher price than what they could pay, primarily due to concerns about what price signals to others about their prestige, unless strong social cues are present indicating that paying a low price is acceptable.

In the context of pay-what-you-wish pricing, consumers are provided with the unusual chance to choose their own prices. Thus, individuals should be highly motivated to save money on the product purchase by offering a low price. Marketers adopting a pay-what-you-wish pricing scheme often provide a price guideline indicating the regular price of the product. We hypothesize that the price that consumers offer will often be lower than the reference price based on the regular market price, because consumers are motivated to take advantage of the chance to pay less in the pay-what-you-wish shopping context.

However, when individuals are shopping with another person on whom they wish to make a good impression, they will be more concerned about how the other person makes judgments about them based on the price they offer. Individuals then feel pressure to offer a higher price when they desire to be evaluated favorably by another person in the pay-what-you-wish shopping context.

We suggest that the positive effect of impression motivation on price paid is mediated primarily by prestige sensitivity. Consumers will favor high prices due to inferences about the prominence and status that higher prices signal to other people about them. It is also possible that consumers might become less price-conscious when they are motivated to make a good impression. Finding a low price and saving money might no longer be their primary goal to be achieved in the shopping situation when offering a lower price generates social costs of looking cheap or stingy.

If a social signal is present indicating that it is acceptable to offer a lower price, the social pressure to offer a higher price will be diminished. The other person's self-presentational behaviors, verbal communications or personal possessions can signal whether or not the other person expects the focal individual to pay more. For example, how much the other person pays for his or her product can directly signal what the other person thinks is appropriate to do.

In study 1, we tested our predictions in a pay-what-you-wish pricing context. Participants were told that they were at an art mu-seum either with an admired friend or with their best friend, and they were given a chance to pay as much as they wished for a ticket. Participants had to decide how much to pay either before the other person made a decision or after the other person paid a relatively low price. We found that people indeed generally paid a lower price than the regular suggested price. Also, an admired friend (vs. best friend) who stimulated impression motivation increased the price paid by participants, and the positive effect of impression motivation on price paid was mediated primarily by prestige sensitivity and, to a lesser extent, by price-consciousness. In addition, when an admired friend paid a price that was relatively low before participants had to make a decision about how much to pay, this decreased the pressure to pay a higher price.

In study 2, participants imagined that they were either with a date or their best friend when they decided to pay what they wished to pay for an art museum ticket. We used indirect social cues (i.e., lifestyle of the other person inferred from conversation) to signal what is desired by the other person (frugal vs. materialistic values). We also included a control condition in which participants were alone. We again found that participants paid a lower price than the regular price, but a materialistic date (vs. a materialistic best friend or frugal date) increased the price paid. The price paid in the presence of one's best friend or a frugal date was not different from the price paid alone. The positive effect of impression motivation on price paid was mediated by prestige sensitivity.

The results of these two experiments suggest that people are likely to take advantage of pay-what-you-wish pricing opportunities by paying a lower price than the regular suggested price. As predicted, however, when people are concerned about making a favorable impression on another person who is present in the shopping situation, they pay a higher price than what they would have paid if they did not have to impress the other person or if they were alone. Also, the findings suggest that the positive effect of impression motivation on price paid is mediated primarily by prestige sensitivity and, to a lesser extent, by price-consciousness. Further, the findings suggest that if there are social cues indicating that it is appropriate to pay a lower price, the pressure to pay a higher price in the presence of the other person who motivates impression management is attenuated. This research adds to the literature examining interpersonal influences and the role of price in consumption decisions.

Inward Looking: The Effect of Lateral Orientation on Consumer Preference, Perceived Usability and Intent to Purchase

Dante Pirouz, University of Western Ontario, Canada
James M. Leonhardt, UC Irvine, USA
Jesse R. Catlin, UC Irvine, USA

EXTENDED ABSTRACT

If a marketer were to turn to the literature for guidance on how to position a product within an advertisement, s/he would find conflicting results in terms of whether products are preferred facing left or right. Given the sporadic results, s/he may reasonably conclude that facing direction does not matter and thus may orient products within an advertisement based simply on intuition or formatting practicalities. Results from the present research help reconcile these disparate results and helps inform the marketer that spatial orientation is an important component that impacts consumer perceptions. Specifically, the direction a product is facing affects how consumers evaluate products.

In this paper, we limit our focus to the horizontal component of spatial orientation referred to as lateral orientation. Freimuth and Wapner (1979) consider lateral orientation as consisting of two parts: 1) the lateral position of an object along the horizontal midline and 2) the directionality of an object. The directionality of a product refers to the direction a product is perceived to be facing and/or moving. In a first experiment it is shown that spatial orientation has an effect on preference. Precisely which components of a given spatial orientation affect aesthetic appreciation is clarified in a second experiment. In a third experiment we look at whether orientation impacts perceived usability. In a fourth experiment we find test whether orientation affects intent to purchase or usability and the mediator of the effect, using a real advertisement.

Past consumer research on aesthetics has largely focused on the design of the product itself (Bloch 1995; Whitney 1991) and shows that aesthetics affect consumer perceptions of product quality (Garvin 1984; Zeithaml 1988), product differentiation (Dickson and Ginter 1987) and competitive advantage (Holt 1985; Kotler and Rath 1984). Less research has explored the aesthetic ramifications of how a product is oriented within a visual space, which can be referred to as a product's spatial orientation. In consumer research, spatial orientation has been shown to affect visual attention, eye movement (Janiszewski 1998; Rosbergen, Pieters, and Wedel 1997), and even perceptions of weight (Deng and Kahn 2009). An understanding of spatial orientation is important for marketers since it is one of the first aspects of a product processed by the visual system (Flavell and Draguns 1957). For instance, during brief exposures (< 5 s) products are assessed according to their spatial orientation while at longer exposures a more feature (design) based product assessment occurs (Freimuth and Wapner 1979).

Presently, the literature remains conflicted about preferences for right vs. left-facing objects. Some studies have shown a preference for rightward (right facing à) directionality (Christman and Pinger 1997; Freimuth and Wapner 1979; Mead and McLaughlin 1992), while others report instances where rightward directionality becomes insignificant (Christman and Pinger 1997) or even a general preference (Banich, Heller, and Levy 1989) for leftward (left facing ß) directionality. In addition, various studies have reported moderators of directionality preference such as handedness (which is correlated with hemispheric asymmetries) and cultural reading (Braine 1968; Chokron and De Agostini 2000; Christman and Rally 2000; Heath et al. 2005; Nachson 1985).

Support for rightward directionality comes, in part, from an attentional scanning hypothesis (Beaumont 1985; Graffon 1950; Wölfflin 1928). According to this hypothesis, rightward directionality is preferred because it coincides with the direction in which visual attention automatically orients across the visual field. Rightward scanning direction is thought to be the result of visual attention being initiated by the visuospatially oriented right hemisphere (Bradshaw and Nettleton 1983; Bryden 1982; Kosslyn 1987).

In experiment 1 we found lateral orientation to affect preference. Specifically, we found a set of products directed inward to be preferred over the same set of products directed outwards. These findings led us to conclude that preference for directionality was dependent on whether the product was positioned to the right or left of center. Experiment 2 tested for other factors potentially affecting preferred directionality, such as hemispheric processing asymmetries and or reading and writing direction, and found no effect, thus confirming that a preference for right versus left facing direction is dependent on the products lateral position relative to the center of the display. Experiment 3 looked at whether orientation impacts the perception of usability of a product. The results showed that inward facing products were perceived as more usable than outward facing ones. In experiment 4, a real advertisement (taken from a magazine and altered to obscure the brand name and logo) was used to determine whether orientation might impact intent to purchase whether the effect is mediated by processing fluency. Results of this experiment showed that participants who saw the ad with the inward facing product (car) versus the outward facing product had a higher intent to purchase and higher usability rating of the product and that this effect was fully mediated by processing fluency. These effects do not covary with gender or handedness.

In general, the finding that the way in which a product is orientated within a display can have a significant effect on its perceived usability is surprising since nothing about the product itself has changed; rather it is merely displayed in a different lateral orientation. This result supports the view that product evaluations are partially the result of how the stimuli in question are processed and are not the result of the stimuli themselves.; studies by Winkielman et al. (2006) support this view. The biological and psychophysical literature offer possible explanations, and areas for future research, for the occurrence of a preference for inward (versus outward) directionality.

Sticking to it?
How Consumer Goal Progress Affects Goal Perseverance

Aaron Garvey, Pennsylvania State University, USA

EXTENDED ABSTRACT

How does progress toward a goal impact the tendency to pursue that goal? Prior research has identified inconsistent effects of consumer goal progress upon goal perseverance; one stream of research suggests that progress increases the tendency to pursue the focal goal (e.g., Kivetz, Urminsky, and Zheng 2006; Nunes and Dreze 2006), whereas an alternative stream proposes that progress has no such effect (e.g., Fishbach and Dhar 2005; Wilcox, Vallen, Block, and Fitzsimons 2009). The present research introduces a characteristic of goals to help resolve this conflict—cumulative benefits associated with goal progress. The presence of cumulative benefits is proposed to influence perceptions of sunk costs (Arkes and Blumer 1985; Cunha and Caldieraro 2009) associated with goal progress that, in turn, affect goal perseverance.

Cumulative benefits refer to the intrinsic value of goal progress *independent from* the end state. Benefits are cumulative if received as a function of progress prior to achieving the end state (e.g., weight loss), whereas benefits are all-or-nothing if they are only received upon achieving the end state (e.g., completing a marathon). All-or-nothing benefit goals are expected to result in greater perseverance as a function of progress compared to cumulative benefit goals (H1). Differential perceptions of sunk costs as a function of progress are proposed to mediate this effect (H2). In the case of all-or-nothing benefits, higher perceptions of sunk costs due to progress will enhance goal perseverance, whereas the presence of cumulative benefits will mitigate perceptions of sunk costs, thereby also mitigating perseverance.

This research provides several distinct and important contributions. First, the theory and findings shed light on how consumers do, and do not, 'stick' to pursuing goals following progress. Second, this work identifies an underlying process to account for the observed effect of cumulative and all-or-nothing benefits upon goal perseverance, namely differential escalation of perseverance due to perceived sunk costs. Third, this work contributes to resolving disparate findings in the literature regarding goal progress. Fourth, doing so has obvious implications for consumer welfare inasmuch as goal achievement is central to well-being. Finally, the present research has substantive implications for the design and management of consumer loyalty and similar marketing programs.

Three empirical studies were conducted to evaluate the proposed hypotheses.

Study 1

A preliminary study was conducted to determine whether cumulative (vs. all-or-nothing) benefits moderate the influence of goal progress upon goal perseverance. Specifically, progress should increase perseverance more so in the case of all-or-nothing than cumulative benefits.

Method. Participants consisted of 252 university students. A 2(Goal Progress: High/Low)x2(Benefit Type: All-or-Nothing/Cumulative) between subjects design was employed. Participants were placed into a first person scenario in which they were members of a café loyalty card program accumulating 10 stamps toward a free coffee. Subjects were informed of their progress to date (3 or 7 stamps) and the type of benefit associated with progress (free $2.50 coffee for 10 stamps or $.25 discount per stamp). Participants answered four items measuring intent to complete the loyalty card.

Results and discussion. ANOVA of the goal perseverance measure (coefficient α = .91) revealed the predicted two-way interaction of progress and benefit type (F(1,226)=4.69; p<.05). Furthermore, for an all-or-nothing goal, progress increased perseverance (F(1,226)=5.47; p<.05), whereas progress had no effect upon perseverance in the case of a cumulative benefit goal (F(1,226)=.55; p=.46). These results directly support H1, providing evidence for the moderating role of cumulative (versus all-or-nothing) benefits in determining the influence of progress upon perseverance.

Study 2

Study 2 was conducted to evaluate the underlying role of sunk cost perceptions (H2), and to examine "hybrid" goals which provide both all-or-nothing and cumulative benefits. Sunk cost perceptions should drive greater perseverance in the case of an all-or-nothing goal versus a hybrid goal.

Method. Participants consisted of 217 university students. A 2(Goal Progress: High/Low)x2(Benefit Type: All-or-Nothing/Hybrid) between subjects design was employed. The scenario was similar to study 1 except i) participants in the hybrid condition received both the all-or-nothing and cumulative benefits employed in study 1 (effectively doubling total compensation for completing the card) and ii) two items measuring sunk cost perceptions were included.

Results and discussion. ANOVA for goal perseverance (coefficient α = .93) revealed the predicted interaction between progress and benefit type (F(1,195)=4.15; p<.05). For all-or-nothing benefits progress increased perseverance (F(1,195)=11.54; p<.01), whereas in the hybrid condition (all-or-nothing plus cumulative benefits), the effect of progress was not significant (F(1,195)=.18; p=.67). A bootstrap mediation analysis indicated that the indirect effect of goal progress upon perseverance through sunk cost perceptions was significantly stronger in the case of an all-or-nothing versus a hybrid goal (95% CI: .82 to 2.03). These results support H1 and H2.

Study 3

Study 3 examined the effects of all-or-nothing versus cumulative benefits upon goal perseverance during actual goal pursuit with a real outcome.

Method. Participants were 355 university students. A 2(Goal Progress: High/Low)x2(Benefit Type: All-or-Nothing/Cumulative) between subjects design was employed. Participants chose whether to adopt a goal to win a raffle prize that entailed completing 10 tasks to earn tickets. The all-or-nothing (cumulative) condition provided 10 tickets upon successfully completing all 10 tasks (1 ticket per task). At any time participants could abandon the raffle tasks to play a computer game. Participants encountered a difficult, open ended word search puzzle task after completing either 2 (low progress condition) or 8 (high progress condition) simple evaluation tasks. The number of correct words found served as the primary measure for perseverance. Two items measuring sunk costs were recorded.

Results and discussion. ANOVA of goal perseverance revealed the predicted two-way interaction of goal progress and benefit type (F(1,260)=5.56; p<.05). For an all-or-nothing goal, progress increased perseverance (F(1,260)=4.07; p<.05). In contrast, the effect of progress for a cumulative goal was not significant (F(1,260)=1.70; p=.19) A bootstrap mediation analysis indicated that the indirect effect of progress upon perseverance through sunk costs was signifi-

cantly stronger for an all-or-nothing goal compared to a cumulative goal (95% CI: .07 to 1.63). Supporting H1 and H2, all-or-nothing benefits increased perseverance as a function of progress due to exacerbated sunk costs, whereas cumulative benefits mitigated this effect.

The Nonanalytic Influence of Memory on Product Placement Consequences

Tamara Ansons, University of Michigan, USA
Jason Leboe, University of Manitoba, Canada

EXTENDED ABSTRACT

Despite the enthusiastic use of product placements, researchers have not determined whether or not this form of advertising produces profitable outcomes for featured brands. In a comprehensive review, Balasubramanian, Karrh, and Patwardhan (2006) proposed that outcomes of product placements fall into three broad categories: cognitive, affective and conative/choice effects. Although cognitive outcomes, or memory effects, such as product recognition and recall, have received the most attention from consumer researchers, research that has examined the relationship between the different effects, have revealed an inconsistent association. Most consistent, however, appears to be a negative association between memory effects and evaluation and choice measures (Cowley and Barron 2008; Law and Braun 2000; Matthes, Schemer, and Wirth 2007). To accommodate the complex associations that have been found in previous studies, the current framework emphasizes how the interaction between memory processes and task features give rise to measurable outcomes of product placement.

In past frameworks, memory has been treated as being used more analytically to guide brand preferences. Mainly, if viewers remember a brand being featured during a product placement event, this is thought to instigate a negative response toward the brand through the activation of persuasion knowledge (Campbell and Kirmani 2000; Friestad and Wright 1994). Contrasting this analytic use of memory, we examine how nonanalytic influences, meaning processes that are irrelevant to the current task (Jacoby and Brooks 1984), contribute to consequences observed for brands that are featured during a product placement event. As has been emphasized in other studies (Whittlesea and Price 2001), the nonanalytic influence on subjective judgments is expected to arise out of perceptual fluency that occurs for brands that are presented during a product placement event.

Methodology

Participants were presented with a narrative, which was an adapted excerpt from a novel (Footner 1940). Embedded within the narrative were 20 different brands that varied across a number of different product categories (e.g., bottled water, electronics, clothing). Each of the brands were presented either once or five times within the narrative. Four versions of the passage was created so that, one of two brands from a certain product category appeared during the narrative.

Participants then completed a filler task before completing a recognition task and then a brand choice task. In both the recognition and brand choice task, participants were presented brands that appeared in the narrative and new brands and were asked to judged their recognition for those items (1 = *low* and 4 = *high* on both familiarity and recollection following Higham and Vokey 2004) and their likelihood to select a brand for a close friend (1= *Definitely would not select* to 9 = *Definitely would select*).

Summary of Main Findings

Study 1

Participants' performance on the recognition task indicated that they were better able at recognizing brands that were presented five times in the narrative, compared to brands that were presented once in the narrative. Despite the fact that participants were better able to remember brands that were presented five times, participants reported higher choice ratings for brands that were presented once (5.70 vs. 6.20), $F(1, 90) = 11.83$, $MSE = 0.96$, $p = .001$, and five times (5.70 vs. 6.31), $F(1, 90) = 14.16$, $MSE = 1.18$, $p < .001$, compared to brands that were not presented in the narrative.

Studies 2 and 2a

A possible alternative explanation for the findings observed in study 1 is that participants experienced narrative transportation (Green and Brock 2000), or were highly engaged with the narrative, which lead to a positive response to featured brands (Escalas 2004, 2007). If this were the case, then disrupting the extent to which participants were engaged with the narrative (by presenting the narrative in a random order to some participants) should result in a more negative response to the featured brands. Although participants reported being more engaged in the sequential narrative, compared to the randomly presented narrative, (3.23 vs. 2.71), $t(80) = 3.51$, $p = .001$, choice ratings were only influenced by the prior presentation of the brand, $F(2, 160) = 7.75$, $MSE = 0.59$, $p = .001$. Overall, participants reported higher brand choice ratings for brands that were presented once, compared to brands that were new (6.30 vs. 5.84), $F(1, 81) = 17.28$, $MSE = 0.50$, $p < .001$, and to brands that were presented five times (6.30 vs. 5.99), $F(1, 81) = 6.06$, $MSE = 0.67$, $p = .016$. However, this effect only occurred when the brand's prior presentation in the narrative was not made salient (study 2a).

Study 3

If the presentation of a brand within a narrative activates persuasion knowledge and that information is used analytically when completing the choice task, then altering the activation of persuasion knowledge (by presenting brands blatantly or subtly) should moderate influence of a brand's prior presentation on choice ratings. Although the blatant presentation of the brand resulted in higher persuasion knowledge ratings, compared to when the brand was subtly presented for brands that were presented five times, (5.68 vs. 4.62), $t(121) = -3.02$, $p = .003$, and once, (4.20 vs. 3.29), $t(121) = -2.67$, $p = .009$, analyzing the choice ratings indicated only a main effect of brand presentation number, $F(2, 238) = 3.92$, $MSE = 0.72$, $p = .02$. Overall, participants reported significantly higher choice ratings for brands that were presented five times in the narrative, compared to brands that were new (6.11 vs. 5.81), $F(1, 122) = 6.03$, $MSE = 0.91$, $p = .015$, and compared to brands that were presented once during the narrative (6.11 vs. 5.92), $F(1, 122) = 4.23$, $MSE = 0.52$, $p = .042$.

Concluding Comments

Together, these studies provide evidence in support of the nonanalytic influence of memory. Since choice ratings were not influenced by the level of engagement nor the activation of persuasion knowledge, the nonanalytic influence of memory, and not a more deliberate influence of memory, appeared to influence choice ratings. More broadly, these findings suggest that product placements do result in positive outcomes for featured brand, based on the nonanalytic influence of memory.

Evaluative Conditioning Revisited: An Affective Information Processing Model

Jonathan Hasford, University of Kentucky, USA
David Hardesty, University of Kentucky, USA
Blair Kidwell, University of Kentucky, USA

EXTENDED ABSTRACT

When attempting to influence consumer attitudes toward a particular product, companies often pair brands with naturally appealing images which subsequently transfers the favorable reaction from the image to the brand. This process is known as *evaluative conditioning* and has garnered significant attention by consumer researchers (e.g. Gibson 2008; Stuart, Shimp, and Engle 1987; Sweldens, Van Osselaer, and Janiszewski 2010) since the seminal work of Gorn (1982). Despite nearly three decades of research in evaluative conditioning, one fundamental question remains unanswered; namely, what is the underlying theoretical process that produces evaluative conditioning effects? Despite several proposed models of the evaluative conditioning process, no theoretical approach is capable of fully explaining why the transfer of attitudes from the unconditioned stimulus (i.e. appealing image) to the conditioned stimulus (i.e. brand) occurs (Hofmann et al. 2010). The current research uses an affect-as-information perspective (Schwarz and Clore 1996) to explain evaluative conditioning effects in food choice.

A primary concern within our model is how individuals process emotional information. Specifically, we are interested in understanding how conditioning transfers emotional information via multiple information processing pathways. Whether individuals thoughtfully consider the emotion present or simply rely on affective cues to make evaluations could differentially impact subsequent attitudes that are developed from conditioning. Thus, to further develop the affect-as-information model, we investigate emotional information processing differences and their impact on subsequent evaluations.

Affect-as-Information Perspective

Prior research has suggested that affective transfers may occur during the conditioning process (e.g. De Houwer, Thomas, and Baeyens 2001; Sweldens et al. 2010). We extend this perspective and suggest an affect-as-information model of evaluative conditioning; conditioning occurs based on how individuals process the emotional information present within the unconditioned stimulus. This perspective is based on the role of emotion in initial attitude formation (e.g. Schwarz 1997; Wood 2000) as well as models of attitude formation (Bagozzi, Tybout, Craig, and Sternthal 1979; Fishbein 1967; Schwarz and Clore 1996).

Individuals can process the emotion present in the unconditioned stimulus in one of two ways. Traditional perspectives on the role of affect in information processing suggest that System 1 (implicit, nonconscious) processing typically considers emotion automatically (Evans 2008; Johar, Maheswaran, and Peracchio 2006). However, emotion can also transfer between brand and image consciously, which facilitates explicit information processing (Griskevicius, Shiota, and Neufeld 2010).

The conscious transfer of emotion between stimuli is also dependent on individual characteristics. Individuals differ in their ability to process emotional information (Bless et al. 1996). Individuals who are skilled in using, understanding, and managing emotional information may recognize that emotions elicited from the unconditioned stimulus do not necessarily indicate diagnostic information about the conditioned brand. Conversely, less-skilled others may focus on the emotional cues from the unconditioned stimulus as a primary determinant of subsequent evaluations. This individual dif-

ference is critical in understanding the impact of emotional information transferred via conditioning.

The affect-as-information perspective is able to explain several shortcomings of existing evaluative conditioning theories outlined by Hofmann et al. (2010). Contingent aware participants (i.e. those who recognize the pairing of unconditioned and conditioned stimuli) should demonstrate stronger conditioning effects as they more thoughtfully consider the emotion present in the conditioning process. Furthermore, affect-as-information can explain post-conditioning attitudinal changes in the conditioned stimulus when the valence of the unconditioned stimulus changes. Individuals will utilize new information on the unconditioned stimulus and re-evaluate the conditioned stimulus based on the affective change in attitude toward the unconditioned stimulus. Lastly, existing theories of evaluative conditioning lack empirical support for the main propositions of each theory. Study 1 is designed to empirically demonstrate the affect-as-information explanation for evaluative conditioning effects.

Study 1

Eighty-nine participants were assigned to the positive conditioning group, where fictitious brands were paired with attractive images, the negative conditioning group, where fictitious brands were paired with unattractive images, or the control group where all images and brands were randomly presented. After evaluating target healthy and unhealthy fictitious food brands, participants were then given a scenario about attending a football game and asked how likely they were to attend. If the affect-as-information perspective explains evaluative conditioning, then the experienced affect from conditioning trials should not only influence attitudes toward the fictitious brands but towards the likelihood of attending the game as well (Pham 1998).

Participants in the positive-conditioning group had significantly higher ratings for the target brand (M = 5.25) than those in the neutral (control) condition (M = 4.01, $p < .05$) and those in the negative-conditioning group (M = 2.06, $p < .01$). Furthermore, in the positive-conditioning group, increased attitudes toward the target brand from conditioning predicted increased likelihood of attending the game ($\beta = .39$, $t = 2.23$, $p < .05$). In the negative-conditioning group, decreased attitudes toward the target brand from conditioning predicted decreased likelihood of attending the game ($\beta = .37$, $t = 2.16$, $p < .05$). Participant attitudes in the control condition were unrelated to likelihood of attending the game. These findings, in conjunction with the refutation of existing evaluative conditioning models by Hoffman et al. (2010), support the affect-as-information perspective underlying evaluative conditioning effects.

Study 2

Having established the superiority of the affect-as-information model for understanding evaluative conditioning effects, we next investigate how individuals differentially process emotional information and suggest that emotional intelligence can limit conditioning's initial transfer of emotion. Eighty-two participants were assigned to the same positive or control conditions from Study 1. Participant emotional intelligence was measured via the Consumer Emotional Intelligence Scale (Kidwell, Hardesty, and Childers 2008). Regression results demonstrated a significant interaction between emotional intelligence and conditioning group ($\beta = -1.61$,

p < .05) where higher levels of emotional intelligence decreased the influence of evaluative conditioning on target brand attitudes. These findings suggest that evaluative conditioning tactics do not influence consumers who have high emotional intelligence, while individuals who lack emotional intelligence are susceptible to attitude change from conditioning.

Together, the results of two studies provide new insights into evaluative conditioning research. First, a new theoretical explanation of evaluative conditioning effects is provided via the affect-as-information perspective. Secondly, we show that the ability to thoughtfully understand and utilize emotions (i.e., emotional intelligence) fundamentally changes how individuals process emotion from conditioning trials. We hope this research provides a new dominant perspective in explaining evaluative conditioning effects and furthers interest in this popular domain.

Bolstering versus Counterarguing Mindsets:
Implications for the Effectiveness of Persuasive Messages

Alison Jing Xu, University of Toronto, Canada
Robert S. Wyer, Jr., Chinese University of Hong Kong, Hong Kong

EXTENDED ABSTRACT

People who encounter a persuasive communication might either (a) generate thoughts that bolster the communicator's point of view or (b) attempt to refute the implications of the communication. These dispositions could obviously depend on individuals' prior agreement or disagreement with the point of view being expressed. However, they could also be influenced by a mindset that is activated by the behavior that participants performed before the persuasive communication is encountered (Wyer and Xu 2010). We proposed and found that inducing participants to make supportive elaborations about a series of propositions activated a bolstering mindset that increased the effectiveness of an unrelated advertisement they encountered subsequently. However, inducing participants to refute the implications of a series of propositions activated a counterarguing mindset that decreased the ad's effectiveness. These mindsets had more impact when the cognitive behavior they activated differed from the default behavior that was likely to occur in the absence of these mindsets. However, when a persuasive communication is difficult to refute, a counterarguing mindset that increases participants' awareness of this difficulty could increase their perceptions of the communication's validity and, therefore, could increase its effectiveness rather than decreasing it. Finally, watching a political speech or debate activated different mindsets, depending on participants' a priori attitude toward the politicians involved, and these mindsets influenced the impact of an ad that was presented later. Four experiments tested these possibilities.

Experiment 1 investigated the influence of mindsets on the impact of appealing ads. Participants performed two ostensibly unrelated tasks. Participants in *bolstering mindset* conditions generated thoughts about propositions with which they typically agreed (e.g., "Reading enriches the mind"). In contrast, participants in *counterarguing mindset* conditions generated thoughts about the negations of these propositions (e.g., "Reading is bad for the mind"). In *control* conditions, participants were asked to write three short essays to show their knowledge of neutral topics such as the pyramids of Egypt. After that, all participants were exposed to an ad about a vacation spot and they (1) rated the attractiveness of the vacation spot (2) evaluated the persuasiveness of the ad, and (3) wrote down the thoughts they had about the ad. The results showed that inducing a counterarguing mindset increased the number of negative thoughts that participants generated, and consequently, decreased their evaluations of the vacation spot and the persuasiveness of the ad. However, inducing a bolstering mindset nonsignificantly increased the number of positive thoughts generated, and consequently, increased their evaluations of the vacation spot and persuasiveness of the ad. Mediation analysis showed that the type of thoughts mediated the influence of mindsets on product evaluations.

Experiment 2 explored the influence of mindsets on the impact of an unappealing ad. The results showed that when the ad was unappealing, counterarguing was the default processing strategy. Therefore, inducing a counterarguing mindset had little additional negative effect. However, inducing a bolstering mindset had a significant positive effect on product evaluations.

Experiment 3 showed a boomerang effect of the counterarguing mindset. Bolstering and counterarguing mindsets were induced as in Experiment 1. Then, these and control participants read an appeal from UNICEF for donations to help disadvantaged children in Africa get an education. Participants then reported their intentions to make a monetary donation and decided how much they would be willing to donate. Because (a) donation appeals usually urge individuals to engage in altruistic behaviors that have socially desirable implications, and (b) the communicators have no intrinsic self-interest in the success of persuasion, we expected that recipients would find it difficult to generate arguments against the appeal's validity. Therefore, inducing a counterarguing mindset would increase participants' perceptions of the appeal's validity and would consequently *increase* its effectiveness rather than decreasing it. Results confirmed these expectations. Participants who adopted a counterarguing mind-set reported higher donation intentions and were willing to donate more money than participants in the bolstering mind-set and control conditions, which did not differ from each other.

Experiment 4 examined whether covertly generate arguments for or against a message without expressing them overtly would be sufficient to activate a general disposition to elaborate or counterargue. Participants were self-categorized as Republicans, Democrats, or Independents, and they were randomly assigned to one of four conditions. In two *speech* conditions, participants first watched either (a) a 10-minute video of Barack Obama's speech on his economic rescue plan in the 2008 presidential campaign or (b) a comparable segment of a speech on economic policy by John McCain. In a third, *debate* condition, participants watched a 10-minute video of the third Presidential debate between John McCain and Barack Obama on their proposed economic plans. In *control* conditions, participants were not exposed to any video. Then, all participants watched a video-taped speech by the president of Toyota that was intended to increase consumers' confidence in Toyota products' safety. After receiving these materials, participants reported their attitudes toward Toyota.

We expected that participants with a strong a priori preference for one of the two candidates would be motivated to generate supportive elaborations of a speech by their preferred candidate but to counterargue the assertions made in a speech by the opposing candidate. On the other hand, both Democrats and Republicans should be highly motivated to support their favorite candidate when watching the presidential debate and, therefore, should acquire a bolstering mind-set in this condition. When participants were politically independent, different effects were expected. These participants were expected to be relatively indifferent to the two candidates and to take their assertions at face value. To this extent, they should elaborate the implications of the speech regardless of who delivers it, and should develop a bolstering mindset. When these participants listened to the presidential debate, however, we expected them to follow the two candidates' attempts to refute one another's positions and, in doing so, to covertly counterargue themselves. Thus, we expected them to acquire a counterarguing mindset. In all cases, activating a bolstering mindset would increase participants' evaluations of Toyota, whereas a counterarguing mindset would decrease their evaluations of Toyota. Because Toyota is a favorable brand, a counteraruing mindset would have a stronger influence than a bolstering mindset does. Results confirmed these expectations.

The present series of studies provide the first demonstration of the effects of a behavioral mindset on the impact of a persuasive communication. In doing so, they extend our general understanding

of mindsets in three ways. First, mindsets have more impact when the cognitive behavior they activated differed from the default behavior that was likely to occur in the absence of these mindsets. Second, when the behavior induced by a mindset is unsuccessful in attaining the goal to which it is relevant, it can have a boomerang effect. Finally, a mindset can be activated not only by overt behavior but also by unobserved cognitive activity that people engaged in in the previous situation.

Seeing Things from the Other Guy's Point of View:
Self-Other Difference in the Context of Endowment

Didem Kurt, University of Pittsburgh, USA
J. Jeffrey Inman, University of Pittsburgh, USA

EXTENDED ABSTRACT

Perspective taking shapes our perception of the world around us and thus, our consumption decisions. However, an accurate understanding of others' perspective cannot be easily achieved (e.g., Van Boven, Dunning, and Loewenstein 2000; Van Boven and Loewenstein 2005). In this paper, we examine the economic magnitude of failed perspective taking by consumers assuming the same role in the context of endowment. Specifically, we investigate whether owners and buyers systematically mispredict the valuation of an object by other owners and buyers, respectively. This is an important question to address since biased predictions may lead people to engage in transactions that are suboptimal (e.g., buyers may overbid for a house). In addition, post-transaction upward external comparisons in trading (e.g., Is the price I paid higher than the price others in a similar situation paid?) have been shown to negatively impact both buyers' and sellers' satisfaction with a transaction (Novemsky and Schweitzer 2004).

We maintain that even being in the shoes of others (e.g., being an owner and estimating valuation of other owners) does not enable people to accurately predict the impact of endowment and lack of ownership on others. We base our prediction on previous research suggesting that people underestimate the extent to which an affective experience influences preferences and choices of others in the same role (e.g., Loewenstein 1996; Faro and Rottenstreich 2006), resulting in a self-other difference in the *value function* of prospect theory. Specifically, we argue that owners fail to appreciate the extent to which endowment affects other owners, whereas buyers fail to realize the extent to which lack of ownership affects other buyers. Accordingly, we predict that owners underestimate the average selling price demanded by other owners, whereas buyers overestimate the average purchase price offered by other buyers. In conjunction, biased estimations by both groups will translate into failed prediction of the endowment effect.

In Study 1, participants ("owners") who were endowed with a coffee mug indicated the lowest price at which they are willing to sell their mugs. They then estimated the average lowest price at which other participants would be willing to sell their mugs ($2 reward was offered to those with close estimations to ensure incentive compatibility). In a separate session, participants ("buyers") who were not endowed with mugs indicated the highest price at which they would be willing to receive the mug instead of that amount of cash. Then, they estimated the average highest price at which other participants would choose to receive the mug instead of cash. As predicted, owners underestimated the average selling price of other owners by 19%. Conversely, buyers overestimated the average buying price of other buyers by 26%. The results also show that there is no significant difference in the estimated average valuations between owners and buyers, suggesting that while estimating other people's valuations, the participants do not anticipate the endowment effect.

Previous research has shown that higher level of perceived general similarity to a target is associated with greater empathy and perspective taking (e.g., Krebs 1975; Batson and Shaw 1991). In Study 2, we investigated whether priming similarities between participants and comparison targets (i.e., average undergraduate student at the same university) might reduce the magnitude of owners' and buyers' prediction errors. Participants assigned to the similarity condition were asked to write down "three ways in which you are similar compared to the average undergraduate student at <school name>." Those in the control condition were not given this task. The average prediction error of owners was reduced by 59% in the similarity condition. Furthermore, similarity priming eliminated overestimation by buyers, whereas overestimation in the control condition is still positive. Accordingly, we find that when estimating others' valuations, participants in the similarity condition anticipate the endowment effect, while participants in the control condition again fail to predict the endowment effect.

In Study 3, to provide further evidence on the proposed underlying mechanism for our findings, we measure participants' perspective taking and empathy (e.g., Davis 1983; Galinsky et al. 2008) and examine their impact on documented estimation errors. We find that greater perspective taking ability is associated with lower estimation errors when participants are high, but not low, in empathy. Overall, the results suggest that owners and buyers with high perspective taking ability and empathy predict others' valuations with the highest accuracy.

Enhanced understanding of the perspective of others in the same role can help consumers avoid suboptimal economic decisions. Our research demonstrates that consumers fail to take an accurate perspective of others even when they are in the shoes of others and that perspective taking can be enhanced by helping individuals consider similarities between themselves and the targets.

Connected Consumers: The Influence of Temporal Sense of Community, Socio-Emotional Experience, and Satisfaction on Event Loyalty

Steffen Jahn, Chemnitz University of Technology, Germany

Hansjoerg Gaus, Saarland University, Germany
T. Bettina Cornwell, University of Oregon, USA

EXTENDED ABSTRACT

More than a decade ago, sociologists and marketing researchers identified a rise in postmodern communities held together through shared emotions and consumption practices (Cova 1997). Across contexts, consumption plays a role in bringing people together, and delivering what Cova (1997) calls 'linking value.' Linking value refers to a "product's, or service's contribution to establishing and/or reinforcing bonds between individuals" (Cova and Cova 2002, 603). Live events hold great potential in offering linking value since they are staged anchoring places for consumer collectives.

Existing marketing research, however, has mainly considered live events as a communications platform for brands (Cornwell 2008; McAlexander, Schouten, and Koenig 2002). In spite of events' economic relevance, our understanding of mechanisms that link antecedents with consequences of linking value offered by events is limited. The aim of the present research is to provide a framework that sheds light on the development of linking value and how it may relate to loyalty.

