Advances in Consumer Research, Volume 39

Rohini Ahluwalia, Tanya L. Chartrand, and Rebecca K. Ratner, Editors

Preface

The 39th annual North American Conference of the Association for Consumer Research was held at the Hyatt Regency St. Louis at The Arch in St. Louis, MO from Thursday, October 13 through Sunday, October 16, 2011. This volume consists of research presented during this conference. The volume is organized by type of research submission and includes the following: Special Session Summaries, Full Competitive Papers, Competitive Extended Abstracts, Film Festival Abstracts, Roundtable Summaries, and Working Paper Abstracts.

The theme of ACR 2011 was "Building Connections," reflecting the role of St. Louis as the historic Gateway to the West. The goal for the conference was to promote connections between researchers from different areas of consumer research, different theoretical perspectives and methodologies, and between academia and industry. By all accounts this goal was met; the quality of the research was exceptional and people and perspectives were brought together in many ways.

There were several changes at the 2011 conference that reflected our Building Connections theme. First, we introduced an opening Plenary Session; we kicked off the conference Thursday with a session immediately preceding the Thursday night reception. This plenary session was designed to bring the ACR community together for a lively discussion and Q&A with panelists. Second, we created a "Coffee Connections Lounge", complete with sofas, tables, and coffee, which was designed to facilitate conversation during breaks in the program. During the Long Coffee Breaks, participants were invited to connect with researchers with similar interests. Third, we added some social media in the form of Twitter. Conference attendees were encouraged to tweet about the presentations or other conference events, which appeared on a "Twitter Fountain" displayed in a central location. Finally, we introduced ACR At-A-Glance this year, which consisted of a one-page fold-out in the program that identified the session topics, time slots, and room numbers. This provided a quick way to make connections between the various topics featured at the 2011 conference, and to make it easier for attendees to find their way to the next session.

We would like to thank the generous donors who provided financial support for this year's conference. We also want to thank all the people who provided us with invaluable help with this conference. We especially want to thank the Associate Editors, the Senior AEs, the members of the ACR program committee, the working paper reviewers, film festival reviewers, and competitive paper reviewers. In addition, we owe a special thanks to all the student volunteers from University of Minnesota, Duke University, and University of Maryland who helped us tremendously. Finally, we thank Rajiv Vaidyanathan, executive director of ACR, for his support throughout the process, and to Sharon Shavitt for trusting us with this conference and giving us the opportunity to give back to the amazing community of consumer behavior researchers.

ACR Presidential Address 2011

What's New? Novelty in Consumer Research

Sharon Shavitt, Walter H. Stellner Professor of Marketing, University of Illinois at Urbana-Champaign, USA

This is a slightly expanded version of the address given in St. Louis, October 14, 2011

I want to talk about your next paper. The next piece of work you will submit for review. In this talk, I will address one of the most important criteria that will determine whether it is accepted or rejected. Surprisingly, it's the least understood criterion. Everyone will judge your work on it, but no one quantifies or defines it.

I'm going to talk about novelty in research. How we assess it. Why we seek it. And what are the consequences.

The topic for this talk was inspired by a review of one of my old manuscripts. Perhaps you have a review just like it – the kind that haunts you long after the paper is published. Years ago, my student and I submitted such a paper to one of our top journals. It addressed how attitudes can shift when people anticipate a group discussion. We got good feedback, but one reviewer complained that the paper lacked novelty: "The additional contribution seems marginal. We already know that reference groups influence judgments."

That review changed my view of our field. It was accurate – we do know that reference groups influence judgments. But does that mean we're finished with this entire domain? When is a topic *spent*? How do we decide if something has already been done, or if it's novel? I couldn't stop asking myself these questions.

The view of novelty in that review reminds me of the *New Yorker* cartoon where one caveman says to the other, "Og discovered fire, and Thorak invented the wheel. There's nothing left for us."

It's easy to get the feeling that it's all been done. We could have stopped with Og and Thorak. Yet, people have found ways to keep innovating. We have novelty, but we don't always recognize it.

In this address, I will describe the subjective ways we assess novelty. I will discuss our deeper motivations for seeking it. And I will propose that if we worried less about pursuing what's new, we could enhance innovation in our field.

WHO CARES ABOUT NOVELTY?

We all do. We are all judged on it. We all try to claim it for our research. Making a convincing claim is getting harder as the field rapidly grows. But it's urgent for junior scholars. They need to carve out their niche while the tenure clock is ticking. There is a lot on the line.

For us older scholars, novelty is also important. It's a way of ensuring we have made a mark. Our life's work has mattered because we did something new.

Why is novelty so important to these goals? Because, in the academic world, novelty is status. It's the Gucci, Vuitton, and Lamborghini of research -- all rolled into one. Novelty compensates for other flaws (Rozin, 2009), like Botox, smoothing out the wrinkles in our studies. Novelty assures our findings will get attention and admiring glances. If we're lucky, maybe publication in *JSSR* -- the *Journal of Short Sexy Results*. Who wouldn't want that?

Journals want novelty, too. Want it and demand it. Each editorial we read tells us to send in only our most novel work. One marketing journal's website insists that,

> *"All submissions must be interesting,..."*
> *"...The editors...especially encourage research that is novel, visionary or pathbreaking."*

Clearly, the bar is high for judging the novelty of your next paper.

WHAT'S NEW? DEFINING NOVELTY

Novelty can come in various forms. So, when you ask people, "what is novelty in research?" they will say: It is a new area, a new idea, a new finding or method. That is fine, but it still leaves the question – what's "new?"

The subject of novelty has been addressed in the sociology of science. Robert Merton (1973 [1942]) and others described how scientists get credit for original discoveries, and the rewards that follow from that (see Guetkow, Lamont, & Mallard, 2004, for a review). This classic work dealt with a number of issues, except what novelty actually is. What is the threshold for calling something "novel?"

There really is no authoritative work on that. The word "novel" is used – a lot— but always as if the concept is self-evident. As if everyone who looked at a piece of research would judge its novelty the same way.

The difficulty in defining novelty is immediately apparent to those who try. C.W. Park (2011), editor of the *Journal of Consumer Psychology*, offered helpful guidelines on submitting novel work to *JCP*. He acknowledged that judging novelty,

> *"involves a high degree of subjectivity… The bottom line is that [novel papers] …cause readers to slap their forehead, exclaiming 'Silly me, …why didn't **I** observe this?'"*

I think this statement may be as good as it gets in defining novelty. It recognizes that novelty in research confers status and elicits envy.

When you submit your next paper, you may be told that it does not seem new, or that enough has been done on your topic. That kind of feedback can feel quite discouraging, especially if you are a young scholar eager to establish yourself. Fear not. You are in good company:

> *"For my annual review in 1974, the department head suggested that I move away from pricing research as I had done about all that could be done in this area."*

This is Kent Monroe (2008, p. 16) speaking when he was named ACR Fellow for decades of pioneering work on pricing. I mention this quote for two reasons. One is to reassure you that the best have faced this criticism. Another is to support the plausibility of three points I want to make about novelty.

(1) *Novelty is not an intrinsic attribute (of a theory, a finding, or anything else).*
 -An assessment of novelty is a mental construction.
 -It draws from feelings and subjective experiences.
 -And it is sensitive to context. How we judge it depends on where we're standing.

We don't have to look far to see what kinds of factors can impact judgments of novelty. We can just look at the research we conduct or cite: Research on fluency and metacognition, on thinking styles, and values. In fact,

(2)   *The way we seek novelty in research is tied to our core values.*

Because values are not universal, neither is the way we understand novelty, as we'll see. And my final point:

(3)   *Pursuing novelty in research has unintended consequences.*

Of course, we need novelty if we hope to push the boundaries of knowledge. At the same time, any criterion applied reflexively is bound to cause trouble. I will offer some reasons to loosen up when it comes to judging the novelty of each other's work.

HOW DO WE ASSESS NOVELTY?

Let's consider my first point: Novelty is a mental construction. I think that something is perceived to be novel when it,
- feels unfamiliar and surprising and
- does not appear subsumed by existing categories.

Seen-Before Judgments

For research to seem novel, it has to be experienced as unfamiliar – as something we haven't seen or learned before.

As John Lynch (1998) noted in an earlier presidential address, reviewers will often assert that a finding is already well known without providing references to back it up. In principle, if you already know something you should be able to say where you saw it. In practice, it's not so easy.

In fact, entire paradigms in psychology have been based on the fact that people are not good at judging whether they have seen or experienced something before. Consider mere exposure effects (e.g., Zajonc, 1968; Bornstein, 1989), false-fame effects (e.g., Jacoby, Kelley, Brown, and Jasechko, 1989; Jacoby, Woloshyn, & Kelley 1989), and various false memory paradigms (e.g., Koriat, Goldsmith, & Pensky, 2000; Lakshmanan & Krishnan, 2009; Rajagopal & Montgomery, 2011). Conscious recollection of past exposures is not at all accurate. This is why people can confuse fluency from an irrelevant source with familiarity.

In consumer research, as well, studies show that when something feels easy to process or when an experience evokes imagery, it creates a false sense of familiarity. People think they've already been there, done that – when they haven't, and didn't (see Rajagopal & Montgomery, 2011; also Lakshmanan & Krishnan, 2009; Mehta, Hoegg, and Chakravarti, 2011; Schlosser, 2006).

It's hard for people to remember every piece of research they've ever seen. This is especially so with increasing online exposure to science blogs, TED talks, journal feeds, etc. (see Lutz, 2011). Many assessments of novelty are probably not based on exact recall of past work. They reflect a vague sense of whether a topic feels saturated. So, if something about your next paper feels too fluent, instead of taxing their memory, people may assume it's all been done.

Feelings of Surprise

For research findings to be experienced as novel, they also need to feel somewhat surprising. But here too, as some have observed, our feelings can be misleading (Lynch, 1998; Lilienfeld, 2011).

One can fall prey to the hindsight bias – the feeling that one "knew it all along" (Fischhoff, 1975; Wood, 1978). People who know an outcome tend to overestimate its likelihood. This is one rea-

son that surveys show the general public tends to dismiss behavioral research (Lilienfeld, 2011). It *feels* like common sense.

The hindsight bias has been demonstrated many times, in many populations (Bernstein et al., 2011; Pohl, Bender, & Lachmann, 2002) and domains (see Bernstein et al., 2011, for a review). Could it also affect an expert's view of whether a research finding is surprising?

Sure. As just one example, Lily Wong (1995) in educational psychology showed people lists of findings about teaching that were either actual well-replicated findings, or their opposites. When asked to select which were the real findings about teaching, experienced teachers were no more accurate than novices – which is to say, not accurate at all. And both groups tended to rate their selected findings as obvious.

If reviewers dismiss the novelty of your next paper, saying, "it's not surprising," how much weight should we put on such feelings? Once people know your findings, they can feel obvious in an illusory way – even to experts (Wong, 1995; see also Arkes et al., 1981; Knoll, 2010).

Construal Level and Novelty Categorization

To assess whether findings are novel, we also need to consider mental representations of "what everyone already knows" (Kaufer & Geisler, 1989), and decide whether the findings can be subsumed by those categories. Recent work by psychologist Jens Förster suggests that perceived novelty is a by-product of this sort of process (Förster, Liberman, & Shapira, 2009; Förster, Marguc, & Gillebaart, 2010). Events are experienced as novel when they don't seem to fit existing categories.

But this, too, is a matter of perspective.

To understand the experience of novelty, Förster and his colleagues build on a theory that has inspired a great deal of consumer research, Construal Level Theory (e.g., Trope & Liberman, 2003). They emphasize that anything can be experienced as either novel or old: Any new town we visit could be seen as "just another city;" any new person we meet could be "just another person" (Förster, et al., 2009, 2010).

Whether we define something as "new" depends on how broad or abstract is the category we call "old." And *that* has to do with our psychological distance from it.

Distance from something leads to the use of broader categories to represent it. This makes it easy to subsume new things, making them feel old and familiar. Innovation becomes harder to appreciate.

So it is in consumer research. If someone isn't close to the subject, they tend to classify knowledge at an abstract level. They might say: *We already know that consumers link possessions to the self.* Or: *We know that messages are more persuasive when they match one's motives.* These broad categories subsume a lot of the work in our field, and probably a lot of future work, too.

As a result, if you want to increase the chance that your next paper will be seen as novel, some will tell you to go and explore a whole new area, apart from what others have done.1

Still, as we've seen, novelty is in the eye of the beholder. It's a mental construction. And the size of the bins we use to classify existing knowledge is arbitrary. We don't have to insist on novelty at the "never-been-done" level.

So, why do we?

WHY DO WE SEEK NOVELTY?

To answer this question, let's consider a finding in the sociology of science. A few years ago, Michele Lamont and a team of colleagues, supported by the National Science Foundation, set out

to examine how scholars perceive originality (Guetzkow, Lamont, & Mallard, 2004). They were looking for variations between disciplines. So, they interviewed panelists for American fellowship competitions in social sciences and humanities. As it turns out, the most interesting thing they found isn't what differed between disciplines, but what was the same. Across disciplines, from art history to sociology, reviewers saw the originality or novelty of a proposal as a sign of the applicant's *moral character*.

People who submitted proposals seen as novel were described as courageous, independent, intellectually honest, and "thinking for themselves." They were praised and respected as authentic scholars with high integrity.

To be independent and courageous demonstrates that one is pursuing one's own authentic interests. Reviewers deeply valued these qualities and wanted to reward them (for similar perspectives, see King, 2010; Zaltman, LeMasters, & Heffring, 1985).

On the other hand, applicants whose work was seen as lacking in novelty were viewed as morally deficient. Reviewers scorned them as conformist, derivative, lazy, traditional, and "riding the bandwagon." These were not scholars who had genuine intellectual passion.

So, novelty judgments – subjective as they are – were more than an assessment of someone's ideas. They were an assessment of the person, as well.

I was fascinated by this, and wondered, why the moral meaning of novelty? Then it hit me: There is a direct line between this novelty ideal and Western values. To be admired in Western individualist societies you have to be independent, authentic, honest, and nonconforming (e.g., Markus & Kitayama, 1991; Triandis, 1995). You've got to act on your passions and pursue your own unique interests. This is the perfect model of an authentic, independent, path-breaking scholar. In other words, this is where the values of our science map onto the values of our culture.

Defining novelty as "independent and different" is ingrained in our value system. We don't question it. It's assumed that you should blaze a separate intellectual trail. A trail that sets you apart.

For those of us who are Western individualists, this model of novelty is a perfect fit. We expect the same from ideas as we do from people: to be unique and independent. We are socialized to meet these expectations. As Ashok Lalwani and I have found in our research, individualists really do strive to present themselves in these terms (Lalwani, Shavitt, & Johnson, 2006; Lalwani & Shavitt, 2009).

What's more, as Richard Nisbett and many others have shown, Westerners tend to think in ways that sharpen differences. They separate and distinguish things, disconnecting things from their context, choosing one side or the other (e.g., Nisbett, et al. 2001; Nisbett, 2003; Oyserman & Lee, 2008; see Koo & Shavitt, 2011, for a review). This *analytic thinking style* is perfectly suited to the task of differentiating oneself, and one's ideas, from others (see MacInnis, 2011).

CONSEQUENCES OF NOVELTY SEEKING

Looking at novelty through the lens of cultural values suggests some consequences, and in the last part of my talk I'd like to address them.

Novel = Different?

Our standard for novelty is about setting yourself apart. But reflecting on the values that drive our novelty standards helps us to evaluate those standards. If they reflect a cultural ideal, is it the only ideal we should pursue?

I don't think so. Consumer research is globalizing fast. New scholars around the world are ready to contribute. Many are based in non-Western cultures that are collectivistic. In their day-to-day lives, being called "unique" and "independent" is not a compliment. Conformity and interdependence are more valued (Markus & Kitayama, 1991; Kim & Markus, 1999). Relationships are valued (Triandis, 1995).

In these societies, people are socialized to think in ways that connect and integrate, putting things together instead of pulling them apart, seeking resolution instead of choosing sides (Nisbett, et al., 2001; Nisbett, 2003; Oyserman & Lee, 2008). This holistic thinking style helps one to see relationships and to integrate things into a bigger picture. And this is not only a cultural pattern – individuals also differ in the values and thinking styles they tend to adopt (Choi, Koo, & Choi, 2007).

What does this mean for consumer research? There is no doubt that scholars around the world can meet the same standards for novelty. But imposing one standard at the expense of others is a mistake. We miss opportunities to leverage relational values and skills. Relational skills help us to represent connections between ideas.

Indeed, as Debbie MacInnis (2011) points out in a recent essay, our thinking skills foster specific types of novel contributions. Analytic thinking skills foster typologies that highlight differences. It's no surprise, then, that MacInnis's analysis of our field's conceptual papers over the last 25 years reveals a clear emphasis on *differentiation*. Integration papers are rare.

Yet, those are valuable innovations. McGill, Peracchio, and Luce (2011) point out in their editorial that, from a historical standpoint, the most important breakthroughs in science have been integrations. They innovate by unifying – highlighting parallels across areas, resolving contradictions, and enhancing understanding. Classic examples include Petty & Cacioppo's (1986) Elaboration Likelihood Model, which unified distinct routes to persuasion under a common set of processing assumptions. In a current example, Press and Arnould (2011) show that identification with a firm happens in a parallel way for consumers as for employees. These are valuable innovations. We need more integration.

To get there, we need to broaden our view of novelty. We should encourage authors who have a relational view of the field, wherever they come from, to find novel connections, or to build new integrative frameworks (e.g., Deighton, et al., 2010). If your next paper does these things, we should reward that.

Fragmentation

When we mainly reward the kind of novelty that sets us apart, we don't foster integration. Instead, this fragments the field.

Consider our incentives. We reward novelty at the paper level. So, papers get published on the basis of their difference from other work, not their connection to it. Many have raised concerns about what this does to the literature (e.g., Guetzkow, et al., 2004; Hubbard & Lindsay, 2002; Wyer & Shavitt, 2005).

These incentives for novelty affect what we study. Authors are encouraged to publish one paper on a topic and then go on to something different under the assumption that follow-ups will not be published.

These incentives also impact how we write. To be seen as novel, we have to apply new labels. So, we try to "name it and claim it" or "RE-name it and claim it." This doesn't foster connection, either.

Incentives for novelty even encourage us to position our own articles as having little to do with one another, instead of building on each other. It becomes harder than it should be to grasp the big picture in the field because authors are reluctant to connect the dots.

Where's the Theory?

Finally, our novelty incentives can get in the way of original theory building (Wyer & Shavitt, 2005). The shortage of original theories within our field has been widely recognized (see Frazier, 2011; MacInnis, 2004, 2011; Yadav, 2010). Yet, few theories that have a broad impact can be delivered in one paper. Building and testing a theory takes multiple papers reporting a program of research that shows generality, boundaries, and convergence around a core insight.

Authors who try may be told, "this is not novel because it is derivable from past work." But testing an extension of a theory is, by definition, derivable from past work.

What if we changed our incentives, and worried less about whether every paper is different? We would have the scope needed to build and test our own theories. And I think we would do it. In other words, we could greatly enhance originality at the macro level by relaxing the novelty constraint at the paper level.

Reviewers – all of us – play a key role in this. So do editors and other gatekeepers. Some have signaled openness to different types of novelty (e.g., Deighton, et al., 2010; Erdem, 2010), but it would help to be more explicit, to tell reviewers: Don't just ask, is it new? Ask, what's the connection? Encourage authors to link their findings to past work, don't penalize them for it. Seek contributions that integrate and connect. Reward systematic extensions that establish new theories in our field.

CONCLUSIONS

In summary, let us approach assessments of novelty with caution. They are mental constructions, influenced by the same factors we study: fluency, hindsight, level of construal. And the way we seek novelty reflects deeply held core values.

This means that we can acknowledge the value of novelty in research without imposing one criterion uniformly (Alba, 2012). We need more than one kind of novelty – things that differentiate and things that integrate. It would make our literature more coherent and enable originality in theory building.

Our theme at ACR this year is "Building Connections." In fact, this is a frequent theme for ACR conferences, along with bridges and confluence. We seem to yearn for a more integrated field. Let's consider whether our expectations for novelty are getting in the way. We can build more connections when we're less focused on setting ourselves apart.

CODA

In closing, I want to offer an invitation and some thanks. First, I invite you to a Roundtable Session right after this luncheon. In it, we discuss recommendations by an ACR Task force appointed this year to plan for the growth and globalization of our field. This task force, chaired by Joel Huber and Don Lehmann, made several recommendations to enhance the field as it expands, including suggestions for new and existing publication outlets and conference structures. The task force charge and report can be read, and your input provided, on the ACR website at www.acrwebsite.org/ .

Finally, I want to thank several people. First, I am grateful to the present and past officers and board members of ACR, for creating and nurturing such a stimulating association.

Next, thank you to my friends who gave me such generous and helpful input. And to my students who helped with details. I am so grateful.

Last but not least, thank you to my family for all of their patience and encouragement. My parents, for believing in me always. My husband, Steve, who has been supportive and helpful beyond

words. And my daughters, who found their own ways to cope with me being too busy: Arielle who worked alongside me on her homework so that we kept each other company, and Ellie who cheerfully repaid me by sneaking onto my computer to type nonsense words into this talk. I hope I found them all.

Thank you.

ENDNOTES

1This talk focused on novelty as defined in terms of unexplored topics or areas. Although I did not have time to address it, another important type of novelty is represented by findings that challenge existing beliefs in established areas. In some scientific disciplines, publication incentives reward this type of novelty, emphasizing results that question established ideas or reverse accepted findings. Jonah Lehrer (2010) analyzed the cumulative impact of these novelty-seeking publication incentives in several scientific fields. His review shows how these incentives give rise to oscillations in the accepted knowledge base. In short, pursuing this type of novelty can also produce unintended consequences that impact the reliability and credibility of scientific knowledge.

SESSION OVERVIEW

Conventional wisdom suggests that economic recessions lead consumers to decrease spending and be more cautious with their money. Consistent with previous recessionary periods, the most recent economic downturn has led consumers to downsize spending on everything ranging from groceries to homes. For example, many people are trading in their vacations for a "stay-cation," choosing to vacation in the low-cost destination of their own home.

But while aggregate spending decreases during recessions, much less is known about how economic recessions influence the specifics of consumer behavior, including the possibility that economic downturns might *increase* spending on various products. Economists have established that recessions are reliably associated with increased spending on two types of products: traditional inferior goods (e.g., spending more on tuna rather than salmon) and morale boosters (e.g., going to see a Charlie Chaplin film in the great depression). The current session presents evidence that economic downturns lead to a richer assortment of strategic spending.

The four papers in this session all present emerging research examining how economic recessions influence consumer behavior. The first two papers focus on how economic downturn cues influence desire and spending for specific product categories. The last two papers focus on how economic booms and busts influence financial decision-making. Unlike most previous research looking at recessionary spending, all four papers include studies with experimental methodologies to test the influence of economic recession cues on consumer behavior.

The first paper by **Hill, Rodeheffer, Griskevicius, and Durante** examines the "Lipstick Effect" – the notion that recessions increase spending on beauty products, such as the increase in lipstick sales during the great depression. Across a series of experiments that manipulate recession cues, they find that while recession cues decrease desire to spend on most types of products, recession cues increase women's desire to spend on beauty products, including lipstick.

The second paper by **Yabar, Stapel, and Pieters** investigates the links between economic downturns and people's need to belong. Across three experiments they find that recession cues lead consumers to desire products that facilitate social connectedness, including increasing consumers' willingness to pay for products related to affiliation.

This third paper by **Griskevicius and Ackerman** investigates whether economic uncertainty leads people to save or splurge. They find that economic uncertainty has vastly different effects depending on whether people grew up feeling poor or wealthy. Recession cues led individuals who grew up relatively wealthy to save for the future. But recession cues led individuals who grew up relatively poor to splurge on immediate rewards.

The final paper by **Millet, Lamey, and Van den Bergh** examines how financial decision-making changes in booms and busts. Using both time-series and experimental methods, they find that people are drawn toward achieving gains during economic expansions, but people are drawn toward avoiding losses during economic contractions.

Overall, this session builds connections by addressing an important theoretical and practical question—how economic recessions influence consumer behavior—from different theoretical perspectives. The papers in this session address this question by drawing on regulatory fit theory, evolutionary theory, and life history theory. Furthermore, the session presents research based on both experimental and time-series methodologies. As such, the session would be of interest to a breadth of consumer researchers, including those interested in motivation, affiliation, regulatory fit, financial decision-making, risk, intertemporal choice, and evolutionary approaches to consumer behavior.

Economic Recessions Increase Spending on Beauty Products: Experimental Evidence for the Lipstick Effect

EXTENDED ABSTRACT

The year 2007 began with what has been considered by many economists to be the worst economic recession since the great depression. Consistent with previous recessionary periods, consumers downsized spending on everything ranging from groceries to homes. Although spending on most consumer products during the recent recession has predictably declined, one class of products has fared unusually well: beauty products (Schaefer, 2008). For instance, sales figures from one of the world's biggest cosmetics companies – L'Oreal – showed that during 2008, a year when the rest of the economy was suffering record declines in sales, they experienced

sales *growth* of 5.3% (Elliot, 2008). The notion that women may spend relatively more money on attractiveness-enhancing products during times of economic uncertainty has been dubbed the "Lipstick Effect" (Nelson, 2001). The lipstick effect has been observed in several recent economic downturns, and it is even believed to have occurred during the Great Depression, when sales of women's cosmetics products boomed unexpectedly.

In the current research, we experimentally examine the idea of the lipstick effect. To understand how and why economic recessions might influence consumer behavior, we draw on the framework of life history theory (Kaplan and Gangestad 2005; Stearns 1992). Life history theory is an established theoretical framework in evolutionary biology and behavioral ecology used to predict how and why organisms, including humans, allocate effort among the various tasks needed for survival and reproduction. Because energy and resources are inherently limited, life history theory highlights that organisms face important trade-offs in how they allocate resources at a given point in life.

A key tradeoff faced by all individuals is between allocating resources toward *immediate reproduction vs. future reproduction*. Resource allocation to immediate reproductive effort, such as women's allocation of resources to enhance their appearance, is predicted to be favored in environments where there is unpredictability in the availability of critical resources (Ellis et al. 2009). When the present and future are highly uncertain, individuals should invest more in immediate reproduction because this strategy enhanced reproductive fitness in uncertain environments (Ellis et al. 2009).

In three studies we manipulated perceptions of resource unpredictability by priming people with cues to an economic recession. We predicted that recession cues should decrease desire to spend on most consumer products. However, we specifically predicted that recession cues should increase women's desire to purchase products that aid in facilitating mating, such as lipstick or other beauty-enhancing products.

In Study 1, we experimentally manipulated cues to economic recessions by having people read a news article about the recent economic recession or having them read a control article. We then examine how these primes influence women's and men's desire to purchase products that can enhance beauty (e.g., clothing, make-up) and produce that cannot enhance beauty (e.g., office supplies, electronics). Findings demonstrated that the economic recession article significantly *decreased* men's and women's desire to purchase products that did not enhance physical attractiveness. However, the same recession cues significantly *increased* women's desire to purchase products that could enhance attractiveness.