Existing research on this topic either focused on consumer-consumer interaction (CCI) or brand communities. Regarding the nature of CCI processes, Arnould and Price (1993) showed that intimate and extended experiences lead to an evolving feeling of communion that is shaped by direct interaction in small groups around common problems and can be fostered by service staff. Generally, however, CCI researchers have paid relatively little attention to services where CCI is one of the main sources of value creation (Nicholls 2010). Exceptions include small-scale establishments patronized by a group of regular customers, such as taverns or laundromats (Rosenbaum 2006). In the context of larger live events, existing research has not yet answered how CCI may relate to loyalty.

Brand community research, on the other hand, found that brand community engagement increases brand loyalty and that brandfests are able to foster community engagement (Algesheimer, Dholakia, and Herrmann 2005; Bagozzi and Dholakia 2006; Carlson, Suter, and Brown 2008; McAlexander et al. 2002). Brand admirers are thought to identify with other brand admirers, which places emphasis on their social identity. As a consequence, social norms foster loyal behavior (Algesheimer et al. 2005; Dholakia, Bagozzi, and Pearo 2004). Findings from this literature, however, cannot be transferred directly to the general event context. This is because the loyalty object in brand community research is the brand itself. Events in the form of brandfests can increase brand loyalty (Carlson et al. 2008; McAlexander et al. 2002). Consumer-organized events additionally evoke intentions to repeat such events within the same small friendship group (Bagozzi and Dholakia 2006). Importantly, many live events differ from those mentioned. For these events, the baseline event loyalty may be much lower due to the absence of a dominating brand influence. In addition, the normative influence of an in-group might be rather low in many situations.

Extending this work, we argue that events are able to reveal an otherwise latent consumption community (more precisely, events provide the platform on that attendees can jointly uncover and reveal their latent bonds through shared emotions). Need to belong theory maintains that social environments can facilitate intrinsic motivation by supporting people's innate need to belong (Baumeister and Leary 1995; Mead et al. 2011). We contend that the social environment at events can support people's need to belong via a mechanism that transforms shared emotions (the socio-emotional experience) into a temporal sense of community. Satisfying people's need to belong then activates the intrinsic motivation to repatronize this event. Our framework is different from one that highlights social norms and outgroup devaluation, such as social identity theory. Rather, it highlights the intrinsic motivation fostered by social interaction in a context of shared interest. The present research contributes to both our understanding of communal consumption phenomena as well as the relevance of such phenomena for individual loyalty. It complements existing research that identified normative pressure as a main mechanism by offering an alternative that is more in line with a consumer value perspective.

To test our conceptual model, we conducted a large-scale survey among 596 visitors of a music festival (28% female, mean age 21.8 years). Results show that attendees' repatronage intentions are influenced not only by overall satisfaction with the event and the socio-emotional experience but also by consumers' temporal sense of community. That is, the linking value that is co-created during events plays a crucial role in attendees' loyalty processes. As expected, consumers' socio-emotional experience is a main driver of temporal sense of community. By means of an alternative model we show that the mechanism of social connectedness on loyalty is direct and not mediated by satisfaction. Thus, satisfying the need to belong adds linking value to an event which increases consumers' intent to patronize again.

Last but not least, our results show that the classic antecedent of loyalty, customer satisfaction, may vary in explanatory power when evaluating collective hedonic experiences such as festivals. Considering a large number of events to be attended because of consumers' need for affiliation and hedonism (Tinsley and Elredge 1995) supports our theory that communal phenomena may individually motivate consumers to be loyal toward the platform for such social interaction. This extends our knowledge in that it is not only norms and intergroup relations that work as mechanisms behind loyalty effects.

How "Healthy Eating" Packaging Cues Affect Purchasing and Consumption Behavior

Xiaoyan Deng, The Ohio State University, USA
Barbara Kahn, University of Pennsylvania, USA
Sara Michalski, General Mills, USA

EXTENDED ABSTRACT

Research has consistently shown that consumers oftentimes use external cues to make consumption volume decisions (Chandon and Wansink 2007; Scott, Nowlis, Mandel, and Morales 2008; Vale, Pieters, and Zeelenberg 2008; Wansink and Chandon 2006). According to Brian Wansink (http://mindlesseating.org/faq.php), "Most of us don't overeat because we're hungry. We overeat because of family and friends, packages and plates, names and numbers, labels and lights, colors and candles, shapes and smells, distractions and distances, cupboards and containers." As the obesity crises escalates that currently 34% of adults and 17% of children are obese (Belluck 2010), marketers and researchers have been studying the effects of external cues on consumption rates and how cues can be used to control or prevent overeating.

In this research, we focus on the effects of "healthy eating" packaging cues, more specifically verbal nutrition claims and visual product images featured on the package, on consumers' purchasing and consumption decisions. Across four studies we address several important questions. First, how do packaging cues affect consumers' in-store purchasing and at-home consumption decisions? Second, do verbal and visual cues interact? Third, can packaging cues affect consumers when they are mindless as well as when they are mindful?

Our research reports four important findings. First, in the store, verbal claims can interact with visual cues to affect purchase intentions, but only if the verbal claims are ambiguous. Second, this interaction between ambiguous verbal cues and visual cues only occurs when consumers are mindful. When they are mindless, an independent effect of visual cues is observed. Third, packaging cues influence consumers differently in the store environment from the way they influence consumers at home. Once the package is purchased and taken out of the store, consumers process information more heuristically and there is no interaction between verbal and visual cues even in a mindful state. When making consumption decisions (rather than forming intentions), when consumers are mindful they are influenced only by verbal cues, and when mindless they are only influenced by visual cues. Finally, we find evidence of a boomerang effect that visual cues that indicate "perceived lightness" of a healthy product in store and thus increase purchase and consumption likelihoods for those healthy products which is a socially responsible behavior, backfire in consumption occasions at home by causing consumers to eat more, which is an unhealthy practice.

Our findings contribute to the literature on packaging. Previous research has shown that packaging cues can both influence purchase intentions and later consumption evaluations, when the product experience is ambiguous. For example, Levin and Gaeth (1988) showed that product packaging (identifying ground beef as 75% lean or 25% fat) could affect evaluations towards the product, and even have effects on perceived tastiness of the beef, although the latter effects were somewhat mitigated by tasting the food. We add to this literature by showing that packaging effects can not only frame purchase intentions and consumption evaluations, but can also affect consumption quantities.

Like the previous research, we show that packaging effects are stronger for ambiguous cues (in our case, ambiguous verbal cues).

We however add another moderator: whether the consumer is mindful or not is important in predicting the effects. And unlike most of this previous research, we find boomerang effects rather than consistent evaluations between purchase and consumption occasions. In that regard, our findings are more similar to those described by Vale, Pieters and Zeelenberg (2008) and Wansink and Chandon (2006) who showed that small package formats and low-fat nutrition labels can "backfire" as consumers no longer feel the need to regulate their own behavior. However, our results differ from these more recent studies in that we find these effects not only with nutritional labeling that is evaluated mindfully, but rather also through visual cues that are evaluated mindlessly. Our findings therefore also contribute to the literature on mindless eating by introducing a new marketing cue that influences this type of behavior. We find that when consumers are eating mindlessly, the location of the product image on the package can affect how much consumers eat.

Does a Crowded Store Lead to a Crowded Mind?
Crowding and Mental Construal of Product Features

Ahreum Maeng, University of Wisconsin-Madison, USA
Robin Tanner, University of Wisconsin-Madison, USA

EXTENDED ABSTRACT

Consider the following scenario: You are shopping for a new DVD player at a retailer. You visit the store on a Saturday when the store is crowded and the aisles are full of browsing shoppers. You eventually pick out a DVD player to purchase but decide to think it over at the weekend. You go back early Monday morning when the store is substantially emptier and return to the DVD player aisle to once again compare the players in your consideration set. The question is might the less crowded store environment cause you to mentally construe features of the DVD players differently than on your prior visit, thus potentially causing you to change your choice? The goal of the present research is to investigate this fascinating possibility through the lens of construal-level theory (CLT; Trope and Liberman 2003). Our core theoretical model is that socially crowded environments lead to tense arousal (Worchel and Teddlie, 1976) causing individuals to narrow their conceptual scope (Tucker and Williamson, 1984) which leads them to rely more on lower level construals.

Study 1 used a 2 X 2 design (N = 284) with crowdedness (crowded or uncrowded) and product feature (desirable or feasible) manipulated between subjects. To manipulate crowdedness we utilized a semantic priming approach based on a Cartesian coordinate task (Williams and Bargh, 2008). Specifically, participants viewed a Cartesian plane on which either two (uncrowded condition) or eight (crowded condition) points were plotted. Next, in a supposedly unrelated rating task participants were then asked to rate a DVD player (described over eight attributes) on a 7-point scale (1 to 7). One of the attributes of the DVD player was varied to be either feasibility orientated ("manual is easy to use") or desirability orientated ("player is made of high technology materials"). Results revealed no main effect of either crowdedness or product feature but did reveal an interaction between the two (F(1, 280) = 5.02, $p <$ .03).). Participants in the uncrowded condition rated the DVD player with the desirably feature higher (M = 5.77) then the player with the feasibility feature (M = 5.43). In the crowded condition, however, the player with the feasible feature was rated higher (M = 5.75) than the one with desirable feature (M = 5.46).

Study 2 (N=131) was designed to generalize the results of study 1 by using both a different crowding manipulation and also a different measure of construal level. To prime the level of crowdedness, participants were asked to complete a picture perception study that required them to record their thoughts on a picture of either a crowded or uncrowded scene. Next, in a supposedly unrelated camping trip study, participants were tasked with sorting 38 camping equipment items into mutually exclusive groups of like items. This measure was borrowed from Liberman et al. (2002) who showed that construal level moderates the number of categories created (with higher level construals leading to fewer discrete categories being perceived). Results revealed that participants did indeed generate more discrete categories after being primed with the picture of a crowded scene (M = 6.0) than did participants primed with the picture of a less crowded scene (M = 5.35; $t(129)$ = -2.491, $p<$.02). Next, to investigate the underlying mechanism, we coded participants' descriptions of how they would feel in the primed scenes in terms of whether they did (coded 1) or did not (coded 0) mention stress or anxiety. Supportive of our theoretical model, this data was used in a mediation analysis

(z= 2.08, p < .04) which revealed that stress/anxiety (i.e., tense arousal) did indeed mediate the effect of the level of crowding on the number of categories that participants generated.

In studies 3a and 3b, rather than relying on primes of crowdedness, we utilized an actual crowding manipulation with participants completing both studies in a small breakout room that was either uncrowded (3 participants at a time) or crowded (16-24 participants at a time). Study 3a utilized the same DVD rating measure as study 1 and the results replicated that study. A 2 (level of crowdedness: crowded vs. uncrowded) x 2 (product feature: feasible vs. desirable) ANOVA revealed no main effects but an interaction between the two ($p <$ .01) with a similar pattern of means to study 1. Study 3b utilized another form of categorization task that required participants to rate on a 1-10 scale whether pairs of typical and atypical exemplars belonged in a relevant category. For example, in the furniture category, chair and sofa were presented as typical exemplars, whereas radio and clock were presented as atypical exemplars. Consistent with prior findings in the CLT literature, we predicted that while crowding would not affect the rated fit of the typical exemplars, the atypical exemplars would be perceived as having greater category fit in an uncrowded environment (where was argue participants rely on higher level construals). Results supported this prediction with main effects of exemplar type and crowding being qualified by the predicted interaction ($F(1,170)$=3.23, $p <$ 0.07). As expected, participants who were in the crowded room were less inclusive in their categorization of atypical exemplars (M=3.74) than those in the less crowded room (M=4.33; $t(170)$=-2.85, $p <$ 0.01).

In summary, four studies supported the idea that the crowdedness of the consumer's environment appears to influence the way in which environmental features are mentally construed. Crowding led participants both to prefer a product described with concrete features over one described with abstract features, and also to be less inclusive in categorization tasks. We believe this finding has considerable implications. First, our data suggest that CLT may be defined too narrowly in focusing purely on raw distance per se, and that other factors (such as physical or psychological crowding) may also influence the way we construe our environments. Second, from a pure marketing perspective, one can imagine a plethora of practical implications such as whether high and low traffic stores should use subtly different persuasive appeals.

Segmenting Customers According to their Multidimensional Contact Sequences –
Application of A Multidimensional Sequence Alignment Approach

Sascha Steinmann, University of Siegen, Germany
Gunnar Mau, University of Siegen, Germany
Hanna Schramm-Klein, University of Siegen, Germany
Günter Silberer, University of Goettingen, Germany

EXTENDED ABSTRACT

It is increasingly common for firms to employ online distribution channels alongside its offline distribution channels and marketing channels to rely on these complex combinations as a source of competitive advantage and better serve their customers (Geykens et al. 2002). In such environments, many customers have become multi channel users. They realized contacts between the firm and themselves at different contact points, e.g. store, homepage across the purchase process (Rangaswamy and van Bruggen 2005). These customer contacts are a fundamental element for the attainment of customer knowledge for a supplier. Not only are the kind and number of the customer contacts in a specific process phase relevant to this, but also their functions and importance, not to mention the sequence of these three dimensions during the purchase process.

In general, customer behavior can be viewed as a sequence of interdependent actions over time (Hägerstrand 1970). However, customer behavior in marketing research is mostly treated as a chain of independent activities. Thus, the sequential order and obvious relations of the activities are often neglected. Therefore, Abbott's (1995, p. 94) statement "We assume intercase independence even while our theories focus on interaction" is largely true for marketing research concerning the segmentation of the customers regarding their individual behavior through across the purchase process. Hence, an analysis of the multidimensional sequence of the customer contacts (dimension 1), their functions (dimension 2) and their im-

portance (dimension 3) could provide crucial insights into customer behavior, as well as the needs and preferences of the customers over time. Therefore, this study will demonstrate how multidimensional customer contact sequences can be measured and form the basis for multidimensional customer segmentation. For this, customer contact sequences of N=304 customers with a retailer for consumer electronics were surveyed in across the different phases of the purchase process (pre-purchase, purchase, and post-purchase phase).

To gain deeper insights in the differences of customer behavior and powerful clusters, the multidimensional contact sequences were characterized by three dimensions: the customer contact sequence, the sequence of the functions related to the customer contacts, and the sequence of the contact importance. To account for obviously interdependencies between the three dimensions we used a multidimensional sequence alignment approach which identifies elements that can be aligned simultaneously without calculating the costs twice, called "OTMSAM" (Joh et al. 2002). In doing so, the differentiation into four clusters proved to be the best solution (see table 1).

The centroid of the first cluster has realized the lowest number of customer contacts across the purchase process. After two very important contacts with newspaper and TV-advertising in the pre-purchase phase which were used for price comparison and selective information, the desired product was bought in the store. The first contact in the centroid of cluster 2 was realized with the store and was used to obtain general information about the retailer's offers.

TABLE 1
Description of the Clusters by Centroid Sequences

Multidimensional Centroid Sequences					
Cluster 1 (n = 115)					
Contacts		Newspaper advertising	TV-advertising	Store	
Functions[1]		PC >	GI >	P	
Importance[2]		6	6	4	
Cluster 2 (n = 75)					
Contacts	Store	retailer's homepage	Sales staff	Store	
Functions	GI >	SI >	SI & A >	P	
Importance	5	5	6	6	
Cluster 3 (n = 74)					
Contacts	TV-advertising	Newspaper advertising	Advertising at the PoS	Sales staff	Store
Functions	GI >	GI >	SI >	A >	P
Importance	5	5	5	6	6
Cluster 4 (n = 40)					
Contacts	Advertising at the PoS	Advertising at the PoS	Sales staff	Store	Store	Sales staff
Functions	GI >	GI >	A >	A >	P >	A
Importance	5	5	4	6	6	6

[1] GI = "general information", SI = "selective information", PC = "price comparison", P = "purchase", A = "advisory"; [2] inquired on a six-step rating scale, 1 corresponds to *entirely unlikely*; 6 corresponds to *very likely*

This contact was followed by a contact with other websites which was used for selective information. These two customer contacts were both realized during the pre-purchase phase and were rated as important contacts. During the purchase phase the product was bought after a consultation of the sales staff. Such contacts were of specific relevance and were therefore rated as very important contacts. The centroid of cluster 3 shows that these customers realized the highest number of contacts in the purchase phase. They sought contact with TV- and newspaper advertising in the pre-purchase phase to obtain general information. These contacts with different kinds of the retailer's advertising were both evaluated as important contacts. During the purchase phase customers' of the third cluster often realized contacts with advertising at the Point-of-Sale which were used for selective information. Such contacts were also rated as important. The following consultation of the sales staff and the purchase of the product in the store were of highest importance to the customers of cluster 3 and evaluated as very important contacts.

The centroid of the fourth cluster shows that these customers realized the highest number of customer contacts across the whole purchase process as well as in the pre-purchase phase. Furthermore, the customer contacts in this multidimensional centroid sequence cover all phases of the purchase process. It is noticeable that all contacts prior to the purchase were realized in the store. After two contacts with different kinds of advertising at the Point-of-Sale for obtaining general information, these customers sought contact with the sales staff followed by two customer contacts in the store for advisory functions. With regard to these findings one may conclude that the opportunity of direct product contacts in the store are of specific relevance to the customers in cluster 4. In the post-purchase phase a contact with the sales staff was used for advisory functions as well. This contact was evaluated as a very important by this customer.

Furthermore, the results of a multinominal logistic regression (Hosmer and Lemeshow 2000) on the cluster level show that cluster membership can be satisfactorily explained and predicted by the sequencing of customer contacts. With regard to the differences in the number of realized contacts as well as of the realized customer contact points, we used the number of the ten most frequently realized transitions (substrings) of two consecutive contacts as independent variables in a first multinominal logistic regression model with the cluster membership as dependent variable. In the second logistic regression model, we control for further variables which could be associated with cluster membership (product related and socio-demographic variables). As model 1 indicates, the sequence information are strongly associated with segment membership and provide a correct classification of 74.6% of the customers. The statistical association between the substrings and cluster membership remains robust, even though significance level of parameters decreases, and correct classification increases slightly (81.4%) when the control variables are included in model 2. Especially, substrings including contacts with the store, contacts with different kinds of the retailer's advertising as well as customer contacts with the sales staff, the price of the product and internet affinity are contributing factors in explaining cluster membership.

The Influence of Outcome Alignability on Risky Medical Decisions

Partha Krishnamurthy, University of Houston, USA
Adwait Khare, University of Texas at Arlington, USA

EXTENDED ABSTRACT

People often find themselves having to choose between options that offer certain but moderate outcomes and those that offer uncertain, but potentially excellent outcomes or poor outcomes. There is a rich tradition in decision-making research of studying how people make decisions when options vary in the level of risk associated with the outcomes. Much of this research, however, has been based on options with numerical outcomes.

Although decision-makers often face options with numerically stated outcomes, it is fairly common for decision-makers to confront risk involving non-numerical, qualitative outcome states as well. In medical decision making, for example, health risk information can be conveyed via different information formats such as numeric, verbal, and visual (Lipkus 2007). Consumers, for instance, commonly choose from medicines which provide different levels of qualitative improvement (strong, medium, mild) in pain felt by patients. Similarly, physicians and nurse practitioners routinely use the Wong-Baker FACES Pain Rating Scale which has no numerical aspects to "measure" the level of pain reported by the patients.

Therefore it is important to consider whether the findings from risky contexts involving quantitative outcomes extend to situations with qualitative outcomes. If risk preference is found to be different for qualitative and quantitative outcomes, it can have important implications for strategically presenting risk information. Yet, an analysis of the studies featured in Kühberger's (1998) meta-analysis on risk-preference shows no study on this topic. Thus, our aim is to examine the effect of quantitatively versus quantitatively described, but equivalent, medical outcomes on risk preference.

There is reason to believe that the qualitative–quantitative distinction may be consequential in regards to risk-preference. Our core thesis is as follows. We start with the premise that the evaluation of a risky choice option arises from consideration of both its upside and downside outcome. Therefore, factors that alter one's ability to simultaneously consider both the upside and downside outcome ought to influence the evaluation of the risky option. One such factor relates to how the outcomes are described, qualitative versus quantitative.

Quantitative outcomes lend themselves to numerical calculations and therefore allow for a joint consideration of both the upside and downside outcomes of the risky option. As noted by Kahneman and Tversky (1979), the risky option is evaluated by multiplying each subjectively evaluated numerical outcome with its subjective probability and then adding such products of all the outcomes. Qualitative outcomes, on the other hand, are not amenable to such calculations, and therefore impede consideration of both upside and downside outcome in the risky option. We further argue that when faced with a choice between focusing on the upside versus the downside risk, people will focus on the downside and show greater tendency to avoid the risky outcome. This thesis leads to two predictions. First, qualitative outcomes will induce a focus shift that will be revealed in elevated threat perceptions of the risky option. Second, this focus shift will induce a choice shift against the risky option.

In three studies, we manipulate outcome alignability as high (quantitative outcome information) or low (qualitative outcome information) and demonstrate that (a) risk preference reduces when alignability is lower (study 1), (b) the reduction in risk-preference is mediated by threat perceptions of the risky option (study 3), and (c) the impact of alignability is robust to variations in the operationalization of the equivalence between quantitative and qualitative outcome information (study 2). The findings largely comport with our predictions.

The Effect of Regulatory Focus on the Influence of Injunctive and Descriptive Social Norms

Vladimir Melnyk, Maastricht University, The Netherlands
Erica van Herpen, Wageningen University, The Netherlands
Arnout R. H. Fischer, Wageningen University, The Netherlands
Hans C. M. van Trijp, Wageningen University, The Netherlands

EXTENDED ABSTRACT

Consumers encounter marketing messages using social norms in a variety of situations and contexts where different goals can be dominant. These goals can relate to their hopes and aspirations (i.e., promotion focus) or to their potential losses and duties (i.e., prevention focus) (Avnet and Higgins 2006; Freitas and Higgins 2002). These two focuses prime different routes of motivation for product choice, and may determine the effectiveness of social norms. The influence of norms on actual behavior may depend on its congruence with the consumer's self-regulatory focus.

Social norms can be formulated as descriptive or injunctive norms (Cialdini et al. 1990). Descriptive norms describe the typical behavior of others, and set behavioral standards from which people may not want to deviate (Schultz et al. 2007). Injunctive norms prescribe a behavior, and refer to what people should do in a given situation.

Depending on which regulatory focus is activated at the moment of facing social norms, consumers can be more responsive to either of the norm's formulations. Descriptive norms provide social proof that indicates possible beneficial behaviors (Cialdini 2006; Schultz et al. 2007), and therefore, these norms relate to the achievement of goals. In contrast, injunctive norms provide a request, and following this request is a way to avoid negative consequences (e.g., social disapproval or punishment) (Cialdini et al. 1990). Therefore, injunctive norms relate to prevention focus. The aim of this paper is to investigate the effect of compatibility between injunctive versus descriptive social norms on the one hand, and promotion versus prevention regulatory focus on the other hand to determine which formulation of social norms is the most effective under prevention and promotion focus.

Although social norms can provide a powerful instrument to influence consumers' attitudes, intentions, and product choice, the marketing literature has surprisingly few papers on the topic. Yet, to make optimal use of social norms, it is crucial for marketers to understand under which conditions the effect of social norms can increase the desired behavior or can backfire, and more specifically how to use different social norms in different situations.

Two experiments examine the consequences for attitudes and behavioral intentions of the different norms under prevention and promotion focus. Experiment 1 ($N = 100$) had a 2 (norm formulation: descriptive vs. injunctive) ´ 2 (primed regulatory focus: prevention vs. promotion) between subject design. Formulation of the social norm was manipulated in a fictitious webpage with promoted either a descriptive norm ("Wageningen students buy Fair Trade coffee") or an injunctive norm ("Wageningen students should buy Fair Trade coffee"). To prime regulatory focus participants were asked to write down one or several positive situations that they would like to achieve (vs. negative situations they would like to avoid, for prevention focus condition) within the next few weeks, and describe strategies that they could use to successfully promote this goal (vs. prevent those negative situations, for prevention condition). Experiment 2 ($N = 109$) had 2 (norm formulation: descriptive vs. injunctive) ´ 2 (ingrained regulatory focus: prevention vs. promotion) between subject design. The manipulation of norm formulation was similar to Experiment 1except that it was about organic milk. Regulatory focus was incorporated

within the message by providing either prevention- or promotion-related statements. For example, the title of the message ended either with a prevention statement "…to prevent harm to the environment" or with a promotion statement "…for a better environment". Consistent with our expectations results of both experiments show that the effect of descriptive norms is lower when prevention goals are salient than when promotion goals are salient. Unlike descriptive norms, injunctive norms are not affected by regulatory focus.

This study has several managerial implications. In particular it shows that descriptive norms are most successful when a goal approach focus rather than a loss avoidance focus is present. The research also shows that the wording of a normative message can activate a gain or loss avoidance focus. A marketer should therefore carefully design the wording of normative messages, the context in which such a message is received by consumers, as well as the channels of communication. Messages which are focused on problem avoidance may not be very well suited for descriptive norms and should use injunctive norms as a default. Messages using descriptive norms, such as campaigns based on communicating a favorable statistic of the majority of others that perform a behavior, should be conveyed in the context of achieving goals.

This research increases our understanding of the influence of social norms on decision making by showing differential effect of regulatory focus for descriptive and injunctive norms in the promotion of sustainable products, which occurs because different formulations of social norms are compatible to promotion or prevention focus. More specifically, descriptive norms are oriented towards benefits and have a better fit with a promotion than prevention focus, while this is not so for injunctive norms.

Childlike Anthropomorphic Characteristics in Products

Katarina Hellen, University of Vaasa, Finland
Maria Sääksjärvi, Delft University of Technology, The Netherlands

EXTENDED ABSTRACT

Anthropomorphism, the tendency to see humanlike qualities, such as faces, motivations, and emotions in non-human agents, has been studied in psychology and marketing (Epley, Waytz and Cacioppo 2007; Serpell 2002; Woodside, Sood, and Miller 2008). Previous literature on anthropomorphism has tended to address it as an aggregate concept. In actuality, literature on brand personality indicate that consumers do not perceive brands to just have "a human personality" but that they perceive personalities in more refined ways, for example "rugged", "sophisticated" or "friendly" (Aaker 1997) indicating that people anthropomorphize in a more refined way that previously thought. In this paper, the focus is on anthropomorphism of a specific product – products with childlike characteristics and the purpose was to investigate the nature of childlike anthropomorphic products and consumer reactions to them. Childlike anthropomorphic characteristics are likely to be interesting for marketers as scholars have suggested that humans are deeply programmed to respond positively to children and that this positive reaction extends to adults, animals, and objects to which people attribute childlike features (Morreall 1991; Serpell 2002). These feelings invite people to bond and interact with babies (Langlois et al. 1995; Morreall 1991).

We conducted four studies to examine childlike anthropomorphism. Study 1 was in-depth interviews with consumers (N = 10), five females and five males, conducted to understand their associations with childlike anthropomorphism. After freely discussing the concept of childlike anthropomorphism, the respondents were shown a booklet with 12 childlike anthropomorphic products that they were asked to evaluate. The purpose of Study 2 was to generate dimensions and items for a scale of childlike anthropomorphism in products. To reach this purpose, we used our qualitative study (Study 1) and previous literature. Based on these sources we identified 70 items to that referred to childlike anthropomorphism. We included the items in a questionnaire in a random order. We asked a sample of students (N = 202, 36.8 % females, mean age = 21) to indicate the extent to which the 60 items described their perceptions of well-known products (1 = "not at all", and 7 = "very much so"). 12 products in total were tested, ranging from purses to technical devices such as phones and laptops. The results showed that childlike anthropomorphism in products refers to four distinct dimensions: sweetness, sympathy, simplicity, and smallness.

In Study 3, we reduced the number of scale items by conducting both exploratory and confirmatory analyses. To test the stability of the scale, we employed a new sample of respondents (N = 224, 51.3 % females, mean age = 23). The procedure of study 2 was repeated with one exception; this time, each respondent evaluated only one product. 71 participants evaluated the symbolic product (the pink purse), 77 participants a utilitarian product (e.g., a razor) and 76 a symbolic and utilitarian product (e.g., a camera). Each participant saw a color picture of the product and was asked to rate the product on the 23-item scale. The questionnaire also included Aaker's (1997) brand personality scale. The results showed that childlike anthropomorphism is best represented by a second-order factor model with the four sub-dimensions of sweetness, sympathy, simplicity, and smallness. In Study 4, we focused on the nomological validity of the childlike anthropomorphic product scale by linking it to product evaluation (Oliver 1993) and willingness to attach (Thomson, MacInnis, and Park 2005). On the basis of prior literature on childlike products, we expected childlike anthropomorphism to affect these concepts positively (Lorenz 1943; Morreall 1991; Kinsella 1995; Saunders 1992; Yano 2004). Recognizing human characters in products makes consumers care for their products and feel warmly towards them and thereby it can be expected that childlike anthropomorphic products predict positive product evaluations. Thus, we predict that infant anthropomorphism is positively related to evaluation. Moreover, pioneering work on attachment originate in the realm of parent–infant relationships. According to Bowlby (1980), an attachment is an emotion-laden target-specific bond between a person and a specific object (a person or a physical object). As human infants are associated with strong positive affect and sensitivity to babies has been argued to have evolved in humans to bond and to care for their offspring, it can be expected that childlike anthropomorphism is positively related to willingness to attach to a product. A total of 214 students participated in Study 4 (N = 214, 54.7 % females, mean age = 24). Each respondent evaluated one product. 75 participants evaluated the symbolic product (the pink purse), 73 participants randomly one of the 4 utilitarian products and 66 randomly one of the 11 symbolic and utilitarian products. The questionnaire also included Thomson, MacInnis, and Park's (2005) brand attachment scale. Simple regressions showed that childlike anthropomorphism had a positive impact on product evaluation. We also found a positive relationship between childlike anthropomorphism and willingness to attach. There were clear differences between the genders: women considered the products to be sweeter, whereas men considered the product to simpler and more sympathetic. No differences were found regarding smallness.

Across samples, it was demonstrated that childlike products have four separate dimensions – sweetness, sympathy, simplicity, and smallness. The results show that consumers are attracted to childlike anthropomorphic products, and that they are willing to attach to such products. The results also suggest a gender effect. Both men and women were found to react positively to childlike anthropomorphic characteristics, but they evaluated the dimensions of the scale differently. Across all the three quantitative studies, results show that men perceived childlike characteristics as more sympathetic than did women. This result may be based on that this characteristic in women is a mating cue for men (Baumeister 2010), as men are attracted to women who are perceived as kind and lovable as such qualities are taken as indications that they are good mothers and partners. Further, men are not as sensitive as women to detecting sweetness, who may perceive the childlike products as kind and helpless, triggering feelings of caretaking and protection.

Psychological Distance in Hedonic Prediction and Consumption:
The Surprising Impact of Distant Events

Jane Ebert, University of Minnesota, USA
Tom Meyvis, New York University, USA

EXTENDED ABSTRACT

Would you prefer a film based on a true story or one that is fictitious, a recently written novel or one written five years ago? For experiential decisions such as these, individuals are often guided by how they expect the experience will make them feel, and their expectations are often wrong: they overestimate the impact of the hedonic experience (Gilbert, Driver-Linn, and Wilson 2002; Kahneman and Snell 1992). Explanations for this bias have focused on predictors' *failure to consider* the context around the focal hedonic experience (Gilbert et al. 2002), such as the effects of experiences occurring subsequent to the focal experience. In contrast, we explore a process where individuals *overconsider* the context around the focal hedonic experience. We focus on psychological distance: a context that encompasses many attributes important in decision-making such as self-relevance, time and likelihood of occurrence, and authenticity (Liberman, Trope, and Stephan 2007).

We propose that psychologically distant events can often have a surprisingly strong emotional impact, equivalent to a similar psychologically near event, because of substantial limitations to the attenuating effect of psychological distance. These limitations result from mechanisms that consumers are not aware of, leading them to overestimate the impact of psychological distance (and underestimate the emotional power of psychologically distant events).

We compare people's predictions and experience of hedonic experiences that are psychologically close or distant, before examining underlying processes and a suboptimal behavioral consequence of the results we obtain. We examine our hypothesis in six studies in which participants either read emotion-inducing newspaper stories or win a prize.

In the story-based studies, psychologically distant experiencers were first told the story was "fictitious" (studies 1A, 2, and 5) or about an event that "happened 10 years ago" (study 1B), while psychologically close experiencers were told the story was "real" (studies 1A, 2, and 5) or about an event that "happened recently" (study 1A). Experiencers then read the story and rated their affective reactions. Predictors read the story and predicted their reactions if they had first been given the information about the story context.

Predictors predict a greater influence of psychological distance on their reactions than experiencers actually experienced. Most often, predictors accurately predict affective reaction to the psychologically close experience and underestimate reaction to the distant experience. In study 3, we replicated this finding with a new experience: winning a prize available immediately (psychologically close) or in 6 weeks (distant).

We examined underlying process in studies 2 and 4. In study 3, we manipulated whether psychological distance information was presented before or after the story, manipulating whether predictors expect it to change experiencers' processing of the story. Predictors overestimate the effect of psychological distance both on experiencers' processing and the direct effect on experiencers' affect. We rule out alternative demand and salience explanations. In study 4, we focus on experiencers. We use the paradigm from study 3, where experiencers who win a prize failed to incorporate psychological distance information. By manipulating whether or not experiencers complete a task after winning the prize, we demonstrate that experiencers who

are no longer absorbed in a hedonic experience are able to incorporate psychological distance information.

In study 5 we demonstrate that these effects can lead to suboptimal decisions. Individuals feel less sad after reading a sad real story than after reading a tragic fictitious story. However, they predict the opposite (that the tragic fictitious story will make them sadder) and so choose to read that story (rather than the less upsetting sad real story).

These results suggest that, when choosing between options that vary on psychological distance attributes, individuals will be influenced by these attributes more than they should, e.g., preferring films based on true stories when, in actual fact, they would be equally happy with fictional films. More generally, this approach connects the affective forecasting literature to work in judgment that examines unwanted or over- correction, such as work on mental contamination (Wilson and Brekke 1994). This approach also builds on prior research that shows that consumers' hedonic experiences are often remarkably insensitive to the context of the experience (e.g., Novemsky and Ratner 2003)—a phenomenon that has recently been attributed to the surprisingly absorbing nature of hedonic experiences (Morewedge et al. 2010). Given the frequency of these effects in judgment, we suspect that this process may prove a common source of systematic error in hedonic prediction.

What Not To Wear? Consumer Government in Wardrobe Self-Help

Annu Markkula, Aalto University School of Economics, Finland
Ilona Mikkonen, Aalto University School of Economics, Finland
Handan Vicdan, Eastern Kentucky University, USA

EXTENDED ABSTRACT

In this paper we empirically illustrate consumer government in the context of wardrobe self-help (WHS for short). By providing an empirical example of consumer government in a cultural text, our research contributes to the scholarly work on the government of consumers (Binkley 2006, Du Gay 2004, Moisander and Eriksson 2006, Moisander, Markkula and Eräranta 2010).

Government as a theoretical concept has recently been applied to marketing and consumer research. It has been argued that in the contemporary marketplace where organizations engage in co-creative practices with consumers, consumers are not only being disciplined with orders and rules (Zwick, Bonsu and Darmody 2008) – in addition, or even instead, consumers are being *governed* (Foucault [1979] 2008, 226).

One of the critical aspects of government is facilitating *self-government*; making people to monitor and reshape their own conduct, for example by enticing them on a path of self-improvement (Rose 1999, Zwick et al. 2008). The creation of a self-governing subject can occur through suggesting and offering consumers a range of technologies of the self (see e.g., Philip 2009) or operations that individuals perform on their "own bodies and souls, thoughts, conduct, and way of being" in order to transform themselves (Foucault 1988, 18, Larsson and Sanne 2005, Philip 2009, Rimke 2000).

In this paper, we empirically illustrate these practices in the context of fashion and clothing. Fashion and clothing are a significant part of the world economy (Allwood et al. 2006, 2) and it is widely accepted that this market is dominantly characterized by constant change and emulation of others (Thompson and Haytko 1997, Murray 2002). The past decade, however, has seen a surge of different types of fashion cultural mediators (McCracken 1988) in the form of TV makeover shows and guidebooks. Illustrative of this new trend is the British *What Not To Wear* brand by Susannah Constantine and Trinny Woodall. The brand claims to resist the dominant discourses of the fashion market, which direct consumers towards constant change and emulation of others (Thompson and Haytko 1997). By means of self-help, this new genre claims to liberate consumers to enlightened personal and social success (Gibbins and Taylor 2010).

The data used for this study consists of four books by Constantine and Woodall, which can be considered an exemplifying example of this new cultural mediator genre: What Not to Wear – The Rules (2002); ready 2 dress. How to Have Style Without Following Fashion (2002); What Your Clothes Say about You. How to look different, act different and feel different (2006) and The Body Shape Bible (2007). We analyzed the books using a discourse analytic approach detailed in Holstein and Gubrium (2005) and Moisander and Valtonen (2006). The level of analysis is the discursive practices through which wardrobe self-help establishes the ideal consumer subject. The analysis focuses on the technologies of the self (Philip 2009) that are offered to consumers to work on their conduct.

In the data we identify three specific, intertwined technologies of the self: 1) normalization, 2) confession, and 3) responsibilization. Normalization refers to discursive strategies which make certain practices of dressing the body seem 'normal' and desirable while excluding others, thus creating categories of right and wrong (Koro-Ljungberg, Gemignani, Brodeur and Kmiec 2007). By suggesting a range of actions through which consumers can learn to make the 'right' choices within the limits of the body, they are invited to turn the disciplining gaze upon themselves. Consumers are requested to confess (Besley 2007) to their erroneous, and to categorize and scrutinize themselves according to the guidelines offered by the style gurus. Finally, happiness is strongly associated with the choice of dress, and the individual consumer is made responsible for making the correct choices (Rimke 2000).

Based on the analysis of our empirical data, it can be concluded that the rhetoric used in wardrobe self-help is geared towards shaping and modifying consumer choice of dress by rigorously and carefully defining the limits of acceptability. The rhetoric strongly emphasizes responsibility on the part of the consumer to make right choices, as is customary to self-help literature in general (Redden 2002, Rimke 2002, Hazleden 2003, Blackman 2004, Philip 2009).

Therefore, WSH cannot be perceived as only liberating and empowering. As we have illustrated, WSH can be conceived as government (Zwick et al. 2008). Despite presenting the emulation of models and celebrities as undesirable and challenging the prevailing business strategy of the fashion and clothing sector, which is based on the notion that the cultural value of clothing is perishable (McCracken 1986), WHS still attempts to act upon consumer conduct. The ideal women is nonetheless defined according to the contemporary beauty ideals. This is also an attempt to change consumers bodily (Corrigan 2008, Entwistle 2001, Joy and Venkatesh 1994, Venkatesh, Joy, Sherry and Deschenes 2010), albeit indirectly.

When Do Metacognitive Experiences Matter?
The Different Roles of Ease of Retrieval

Hélène Deval, Dalhousie University, Canada
Frank R. Kardes, University of Cincinnati, USA
Bruce E. Pfeiffer, University of New Hampshire, USA

EXTENDED ABSTRACT

Although research suggests that judgments are often based on subjective experiences, competing theories of the underlying process coexist in the literature. Schwarz (e.g., 1998, 2004) proposes that metacognitive experiences operate as heuristic cues, suggesting that the effect should be attenuated under high elaboration conditions. In contrast, Petty and colleagues (e.g., 2007, 2009) find stronger effects when people attend to their own thoughts and try to assess their validity (the self-validation hypothesis), suggesting that the effect requires greater elaboration. Since there is empirical evidence for both conceptions, it is possible that the effect depends on differential processing styles at the time of attitude formation that may be related to the specific conditions of the task.

Recall tasks render two distinct sources of information: the recalled content and the subjective experience associated with the recall process (Schwarz 1998). Content and subjective ease of recall can have differential implications for attitude formation. Schwarz and colleagues (e.g., Schwarz et al. 1991; Wänke et al. 1995) conceptualize subjective ease as a heuristic cue, predicting that people are likely to use metacognitive experiences as an input for judgment when adopting a heuristic processing strategy. When adopting a systematic processing strategy, people should rely primarily on the recalled content (Schwarz 1998).

Petty and colleagues (Briñol and Petty 2009; Petty et al. 2007) developed a comprehensive framework for the role of metacognition in judgment based on the self-validation hypothesis. Metacognition refers to second-order thoughts or one's thoughts about thoughts and thought processes. A crucial element of metacognitive thought is the degree of confidence people have about their own thoughts (Petty et al. 2007). The process by which this confidence is assessed is referred to as the self-validation process (Petty, Briñol, and Tormala 2002). Because second-order thought processes require some motivation and ability to go beyond primary cognition (the content of one's thoughts), evaluation of the thought process is more likely to influence judgment when elaborative processing is likely. Conceptually, the self-validation hypothesis suggests that the effect of metacognition is mediated by feelings of confidence or validity associated with a particular argument.

These two empirically supported theories offer competing evidence for the role of metacognitive experiences in attitude formation. To help resolve these competing findings, we investigate the possible differential effect of processing style (memory-based vs. stimulus-based, Hastie and Park 1986) on the use of subjective experience in attitude formation. We expect that the heuristic-cue hypothesis will hold for memory-based processing and the self-validation hypothesis will hold for stimulus-based processing. The following two experiments are designed to test these predictions.

Experiment 1

One hundred and seventy-three undergraduate students were randomly assigned to one of the eight experimental conditions of the 2 (memory-based vs. stimulus-based) X 2 (high vs. low involvement) X 2 (easy vs. difficult) full factorial design. Participants were presented with information about a vacation package. Processing style was manipulated using a processing goal manipulation adapted from Mackie and Asuncion (1990). Involvement was manipulated using an accountability manipulation. Ease or difficulty of processing was manipulated using a reason generation task. After the processing style manipulation and the vacation information, participants were asked to provide either two or eight reasons (easy or difficult) for choosing the package. The primary dependent variable was attitude toward the vacation package.

An ANOVA revealed a three-way interaction supporting our predictions. The ease of processing effect was found in the memory-based condition only under low involvement, supporting the heuristic-cue hypothesis. The ease of processing effect was found in the stimulus-based condition only under high involvement, supporting the self-validation hypothesis.

Experiment 2

Experiment 2 was designed to replicate the findings of experiment 1 using a different stimulus, and different manipulations and operationalizations. Further, since the self-validation hypothesis states that the effect of metacognitive experiences on attitude is mediated by thought confidence, a measure of thought confidence adapted from Briñol et al. 2004 is also captured for analysis.

One hundred and seventy-five undergraduate students were randomly assigned to one of the eight experimental conditions of the 2 (memory-based vs. stimulus-based) X 2 (high vs. low motivation) X 2 (easy vs. difficult) between subjects full factorial design. Participants were presented with information about a 3D HDTV. Processing style was manipulated using a processing goal manipulation adapted from Hastie and Park (1986). Elaboration was operationalized as motivation and manipulated using differing expectations (exciting vs. boring) about an alleged study 2 (Webster 1993). Ease or difficulty of processing was manipulated using a reason generation task. After reading the 3D HDTV information and performing the processing style manipulation, participants were asked to provide either one or ten reasons (easy or difficult) for choosing the TV. Attitude about the TV and thought confidence were measured for analysis.

An ANOVA revealed a three-way interaction supporting our predictions. The ease of processing effect was found in the memory-based condition only under low motivation (elaboration), supporting the heuristic-cue hypotheses. The ease of processing effect was found in the stimulus-based condition only under high motivation (elaboration), supporting the self-validation hypothesis. Further, a mediation analysis (Baron and Kenny 1986) revealed that the effect of ease of retrieval on attitude formation was mediated by thought confidence for stimulus-based judgments, providing additional support for the self-validation hypothesis.

Discussion

Two empirically supported theories offer competing evidence for the role of metacognitive experiences in attitude formation. Across two experiments using different stimuli and a variety of manipulations, we showed that the role of ease of retrieval is contingent on processing style. Subjective ease is used as a heuristic cue when processing is memory-based, while subjective ease impacts attitude

formation through confidence as part of the self-validation process when processing is stimulus-based.

It is possible that these differences may be related to the timing of the subjective experience. When judgments are stimulus-based, people evaluate information as they encounter it. In this case, the initial attitude formation precedes the ease of processing effect. In contrast, when judgments are memory-based, people recall relevant pieces of information while forming a judgment. In this case, the ease of processing effect coincides attitude formation.

"One Size Fits Others":
The Role of Label Ambiguity in Targeting Diverse Consumer Segments

Caglar Irmak, University of South Carolina, USA
David Norton, University of South Carolina, USA
Randall Rose, University of South Carolina, USA

EXTENDED ABSTRACT

Marketers often use product labels to target multiple segments of consumers with a single product. For instance, Calvin Klein's fragrance CK1 is marketed as "unisex," targeting both men and women. APG's Snuggie is labeled as "one size fits all." implying that the same blanket can accommodate a range of adult body types. Such all-inclusive labels point to the "all-fitting" aspect of the product, thereby resulting in the expansion of the potential customer pool. However, we argue in this research that marketers may unintentionally be driving customers away with their omnibus labeling practices because all-inclusive labels communicate to customers that the product is likely to be purchased by not only them but also all sorts of other consumers who may not be like them. We focus on this effect of target market specificity or generality on consumer reactions to such products and develop a counter-intuitive argument that leaving the target market of the product ambiguous may actually benefit marketers.

Previous research has shown that consumers avoid products or behaviors associated with dissociative reference groups, or groups with whom they want to avoid being confused (Berger and Heath 2007, 2008; Simmel 1904/1957; White and Dahl 2006, 2007). Men in a restaurant, for example, avoided steaks labeled as "ladies cut" (White and Dahl 2006), and in product domains perceived to communicate identity, consumers diverged from out-group members' choices more generally (Berger and Heath 2007). Thus, if an all-inclusive product label reminds consumers about other consumer groups with whom they do not want to be associated, it may drive people away from the product.

The value of clear positioning and targeting of brands is so widely accepted that it could be considered a law-like generalization. The merits of these standard marketing activities is not questioned in prominent marketing management texts (e.g., Kotler and Armstrong 2005), However, we argue that leaving the target market ambiguous may help the marketers of products that are targeted to a wide range of consumer segments. We show that the reason people do not like unambiguous information such as all-inclusive product labels is that such information may act as a cue for consumers to consider others in the social space, thus, prompting the inclusion of potentially aversive others. On the other hand, when no social cue is present consumers tend to anchor egocentrically, that is, consider themselves and their preferences as a starting point for evaluating the appropriateness of a product (Naylor, Lamberton and Norton 2011). Therefore, we expect consumers to evaluate products with ambiguous labels more favorably than products with labels that specify an extended target market. We tested our prediction in three studies.

In study 1, we presented participants with a fragrance that is either labeled for both men and women (i.e., unisex) or labeled ambiguously such that the product's gender appropriateness is not specified. We found that consumers evaluate products with ambiguous labels more favorably than products with labels that specify an extended target market.

In the second study, participants were either primed by self or others or were not primed. Then in an ostensibly unrelated task, they were shown three different products (in counterbalanced order: a ball cap, a travel pillow, and a Snuggie) which were either labeled as "one-size-fits-all" or had no such label. Participants were asked to evaluate the products and indicate their purchase likelihood. The results revealed that ambiguous labeling (vs. one-size-fits-all labeling) led to more positive reactions when participants were primed to think about the self. The control condition showed a similar effect, suggesting that consumers generally anchor on themselves when evaluating products with ambiguous labels. However, in the condition where participants were primed to think of others, there was no significant effect of labeling on consumer reactions, indicating that one-size-fits-all labeling makes people think about others in the target market of the product.

While study 1 findings were in line with our predictions, the results may be explained by consumers' perception that the product labeled "one-size-fits-all" was less customized to them as compared to the product with an ambiguous label. Study 3 was designed to assess this alternative explanation and also test whether the process by which an unambiguous label results in lower product evaluations is due to inclusion of a dissociative group in the target market of the product. Study 3 was therefore a 2 (Customization: non-customized v. customized) x 2 (Label: English only v. English + Spanish), between-participants design. Students were randomly assigned to one of the four conditions above and evaluated a frozen yogurt. In the customization condition, they were able to select from 18 different items to create their own frozen yogurt concoction. In the non-customized condition they were presented with the list of potential menu items, but did not actually select any items. In the English and Spanish condition, menu items were listed in both English and Spanish (e.g., "strawberries/ fresas"). Participants were asked to evaluate their frozen yogurt, indicate their likelihood of purchase and willingness to pay. They were also asked to estimate the size of the target market (expressed in percentage of the US population) for the product. Aversion to Hispanics was measured using a seven-item scale. Results suggest that the inclusion of others in the potential target market lowers the evaluation of a product, but only when the included group is aversive. When consumers are allowed to customize their product, the label effect persists, suggesting that perceived customization level of the product is unlikely to be the underlying process. Further, the estimated market size mediates the relationship between the label and product evaluation, suggesting that those who would choose not to associate with Hispanics are less likely to favor products that target these consumers.

Our findings indicate that marketers may unintentionally be decreasing the attractiveness of their products while attempting to expand their target market. Labels that contain language aimed to attract diverse consumer segments cue consumers to the notion that others may purchase the product as well. When these "others" are seen as an aversive group, consumer reactions are negatively influenced.

The Eyes Have It: Eye Tracking Analysis of Anthropomorphic Car Fronts Using Spatiotemporal Scan Statistics

Christian Purucker, University of St. Gallen, Switzerland
Jan R. Landwehr, University of St. Gallen, Switzerland
David Sprott, Washington State University, USA
Andreas Herrmann, St. Gallen Universität, Switzerland

EXTENDED ABSTRACT

In marketing research, the use of eye tracking methods is widespread and extends across various contexts, such as the effects of TV advertisements on brand perception during fast forwarding (Brasel and Gips 2008), the impact of certain elements in print advertisements on attention-direction (Rosbergen, Pieters, and Wedel 1997), or the positioning of banners in online-advertisements on advertisement perception (Hervet et al. 2010).

Usually, these studies employ eye tracking data analyses that rely heavily on the definition of regions of interest (ROIs; cf. Duchowski 2007). With this method, regions (most commonly rectangular) are marked to encompass certain parts of the stimulus; from these regions, classical eye tracking metrics are calculated (e.g., the total gaze duration). While heavily used by researchers, classical ROI eye tracking metrics are prone to at least four methodological limitations. First, data quality is closely related to the reliability of the ROI definition, and thus highly dependent upon the researcher's ability to define properly the ROI. Areas within the ROI unrelated to the experimental manipulation may add noise to the underlying signal, indeed an ROI may even consist of subregions that behave in opposing ways. This is a serious downside, especially when considering that there is no convention suggesting how tight ROIs need to be defined. Procedures or further descriptions of ROI definitions are usually not provided by most authors in the literature reviewed. Second, the use of classical filter mechanisms in combination with the ROI method may result in misleading data reduction. Third, it can be argued that the definition of ROIs does not reflect physical realities of the human field of view, which suggests a region of decreasing acuity around the fovea (Irwin 1992). Research findings that participants remember objects without a registration of gazes underscore this problem (Kuisma et al. 2010). Finally, ROI analysis can only discover effects previously hypothesized by the experimenter and thus may miss out on a central benefit of eye tracking. In the current research, we develop a new method relying upon spatiotemporal scan statistics that can overcome the limitations of ROI analysis, by offering a convenient way to analyze and visualize eye tracking data.

Spatiotemporal scan statistics automatically identify clusters of points in a point process that differ from the distribution expected under a baseline condition. These statistics, as implemented in the SaTScan software, are widely used in epidemiology to identify disease clusters (Kulldorff et al. 1998). While these statistics are not explicitly limited to epidemiological settings (Kulldorff 1997), applications in other contexts are rare. The use of scan statistics in eye tracking is novel and promising, as it provides a data driven approach to identify deviant gaze clusters. Implementing the scan statistic to eye tracking data assumes that a point process can account for the distribution of data, such as the Bernoulli model. Gaze points observed under a baseline condition are treated as non-cases, while points observed under an experimental variation are treated as cases. For a certain region in space, the probability of a gaze point being a case can thus be calculated. A likelihood ratio test statistic is calculated on the basis of the observed and the expected case to non-case-ratio (Kulldorff 1997). This procedure is applied to the whole study region by moving around a scanning window systematically in space and time. The window varies in size as it moves across the plane, so that for all points all possible window sizes are tested. The statistical significance of the clusters is then evaluated with Monte Carlo simulation (Kulldorff 1997).

The two methods of eye tracking data analysis, the classical ROI-based approach and our technique based on spatiotemporal scan statistics, are compared in an eye tracking experiment focused on perception of car faces. The theoretical grounding of this research is based on findings on anthropomorphic car fronts and literature on schematic faces regarding threat perception that suggest specific differences in the attention-capture of certain features of a car face. In particular, it is expected that car faces resembling threatening faces are avoided by the viewer in the long run.

Participants looked at a series of car faces for 10 seconds each, and rated them afterwards. Twenty-nine students participated in a 2 (headlights or eyes) × 2 (lower air vents or mouth) × 2 (side air vents) within-subjects experiment, whereby each feature existed in a threatening and a non-threatening variant.

Results provide some support for the theoretical expectations of face perception, in that threatening headlights were looked at for shorter periods of time over the whole experiment. Differences between the two eye tracking methods emerged. The ROI technique produced different results depending upon the ROI definition used, and thus clearly illustrates the problems associated with the method. While the scan statistic generally confirmed the key findings of the ROI method, more detailed results were provided by this new method (e.g., with respect to when and where significantly differing gaze clusters emerged). Results also clearly indicate the superiority of the method in terms of visualizing differences in gaze behavior between stimuli.

In summary, while several limitations exist for classical eye tracking analyses that rely on ROIs, these problems do not occur with the data driven approach provided by the scan analysis. In our study, results derived from ROI analysis were partially confirmed by the new method, but clear differences emerged such that greater details could be derived from the scan statistic. Due to the combination of a statistical methodology with a visualization technique, the method is not only attractive to academic eye tracking researchers, but also to marketing practitioners who often rely upon data visualization techniques that do not provide a statistical criterion for hypothesis testing, such as heatmaps. The use of our technique in that field will clearly lead to better practical use of eye tracking data. Finally, our research provides valuable insights for researchers and designers interested in anthropomorphic product design, as the impact of mechanisms of biological preparedness could be demonstrated. In our experiment, threatening and non-threatening car fronts clearly exerted different effects on viewer attention.

Appreciating the Local versus Trusting the Global:
Shifting Standards in the Evaluation of Product Failures

Eda Sayin, Koc University, Turkey
Nilufer Aydinoglu, Koc University, Turkey
Aysegul Ozsomer, Koc University, Turkey
Zeynep Gurhan-Canli, Koc University, Turkey

EXTENDED ABSTRACT

Consumers have subjective judgment standards, beliefs, and expectations as they evaluate different product groups. Their judgment standards determine the expected performance level of a product, and hence affect evaluations. In this paper, we investigate the effect of shifting standards on consumer evaluations of local and global brands, specifically when there is a product-harm crisis.

A product-harm crisis can be defined as "a well-publicized event where a product is defective or even dangerous" (Dawar and Pillutla, 2000). It has been shown to affect the long-run quality perceptions of a company, and can tarnish a company's reputation, cause market share and revenue loss, and eventually destroy brand equity (Heerde et al., 2007). Corporate response is a crucial determinant of the impact of a product crisis on consumer beliefs that constitute brand equity. A product-harm crisis need not inevitably be detrimental to the company. A company may emerge stronger after a crisis if it responds quickly and effectively to maintain consumer confidence in the brand (Dawar and Pillutla, 2000). Building on shifting standards theory from the social psychology literature, we hypothesize that effective response strategies differ for local and global brands and investigate the most effective strategies for both.

Literature on global and local brands suggests that consumers may prefer global brands to otherwise equivalent local brands since global (as opposed to local) brands are associated with higher levels of quality, prestige and status (Steenkamp et al., 2003). On the other hand, there is evidence documenting a home country bias for local brands based on ethnocentric desires to boost local economies or better customization (Papadoupolos et al., 1990). Local brands have also been associated with feelings of tradition, nationalism and patriotism. Such disparate prior belief structures may result in the shifting of standards with which consumers evaluate global versus local brands. Prior expectations work as a decision heuristic in the interpretation of a product-harm crisis (Darley and Gross, 1983). Selective information processing occurs and consumer expectations provide a buffer for brand equity against the firm's failure to respond effectively and consumers interpret new information in line with their prior beliefs (Dawar, 1998). Using a series of two laboratory experiments, we demonstrate that different consumer perceptions regarding global and local brands lead to different expectations and shifting standards of evaluations for these global and local brands.

Study 1 focuses on the context of single incident product failures to test our underlying contention that consumers may be subject to shifting standards when evaluating global versus local brands. A laboratory experiment demonstrates that consumers have higher expectations of product performance for global brands and that their negative reaction after a product failure would be stronger for global brands compared to local brands. It also shows that consumer evaluations after a product failure would be mediated by consumer expectations and that the mediating effect of the expectations would be moderated by cosmopolitanism (consumer identification with global or local culture). We find that higher expectations for global brands have possible negative effects on brand preference, and that this negative effect is less for individuals with higher cosmopolitanism, compared to those with lower cosmopolitanism.

Study 2 focuses on the context of a major product-harm crisis and explores different consumer reactions toward global and local brands based on how the firms respond to the crisis. How a company responds (whether it takes the responsibility or whether it offers compensation) in case of a product failure is a critical moderator regarding the damage to customer evaluations. Our second study demonstrates that consumers have different evaluations for (global vs. local) brands in terms of taking *responsibility* and *compensating*. When a global company declares no responsibility and does not provide compensation after a product-harm crisis, consumer evaluations are impacted less in comparison to local brands. As consumers have higher quality associations with global brands, they have a tendency to trust global brands and attribute the responsibility to third parties when the global brand declares no responsibility. However, when a global brand declares full responsibility and compensates, it is not as positively evaluated as a local brand, especially by consumers with low cosmopolitanism. When consumers identify themselves with the local culture, they feel more attached to the local brands and the compensation offered by the local brand has more positive effect on evaluations, when compared to global brands.

Accordingly, our combined set of results demonstrate that consumers have different expectations and hence shifting standards when evaluating global versus local brands, specifically when there is a product failure or a more massive product-harm crisis. We further show that their evaluations are affected differently following the specific responses of the firms to the crisis and in line with their level of identification with global or local consumer culture. As such, building on the shifting standards theory from social psychology, our research contributes to the work on product-harm crisis and global and local brand preference within consumer behavior, and have important implications for managers.

When Do (and Don't) Normative Appeals
Best Influence Consumer Conservation Behaviors?

Katherine White, University of Calgary, Canada
Bonnie Simpson, University of Calgary, Canada

EXTENDED ABSTRACT

This research explores how to most effectively encourage positive conservation behaviors. We do so in the domain of relatively unfamiliar conservation behaviors such as grasscycling and composting. While past research on encouraging conservation behaviors has produced mixed results, one commonly used framework in literature is to examine the effectiveness of different types of appeals in encouraging positive conservation activities. These include self-benefit appeals (based on benefits to oneself), descriptive norm appeals (based on what others are actually doing), and injunctive norm appeals (based on what others think ought to be done).

This research proposes that the effect of appeal type depends on whether the person is encouraged to think about the action in terms of the level of self as an individual (e.g., "why might I grasscycle?") versus the group (e.g., "why might we, as a community, grasscycle?"). In particular, we suggest that matching the type of normative message with a goal-congruent mindset might lead to particularly favorable conservation attitudes, intentions, and behaviors. That is, when the consumer's mindset is at the individual level of the self, benefit appeals might be particularly effective. However, when the consumer's mindset is at the collective level of the self, descriptive norms and injunctive norms might work best.

Three studies were conducted that examined the moderating effect of the individual's mindset (individual level of self vs. collective level of self) on the effectiveness of norm-based appeals in influencing conservation behaviors. The first study examined the effects of the appeals on participants' attitudes towards grasscycling in a laboratory setting. Grasscycling involves leaving ones grass clippings on the lawn so that they can decompose, returning nutrients to the soil, rather than throwing them in the landfill. The second study was conducted in collaboration with a metropolitan city, where marketing communications were manipulated and delivered to households and changes were measured in grasscycling participation. Finally in study 3, we use the public vs. private nature of the setting to manipulate level of self in the context of composting intentions.

In the first study, the nature of the message was manipulated (injunctive norm, descriptive norm, benefit appeal) along with the consumer's mindset (e.g., individual self versus collective self) and these conditions are compared to an information-only control condition. As a preliminary test of the predictions derived from the literature, a 2 (Level of Self: individual vs. collective) x 3 (Message Appeal: normative message vs. injunctive message vs. benefit message) between subjects design was utilized, and a control group that received information only was also included (making for seven experimental conditions). A community sample was randomly assigned to view one of the seven possible messages, and they reported their attitudes towards grasscycling. Results indicated that when a collective level of self was activated, injunctive norms and descriptive norms resulted in more positive attitudes than the benefit appeal. Also as predicted, when the individual level of self was activated, participants reported more positive attitudes to the benefit focused appeal as compared to both the individual self/injunctive norm condition and the information only control condition.

Study 2 tested the effectiveness of six different versions of a marketing message on community residents' actual grasscycling behaviors. A 3 (Appeal Type: descriptive norm, injunctive norm, self-benefit norm) x 2 (Mindset: individual self vs. group self) experimental design was used, which also included a control condition that received no marketing message, resulting in seven conditions total. A pretest-posttest design was utilized, in which the grasscycling behaviors of households were measured for three weeks before and three weeks after exposure to a version of an advertising appeal. Appeals were delivered in door-hanger form, developed in conjunction with the city. Households ($N = 696$) were selected for participation in the project and randomly assigned to conditions. The dependent measure was the average amount of grass disposed of in the garbage, as put out for weekly garbage collection by each household. This was recorded for 3 weeks at Time 1 (T1 – prior to the marketing intervention) and three weeks at Time 2 (T2 – subsequent to the marketing intervention). Consistent with the hypotheses, when a collective level of self was activated, descriptive norms and injunctive norms resulted in significantly less grass disposal in the garbage at T2 than did the benefit appeal. In addition, when the collective level of self was activated, both the descriptive and the injunctive norm conditions led to more positive actions than the control condition. Also as predicted, the individual/benefit condition led to decreased grass disposal as compared to both the individual self/ injunctive norm condition and the control condition.

In Study 3 an additional conservation behavior, composting, was examined. As well, the setting (public vs. private) was used to manipulate the individual level vs. collective level of the self, and we investigated the potential mediating role of perceived self-efficacy. One hundred and three participants were told their responses to the study would either be public or private. The manipulation of setting was crossed against a manipulation of appeal type (benefit, descriptive norm, injunctive norm), and participants completed measures of composting intentions and perceived efficacy. The results revealed that injunctive appeals were particularly effective in a public setting, while benefit appeals were particularly effective in private. Further, the results were mediated by perceived self-efficacy.

This research highlights the most effective ways to frame messages to encourage changes in consumer conservation behaviors. The combination of the activation of the collective level self with injunctive norm or descriptive norm appeals is particularly effective in influencing conservation behaviors. In addition, the combination of the individual level of self and the communication of benefits positively predicts conservation behaviors. Thus, those wishing to encourage positive conservation behaviors should match their marketing communications, combining the activation of the collective self with injunctive or descriptive norm appeals; or combining the activation of the individual self with benefit appeals.

Is It Worth the Money?
The Effect of Regulatory Focus on Consumers' Price and Quality Sensitivity

Woo Jin Choi, Texas A&M University, USA
Haipeng (Allan) Chen, Texas A&M University, USA

EXTENDED ABSTRACT

Many consumption decisions involve choosing between a more expensive product with better quality and a cheaper product with inferior quality. Despite the prevalence of such trade-offs, little research has examined consumers' sensitivity to price relative to their sensitivity to quality. In this research, we examine this issue through the theoretical lens of regulatory focus (Higgins 1997).

Regulatory focus theory distinguishes between two basic motivational orientations that individuals employ in the pursuit of their goals: promotion and prevention. One robust finding in this literature is that promotion-oriented people are more sensitive to gains, whereas prevention-oriented people are more sensitive to losses (Avnet and Higgins 2006; Wang and Lee 2006; Aaker and Lee 2001). While quality information can be either promotion or prevention focused (Wang and Lee 2006; Aaker and Lee 2001), to the extent that price is a "give" component to be minimized and quality is a "get" component to be maximized (Monroe 2003; Zeithaml 1988), we propose that *relatively speaking* promotion-oriented consumers will pay more attention to product quality, whereas prevention-oriented consumers will pay more attention to product price. The differential attention paid to price and quality information should, in turn, lead to preferences for products of high quality by promotion-oriented consumers, and preferences for products with low prices by prevention-oriented consumers.

In addition, we further predict that the proposed effect should only exhibit itself under circumstances in which price and quality compete for attention. Under circumstances where price and quality do not compete for attention, we predict that the effect of consumers' regulatory focus on their choices will diminish. For example, consumers may have a high reference point such that they have a sufficiently large budget to afford even the more expensive product, but they have also high quality expectations that cannot be met by either product. In other words, both products represent gains on price and losses on quality. On the other hand, consumers may have a low reference point such that they have a budget that is insufficient to afford even the cheaper product, but they also have low quality expectations that can be satisfied by both products. In other words, both products represent losses on price and gains on quality. Under those circumstances, consumers may be more attentive to the attribute on which both products represent a loss and thus they may pick the product that minimizes the loss, thus mitigating the effect of consumers' regulatory focus on their product choices.

We conducted two pretests and three experiments to test our underlying assumptions and predictions. In the first pretest, we found that participants were more likely to mention "quality" in thinking about what they wanted to get and they were more likely to mention "price" in thinking about what they wanted to avoid in a making a purchase, confirming our assumption that quality is a get component to be maximized and price is a give component to be minimized in a purchase.

In a second pretest, participants were asked to sort a list of 26 words into two groups; In addition to price and quality, the list included 12 promotion-related words and 12 prevention-related words. The results indicate that the word 'quality' is more likely to be grouped with promotion words while the word 'price' is more likely

to be grouped with prevention words, supporting the proposed association between quality (price) and a promotion (prevention) focus.

Experiment 1 then tested the effect of regulatory orientations on consumers' product choices by measuring people's chronic regulatory focus. The results demonstrated that, as predicted, consumers with a chronic promotion (vs. prevention) focus were more likely to choose a more expensive smartphone with better quality over a cheaper smartphone with less quality. We replicated these results in a second experiment by manipulating regulatory focus, using digital cameras as the focal product.

In our final experiment, we tested the proposed boundary condition due to reference point as well as the underlying process of the effect. Consistently with our predictions, we replicated the effect of regulatory focus in the middle reference point condition where the budget and quality expectations were between the two products. However, in the high and low reference point conditions, where price and quality did not compete for consumers' attention, the effect of regulatory orientation was diminished such that participants in the high (low) reference point condition tended to prefer the more expensive (cheaper) product regardless of their regulatory orientations. We also found that attention to quality versus price mediated the effect of regulatory orientation on product preferences.

Our research contributes to the literature in marketing and regulatory focus theory in several important ways. First, by introducing motivation into the equation on price (vs. quality) sensitivity, we contribute to extant research that has modeled price sensitivity as a function of situational factors (e.g., consumption occasion; Wakefield and Inman 2003), strategic variables (e.g., competition; Van Heerde et al. 2008), consumer demographics (e.g., income; Hoch et al. 1995) and other consumer attributes (e.g., brand loyalty; Bell and Lattin 2000).

Second, most research on regulatory focus has centered around the fit between quality-related product attributes and consumers' motivational orientations and typically employs price as a dependent variable to measure the consequences of such a fit (e.g., Avnet and Higgins 2006, 2003; Higgins, Idson, Freitas and Molden 2003). The current research expands upon these studies by considering both price and quality as relevant product features that can simultaneously affect the consequences of the regulatory fit. In doing so, we contribute to regulatory focus theory by introducing price as a critical component into this theoretical framework.

The findings of this research are relevant to marketing practitioners as well. For example, marketers may be able to influence the inclinations of consumers who are deciding between products with different prices and quality. In addition, given the link between culture and regulatory focus (Aaker and Lee 2001; Lee, Aaker and Gardner 2000), our findings can also help companies competing in an increasingly global market to better tailor their marketing campaigns to consumers from different cultural backgrounds.

Perception-Specific Average Causal Effects:
Implications for Experimental Consumer Research

Walter Herzog, WHU, Germany

EXTENDED ABSTRACT

In experimental consumer research, it seems quite natural to assume that participants' treatment perceptions moderate treatment effects. For example, Cognitive Evaluation Theory (Deci and Ryan 1985; Dholakia 2006) predicts that a loyalty reward *increases* repurchase intentions relative to a "no reward control condition" if consumers interpret the reward as a sign of appreciation. The *same* reward, however, is hypothesized to *decrease* the repurchase intentions of consumers interpreting it as a manipulative trick of the firm. At first glance, these hypotheses can be tested by means of a trivial interaction analysis; treatment assignment (reward versus no reward) and treatment perceptions (appreciative versus manipulative reward interpretation) interact in producing effects on repurchase probability. However, two problems occur on closer inspection.

First, treatment perceptions are unobserved or "latent" in the control condition because the treatment is obviously absent. Second, treatment perceptions are influenced by a multitude of background variables. For example, Cognitive Evaluation Theory predicts that certain prior experiences with the firm (e.g., empathic behavior on the part of the rewarder) shape consumers' interpretation of the reward as "appreciative" or "manipulative," thereby influencing the reward's expected effect on repurchase probability. That is, the background variable's influence on the treatment effect (moderation) is assumed to be mediated by treatment perceptions which are unobserved in the control condition. This proposition is similar (though not technically equivalent) to a "mediated moderation hypothesis" (Muller, Judd, and Yzerbyt 2005) with the important difference that the mediator (classes of treatment perceptions) is categorical and missing for control group subjects.

Although treatment perceptions are important components of many psychological theories, a suitable statistical model has not yet been developed to meet the two mentioned challenges. Based on Rubin's Causal Model (Rubin 1974, 2005) and recent advances in psychometrics (Little and Yau 1998), biometrics (Frangakis and Rubin 2002), and econometrics (Angrist, Imbens, and Rubin 1996), a new method is proposed to estimate *perception-specific average causal effects* (PACE) of a treatment, that is, causal effects of the objectively same treatment for subjects assigning different meanings to the treatment (e.g., "appreciative" versus "manipulative" interpretations of a reward).

Furthermore, the model allows for a direct test of the aforementioned mediated moderation hypothesis with a categorical, partially latent mediator: Background variables (e.g., the rewarder's empathic behaviors) are allowed to influence the treatment effect on the dependent variable *directly* and *indirectly*: First, the background variable can influence the treatment effect directly which is modeled via a simple interaction effect of the background variable and treatment assignment. Second, the background variable can influence the treatment effect indirectly by increasing or decreasing the odds of positive versus negative treatment perceptions which in turn affects the overall treatment effect. If the first route of influence is *not* significant and the second route of influence is significant, the hypothesized treatment perceptions fully mediate the impact of the background variable on the treatment effect. However, if the first route of influence is significant, other mechanisms or other treatment perceptions might be at work in creating the background variable's influence on the treatment effect.

The method is illustrated by means of a prototypical experiment with N=91 student subjects who were assigned to a "loyalty reward condition" (a price reduction for meals at the university's cafeteria) or a control condition (no loyalty reward). In addition to the subjects' appreciative versus manipulative reward perceptions, a number of background variables were measured such as the students' experiences with the cafeteria's employees, that is, their empathic, customer-oriented behaviors. The dependent variable was loyalty intentions. Deci and Ryan's (1985) Cognitive Evaluation Theory suggests that (a) the reward has a PACE>0 for "appreciative perceivers," (b) the reward has a PACE<0 for "manipulative perceivers," and (c) "autonomy-supportive" interpersonal behaviors (empathy) on the part of the reward provider increase the likelihood of appreciative relative to manipulative reward perceptions, thereby improving the reward's overall effect. The latter hypothesis implies that there is no direct effect of empathy on the treatment effect but an indirect effect via specific treatment perceptions. The results are perfectly in line with Deci and Ryan's (1985) predictions: All parameters were significant except for the direct effect of empathy on the treatment effect, that is, full mediated moderation via Deci and Ryan's (1985) postulated reward perceptions is supported. Overall, the results reveal that loyalty rewards are not by definition beneficial or counterproductive—contextual factors shape a reward's "metamessage" and thus *indirectly* its overall effect. This simple illustration shows that the PACE model has the potential to scrutinize so-far untestable assumptions of psychological theories.

Finally, a simulation study was performed to test the robustness of the PACE estimates under varying sample size conditions. The population model matched the estimated model discussed in the former paragraph. Four sample size conditions (N=50, 100, 150, 200) were examined. The analysis suggests that (a) the bias of the PACE estimates is negligible for all sample size conditions and (b) the PACE estimates reach an acceptable power level (80%) for N=100. Overall, the simulation study implies that the PACE model can indeed handle the small sample sizes typically generated in laboratory experiments.