In Study 2, we directly manipulated perceptions of product function by varying how the same products (e.g., jeans, boots, perfume) are advertised. Specifically, product slogans were manipulated to touted product benefits directly related to mating (e.g., the opposite sex finds it irresistible) or benefits unrelated to mating (e.g., feels great). Economic recession cues were manipulated by having women view a slideshow with visual images of economic recession or control images. Consistent with predictions, viewing images of economic uncertainty led women to desire products advertised as serving a mating function. But when the same products were advertised as serving a function not directly related to mating, economic recession cues no longer enhanced their desirability.

Study 3 examined a key individual difference moderator, which provided insight into which women drive the lipstick effect. Life history theory predicts that there are individual differences in people who prioritize immediate reproduction vs. future reproduction. This literature points to a particular individual difference: experiencing *earlier pubertal development* is considered to be a physiological marker of favoring immediate over future reproduction (Ellis 2004). We therefore predicted that cues to economic uncertainty would produce the strongest lipstick effect for women who had earlier – compared to later – pubertal development.

Conceptually replicating the first study, Study 3 found that economic uncertainty led women to be *less* interested in products that do not enhance appearance. Conversely, economic uncertainty led women to be *more* interested in products that do enhance appearance. Critically, the increased desire for beauty product was driven by women experiencing earlier pubertal development. This means that women who underwent puberty at earlier ages were especially likely to respond to economic uncertainty by wanting beauty products.

These studies provide the first experimental evidence of the lipstick effect. We show that while cues to economic recessions lead to a diminished desire for most types of products, recession cues increase women's desire for products that can enhance attractiveness. This research provides novel insight into how and why economic recessions influence women's consumer preferences.

Paying More for "Us" In Times of Crisis: Economic Downturns Increase the Need to Belong

EXTENDED ABSTRACT

Conventional wisdom holds that during economic downturns consumers react by economizing: they spend less and they defer expenses (Katona 1975). For instance, in times of economic crisis consumers become more price conscious, buying more private label products and discounted goods. Thus, when an economic crisis hits, governments and companies tend to focus on providing financial and economic incentives aimed at promoting consumption. During the most recent economic crisis, for example, governments subsidized housing and reduced the cost of borrowing, attempting to promote spending. Likewise, Sam's Club introduced a program to facilitate loans for shoppers of up to $25,000.

Although these economization strategies may help consumers to deal with the effects of an economic crisis on their personal finances, they do not necessarily help manage the psychological implications of a crisis, such as feelings of threat and fear. Psycho-

logical research suggests that a natural reaction to cope with the self-threatening consequences of an economic crisis is an increase in the need to be connected with others. When people feel threatened, they seek the support of others. From an evolutionary perspective, social connections are devices of self-preservation linked with an increased safety in numbers as well as with an improved ability to gather food and to obtain empathy of social groups. Given the potential advantage of sharing resources, and the competitive disadvantage of the lone individual if other people are in groups, social groups confer protection and survival benefits to their members (Kenrick et al. 2010). Consequently, threat and fear signals activate a desire for affiliation and social connectedness (Baumeister and Leary 1995). When experiencing an increased desire for connectedness, individuals tend to allocate their attention to social opportunities and try to build connections with others—both real others as well as "snack" on symbolic reminders of others (Gardner, Pickett and Knowles, 2005; Griskevicius et al. 2009).

This logic suggests that that when an economic crisis hits, the need for connectedness should increase, which should affect consumer choices. In the present research, we test the idea that cues of economic downturn might produce a higher preference and willingness to pay for products and advertisements that signal social connectedness, such as images of people or product popularity appeals. This suggests that in times of economic hardship, people might be willing to pay a premium for "we" products that signal social connectedness.

Study 1 manipulated economic recession cues by having participants read either a news story about the recent recession or a control story. Participants then indicated the attractiveness of, and their willingness to pay for, various advertised products. For half of the participants, the products were advertised with "me" slogans that focused on the consumer (e.g. "ready for you"); the other half of participants viewed ads with "we" slogans focused on social connectedness (e.g. "ready to share"). Findings showed that economic downturns led consumers to evaluated more positively slogans that positioned the product as being jointly usable instead of just for the self. Consumers were also willing to pay more for the products advertised as collectively usable.

Study 2 again primed either economic recession cues or control cues. Participants then evaluated products that were in two types of packaging: half of the packages showed multiple people, and the other half showed a single person. Findings showed that people in the economic crisis condition had a higher preference and were willing to pay more for products that featured pictorial cues of social connection (e.g. an image of multiple people) in their packaging.

Study 3 again primed either economic recession cues or control cues. Participants were then shown pictures of pairs of products together with a description about the price, quality, and percentage of consumers who preferred each of the products in the pair. In each pair the product described as preferred by a majority of consumers was also described as having a lower quality and a slightly higher price than the less popular product. Findings revealed that economic recession cues increased desire for products with popularity appeals (e.g. "60% of consumers preferred this product"), even leading people to choose the popular products when it was the most expensive and lowest quality alternative.

Taken together, these findings suggest that in times of economic crisis, consumers' need to belong is increased and therefore their preference for social connecteness products increases. A better understanding of the effect of fundamental needs, such as the need to belong, on consumer spending in face of economic contractions is important to further understand consumer reactions to economic downturns. For marketers, understanding how fundamental needs, in particular the need to belong, affect consumer spending patterns could help them sharpen and rethink the value they provide to consumers in times of economic uncertainty. Additionally, a policy-relevant insight of this research is that factors like social belonging can help promote consumer spending and thus economic recovery, while avoiding some of the risks associated with economic incentives. For example, the traditional approaches of focusing on economic incentives to stimulate the economy have the risk of slowing economic growth further if falling prices and retailer promotions lead consumers to delay purchases in the expectation of additional promotions and price cuts.

Does Economic Uncertainty Lead People to Save or Splurge? It Depends on One's Childhood Environment

EXTENDED ABSTRACT

How do economic recessions influence desire for immediate rewards, such whether people splurge on the lottery? Examining the effect of the most recent economic downturn on U.S. state lottery sales shows mixed results, averaging to a null effect of the recession on lottery sales (Cousins 2009). Published research also paints a mixed picture. One study, for example, showed that lottery sales increase as unemployment goes up (Mikesell 1994), but another study found that unemployed individuals tend to be risk-averse (Diaz-Serrano and O'Neill 2004). Summarizing the average effect of recessions on lottery spending, Clyde Barrow, the director of the Center for Policy Analysis at the University of Massachusetts, observed in a recent interview that in economic downturns, "lottery sales are typically flat" (Saldinger 2009).

We propose that there may be more to this flat effect on lottery spending—and on intertemporal choice and financial decision-making more generally—than initially meets the eye. We examine how economic uncertainty influences intertemporal choice, saving, and borrowing. To address this question, we draw on the framework of life history theory (Stearns 1992). Life history theory (LHT) was originally developed in evolutionary biology and behavioral ecology, but is now increasing being applied to study human behavior.

According to a life history framework, individuals, including humans, can follow a variety of different life history strategies. Life

history strategies exist along a slow-to-fast continuum (Promislow and Harvey 1990). Slower strategies are associated with reproducing at a later age and having fewer offspring. Faster strategies have the opposite characteristics, being associated with reproducing at an earlier age and having more offspring. In addition to reproduction, each strategy is associated with a specific type of orientation toward the world. Faster strategists tend to be opportunistic in that they take more risks and desire immediate gratification for short-term benefits. In contrast, slower strategists tend to be long-term planners who take fewer risks and delay gratification for future payoffs (Nettle 2010).

Recent research has begun to test how experimentally priming people with cues of an unpredictable environment—a key determinant of life history strategies (Ellis et al. 2009)—influences outcomes related to fast and slow life history strategies. Findings show that the salience of unpredictability produces divergent life history strategies for different groups of people (Griskevicius et al. 2010). Unpredictability cues have a different effect on people who grew up in a relatively resource-scarce environment (e.g., "I felt relatively poor when growing up") than on those who grew up in a relatively resource-plentiful environment (e.g., "I felt relatively wealthy compared to the other kids in my school"). For lower childhood SES individuals, unpredictability cues led to a preference for earlier reproduction. This suggests that unpredictability cues shift people from lower-SES childhoods toward a faster strategy. Conversely, for individuals who grew up in higher-SES environments, the same cues led to a preference to delay reproduction, consistent with shifting to a slower strategy.

The current research examine how cues to resource unpredictability (i.e., economic recessions) influence intertemporal choice. As discussed earlier, faster life history strategies are associated with desiring immediate rewards, whereas slower strategies are associate with delaying gratification for future payoffs. Thus, building on previous research highlighting the importance of childhood environment (Griskevicius et al. 2010), we predicted that individuals who grew up in relatively resource-scarce environments would respond to economic uncertainty cues by value the present. In contrast, individuals who grew up in relatively resource-plentiful environments should respond to economic uncertainty cues by valuing the future.

Study 1 examined how economic uncertainty influenced intertemporal choice. Participants read a news story about either the recent economic recession or a control story. Participants then made a series of financial choices in which they chose between receiving a reward tomorrow or receiving a larger reward in the future (e.g., $31 tomorrow vs. $50 in 2 months). The study had real monetary incentives, meaning that participants would actually receive their chose reward for one of their choices.

Findings showed that economic recession cues had a different effect on people as a function of their childhood environment. The salience of economic uncertainty led people who had higher-SES childhoods to value the future, increasing their likelihood of choosing the larger, later reward. Conversely, economic uncertainly cues led people who had lower-SES childhoods to value the present, increasing their likelihood of choosing the smaller, immediate reward.

Study 2 used a different manipulation of economic uncertainty, where people saw a slide show of images depicting a recession or a control images. Participants then indicated their desire to save money for the future and their desire to borrow money for immediate expenditures. Conceptually replicating findings from the first study, results showed that economic recession cues had diverging effects as a function of people's childhood SES environments. Economic uncertainty led people who had higher-SES childhoods to want to save money for the future and not go into debt. Conversely, eco-

nomic uncertainly cues led people who had lower-SES childhoods to decrease savings and increase desire to borrow money for immediate expenditures.

Study 3 attempted to extend the findings from the first two studies by examining the hormonal mechanism by which economic uncertainly cues influence intertemporal choice. Preliminary findings show individuals from lower-SES backgrounds respond to economic uncertainty with increases in both Testosterone and increases in Cortisol. This suggests that lower-SES childhood individuals respond to resource unpredictability by becoming both more action-focused and more anxious, consistent with desiring immediate rewards. Overall, these findings show how, when, and why economic uncertainty influences financial decisions related to intertemporal choice.

Financial Decision Making in Hard and Prosperous Times

EXTENDED ABSTRACT

Global and national economies alternate between hard and prosperous economic times. These business cycle fluctuations also influence individuals within the economy. For example, economic recessions are associated with poorer health (Bambra 2010). We propose that economic expansions and contractions influence consumer financial decision-making.

Financial decisions depend both on expected returns (i.e., potential benefits) and expected risks (i.e., potential costs; Mellers 2000; Raghubir & Das 2010). Although the achievement of financial benefits and avoidance of risk are often taken into account simultaneously, these concerns can be managed separately (Zhou & Pham 2004). For example, regulatory fit theory (Higgins 2000) states that individuals with a promotion focus (i.e., a self-regulatory focus on approaching desired opportunities) make decisions primarily on the basis of positive outcomes. In contrast, individuals with a prevention focus (i.e., a self-regulatory focus on the prevention of losses) make decisions based primarily on avoiding negative outcomes (Idson, Liberman, & Higgins 2004). While a promotion focus might be especially manifest itself during economic expansions, a prevention focus might be more pronounced during economic contractions.

Hence, we hypothesize that people should be predominantly drawn toward achieving gains during expansions, but especially drawn toward avoiding losses during economic contractions.

Study 1 examined whether cues to business cycle fluctuations influence likelihood estimates of financial outcomes. Participants read a short scenario describing either an economic recession, prosperity, or a control condition. Afterwards, participants indicated the perceived likelihood of positive and negative outcomes of 8 financial investment decisions (e.g. "investing 5% of your annual income in a very speculative stock"). Participants indicated for each decision the chance of both a positive and a negative outcome. Findings showed that the perceived likelihood of a negative outcome is higher in the contraction than in the expansion and the control condition. However, the perceived likelihood of a positive outcome is higher in the expansion than in the recession and the control condition.

Study 2 aimed to demonstrate behavioral consequences of business cycle fluctuations. Participants were again primed with cues to an economic recession, expansion, or control cues. Then, participants made a series of financial choices related to gains or related to losses based on Hsee and Weber (1999). Each question offered a choice between a safe and a risky option. In the gain set, participants could receive money, while in the loss set they could pay fines. Consistent with Study 1, findings showed that people became more risk-averse for losses in the contraction condition. However, people become more risk-seeking for gains in the expansion condition.

Study 3 used a time-series methodology that mirrored the experimental studies. Findings showed that consumption of financial products that are especially focused on the achievement of gains (i.e. gambling) or the prevention of losses (i.e. purchase of insurances) covaried with the business cycle in the predicted fashion. Gain achievement focused consumption is affected by expansions, but not by contractions, whereas loss prevention focused consumption is affected by contractions, but not by expansions.

In sum, the present set of studies provides support for the hypothesis that business cycle fluctuations selectively influence financial decision-making. We provide causal evidence that cues of business cycle fluctuations influence financial decision making (studies 1 and 2) and investigated the relationship between financial decision making and business cycle fluctuations over a substantial time period, making use of real consumption behavior over several business cycles (study 3). Our studies suggest that business cycle fluctuations might trigger different motivational systems that affect financial decision making.