Consumer Citizenship Behavior:
The Effects of Social Identification on Interpersonal Helping Behavior Among Consumers

Jeff Allen, University of Central Florida, USA
Carolyn Massiah, University of Central Florida, USA
Zachary Johnson, University of Central Florida, USA
Kristin Bowman, University of Central Florida, USA

EXTENDED ABSTRACT

The impact of "citizenship-like" behavior, voluntary interpersonal behavior that benefits the organization, has generated a great deal of interest across disciplines. This research classifies these behaviors as Organizational Citizenship Behaviors (OCBs); that is, the extra role discretionary initiatives of employees engaged in various work behaviors (see Lepine, Erez, and Johnson 2002). This study further expands the concept of citizenship behavior to include interpersonal helping behavior that occurs among consumers in the midst of other consumers. Specifically, the relationship between social identification and helping behavior among consumption community members is investigated. The research demonstrates how this form of consumer behavior creates value for product-based as well as service-based organizations.

Social identification is the perceived belongingness to any social group, formal or informal. According to Social Identity Theory, individuals develop a social self that is attached or connected to the group and its providence (Ashforth and Mael 1989). Members of a social group are more apt to help one another because membership instills a sense of obligation to the group and its individual members (May and Hoffman 1991). It is this sense of responsibility that leads to higher levels of helping behavior (Sturmber, Snyder, and Omato 2005).

The present study differs from current consumer behavior research on interpersonal helping behavior which implies that consumption community members will receive help and non-members will not (Muniz and O'Guinn 2001). Rather than an implied dichotomy, this research presents helping behavioral intentions as falling along a continuum, suggesting that interpersonal helping behavior is not influenced by membership alone. A consumer who perceives a stronger attachment to a community is more likely to engage in helping other members than a consumer with a weaker attachment.

Data for the study was collected at Biketoberfest, a biker rally held in Daytona Beach, Florida that attracts 200,000 plus bikers annually. Self-report surveys were distributed to male bikers during the event. Identification with the biker community and particular subgroup were treated as separate constructs. Respondents (n = 152) were first asked whether they belonged to an organized (e.g., Harley Owners' Group, Racing Club, Antique/Restoration Club) or an informal subgroup (e.g., Iron Butt Gang, Bikers for Jesus, close group of friends) of bikers within the biker community. If a member of more than one subgroup, they were asked to specify club/group most important to them. Respondents were instructed to answer each question twice, once regarding bikers in the subgroup they specified and again for bikers not in their club/group. The helping behavior intentions are of three types: altruistic, product-related, and behavioral scenarios. All items were measured on a 7-point agreement scale ranging from 1="Strongly Disagree" to 7="Strongly Agree."

Item analysis for each scale began by inspecting inter-item correlations for r's < .30 and item-to-total correlations for r's $\geq$ .50. This resulted in deleting several items from the social identification and scenario scales. Reliability for the measures of each construct was assessed using Cronbach's alpha. Alphas ranging from .74 for subgroup identification to .94 for measures of altruistic helping behavior indicate that the scales are internally consistent (Nunnally and Bernstein 1994).

To test the proposed hypotheses, a multivariate multiple regression model using the unweighted least squares technique was employed. Social identification at the community and subgroup levels within the community served as independent variables and the three types of helping intentions were used as simultaneous dependent variables. Initially, a dummy variable was created to capture any difference in helping behavior for informal compared to organized subgroups. However, subgroup formality was nonsignificant in the model and was omitted from further analysis.

Hypothesis #1, that identification with the biker community would have a positive effect on helping other members at the community level, was supported. Estimated paths from community identification to helping behavior at that level were significant (p's < .05) whereas paths to helping behavior at the group level were not. Hypothesis #2, that subgroup identification-helping relations would be stronger for subgroup members than for community members outside of the group, was also supported with one exception. While the path estimates were significant and stronger at the subgroup level, altruistic behavior was significantly related to identification with bikers at the community level as well (i.e., standardized β's = 2.24, p <.001 vs. 1.23, p < .01, in that order).

Our results support a positive relationship between social identification and helping behavior at the larger community level. However, consumption communities are comprised of subgroups in which members of each share an identity. Our findings suggest that when members' identity is salient at the subgroup level, identification-helping relations were stronger for subgroup members than for community members not in their group. Interpersonal proximity and the collective motives arising from the group engender a strong sense of responsibility which makes interpersonal helping more likely between fellow members (Mael and Ashforth 2001; Turner 1984).

Members' subgroup identification was not related to any helping behaviors pertaining to community members outside of their subgroup except for behavior that was altruistic in nature. Interestingly, altruistic behavior may be egoistically motivated, making it difficult to distinguish altruism from self-interest. Underlying reasons of self-interest may motivate this type of behavior, but to a lesser extent than social identification at the community level.

The current research indicates that identification was significantly related to product-based helping behavior with other bikers in the community. This behavior was also evident at the subgroup level. From a marketing standpoint, product-based organizations should develop increasingly bonded relationships with consumers, but have been less clear concerning customers' roles compared to their service-dominant counterparts. This study demonstrates how consumers can voluntarily act on behalf of either a service- or product-based organization to contribute to its success. Together, the findings imply that consumers on their own can act as partial employees to co-create value that benefits the product-oriented organization (Pralahad and Ramaswamy 2000). One way a firm can foster consumer citizenship behavior is by forming communities around its product or service. Through organizationally sponsored community

events the bonds that are formed benefit the organization as well as strengthen the consumption community.

EXTENDED ABSTRACT

Mounting research in the tradition of sound symbolism supports the presence of intuitive associations between the sounds contained in words and the objects to which they refer (Hinton, Nichols, and Ohala 1994). One line of work has investigated vowel sounds, ranging from front to back based on the location of the tongue relative to the front of the mouth during articulation. Consider the vowels in the following words, which progress from front to back: bee, bin, bay, bet, ban, cot, home, put, boot (from Klink 2000). All else equal, consumers infer that objects with names including relatively frontal vowel sounds are more sharp, hard, and angular, among others (for a review, see Shrum and Lowrey 2007). Importantly, these inferences translate to behavioral consequences. Yorkston and Menon (2004) found that participants preferred a hypothetical ice cream named Frosh (back vowel) over Frish (front), inferring the former to be especially smooth and thick (features characteristic of back vowels). Taken together, research to date has documented an association between vowel sounds contained in words and the physical properties of the referents.

The present investigation extends beyond what consumers think about an object as a function of vowel sound to how they think about it – that is, the manner in which they represent it and process relevant information. Toward this end, we draw upon the perspective of construal level theory (Trope and Liberman 2010). It posits that a target can be mentally represented either in terms of primary, essential features (high-level construal) or secondary, incidental features (low-level construal). Past research suggests that, when construing a product at a high level of representation, consumers show greater sensitivity to primary over secondary features of that product; lower-level construal reduces or reverses such differentiation.

To explore the relationship between vowel sound and mental construal, we consider a feature common to both: degree of precision. Relative to high-level, low-level construal gives rise to greater precision across a host of applications (e.g., Liberman, Sagristano, and Trope 2002). Similarly, the aforementioned characteristics associated with front vowels – sharpness, hardness, angularity – cohere around a sense of greater precision (see Lowrey and Shrum 2007). Thus, front vowels and low-level construal correspond to relatively fine-grained precision relative to the coarser scale of back vowels and high-level construal.

If vowel sound can manipulate construal level, brand names including front vowel sounds might elicit low-level construal of products, whereas back vowels might elicit high-level representation. We test this prediction in three studies, exploring the tradeoff between low- and high-level sources of value and utilizing vowel sound as the construal manipulation. When given a brand name including a back vowel, consumers should prefer products carrying good high-level but poor low-level value versus the opposite; this differentiation should be attenuated or reversed in response to front vowel names.

Study 1 asked participants to evaluate a fictitious ice cream, given a name that included either a front vowel (Frish) or a back vowel (Frosh). Additionally, participants were informed that the ice cream carried either good high-level value but poor low-level value (having a very good taste but being in an inconvenient location) or the opposite (poorer taste, convenient location). Upon indicating their willingness to purchase the ice cream, participants strongly preferred the ice cream named Frosh when defined by the former rather than the latter set of characteristics; this pattern was significantly attenuated for Frish, suggesting that the importance of secondary value (location) in evaluation was enhanced as a result of a front vowel sound.

Studies 2 and 3 provide important replications of this general effect. In Study 2, we tested hand lotions given the name either Kira's (front vowel) or Kora's (back vowel) and used the following characteristics: good absorbability (high-level value) but an ugly gift bag (low-level value) or the opposite (poor absorbability, beautiful gift bag). As in Study 1, the name Kora's resulted in a much stronger differentiation in preference (for high- over low-level value) than did the name Kira's. To show that front vowels do not simply reduce general differentiation, Study 3 tested the names Dari (front vowel) and Daru (back vowel) in the domain of massages. The results indicated that Dari led participants to significantly prefer short-term over long-term pain relief, whereas the opposite pattern of evaluations evinced for the massage named Daru. Thus, we conclude that both back and front vowel sounds are associated with high- and low-levels of construal, respectively.

Across three studies, the vowel sounds included in words affected the level at which consumers represented and evaluated their referents: Front vowels elicited low-level construal while back vowels elicited high-level construal. This held using different operationalizations of high- versus low-level value and different specific vowel sounds (in different pairings) across the studies. Further, we observed a consistent effect of vowel sound independent of location in the word: the only vowel (Study 1), the first of two vowels (Study 2), and the second of two vowels (Study 3).

Given the staggering number of words encountered daily, the implications of the present research are as many as they are ubiquitous. The subtle manipulation of name successfully elicited different levels of mental representation, powerful enough to affect preferences and behavioral intentions. These studies contribute a novel example of a growing body of research documenting the incidental ways in which language influences thought (e.g., Boroditsky 2000), showing that vowel sounds impact not only the what but also the how of mental representation. These results also open the possibility for a volume of future work examining the relationship between sounds and mental processing – particularly for other construal-dependent domains. Finally, our work suggests that in an applied context, people making appeals to popular opinion (e.g., marketers, political candidates) would be well advised to use names (or perhaps even groups of words) that take into account the features that they want their audience to value. In sum, our evidence suggests that very subtle linguistic cues can influence the very nature of mental representation.

Maintenance Versus Attainment Goals: Preference of Goal Fulfilling Strategies and Influence of Change in Life Circumstances on Goal Pursuit

Napatsorn Jiraporn, State University of New York at Binghamton/Oswego, USA
Kalpesh Kaushik Desai, State University of New York at Binghamton, USA

EXTENDED ABSTRACT

Relapse is common in multiple goal domains such as the failure to maintain smoke cessation behavior and the weight gain among dieters who have successfully lost weight. However, the goal literature has focused mainly on attainment goals in which the desired state exceeds the current state but has neglected the maintenance goals in which the current state is equal to or better than the desired state (Brodscholl, Kober, and Higgins 2006). High record of relapse casts doubt on whether research findings about attainment goals are applicable to maintenance goals. Our research aims to contrast these two goal types.

First, we hypothesize that maintenance goals are characterized by a more ambiguous endpoint of the goal pursuit than attainment goals (H1). This is because maintainers are already in the desired state so the endpoint in terms of when to stop pursuing the goal is less clear. In contrast, attainers have the desired state as a clear endpoint of the pursuit. Second, using mental simulation (Taylor et al 1998) as our theoretical underpinning, we examined how maintainers and attainers evaluate goal fulfilling strategies. Prior research (Thomson, Hamilton, and Petrova 2009) shows that consumers are chronically sensitive to outcomes. However, maintenance goals are less temporally bounded so they should make maintainers focus on the process of using a strategy. Thus, we hypothesize that maintainers will engage in both process-focused and outcome-focused mental simulation. In contrast, attainers, who try to close the gap between the current and the desired state, should engage in more outcome-focused (vs. process-focused) mental simulation (H2) Moreover, because maintainers will consider only strategies that are feasible to use and effective whereas attainers will consider any strategy that seems to deliver satisfactory outcomes, maintainers should consider and use fewer strategies that attainers (H3). Lastly, we examined how the two groups of consumers make trade-off between effort intensity and temporal dispersion of strategy implementation. Specifically, we investigated preference between a temporal dispersed – effortfully less intense strategy (e.g. 15 minutes exercise, 6 times per week) vs. a temporally concentrated – effortfully more intense strategy (e.g. 45 minutes exercise, 2 times per week). We hypothesize that maintainers will prefer the former strategy because it appears to be more feasible to implement whereas attainers will prefer the latter strategy because they are more subject to instrumentality bias, a naïve belief that more intense effort will lead to a better reward (H4).

Study 1 (n = 120) with a 2 (goal type) x 2 (replicates: cholesterol and savings goals) design supported H1, H2, and H3 in both goal domains. The results showed that maintenance goals had a less clear endpoint than attainment goals (($M_{Maintainers} = 4.12$ vs. $M_{Attainers} = 5.28$, $F(1, 107) = 23.82$, $p < .01$). Maintainers considered fewer number of strategies than attainers ($M_{Maintainers} = 3.09$ vs. $M_{Attainers} = 4.07$, $t(59) = 3.05$, $p < .01.$). Lastly, maintainers engaged in both process-focused and outcome-focused thinking ($M_{Process} = 5.12$ vs. $M_{Outcome} = 5.02$, $t(32) < 1. p > .20$) while attainers engaged more in outcome-focused thinking ($M_{Process} = 4.15$ vs. $M_{Outcome} = 4.9$, $t(27) 2.93$, $p < .01$).

Study 2 (n =120) using a 2 (goal type) x 2 strategy type (temporally dispersed – effortfully less intense vs. temporally concentrated – effortfully more intense) design with the latter as a repeated measure successfully replicated all findings from study 1 and tested H4 in both cholesterol and savings domains. Maintainers preferred a temporally dispersed – effortfully less intense strategy ($M_{Less\ Intense} = 5.30$ vs. $M_{More\ Intense} = 4.54$, $t(33) = 3.01$, $p < .05$) but inconsistent with H4, attainers viewed both strategies as equally attractive ($M_{Less\ Intense} = 5.40$ vs. $M_{More\ Intense} = 5.42$, $t(28) < 1$, $p > .20$).

Study 3(n =40) measured goal type among actual gym users to replicate findings from studies 1 and 2 and tested H3 in the weight goal domain. Consistent with previous studies, maintainers used fewer strategies than attainers ($M_{Maintainers} = 3.25$ vs. $M_{Attainers} = 4.50$, $t(60) = 2.23$, $p < .05$), supporting H3. H4 was supported as maintainers preferred a temporally dispersed – effortfully less intense strategy (N= 10 vs. 5, $\chi2 (1,14) = 2.21$, p < .05) whereas attainers preferred the temporally concentrated – effortfully more intense strategy (N = 6 vs. 17, $\chi2 (1,24) = 5.26$, p < .05) Moreover, attainers showed stronger belief in the instrumentality bias, a belief that more intense effort will give a better reward, than maintainers ($M_{maintainers} = 3.70$ vs. $M_{attainers} = 5.76$, t(38) = 5.47, p < .01). Mediation analysis confirmed that instrumentality bias mediates the effort of goal type on strategy choice.

Study 4 (n =54) with a 2 (goal type) x 2 (process-focused vs. outcome focused mental simulation) was conducted among gym users. The mental simulation was manipulated to test whether it is the underlying reason why maintainers considered fewer strategies than attainers. As predicted, we observe no difference in the number of strategies used across process-focused and outcome-focused conditions for maintainers, showing that maintainers naturally engage in both types of thinking ($M_{process} = 3.16$ vs. $M_{outcome} = 2.88$, $t(20) < 1$, $p > .20$). In contrast, attainers who were primed to be process-focused vs. outcome-focused reported fewer strategies ($M_{process} = 2.50$ vs. $M_{outcome} = 4.36$, t(32) 3.60, p<.01). Thus, it is likely that mental simulation is the underlying reason why maintainers consider fewer strategies than attainers.

After providing clear evidence that the two goal types differ, we proceeded to examine how life circumstances impact goal adherence of maintainers and attainers. Study 5 (n=109) with a 2 goal type (maintenance vs. attainment) x 2 life circumstance (change vs. stability) between subjects design showed that when going through change in life, attainers and maintainers did not differ in the number of goal-consistent choices selected ($M_{maintainers} = 2.08$ vs. $M_{attainers} = 2.12$, $t(48) < 1$, $p > .05$) indicating that changes in life circumstances did not help or hurt maintainers vs. attainers. However, in the stability condition, maintainers selected fewer number of goal-consistent choices than attainers ($M_{maintainers} = 1.30$ vs. $M_{attainers} = 2.50$, $t(49) = 3.18$, $p < .01$) indicating that when there is stability in life circumstances, maintainers exhibit lower goal adherence than attainers. Further analysis revealed that maintainers predicted that the goal would be easier and therefore, lessened their self-regulation and showed lower goal adherence.

Results across these five studies robustly established that maintenance goals differ from attainment goals in many important aspects. This research helps managers recognize that consumers striving different goal types are not homogenous and distinct marketing strategies are needed to serve the two consumer groups.

Do I Value it Because I Own it or Because I am Averse to Losing Things?
The Effects of Identity, Self-Threat, and Gender on the Endowment Effect

Sara Loughran Dommer, University of Pittsburgh, USA
Vanitha Swaminathan, University of Pittsburgh, USA

EXTENDED ABSTRACT

People typically demand more to relinquish the goods they own than they would be willing to pay to acquire those goods if they did not already own them. This phenomenon is known as the endowment effect.

There are two primary explanations for why the endowment effect occurs. The first is that we have a strong psychological association with objects that we own, potentially due to the ability of our possessions to define and enhance our view of self, which may induce a greater liking for our possessions (Morewedge et al. 2009). In support of this notion, Gawronski, Bodenhausen and Becker (2007) have noted choice of an object results in an association between the object and the self, leading to an increase in evaluation of the chosen object. We call this explanation for the endowment effect the 'self-enhancement account'.

The second explanation for the endowment effect is based on the principle of loss aversion (Kahneman and Tversky 1979; Thaler 1980). Loss aversion refers to the tendency for people to strongly prefer avoiding losses than acquiring gains (Kahnemann and Tversky 1979). Sellers typically think of selling as a loss and buyers typically think of buying as a gain, therefore sellers expect to suffer more than buyers expect to benefit. As a result, sellers demand more compensation than buyers are willing to provide, resulting in higher selling prices than buying prices for an identical good (Kahneman, Knetsch and Thaler 1991). This 'loss aversion account' has traditionally dominated the explanation for why we observe the endowment effect.

Recent research has tried to disentangle the self-enhancement account from the loss aversion account in explaining the endowment effect (Morewedge et al. 2009). We extend this work by identifying two moderating conditions that sort out the self-enhancement versus loss aversion explanations for the endowment effect: self-threat and gender. We suggest that under conditions of self-threat, identity-consistent objects can be used for self-enhancement to alleviate the self-threat, resulting in even greater selling prices for identity-consistent objects. Under a self-threat, when males and females are endowed with an identity-*in*consistent good, however, gender differences emerge. Specifically, the pattern of findings indicates that males are more likely to use goods for self-enhancement, whereas females are more likely to exhibit loss aversion.

In the first study, our results show that the identity-consistent nature of a good moderates loss aversion, but only under a self-threat. When the object is neutral (a plain pen), the gap between selling prices and buying prices is similar under self-threat and no self-threat conditions. In contrast, when the object is identity-consistent (a pen with a university logo), the gap between selling prices and buying prices widens for the self-threat condition relative to the no self-threat condition, indicating that individuals are using these objects to self-enhance.

In a second study, we use a different identity-consistent good and replicate the results from the first study. We also find some evidence that sellers are holding on to their identity-consistent good to lessen some of their anxiety and negative self-views (i.e., to self-enhance). Although there were no significant differences in reported self-views across the buying and selling conditions in the self-threat condition before the endowment effect experiment, following the

endowment effect experiment, sellers reported lower anxiety (i.e., higher views of self) than buyers. This is evidence that the endowment effect results in the identity-consistent condition may be a result of using objects to enhance participant's view of self following a self-threat.

The first two studies provided support for the self-enhancement explanation, but there was limited evidence of the loss aversion explanation. For identity-inconsistent goods, if the loss aversion account is at work, individuals should continue to value the endowed object highly and thus we would expect to see the endowment effect across all conditions. If, however, self-enhancement is at work, then under a self-threat we would expect selling prices to drop as individuals attempt to self-enhance by derogating the out-group. Thus, valuations of an identity-inconsistent good may help us disentangle the self-enhancement and loss aversion account

Under what conditions could an identity-inconsistent good prompt self-enhancement versus loss aversion? Carr and Steele (2010) demonstrate that women are more loss averse than men in the context of decision-making, particularly when faced with a self-threat (e.g., stereotype threat). We hypothesize that in the case of an identity-inconsistent good, males and females will show varying patterns of behavior, due to a differential sensitivity to losses. Specifically, it is expected that females will continue to demonstrate higher selling prices relative to buying prices, which is consistent with a loss-aversion account, whereas males will demonstrate no increase in selling prices relative to buying prices, which is consistent with a self-enhancement account.

In a third study, we find that under self-threat, males lower their selling prices for an identity-inconsistent possession, presumably to show rejection of the out-group, thus eliminating the endowment effect. Females, however, show no such change in selling prices. Thus, following a self-threat loss aversion for an out-group good is eliminated for males but remains unchanged for females. These results indicate that loss aversion may explain the endowment effect for females, particularly when they are endowed with an undesirable good. In contrast, self-enhancement explanation continues to explain the existence of endowment effect for males, because when the nature of the good changes, it causes the endowment effect to disappear.

Our results contribute to the burgeoning stream of research which disentangles the self-enhancement and the loss aversion accounts in explaining the endowment effect (Morewedge et al. 2009). Specifically, we show that under a self-threat, males use objects to help them self-enhance while females fear losing objects (of any identity association).

Chocolate Cake Please! Why Do We Indulge More When it Feels More Expensive?

Rajesh Bagchi, Virginia Tech, USA
Lauren Block, Baruch College, USA

EXTENDED ABSTRACT

As unemployment and financial worries increase during this era of global recession, so too do sales of high calorie indulgence items (Miles 2009). Nutritionists call this phenomenon "recession obesity" and attribute it to the low cost of junk food relative to healthier alternatives (Everett and Grogan 2009). We suggest a psychological motivation that drives high calorie indulgences. Specifically, when the imputed costs of payment are higher, such as when making purchases using cash (vs. a credit card) or when pain associated with cash spending is higher, increasing the hedonic benefits of consumption blunts the pain of payment.

A growing literature on the psychological differences in "pain of payment" demonstrates that the use of a credit card leads to more spending compared to cash or checks (Prelec and Simester 2001). A recent explanation argues that the more transparent the outflow, as in cash (versus credit), the greater the pain of payment (Raghubir and Srivastava 2008). In other words, the imputed cost of consumption (defined as the answer to "How much is this pleasure costing me?" Prelec and Loewenstein 1998) is greater for cash than for less vivid forms of payment.

We suggest that the greater the imputed cost of consumption, the greater the likelihood of choosing a more indulgent, high-calorie food. Support can be found in the literature on mood management that demonstrates that when individuals experience negative affect, they seek reparative action, such as through shopping (Tice, Bratslavsky, and Baumeister 2001; Woodruff 2001). Individuals seeking to repair negative moods consume larger amounts of snack foods (Tice et al. 2001) and more hedonic and indulgent foods (Garg, Wansink, and Inman 2007). Because the pain of payment is higher with cash than with other decoupled forms of payments (such as credit), we posit that consumers choose more indulgent foods when purchasing with cash.

In Study 1, we tested if consumers paying in cash indulge more in higher calorie consumption than do those who pay with a card. We recruited 125 customers at a national frozen yogurt franchise retailer. Respondents reported the product purchased and provided responses to several other measures. Indulgence was measured as total calories consumed. As expected, consumers who paid with cash consumed more calories than those who paid with a card (credit or debit; M_{cash} = 439.09 k cal vs. M_{card} = 301.85 k cal; F (1, 122) = 10.85, $p < .002$) and imputed higher costs when paying with cash (M_{cash} = 4.49 vs. M_{card} = 3.84; (F (1, 122) = 6.40, $p < .02$). These costs mediated the effects of method of payment on calorie consumption.

We then replicated these findings in the lab. We recruited 147 undergraduates and first made the payment mechanism (cash or credit) salient, then asked participants to choose products from a menu using that payment method. Consumers who paid with cash selected higher calorie foods relative to those who paid with card (M_{cash} = 500.92 k cal vs. M_{card} = 423.49 k cal; F (1, 144) = 4.60, $p < .04$) and also imputed higher costs (M_{cash} = 3.70 vs. M_{card} = 3.25; F (1, 143) = 3.95, $p < .05$; one participant did not respond).

Because our theorizing is predicated on differences in imputed costs associated with cash vs. credit rather than method of payment per se, in Study 3, we vary earning difficulty. The more difficult it is to earn money, the more painful it is to make a payment, and the higher the imputed cost will be. We recruited 229 undergraduates to select food items for an afternoon snack from a menu. All partici-

pants were told they would be paying with cash earned at their new job. As expected, when difficulty of earning was higher versus lower, consumers selected foods with more calories ($M_{high\ difficulty}$ = 430.77 k cal vs. $M_{low\ difficulty}$ = 348.57 k cal; F (1, 226) = 6.82, $p < .01$). Moreover, participants' perceptions of imputed costs were higher when difficulty of earning money was higher ($M_{high\ difficulty}$ = 4.12 vs. $M_{low\ difficulty}$ = 3.24; F (1, 226) = 24.50, $p < .0001$). Imputed costs also mediated the effect of difficulty of earning on indulgence. We also found that consumers were happier when they consumed more calories in the high imputed costs condition relative to the low imputed costs condition. Thus, the pain of payment is mitigated by an increase in positive affect from consuming the indulgent item. We also test this in Study 4.

Study 4 used a 2 (Imputed Cost: Difficult vs. Easy) x 2 (Food Purchase: Indulgent vs. Not-indulgent) between subjects design, identical to study 3 with the exception that we told half the participants they purchased a slice of a chocolate cake, while the rest learned they purchased a fruit salad.

Participants completed the PANAS scale twice, immediately after the pain of payment manipulation and again after they were informed about food choice. The difference between these two time measurements was regressed on the independent variables. A significant main effect of imputed cost (F (1, 66) = 3.81, $p < .06$) and an interaction of imputed cost by food purchase emerged (F (1, 66) = 4.06, $p < .05$). The purchase of an indulgent dessert increases positive affect when the imputed cost of payment is high versus when the imputed cost is low (F (1, 66) = 7.75, $p < .01$). There is no difference in positive affect for the non-indulgent dessert across levels of imputed cost (F < 1). When imputed cost was high, choosing the chocolate cake led to a directionally higher increase in affect relative to when the fruit salad was chosen (F (1, 66) = 2.27, $p = .13$). These effects were not significant when imputed cost was low.

Together these studies suggest that when imputed costs are high, consumers indulge more. These finding have important implications for consumers, managers, and public policy analysts, but particularly for low-income consumers, who tend to have less access to available credit and for whom earning sustainable wages is more difficult.

Identity Representation in Customization

Kelly Herd, Indiana University, USA
Page Moreau, University of Colorado, USA

EXTENDED ABSTRACT

Identity, what comes to mind when we think of ourselves, includes two major components: a personal identity related to the independent self (i.e., individual traits, characteristics or goals) and a social identity related to the interdependent self (i.e., traits, characteristics and goals that are linked to group membership or personal relationships) (Kirmani 2009; Oyserman 2009). These identities have important implications for the way the self is construed and ultimately represented (e.g., Brewer 1991; Brewer and Gardner 1996; Kleine, Kleine and Allen 1995; Oyserman 2009). Because consumers can have multiple identities that are simultaneously activated and driving behavior (e.g., Oyserman 2009), the current work will separate identity motives (personal and social) and differentially examine their influence on consumers' valuation of customized products and meaning creation. We propose that identity-based motivation, the "readiness to engage in identity-congruent action" (Oyserman 2009, p. 250), is a key factor both prompting consumers to engage in customization activities and influencing how they evaluate the resulting outcomes.

Our first study examines how the activation of an identity motivation enhances the positive influence of design freedom (i.e., the ability to upload images) on consumers' reactions to customized products (i.e., their evaluations at the time of design and satisfaction at delivery).

In this study, two factors were manipulated between-participants: (1) Identity Prime (identity prime vs. no prime) and (2) Design Freedom (low vs. high). All participants go to a live website, designed "skins" (covers for their cell phones or MP3 players) and then received the actual product several weeks later, at which point we capture satisfaction measures.

We find that product evaluations were higher when design freedom was high ($M_{\text{High Design Freedom}}$ = 5.6 vs. $M_{\text{Low Design Freedom}}$ = 4.8; $F(1, 94)$ = 6.61, p = .01). This effect was enhanced when participants were exposed to the identity prime, and the interaction was significant ($F(1, 94)$ = 4.64, $p < .05$). When participants were primed with identity, the level of design freedom mattered significantly ($M_{\text{Identity Prime, High Design Freedom}}$ = 5.8 vs. $M_{\text{Identity Prime, Low Design Freedom}}$ = 4.7; ($F(1, 47)$ = 4.14, $p < .05$). When participants were not exposed to the identity prime, however, the effect was less pronounced ($M_{\text{No Prime, High Design Freedom}}$ = 5.5 vs. $M_{\text{No Prime, Low Design Freedom}}$ = 5.0; $F(1, 46)$ = .86, n/s). We also find that at delivery ten days later, these effects remained.

When identity-primed participants were asked to think about the events in their lives where the device had played an important role, we found great variance in the types of events and experiences that participants described. Thus, in order to better understand the influence of different identity motives on customization, it is important to isolate the effects of these different identity-based motivations (social and personal).

In this study, all participants (N = 87) design customizable coffee mugs and we manipulate two factors were manipulated between-participants: (1) Motivation Primed (social vs. personal identity) and (2) Design Freedom (low vs. high). A two-way ANOVA revealed a significant interaction between the two independent factors ($F(1,84)$ = 4.6, $p < .05$). Participants reported higher evaluations of their mugs when allowed high versus low design freedom $M_{\text{High Design Freedom}}$ = 5.6 vs. $M_{\text{Low Design Freedom}}$ = 5.1). This effect was more pronounced for those primed with personal identity motivations ($M_{\text{Personal, High Design Freedom}}$ = 5.7 vs. $M_{\text{Personal, Low Design Freedom}}$ = 4.7; $F(1, 42)$ = 8.4, $p < .01$) than with social identity motivations ($M_{\text{Social, High Design Freedom}}$ = 5.5 vs. $M_{\text{Social, Low Design Freedom}}$ = 5.5; $F(1, 41)$ = .1, n/s). The analysis also revealed a significant interaction between the two manipulated factors on satisfaction at pickup ($F(1, 49)$ = 4.13, $p < .05$).

Finally, the third study examines how the situational activation of personal identity motivation moderates the effects of a chronic identity motivation (need for uniqueness) to influence consumers' reactions to customized products. As Berger and Heath (2007) indicate, individuals have a "drive to differentiate themselves from others," a need for autonomy influenced both by the individual's relatively stable need for uniqueness (NFU; Tian et al. 2001) and by situational factors leading the person to feel undifferentiated (p. 121).

All participants (N = 67) in this study design a t-shirt using an online website. We manipulate personal identity (salient vs. not salient) and measures chronic need for uniqueness (Tian et al. 2001). We find a main effect of NFU on evaluations (b = .43, t = 2.99, $p < .01$), as well as a main effect of motivation salience (b = 15.9, t = 2.42, p = .01). The main effects were qualified by an interaction (b = -.39, t = -2.20, $p < .05$). To better interpret the interaction, we used a spotlight analysis (Fitzsimons 2008) and find that the slope of NFU was significant and positive when personal identity motivation was not made salient (b = .08, t = 2.11, $p < .05$). When the motivation was made salient, however, the slope of NFU was not significantly different than zero (b = -.01, t = -.45, n/s).

From this study, we conclude that simply making personal identity salient at the time of customization can increase product evaluations for consumers with a low chronic identity motivation and allow them to find greater meaning in the products they create.

These studies demonstrate that simply making salient an identity motivation prior to design can significantly influence product evaluations, product satisfaction and the effectiveness of the customization options (i.e., design freedom). Franke and Schreier (2008) suggest that providing consumers with a sufficiently large solution space is essential for customization companies. Our research qualifies this finding, suggesting that customization options offering a high degree of freedom (i.e., image upload) are only effective when certain identity motives are driving customization. Such a finding is important for firms striving to maximize the profitability of customized offerings.

Talisman Insurance: Does Insurance Coverage Help You Avoid Tempting Fate?

Eric Dolansky, Brock University, Canada
Robert Schindler, Rutgers University, USA
Grant Adams, Rutgers University, USA

EXTENDED ABSTRACT

The feeling that one is "tempting fate" is a common one, and this type of magical thinking could also extend to consumer decisions about insurance. Three studies are presented in which it is shown that individuals estimate a lower probability of a prized possession breaking when it is insured.

In our everyday lives we have all come into contact with magical thinking. Often, everyday instances of magical thinking involve a reluctance to "tempt fate." For example, one might feel that if an umbrella is left at home, there will be a heavy rain. The purchase of property insurance, such as automobile insurance and homeowners insurance, might also be related to magical thinking. While insurance is designed to protect against the financial consequences of a negative event, it might also be viewed as a "talisman" – a means of protecting against the occurrence of the negative event (Tykocinski 2008). The question addressed by this research concerns whether there may be a magical component to the consumer's motivation to buy property insurance.

In a series of experimental studies, Risen and Gilovich (2008) found that when a test scenario's protagonist carried out an action that tempted fate, the protagonist was judged more likely to suffer a negative event than a protagonist who did not tempt fate. Schindler (2009) found that in Japanese price advertisements the number 8, which is considered lucky in Japanese culture, occurred among the rightmost digits of advertised prices far more often than did any other nonzero digit. Kramer and Block (2008) found that positive superstitions pertaining to product attributes (such as color) result in higher satisfaction ratings after product failure.

There is also evidence that the motivation for purchasing property insurance goes beyond the knowledge that one will receive compensation in the event of a financial loss (Tykocinski 2008). An example of what might be involved in this further motivation is provided by Hsee and Kunreuther (2000). They found that, even if the amount of monetary compensation is held constant, the consumer's affection for an object affects his or her desire to have it insured.

Three experimental studies were carried out to test five hypotheses related to talisman insurance. Study 1 was designed to investigate whether the presence of insurance would lead to lower probability estimates of a prized possession breaking (H1) and whether superstitiousness moderates that effect (H2). The scenario presented was one in which respondents imagined that they had just moved to a new city and had left back an heirloom punchbowl. A cousin offered to bring the punchbowl, and whether it was insured differed across conditions. Participants were asked to estimate the likelihood of the bowl breaking en route. A superstitiousness scale was used to create the second condition in the study.

This study showed that while there was no effect of insurance on likelihood estimates of breakage among low-superstitiousness participants (determined by median split), there was a difference in these estimates among high-superstitiousness participants ($p = 0.041$). There was also a significant interaction ($p = 0.02$), supporting H2.

Study 2 used the same design and scenario as Study 1, but rather than examine dispositional superstition, superstitiousness was manipulated using a priming task. It was predicted that the prime would produce effects similar to those based on dispositional super-stition in Study 1 (H3). A word-completion task was designed with one version having superstition-related words (e.g. "superstition," "luck," "charm") and another version having only neutral words (e.g. "superhero," "duck," "chant").

The results indicated that the primes were successful. Whereas there were no effects of insurance in the non-primed group, there was a significant effect of insurance in the primed group ($p = 0.01$). The interaction found in Study 1 was also replicated here ($p = 0.42$) Furthermore, in both Studies 1 and 2 questions were asked concerning punchbowl mishaps not covered by insurance, such as whether it would be scratched or arrive late. In both studies it was found that the likelihood estimates of these mishaps were largely not affected by the breakage insurance.

Study 3 examined the role of affect toward the object, keeping constant the size of the insurance payment. Within the paradigm of talisman insurance, it seems that greater affect toward an object would lead to more of a sense that moving it would be tempting fate and thus there would a greater perceived likelihood that the object would be lost (H4). A greater probability of loss would lead to insurance having greater value as protector, and there would be higher willingness-to-pay for insurance (H5).

A different moving scenario was used in this study. An antique clock that the participant is told he has high [low] affect for is being moved, and may get lost. Insurance can be bought that will provide $100 in the case of loss. Participants were asked to provide their maximum willingness-to-pay for this insurance. In the second part of the study, participants were told that policies had changed, and that the clock would now be insured [uninsured] regardless of previous willingness-to-pay. They were then asked to estimate the likelihood of the loss of the clock.

The results of Study 3 confirm the finding of Studies 1 and 2 that the presence of insurance lowers the perceived probability of loss. They also support H4 and H5: – affect toward the clock increased the estimated probability that the clock would be lost ($p = 0.006$) and there was a significant correlation between probability of loss and willingness-to-pay for insurance ($p = 0.003$). These results provide evidence that there is a talisman component to insurance and that affect increases the sense that protection is required.