SESSION OVERVIEW

Many marketers consider the expression "sex sells" to be a self-evident maxim. Sex and money have been a ubiquitous marketing power-pair for nearly a century. Modern consumers are inundated with sexual images and messages. From billboards to storefronts, from media advertising to media content and programming, from magazine covers to music, art, sports, and most types of entertainment, sexual cues pervade the modern world. From a marketing perspective, the connection between sex and money is not surprising: Many people are innately drawn to sexual cues, making them an effective method for attracting consumers' attention. More surprising, however, is that considering the omnipresence of sex and money in our environment, so little research has examined how sexual cues and mating concerns actually influence financial decisions.

The four papers in this session all present emerging research examining how, why, and when sex influences financial decisions. The first paper examines how women's sex hormones associated with the monthly ovulatory cycle influence economic decisions. The second paper examines how sex ratio—the ratio of men to women in the environment—influences saving, borrowing, and spending. The final two papers examine how sex cues in the environment influence financial risk-taking for men (paper 3) and for women (paper 4). Taken together, the session presents a deeper understanding of when, why, and how sex does and doesn't sell.

The first paper by **Durante, Griskevicius, Cantu, and Simpson** investigates how the monthly ovulatory cycle influences women's choices in the Dictator Game. They find that the effects of ovulation depend on whether women are playing against a man or a woman. Ovulating women gave significantly more money to attractive men, but ovulating women gave much less money when playing against attractive women.

Griskevicius and Ackerman examine how the ratio of men to women in the environment—known as sex ratio in animal behavior—influences saving, borrowing, and spending. They find that male-biased sex ratios (a scarcity of women) lead men to discount the future, decreasing savings and increasing borrowing for immediate expenditures. A scarcity of women also increased expectations that men will spend more during courtship.

Van den Bergh and Millet examine how sexual cues influence men's preferences for financial risk. They show that sexual cues produce financial risk-aversion, leading men to take a bird in the hand rather than two birds in the bush. Sex cues essentially cause men to prefer certain (but smaller) gains over uncertain (but larger) gains.

Finally, **Li, Kenrick, and Neuberg** examine how mating cues influence women's financial decisions. They find that mating cues generally don't influence women's financial risk preferences. However, mating cues do lead women to become more financially risk-seeking when the monetary choices can serve as a signal to specific audiences.

Overall, this session builds connections by addressing an important theoretical and practical question—the relationship between sex and financial decisions. Two of the papers aim to answer the basic question of how sex cues influence financial decisions for men and for women, and the two other papers elucidate on these effects by examining hormonal mechanisms and by examining more complex sex cues that include the ratio of men to women. As such, the session would be of interest to a breadth of consumer researchers, including those interested in sexual advertising, hormones, financial decision-making, risk, intertemporal choice, and evolutionary approaches to consumer behavior.

Ovulatory Cycle Effects on Women's Financial Decisions in Economic Games

EXTENDED ABSTRACT

Emerging research in evolutionary biology shows that women's psychology and behavior changes during the brief window each month when women are fertile—the days around ovulation. These hormonally-regulated shifts have traditionally been believed to be linked to mating. For instance, women's mate preferences non-consciously shift around ovulation toward desiring men who show classic biological indicators of male genetic fitness, such as facial symmetry and social dominance (Gangestad and Thornhill 2008). Women are also more likely cheat on their relationship partner when they are ovulating (Gangestad et al. 2002).

More recent research has begun to uncover that the ovulatory cycle doesn't just influence mating. Instead, ovulation also appears to regulate behaviors linked to same-sex competition with rivals. For example, women's clothing choices non-consciously shift around ovulation toward sexier and more revealing outfits (Durante et al. 2011). This hormonally-regulated shift is not related to appearing more desirable to men, but is instead driven by trying to outcompete rival women (Durante et al. 2011). Such same-sex competition effects for ovulating women parallel findings in many non-human primates. For example, ovulation is known to lead primates to become more aggressive and competitive with other females (Wallen 1995).

The current research examined how the ovulatory cycle influences women's financial decisions in economic games. We investigated whether ovulating women might become more generous or more competitive when splitting money among themselves and another person. Given that previous research shows that the ovulatory

cycle has independent effects on mating and on same-sex competition, we hypothesized that ovulation would have a different effect depending on whether women were exchanging resources with a man or with a another woman. We predicted that ovulation should lead women to be more fair and generous when splitting resources with a desirable man. In contrast, we predicted that ovulation should lead women to be more competitive and spiteful when splitting resources with an attractive woman.

Study 1examined how the ovulatory cycle influenced women's decisions between making "equitable" versus "competitive" financial offers to another person. Using a modified version of the Social Value Orientation inventory (Van Lange 1999), participants were presented with the following hypothetical options: (A) You get $480, other person gets $480; (B) You get $280, other person gets $80. Whereas option A represents an equitable split, option B represents a competitive split. Choosing option B signifies that a person is willing to take less money for themselves so that the other person receives an even lesser amount.

Participants were told that the other person is either an attractive man or an attractive woman. To determine whether women were ovulating, we used an established counting method (Haselton and Gangestad 2006). Findings showed that when the exchange partner was an attractive man, ovulating women were more likely to choose an equitable split. However, when the exchange partner was an attractive woman, ovulating women were more like to choose the competitive option. This means that ovulating women were willing to take less money for themselves as long as another attractive woman received even less money.

Study 2 extended these findings by having ovulating and non-ovulating women play the Dictator Game using real money. Using a more stringent methodology, ovulation was confirmed using urine hormone tests. Female participants were assigned to the role of Proposer in the Dictator Game. They were given $5, and their task was to dictate how to split the money between themselves and another person. The women would get to keep the amount of money they left for themselves, and this amount was not contingent on the other person, meaning that they could give as much or as little as they wanted.

Women were paired in the game either with an attractive woman or an attractive man. When women were not ovulating, they gave about 40% of their monetary endowment to the man and the woman. When women were not ovulating, women's decisions were similar regardless of whether they were playing a man or woman. However, ovulation had drastic effects. When playing with an attractive man, ovulating women's giving went up to 72% of their endowment, meaning that some women gave more than half of the money to the man. In contrast, when playing with an attractive woman, ovulating women's giving went down to 17% of their endowment. This means that while ovulating women become more generous when playing with a man, they became more spiteful when playing with an attractive woman.

These studies provide the first evidence that economic decisions are influenced by the ovulatory cycle. Results of both studies support the idea that women use financial decision both for purposes of courtship and for purposes on intra-sexual competition, become more intra-sexually competitive near ovulation.

The Influence of Sex Ratio on Saving, Borrowing, and Spending

EXTENDED ABSTRACT

The ratio of males to females in a population is known to be an important factor in determining animal behavior. Animal research shows that imbalanced sex ratio tends to have the strongest effects on male behavior. The most commonly observed pattern is that what females become scarce (male-biased sex ratio), males intensify competition and invest in immediate mating effort. For example, as sex ratio shifts from female-biased to male-biased, male grey mouse lemurs allocate more effort on mate search and courtship (Eberle and Kappeler 2004). Similarly, male European bitterlings intensify intra-sexual competition over mates when females become scarce (Mills and Reynolds 2003).

Sex ratio also varies in human populations. For example, whereas Las Vegas, Nevada, has 1.16 men per every woman, Birmingham, Alabama, has 0.88 men per every woman (Kruger 2009). Sex ratios can also vary between nations. Multiple Asian countries have recently become strongly male-biased. In the most striking case, China will soon have a surplus of over 40 million men, producing an adult sex ratio of over 1.2 men for every woman (Hesketh 2009).

Correlational research at the population level has begun to examine how sex ratio relates to various human behaviors (Guttentag and Secord 1983). Paralleling findings in animal behavior, a scarcity of women in human population is associated with increased competition. For example, male aggression and violence increase as populations become more male-biased (Barber 2003), whereby men amplify competition and immediate mating effort when there is a scarcity of women.

We hypothesize that sex ratio may have a much broader impact on human behavior, affecting many critically important areas of human life, including financial decision-making. Because a male-biased sex ratio is expected to shift men toward prioritizing immediate mating effort and competition, shifts in sex ratio may influence men's desire for immediate monetary resources, which can then be used for expenditures on mating effort and competition.

In Experiment 1 participants viewed photo arrays of men and women that were ostensibly indicative of the local population. The arrays were either male-skewed, female-skewed, or equal sex ratio (control). Then, participants made a series of financial choices involving real monetary incentives. For example, people chose

between receiving $37 tomorrow versus $54 in 33 days. Findings showed that sex ratio had no effect on women's intertemporal choice. For men, however, sex ratio produced a large effect. As predicted, a male-biased ratio led men to opt for immediate financial rewards when compared to either a female-biased or an even sex ratio. This means that as women become scarce, men desired immediate monetary rewards.

In Experiment 2 participants read news articles describing the local population as either male-biased or female-biased. Participants then indicated how much money they would save each month from a paycheck, as well as how much money they would borrow each month for immediate expenditures. Findings showed that sex ratio again had no effect on women's financial desires. However, male-biased sex ratios led men to save less money, cutting their monthly savings by 42%. Male-biased sex ratios also led men to want to borrow 84% more money for use toward immediate expenditures.

Whereas the first two experiments examined how sex ratio influenced the desire to acquire immediate monetary resources, the third experiment investigated whether sex ratio has parallel influences on how monetary resources are spent. Recall that in both human and non-human animals, male-biased sex ratios are associated with increased investment by males in mating effort. Thus, if men value immediate financial yields under male biased sex-ratios as a means of attracting mates, then men should be expected to spend more on mating-related expenditures when the sex ratio is male-biased.

Experiment 3 examined how sex ratio influenced the amount of money people expected men to pay for three mating-related expenditures: a romantic Valentine's Day gift, an entrée for a dinner date, and an engagement ring. Because females become choosier and males invest more in mating effort under a male-biased sex ratio, we predicted that men would be expected to pay more for the same mating-related expenditures when women were scarce. Supporting predictions, findings showed that when the sex ratio was male-biased, men were expected to pay $6.01 more for a Valentine's Day gift, pay $1.51 more for an entrée on a dinner date, and pay $278 more for an engagement ring.

Our findings highlight people's sensitivity to a particular feature of the social environment—the ratio of adult men to women. Just as sex ratio has important effects on animal behavior, we find that sex ratio has theoretically consistent effects on human behavior. However, the effects of sex ratio on humans are not limited to the traditional domains of study, which include mating, parenting, and aggression. Instead, sex ratio also appears to influence other life domains that may be even more relevant to daily behavior.

Men, Sex, and Risk: Turning Up the Heat on Men's Financial Decisions

EXTENDED ABSTRACT

In this research we address a basic question: Do sexual cues lead men to prefer more financial risk or less financial risk? For example, does interacting with an alluring woman—or merely seeing an ad with a sexy model—lead men to be safer with their money or to gamble? At first glance, the answer to this question might appear obvious. Not only do sexual cues lead to impulsivity (Van den Bergh, Dewitte and Warlop 2008), but sexual arousal has been linked to risk-proneness. For instance, sexually aroused men report a greater willingness to engage in risky sexual activities (Ariely and Loewenstein 2006), and exposure to images of nude Playboy models leads men to be more willing to behave in a sexually forceful manner (Loewenstein, Nagin and Paternoster 1997).

Drawing on research on how decision-making is influenced by cold and hot psychological systems (Metcalfe and Mischel 1999), we propose that sexual cues produce a tendency to maximize the probability of monetary rewards. When the cold, cognitive system is compromised (e.g., people are unable to deliberate), people prefer smaller, certain rewards over larger, risky rewards (Whitney, Rinehart, and Hinson 2008). We hypothesize that activating the hot spots of the affective system, rather than overloading the cool nodes of the cognitive system, leads to financial risk-aversion. We therefore predict that sexual cues should not lead men to become more financially risky, but instead, cause them to become financially risk-averse.

In Experiment 1 we manipulated sex cues by having the same female research assistant wear either plain/unrevealing attire or wearing revealing/sexy attire. Participants then made a series of financial choices between safe (certain) vs. risky (uncertain) financial options. For example, do you prefer to: Receive $70 for sure or 50% to receive $200. Findings showed that men chose the certain option more often after exposure to a research assistant in sexy clothing than after exposure to the same research assistant in plain clothing.

The next study extended these findings by examining a key individual difference moderator. We hypothesize that sexual cues lead men to choose certain options because sexual cues activate a general reward-seeking system that seeks immediate gratification. If so, we predicted that the effects of sex cues should be strongest for men who have a sensitive reward system. In Experiment 2 sex cues were manipulated by having male participants inspect and touch either a T-shirt or lingerie. Then, participant engaged in a probability discounting task, allowing us to assess preferences for financial risk. The sensitivity of the general reward-seeking system was assessed via an established individual difference measure (Torrubia et al. 2001). Findings again showed that sexual cues led to a preference for smaller, certain rewards over larger, uncertain rewards. In addition, this effect was moderated by the sensitivity of people's reward system. As predicted, the effect was most pronounced among men with a sensitive reward system, but become weaker for men with a less sensitive reward system.

We hypothesize that sexual cues should produce a desire to maximize the probability of monetary rewards. This means that the sexual system should play a critical role in evaluating *certain* rewards but less so in evaluating merely *probable* rewards. In Experiment 3, sexual cues were manipulated by having male participants

view photos of women who were either wearing unrevealing clothing or wearing a swimsuit/lingerie. Participants then engaged in a probability discounting task that included a safe and a risky prospect. Findings showed that exposure to bikini models led to a higher valuation of smaller monetary rewards in the certain condition, but not in the risky condition. That is, sexual cues instigate risk aversion only when a sure prospect could be obtained.

Using varied methodologies to enhance validity and generalizability, in three experiments we found that sex cues led men to be financially risk-averse. In addition, we tested two key

moderators of this predicted effect that provide insight into the underlying mechanism. This

research not only shows how, why, and when sexual cues influence risky financial decisions,

but it also contributes to a growing body of research documenting that a desire for a reward in one domain (e.g., sex) influences decisions about rewards in other domains (e.g., money).

Women, Sex, and Risk: Mating Motivation and Financial Risk-Taking in Women

EXTENDED ABSTRACT

Little is known about how mating cues influence women's behavior. The current research examined how mating cues affect women's financial risk-taking. There is little reason to believe that mating cues by themselves will influence women's preferences for risk. Indeed, mating cues seldom influence female choice patterns (e.g., Wilson and Daly 2004; Roney 2003). Nevertheless, to the extent that financial decisions may function to alter others' perceptions, underlying psychological systems regulating financial decision-making may be sensitive to the presence of others (Bateson et al. 2006; Burnham and Hare 2007; Haley and Fessler 2005). The lack of effects of mating cues on female choice in prior research may therefore stem from

failing to take into account potential audience effects. The present research addresses this shortcoming by taking into account both mating motivation and audience effects among female decision-makers.

In Study 1, mating cues were manipulated by having participants read a guided visualization scenarios designed to elicit either a mating motivation or no motivation. Then, participants were assigned to one of two audience conditions. Those in the no-audience condition were told they were randomly selected not to share their answers with anyone and were reminded that their answers would be completely anonymous. Participants in the audience condition were told they were randomly selected to share their answers with two men and two women completing the same study in other rooms in the lab. Participants then made three decisions, choosing for each a sure gain (e.g., $10 for sure) or a chance of gaining more money accompanied by a risk of gaining nothing (e.g., a 90% chance of getting $15 and a 10% chance of getting nothing). Findings showed that a mating motivation did not influence women's risk when choices were anonymous. However, women became riskier in the mating condition when they thought they were going to be sharing their answers with an audience.

Because the audience condition in Study 1 involved a mixed sex audience, it is not clear for whom the participants were displaying riskiness. That is, women could have been displaying their riskiness to members of their own sex. Or, women could have been displaying riskiness to members of the opposite sex. Alternatively, it is possible that women only engage in financial risk-taking when both potential mates and competitors are present.

In Study 2, we aimed to explore this question by employing a more comprehensive array of possible audience compositions. The mating motive manipulations were the same as in Study 1 (mating versus control scenarios), but four audience manipulations were included. In the no audience condition, participants were told their answers would be completely anonymous. In the all-female condition, participants were told they would be sharing their answers with four women. In the all-male condition, participants were told they would be sharing their answers with four men. And in the mixed-sex condition, participants were told they would be sharing their answers with two men and two women. Financial risk-taking was measured using the same items as in Study 1. Results revealed that there was only one condition in which mating motives led women to take more financial risks – when they were in the presence of a mixed-sex audience.

Taken together, these studies reveal that a mating motivation by itself did not influence women's financial risk preferences. However, a mating cue in conjunction with an audience did lead women to take more financial risks. The second study revealed that an all-male or an all-female audience does not appear to elicit more risk. Instead, in both studies it was only when a mixed-sex audience was introduced that women took more risks. Therefore, the present findings suggest that two distinct processes might be driving female financial decision making: Intrasexual selection and intersexual selection. Intrasexual selection involves competition between members of the same sex for mating access to members of the opposite sex. Intersexual selection, in contrast, involves preferential choice exerted by members of one sex for members of the opposite sex. Mating motivation increased the willingness to take financial risks only when female rivals could be outdone (intrasexual selection), and at the same time mates could be secured (intersexual selection). If one of these conditions is not met (e.g., rivals cannot be outdone or opposite sex individuals are not around), women appear to adopt a risk-avoidant strategy and do not experience a need to engage in financial risk seeking.

Nicholas Lurie, Georgia Tech, USA

Paper #4: Persuading Others Online: The Consumer as Media Planner
Yu-Jen Chen, University of Maryland, USA
Amna Kirmani, University of Maryland, USA

SESSION OVERVIEW

General orientation and objectives: Research on online WOM has shifted from a focus on the role of consumers as information providers to a focus on why consumers talk about product experiences on the Internet. We examine how motivation affects consumers' online posting decisions and how posting impacts both message posters and receivers, to better understand the new world of online interpersonal communication. The objective of this session is to study the relationship between the antecedents (e.g., motivation, consumption experience, target audience, and temporal proximity cues) and consequences of online posting on both posters' behavior (e.g., online or offline, linguistic mimicry, posting frequency, where to post) and readers' perceptions (e.g., perceived helpfulness and inferred poster's motive).

Issues and topics to be covered: All four papers share a common focus on deepening our theoretical understanding of factors that influence consumers' online posting behaviors, and how these behaviors influence downstream WOM effectiveness. Specifically, these papers focus on the role of motivation in affecting online WOM senders in terms of why they talk (papers 1, 2, 3, and 4), what they talk about (papers 2 and 3), and where they talk (paper 4). Each paper has a unique perspective on these topics.

The first paper, by Berger, examines whether there are different drivers of online and offline WOM. It proposes that online WOM requires a higher threshold for discussion, so there is a stronger link between whether something is interesting and whether it gets talked about online rather than offline. The second paper, by Moore and McFerran, introduces the notion of linguistic mimicry in online WOM and shows that copying others' language use is dependent on whom forum posters are conversing with. Specifically, posters are more likely to mimic similar forum members than dissimilar others. Similarly, the third paper, by Chen and Lurie, investigates posters' language but focuses on how readers infer posters' motives by temporal proximity cues in a review (e.g., "today" or "just got back"). They show that when these cues are present, readers may infer that poster's have a self-enhancement motive, which attenuates perceived helpfulness of a negative review. The last paper, by Chen and Kirmani, discusses how posters with an influence motive (e.g., self-enhancement or persuasion) make their decision of *where* to post on an online discussion forum. The results provide initial evidence that posters, depending on their message valence and consumption

benefit, will use persuasion knowledge in strategically choosing a forum to maximize their impact.

These papers address commonalities and differences in the antecedents and consequences of online WOM, and build connections by providing a more complete picture of online WOM. This session will benefit WOM researchers by showing why, how, and where consumers share their experiences on the Internet, and will provide suggestions for marketing practitioners for developing strategies that encourage customers to talk about their experiences.

Potential audience: The session will appeal to researchers interested in the antecedents and consequences of WOM (online and offline) and more generally, to those interested in motivation, social influence, communication, and persuasion.

Potential contribution: This session makes theoretical contributions to research on WOM communication in marketing. While these four papers all feature factors related to posters' motivation, each takes a unique perspective to explain the role of motivation in shaping diverse subsequent behaviors. Taken together, these papers substantively deepen our understanding of the role of different components in WOM and how each relates to the others.

State of completion: Data have been collected for the studies described in all four papers.

Different Drivers of Online and Offline Word of Mouth

EXTENDED ABSTRACT

Word of mouth is frequent and has an important impact on consumer behavior. Consumers talk about new running shoes, write reviews about bad hotel stays, and share information about the best way to get out tough stains. But while recent research has shown that word of mouth (WOM) impacts everything from the products consumers buy to the drugs doctors prescribe, this research has treated different types of WOM (e.g., online reviews and face-to-face discussions) as the same. But are the factors that drive people to share online WOM (e.g., reviews, blog postings, and product ratings) the same as those that drive them to have face-to-face discussions, or might there different factors drive online and offline WOM?

Looking across prior papers hints at an intriguing possibility. More interesting *New York Times* articles are more likely to make the most emailed list (Berger & Milkman 2011). In contrast, however, more interesting products do not get any more face to face word of mouth (Berger & Schwartz 2011). These two papers relied on different datasets that used different subject populations, making it hard to directly compare their results, but might it be the case that interest plays a different role in online and offline WOM?

We suggest that there are some important differences in psychological drivers of online and face-to-face WOM. In particular, we suggest that face-to-face interactions may have a lower threshold for discussion. It is awkward to have dinner with a friend in silence, or ride in a cab with a colleague without conversing, and so few things will be deemed too boring to talk about. In a sense, the outside option is to not talk at all, and talking about anything is better than that. With online WOM, however, the threshold for discussion is often higher. Most decisions to post a review or share a news article are not driven by the need to fill conversational space, but by the belief that there is useful or interesting information to be passed along. Con-

sequently, factors like interest may have a greater impact on online transmission. While more interesting products (e.g., iPads or Hollywood movies) may get more online WOM than their less interesting counterparts (e.g., Walmart and toasters) these types of products may get similar amount of offline WOM.

Carefully studying this possibility is hampered, however, by data availability. One could imagine comparing the relationship between the amount of interest a brand evokes and the amount of WOM it receives online and offline, but aggregate data introduces selection issues. If certain types of people are more likely to share WOM online, than it might be those doing the talking, rather than the channel, that is driving any observed patterns in online vs. offline data.

We avoid this difficulty by using a unique individual level dataset from the WOM marketing firm KellerFay. It contains over 35,000 brand and product mentions from a nationally representative sample of approximately 6,000 people who recorded all the WOM they shared, as well as the channel they shared it through (e.g., face to face or online) over a one day period. By looking people that talk both online and off, and controlling for variation at the individual and product levels, we can examine the causal impact of channel (i.e., online vs. offline) on WOM.

We compiled a list of all the brands and products mentioned by the survey respondents and then had independent raters code them based on how interesting each product or brand would be to talk about (1 = not at all, 7 = extremely). Different raters' ratings were highly correlated ($r = .68$) and we averaged across raters to create a product interest score for each product. We then examined how this related to online and offline WOM.

Consistent with our theorizing, results indicate that interest plays a different role in driving online and offline WOM. While more interesting products received more WOM online than less interesting products ($p < .01$) there was no relationship between interest and face-to-face WOM ($p > .70$). Further, to ensure that our results were not driven by outside raters rating how interesting the products were, we also conducted a follow-up study (Study 2) where participants recorded what they talked about in a given day but then rated interest themselves. We find the same results. While more interesting products get more online WOM than more boring ones, there is no relationship between interest and offline WOM.

Taken together, these two studies deepen our understanding of the drivers of word of mouth. While a great deal of research has shown that WOM has important consequences, less is known about why people talk about and share certain things rather than others. Accordingly, this work shows that there are some important differences in what leads people to talk face to face versus share things online.

Linguistic Mimicry in Online Word of Mouth

EXTENDED ABSTRACT

New digital media has changed WOM radically in terms of how and with whom consumers share consumption experiences. We now converse with thousands of other consumers through online forums, email, text messages, and websites such as Amazon.com. There are documented consequences of WOM for firms and consumers (Chevalier and Mayzlin 2006). However, past work has not focused on WOM as a conversation (only as a single interaction; but see Cowley 2007) or on how *specific* language use in WOM impacts consumers (Moore 2012). We address these gaps in the literature by introducing *linguistic mimicry* to consumer research. This allows us to break down language into specific parcels and to examine how mimicking WOM language (and being mimicked) affects the flow and content of online interactions.

Linguistic mimicry measures how closely individuals match others' word use in conversation. New software can calculate linguistic mimicry between two or more individuals engaged in conversation in terms of style (e.g. article, pronoun, conjunction use) and content (e.g. use of emotional, cognitive, social words) (Pennebaker et al. 2007). As with behavioral mimicry (e.g. mannerisms, talking speed), linguistic mimicry acts as a "social glue" that both reflects and creates bonds between people. For example, higher levels of linguistic mimicry increase romantic interest between individuals who are speed dating (Ireland et al. 2011) and increase group performance and cohesion (Gonzales, Hancock, and Pennebaker 2010). However, work in this new area is largely correlational, and has examined neither the consequences of mimicry in a marketing context, nor variables that predict linguistic mimicry. Using field and experimental data, we examine the causal relations between social variables that predict mimicry, levels of linguistic mimicry, and consequences of mimicry.

We expect linguistic mimicry to be influenced by similarity; for example, forum members who live in the same location should mimic one another more than they should mimic those do not share this characteristic. In addition, mimicry should impact consumers' attitudes and behavior. Consumers should feel a greater sense of affiliation with those they mimic (Jefferis, van Baaren, and Chartrand 2003), which should increase posting frequency within a forum and information sharing outside the forum (e.g. Twitter). *Being* mimicked by others will also have important consequences. Individuals who are mimicked by similar others will likely feel more group affiliation and post more frequently, while those who are mimicked by dissimilar others will likely feel less affiliation and post less frequently. We examine these predictions in two studies, one using online forum data and a second using experimental data.

In study 1, we downloaded an entire product review forum from a parenting discussion site (1386 posts, 241 users). We coded how much personal information users disclosed about themselves (e.g. location, gender) and their children (e.g. gender, names, ages, or birthdates) in their profile, such that higher numbers indicate more disclosure. We also calculated how similar consecutive posters were to one another, personally (i.e. same gender or not) and in terms of their children (i.e. same gender or not). We then calculated mimicry of linguistic style (e.g. articles, pronouns) and content (e.g. cognitive words, emotion words) for consecutive posts; that is, how much an individual mimicked the post immediately prior to theirs. Personal similarity and self disclosure predicted mimicry. The more similar a poster was to the poster immediately preceding them, the less they mimicked this individuals' linguistic style (e.g. articles, pronouns) and cognitive word use, but the more they mimicked positive linguistic content (exclamation marks, assent words). Similar levels of self disclosure also predicted decreased mimicry of cognitive words as well as decreased mimicry of non-fluencies (e.g. uh, um).