These studies constitute first steps toward understanding how consumers may act on a sense of tempting fate. The findings indicate that individuals do, at least under some circumstances, view insurance as conferring protection that it rationally cannot. More broadly, this investigation illustrates how traditional figures of speech, such as "tempting fate," may correspond to demonstrable psychological phenomena and illustrates how subjecting these traditional concepts to scientific scrutiny can both have practical and theoretical implications.

Body and Mind: How Mindfulness Enhances Consumers' Responsiveness to Physiological Cues in Food Consumption

Evelien van de Veer, Wageningen University, The Netherlands
Erica van Herpen, Wageningen University, The Netherlands
Hans van Trijp, Wageningen University, The Netherlands

EXTENDED ABSTRACT

External cues in the eating environment regularly override physiological hunger and satiety cues, which has led scholars to characterize eating as *mindless* (Wansink 2004). Whereas it is well known that consumers often fail to attend to physiological cues in their eating behaviour, it is not known whether potential remedies exist to help consumers be more responsive to these cues. The current study demonstrates that *mindfulness,* a state of 'heightened awareness of what is going on at the present moment'(Brown and Ryan 2003) improves consumers' responsiveness to physiological cues. We demonstrate this for mindfulness as a trait as well as for state induced mindfulness, and show that even a short mindfulness training is powerful enough to affect consumers' responsiveness to hunger and satiety cues. Finally, the object of attention matters: Only mindful attention to the body helps consumers to rely on these cues.

The body's feedback system affects not only within-meal consumption but also, and perhaps more importantly, when and how much to eat at a later point in time. This is important because being able to compensate for previous consumption appears to be a critical determinant of maintaining a stable body weight (Cornier et al 2004). Compensation ability is generally impaired when consumers are distracted (Higgs and Woodward, 2006; Mittal et al in press). Consumers may also chronically be more or less responsive to physiological cues. Restrained eating, a form of constant but often unsuccessful dieting, has frequently been associated with a failure to compensate for previous consumption (Herman and Mack 1975) Constant dieting has apparently taught them to ignore bodily sensations (Heatherton, Polivy and Herman 1989). In contrast, people who regularly exercise appear better at compensating for previous consumption (Long, Hart and Morgan 2002). Combining these findings gives an indication that attention, and in particular attention to the body, plays an important role in responsiveness to hunger and satiety cues.

Mindfulness is defined as an 'enhanced attention to what is going on at the present moment' (Brown and Ryan 2003) Mindfulness has been related to beneficial psychological health outcomes, mostly within clinical contexts and longer-term interventions. We propose that mindfulness' ability to foster a mental state of focused attention is relevant for responsiveness to physiological cues. Mindfulness trainings vary in whether they teach individuals to focus attention on bodily sensations, stimuli in the environment or on both simultaneously (Bishop et al. 2004). In the current study we therefore also examine whether the object of mindful attention matters. Can mindful attention per se increase responsiveness to hunger cues, or does it matter where this attention is directed?

In Experiment 1 we assessed the effects of chronic mindfulness assessed by the MAAS (Brown and Ryan, 2003) on compensation for previous food consumption. Participants consumed either a high caloric or a low caloric milkshake. In a second part of the experiment, participants evaluated neutral video fragments with a bowl of M&M's placed next to their screens. The amount of M&Ms consumed constituted the dependent variable. The results show that, the interaction between caloric content of the milkshake and dispositional mindfulness significantly predicted consumption amount. More specifically, high mindful participants ate fewer M&Ms when they had previously consumed a high caloric milkshake, than when they had previously consumed a low caloric milkshake. For low mindful participants, the effect of the caloric content of the milkshake did not affect later consumption.

Experiment 2 assessed whether a mental state of mindfulness can be elicited through short audio fragments of mindfulness instructions. Participants listened to a short mindfulness instruction (around four minutes) recorded by a yoga teacher. These instructions focused either on the body or on the environment. In the control condition, participants listened to a recorded story. Results demonstrated that both mindfulness instructions elicited similar levels of state mindfulness, but with foci of attention on the body and environment, respectively.

In Experiment 3, we tested the effects of these same mindfulness manipulations on individuals' capability to compensate for previous consumption. Participants listened to one of the mindfulness instructions conditions. They then consumed either a small Snickers or a large Snickers. In a second part of the experiment, participants evaluated cookies. At the end of the experiment, participants' cookie consumption was assessed. In line with our expectations, there was a significant interaction between portion size and mindfulness. Only in the attention to body condition did portion size have an effect on cookie consumption, such that participants who had been served a large chocolate bar ate fewer cookies than participants who been served a small chocolate bar.

Together, these experiments show that mindfulness improves an consumers' responsiveness to internal cues in food consumption. Furthermore, these results indicate that it matters where this attention is directed, as only mindful attention to the body produced these results. Our findings are in line with findings that have shown that distraction undermines compensation behaviour, namely we have shown that the opposite side of the coin, an enhanced state of attention, can improve compensation behaviour. Our findings add to the mindfulness literature in that, until now, the concept of mindfulness has mostly been applied in clinical contexts. For mindfulness research in general, it may be worthwhile to distinguish between the object of attention in different mindfulness trainings, as our findings suggest these have different effects.

On a practical level, our study shows that consumers can enhance their responsiveness to hunger and satiety cues, an important determinant of a constant body weight. Our findings give consumers more guidance on how responsiveness to hunger and satiety cues can be achieved. Simply focusing on several general and more accessible aspects of the body, such as breathing and posture, can improve eating patterns.

Stereotype Processing's Effect on the Impact of the Myth/Fact Message Format:
The Role of Personal Relevance

Marie Yeh, Kent State University, USA
Robert D. Jewell, Kent State University, USA
Michael Y. Hu, Kent State University, USA

EXTENDED ABSTRACT

This study examines the myth/fact message format within the social marketing context of mental illness (MI). People with mental illness are stereotyped and stigmatized such that many social marketing efforts have been pursued to change widely held misperceptions about them (Hinshaw and Stier 2008). One method used to counter widely held misperceptions for mental illness, as well as a number of other social and health issues, is the myth/fact message format, which frames the message by first stating the myth, the incorrect viewpoint, which is then followed by the counter viewpoint labeled as fact. The use of the myth/fact message in the context of mental illness includes countering negative aspects of the stereotype that surrounds the ailment.

It has been well documented that stereotypes, as well-learned beliefs about the characteristics, attributes and behaviors of members of certain groups, are automatically activated in the presence of a member (or symbolic equivalent) of a stigmatized group; however, those motivated to do so, can intentionally inhibit the automatically retrieval of stereotypes (Devine 1989). This suggests that only those with some kind of motivation will suppress the stereotype. We hypothesized that personal relevance will provide this motivation and that without it, differences in attitudes will not occur due to differences in message format. In addition, we hypothesized that the use of the myth/fact message format, which explicitly expresses a negative aspect of the stereotype, strengthens the association of the negative aspect (Fazio et al 1986; Hunt and Ellis 1999) and consequently, weakens the following fact's ability to discount that negative view. Conversely, utilizing a fact only, rather than the myth/fact approach, should instantiate a new positive belief without reinforcing the negative aspects of the stereotype. But this effect will only be seen in those with personal relevance who have the motivation to suppress the stereotype.

As a commonly used social marketing format, the intent of those who use the myth/fact message is arguably to educate and correct misperceptions. Therefore, we also examined the differential effect of message format on perceived learning. Here we hypothesize the exact opposite effect of personal relevance from what was hypothesized regarding message format's effect on attitudes. As those with personal relevance are familiar with the issue of mental illness, we hypothesize that those with personal relevance will not report differential levels of perceived learning due to message format. However, those without personal relevance would view the myth/fact message format as a heuristic cue for learning and would report higher levels of perceived learning under the myth/fact format than under the fact only condition.

320 students from a large Midwestern university were surveyed in a 2 x 2 x 3 x 2 factorial with one within subject factor (time 1 and time 2) and three between subjects factors, message format (Myth/Fact vs. Fact only) which was manipulated, number of messages (1,3 or 5) which was also manipulated and personal relevance (relevant or not) which was measured. As no differences were found on the number of messages, we collapsed the analysis across number of repetition cells. Attitudes towards mental illness as measured by a scale created for the study and perceived learning about mental illness scale were dependent variables.

Our results demonstrated the differential impact of the myth/fact versus fact only message format on attitudes towards mental illness; specifically, a fact only appeal was more effective in engendering desired behavioral and attitudinal responses. This effect, however, was moderated by personal relevance with MI such that those high in personal relevance reported more unfavorable attitudes under myth/fact than under fact only; those low in personal relevance showed no difference. This finding supports our first set of hypotheses and indicates the role of motivation in suppressing the stereotype. Personal relevance also impacted perceived learning differently than attitudes such that those low in personal relevance reported higher levels of self-reported learning than those high in personal relevance.

We suggest that those for whom the issue of MI is personally relevant were motivated to suppress the stereotype thus overall their attitudes towards mental illness were more favorable. However, those with personal relevance with MI had an existing cognitive schema of non-stereotypical beliefs which was reinforced by the fact only message while the inclusion of the myth reinforced the negative aspects of the stereotype. Personal relevance had the opposite effect on perceived learning reinforcing well-established research findings that find that learning does not lead to attitude change. Findings suggest that while the myth/fact message format may be more effective in enhancing people's perception of learning, its effects on attitudes, the typical focal point on social marketing campaigns targeting misconceptions about stereotyped and stigmatized groups, may be the opposite. Social marketers should carefully consider the goal of a campaign before deciding to use the myth/fact message format.

The Effect of Social Threats on Consumer Materialism

Eric Levy, University of Cambridge, UK

EXTENDED ABSTRACT

Why are consumers materialistic? Prior research has identified two paths that lead to materialistic behavior (Kasser 2002): a) exposure to materialistic role models, such as through societal influence, peers, and television (Shrum, Burroughs, and Rindfleisch 2005), and b) events that decrease self-esteem and thereby encourage substitution of love for material objects for real social connections. Although it is known that threats to self-esteem can lead consumers to self-enhance through materialistic purchases, the psychological underpinnings of this effect are not well understood. We propose that such materialistic behavior occurs when the threat to consumers' self-esteem challenges their social (as opposed to private) self-concept. In such circumstances, materialistic pursuits provide a means for repairing one's social self-esteem to the extent that they are likely to impress others.

Four studies utilizing multiple measures of materialism test this proposition. Study 1 tests H1, that social threat will increase preference for materialistic goods significantly more than will performance threat. The study was a 3-group design (threat type: social vs. performance vs. none), and the dependent variable was a chance to win a $100 gift certificate from a more or less materialistic department store (Nordstrom vs. Macy's). A one-way ANOVA found significant differences in materialism (measured by the dollar amount allocated to Nordstrom) between conditions, ($M_{control}$ = $59.96, $M_{performancethreat}$ = $58.96, $M_{socialthreat}$ = $87.08; $F(2, 69) = 4.43$, $p = .01$). Supporting H1, planned contrasts revealed significant differences between the control and social threat conditions ($F(2, 69) = 6.54$, $p < .01$), and between the social threat and performance threat conditions ($F(2, 69) = 6.75$, $p = .01$), but no differences between the control and performance threat conditions ($F(2, 69) = .01$, $p = .93$). Study 1 provided preliminary evidence for our key hypothesis that materialism is a result of social threat.

Study 2 examined the underlying psychological process by testing H2, that social self-esteem (but not performance self-esteem) mediates the effect of social threat on materialism. This study employed a 2 (threat type: social vs. performance) x 2 (threat status: threat vs. affirmation) between-subjects experimental design. The Richins (2004) short-form materialism scale (Success Subscale), and the State Self-Esteem Scale (SSES) (Heatherton and Polivy 1991) were the key dependent variables. An ANOVA replicated H1, ($F(1, 180) = 3.99$, $p < .05$). Planned contrasts revealed that materialism was greater in the social threat than social affirmation condition, ($F(1, 180) = 4.08$, $p < .05$), but not greater in the performance threat than performance affirmation condition, ($F(1, 180) = .65$, NS. Consistent with our predictions, social threat resulted in significantly lower social self-esteem for participants than did social affirmation ($F(1, 92) = 8.30$, $p < .01$), while participants in the social threat and social affirmation conditions did not significantly differ on measures of performance self-esteem ($F(1, 92) = .84$, NS). Furthermore, using a Baron and Kenny (1986) and Sobel (1982) test, we found support for H2, that social self-esteem (but not performance self-esteem) mediated the effect of social threat on materialistic behavior.

Study 3 provided further insight into how people's social relationships affect materialistic behavior, by testing whether certain relationships can be threat-reducing, and thus decrease materialism following a social threat. The study tests H3, that following a social threat, non-contingent social acceptance will decrease materialistic behavior but contingent social acceptance will not decrease materi-

alistic behavior. Participants rated the desirability of 4 conspicuous luxury items: a BMW 5-series car, a private yacht, a Malibu vacation home, and a luxury house. The study was a 3-group between-subjects design (affirmation type: contingent acceptance vs. non-contingent acceptance vs. none). All participants were exposed to the social threat, and then were randomly assigned to one of the three experimental conditions. H3 was analyzed with a 1-way ANOVA, and significant differences in materialism were found between the groups, ($F(2, 132) = 3.68$, $p < .05$). As predicted, planned contrasts revealed a significant difference between the control and non-contingent acceptance conditions ($F(2, 132) = 4.88$; $p < .05$), and between the contingent and non-contingent conditions ($F(2, 132) = 5.98$, $p < .05$), but no differences between the control and contingent acceptance groups ($F(132) = .04$, NS).

Our theory holds that materialism is not simply a substitute for social relationships, but rather that people use material goods in an attempt to impress others following a social threat. Thus, Study 4 tests H4, that relative to a no-threat condition, social threat will increase preference for materialistic goods positioned to a social-adjustive attitude function, but not to a utilitarian attitude function. Participants rated the desirability of 3 luxury items: a watch, a briefcase, and a camera, positioned to either a social-adjustive function or utilitarian function. We employed a 2 (threat type: social vs. none) x 2 (attitude function: social-adjustive vs. utilitarian) between-subjects experimental design, and an ANOVA supported H4, ($F(1, 222) = 5.04$, $p < .05$). Planned contrasts revealed that materialism was greater for social threat than no threat when the luxury goods were positioned to a social-adjustive attitude function ($F(1, 222) = 4.15$, $p < .05$), but not when the luxury goods were positioned to a utilitarian attitude function ($F(1, 222) = 1.32$, NS). Consistent with our theory, social threat resulted in significantly lower social self-esteem for participants than did no threat ($F(1, 224) = 14.43$, $p < .001$).

In sum, four studies provided evidence for our theory. Study 1 showed that social (but not performance) threat led to increased materialism. Study 2 found that social (but not performance) self-esteem mediated this effect, and also replicated the results of study 1. Study 3 established that thinking about a social relationship in which one is accepted non-contingently (i.e., for one's intrinsic self) reduces materialism following a social threat. Finally, study 4 found that materialistic goods positioned toward a social (but not utilitarian) function are preferred more following a social threat, as compared to a no-threat control condition.

Is Breaking Up Hard to Do? An Investigation of Consumer Response to Sponsor Exit

Julie Ruth, Rutgers University, USA
Yuliya Strizhakova, Rutgers University, USA

EXTENDED ABSTRACT

Most sponsorship research focuses on consumer response to the initiation and maintenance of arrangements between brands and properties they sponsor (Johar and Pham 1999; Pope, Voges, and Brown 2009; Ruth and Simonin 2003, 2006). Less research examines how consumers respond to brands that end sponsorship arrangements. This lack of research is surprising given that sponsor turnover is common and that consumers are exposed to information about the end of sponsor-property relationships.

We investigate consumer responses to a brand's decision to end or "exit" a sponsorship arrangement. Relationship research suggests that *severing a* relationship is a negative act that harms attitudes (Duck and Wood 1995; Fournier 1998; Impett et al. 2010). We expect that consumers will perceive sponsorship exit as a negative act that will transfer negative affect to the departing brand. Research also suggests that pre-existing brand attitudes shape how consumers receive and evaluate new information about a brand (e.g., brand alliances; Simonin and Ruth 1998), and so we incorporate this characteristic into theory building.

Extant sponsorship research shows that consumers are affected by their perceptions of the brand's motives in entering sponsorship relationships (Rifon et al. 2004), and prior brand attitudes can moderate these effects (Javalgi et al. 1994). Based on this and other extant sponsorship research, we propose an interaction effect of prior attitudes toward the brand and sponsor motives on attitudes and purchase intentions toward the departing brand. Likewise, given that numbers are used as heuristics (Goldberg and Hartwick 1990), we develop hypotheses regarding the role of duration of the brand-sponsorship relationship and roster size.

Two studies investigate the effect of the extent to which the brand was well-liked initially, the brand's motives associated with exit, sponsorship relationship duration, and number of brands that remain as co-sponsors upon sponsor exit. Findings suggest that sponsor exit has negative effects on attitudes toward the departing brand, especially among consumers who initially perceive the brand favorably. Sponsor motives, sponsorship duration, and remaining roster size moderate these effects.

If It's Similar, it's More Likely…But Can It Be Worth It?
The Impact of Manipulating Perceived Similarity on Probability Judgments
and Outcome Value

Elise Chandon Ince, Virginia Tech University, USA
Hui-Yun Chen, Virginia Tech, USA
Robyn LeBoeuf, University of Florida, USA

EXTENDED ABSTRACT

Sweepstakes have often been used to generate excitement and raise awareness by giving customers opportunities to win the featured prizes. Both the featured prizes and the odds of winning the prizes determine the attractiveness of sweepstakes. Customers, however, usually do not have access to the true odds of winning. Therefore, customers are prone to use other cues to form probability judgments and evaluate the sweepstakes.

According to the probability judgment literature, people develop intuitive probability judgments from extraneous cues such as descriptions of the event (Tversky and Koehler 1994), or the representativeness or availability of exemplars (Kahneman, Slovic, and Tversky 1982). Construal level theory suggests that probability judgments are sensitive to another cue, the perceived proximity to the individual affected by the event. Recently, studies conducted by Wakslak and Trope (2009) manipulated construal level and found that high-level construals, which increase one's subjective distance from an event, lowered subjective probability judgments about the event's likelihood. Put differently, activating concrete construals increases people's perceptions that a target event will occur. We suggest that when an individual affected by an event seems proximal (vs. distant) to the self, that proximity will activate a concrete mindset, and thus, the event in question will seem relatively likely to happen for the self.

Previous research has also shown that limited, scarce resources are deemed more desirable, even when there is no legitimate basis to use scarcity to infer value (Inman, Peter, and Raghubir 1997). If people use an item's perceived scarcity as a heuristic that signals its value, then events that seem unlikely to occur (e.g., "my chances of winning this sweepstakes are low") may also seem to be more valuable, or to have greater impact more generally. Thus, it may be the case that when events happen for distant (vs. proximal) others, the events may seem less likely to occur for the self and thus to seem more valuable, or to more generally have a greater impact.

Therefore, we posit that:

Hypothesis 1   *An event happening to a socially close person will be perceived as more likely to happen to the self than an event happening to a socially distant person, which in turn will reduce predictions about the impending event's magnitude.*

Hypothesis 2   *The relationship between proximity, probability judgments, and perceived magnitude, as defined in H1 will hold true both for positive and negative events.*

Hypothesis 3   *Questioning the validity of the scarcity heuristic reverses the negative impact of probability judgments on the event's magnitude.*

Three studies were conducted to test our predictions. The first study tested H1 and H2. Study 2 replicated the findings, offered a dif-

ferent manipulation of the concept of proximity, and provided further evidence of the mechanism at play. Study 3 provided evidence that the link between perceived probability and predicted magnitude is due to an accessible belief that scarce items are valuable.

Study 1 directly tested the relationships among proximity, probability judgment, and perceived magnitude for two events (getting a flight upgrade and being a victim of credit card fraud). We predicted that greater proximity to a target experiencing one of these events would lead people to perceive the event as more likely to happen for the self, but less valuable or lower in magnitude (e.g., a flight upgrade would seem more likely but less valuable when a close vs. distant other had received an upgrade). Proximity was manipulated by asking participants to focus on how they were similar or dissimilar to the target individual. As expected, participants who focus on what they had in common with the target individual deemed the event more probable, but predicted that the event's magnitude would be less.

Study 2 replicated these results by manipulating proximity through a different implementation. A feeling of powerlessness was induced to make the target individual appear closer, as feeling powerless reduces the social distance between oneself and others (Rucker, Dubois, and Galinsky 2011). Participants were primed with either high power or low power words and then, on an unrelated task, were told that a radio was giving out concert tickets and that a target individual had already won one. They were then asked to indicate the probability of wining the concert ticket themselves as well as the ticket value. Participants who felt powerless and thus closer to the target individual felt that they were more likely to win, but in return thought that the concert ticket was worth less. We replicated our findings with a negatively valenced event: participants who felt powerless thought that they were more likely to get a flat tire on their way to school (which had just happened to a target individual), but also believed that the price of changing the flat tire would be lower than those who felt powerful. A mediation analysis confirmed that probability judgment mediates the relationship between proximity and outcome value.

We proposed earlier that the scarcity heuristic (i.e. the idea that what is scarce is valuable) explains why people's subjective probabilities that an event will occur and their perception of the event's outcome are negatively correlated. The objective of study 3 was to reverse this relationship. If participants were made aware that scarcity is not always negatively correlated to value, then we should expect opposite results: low probability judgments should not increase, but perhaps even decrease, the perceived outcome value. In study 3, we asked participants to read a short paragraph that was either highlighting that diamonds are scarce, therefore highly valuable, or highlighting that diamonds are relatively common in nature and that their scarcity is a myth put forward by the diamond industry. We found that when participants were primed with the "scarcity is a myth" explanation, proximity still increased probability ratings, but also increased perceived value. In other words, the closer the target individual, the more likely and the more valuable the event.

The current research extends the construal level theory literature and examines the indirect impact of varying psychological distance

on perceived event magnitude, with implications for understanding how consumers perceive and anticipate uncertain future events.

Generative Literacy and Consumer Empowerment

Rama Jayanti, Cleveland State University, USA

Michael Wachter, Cleveland State University, USA

EXTENDED ABSTRACT

Responding to the inherent complexities of today's knowledge-intensive economy and the resulting knowledge-intensive consumption, consumer researchers have begun to address consumer literacy (e.g., Wallendorf 2001; Adkins and Ozanne 2005; Ozanne, Adkins, and Sandlin 2005; Viswanathan, Rosa, and Harris 2005). So far, researchers' conceptualization of consumer literacy entwines educational and functional literacy. Equating educational literacy with consumer literacy seems, at the very least, rather limiting given the inherent diversity in products available for consumption in the marketplace and the resulting diversity in complexities related to consumption.

Specifically, while the foundation of educational literacy can be important for consumer literacy research, consumer literacy goes beyond educational literacy. For example, in complex consumption categories involving finance and health related offerings in the marketplace, literacy is highly context specific and knowledge intensive. Consequently, there has been burgeoning interest in functionally rooted financial literacy (e.g., Emund 2010; Huston 2010) and health literacy (e.g., Adkins and Corus 2009: Bone, France, and Aiken 2010) in consumer research. However, despite the seeming importance of the issue of consumer literacy, there is much confusion in the consumer literature regarding the definition/conceptualization and treatment of literacy.

Therefore, we first review the current research on consumer literacy with reference to the conceptualization/ definition and major findings. Second, building on our review, we elaborate on functional versus educational literacy, develop a model of generative literacy, and introduce the notion of a generative cycle of educational and functional literacies for consumer empowerment.

This paper makes several contributions to the consumer literacy research domain. First, our comprehensive and systematic review with reference to the conceptualization/ definition, products focused on, nature of research, and major findings reveals interesting insights into the links between consumer literacy and empowerment, conceptual inconsistencies, public policy issues, and normative strategies for firms. Here, we critically analyze the literature and consciously look for integrative elements and conceptual lacunae in consumer literacy research. Second, building on our review and critical analysis, we (i) propose a 2X2 matrix that helps categorize the differences between low and high levels of educational and functional literacy, reflecting four possibilities that are distinct and present different challenges to researchers and practitioners alike, (ii) summarize the differences between educational and functional literacies, and (iii) develop a figure that illustrates the relationships and moderating factors derived out of the extant literature. Third, we develop and introduce the notion of the generative cycle of educational and functional literacies for consumer empowerment. Herein, we depict dynamic affordances and productive inquiry as linking mechanisms between educational and functional literacies. Overall, our research has several implications for future research as shown in the brief research agenda that follows.

In discussing a research agenda for consumer literacy, we first focus on the context of discovery and, then, the context of justification. As the scope of this research is conceptual, there are several avenues of future research in the context of discovery. First, our integrative and critical review can be subjected to conceptual scrutiny.

Second, the conceptual model of generative literacy that emerged from analysis can be evaluated with reference to parsimony (errors of commission) and comprehensiveness (errors of omission). Furthermore, our conceptualization of generative literacy and the generative cycle of educational and functional literacies for empowerment can also be investigated for conceptual adequacy, consistency, and validity. Third, drawing on the seminal work of Cook and Brown (1999), we introduce the concepts of productive inquiry and dynamic affordances in the context of the generative cycle of educational and functional literacies for empowerment. These two concepts need further development and clarification.

As to the context of justification, our research brings forth concepts such as generative literacy, cognitive predilections, identity management, productive inquiry, dynamic affordances and two new frameworks in the conceptual model of literacy and the generative cycle of educational and functional literacies for empowerment that can be subjected to empirical scrutiny, that in turn, provides several new avenues for future research.

In order to equip the vast majority of people who live on the other side of the social divide with capabilities that they value, transformative consumer research has to take into consideration the generative nature of literacy and strive to balance both educational and functional perspectives for true self and societal empowerment.

On Braggarts and Gossips:
Why Consumers Generate Positive But Transmit Negative Word of Mouth

Matteo De Angelis, Luiss University, Italy
Andrea Bonezzi, Northwestern University, USA
Alessandro M. Peluso, Luiss Guido Carli University, Italy
Derek Rucker, Northwestern University, USA
Michele Costabile, Luiss Guido Carli University, Italy

EXTENDED ABSTRACT

Academic research has widely recognized the paramount importance of word of mouth (WOM), the flow of informal communications about products and services that influences 70% of all buying decisions (Balter 2008). Yet a controversy still exists about whether positive or negative WOM prevails in the marketplace, with some studies indicating that negative WOM is more prevalent than positive WOM (e.g., Kamins, Folkes, and Pernes 1997), and others suggesting the opposite is true (e.g., East, Hammond, and Wright 2007). We identify an important moderator that may solve this controversy. We argue that WOM valence varies systematically across two stages over which WOM unfolds. We call these stages *generation* and *transmission*. Consumers *generate* WOM by talking about their own experiences with products, while *transmit* WOM by passing-on information about other people's experiences. We predict that positive WOM tends to be more prevalent than negative WOM in the *generation* stage, whereas negative WOM tends to be more prevalent than positive WOM in the *transmission* stage. What may account for these seemingly contradictory tendencies in generation and transmission? We suggest that consumers engage in WOM to express themselves, particularly to satisfy their basic need to self-enhance (Sedikides 1993; Baumeister 1998). We argue that this need leads consumers to talk about their own positive experiences (thus generating positive WOM) as a direct way to self-enhance (e.g., Shrauger 1975), as well as about negative experiences they heard occurred to others (thus transmitting negative WOM) as an indirect way to self-enhance (e.g., Tesser 1998).

We tested this explanation in three experiments. Experiment 1 tested whether people indeed tend to generate positive WOM but transmit negative WOM. Ninety-three participants were assigned to a 2 (WOM stage: generation vs. transmission) ´ 3 (social setting: talking to a colleague at work, to a person met at a party, or to a stranger on an airplane) between-participants design, and invited to write what they would say to describe product experiences occurred to themselves or to someone else. To assess WOM valence, respondents were asked to rate the valence of each experience on a nine-point scale (1 = very negative, 9 = very positive). Results showed that participants described more positive experiences when they wrote about their own experiences ($M = 6.61$) compared to when they wrote about others' experiences ($M = 4.37$, $F = 15.54$, $p < .01$). This effect of WOM stage was consistent across the three settings, with contrasts that were all significant (ts ³ 2.20, ps < .03).

Experiment 2 tested whether consumers generate positive WOM but transmit negative WOM as a way to self-enhance. We reasoned that people should exhibit this tendency when their need for self-enhancement is relatively high. We then measured self-esteem as a way to appraise the strength of individual self-enhancement motive, with lower self-esteem triggering a stronger need to self-enhance (Shrauger 1975). Two hundred forty participants were assigned to a 2 (WOM stage) ´ 2 (experience valence: positive vs. negative) between-participants design, and invited to read a description of a new brand of laptop computers. WOM stage was manipulated by asking participants to imagine that they had purchased the laptop and used it for about one month (WOM generation), or that they had been told by a third person who had purchased the laptop about her experience (WOM transmission). Experience valence was manipulated by asking them to imagine that the user (them or the third person) felt satisfied (positive experience) or dissatisfied (negative experience) with the product. Participants then completed a three-item measure of likelihood to engage in WOM and a self-esteem scale. The data were examined with a regression analysis, with WOM likelihood as dependent variable, and WOM stage (coded as 0 for generation and 1 for transmission), experience valence (coded as 0 for negative experience and 1 for positive experience), self-esteem, and all interaction terms as independent variables. Results showed a two-way interaction between WOM stage and experience valence ($b = -.74$, $p < .001$) that was consistent with the basic effect found in experiment 1. They also revealed a three-way interaction among WOM stage, experience valence, and self-esteem ($b = .71$, $p < .001$), indicating that self-esteem moderates that basic effect. A spotlight analysis on individuals low versus high in self-esteem (±1SD from the mean) confirmed that only consumers with a low self-esteem tend to generate positive WOM ($M_{Pos} = 5.49$ vs. $M_{Neg} = 4.50$, $t = 4.19$, $p < .001$) but transmit negative WOM ($M_{Neg} = 5.00$ vs. $M_{Pos} = 4.42$, $t = 2.83$, $p < .01$).

Experiment 3 provided convergence on the proposed psychological mechanism. We manipulated, instead of measuring, need to self-enhance through a manipulation of threat to participants' self views. We expected that people in the threat condition generate more positive WOM but transmit more negative WOM than people in the no-threat condition, because threat inherently triggers a stronger need to self-enhance (Tesser 1988). Seventy-one participants were assigned to a 2 (WOM stage) ´ 2 (self-view: threatened vs. non-threatened) between-participants design. They were asked to write a consumption experience that occurred to them (generation) or that they heard occurred to someone else (transmission), and to rate this experience on the same scale as in experiment 1. ANOVA showed a two-way interaction ($F = 9.55$, $p < .017$), with participants under threat describing more positive experiences than participants under no threat ($M_{threat} = 7.61$ vs. $M_{no-threat} = 6.33$, $t = 1.76$, $p < .03$) in generation, but more negative experiences in transmission ($M_{threat} = 3.82$ vs. $M_{no-threat} = 5.64$, $t = 2.63$, $p < .01$).

Overall, this research offers a novel perspective on the controversy about prevalence of positive or negative WOM. By distinguishing *generation* from *transmission* we further our understanding of when positive WOM is more likely to be shared than negative WOM and when the opposite is more likely to occur. Furthermore, by showing that people engage in WOM generation and transmission as a way to self-enhance, we offer a parsimonious theoretical account that explains why consumers tend to generate positive but transmit negative WOM.

The Effectiveness of Sponsorship in Legitimacy Formation – The Moderating Role of Pre-Existing Satisfaction

Barbara Caemmerer, ESSCA School of Management, France
Raluca Mogos Descotes, IUT Charlemagne, Nancy University, France

EXTENDED ABSTRACT

Conceptualization

Sponsorship activities have gained great importance in marketing communications as well as academic attention over the last decade (Dalakas and Levin 2005; Roy and Cornwell 2004). Traditionally, there has been the notion that sponsorship activities are carried out in order to reach commercial targets (Cornwell et al. 2006; Jagre, Watson, and Watson 2001). However, with growing awareness of the importance of establishing good relationships with important stakeholder groups (Ferrell and Ferrell 2008), the scope of sponsorship has broadened. For example, Dean (2002) highlights that management objectives concerning sponsorship may be both, economic (such as increased brand awareness and profits) as well as noneconomic (such as goodwill and improved community relations) in nature. Despite this recognition, the majority of studies in this field of research have focused on the assessment of the economic effectiveness of sponsorship activities (Gwinner 1997).

Our study contributes to the extant literature by investigating how event sponsorship impacts on the formation of organisational legitimacy which is broadly defined as the "acceptance of an organization by its environment" (Kostova and Zaheer 1999, 64). From an institutional theory perspective, gaining legitimacy is important as it enhances the likelihood that organisations are able to extract scarce resources from their environment and is thus critical to organisational survival (Meyer and Rowan 1977; Suddaby and Greenwood 2005). However, to our knowledge the effectiveness of sponsorship in the formation of legitimacy has not been explored yet.

We further contribute to knowledge by examining the moderating role of pre-existing attitudes towards the organisation on the link between sponsorship and legitimacy. Most of the sponsorship studies have focused on the balancing effects between attitudes towards the sponsored entity, congruence between the sponsored entity and the sponsor, attitudes towards the sponsorship and the resulting attitudes towards the sponsor (Dalakas and Levin 2005; Dean 2002). The underlying assumption has usually been that positive attitudes towards the sponsored entity will transfer to the sponsor. Therefore, very few studies have controlled for pre-existing attitudes towards the sponsor and their possible impact on the effectiveness of the sponsorship activity. However, there is some evidence to suggest that pre-existing attitudes play a moderating role in sponsorship effectiveness (Basil and Herr 2006).

Finally, we also contribute to the literature by examining the hypothesised model in a public sector context. While there is a growing body of knowledge concerning the sponsorship of regional or local charitable events of private sector organizations to develop community relations and increase goodwill, little is known about the use of sponsorship as a tool to develop relations with important stakeholders by public sector organizations. However, public sector organizations are under huge political pressure to establish and maintain good relations with important publics such as their electorate (McNulty and Ferlie 2004; Sanger 2008). Moreover, public sector organizations increasingly invest resources into the support of local events such as concerts and sports events (Walliser 2006). For these reasons, we believe that it is important from a public administration perspective to investigate the effectiveness of sponsorship activities in a public sector environment.

Method

Using a pre-tested questionnaire, responses from 300 spectators of the finals of the Handball French League Cup tournament in Nantes, which was sponsored by Nantes City Council, were captured assessing the following constructs: 1) Attitudes towards the event (Simmons and Becker-Olsen 2006), 2) perceived sponsor-event congruence (Simmons and Becker-Olsen 2006), 3) attitudes towards public sponsorship (Walliser et al. 2005), 4) legitimacy (Sabadie 2003), and 5) pre-existing satisfaction with Nantes City Council (Sabadie 2003). The procedure yielded 275 usable questionnaires. Hypotheses were tested using partial least squares path modelling (PLSPM) (Chin 1998; Fornell and Bookstein 1982). The moderating effects were tested by performing a median split on the basis of pre-existing satisfaction. This enabled the comparison of two sub-samples.

Major Findings

Our study makes three contributions to the extant literature. First, we assess through which mechanisms events sponsorship impacts on organisational legitimacy (Deephouse and Carter 2005). The estimation of our sponsorship model demonstrates that 1) attitudes towards the sponsored event, 2) positive attitudes towards the sponsorship activity, as well as 3) perceived event-sponsor congruence significantly impact on organisational legitimacy amongst customers. Comparing the three effects, we contribute to the extant literature by showing that attitudes towards the sponsorship activity itself have a stronger impact on organizational legitimacy than attitudes towards the event as well as perceived event-sponsor congruence (Cornwell et al. 2006).

The second main contribution of our study relates to the investigation of the moderating role of pre-existing attitudes towards the sponsor on sponsorship effectiveness (Speed and Thompson 2000). Our results provide insight into an interesting dynamic of the sponsorship model when pre-existing satisfaction with the sponsor is controlled for. First of all, we show that the model has a much stronger explanatory power for the sub-sample with positive pre-existing attitudes than for the sub-sample with negative pre-existing attitudes. Further, we can observe that all but one of the moderated links strengthen with increased pre-existing satisfaction. These findings suggest that customers who hold more positive attitudes towards the sponsor in advance tend to evaluate the sponsorship activities of the organisation more favourably. Therefore, there is some support for the overarching hypothesis of our study that pre-existing attitudes towards the sponsor moderate sponsorship effectiveness with regards to non-economic objectives, here legitimacy formation.