In study 2, we extended the inquiry into a lab setting. We asked undergraduate seniors ($N = 102$) to think of a recent positive or negative visit to a well-know chain of coffee shops. Next, participants read a positive or negative online review of the chain, allegedly written by an undergraduate at another college (dissimilar) or at their college (similar); they then wrote a review of their own. In this study, participants' linguistic style and content mimicry was predicted by the interaction between similarity, participants' evaluations, and the other writer's evaluations. First, regardless of similarity, individuals were least likely to mimic linguistic style when the audience had positive but they had negative evaluations of the coffee shop. Con-

tent word use in terms of punctuation, cognitive, and social words, was predicted by similarity and evaluations. For example, participants showed less mimicry of cognitive words when they shared negative as opposed to positive evaluations with a similar audience. These differences in mimicry predicted important outcomes for participants in terms of their liking of the coffee shop and their liking of the other reviewer. Increased style mimicry increased participants' liking of their experience, while mimicry of social words decreased their liking. Most importantly, the more participants mimicked their audience's content words, the more they liked the audience.

We provide the first examination of linguistic mimicry in marketing. Using field and experimental data, we investigate the antecedents and consequences of linguistic mimicry; we find the first evidence that linguistic mimicry is predicted by whom one's audience is, and that mimicry has consequences for consumers' evaluations of their own experiences as well as their relationships with other consumers. Several other studies, involving both lab and field data, are in the planning stage. This project contributes to theory and methodology in both marketing and psychology, and will lead to important conclusions for managers as well as for consumers engaged in online WOM. Further, it should open the door for other research in this area.

Temporal Contiguity and the Negativity Bias in Online Reviews

EXTENDED ABSTRACT

Online Word-of-Mouth (WOM) is as an important information source for consumers (Chevalier and Mayzlin 2006). However, not all reviews have similar effects on consumer behavior. Although positive reviews tend to more prevalent than negative reviews (Fowler and Avila 2009), they have less impact than negative reviews on product sales (Chevalier and Mayzlin 2006) and evaluations (Herr, Kardes, and Kim 1991). While many have documented the disproportionate impact of negative information (Fiske 1980), little attention has been paid to factors that take away the negativity bias.

One explanation for a negativity bias in online reviews is that positive reviews are more likely to be seen as self-serving. In particular, readers may infer that the writers of positive reviews are trying to feel good about their purchase decisions and demonstrate their good taste. Writers of highly positive reviews may also be seen as less discerning (Schlosser 2005). In other words, positive reviews are less likely to be seen as "caused" by the product or service experience. Negative reviews, on the other hand, are more likely to be viewed as caused of the reviewer's experience since there are less self-serving reasons to write negative reviews. This suggests that cues that enhance the causal connection between product or service experiences and the review should increase the perceived usefulness of positive reviews.

Attributions of causality are often based on temporal contiguity between input and output events (Michotte 1963). For example, perception of causality between two physical events (e.g., ball A hitting ball B and ball B moves) is reduced when temporal contiguity is missing (Michotte 1963). This suggests that the presence of cues to temporal contiguity between product experience and product review will enhance the perceived usefulness of positive reviews. We test these ideas in three studies.

Study 1 examined the effect of temporal contiguity cues on the perceived usefulness of positive and negative reviews on a real website. Over 65,000 restaurant reviews were collected from the popular website Yelp. For each review, we used a computer program to determine the presence of keywords indicating temporal contigu-

ity. Hand coding a sample of 500 reviews showed that the computer program correctly coded over 90% of reviews. Review valence (1-5 stars, with 5 being best) served as the other primary independent variable of interest and the number of people finding the review helpful served as the dependent measure. In support of our predictions, a negative binomial regression shows that the presence of temporal contiguity cues moderate the relationship between review valence and usefulness. In reviews written without temporal contiguity cues, review usefulness is negatively related to review valence. However, in reviews written with temporal contiguity cues, there is a non-significant relationship between valence and usefulness.

Although the secondary data supports our predictions, one might argue that temporal contiguity cues decrease the usefulness of negative reviews rather than increase the usefulness of positive reviews as we have hypothesized. To examine this possibility, we conducted a lab study (Study 2a). Using a lab study also addresses potential self-selection issues in the secondary data. The lab study manipulated review valence at two levels (positive vs. negative) and also manipulated the presence of temporal continuity cues (present or absent) between-subjects. Participants were randomly assigned to one of the four experimental conditions in which they first read then evaluated a restaurant review. Results show that the presence of temporal contiguity cues significantly increased the usefulness of positive, but not negative, reviews. This provides evidence for the prediction that temporal contiguity cues increase the usefulness of positive reviews more than negative reviews.

An additional lab study (Study 2b) examined how temporal contiguity cues affect reader attributions. Respondents were randomly assigned to read one of the four reviews used in study 2A. After reading the reviews, review attributions of the causes for the review were measured on Likert scales. Confirming our proposals, participants felt more strongly that positive (versus negative) reviews were caused by the reviewer. In addition, the presence of temporal contiguity cues reduced attributions that reviews were caused by the reviewer for positive but not negative reviews.

Although the negativity bias is well documented word-of-mouth and other contexts, this research is the first to demonstrate a way to overcome this bias by changing consumer attributions about the motivations of word-of-mouth providers. In particular, simple textual cues to temporal contiguity can remove differences in the perceived usefulness of positive and negative reviews. Our examination of temporal contiguity cues in secondary data and lab studies documents and explains these effects.

Persuading Others Online: The Consumer as Media Planner

EXTENDED ABSTRACT

Although substantial research has studied *what* people post on the Internet, little attention has been paid to the question of *where* consumers post. In this paper, we examine how consumers decide where to post their consumption experience. We suggest that given the plethora of choices about where to post, consumers must become intuitive media planners for scheduling their online messages. As media planners, they must access their intuitive theories or persuasion knowledge (Friestad &Wright, 1994) about which type of website or forum may allow their post to achieve maximal impact.

We examine the posting choice of consumers whose motive is to influence others, either for intrinsic reasons, such as self-enhancement, or for extrinsic reasons, such as being hired by a buzz agent. We expect that an influence motive activates persuasion knowledge. Within the context of an online discussion website, we focus on the

decision of which specific forum to post in. We categorize forums into two groups: those with a more homogeneous audience with high brand loyalty (e.g., Nikon Forum), and those with heterogeneous audience with neutral attitude toward different brands (e.g., Digital Camera Open Forum).

We propose that consumers use persuasion knowledge to choose a forum based on two factors: valence of the post (positive or negative message) and the nature of the consumption experience (e.g., utilitarian or hedonic), both of which affect the post's ability to draw attention and convince others (Godes & Mayzlin, 2009). We propose that negative messages are likely to be more salient on homogeneous forums, while positive messages may be more salient on heterogeneous forums. In addition, the nature of the experience (hedonic vs. utilitarian) should moderate this effect. Specifically, while product evaluations that reflect utilitarian benefits are likely to focus on functional and objective attributes, product evaluations that reflect hedonic benefits are likely to focus on subjective experience (Sen & Lerman, 2007). As a result, a post of subjective but negative brand experience may be less convincing on a brand forum, where people are high in brand loyalty, than on a product category forum, where people have low brand loyalty and are more open to different opinions. Similarly, a post of subjective but positive experience may be highly supported on a brand forum rather than a product category forum.

We conducted three experiments to test our hypotheses. Study 1 tests the basic premise that influence-motivated posters will choose a different forum based on message valence after having a utilitarian consumption experience. All participants were asked to imagine they just purchased a Dell laptop with either positive or negative experience and they wanted to post their experience for one of the three types of influential motive: self-enhancement, persuasion, or reward-seeking. In the self-enhancement condition, participants were told that their goal was to choose a website such that "forum users will be interested in your post and consider you a knowledgeable expert". In the persuasion condition, the participants' goal was to choose a website such that "forum users' purchase decisions will be affected by your post". In the reward-seeking condition, participants were told that they were paid to post to make some impact. The results show that participants across all three influence motives preferred a homogeneous forum (Dell Review Forum) when posting positive experiences but preferred a heterogeneous forum (Computer Review Forum) when posting negative experiences. In addition, measures of persuasion knowledge revealed that participants made their choices based on the audience characteristics of the two forums.

Study 2 examined whether the type of consumption experience (utilitarian or hedonic) moderated the results. We assessed participants' focal consumption experience by measuring their relative interests in watching either a fun or useful cooking video. We then manipulated message valence by playing either a fun or useful video such that watching a matching video would lead to a positive review and mismatching videos would lead to a negative review. After writing the review, participants saw two forum options for posting and indicated their forum choice and relative preferences. A 2 (consumption experience) x 2 (message valence) ANOVA on relative preferences (1: Chef Forum - homogeneous; 10: General Cooking Forum - heterogeneous) revealed a significant interaction ($F(1, 130) = 8.79$, $p < .01$). Specifically, in the utilitarian conditions, the significant contrast between positive and negative valence replicated our finding in study 1 ($M_{positive} = 6.80$ vs. $M_{negative} = 5.51$; $F(1,130) = 4.49$, $p < .04$). In contrast, in the hedonic conditions, we found a significant contrast between positive and negative valence that flipped the pattern ($M_{positive} = 4.83$ vs. $M_{negative} = 6.45$; $F(1,130) = 4.43$, $p < .04$).

Study 3 further examined the process by manipulating posting motive as either to influence or to affiliate with others. The study showed that the predicted effects occurred only in the influence motive condition, suggesting that persuasion knowledge underlies these effects.

The paper makes two major contributions. First, to our knowledge, this is the first paper in the consumer behavior literature to consider where consumers post. Second, the paper demonstrates that consumers may act as intuitive media planners when posting their online messages. Thus, when they have an influence motive, they use persuasion knowledge to choose a posting forum that will be most effective in persuading others to their viewpoints. This extends the literature on persuasion knowledge to a media planning context.

Paper #4: From Blemishing to Blossoming: The Positive Effect of Negative Information

Danit Ein-Gar, Tel-Aviv University, Israel
Baba Shiv, Stanford University, USA

SESSION OVERVIEW

This session proposes that factors traditionally thought to weaken a message's delivery or content can actually enhance its persuasive appeal under specific conditions. In particular, using a powerful individual as a spokesperson, directly addressing an audience's questions, and including consistent or favorable arguments in a message have all been suggested or alluded to increase persuasiveness (for reviews, see Petty and Wegener 1998; Dillard and Pfau 2002). In contrast to these perspectives, the present session assembles papers that demonstrate circumstances under which the opposite, and more counterintuitive, outcomes hold. Papers 1 and 2 focus on message communication and examine how a communicator who feels powerless or provides evasive answers can actually be a better persuader. Papers 3 and 4 focus on message content and investigate when including inconsistent opinions or unfavorable product features increases persuasion.

Past work has equated effective communication with high levels of power (Kipnis 1972). However, Dubois et al. demonstrate powerlessness can heighten persuasiveness– provided the context highlights warmth, and/or that recipients value warmth. In their research, persuaders experimentally made to feel powerless displayed greater warmth, which spilled over their delivery style and increased success. Moving to another facet of communication – the art of answering questions – Rogers and Norton show that dodging questions can yield greater effectiveness than merely answering the question, when speakers respond to a question with answers that *seem* to address the question (e.g., stating a similar topic).

The final two papers examine situations under which adding counter-attitudinal information to a message's content can enhance its impact. Reich and Tormala examine how conflicting evidence influences message receptivity. Their data show conflicting messages can be more effective than consistent ones, provided the arguments presented are strong and/or the source is trusted. Ein-Gar and Shiv's work shows that providing consumers with positive information followed by a minor piece of negative information appears to enhance their overall evaluations of a target relative to providing exclusively positive information, but only when processing effort is low. These effects shed new insights into the "inoculation" view of persuasion by suggesting that including negative information can ironically make positive information more salient.

This session is of interest to a broad swath of consumer researchers and of special interest to those interested in communication, information processing, persuasion and social judgment. By providing a series of thought-provoking findings of when previously documented negative influences on persuasion can actually serve as benefits to persuasion, this session offers novel insights on persuasive processes and paves the road for future research.

Using Communicator Power to Foster Warmth or Competence

EXTENDED ABSTRACT

The choice of a spokesperson to promote an idea or a product is one of the most difficult yet important choice organizations have to make. Such a choice will likely guide recipients' favorable or unfavorable responses. From simple consumers to successful CEOs, one key feature on which spokespersons differ is their level of power – defined as perceived or actual control over resources or other people (Magee and Galinsky 2008). As a central basis of social hierarchy, power deeply permeates to individuals' everyday experiences through both chronic (e.g. one's socio-economic status) and momentary (e.g. choice of options) factors.

We propose that states of powerlessness and power systematically affect communicators' delivery style of persuasive appeals along two foundational dimensions of social judgments: warmth and competence (Cuddy et al., 2008). Where warmth captures how good-natured and trustworthy a communicator is perceived to be, competence refers to perceptions of skillfulness and confidence attached to a communicator. How might power affect communicator delivery style? Given research showing powerlessness increases one's ability to take others' perspective (Galinsky et al. 2008) and compassion (Van Kleef et al. 2008), states of powerlessness might enhance communicators' warmth. In contrast, given research linking power with action-orientation (Galinsky et al. 2003 and confidence (Briñol et al. 2007), power might enhance communicators' competence. If true, powerless communicators should be more persuasive than powerful and baseline communicators when advocating "warm" products or ideas (e.g. charities, see Aaker et al. 2010). Three experiments test these hypotheses and explore consequences for persuasion. Analyses used ANOVAs and t-tests as appropriate.

Experiment 1: Can powerless communicators trump powerful ones? Participants were divided into communicators and recipients. We manipulated communicators' power through an episodic recall task (Galinsky et al. 2003). Next, communicators wrote the promotional content of an ad appeal for a charity project (funding for a community bus) promoted by a ".org". Finally, we presented the ad to recipients, and gave them the option to donate money for the project. The ad was standard, except a portion of the copy executed by communicators whose power was manipulated. An ANOVA revealed a main effect of power, $p < .01$. Recipients gave $4.30 on average to low-power communicators, but only $1.74 to high-power communicators. In addition, communicators' perceived warmth mediated the amounts donated (95% CI = -.350; .096), suggesting powerlessness can yield more effective communication than states of power.

Experiment 2: Powerless candidate, but powerful president? Experiment 2 tested whether the acquisition of power changed communicators' expressed warmth versus competence. We randomly presented undergraduates with short seconds interview excerpts of

Barak Obama with the same interviewer performed when Obama was a candidate (i.e., not in power) or the president-elect (i.e., in power). The excerpts were cut from actual interviews by a research assistant blind to the hypotheses. Importantly, any information that could allow participants to know Obama's position at the time of the interview was removed (i.e., any sentence or action mentioning or implying he was a candidate or a president at the time of the interview). After viewing a series of excerpts, participants rated Obama' warmth and competence (α = .91 and α = .87, respectively; items from Cuddy et al., 2008). Obama was judged warmer when candidate than when president, $p < .01$, but more competent when president than when candidate, $p < .01$ regardless of participants' political affiliations, and despite the fact participants did not know whether Obama was president or candidate when the interview was produced. Thus, powerlessness (power) might foster communicator warmth (competence).

Experiment 3: Communicator's effectiveness as a function of Recipient Power. Our last experiment provides experimental evidence of the effectiveness of powerful and powerless communicators against different populations. That is, we reasoned that changes in power may not only affect communicators but also recipients' sensitivity to certain aspects of the communication in the same direction. Put differently, what states of high (low)- power foster at the delivery stage might also be what high (low)-power recipients weigh at the reception stage. If true, powerless communicators might be more effective against powerless recipients since those are particularly sensitive to warmth. In contrast, powerful communicators might be more effective against powerful recipients since those are particularly sensitive to competence.

Undergraduates were assigned to a 3 (communicators' power: baseline, low, high) × 3 (recipients' power: baseline, low, high) between subject design. Both communicators' and recipients' power was manipulated as in experiment 1. Communicators wrote a persuasive message promoting their university. These messages were then randomly presented to recipients who judged the message on three dimensions: persuasiveness, competence, and warmth. Results revealed high-(low-) power recipients found high-(low-) power communicators more persuasive than low-power (high-power) and baseline communicators. Among baseline recipients, there was no effect of power on persuasion. In addition, regardless of recipients' power, high-power communicators were judged as more competent than both baseline and low-power communicators. In contrast, regardless of recipients' power, low-power communicators were judged as warmer than both baseline and high-power communicators. Further analyses revealed competence (95% CI = .072; .703), but not warmth (95% CI = -.051; .198) mediated the effect of communicator's power on persuasiveness. In contrast, low-power recipients found that warmth (95% CI = -.223; .152), but not competence (95% CI = -.641; -091) mediated the effect of communicator's power on persuasiveness.

Discussion. These experiments offer a framework for understanding how power affects the communication and reception of persuasive messages, and suggests temporary states of power unilaterally shift one's expression and sensitivity to competence and warmth leading powerless and powerful communicators to yield effective communication, but for different reasons. Implications for social policy and political communication will be discussed.

The Artful Dodger: Answering the Wrong Question the Right Way

EXTENDED ABSTRACT

Many in public life seek to master the artful dodge, frequently attempting to wriggle out from answering questions they would rather avoid. Though perhaps most grating when performed by politicians, question-dodging occurs in a wide array of other contexts as well: from corporate executives avoiding reporters' requests for their expectations for the next fiscal quarter, to employees sidestepping their bosses' questions as to why they are late for the third straight day, to spouses evading their partners' inquiries as to their whereabouts the previous evening. Among relevant marketing and consumer domains, consider the public relations officers who deal with tough questions from consumers, regulators, and the media in the aftermath of product-safety crises; tactics in customer relationship management (CRM) for pacifying clients even when unable to actually solve their substantive problems; or a salesperson skillfully evading questions about the true value of buying dealership rust-proofing for new car, or about the accident history of a used one.

But are such attempts to dodge successful? Most importantly, what determines whether a dodge is successful – when a speaker's answer to the wrong question goes unnoticed, and therefore unpunished? In the experiments that follow we show that dodges succeed when speakers respond to a question by responding with answers that *seem* to address the question, but which in fact address an entirely different, though similar, question. For instance, a politician in a debate asked about the illegal drug problem in America whose answer stresses the need for universal healthcare has engaged in a successful dodge if listeners have both forgotten that she was even asked about drugs, and evaluate her highly. Indeed, we show that in some cases, speakers end up better off by answering the *wrong* question well than the right question poorly.

Experiment 1. We asked participants to listen to a brief excerpt from a debate between two politicians. For the second politician, we varied the question asked – about healthcare, the illegal drug problem, or the War on Terror – but this politician always gave the same answer about healthcare. Thus we varied whether the politician answered the question asked (about healthcare), a similar question (the drug problem), or a dissimilar question (the War on Terror). As predicted, results showed that when the politician answered a similar question, participants forgot the original question – a successful dodge – and rated him highly; in contrast, when the politician answered a dissimilar question, participants noticed the effort to dodge and penalized him accordingly. Overall, speakers could get away with dodging questions without punishment when answering a question similar to the one asked. In everyday life, of course, people usually attempt to dodge questions when they are not prepared with a good answer to the question asked – for example, when an employee's boss pops into her office unannounced to inquire as to her lateness, leaving her to stammer through a poorly phrased answer.

Experiment 2. In experiment 2, we compared the efficacy of dodging questions by answering a similar question to bumbling through an answer to the actual question. Results showed that providing a good answer to a similar question resulted in evaluations similar to providing a good answer to the actual question (replicating experiment 1); most interestingly, providing a good answer to a similar question resulted in *higher* interpersonal ratings than answering the actual question poorly. How might we improve people's ability to detect dodges? Interestingly, television networks have taken steps to curtail politicians' efforts to dodge questions during political debates by posting the question asked of politicians for the duration

of their answers. We tested the efficacy of this procedure in the next experiment.

Experiment 3. Participants watched the same excerpt as in experiment 1; as before, we varied the question asked of the second politician – about healthcare or the illegal drug problem – and the politician always answered about healthcare. In addition, however, we also added two conditions which were identical to these, except that in both versions, the text of the question remained on the screen while the politician answered; here, we expected participants to notice the effort to dodge. As in experiments 1 and 2, without the aid of the question on the screen, dodging by answering a similar question was quite successful. In contrast, participants who were aided by having the actual question on the screen were nearly as good at remembering the actual question as those who heard the politician answer the actual question.

Discussion. These results suggest that the emerging strategy used by television networks to increase viewers' ability to recall the original question does in fact increase the detection of dodges. In many real-world situations, however, similar interventions are unlikely to be feasible: it would be difficult to ask an acquaintance or salesperson to hold up a sign indicating what question he was meant to be answering, for example. Accordingly, increasing dodge detection in everyday social and consumer interactions may be no easy task. At the same time, intervening to reduce the incidence of successful dodging is essential if we wish to reverse the results from our second experiment, and ensure that those who answer the right question with substance are preferred over those who answer the wrong question with style.

The Persuasive Power of Contradicting Oneself

EXTENDED ABSTRACT

When people seek to persuade others, or gain their support, they often do so by conveying a consistent message, or repeating their arguments and opinions. Indeed, past research suggests that, compared to stating an argument or expressing an opinion just once, repeating that argument or opinion can make it seem more valid or true (Begg et al., 1992), which can give it more persuasive impact (Moons et al., 2009). Despite the intuitive appeal of this strategy, and empirical support for its potential value, we explore the possibility that under some conditions contradicting oneself (e.g., initially opposing something and then later supporting it) can offer a persuasive advantage. In particular, we test the hypothesis that some message sources are more persuasive when they deliver conflicting rather than consistent messages. The rationale is that, assuming recipients trust the source of a message, that source can induce the perception that he or she gathered new information by contradicting him- or herself. As a consequence, message recipients can be induced to process more deeply via contradictions, which promotes persuasion in response to strong arguments. We investigate this notion across 3 experiments.

Experiment 1. Participants were randomly assigned to receive different kinds of advice. In every condition, they were told to imagine that they had sought medical advice from a friend regarding a suspicious mole on their arm. In the *conflicting advice* condition, the friend was initially reassuring (saying that there is no reason to worry), but then changed his mind a few days later (saying that on second thought, it would be a good idea to remove the mole in order to conduct a biopsy). In the *time 1 advice only* condition, the friend initially suggested that it would be a good idea to remove the mole to conduct a biopsy. In the *time 2 advice only* condition, the friend recommended the biopsy after a few days. The rationale for getting the biopsy was identical across conditions. We varied merely the timing of this recommendation, and whether it had been preceded by different advice. Results indicated that participants found the advice more compelling and were more likely to remove the mole in the conflicting advice condition than in either of the one-time advice conditions, which did not differ from one another.

Experiment 2. Next, we sought to replicate this effect in a different setting, and explore the underlying mechanism. All participants received advice (or a persuasive recommendation) twice, but we varied whether it was consistent or conflicting. Undergraduate students read about a friend who offered his opinion about a new university policy on two different occasions. In the *consistent message* condition, the friend expressed a positive opinion on both occasions in which the topic was raised, elaborating on his opinion and the arguments in favor of the policy on the second occasion. In the *conflicting message* condition, the friend expressed an initial negative opinion followed by a change of mind a week later, at which time he elaborated on his opinion and the arguments in favor of the policy. To permit a test of processing differences, we also manipulated argument strength such that the friend offered strong or weak reasons to implement the policy on the second occasion. Results indicated a significant interaction between message consistency and argument strength on attitudes. Argument strength had a greater effect on attitudes in the conflicting message condition than in the consistent message condition, consistent with the notion that conflicting messages can stimulate greater processing. Viewed differently, under strong but not weak argument conditions, the conflicting message produced more favorable attitudes than did the consistent message. Moreover, this processing difference stemmed from participants' perception that the source of the message had gathered new information between the first and second time he offered his opinion.

Experiment 3. In experiment 3, we sought to show that a conflicting message would only foster increased processing when the source was trusted. The rationale was that only when people trust the source should they make favorable attributions (to acquiring new information) based on the contradictory messages. Here we used the same core paradigm as in experiment 2, but we manipulated the trustworthiness of the source prior to the delivery of the message. As predicted, there was a three-way interaction between message consistency, trustworthiness, and argument quality. This three-way interaction involved 2 two-way interactions of opposing patterns. Under high trust conditions, we replicated the effects from experiment 2. Under low trust conditions, we found a significant message consistency × argument quality interaction but in the opposite form. In this case, the argument quality effect was significant in the consistent message condition but not in the conflicting message condition. Thus, contradicting oneself before offering strong arguments can promote persuasion under high trust conditions, but it backfires under low trust conditions. Consistent with our information processing perspective, these effects were mediated by thought favorability.

Discussion. In summary, conventional wisdom and past research suggest that if a persuader seeks to change someone's attitude, he or she would benefit from delivering a consistent and/or repetitive message. In contrast, our research suggests that contradicting oneself, or changing one's mind, can sometimes offer a persuasive advantage. Our findings are consistent with an information processing account, suggesting that a conflicting message can grab attention and increase message processing under some conditions. This increased processing, in turn, can promote persuasion when strong arguments have been presented. Implications for understanding numerous counterintuitive means of influencing attitudes and behavior will be discussed.

From Blemishing to Blossoming:
The Positive Effect of Negative Information

EXTENDED ABSTRACT

Imagine that you are considering a new restaurant and reading reviews of it online. Most of the reviews are very good: Great food, pleasant music, relaxed atmosphere. Then you come across a review that mentions that there is no parking nearby, a piece of information that is negative but not quite central to your value proposition for restaurants. How does this small dose of negative information influence the positive impression you had begun to form of the restaurant? Could this weak piece of negative information actually enhance your positive reaction? Intuition and past research generally suggests that if weak negative information has any effect at all, it ought to be negative—that is, it should undermine the favorable impression you had begun to form. In contrast to this notion, we propose that weak negative information can sometimes bolster, or intensify, initial favorable impressions arising from positive information.

The rationale for this effect is that when consumers receive negative information after already receiving positive information, especially if that negative information is relatively minor and just "blemishes" the product, it ironically highlights or increases the salience of the positive information. This boosts the impact of the positive information and fosters more positive evaluations. Of importance, though, if true, this effect should only occur when negative information follows positive information, and when consumers' processing effort is relatively low as low processing orients consumers toward primacy effects and makes them less likely to thoughtfully consider the negative implications of subsequent negative information (Kruglanski and Webster 1996). We present four experiments investigating this *blemishing effect*.

Experiment 1. This initial experiment sought to test the hypothesis that, under conditions of low processing effort, consumers might evaluate a product more favorably when they received a weak negative piece of information about it following positive information. To test this hypothesis, we presented participants with all positive (5 positive attributes) or both positive and negative (4 positive and 1 negative attribute) information about a pair of hiking boots under high or low processing conditions, and then measured their interest in purchasing the boots. To manipulate processing effort we used a divided attention task adapted from past research (e.g., Fitzsimons and Williams 2000). Results indicated the predicted interaction, such that under low processing conditions, participants were more interested in purchasing the boots when they were presented with a weak negative attribute compared to when they were presented with only positive attributes. Under high effort conditions, this effect was reversed.

Experiment 2. This second experiment aimed to replicate the effect in a field setting. Students were approached on campus either immediately prior to taking an exam (low processing [high distraction] condition) or while they were simply walking around outside (i.e., high processing [low distraction] condition) and were offered a chocolate bar. In the *positive only condition*, the experimenter listed three positive attributes. In the *positive + weak negative condition*, the experimenter also briefly mentioned that the chocolate bar was a bit broken. We found a significant interaction, such that under low processing conditions, participants purchased more chocolate bars when a negative attribute was mentioned than when there was only positive information. By contrast, under high processing conditions, participants purchased more chocolate bars when there was only positive information presented.