This links into the third area of contribution to the extant literature. In relation to the above discussed results we highlight that, first of all, public management needs to further emphasize the implementation of programs that enhance citizen satisfaction. Such initiatives may include in particular the development of an external service orientation (Parkington and Schneider 1979) through which improved and tailored services can be delivered. If such initiatives are not in place and citizens have negative service experiences and

resulting low levels of satisfaction with the public service provider (van Ryzin et al. 2004), sponsorship activities will have less strong an impact on the achievement of non-economic objectives, such as the formation of legitimacy. Focusing on the sponsorship model in particular, it is important to note that public sector bodies should pay attention to the explicit communication of the reasons for the sponsorship activity. Pursuing this perceived event-sponsor match is important (Simmons and Becker-Olsen 2006) as it impacts directly on legitimacy, as well as indirectly through its impact on positive attitudes towards the sponsorship activity.

Reversing Ease of Retrieval Effects with Sensory Product Experience

Kelly (Kiyeon) Lee, University of Toronto, Canada
Andrew Mitchell, University of Toronto, Canada

EXTENDED ABSTRACT

Prior research on the ease-of-retrieval effect has shown that ease (vs. difficulty) of retrieval leads to more favorable judgments in the different types of tasks such as recalling instances from the past memory (e.g., Schwarz et al. 1991), listing counterarguments after reading persuasive messages (e.g., Petty, Brinõl, Tormala, and Wegener 2007), and providing reasons for or against choosing one brand over another after reading advertisements (e.g., Wanke, Bohner, and Jurkowitsch 1997).

This research examines whether previous findings of these effects can be extended to product evaluations based on sensory product experience. We believe that these effects with sensory product experience will produce different outcomes compared to prior research because direct product experience will provide a rich base of sensory information as opposed to situations where individuals merely recall instances or read persuasive messages/advertisements. In addition, sensory information obtained from direct product experience is real and is not to be doubted. However, how one interprets this experience will determine how it is evaluated. Examples of product experiences include testing the comfort of a mattress or the sound quality of a stereo (Shapiro and Spence 2002; Wright and Lynch 1995). We expect that the interactive effect of metacognitive experience and sensory information will lead people to magnify the information generated in direct sensory experience situations in spite of having the same subjective feeling of ease or difficulty as in indirect experience situations.

We conducted four experiments to test our expectations. The purpose of experiment 1 is to test our expectations using a soft drink taste test. Participants were told that a company recently developed a new soft drink targeting a young adult group and that the company wanted to know the strengths or weaknesses of this drink. After tasting the drink, participants were asked to generate 10 reasons or 2 reasons why they like or dislike the drink. Even though our participants found it to be more difficult to generate 10 reasons than 2 reasons, they evaluated the drink more positively when listing 10 reasons than 2 reasons in positive-reasons-generation conditions. However, the reverse was true for negative reasons: they evaluated the drink less positively when they listed 10 reasons than 2 reasons in negative-reasons-generation conditions.

The goal of experiment 2 is threefold: First, to generalize our findings of experiment 1, we employed a different product - a hand lotion. Second, we aimed to rule out a motivation account for the findings of experiment 1 by manipulating high vs. low motivation. Previous research has indicated that individuals tend to rely on thought content under high involvement whereas they are more likely to focus on metacognitive experience as a heuristic cue under low involvement (Rothman and Schwarz 1998). Participants in experiment 1 were highly motivated since they were the target market of the drink and their evaluations would be incorporated in the development of the soft drink, which may lead them to rely on thought content, not on metacognitive experience. In experiment 2, we used the same instructions of experiment 1 for the high motivation condition. For the low motivation condition, participants were told that the target market of the hand lotion was older adults and that their opinions would remain anonymous and be used after aggregating them with those of other groups (Maheswaran and Sternthal 1990; Petty, Harkins, and Williams 1980). If we find consistent results un-

der high and low motivation conditions, this indicates that our findings are not due to motivation. Third, we tested whether confidence in thoughts mediates attitude formation drawing on attitude confidence literature on ease-of-retrieval (e.g., Tormala, Falces, Brinõl, and Petty 2007; Tormala, Petty, and Brinõl 2002). We replicated the findings of experiment 1 using the hand lotion: Participants reported greater difficulty in generating 8 reasons than 2 reasons. However, they evaluated the hand lotion more (less) favorably when generating 8 than 2 positive (negative) reasons. Further, we did not find any difference in product evaluations between high and low motivation conditions, which rules out the motivation account. In addition, we found that confidence did not mediate the effects. These findings provide further evidence for the magnified effect of metacognitive difficulty on product evaluations.

Experiment 3 was conducted to rule out another alternative account—a thought-content-effect account. Although we replicated our findings using hand lotion, it may be argued that it is not clear whether participants rely on metacognitive experience or just on thought content (e.g., reasons). To address this issue, we employed a yoked design used by Wänke, Bless, and Biller (1996). The effect of subjective experience should influence only those who generate reasons themselves as demonstrated in experiments 1 and 2. When participants are asked to read reasons generated by others, they make judgments about a test product based on the content of reasons (thoughts) since they do not have subjective experience. We found that individuals (readers) who did not have subjective feeling of ease or difficulty did not show any differences in their attitude toward the hand lotion based on the number of reasons within the same valence, which is different from findings in experiment 2. This indicates that only generators who write their own reasons and feel metacognitive experience (i.e., feeling of ease or difficulty) can show the magnified effect of metacognitive experience on product evaluations.

Taken together, our findings showed that metacognitive difficulty magnifies thought content in the context of direct product experience, which is contrary to previous findings in different contexts. Across experiments 1-3, we obtained the same results in different sensory products (e.g., a soft drink, a hand lotion) and ruled out a motivation account in experiment 2 and a thought-content account in experiment 3.

We believe that this research make several important contributions. First, it contributes to extend our understanding of the role of metacognition in the context of direct product experience by demonstrating that metacognitive difficulty magnifies thought content. Second, it demonstrates the importance of investigating product usage since consumers may have consistent preference by engaging in direct product experience prior to purchase and firms may have better understanding of consumers' preference and demand.

The Impact of Incidental Ownership of Objects on Subsequent Behavior

Liad Weiss, Columbia University, USA
Gita V. Johar, Columbia University, USA

EXTENDED ABSTRACT

Every single day we acquire new objects – either because we choose them or through some other incidental route such as "hand-me downs" or gifts we never asked for. While it is true that who we are causes us to choose one kind of object over another, is it possible that incidentally acquired objects could cause us to act in ways consistent with those objects? Indeed, the notion that 'we are what we have' is deeply rooted in theories of the "self" (Belk 1988). Previous research has portrayed a motivational process of identity-construction, where people acquire products in order to manage their identity (e.g., Reed 2004). Such research (implicitly) assumes that *wanting* an "identity update" and *choosing* to achieve it via product ownership are necessary conditions for people's identity to be affected by products they own. Extending that research, we demonstrate that these conditions are not necessary, namely that a product can affect people's identity and subsequent behavior even when it was incidentally obtained (e.g., a gift) and the owners have no desire to "update" their identity.

Previous "product-to-behavior" research has shown that product characteristics can affect behavior through brand exposure (via goal activation; e.g., Mazar and Zhong 2010) and product usage (via self-signaling; Gino, Norton, and Ariely 2010). Adding to this literature, we suggest---product ownership---as another route through which product characteristics can affect behavior. We predict that people will behave consistently with product characteristics when they own it (assimilation), but contradictory to them when they interact with the product but do not own it (contrast). Furthermore, we propose a cognitive framework, Egocentric Categorization, to account for these assimilation and contrast effects. Our framework suggests that people may categorize owned and non-owned objects in terms of the category "self" similarly to the way they categorize in-group and out-group members in terms of that category. Further, just like people behave in assimilation to characteristics of 'in-groups' but in contrast to characteristics of 'out-groups,' we suggest that they may behave in assimilation to characteristics of owned objects but in contrast to characteristics of non-owned ones they interact with. Thus, in the ethical behavior domain, for example, when people interact with a product associated with greater (vs. lower) moral characteristics (e.g., reliability, authenticity), they may behave more ethically if they own it but less ethically if they do not.

Our framework predicts that ownership affects behavior through its effect on how people see the self; hence, if people do not "refresh" their self-evaluation after interacting with a product their subsequent behavior cannot reflect product characteristics. People who are low on self-awareness (the state) or private self-consciousness (the trait) tend to reevaluate the self less frequently and their behavior is generally less correlated with their internal states (Gibbons 1990). Therefore, we predict that changes in behavior as a consequence of product ownership are less likely among individuals with lower self-awareness or self-consciousness.

We conducted two laboratory experiments to investigate the aforementioned predictions. We restricted our attention to fidelity in behavior as the dependent variable and used headphones varying in fidelity as the stimulus product category. The headphones differ on fidelity in terms of the extent to which sound is truthfully reproduced and loyal to the original recording. As a cover story, participants in both experiments were asked to help the department of music in selecting gift headphones for invited visitors.

In Experiment 1, the headphones were described as being either high (the "Authentic-Sound" headphones that reproduce the sound exactly as it was recorded) or moderate (the "Better-Sound" headphones that improve the original sound) on fidelity. A separate pretest verified that the high-fidelity headphones were comparable to the moderate-fidelity ones on attractiveness and quality but higher on truthfulness. Two-thirds of the participants were assigned to receive either the set they evaluated ("ownership" condition) or another set ("no-ownership" condition). Another third of the participants (control condition) were informed that they would receive an additional $2 for their input and did not receive any ownership information. Subsequently, after trying on the headphones, evaluating them, entering them into big envelopes and putting them aside, participants' self-awareness was increased by asking them to describe their mirror-image. Finally, in an ostensibly separate study, participants' cheating behavior was surreptitiously documented in a trivia knowledge quiz that incentivized good performance (participation in a $50 lottery) and provided an opportunity to artificially improve one's score by self-reporting their performance.

The results show that, the interaction between ownership and fidelity description on ethical behavior was significant in the predicted direction. In particular, participants in the "ownership" condition acted with *greater* fidelity when the perceived product fidelity was high (vs. moderate). That is, they adjusted their behavior to align with the perceived characteristics of headphones they were randomly assigned *to own*. By contrast, participants in the "no-ownership" condition acted with *lower* fidelity when perceived product fidelity was high (vs. moderate). That is, they contrasted their behavior to the perceived characteristics of the headphones they were randomly assigned *not to own*. It is important to note that, within the control condition, when the ownership construct was not activated, fidelity did not affect cheating behavior. Further analysis showed that owning (vs. not owning) the headphones decreased cheating when the set was described as high on fidelity but did not affect cheating when the set was described as moderate on fidelity. Repeating the same analyses using the amount of cheating as a continuous variable yielded a similar pattern of results.

Experiment 2 complemented the testing of our theoretical framework by varying participants' (measured) self-consciousness level (vs. keeping it high) across conditions while introducing only the high-fidelity headphones in all conditions. They were assigned either to own or not to own these headphones. The same cheating documentation method of experiment 1 revealed that owners (vs. non-owners) of the high-fidelity headphones were less likely to cheat (as found in study 1). Furthermore, consistent with our account that product characteristics affect behavior through an effect on people's self, this difference between owners and non-owners was apparent only among self-conscious individuals.

Odd-Ending Price: Justification for the Hedonic Purchase

Jungsil Choi, University of Kansas, USA
Surendra Singh, University of Kansas, USA
Priyam Rangan, University of Kansas, USA

EXTENDED ABSTRACT

In the present paper, we introduce psychological pricing as a means of reducing feelings of guilt associated with the hedonic purchase. We contend that an odd-ending price, which is known to have a discount image (Schindler and Kibarian 2001), will enable a consumer to feel less guilt upon product purchase than an even-ending price.

Odd-ending pricing is a well-researched topic, and several studies have focused on uncovering the mechanism of why and how consumers respond to odd-ending vs. even-ending pricing (Bizer and Schindler, 2005; Manning and Sprott, 2009; Schindler and Kirby, 1997; Thomas and Morwitz, 2005). One of the mechanisms that explain why people perceive an odd-ending price to be cheaper than an even-ending price is the perceived gain effect of odd-ending pricing. Because round numbers are easily accessible in memory, they serve as reference points in price evaluation (Kahneman and Tversky, 1979). Therefore, an odd-ending price gives consumers the impression that they are receiving a discount (i.e., the amount subtracted from the even-ending price; Bader and Weinland 1932; Kreul 1982; Schindler and Kirby 1997).

Another mechanism is related to a consumer's tendency to ignore a price's rightmost digit/s (Bizer and Schindler 2005; Coulter 2001; Manning and Sprott 2009). Because of the habit of reading multiple digit numbers from left to right, people's attention to the rightmost digits is reduced. Price recall tests show that people make more errors when the price of the purchased product is odd-ending rather than even-ending because of the lack of attention paid to the odd-ending price (Schindler and Wiman 1989). This underestimation for the rightmost digits causes consumers to perceive an odd-ending price as being cheaper or as a discount (Quigley and Notarantonio 1992, Schindler and Kibarian 2001).

The present study suggests that utilization of the odd-ending pricing strategy, known to have a discount image, reduces guilt from purchasing a hedonic product, consequently increasing demand for hedonic products. We demonstrate this hypothesis by identifying the mechanism by which an odd-ending price reduces the guilt associated with the hedonic purchase when there is insufficient justification (Study 1) and insufficient motivation to purchase (Study 2). We also show that odd-ending price significantly increases demand for hedonic items, but not for utilitarian items in Study 3.

In Study 1, we used 2 (price difference: odd-ending vs. even-ending) x 2 (justification: volunteering job vs. must-job) between-subjects design. We manipulated justification-available vs. justification-unavailable conditions by having participants imagine two different scenarios about consuming massage services. We find an interaction effect of price × level of justification on feelings of guilt ($p < .05$). Pairwise comparisons show that when level of justification is low, people feel less guilty when the price of massage services is odd-ending compared to even-ending ($p < .05$). However, when a level of justification is high, there is no significant difference in feelings of guilt in terms of price difference ($p = .30$).

There is an interaction effect of price × level of justification on participants' likelihood ($p < .01$). Pairwise comparisons show that people are more likely to consume the hedonic service when the price is odd-ending than even-ending ($p < .05$) when level of justification is low. However, when justification is available, there is no

significant difference in the consumption likelihood in terms of price difference ($p > .23$). Moderated mediation analysis shows that feelings of guilt mediate the effect of price-ending on the likelihood of consuming massage services only when level of justification is low ($p < .05$), but the mediated relationship is not observed when level of justification is high ($p > .31$).

In Study 2, we used 2 (price: odd-ending vs. even-ending) x 2 (motivation: sufficient motivation vs. insufficient motivation) between-subjects design. We manipulated level of motivation to purchase a product (headphones) by having participants imagine two different scenarios. We included brand familiarity, the purchase relevance, and the degree of knowledge in a product category in all the analyses as covariates. We find similar results of the first study. When people have sufficient motivations to buy headphones, they are not affected by price difference, but they are when they do not have sufficient motivations. Price difference affects feelings of guilt on purchasing the product, overall purchase feelings, and the purchase likelihood only when participants imagined not having sufficient motivations to buy the product.

In Study 3, we demonstrate whether different pricing affects choice of options in terms of option type. For instance, customers add options to their chosen basic model, especially when they buy a car or a new computer. Some options are specific to hedonic pleasure and others to functional utility. We expect that odd-ending pricing will differentially affect purchase decisions when customers choose to buy either hedonic options or utilitarian options. In particular, we hypothesize that an odd-ending price will increase the likelihood of choosing a hedonic option but will not affect the likelihood of choosing a utilitarian option.

As expected, the likelihood of purchasing hedonic options was affected by the type of price. Particularly, wing spoiler was significantly different in terms of price type ($p < .01$). An odd-ending price had a significant impact on the purchase likelihood. We find a marginal difference in the likelihood of purchasing 18" alloy wheel in terms of price type ($p = .07$). However, there was no difference in the likelihood of choosing full nose mask ($p > .4$) and floor mats ($p > .8$). Both full nose mask and floor mats were defined as utilitarian items in the pretest.

This study illustrates when odd-ending pricing strategies become more effective in increasing demand. Theoretically, this study points to another variable that moderates evaluation decisions for hedonic (vs. utilitarian) purchases, by showing the effect of an odd-ending price on purchase intentions. While most previous studies have focused on the efficacy of odd-ending pricing, few studies have revealed why its effect is significant, especially in terms of purchase context. The effect of odd-ending pricing seems to be a subtle but significant stimulus that enables consumers to get past guilt, and make the product purchase.

Choosing for a Certain Future: Relying on Hard vs. Soft Attributes When Options Are Temporally Distant

Jiao Zhang, University of Miami, USA

EXTENDED ABSTRACT

Choice and consumption are often temporally separated. For example, people often reserve hotels or rent cars for a future vacation. How does the temporal distance between choice and consumption influence preference and choice? Prior research shows that as the temporal distance increases, affect-based outcomes are discounted more than cognition-based outcomes (e.g., Metcalfe and Mischel 1999); the weight of low-level attributes – peripheral, feasibility attributes – decreases while that of high-level attributes – central, desirability attributes – increases (e.g., Liberman and Trope 1998; Trope and Liberman 2000, 2003).

The present research studies how temporal distance influences the weight of "hard attributes" vs. "soft attributes." An attribute is a hard attribute if it is objective and unequivocal as to which of two options is better on it, and a soft attribute if it is subjective and malleable as to which of the two options is better (Hsee et al. 2003). Examples of hard attributes include the size of a house and the resolution of a digital camera. Examples of soft attributes include the style of a car and the smell of a perfume.

Why should temporal distance influence the weight of hard vs. soft attributes? Research shows that preference uncertainty increases with temporal distance from outcomes (e.g., March 1978; Salisbury and Feinberg 2008; Simonson 1990). Increases in preference uncertainty or perceived risk encourage individuals to choose in a way that appears safe (e.g., Bettman 1973; Dowling and Staelin 1994; Erdem 1998). Individuals tend to believe that basing choices on hard rather than soft attributes is more rational and safer (Hsee et al. 2003). Consequently, we propose that an increase in the temporal distance between choice and consumption would increase preference for options superior on hard versus soft attributes.

Two factors potentially moderate the effect. One is response mode, choice vs. purchase intent. Because individuals tend to feel a weaker need to appear rational when indicating purchase intents than when making choices, we hypothesize that the effect will be found in choice but not in purchase intent. Another is the ease of changing one's choice. Because preference uncertainty has weaker consequences when changing one's choice is easy rather than difficult, we hypothesize that the effect will occur when changing choice is difficult but not when changing choice is easy.

We tested these predictions in three studies. In Study 1, participants were choosing between two stereos differing in sound-richness and sound-powerfulness. Two factors were manipulated between-participants. The first was whether participants would receive the purchased stereo immediately or in three weeks. The second was attribute hardness. In one condition (sound-richness-soft), participants were told that they personally found Model A's sound richer than Model B's, but Model B was more powerful (150 watts) than Mode A (50 watts). In another condition (sound-powerfulness-soft), participants were told that they personally found Model B's sound more powerful than Model A's, but Model A had a higher sound-richness rating (150) than Model B (50). In a third condition (both-attributes-hard), participants saw both the sound-richness ratings and the wattages. As predicted, when one of the two attributes was soft, more participants chose the stereo superior on the hard attribute when they would receive the chosen stereo in three weeks rather than immediately. By contrast, when both attributes were hard, temporal distance did not influence choice.

Study 2 tested the role of response mode. The study involved two graphing calculators: one had a better brand (Texas Instruments) and came with a $15 Starbucks gift card; another had a less attractive brand (Hewlett-Packard in one condition and Compaq in another) and came with a $30 Starbucks gift card. The study was a 2 x 2 x 2 between-participants factorial design. The first factor was temporal distance: The purchased calculator and the gift card would be received either in three days or in three weeks. The second factor was the hardness of brand. A pretest showed that Texas Instruments was moderately more attractive than Hewlett-Packard but strongly more attractive than Compaq. We reasoned that the greater the difference in attractiveness between two brands, the harder the difference. The third factor was response mode, choice vs. purchase intent. The results showed a significant three-way interaction. As predicted, in the brand-name-soft condition, an increase in temporal distance increased preference for Hewlett-Packard in the choice condition but increased preference for Texas Instruments in the purchase-intent condition. By contrast, in the brand-name-hard condition, regardless of response mode, an increase in temporal distance slightly increased preference for Texas Instruments.

Study 3 examined the effect of ease of changing choice. Participants were asked to imagine that they wanted to rent a convertible for a weekend vacation in Key West, Florida. They noticed that a well-known car rental company was offering two deals, one featuring a Ford Mustang V6 convertible and the other featuring a Chrysler Sebring convertible. The Mustang convertible came with a $30 gift certificate and the Sebring came with a $50 gift certificate; both certificates were redeemable at any restaurant. In a pretest, participants rated Mustang as being more attractive than Sebring. Notice that the difference in car was relatively soft while that in gift certificate was relatively hard. The study was a 2 x 2 between-participants factorial design. The first factor was the timing of the vacation: next weekend or during a weekend in two months. The second factor was the difficulty of changing one's choice: In the change-easy condition, participants were told that no deposit was required for making a reservation and they could cancel the reservation or switch to the other deal at any time; in the change-difficult condition, participants were told that a $10 deposit was required for making a reservation and that the deposit would not be refunded if they cancelled the reservation or switched to the other deal. As predicted, in the change-difficult condition, preference for Sebring was stronger when the vacation was in the distant rather than near future; in the change-easy condition, preference for Mustang V6 was stronger when the vacation was in the distant rather than near future.

Having versus Consuming: How Failing to Estimate Usage Frequency Affects Consumer Preferences for Multi-Feature Products

Joseph Goodman, Washington University in St. Louis, USA
Caglar Irmak, University of South Carolina, USA

EXTENDED ABSTRACT

While the demand for multifunctional products (e.g., smart phones) soars, most consumers do not use the additional features that come with such products (Techview 2009). This conflict between purchase and usage behavior is explained by the complexity of product features. Consumers underestimate learning costs at the time of purchase (Meyer, Zhao, and Han 2008) and fail to take the usability factors into account (Thompson, Hamilton, and Rust 2005) when they purchase multifunctional products.

Consumer research on multifunctional products thus far has focused on consumer reactions to products with novel and complex features (Mukherjee and Hoyer 2001; Thompson et al. 2005). However, in many product markets (e.g., mobile phones, vacation resorts) consumers shop for products with multiple, yet simple, features. When consumers are familiar with a product and its features, they are less likely to underestimate learning costs and usability is unlikely to be a factor in product choice (Kahn and Meyer 1991). Still, even for simple product purchases, for instance, when choosing between pay-per-use and a flat fee for using a swimming pool, consumers often overestimate higher-than-average usage incidents, leading them to overpay for such products (Nunes 2000). Thus, research suggests that consumers are generally poor in accurately predicting their usage rate of products and product features before purchase.

We build on this body of research by testing whether consumers fail to estimate (rather than underestimate) their usage rate of product features. To do so, we let consumers estimate their usage frequency of each feature before choice to determine whether estimation alters their preferences. If consumers fail to estimate usage before choice, usage estimation may lead to a preference reversal, whereby a few-feature product is more likely to be preferred over a product with a greater number of features.

Further, we argue that since usage rate estimation is not likely to fit the mental representation of the product at the time of purchase (Thompson et al. 2005; Trope and Liberman 2010), consumers may need to exert the extra cognitive effort required for estimating usage rate of features before purchase. Consumers with high need for cognition (NFC; Cacioppo, Petty, and Kao 1984) are more likely to think about usage rate of features and try to assess the value of each option when evaluating alternatives in the decision making process as they generally put greater effort to make more accurate decision (Levin, Huneke and Jasper 2000). Accordingly, we predict that when consumers estimate their usage rate of product features before choice they will be more likely to prefer the few-feature product compared to the many-feature product, and this effect of usage estimation on preferences will be stronger (weaker) for those who are low (high) in need for cognition.

In study 1, we demonstrate that consumers prefer a cell phone with a lower (vs. higher) number of functions when they estimate their usage rate of functions before choice compared to control. Further, we show that the effect of usage estimation is moderated by participants' level of NFC such that the effect is stronger for those who are low (high) in need for cognition.

In study 2, we extend the effect to another, low-complexity product domain (i.e., vacation resorts) and show that (1) consumers assess whether a feature is desirable, but do not consider usage frequency, ruling out a heuristic-based explanation of the effect (i.e., "more functions is better), (2) the effect is independent of learning cost, (3) usage estimation reduces the importance of the additional features on the many-feature product and, as a result, makes consumers more likely to prefer the few-feature product.

Finally, in study 3, we provide further evidence for the underlying mechanism of why consumers fail to estimate their usage frequency of feature before choice. We demonstrate that the level of materialistic values (Richins 2004) moderates the effect such that usage rate estimation shifts preferences toward the low-feature product only for those consumers who are low in materialistic values.

Findings from this research have several important contributions. First, in contrast to research showing overestimation of usage as a reason for consumers purchasing multifunctional products (e.g., Meyer et al. 2008), our research demonstrates that the failure to estimate usage rate is an important factor in such consumer decisions. Second, our findings suggest that consumers approach multifunctional product purchase occasions with a mindset of acquiring and spending (cf. Rassuli and Hollander 1986), rather than considering the utilitarian aspects of such products (e.g., how often they are going to use the product features). In line with this contention, we observe the effect only for consumers who are low in NFC (Cacioppo et al. 1984) or low in materialism (Richins 2004). Third, we show that estimation of feature usage rate before choice reduces the importance of features and leads to preference reversals similar to those demonstrated in research on trivial attributes (Brown and Carpenter 2000; Simonson, Carmon, and O'Curry 1994). Finally, in today's economy these findings are especially important as they prescribe to consumers a tool to help avoid overspending and save money.

When Humanizing Brands Goes Wrong:
The Detrimental Role of Brand Anthropomorphization amidst Product Wrongdoings

Marina Puzakova, Drexel University, USA
Hyokjin Kwak, Drexel University, USA
Joseph Rocereto, Monmouth University, USA

EXTENDED ABSTRACT

Prior research has established that anthropomorphization of a brand has positive implications for consumers' perceptions and behaviors. For instance, human qualities of emotionality and thought of the M&M brand's characters transfers to the M&M brand, creating a point of differentiation and connection with consumers. What consequences does the marketing tactic of anthropomorphizing a brand have when the brand catches the glare of negative publicity arising from negative brand performance? In September of 2008, independent sources indicated that traces of melamine, a poisonous substance, could be potentially present in M&M's candies. Would consumers' reactions to the incidents of negative media coverage have been different if the M&M brand had been non-anthropomorphized in its marketing promotions?

Our research demonstrates that anthropomorphization of a brand triggers less favorable attitudes toward the brand when consumers are exposed to information regarding negative brand performance. This phenomenon is attributed to the fact that the anthropomorphization of an entity makes individuals see this entity as mindful and intentional, and, thus, to be fully accountable for its actions. In times when people did not attribute intentional capacities strictly to humans, animals and objects alike were subjects for prosecution (Berman 1994; Epley and Waytz 2009). In turn, greater responsibility for an action created greater willingness to punish a target of negative behavior. Prior research in marketing has also established that a firm or a brand's wrongdoings, determined to be intentional, are perceived more negatively than actions categorized as accidental (Folkes 1984; Klein and Dawar 2004). Evidence from previous research indicates that consumers may perceive the locus of responsibility for a failure as external, that is, brand-related, or internal, or context-related (e.g., consumer, external suppliers, retailers); (Laufer and Gillespie 2004). Given negative brand performances, brands that are depicted with anthropomorphic features are more likely to be viewed as committing intentional acts than brands positioned without humanized elements.

Furthermore, our research extends the premise that people apply social beliefs to agents that are being anthropomorphized and interpret the actions of humanized entities in light of this social knowledge. Specifically, we theoretically conceptualize and empirically demonstrate that consumers' implicit theories of personality affect their perceptions of anthropomorphized brands when the brands catch a glare of negative publicity. Researchers in social psychology suggested that a fixed view of personality is associated with a greater emphasis on relying on others' traits in predicting their behavior across various situations (Chiu et al. 1997). By contrast, individuals, who endorse an incremental theory stance, take into account contextual information, do not expect that the same behavior recurs across situations, and are less likely to change their perceptions of transgressors based on a single incident (Dweck and Molden 2008). Precisely, individuals who believe in personality stability view anthropomorphized brands that undergo consumers' backlash from negative performance less favorably than non-anthropomorphized brands. The opposite holds true for consumers who accept the incremental view of personality malleability. That is, consumers who believe in incremental theory, view anthropomorphized brand more favorably than non-anthropomorphized when they deal with negative information about the brand.

We examine hypothesized effects in two experiments. Experiment 1 investigates whether anthropomorphizing a brand creates less favorable perceptions of a brand when consumers learn negative brand information. The results of Experiment 1 demonstrate that a brand represented with humanlike features (e.g., human visual elements of the product, ad copy written in the first, as opposed to in the third person) creates less favorable attitude toward and less trust in the brand. Experiment 2 explores the moderating role of implicit theory of personality. Implicit theory of personality was manipulated by having respondents read an article supporting either entity or incremental theory. The findings of Experiment 2 reveal that anthropomorphized, as opposed to non-anthropomorphized, brands trigger negative reactions from consumers that advocate entity theory stance. They also attribute greater responsibility to the anthropomorphized versus the non-anthropomorphized brand. In contrast, we found that incremental theory proponents have more positive attitude toward the anthropomorphized brand and do not attribute greater brand responsibility for negative brand actions. They are more likely to allow the possibility of inconsistent behaviors, and therefore, are less likely to be negatively affected by the information regarding negative brand performance.

In conclusion, previous research is silent to the question of how the anthropomorphization of a brand affects consumers' perceptions if the brand undergoes public backlash, arising from factual negative information. To our knowledge, this research represents the first theoretical and empirical documentation of the negative effect of brand anthropomorphization on consumers' attitude toward the brand adversely envisaged by mass media.

The Globalness Route toward Brand Equity: How Consumer and Brand-Level Factors Change the Route to Success

Bernhard Swoboda, Trier University, Germany
Karin Pennemann, Trier University, Germany
Markus Taube, Mercator School of Management, Germany
Thomas Foscht, University of Graz, Austria

EXTENDED ABSTRACT

The objectives of the present study are to examine (1) how perceived brand globalness (PBG) and perceived brand localness (PBL) serve as halos for brand equity within the service sector (2) mediated by hedonic and functional values and (3) moderated by consumer and brand-level factors.

In the context of consumer products PBG is positively related to consumers' purchase likelihood via quality and prestige (Steenkamp, Batra and Alden 2003). However, results are not consistent (Dimofte, Johansson and Ronkainen 2008) regarding the benefits of global brands. Retailing, for instance, is originally a local business. Thus, retailers are closer to the customer (Evans and Bridson 2005) and see the need for adaptation. Moreover, such local, adapted brands are perceived as higher in affinity and quality (Kapferer 2005).

We propose the indirect impact of PBG and PBL on brand equity mediated via hedonic and functional values (Sweeney and Soutar 2001). Values as a ratio of salient 'give' and 'get' components (Zeithaml 1988) are especially important within the service context (Sweeney and Soutar 2001). Due to their higher accessibility, hedonic (emotional) values especially are preferred (Feldman and Lynch 1988; Verplanken, Hofstee and Janssen 1998). Yet, choosing which route (functional and/or hedonic) toward brand equity is most beneficial depends on brand-level factors such as a brand's country-of-origin and consumer-level factors like consumer identity (Zhang and Khare 2009).

Country-of-origin acts as a halo (Han 1989), which explains how consumers draw inferences from country image specific associations to an object from this country (e.g. products, brands). Quality beliefs (Han 1989) and social status (Batra et al. 2000; Ger and Belk 1996) are inferences drawn from country image and impact consumers in their evaluation of global and local brands.

Furthermore, we apply social identity theory (Tajfel and Turner 1979; Brewer 1991) to explore the moderating role of consumer-level factors. Consumers' identity can be characterized as global or local and therefore evokes preferences for global or local brands due to identification reasons (Zhang and Khare 2009).

We collected consumer data (n=1188) nested in 36 service brands within China as an emerging market. Brands can be grouped according to their origin in Western, Asian and Chinese brands. The hypotheses are tested across three service industries, including fashion retailing, food retailing, and restaurants, assigning equally twelve brands per industry and brand origin to further increase the generalizability of results. We applied classical checks of validity, reliability, and measurement invariance. The model was conceptualized as a moderated mediation and attempted to explain how and when a given effect occurred (Preacher, Rucker and Hayes 2007). First, we estimated the structural model and then conducted the mediation analysis according the suggested procedure by Baron and Kenny (1986) and evaluated other plausible rival models. Finally, we performed two multi-group analyses using brands' country-of-origin and consumer identity as moderators after splitting the sample according the moderators to finalize the moderated mediation.

Results show that PBG and PBL indirectly enhance brand equity and our study shows how. The results emphasize the mediating role of hedonic and functional values, whereby hedonic values, such as socio-emotional value, is a full mediator and functional value, such as quality value, plays a subordinate role as a partial mediator. Which route to success PBG and PBL take depends on brand as well as consumer-level factors.

The brands' country-of-origin is relevant in the way brand equity is built in the consumers' mind. For brands originating from (cultural) peripheral Asian countries, PBG instead of PBL is the primary driver for brand equity via socio-emotional value and quality value in a fully mediated causal chain. Surprisingly, these cultural peripheral brands cannot use their cultural affinity in terms of PBL. Besides, we find evidence that the path to brand equity is based on the functional component quality value, while the direct impact of socio-emotional value disappears. We conclude that cultural peripheral brands like Asian brands are purchased out of cognitive evaluation and without a direct affective appeal. Referring to consumer cultural theory (McCracken 1986) we conclude that brands originating from cultural peripheral countries do not match Chinese identity. This mismatch constrains the building of brand equity.

Brand equity of Western brands is primary driven by PBG fully mediated by socio-emotional value and partially mediated by quality value. Brand equity of Chinese brands is driven by PBL. We conclude that brands with a Western appeal and domestic brands carry cultural values that activate a direct affective impact on brand equity, which is just partially mediated via quality value.

Consumer identity impacts the way brand equity is built in consumers' minds. PBG is the primary driver for brand equity when consumers' identity is global. The mediating role of quality value varies upon the level of consumer identity. For local consumers, emotional appeals seem directly accessible and diagnostic to create brand equity – for global consumers the path to brand equity essentially leads via quality value.

For practitioners our results are useful in several aspects. It is obvious that Western retail brands, like French retail brand Carrefour, try to adapt to the Chinese environment. But it is also obvious that Western brands should not conceal their rather global identity due to the naturally competitive advantage of Asian and Chinese brands especially to deliver local cultural values. The recommended strategy is to leverage brand equity driven by PBG but also cater on the functional basis for specific needs; thus, do not import standardized concepts that ignore specific needs.

It is All About Subtlety:
Subtle Efforts to Remedy Subtle Service Failure

Fang Wan, University of Manitoba, Canada

L.J Shrum, University of Texas at Austin, USA

EXTENDED ABSTRACT

Service failure and recovery are complex and dynamic constructs (Bonifield and Cole 2007). However, most existing literature focused on blatant and outrageous service failure (Bonifield and Cole 2007; O'Donohoe and Turley 2007) and the role of strong and outward emotions such as anger in service failure and recovery (Bonifield and Cole 2007; O'Donohoe and Turley 2007). Our research explores an understudied area—the effectiveness of recovery strategies in a subtle service failure situation that involves a passive negative emotion embarrassment. Drawing on research on embarrassment (Grace 2007; Keltner and Buswell 1997) and goal automaticity (Bargh 2002; Leary 1995), we identify that even perfectly friendly and personalized service encounter can fail when it violates contextually activated social goals. More importantly, we propose that in such a situation with a subtle service failure, the effectiveness of various recovery efforts is impacted by subtle cues such as types of recovery strategy, awareness of the recovery efforts and time of service evaluation. Three experiments are reported to demonstrate the impact of these subtle cues in ameliorating the service experience.

In Experiment 1, we identified a service setting with a subtle failure. Specifically, we examined a personalized service scenario in which the server unintentionally discloses the customers' privacy (i.e., reminding the customer of their previous unhealthy food choice in a restaurant) and jeopardize their contextually activated social goals (i.e., impression management goal when dining with a date for the first time plus health goal if the date is a fitness instructor). By conducting a 2 (personalization: high vs. low) by 3 (social goal: dining with a friend, a date, a date as a fitness instructor) between-subjects experiment with restaurant dining scenarios, we identified that even high-personalized service may cause subtle service failure (evoke felt embarrassment and incur negative service evaluation) if this service unintentionally violates the customer's contextually driven social goals. The subtle service failure scenario (high personalization and dining with date as fitness instructor) identified in this study is utilized in the following experiments.

In Experiment 2 we examined whether the server or customer is the recovery initiator will make the service recovery more effective. As research on embarrassment suggests that either the person who feels embarrassed or the others who evokes the embarrassing situation can relieve the felt embarrassment (Miller 1995). We designed strategies with the server (or self) initiating an attempt to mitigate the transgression: "Well, you (or I) may like trying something else today." We further argue that high awareness of server's recovery efforts can exacerbate the attention paid to the previous service failure and can incur more negative attributions about the server, making recovery efforts futile (Kelley 1972; Main et al. 2007). We tested the hypothesis with a 2 (remedy initiator: self vs. server) × 2 (awareness of the remedy effort: high vs. control) between-subjects design, plus a no-remedy control condition. We manipulated awareness of the recovery efforts by measuring responses to the self or the server's recovery attempts either before (high awareness condition) or after (control condition) service experience related measures. ANOVA analyses yielded significant interaction effects ($F(1, 110) = 4.08, p < .05$), supporting our hypotheses.

Experiment 3 further explores the effectiveness of recovery efforts by examining the different recovery strategies a server can take, as well as the effect of time. Based on service recovery (Hoffman, Kelley, and Rotalsky 1995) and embarrassment literature (Keltner and Buswell 1997), we designed two types of server's recovery strategies, direct (directly correcting the transgression) versus indirect (offering a free coupon—distracting the attention). In addition, according to emotion regulation (Gross et al. 2007) and interpersonal relationship literature (Fletcher and Clark 2002), we argued that distraction (indirect recovery) may help reduce the felt embarrassment and enhance service evaluation in the short run. However, in the long run, the direct recovery (confronting the issue) can be more effective in helping reduce felt embarrassment, and therefore, ameliorate the service experience. In this study, a 2 (recovery method: direct vs. indirect) by 2 (timing of evaluation: immediate vs. delayed) between-subject design was adopted to test the hypothesis. ANOVA findings supported our hypotheses with a significant interaction of the two manipulated factors ($F(1,92) = 7.08, p < .01$). Two post-hoc experiments further explored why different recovery strategy (direct vs. indirect) created different results when there is a time lag. Results suggested that indirect (vs. direct) recovery suppresses negative emotions in the short run and backfires in the long run.

Taken together, our research examines the subtle service failures and recoveries that involve a passive emotion such as embarrassment. Theoretically, service failure, recovery, and emotions are complex and dynamic processes that may vary dramatically from one situation to another (Bonifield and Cole 2007). We provide nuances of a complex interaction between subtle recovery efforts and consumers' perceptions and subsequent reactions. To service managers, the most important message is that service delivery can be personalized but can not be done at the cost of revealing sensitive information. When embarrassing service encounter is incurred, recovery strategies vary depending on whether a short-term or long-term oriented goal is adopted by service managers. In a short run, indirect strategies such as incentives can be effective. But in a long run, direct strategies are more effective.

Affect-Rich Experiencers, Affect-Poor Forecasters: Mispredicting The Influence of Outcome Magnitude and Outcome Probability on Experienced Affect

Eva Buechel, University of Miami, USA
Jiao Zhang, University of Miami, USA
Carey Morewedge, Carnegie Mellon University, USA
Joachim Vosgerau, Carnegie Mellon Univeristy, USA

EXTENDED ABSTRACT

Affective forecasters exhibit an impact bias whereby they overestimate their emotional reactions to future events (Gilbert et al. 1998; Wilson & Gilbert, 2003). Despite many demostrations and proposed reasons for this bias, little attention has been paid to how forecasting errors relate to different magnitudes of the outcomes and to the probability with which outcomes occur.

People generally have the intuition that they will experience greater utility from outcomes that are greater in magnitude (Kahneman & Tversky, 1979) and outcomes that are obtained with a smaller probability (Brandstaetter, Kuehberger & Schnerider, 2002; Mellers, et al. 1997). An interesting question is whether people can accurately predict the impact of quantitative specifications of such outcome characteristics on their experienced affect. Hsee and Zhang (2004) have already studied if forecasters in joint evaluation mode can accurately predict the experienced affect of outcomes if they were encountered in isolation. They found that forecasters in joint evaluation mode overpredict the affective difference that magnitude specifications will evoke for experiences in single evaluation mode because the joint evaluation mode renders them more sensitive to magnitude differences.

In the present research we hypothesize that the difference in sensitivity between forecasters and experiencers is not contingent on the discrepancy in presence of other options. While forecasters report an emotional reaction they are not currently feeling, experiencers can feel the emotion vividly (Loewenstein, 1996; Loewenstein, Prelec & Shatto, 1998). This suggests that forecasters are in a more affect-poor state while experiencers are in a more affect-rich state. Previous research has shown that people in a relatively affect-poor state are more sensitive to quantitative specification such as magnitude and probability information (Hsee & Rottenstreich, 2004; Rottenstreich & Hsee, 2001). Therefore we argue that forecasters are generally more sensitive to information about the magnitude of future outcomes and the likelihood with which the outcome will occur than experiencers and thus overestimate the influence of such information on their experienced affect. An implication for this difference in sensitivity is a reversal of the impact bias whereby forecasters may underestimate their affective reaction in certain situations, such as when the outcome is small or the probability of obtaining it is high.

Study 1 tested if forecasters overestimate the importance of magnitude of the outcome on their experienced affect. Participants of a 2 x 2 between subject design participated in a gamble where they rolled a die and won $1 ($20) if they rolled an even number. What participants didn't know is that the die was rigged so that all participants rolled an even number and won $1 ($20). Forecasters predicted how happy they would be about winning $1 ($20) if they rolled an even number. They then rolled an even number and received 1$ ($20). Experiencers rolled an even number, received $1 ($20), and were asked to indicate how happy they were after learning the outcome. Consistent with our proposition, forecasters predicted that they would feel happier about winning $20 than $1, but experiencers showed no difference in happiness about winning $1 or $20. Interestingly, forecasters underpredicted the happiness of winning

$1. A follow up study showed that this underprediction also occured for losses of $1.

Study 2 examined if forecasters overestimate the impact of outcome probability on their experienced affect. Participants of a 2 x 2 between subject design played a game in which they could pick a ball from a bag containing 10 balls and win $1 if the ball had a check mark on it. A "draw string bag" was used, making the content of the bag invisible to the participants. In the low (high)-probability condition, participants were told that one (nine) ball(s) had a check mark on it. Unbeknownst to the participants, all 10 balls were winning balls. Forecasters predicted how happy they would be about winning $1 if they drew a winning ball, then drew a winning ball and received $1. Experiencers drew a winning ball, received $1, and were asked to indicate how happy they were after learning the outcome. Forecasters predicted that they would feel happier about winning $1 if their chance of winning was 10% rather than 90%, whereas the experiencers felt equally happy, independent of their chance of winning. Forecasters underestiamteted their happiness about winning $1 with a 90% chance but accurately predicted their happiness about winning with 10% chace. A follow up study showed that this pattern replicated for non-monetary outcomes, such as chocolates.

Study 3 extended the findings of Study 2 to different probability and magnitude specifications. Participants of a 2 x 2 between subject-design played a game in which they could pick one of 10 identical envelopes and win $3 if they drew an envelope containing a winning slip. In the low (high)-probability condition participants were told that two (eight) envelopes contained a winning slip. In reality 5 of the envelopes contained a winning slip of paper and 50% of the participants won $3 (won $0). Forecasters predicted how happy they would be about winning or not winning $3, then drew a winning (losing) envelope and received $3 ($0). Experiencers drew a winning (losing) envelope, received $3 ($0), and were asked to indicate how happy they were after learning the outcome. Forecasters predicted that they would feel happier (unhappier) about winning (not winning) $3 if their chance of winning (not winning) was 20% rather than 90%, whereas the experiencers felt equally happy about winning (not winning), independent of their chance of winning (not winning). Forecasters underpredicted their happiness of winning $3 with a high probability and overpredicted their unhappiness of not winning $3 with a low probability. Process evidence suggests that forecasters are more sensitive to magnitude specifications.

The present research contributes to the existing literature on predicted utility by showing that forecasters are naturally more sensitive to quantitative outcome characteristics than experiencers. Furthermore this research reveals that participants overestimate the impact of outcome magnitude and outcome probability on experienced affect. As a result they exhibit a reversed impact bias whereby they underpredict the affective reactions towards certain outcomes.

Practice What You Preach?

Sunaina Chugani, University of Texas at Austin, USA
Susan Broniarczyk, University of Texas at Austin, USA

EXTENDED ABSTRACT

We take the intriguing position that there is an inherent mechanism built into giving goal-related advice that leads advisors to be less likely to practice what they preach. We posit that when giving advice to pursue (disengage from) a goal, the advisor's expectation that the advice will be acted on allows him to vicariously experience goal progress (regression) through the expected advice-congruent behavior of the recipient. Via goal balancing, this progress (regression) leads the advisor to subsequently disengage from (engage in) the goal (Fishbach and Dhar, 2005) exhibiting advice-inconsistent behavior. When the expectation that advice will be acted on is eliminated (thus taking away the unique vicarious nature of advice-giving), mechanisms such as the desire for consistency, self perception, and goal priming will lead advisors to engage in advice-consistent behavior. Three studies explore these predictions.

Participants in Study 1 advised a friend to either stick to a healthy eating goal or indulge for a special occasion. Advice given was manipulated between subject: to induce participants to give pursue (disengage from) goal advice, scientific evidence was presented stating that individuals should never indulge (indulge occasionally) to increase goal achievement likelihood. After giving advice, participants indicated their preference on an 8-point scale between an unhealthy (1) and healthy snack (8), presented as being a token of thanks while actually serving as a measure of goal-related behavior. As hypothesized, participants who gave advice to stick to the healthy goal preferred the healthy snack less (M=3.6) than those who gave disengage advice (M=4.7, F(1,37)=5.15, p<0.05).

Using an academic goal context, Study 2 explored whether giving advice to pursue a goal leads an advisor to experience heightened goal progress. Participants in a goal-related advice condition gave advice to a friend to study for an exam (pursue academic goal) rather than attend a party in neighboring city. This condition was compared to two controls, one in which participants read about their friend's academic goal-related behavior (read about goal pursuit condition; designed to rule out the possibility that progress results from simple goal activation), and the other in which participants gave advice about what microwave to buy (non-goal advice condition; designed to rule out possibility that progress results from giving advice in any domain, regardless of goal-relevance). After completing one of these conditions and in an ostensibly unrelated task, participants reported what percent of the past twenty-four hours they spent pursuing their own academic goal, which served as a measure of perceived academic goal progress.

Results indicate that individuals in the goal-related advice condition reported an inflated sense of academic goal progress (M=62.67, SD=26.71) relative to the two control conditions together (M=47.42, SD=28.76; F(1,82)=5.84, p<.05), the read about goal pursuit condition alone (M=46.29, SD=28.58, F(1,82)=5.33, p<.05), and the non-goal advice condition alone (M=48.75, SD=29.53, F(1,82)=3.88, p=.05). Thus, participants who gave advice to a friend to pursue the academic goal exhibited more goal progress than individuals who gave non-goal advice and those who simply read about goal pursuit, lending support to our position that advisors experience vicarious goal progress when giving advice to pursue a goal.

Study 3 observed post-advice behavior after turning on and off the vicarious goal progress/regression mechanism by manipulating whether advisors perceived that recipients acted on their advice. This design allowed us to explore the mechanism of vicarious goal progress/regression directly. This study also explored the moderator of goal strength. An advisor will be more attuned to the discrepancy between the current and desired end-state with a goal he is concerned with and invested in (Förster, Liberman, & Friedman, 2007). Therefore, we make the counterintuitive prediction that individuals with high (vs. low) goal strength will be more likely to behave in an advice-inconsistent manner.

First, participants gave advice to a friend about whether to study for an exam (pursue academic goal) or attend a party in a neighboring city over the weekend (disengage from academic goal). Advice given was manipulated between-subject: to induce participants to give pursue (disengage) advice, the test was framed as important (unimportant) and the party as unimportant (important).

After writing down their advice, participants were asked to imagine they called their friend over the weekend to find the friend either acting on given advice or not acting on advice given due to external circumstances. Participants then completed an ostensibly unrelated task where they indicated their preference between watching one of two videos on an 8-point scale: one unrelated to the goal (1 = clips from funny TV shows) and one congruent with the academic goal (8 = how to retain more from studying). Participants watched the videos and answered video questions to complete the cover story. Finally, participants reported the extent to which doing well in school was a priority for them, which served as a measure of academic goal strength.

There was a three-way interaction between advice given, advice acted on, and goal strength on preference between the videos (F(1,83)=3.83, p=0.05). Spotlight analysis (Irwin & McClelland, 2001) indicated that the interaction between advice given and advice acted on was absent among participants with low academic goal strength (F(1,83)=0.09, NS) and present among participants with high academic goal strength (F(1,83)=10.06, p<0.01). Among those with high goal strength who learned that their advice had been acted on, those who gave advice to pursue the goal were subsequently less likely to prefer the goal-related video than those who gave advice to disengage (F(1,83)=3.58, p=0.06) replicating the pattern of advice-inconsistent behavior from Study 1. Conversely, those who learned their advice had not been acted on behaved in a pattern of advice-consistent behavior: giving advice to pursue the goal led to a higher preference for the goal-related video than giving advice to disengage (F(1,83)=7.14, p<0.01).

In sum, this research sheds light on the nascent area of feedback effects of advice-giving on advisors. Three studies provide evidence across two goal domains for the position that advisors experience goal progress/regression when giving goal-related advice to others, leading to advice-inconsistent behavior.

The Big Cost of Small Problems:
Ironic Effects of Malfunction Severity on Consumption Experience

Neil Brigden, University of Alberta, Canada
Gerald Haeubl, University of Alberta, Canada

EXTENDED ABSTRACT

When a product ceases to function properly, the consumer must either take action to remedy the problem or endure the reduced functionality. Naturally, more severe product malfunctions have a greater negative effect on consumption experiences. However, consumers are more motivated to address malfunctions of greater magnitude. This creates the paradox that less severe product malfunctions can result in less favorable consumption experiences than more severe ones because smaller problems are allowed to persist longer. In a series of experiments in which participants faced repair decisions during consumption experiences, we demonstrate this big-cost-of-small-problems effect and examine the underlying mechanism.

We demonstrate that it is indeed possible for minor problems to ironically be more harmful than major ones, even when the cost of repairing the problem is taken into account. We explain this effect by showing that consumers fail to immediately address minor problems because the experienced discomfort fails to reach some threshold that would trigger a response. This effect parallels findings in social psychology where more minor insults have been shown to cause greater distress because they are too small to trigger psychological defenses (Gilbert et al. 2004). Further, we argue that once the decision to not fix the problem is made in the current period, it becomes less likely to be revisited in future periods due to inaction inertia.

Inaction inertia refers to the decreased likelihood of taking an attractive course of action when a similar and superior course of action has been previously foregone (Tykocinski & Pittman 1998; Tykocinski, Pittman & Tuttle 1995). Regardless of what underlies the initial decision to not repair a product, continuing to not repair in subsequent periods, even though the repair continues to be normatively optimal, can be explained by inaction inertia. If a product is worth repairing in a later period, then logically it would have been even better to have repaired the product in an earlier period. An earlier repair would increase the benefit derived as more usage time or usage occasions would still be in the future and thus subject to the improved performance that the repair brings. Thus the initial decision to not repair can be thought of as a missed opportunity, and subsequent opportunities to repair, although potentially still beneficial, will be comparatively inferior.

To test these hypotheses, we conducted a series of experiments where participants were confronted with relatively smaller or larger product malfunctions, made decisions regarding fixing the malfunction, and then reported their enjoyment of the experience. Our evidence shows that smaller malfunctions can indeed lead to inferior consumer outcomes because consumers are less likely to address them.

In experiment 1, participants watched a 10-minute video clip while bursts of audio static (the malfunction) interfered with the consumption experience. The audio static was more frequent in the larger problem condition than in the smaller problem condition. Participants could get rid of the static at any time by pressing a button, but the cost of fixing the problem was that they would hear no audio at all for 1 minute. Participants in the smaller problem condition, despite facing an objectively superior experience reported lower enjoyment (M=6.72) than participants in the larger problem condition (M=7.98), t(82)=2.40, p<.05. This difference was driven by the fact that fewer participants in the smaller malfunction condition chose to fix the problem (65% vs. 88%, Fischer's Exact test, p<.05).

In experiments 2a and 2b, we compared situations where participants could fix a problem at any time versus situations where participants had to decide prior to consumption whether to fix the problem. In these experiments, participants played a computer game and the malfunction was in the form of random moves that interfered with the participants' ability to control the game. When participants could fix the problem at any time, the big-cost-of-small-problems effect was replicated. Participants in the smaller malfunction condition reported less enjoyment (M=5.10) than those in the larger malfunction condition (M=6.53; t(58)=2.08, p<.05). Again, participants who experienced a smaller malfunction were less likely to fix it compared to those who experienced a larger malfunction (63% vs. 89%, Fischer's Exact test, p<.05). By contrast, when participants had to decide prior to the consumption experience whether to fix the problem, no big-cost-of-small-problems effect occurred. Enjoyment did not differ between the smaller malfunction condition (M=5.6) and the larger malfunction condition (M=5.7, t(60)=0.16, p>.8). Fixing rates also did not differ (68% vs. 78%, Fischer's Exact test, p>.1). These results support the hypothesis that consumers can become trapped with smaller problems because they initially put up with them, and then subsequently devalue fixing opportunities because they are inferior to prior fixing opportunities. These results are incompatible with a pure intertemporal-discounting account of the big-cost-of-small-problems effect. Forcing the decision to occur prior to the experience should not eliminate the effect if it was arising merely because of discounting.

In experiment 3, we assigned participants to either experience or forecast enjoyment as if they had chosen to fix or not fix a smaller or larger malfunction using the same game experience as in experiments 2a and 2b. We hypothesized that, if the effect was not due to an affective forecasting error, we should not observe any interactions between experiencing versus forecasting and problem magnitude. As predicted, although forecasts were overly optimistic, they did not differ between problem magnitudes. In addition, the experiencer data provides additional evidence that not fixing the smaller problem in this experience is a non-normative action.

These studies demonstrate that problem magnitude has a dual effect on consumption experience. More severe malfunctions directly reduce consumption enjoyment to a greater degree, but they also indirectly *increase* consumption enjoyment by making it more likely that consumers will address the malfunction. The findings suggest that consumers and marketers might be paying too little attention to minor product malfunctions, allowing them to persist, and suffering disproportionately from them as a result.

The Effect of Positioning of a Target Brand and a Competitive Brand(s) in an Advertisement on a Consumer's Judgment and on the Selection of the Target Brand

Jungsil Choi, University of Kansas, USA
Myer Duane, University of Kansas, USA

EXTENDED ABSTRACT

This paper examines the effect of the positioning of in relation to a comparison brand or brands in a multi-panel table of a comparative advertisement. At issue is the effectiveness of the advertisement as measured by the consumers' product selection.

The use of a comparison table in the comparative advertisements is effective because audiences get comparable information for each product attribute listed in the table. Consumers tend to compare an object in the right panel with the object in the left panel because they have a tendency to read from left to right. This is especially true for English readers (Eviatar, 1995). Prior studies have shown in a sequential observation of two objects, the later serves as the subject of comparison and the object observed earlier serves as the referent (Bruine and Keren, 2003; Sanbonmatsu, Kardes, and Gibson, 1991; Houston and Sherman, 1995). Therefore, the object placed in the left panel is expected to serve as a referent of comparison and the object placed in the right panel a subject of comparison. When a sponsor's product is positioned in the left panel and a comparison product is positioned in the right panel, the reader is exposed to the superior features of the sponsor's product first, followed by the inferior features of the comparison product. An advertisement arranged such that the sponsor's product is placed in the left panel and the comparison product in the right panel of the comparison table, therefore, would evoke more negative thoughts on a comparison product in the right panel than positive thoughts on a sponsor's product in the left panel.

On the other hand, if the physical positioning of a comparison product and a referent product is reversed, the opposite result is hypothesized. The comparison product, when positioned in the left-hand panel, becomes the referent product with which people compare the features of the product in the right-hand panel. Such an arrangement of a target and a comparison product in a comparison table, therefore, might lead people to have more positive thoughts on a sponsor's product in the right-hand panel than negative thoughts on a comparison product in the left-hand panel.

Jain and Posavac (2004) show that a negative comparative advertisement results in unfavorable attitudes toward an advertised product than a positive comparative advertisement because people are more skeptical of negative comparative messages and tend to judge positive comparative messages to be more believable.

Based on the reading habit from left to right, the comparative advertisement should be perceived as more positive when the sponsor's product is placed in the right-hand panel because it will be perceived as a positive comparative advertisement. In addition, people will perceive higher value and quality when a sponsor's product is placed in the right-hand panel because of the preference for "right" (Valenzuela and Raghubir 2009). Thus, it is hypothesized that physical positioning of the sponsor's product and a comparison product in a comparison table will affect the effectiveness of a comparative advertisement. Specifically, a higher value will be ascribed to the sponsor's product when it is placed in the right-hand panel in a comparison table, and the comparative advertisement and the sponsor's product will be viewed more favorably when the sponsor's product is placed in the right panel and a comparison product is in the left panel.

In Study 1, a different perceived value for the target brand was found depending on its position in the left panel versus the right panel in the comparison table. We found when a target brand was positioned in the right panel as opposed to the left panel the respondents perceived a greater value from the target brand (t (75) = 3.22, $p < .01$). Respondents were found to have a favorable attitude toward a target brand when it was positioned in the right panel as opposed to the left panel (t (75) = 2.06, $p < .05$); however, the positioning of a target brand in the right panel as opposed to the left panel in the comparison table did not result in a significant difference in willingness to buy (t (75) =.41, $p > .68$).

In Study 2 the effects of physical positioning in a one-to-one comparison table were extended to those in a one-to-three comparison table, which is also a very common type of a comparative advertisement. A significant difference in attitudes and the purchase likelihood in terms of physical positioning of a target brand was found. When the target brand is placed in the far right panel as opposed to the far left panel, a significant difference was found in the attitude toward the target brand in terms of its position in the table in the comparison advertisement (F (28) = 11.66; $p < .01$); however, a marginal difference was found in the purchase likelihood in terms of the position of the target brand in the table of the comparison advertisement (F (1, 28) = 3.247; $p < .08$).

In Study 3 it was confirmed that physical positioning affects perception of the valence of comparison advertisements. Planned contrasts show the combination of "right-positioning" + a positive advertisement copy is evaluated as more amicable than the combination of "left-positioning" + a positive advertisement copy (t (106) = 2.11; $p < .04$), the combination of "left-positioning" + a negative advertisement copy (t (106) = 2.12; $p < .04$), and the combination of "right-positioning" + a negative advertisement copy (t (106) = 2.24; $p < .03$). The results confirmed the hypothesis that the combination of "right-positioning" and a positive advertisement copy was considered the most amicable, as it corresponded to a positive comparative advertisement. The similar results were found from attitudes toward the target brand and the purchase likelihood.

These findings have obvious practical implications. Marketing managers and advertisers have not had similar studies concerning the effect of physical positioning of a target and a comparison brand in a table in a comparison advertisement. This paper shows how this minor change results in significant differences in the effectiveness of comparative advertisements.

The Effects of Mindset Abstraction on Memory-Based Consideration Set Formation

Fang-Chi Lu, University of Iowa, USA
Dhananjay Nayakankuppam, University of Iowa, USA

EXTENDED ABSTRACT

"*Memory-based consideration set*" is suggested to be a set of products consumers recall from memory when facing needs to be fulfilled, and then they make their final choice from this set (Ratneshwar and Shocker, 1991). Consideration set formation is considered as a fundamental stage of pre-choice decision making. Consumers usually engage in a two-stage decision process, screening available brands/products in a product category to form a smaller subset of brands and then making an explicit utility comparison or cost-benefit trade-off before making their final choice decision. Understanding the formation of consideration sets is important from both theoretical and practical perspectives. Consideration of a brand is suggested to mediate the influence of attitude and attitude strength on choice (Priester et al., 2004). Using the scanner data, Hauser and Wernerfelt (1989) found that 70% of the variance accounted for in choice is explained by consideration.

However, consideration sets are dynamic, being influenced by a variety of factors. First, the composition of consideration sets is influenced by personal goals and motives. Ratneshwar and his colleagues (1996) found that across-category consideration was high when there was either goal conflict or goal ambiguity. Chakravarti and Janiszewski (2003) suggested that motivations, to simplify the choice process or to optimize the choice outcome, determine the size and heterogeneity of consideration sets. Second, attitude and attitude strength influence whether a brand is included in a consideration set (Priester et al., 2004). Finally, situational variables, such as usage situation (e.g., Desai and Hoyer, 2000), assortment size (e.g., Heller, Levin, and Goransson, 2002), and advertising (e.g., Mitra and Lynch, 1995) were also suggested to influence the content of consideration sets. In the same vein, the model of constructed choice processes asserts that preferences are construed during the choice process, and subjective construal, experiential information, attribution, goals and satisfaction influence the choice process in a lower-level perceptual, non-conscious way (Griffin, Liu, & Khan, 2004). Taken together, it is implied that influencing the way consumers construe their choice decisions might alter the nature of a consideration set.

More recently, the construal level theory, proposed by Liberman and Trope (2007), suggests that psychological distance of an object systematically changes how the object is mentally construed, which in turn influences people's thoughts and behaviors. According to the theory, low-level construals are concrete, relatively unstructured, contextualized representations that include subordinate and incidental features or event; whereas high-level construals are abstract schematic, decontextualized representations that extract the gist from the available information. Previous research showed that individuals in concrete mindsets are more susceptible to incidental social influence, and have more flexible attitude toward a certain evaluative object (Ledgerwood, Trope, and Chaiken, 2010).

Building upon the construal level theory, we propose that construal levels used for the mental representation of a choice decision influence the search of alternatives in memory and the composition of the formed consideration set. More specifically, we suggest that individuals in concrete mindsets, compared to abstract mindset, are likely to think more concrete, specific details about certain choice decision contexts, and the concrete, fine-grained mental representations activate more associations in memory, thus leading to bigger consideration sets.

Findings from two studies, using alternative manipulations of mindset abstraction and different decision contexts, provided support for our main hypothesis that concrete mindsets induce bigger consideration sets. In Study 1, abstract versus concrete mindset was primed by asking participants to generate either superordinate categories or subordinate exemplars for 20 objects (e.g., actor, book, movie). Next, participants completed a snack product choice task in which a certain snack choice scenario was given, and participants listed the snack items they seriously consider, their final choice and the factors/attributes they used in forming their consideration sets. Extent of hunger was also measured as a covariant. Results of analyses showed that participants who generated subordinate exemplars had bigger consideration set than the ones generating superordinate categories ($M_{concrete}$=7.92, $M_{abstract}$=5.44, $p<0.01$). The procedure of Study 2 is similar to Study 1 except for that the Navon task was used for mindset abstraction priming. Participants were presented with a series of global letters made up of local letters, and they were asked to identify either the global or the local letters. After that, they formed consideration set in a dinner decision context. Consistent with Study 1, participants who identified the local letters generated larger consideration sets than the ones who identified the global letters ($M_{concrete}$=6.96, $M_{abstract}$=5, $p<0.03$).

We propose that this mindset abstraction effect on size of consideration sets is due to the differential extent of associations activated in memory in concrete versus abstract mindsets. We conducted Study 3 to examine this hypothesis. The Navon task was used prime abstract versus concrete mindsets. After the Navon task, participants completed a word association task in which they listed as many associated words as they can for each of the target words presented. The selected target words, varying in the frequency of word occurrence and the size of their association set size, were adopted from previous research (Meyers-Levy, 1989). Findings of Study 3, supporting our hypothesis of the underlying mechanism, revealed a main effect of mindset abstraction. Individuals in concrete mindsets listed more word associations than the ones in concrete mindset, and the main effect was independent of word frequency and word association set size ($M_{concrete}$=9.05, $M_{abstract}$=6.97, $p<0.03$).

The current research shed light on a construal level effect on memory in consideration set formation domain. From a memory perspective, concrete, relative to abstract, mental representations result in many more memory cues. For example, Dural Coding Theory (Pavio, 1986) suggests that concrete words (e.g., tree, party) can be represented visually and verbally, thus have more associations and are better remembered. Going beyond that, we found that individuals' processing mindset (concrete vs. abstract) influence ease of retrieving alternatives from memory, thus affecting the likelihood of certain products being included in the consideration sets.

McHealthy: How Frequent Dining Programs Increase Healthy Eating Intentions

Elisa Chan, Cornell University, USA
Brian Wansink, Cornell University, USA

EXTENDED ABSTRACT

Fast food restaurants (e.g., McDonald's) are often criticized for cultivating unhealthy eating habits and contributing to obesity in our society (Brownell and Horgen 2003; Nestle 2003). Despite the effort of these restaurants to promote better eating by including more healthy items on the menu, the proportion of obese adults in the United States remains high (e.g. the national prevalence of obesity in adults was 33.8% in 2007-2008, Flegal et al 2010). This phenomenon is referred to as "the American obesity paradox" (Heini and Weinsier 1997) and may partly be explained by the 'health halo' effect which bias calorie estimates and lead to over-consumption (Chandon and Wansink 2007). Apparently, giving consumer more healthy food options does not necessarily translate to them eating more healthily. There is a need to identify ways to promote healthy eating which directly influence consumer's food consumption behavior.

We explore this question in the domain of fast food restaurants and promotional offers. We ask, for example, how having a promotional offer with a long (vs. short) time horizon influences one's healthy eating intention. Drawing on Chandon and colleagues (2000), we acknowledged that the nature of the product seemingly dictate the evaluative emphasis on its promotion. Consequently, we propose that because a long time horizon coincides with the long-term conception of healthy eating, an accumulative, long time horizon promotional offer such as points reward will be more effective in inducing healthy eating intention than an immediate, short time horizon price discount.

Deriving from the theory of goal (Fishbach, Friedman, and Kruglanski 2003), we further propose that this effect of offer will only be evident among individuals whose food consumption decision is dominated by its sensual appreciation (i.e. hedonist). Our reasoning is that hedonist are more likely to have constant struggles between taste and health goals, an accumulative offer (i.e. points reward) makes the health goal temporarily more salient and in turn increases healthy eating intention. Finally, we predict that patrons of a restaurant will be more likely to respond to an offer with long time horizon. They will find a delayed reward offer by a long term promotion more acceptable because of the perceived level of effort.

Results of study 1 supported our hypotheses. To examine the impacts of the independent variable (promotional offer: long time horizon vs. short time horizon) on intention to switch, participants were randomly assigned to either a points reward (i.e. long horizon) or price discount (i.e. short horizon) condition. Points reward and price discount were chosen because they are common. More importantly, they are on the extremes of the time horizon spectrum. On the one hand, point rewards require that people repeatedly make purchases over a period of time to obtain the designated reward which prompts a long term perspective. On the other hand, price discounts provide immediate reward for the purchase which triggers a short term perspective.

As predicted, the two-way interaction between promotional offer x hedonism is significant ($F(1,40) = 5.576$, $p = .02$). A simple main effect analysis revealed that for the high hedonism group, the intention to switch to salad is significant. Specifically, those in the points condition is more prone to make the switch to the healthier salad option than those in the price condition ($M_{points} = 6.08$ vs. $M_{price} = 4.49$, $F(1, 20) = 4.21$, $p = .05$). Moreover, the two-way interaction of promotional offer x patronage is significant ($F(1,40) = 4.554$, $p =.04$). In particular, patrons are found to be more likely to switch to salad than non-patrons in the points condition. The simple main effects of promotional offer on neither patron nor non-patron were significant (p's > .05).

In addition, we believe that two supporting studies in progress will corroborate the results of study 1 and our contention about the temporal orientation elicited by promotional offers and its effect on healthy food choices. First of all, a choice study asks participants to choose between a points reward vs. a price discount for the purchase of a salad. If our hypothesis holds, more people will prefer the points reward in support of our contention that because a healthy food triggers a long term perspective, the promotional offer with the corresponding temporal frame (i.e. points) will more likely be chosen. Secondly, a time frame study aims not only to replicate the results of study 1 but also to provide a temporal orientation measure. If our hypotheses hold, it will provide empirical evidence for our assertion that temporal orientation is the underlying process of the differential impact of the type of promotional offer.

The results of our study show that different types of offer have differential impacts on one's intention to choose a healthy food over an appetitive food. It extends the benefits congruency framework (Chandon, Wansink, and Laurent 2000) to a new dimension. We show that not only do benefits between product and promotion which are congruent in terms of utilitarian or hedonic aspects can improve a target choice; one which is temporally congruent has a similar impact. Our results also contribute to literature on loyalty programs. Extant loyalty programs literature identified effort required, rewards obtained, decisions to join, and likelihood of reaching the reward as the most important issues (Kivetz and Simonson 2003). The current study suggests that the characteristic of the product of which the loyalty program is associated with also play a role.

Interestingly, our results pertain to hedonist – the ones whose actions are often dictated by their sensualities. Moreover, results also reveal that patrons (i.e. existing customers) of a company tend to make the healthy food choice more often when they are given points rewards rather than price discounts. The current study renders a concrete solution to fast food restaurants for their most prominent clientele. Our typical fast food restaurants goers or patrons fit the profile of a hedonist (i.e. those who are more likely to yield to unhealthy yet tasty food). A long time horizon offer is shown to have an influence on healthy eating especially for this group of people. Concisely, we have identified a solution for the loyal-healthy dilemma.

When Creativity Meets Repetition: Frequency Effects Depend on Exposure Duration

Millie Elsen, Tilburg University, The Netherlands
Rik Pieters, Tilburg University, The Netherlands
Michel Wedel, University of Maryland, USA

EXTENDED ABSTRACT

In an increasingly cluttered environment, competition for consumers' limited attention is a key issue. Two strategies that are commonly used by advertisers to maximize attention to their ads are creativity and repetition. Whereas previous research suggests that creative advertising can postpone attention wear-out due to repetition (Pieters, Warlop, and Wedel 2002), it is less clear how combinations of creativity and repetition affect more downstream effects, such as ad and brand evaluation. This research tests the hypothesis that the influence of repetition on evaluations of standard (typical) and creative (atypical) ads critically depends on exposure *duration*. We compare brief and fixed (as when passing billboards by car), long and fixed (as in the case of cinema advertising), and self-paced exposures (as when paging through a magazine). Specifically, we predict that atypical ads do not wear-in at all when exposures are brief and fixed (hypothesis 1), and wear-out faster than typical ads when exposure duration is long and fixed (hypothesis 2), or self-paced (hypothesis 3).

The idea is that comprehension of atypical ads is characterized by a delayed-but-sudden "aha" experience (Topolinski and Reber 2010). For atypical ads to *wear-in*, these ads require at least one exposure that is long enough for this "aha" experience to occur. At such longer exposures, however, processing of atypical ads will lead to more distinctive memory traces and active recognition, and exactly this may accelerate their attitude *wear-out*. We predict the effect of repetition to be critically dependent on the exposure duration, as follows.

When exposures are <u>brief and fixed</u>, atypical ads are liked less than typical ads, because a single glance is insufficient to comprehend them, and this uncertainty is disliked. Subsequent brief exposures do not "add up" to comprehension, hence the negative ad evaluation will not be positively updated. Typical ads, in contrast, which are almost instantly understood ("Ha, it is a car ad"), are immediately evaluated positively. This identification certainty is re-experienced during subsequent brief exposures, which delays wear-out.

When exposures are <u>long and fixed</u>, atypical ads will wear-out faster than typical ads. Because they are unique, atypical ads will leave stronger and more distinctive memory traces, and exactly this may accelerate evaluation wear-out. Upon repeated exposure, atypical ads are more actively recognized as being seen before. This improved memory of atypical ads depresses attitudes, once the novelty of their initial exposure wanes ("Oh, it is that ad again"). In contrast, due to their similarity to other ads in the category, typical ads leave less distinctive memory traces, and generate feelings of familiarity even if they are new. Repeated exposure to typical ads further raises familiarity, and attitudes wear-out less quickly as a result.

When exposure is <u>self-paced</u>, atypical ads should wear-out even more rapidly. Precisely because atypical ads continue to draw attention where other ads wear out, they may be even more readily recognized upon repeated exposure, and evaluations drop even faster. Thus, ironically, the attention-getting qualities of atypical ads may accelerate evaluation wear-out even more.

Three experiments tested these predictions. Experiment 1 tested the idea that many brief exposures to atypical ads are not equivalent to one long exposure. Typical and atypical ads were shown at various exposure durations (from 100 msec to 8 sec) and frequencies (from 1 to 10). As predicted, for atypical ads, comprehension ratings and ad evaluations were very different after many brief exposures as compared to one long exposure, while the differences were much smaller for typical ads. Indeed, many brief exposures to atypical ads did not "add up" to comprehension.

Experiment 2 tested hypothesis 1 and 2. In this experiment, participants evaluated typical and atypical ads that they had seen either zero, one, three or six times in a previous part of the experiment, as well as distracters (which were slightly changed versions of the target ads). Ads were exposed for either 100 msec (brief and fixed) or 10 seconds (long and fixed). As predicted, when exposure duration was brief and fixed, typical ads were immediately evaluated more positively than atypical ads, and additional glances did not improve evaluations of atypical ads, nor deteriorate evaluations of typical ads. Evaluations were driven by differences in comprehension levels between typical and atypical ads, that sustained across the repeated brief exposures. When exposures were long and fixed, atypical ads wore out faster than typical ads, which was predicted to be the result of different bases for recognition (i.e., recollection *vs.* familiarity; Yonelinas 2002). As predicted, participants were well able to discriminate atypical ads from other ads, suggesting that processing of these ads led to distinctive memory traces and active recognition upon repeated exposure. In contrast, false recognition was higher at all frequency levels for typical ads, and this low ability to discriminate suggests that recognition was based on feelings of familiarity, as predicted.

Finally, experiment 3 tested and supported hypothesis 3, that atypical ads also rapidly wear-out under self-paced exposure conditions. However, the accelerated evaluation wear-out of atypical ads was not due to increased attention. Although atypical ads retained attention longer than typical ads at first exposure, subsequently attention quickly dropped, to equal attention levels of typical ads. Rather, atypical ads were more actively recognized than typical ads, as reflected in lower false recognition for these ads at all frequency levels.

Together, the results show that repetition effects crucially depend on the exposure duration. Our predictions and findings are different from two-factor (Berlyne 1970) and related theories, which would predict the opposite, namely that atypical (complex) ads wear-out more slowly than typical (simple) ads, due to positive habituation and later set-in of tedium. Although either one may have positive effects, our results show that combining high creativity and high repetition is less effective. They show that, ironically, exactly because atypical ads attain better memory, the attitudes towards them and their brands wear-out more quickly. On the other hand, typical ads fly under the radar of active recognition, and retain their positive attitudes under repeated exposures as a result. Thus, the "boring" ads appear not so boring after all.

Only a Diamond Can Cut a Diamond: The Regulation of Emotions via System Fit.

Daniel Fernandes, Rotterdam School of Management, Erasmus University, The Netherlands
Lawrence Williams, University of Colorado, USA
Christina Kan, University of Colorado at Boulder, USA

EXTENDED ABSTRACT

Negative emotional states can promote a tendency to indulge as an emotion regulation strategy (Macht 1999; Macht, Haupt, and Ellgring 2005). Emotional eating has been regarded as a way to improve negative mood (Thayer 1989, 2001), to mask stress (Polivy and Herman 1999), or to escape from aversive self-awareness (Heatherton and Baumeister 1991). Food brings comfort in the short-term and, therefore, consumers turn to snacks to heal emotional distress (Kaplan and Kaplan 1957).

Two potential mechanisms through which emotions influence indulgent eating have been identified in the literature (see Macht 2008, for a review). On one hand, negative emotions may prompt a deliberate attempt to regulate emotions, leading people to both increase the amount and decrease the quality of food intake (Booth 1994; Kaplan and Kaplan 1957). In this case, the motivational properties of negative emotions may elicit the tendency to emotion regulate by eating sweet and fatty foods (Macht, Haupt, and Ellgring 2005). This suggests that the deliberative effect of negative emotions on behavior occurs via system 2. On the other hand, negative (and sometimes also positive) emotions may enhance the amount and decrease the quality of food intake due to impairment of cognitive control (Boon et al. 2010; Herman and Polivy 1984). According to this hypothesis, intense emotional experiences are cognitively taxing (Heatherton, Striepe and Wittenberg 1998), and can result in an impairment in one's capacity to make healthy food choices. In these cases, the effect of negative emotions on behavior occurs via system 1.

Specific emotions may influence the consumption of unhealthy food by one of these processes. The process behind the effect of sadness on indulgence is posited to be deliberate and conscious (Tice, Bratlavsky and Baumeister 2001). In an attempt to regulate emotions, consumers shift priorities from longer-term goals to shorter-term ones, placing greater value on choices that offer immediate gratification. In contrast to sadness, anxiety may lead to unhealthy food choices as the result of a more automatic process. Elevated levels of arousal can increase cognitive load, interfering with regulatory processes and decreasing resistance to temptation (Fedorikhin and Patrick 2010). Therefore, the elevated level of arousal that typically accompanies anxiety may cause an interference effect, decreasing the cognitive resources available for self-regulation and, consequently, leading people to give in to temptations. This suggestion is consistent with previous research showing that cognitive resources are a necessary requirement for the functioning of self-regulatory processes and that depletion of these resources can lead to decrements in self-regulation and decision-making (Baumeister, Bratlavsky, Muraven, and Tice 1998; Shiv and Fedorihkin 1999). This is also supported by research in emotional eating, which suggests that mental distraction and depletion can interfere with a dieter's resistance to temptation (Herman and Polivy 1993).

In summary, while sadness and anxiety may both enhance the desirability of high fat and carbohydrate 'comfort foods' (Wansink, Cheney, and Chan, 2003), they may do so via distinct processes. While the effect of sadness is routed by System 2 processing, the effect of anxiety is routed by System 1 processing. Accordingly, when trying to aid people with emotional control and reduce their reliance on indulgence as a coping strategy, we predict that the system-level fit between the emotional process and the regulatory strategy will facilitate effective emotion regulation.

Moreover, given that people develop emotion regulation strategies throughout their lives, we predict that age would moderate these effects in the sense that emotional regulation yields an adaptive and constructive learning process. The 'cope by indulgence' emotion regulation strategy should be most pronounced for individuals who do not habitually use reappraisal strategies. One individual difference that predicts the spontaneous use of reappraisal is age; the maturational changes that accompany age are likely to give individuals more perspective on emotional experiences, suggesting that older individuals are more likely to use reappraisal strategies (John and Gross 2004).

Following this reasoning, in the first study, we find that sadness and anxiety increase the selection of unhealthy and indulgent options only among younger participants. Older participants were able to control their reactivity to the sadness and the anxiety manipulations and, therefore, did not enhance the consumption of unhealthy options relative to the healthy ones. In a follow up study, we confirm that older participants are better at regulating their emotions. In subsequent studies, we examine how sadness and anxiety respond to different regulatory strategies. We show that emotion regulation strategies are more effective when they fit with the route of the effects being regulated. Specifically, the effect of sadness is most strongly regulated by explicit emotion regulation goals, while the effect of anxiety is most strongly regulated by implicit emotion regulation goals.

This paper shows that, although sadness and anxiety lead to the same behavioral outcome, that is, unhealthy food choices, interventions designed to mitigate these negative effects can capitalize on the fact that these emotions affect choice via distinct processes (System 2 vs. System 1). A conscious reappraisal goal better regulates the effects of sadness on choice. Conversely, a nonconsciously operating reappraisal goal better regulates the effects of anxiety on choice. Successful emotional control can be attained through implicit and explicit mechanisms that tap into the effects of specific emotions on behavior. This research sheds light on the breadth of the human repertoire of emotion regulation capacities and the extent to which nonconscious processes exert influence on choice.

Maximizing the Effectiveness of Disaster Relief Contribution: The Idea of Fit to Control

Yoshiko DeMotta, Baruch College, USA
Diogo Hildebrand, CUNY Graduate Center, Baruch College, USA
Ana Valenzuela, Baruch College, USA
Sankar Sen, Baruch College, USA

EXTENDED ABSTRACT

Corporations are often willing to help when a major disaster happens. The goals of corporate contributions are to maximize the benefits to the disaster victims and earn a return in terms of consumer attitudes and corporate image (Porter and Kramer 2006). In corporate social responsibility (CSR) programs, consumers perceive a firm's nonmonetary contributions such as goods, services, and employee volunteerism to help communities to be more effortful and evaluate such contributions more positively than their monetary counterparts (Ellen, Webb and Mohr 2000). Due to drawbacks pertaining to nonmonetary contributions, including implementation difficulty and firms' limited capability of providing goods and services, however, firms often decide to donate money to help communities.

Against prior belief, we demonstrate that monetary contributions will generate more positive consumer evaluations of corporate contributions depending on the cause of the disaster. While all disasters negatively affect society, some disasters are perceived as inevitable tragedies of nature (nature-made disasters), while others are perceived as being caused by human practices (human-made disasters). Nature-made hazards include earthquakes, floods, and naturally occurring wildfires, while human-made hazards include terrorist attacks, riots, and arson. In general, nature-made disasters are considered to be less controllable or preventable by their victims and affected communities than human-made ones (Quarantelli 1993). We propose that the controllability perception of the disaster will have differential effects on consumers' emotions and subsequent evaluations of corporate disaster relief effort. Specifically, a seemingly uncontrollable disaster will elicit higher sympathy, and consumers will perceive a firm's effortful, nonmonetary help to be appropriate. On the contrary, a more controllable disaster will elicit lesser degrees of sympathy, and consumers will process the disaster more deliberatively and will desire more utilitarian, monetary help.

We expect that this effect is moderated by desirability of control (DC), a personality disposition that reflects the degree to which people are motivated to control the environment (Burger and Cooper 1979). Although to have control over outcomes appears to be a basic human need (Deci and Ryan 1985), people vary with respect to the strength of this need. Some people are committed to being in charge and determining the outcome of every situation in life, while others have a weaker urge to control their environment (Burger and Cooper 1979). High DC consumers will be motivated to analyze the causal controllability of a disaster and consequently have higher cognitive and affective responses to it. Accordingly, high DC consumers will have stronger emotional responses toward the disaster victims, which will hypothetically affect their fit perception and company evaluations. In other words, they will form a positive attitude toward a firm's effort when the firm appears to take control over the situation by providing resources that match the needs of the victims and affected communities—a condition we label as *fit perception*. On the contrary, low DC consumers are hardly motivated to achieve control over their environment (Burger and Cooper 1979), and thus may not exhibit differential emotions toward victims of the two disasters, nor be particular about how a firm's effort matches the specific needs of the victims.

Hypothesis 1a	*Consumers with high desirability of control will evaluate a firm's monetary contribution to a man-made disaster relief effort more positively than its nonmonetary contribution to such disaster.*
Hypothesis 1b	*Consumers with high desirability of control will evaluate a firm's nonmonetary contribution to a nature-made disaster relief effort more positively than its monetary contribution to such disaster.*
Hypothesis 1c	*Regardless of disaster characteristics, consumers with low desirability of control will equally evaluate a firm's monetary contribution and nonmonetary contribution.*
Hypothesis 2	*Perception of fit will mediate the effect of contribution type and disaster characteristic on company evaluations.*

Three experiments examined our prediction. As expected, the first two studies found that participants evaluated a firm's contribution of money to a human-made disaster more positively than its contribution of service, whereas they evaluated a firm's contribution of service to a nature-made disaster more positively than its monetary contribution. This effect was found only for high DC participants. In addition, the same effect was mediated by greater fit perception between the contribution type and the disaster characteristic. The third study found further support for the role of controllability of a disaster, demonstrating that when a disaster was described as being uncontrollable (controllable), participants evaluated a firm's contribution of services (money) more positively than its contribution of money (services).

Our research aims to provide a better understanding of the process underlying consumer evaluations of a firm's disaster relief effort. Research has shown that in order to optimize the effectiveness of CSR programs, a clear fit between a firm's business and the cause it embraces is crucial (Lafferty, Goldsmith, and Hult 2004; Pracejus and Olsen 2004). Our study contributes to the literature by introducing a new dimension of fit, which may be particularly useful to better understand the effects of CSR programs toward non-recurring causes such as disaster relief effort. Another contribution of our research is in its practical implications. Substantial numbers of firms of all sizes around the world frequently respond to help victims and communities affected by disasters such as the earthquake in Haiti and 9/11 terrorist attacks. However, the effects of such corporate philanthropy are largely unknown. We provide an initial suggestion that corporate contribution can be perceived more favorably when the fit between the controllability of disaster and contribution type is maximized.

Where There is Smoke, There is Fire:
Adolescent Smoking as a Costly Signal of Dispositional Health

Siegfried Dewitte, K.U.Leuven, Belgium

EXTENDED ABSTRACT

After a sharp decline between the sixties and the eighties, adolescent smoking appears to oscillate around a stable percentage of about 20% in 15 year olds. This is the case, despite the anti-smoking campaigns of the last decades. In this paper, I point at a possible reason for this failure to discourage smoking further. I claim that adolescent smoking may serve as a costly signal of dispositional health, towards potential mates. As dispositional health is a highly attractive feature for potential mates, adolescents with good health are very motivated to signal their health (Buss 1989). Costly signaling theory states that agents endowed with a certain (unobserved) quality can inform others about this quality by displaying behavior that entails a cost that is directly related to the quality (e.g. Zahavi and Zahavi 1997). This means that the cost is quality-dependent, reflecting the fact that although the signal is costly to all individuals, it is relatively less costly to those with the quality than to those without the quality. In this circumstances, those devoid of the quality are better off refraining from displaying such behavior because the cost are disproportionably high to them. This differential cost structure renders the signal trustworthy to the audience. The audience knows that only those with the quality can afford the cost that follows from the signal, and hence, can safely infer from the signal that the agent must have the quality.

As society widely agrees on the health damage that smoking entails, smoking is a good candidate as a signal of dispositional health. Healthy adolescents can better afford the immediate physical costs that smoking entails than their less healthy peers. This claim implies three sets of testable predictions.

First, smoking behavior should be related to objective indices of dispositional health (although, obviously, simultaneously harming current health). In study 1, using a health survey methodology, I indeed found that smoking, although associated with short term health costs such as aches and complaints, was more likely in people with an average blood pressure, in people who need less sleep, and in taller people (all controlled for gender). These three are validated indices of long term physical health in the medical and biological literature, and they are relatively unaffected by current health stressors. Consistent with this hypothesis was the evidence that people with a low dispositional health suffered relatively more if they did smoke than people with a high dispositional health, further adding to the suggesting that smoking may serve as a costly signal of dispositional health.

Second, smoking should be perceived as associated with dispositional health, at least when no other indices of health are available. Indeed, a scenario study manipulating a target's smoking status, confirmed this prediction, but only succeed in providing evidence for the process of conveying information. If the information of the dispositional health was conveyed in other ways (by an active life style of the target person), smoking was not perceived as a signal of health (actually, it was associated with *lower* perceived health, which needs an explanation).

An third prediction bears directly on the impact of campaigns. Assuming that the belief that smoking is bad for one's health has not always been widely shared, the application of costly signaling theory to smoking implies that signals may vary due to the context. To test this, I exposed people either to an anti-smoking campaign or to an anti fat-food campaign. Then they saw a person description, manipulating the target's smoking status. Indeed, the study showed that pre-exposure to a campaign that stresses the health costs of smoking, increased the perception of smoking as a signal of dispositional health.

I close the paper with some recommendations for further studies about the possible costly signaling nature of adolescent smoking, and with recommendations for alternative public policy strategies targeting adolescent smoking and smoking initiation.

Reducing the Pursuit of Material Goods:
The Influence of Positive Affect on Materialism and Conspicuous Consumption

Jin Seok Pyone, Cornell University, USA
Alice M. Isen, Cornell University, USA

EXTENDED ABSTRACT

Much of the previous research has investigated how materialism influences happiness (e.g., Belk 1984; Van Boven and Gilovich 2003). On the other hand, relatively little research has been conducted on the reverse, the influence of positive affect on materialism. In the present research, we examine how mild positive affect that people experience in everyday life influences materialistic and conspicuous consumption behavior.

Based on the affect literature suggesting that positive affect leads to more flexible thinking (Isen 2008) and broadened scope of attention and cognition (Fredrickson and Branigan 2005), we hypothesize that positive affect enables people to think about aspects of their life and their happiness more flexibly (i.e., they can think of various ways of pursuing happiness other than acquiring material goods), and thus they are less likely to rely on material goods as a primary source of happiness or self-worth, while neglecting its other sources.

First, in order to examine a lay theory of materialism, in a pilot study we asked participants to describe materialism in their own words. They defined materialism broadly in two ways: 1) valuing material goods over other, or abstract, values in life (e.g., family or friendship), and 2) engaging in consumption behavior in order to "show off" or signal status. In five studies, we tested the influence of positive affect on materialism as represented in prior research and the lay ideas generated above.

Study 1: What Makes You Happy? Participants were randomly assigned to either a positive or a neutral affect condition. Affect was manipulated using a video clip: a mildly amusing clip (showing a dancing hippo) or a neutral clip (showing moving color bars). After the affect induction task, materialism was measured in a way similar to that used by Chaplin and John (2007). Participants were asked to list things that make them happy using six categories: *Hobbies, Material Things, Achievements, Sports, People, Other.* A ratio index of materialism was obtained by dividing the number of material items by the total number of items, for each participant. The results revealed that people in positive affect reported lower materialism ratios than did those in neutral affect.

Study 2: Money Allocation I - Spending vs. Saving. In Study 2, we measured materialism in the context of impulsive spending behavior. Affect was induced as in Study 1. After the affect induction task, participants were asked to imagine that they received a $500 bonus from the company they had worked for over the last summer, and asked to allocate the $500 between two categories: To Spend and To Save. A 2 (affect: positive vs. neutral) × 2 (category: spending vs. saving) mixed ANOVA, with category as a within-subject factor, revealed a significant interaction between Affect and Category, $F(1, 42) = 7.25$, $p = .01$. People in positive affect allocated less money on spending, and more on saving, than did those in neutral affect, and also they allocated more money to saving than to spending.

Study 3: Money Allocation II - Material vs. Experiential Purchase. In Study 3, following the research by Van Boven and Gilovich (2003), we measured materialism in terms of the type of purchases people pursue (material or experiential). After the affect induction task (as in Study 1), participants were asked what specific things they would like to *buy* or *do* with the $500, and to indicate the amount of money they allotted to each item. A materialism index was created for each subject, by subtracting the amount allocated to experiential purchases (e.g., *going out to dinner with friends, skiing*) from that to material purchases (e.g., *new clothing, handbags*). Results showed that people in positive affect allocated a smaller portion of the money to material purchases (relative to experiential purchases), than did the controls.

Study 4: Conspicuous Consumption I. In Studies 4 and 5, we measured materialism in terms of the underlying motive for buying material goods: the degree to which people want to signal wealth or social status. Participants (all female) were randomly assigned to a 2 (affect) x 2 (signal: high, low) between-subjects design. After the affect induction task, participants were told that they would evaluate a high-end product. Half of the participants saw an image of a Gucci handbag with a salient brand-logo (high signal), and the other half saw a Gucci bag with no logo (low signal). Results revealed that people in neutral (vs. positive) affect perceived the handbag with the salient logo as more attractive, wanted to own it more, and were willing to pay more for it.

Study 5: Conspicuous Consumption II. In Study 5, Conspicuous consumption was measured among male subjects. Participants (all male) read product descriptions about cars from two different brands: a *Low-end* model from BMW and a *Premium* model from Mazda. The BMW model was described so that participants could see that its performance (e.g., engine, fuel efficiency, horsepower, etc) was inferior to that of the Mazda, but as superior as a status symbol. Participants then were asked to make a choice between the two models. The results showed that positive-affect people were more likely to choose the high-end Mazda (performance) over the low-end BMW (status) than were controls.

In sum, results of five studies suggest that under mild positive (vs. neutral) affect, people are less likely to rely on material goods as a primary source of happiness, while neglecting its other sources, and also less likely to engage in conspicuous consumption (i.e., signal status through material goods).

Seeing Man in Man's Best Friend
The Role of Anthropomorphism on Increasing Prosocial Behavior

Brooke Reavey, Drexel University, USA
Marina Puzakova, Drexel University, USA
Hyokjin Kwak, Drexel University, USA

EXTENDED ABSTRACT

Anthropomorphisms are frequently used in for-profit and non-profit marketing communications. The emerging body of work in consumer behavior is consistent that anthropomorphisms increase consumer likability of the product (Aggarwal and McGill 2007; Holzwarth, Janiszewski, and Neumann 2006; Kim and McGill *in press;* Landwehr, McGill, and Herrmann *in press*). When marketers project human-like intentions, motivations, characteristics, conscious will, soul, spirit and emotions onto nonhuman entities, the entity is anthropomorphized (Aggarwal and McGill 2007; Epley, Waytz, and Cacioppo 2007). Marketers frequently display anthropomorphized entities in varying anthropomorphized levels in their consumer-facing marketing functions. These entities range from the less obvious implicit anthropomorphisms, such as a "smile" in a car grill (Landwehr et al. *in press*) (Aggarwal and McGill 2007) to an explicit anthropomorphism, such as a walking and talking squirrel in a TV commercial. Our study contributes to the growing body of literature on anthropomorphism because we identify implicit and explicit anthropomorphism as the varying degrees of anthropomorphism. We define explicit anthropomorphism as: *imbuing a nonhuman entity with observable and apparent human characteristics.* Examples of explicit anthropomorphism include: talking from the first person, moving like a human (i.e. walking, sitting, etc.), wearing human clothes, and having human features (i.e. eyes, lips, limbs, etc.). We define implicit anthropomorphism as: *imbuing a nonhuman entity with indirect and subtle human characteristics.* Examples of implicit anthropomorphism include: a description in the third person that includes conscientiousness and sentimentality using secondary emotions, having the anthropomorphized entity take on a human shape but continue to maintain its nonhuman form (i.e. feminine shaped perfume bottle, watch hands that look like a smile), or move in a somewhat human-like manner but maintain mechanistic tendencies. We show that the varied degrees of anthropomorphized stimuli in the appeal affect the respondents' perceptions and intentions on prosocial behavior. Moreover, while many people, but not all, anthropomorphize dogs, the context of our experiment allows us to explore the appropriateness for anthropomorphism as moderated by one's personal beliefs. To our knowledge, this is the first study to theoretically and empirically demonstrate that the varying levels of anthropomorphism stimuli affect consumers differently.

Additionally, prior research shows anthropomorphizing an entity leads to prosocial behavior because endowing an entity with humanlike capabilities (e.g., secondary emotions) leads to empathic care and concern (Waytz, Cacioppo, and Epley 2010a). Both streams of literature, commercial and prosocial behavior, show that anthropomorphizing the entity has a more positive effect on the transaction than non-anthropomorphizing does. However, most literature in the prosocial realm has focused on how negative ads affect donations. Additionally, prior research has focused on the tendency to anthropomorphize rather than rely or test one's personal beliefs on anthropomorphism. Personal beliefs are found to be less likely to change over time (Paluck 2009a, b) than situational variables. Prior research has discovered that consumers who are deeply religious tend to anthropomorphize less, but since religious beliefs tend to be deeply rooted in one's self-concept, we found that personal beliefs about anthropomorphism influence one's level of appropriateness towards the anthropomorphism. To our knowledge this is the first study to theoretically and empirically demonstrate that anthropomorphism leads to positive prosocial behavior. In this regard, we contribute to anthropomorphism theory by detailing the differences between explicit and implicit anthropomorphism and their effects on prosocial behavior.

The Effects of Temperature Cues on Food Intake

Barbara Briers, Tilburg University, The Netherlands
Davy Lerouge, Tilburg University, The Netherlands

EXTENDED ABSTRACT

According to the World Health Organization Global InfoBase, today in the United States, almost 67% of the people are overweight and about 34 % are obese. Although food marketing practices and (institution-driven) reductions in physical activity are believed to be the two most important causes of obesity (Keith et al. 2006), emerging literature points to potential harmful effects of artificially manipulating temperature by heating or air-conditioning on food intake because it interferes with our physiological system. For instance, Johnson et al. (2011) reasoned that with increased heating the ambient temperature, less energy is needed to maintain core body temperature resulting in higher rates of obesity. Herman (1993) argued that exposures to lower ambient temperatures by means of air-conditioning can induce a heightened food intake because our physiological systems asks for energy resources to keep the core body temperature sufficiently high.

In sum, emerging literature points to a potential connection between ambient temperature and expanding waistlines, but direct evidence is lacking. Moreover, the relationship between temperature has typically been explained by is physiological processes. We agree that such process can affect food intake when people are exposed to coldness or warmth for longer periods of time, like when troops are stationed in the tropics as opposed in cold areas (Johnson and Kark 1947). Yet, we belief more psychological processes are at work when people are exposed to cold or warm temperatures for a shorter period of time, such as for instance people entering an air-conditioned restaurant and/or receiving an iced drink when seated. Our research aims to test this assumption. More specifically, we put forward that merely activating the concept of coldness is enough to induce people to eat more compared to when activation the concept of warmth. In this research, it is argued that 'temperature primes' – even independent of actual ambient temperature – have the potential to affect eating behaviors.

According to behavior priming literature, cognitively priming environmental cues automatically activates the goals associated with these cues, which in turn solicits corresponding behaviors. The activation and execution of these goals require no conscious awareness or regulation (Bargh et al. 2001; Chartrand and Bargh 1996; Bargh 1990). Given that actual coldness (warmth) embodies the goal of increasing (decreasing) food intake to avoid hypothermia; these findings thus suggest that cognitively priming coldness (warmth) may automatically lead to an increased (decreased) need for food calories. Taken together, the main hypothesis of the current research is that merely activating the coldness concept will lead to higher food intake, compared to merely activating the warmth concept. In three studies we provide evidence for this hypothesis.

In a first study, we want to show first that cold primes lead to desire for energy or calories. To measure desire for calories, we will rely on a basic estimation distortion process to assess the extent to which a person values calories (Tajfel 1957). According to Bruner and Goodman (1947) coins tend to be judged as larger than gray discs of the same size, and children with a lower socioeconomic status overestimate the size of coins more than do children with a higher socioeconomic status. Deprived smokers similarly judge the length of a cigarette as longer than do nondeprived smokers (Brendl, Markman, and Messner 2003). These and other studies demonstrate that objects, such as meals or caloric content, appear larger when valued more. Indeed, the results of this study indicated that participants cued with coldness estimated the caloric content of food higher than people cued with warmth.

The second study aimed to provide evidence for this claim by investigation the effect of coldness vs. warmth cues on real consumption amount. Specifically, the results of study 2 illustrated that people cued with coldness ate significantly more compared to those cued with warmth.

If our findings of study 1 and 2 are really driven by coldness cues activating the goal of increasing food intake to avoid hypothermia, then we should also find that that warmth cues should result in an increased desire for more fluids to avoid hyperthermia. This was tested in the study 3. We indeed found that participants cued with coldness wanted significantly more food compared to those cued with warmth, but wanted significantly less fluids.

In sum, our research provides evidence that physiological cues that trigger eating (like temperature) also have the ability to affect food intake in a psychological way: 'temperature primes' – even independent of actual ambient temperature – have the potential to affect eating behaviors. As such, this research opens the debate to what extent short exposures to cold/warm temperatures, such as people entering an air-conditioned restaurant or attending a cocktail party with no air-conditioning, physiologically really are in need for more/less energy to keep up their body temperature. In fact our research indicates that people's reaction to order and/or consume more/less (caloric) food under such circumstances, may also be driven by a psychological need rather than a biological one.

Self in *Selca*, Self-Portrait Photography, as a Model, Photographer, and Consumer

Yoo Jin Kwon, Korea National Open University, Korea
Kyoung-Nan Kwon, Ajou University, Korea

EXTENDED ABSTRACT

Selca is a compound word of self and camera, meaning self-portrait photography in Korea. In this photography, consumers simultaneously play multiple roles: the object of consumption, the creator of the object, and the consumer of the object. To take selca pictures, mostly one stretches one's arm and faces the lens toward oneself. The rapid spread of selca relates to the advent of digital photographing including a diffusion of affordable digital cameras or cell-phones with cameras and the popularity of user-generated contents of Internet social media. This study is to understand how Korean young adults create and view their selca pictures and to conceptualize the meanings of these self-images. The value of our study lies not only in the fact that selca is newly emerging consumption practice but also selca is a context where the complex and dynamic nature of self concepts is manifested.

Consumer researchers with sociological orientation focuses on the Me, self-perception as object and the empirical self (Robert E. Kleine, Kleine, and Kernan 1993). Consumers purchase products in order to highlight or conceal some aspects of self. The consumer-object relationship is well conceptualized by the theory of extended-self (Belk 1988). Belk made the ontological connection of self and possession on the basis of Sartre's (1943) three states of existence (i.e., being, having, and doing). Self-presentation is related to the Me state. At the Me state, people are more sensitive to the self-relevant aspects including how their actions and appearance look to others or evaluation of self.

Data were collected through videotaped, in-depth interviews. Ninety selca enthusiasts were recruited to participate in our interviews. Participant's age ranged nineteen through twenty seven. Descriptive characteristics of the participants, transcripts and observations were analyzed with a constant comparison approach. The interview contents reported in this manuscript, which were initially translated into English, was back-translated by two bi-lingual researchers in this subject area, which was to confirm the accuracy and reliability of the translation.

Our data revealed a few distinctive characteristics of selca. Most characteristics of self-taken photos are related to the fact that the subject of a photograph is the photographer. Our young adult consumers prefer selca to regular photography, because it captures *how they see themselves* rather than *how they look*. Self-centeredness appears to be undeniably a distinct feature of selca: Participants stated that they should be the central feature even in a selca picture with friends. Whether it is a testament shot or a shot with friends or alone, Selca-taking involves a great deal of directing.

Selca involves self who is both the creator and the object of the consumption and selca captures realities and imagery. Our attempt was to untie the complexity of self-images in selca by analyzing how participants accounted for real and unreal aspects of selca and then integrating the ambivalent accounts. Specifically, three themes emerged: (1) construction of self-centered reality, (2) objectified ideality, and (3) extension of self through selca.

Construction of Self-centered Reality. Consumers direct the photographer's effort to setting up environmental conditions within the boundary of reality. Self-centered reality is constructed through different kinds of strategies: selection, learning, and revelation. (1) Selection refers to which part of body or what state of mind participants decide to present. (2) Learning about oneself through selca indicates selca practice as autotelic activities. (3) Revelation refers to that selca captures what other people cannot capture in the person. Two types of self-centered reality also emerged depending on which self consumers choose to present through selca: model self-centered and photographer self-centered reality.

Objectified Ideality. The unreal side of selca embodies the ideality of self-concept. The ideality reflects ideals of beauty and a desirable human character of the society as well as various personal goals. Three strategies emerged as to concretizing the ideality of self: magnifying, negotiation, and multiplying. (1) Magnifying is a way of transforming a reality to an ideality. Many selca techniques are means of exaggerating features that participants want to idealize. (2) Negotiation refers to management of conflicts in taking selca. For example, the two techniques discussed above, high-angle shots and low-angle shots, are incompatible when it comes to a picture of the entire body. (3) Multiplying is to reinforce what is magnified in selca. Many regulars' strategy of possessing many good selca pictures can be understood as a way of multiplying desirable selves. By doing so, the good-looking person in the photos became an existent entity.

Extension of Self through Selca. Consumers juggle between realistic self-awareness and idealized self-images in selca. The discrepancy the participants dealt with is about not only their own selca but also others' selca. Interestingly participants claim that their own selca is true, whereas other people's selca is not true. The dual standard for selca was commonly observed. Participants accept the self-deceptiveness of selca of others to some degree, although they were much more tolerable to their own selca.

Another interesting observation was participants looked back on past selca pictures as actual self at that time. As the memory is reconstructed, a sense of reality at a certain point of time in the past is reconstructed. Gratification people get from good selca pictures is instant, compared to film camera. Therefore, consumers get tempted to take one more picture to get more gratification. The instant gratification spontaneously results in the next action, which creates the iterative process of photographing-viewing-gratification. Consumers embrace the idealized self-image and the realistic ideality whether physical or mental is transformed to the higher appraisal of self (i.e., self-esteem).

We understand selca as a quest for an authentic sense of self. Consumers engage in active and individuated productive consumption, acquiring a sense of authenticity. Through juggling between the reality that individuals define and the objectified positive self images, consumers construct a sense of authentic self. Self-directing and self-deception are features of selca practice as an authenticating act. The popularity of selca in Korea should be understood in its cultural context. In Korea, interdependent self concepts are traditionally dominant and consumers are self-conscious about displaying their effort for self-enhancement. This strong sense of self-consciousness was also observed in the selca practice. At the same time, young generations are exposed to and embrace individualistic self concepts, which are often understood as Western influence. The self-centeredness of selca accords with the individualism of the young generations. By extending self to the hybrid form (e.g., actual and ideal) of self-image, consumers can safely pursue self-enhancement and present self in an acceptable way. Selca embodies how this individualistic self concept is acculturated in a traditionally collectivistic culture by creatively using technological advancements.

Lost in Translation:
The Consequences of Culturally Mismatched Thinking Styles on Familiarity Seeking

EXTENDED ABSTRACT

Westerners in general hold an analytic world view that emphasizes the independence of individual objects, whereas East Asians tend to adopt a holistic view, emphasizing that the world is composed of interrelated elements (Nisbett et al. 2001). Although research has revealed important antecedents and consequences of cultural differences in thinking styles, little attention has been paid to the consequences of engaging in culturally mismatched thinking styles. This is our focus. Rather than examining the impact of one or another thinking style, we examine the impact of having to perform a task that mismatches (versus matches) one's dominant style.

When a given task calls for processing that is not in line with one's culturally dominant thinking style, self-regulation is required. That is, in order to complete the task successfully, one needs to override the inclination to process information in the usual way and force oneself to process it differently. This inhibition of one's dominant processing style is depleting in that it consumes self-regulatory resources that could have been used in subsequent tasks. Indeed, recent research has shown that these cross-cultural experiences come with self-regulatory costs and consequences: a reduced ability to control one's intentions and a greater likelihood of giving in to temptations (Koo et al. 2010).

The present research builds upon this to examine a broader implication of the impact of engaging in culturally mismatched thinking styles – familiarity seeking. If engaging in a mismatched (versus matched) thinking style leads to reduced self-control and increased indulgence, it may also be expected to lead consumers to make other choices that reflect depletion. Making choices and decisions is known to be depleting and thus to impair subsequent efforts at self-control because decision making and self-control draw upon common resources (Vohs et al. 2008). We thus propose that, in turn, feeling depleted may lead people to be less willing to take on additional effort when making choices. People who experience a mismatch (vs. match) in thinking styles, and who consequently feel depleted may opt instead for old familiar consumption experiences.

Study 1 tested the hypothesis that engaging in culturally mismatched thinking styles lead people to make choices that require less effort, increasing the preference for familiar versus novel options. Participants of Asian and European American ethnicities were recruited to represent holistic and analytic thinkers, respectively. Half of the participants in each cultural background were assigned to an analytic task condition: They were shown a picture in which 11 embedded objects were to be found (Monga and John 2008). The rest of the participants were assigned to the holistic task condition, in which they were shown the same picture but with an instruction to focus on the background. Subsequently, participants were shown a scenario in which they had to make choices regarding an upcoming vacation. Participants were then asked to indicate for the categories of hotel, bar/nightclub, and spa, which option they would be more likely to choose, either a familiar favorite location or a new place.

As predicted, a significant interaction was found between participant ethnicity (Asian vs. European American) and their primed thinking style (analytic vs. holistic) on the mean likelihood of se-

lecting familiar (vs. unfamiliar) choices. European American participants were more likely to favor one of the familiar choices in the holistic than in the analytic thinking condition. In contrast, Asian participants were more likely to favor one of the familiar choices in the analytic than in the holistic thinking condition.

Study 2 further examined the impact of culturally mismatched thinking styles on familiarity-seeking tendency in another domain, namely decision making in a restaurant. Specifically, this study tested whether culturally mismatched experiences would lead consumers to prefer familiar to unfamiliar dishes at a restaurant. In addition, this study examined dominant thinking styles via measured chronic thinking style. The study employed a 2 (measured chronic thinking style: analytic vs. holistic) X 2 (induced thinking style: analytic vs. holistic) between subjects factorial design.

Participants were induced to think either analytically or holistically using the same procedure as in Study 1 (Monga & John, 2008). After the thinking-style manipulation, participants were shown a hypothetical scenario in which they had to make choices in a restaurant. They were then asked to indicate whether they would like to choose one of their familiar favorites or a selection from a new menu for each course: an appetizer, a main dish, and a dessert. Then, participants' chronic thinking styles were measured using the 7 point Analysis-Holism Scale (AHS; Choi et al. 2007).

As expected chi-square tests showed that the percentage of participants who selected an old favorite was significantly greater than those who selected a new choice, especially among those who experienced a culturally mismatched thinking style in the case of the appetizer and the dessert (though not the main dish). Overall, we replicated the significant effects of mismatch on the choice of familiar options at a restaurant. This suggests that the effects observed here are not limited to important and consequential choices, or ones that involve significant risk, such as a hotel. They impact smaller decisions, as well, such as the tendency to order items from a familiar menu rather than from a new set of options.

Taken together, the two studies showed converging evidence that people who engage in a task that mismatches (versus matches) their culturally dominant thinking style are more likely to visit places or select consumer options that they already know well. Our findings have novel implications for the understanding of culture, especially the potential consequences of intercultural interactions in subsequent decision making, and for understanding the impact of depletion on familiarity seeking. Exposure to experiences that require a culturally mismatched thinking style is a commonplace situation. Our research suggests for the first time that, paradoxically, these enriching cross-cultural experiences reduce one's interest in novel (vs. familiar) experiences.