Experiment 3. This experiment was designed to demonstrate the effect measuring individual differences is processing. Participants first completed a holistic-analytic processing measure (Choi, Koo, and Choi 2007) and then read a description of some champagne glasses. In the *positive only condition* just one positive attribute was featured. In the *positive + weak negative condition* the product's description included the same positive attribute along with a minor negative—that the glasses did not come in a hard box. After reading the description, participants indicated the extent to which they would be willing to try the champagne glasses. As predicted, we found an interaction on willingness to try. Holistic (low effort) thinkers reported greater willingness to try the product when its description included negative information rather than only positive information. In contrast, analytic (high effort) thinkers reported more willingness to try the product when only positive information was presented.

Experiment 4. Finally, in experiment 4 we tested the role of presentation order. Participants under high or low processing conditions (manipulated using a divided attention task) received a list of favorable attributes for a pair of hiking boots along with a picture of the boots showing damaged packaging (a slightly blemished box). We manipulated whether participants read the positive information and then saw the negative picture, or saw the negative picture and then read the positive information. As hypothesized, participants under low processing conditions evaluated the boots more favorably when they received positive and then minor negative information rather than minor negative and then positive information. Participants under high processing conditions showed no difference, evaluating the boots more moderately regardless of when the negative feature was presented. We also found mediation evidence in this experiment— low processing participants saw the positive attributes as more positive (and the negative as less negative) when the negative information followed rather than preceded the positive information, and these perceptions mediated overall product evaluations. In addition, we ruled out several competing accounts in this study—e.g., those based on two-sided message perceptions or perceived source/information authenticity effects.

Discussion. Overall, we obtained substantial support for the blemishing effect. When processing effort is low, providing consumers with positive information followed by a minor piece of negative information appears to enhance their overall evaluations of a target relative to providing exclusively positive information. This effect stems from low-effort processors tendency toward primacy effects, which are bolstered or intensified by the later appearance of conflicting information. High-effort processors, by contrast, appear to form more modest evaluations when negative information is included, regardless of its timing. Implications for understanding other ironic effects in persuasion and choice are discussed.

SESSION OVERVIEW

Every day, consumers strive to achieve a wide array of short-term and long-term goals. These goals range from very specific goals, such as giving up dessert at dinner, to more abstract goals, such as living a healthy lifestyle. Regardless of the type of goal, the strategies that people adopt are often maladaptive. The objective of this session is to highlight research that examines goal achievement strategies in a fresh yet rigorous manner. Together, the four papers stimulate a new understanding of when and why goal achievement strategies are effective and when they prove to be detrimental. Thus, we present some "tips and tricks" for when various strategies of goal-pursuit will be optimal for goal achievement. Together, these papers suggest that often an avoidance strategy, rather than a moderation strategy, is beneficial; it can be better not to plan rather than plan out the way to achieve our goal; plans can free thoughts and attention for unrelated tasks and goals; and postponing consumption of he-donic goods can ultimately lead to decreased consumption, and thus a greater likelihood of goal achievement.

Kelly Haws, Cait Poynor Lamberton, Hristina Dzhogleva and Gavan Fitzsimons begin the session by examining several potential strategies towards goal pursuit, and show that moderating, rather than eliminating, indulgence or exposure to temptation can prove to be an effective self-control strategy. Specifically, in three studies they find that when a self-control task is easy, a moderation strategy may be advisable, but that when a self-control task is difficult, the same person may undermine their own progress by adopting a mod-eration strategy. Julia Bayuk and Juliano Laran look at the effects that planning has on the likelihood of goal achievement. They find that planning can lead people to feel that the necessary steps are not very effortful, which can lead to a decreased likelihood to engage in the goal directed behavior. Hence, plans can at times backfire. E. J. Masicampo and Roy Baumeister complement that work with an examination of how planning for a goal affects other, unrelated pursuits. They show that just making a plan is enough to get people to reduce the amount of thinking and attention they dedicate to an unfulfilled goal, freeing thoughts and attention for other interests. Lastly, Nicole Mead and Vanessa Patrick look at postponement of he-

donic consumption as a strategy for goal achievement. They find that postponing consumption of a hedonic temptation to an unspecified future time reduces desire for and consumption of that hedonic item.

Together, these papers evaluate some commonly used strategies to achieve a goal, show when these strategies may actually backfire and when they can be effective, and "build connections" amongst a variety of consumer researchers. This session should be of great interest to consumer researchers studying goals or self-control, as well as to those interested in public policy. This work has many im-plications for consumer well-being as people often pursue, yet fail to achieve, goals such as saving money or losing weight. We truly hope that it will encourage interaction and collaboration amongst the numerous consumer researchers studying different aspects of goals–from goal selection and commitment, to goal planning and goal pur-suit, to goal disengagement.

All of the papers in the session are works in progress, and have at least two studies completed.

A Life in Balance or a Slippery Slope?
Exploring the Use and Effectiveness of Moderation versus Avoidance Self-Control Strategies

EXTENDED ABSTRACT

Though decades of self-control research have identified numer-ous techniques to help consumers better achieve their goals, we still have relatively little insight into the conditions under which specific techniques may be more or less fruitful. The present research com-pares the use and efficacy of two frequently utilized self-control strategies: moderation and avoidance (Hoch and Loewenstein 1991). Moderation involves the consumption of some measured quantity of pleasurable good or experience in keeping with pre-established con-sumption limits. By contrast, avoidance entails not consuming any of the "forbidden fruit," perhaps even going out of one's way to avoid all exposure to a potential temptation.

Clearly, in some areas of life complete avoidance is advo-cated. For example, alcoholics may choose to allow no alcohol in their homes or avoid circumstances where drinking is likely to oc-cur. Apparently aware of this fact, consumers often categorize their world of options as acceptable or "off-limits" in order to facilitate goal achievement (Poynor and Haws 2009). However, research also suggests that moderation, rather than complete avoidance, may have positive outcomes. For example, "cold turkey" approaches may lead to detrimental outcomes when strict regulations backfire, prompting a desire for greater indulgence (Cochran and Tesser 1996, Finkel-stein and Fishbach 2010). Incorporating some small amount of in-dulgence into one's life, in fact, may neither harm long-term goals nor preclude one from long-term satisfaction (Krishnamurthy and Prokopec 2010; Haws and Poynor 2008).

Such work suggests that moderating, rather than eliminating, indulgence or exposure to temptation can prove to be an effective self-control strategy. But what determines the relative use and ef-ficacy of moderation as opposed to avoidance strategies for a given individual? We suggest that chronic or situational self-control capa-bilities moderate the use and effectiveness of these two approaches. Specifically, chronically good self-controllers tend to both choose to moderate more often and find more success in doing so. Further, when put in a moderation mindset, individuals with higher self-control exhibit more successful self-regulation than do lower self-

control individuals. Finally, we find that within any given individual, context-specific control capabilities drive their success with moderation as opposed to avoidance strategies. Whereas self-control tasks seen as easy can be managed using either avoidance or moderation, difficult self-control tasks likely require avoidance to be successfully pursued.

In study 1, 137 consumers (41% male, M_{age} = 32.63), reported agreement with statements focused on moderation ("I try to find moderation in my life") and more extreme avoidance strategies ("I tend to think of life in terms of all or nothing."). These responses were combined to create a relative moderation focus. Respondents also provided individual self-control ratings (Tangney et al. 2004) and reported their experience with a number of life outcomes – achievement of diet goals, the presence of harmful addictions, exercise, and subjective well-being. Results showed that higher self-control individuals showed stronger moderation focus than did lower self-control individuals (p < .001). Importantly, individuals with a stronger moderation focus tended to achieve their diet goals, were less likely to have addiction issues, exercised more frequently, and were happier overall (all p < .05). As such, initial evidence suggests that moderation strategies may be more common and effective for higher as opposed to lower self-control consumers.

But can we show that use of a moderation strategy is, in fact, more successful for higher as opposed to lower self-control individuals? Study 2 followed a 2 (moderation v. avoidance prime) x continuously measured eating self-control design. Undergraduate participants (n = 114) wrote short essays about the virtues of either moderation ("everything in moderation") or avoidance ("staying away from temptation"). As part of a subsequent task participants indicated how much that they would like to eat each item on a list of snacks at that moment. Separately, we assessed individual differences in eating self-control (e.g., Giner-Sorolla 2001). Results showed that those who more easily practiced eating restraint showed a higher desire for healthy as opposed to unhealthy foods (p < .0001). However, a significant interaction of primed strategy and individual eating self control also emerged (p < .0001). Individuals primed with an avoidance strategy showed similar patterns of healthy consumption regardless of their level of self-control (p >.8). However, in the moderation condition, consumers high in self-control increased their tendency toward healthy consumption while those lower in self-control decreased their preference for healthy food alternatives. Here, a moderation strategy seemed to be more effective than avoidance, but *only* for consumers higher in self-control in this domain. For consumers who struggle to control their eating, a moderation mindset generated a slippery slope, prompting greater indulgence than an avoidance mindset.

Taken together, results suggest that when a self-control task is easy, a moderation strategy may be advisable, but that when a self-control task is difficult, doing so may undermine goal progress. To test this general theory, study 3 asked participants to rate a series of self-control challenges in terms of their personal difficulty. They then read a scenario presenting a self-control problem in each domain, and stated their likelihood of adopting a moderation or avoidance strategy as well as their anticipated success in each. Results indicate that individuals believe that avoidance strategies will be equally effective regardless of the difficulty of a self-control task. However, participants felt that moderation strategies would yield better results on easier as opposed to harder self-control problems, and thus, showed a higher likelihood to moderate on easy tasks. Given our prior results, these expectations are appropriate for higher self-control individuals, but suggest a reason why lower self-control

individuals, mistakenly applying moderation strategies, may fail to see progress toward their goals.

Overall, this research aims to help consumers more effectively achieve their long-term goals. While for some individuals, and in some areas, moderation strategies may lead to a happy and well-balanced life, we all have weak spots. In these domains, results suggest that avoidance, rather than moderation, is a surer path to self-control success.

It is Just Too Easy: Impact of Planning on Effort and Behavior

EXTENDED ABSTRACT

Consumers live busy lives and often search for ways to simplify them. When the options available are limited, consumers are able

to make decisions more easily and become more likely to purchase a product (Iyengar and Lepper 2000; Tversky and Shafir 1992). In addition, easy processing of information has been shown to affect an individual's liking for both products and advertisements (Labroo and Kim 2009; Schwarz 2004). Common sense also suggests that people would rather do things that are easy than things that require effort. Nevertheless, some research on the effect of ease of performing an action on product evaluations and goal-directed behaviors suggests that people often prefer to engage in behaviors that are more difficult and effortful to execute (Gollwitzer and Brandstatter 1997; Locke et al. 1981; Norton, Mochon, and Ariely 2010). This paper builds on this work and examines how forming a plan to perform a behavior (e.g., purchase a product, experience, or service) affects the perception of effort required to execute the behavior, and in turn, how the effort required influences the likelihood to engage in the behavior. Forming a plan and knowing what needs to be done should make it easier to execute the necessary activities. Thus, forming a plan could lead to a lower perception of effort. We propose that perceptions of higher effort increase consumers' likelihood of performing a behavior. Because forming a plan may decrease perceptions of effort associated this behavior, this may decrease consumers' likelihood of performing the behavior in certain circumstances. We test our propositions with three studies that examine the effect of planning on perceptions of effort and on behavior.

Study 1 shows that forming a plan to engage in a behavior can decrease a person's intention to engage in the behavior. The study employed a 2 (Vacation Type: related to plan vs. unrelated to plan) by 2 (Form Plan: no vs. yes) between-subjects design. All of the participants were told about a cruise vacation, and approximately half of the participants formed a plan to go on the cruise (specify how and when they would book the trip), whereas the other half did not. Results showed that participants who formed a plan to book the cruise stated that they would be less likely to go compared to those who did not form such a plan. To show that the effect is specific to the behavior for which the plan was formed, and not any related behavior, we also asked participants to estimate their likelihood to go on a trip to an alternative destination (Last Vegas), and found that the likelihood to book did not differ depending on whether or not participants formed a plan to book the cruise. Overall, this study shows that planning can lead to a decreased likelihood to engage in a behavior.

Study 2 uses real behavior to show that, when the amount of activities necessary to perform a behavior is high, the performance of a target behavior will seem more effortful for people who form a plan compared to those who do not form a plan, which will increase engagement in the behavior among people who have formed a plan. This two-part study employed a 2 (Effort: moderate vs. high) by 2 (Form Plan: no vs. yes) between-subjects design. During the first part, half of the participants formed a plan specifying how they will save money by dining out less in the upcoming weeks, whereas the other half did not. Effort was manipulated by varying how many things (e.g., going to grocery store more, purchasing groceries, cooking at home) participants were explicitly asked to consider when forming their plan. Exactly a week later, all of the participants were contacted by e-mail and asked how much they spent on dining out in the past week. We found that in the moderate effort condition, forming a plan led to significantly greater spending on dining out compared to not forming a plan. However, in the high effort condition, forming a plan led to significantly lower spending on dining out compared to not forming a plan.

Lastly, study 3 examines how a common marketing occurrence, a price change, affects an individuals' intention to engage in a behavior (purchase a product) after forming a plan to do it. It shows that when a price increase occurs, consumers who form a plan perceive the behavior to be more effortful, and are more likely to make the purchase compared to consumers who do not form a plan. The study employed a 2 (Price Change: no vs. yes) by 2 (Form Plan: no vs. yes) between-subjects design. As in Study 2, some participants form a plan to book a trip to Brazil, whereas others do not. The key dependent variable was participant's likelihood to book the trip. When no price change occurred, participants who formed a plan were less likely to book the trip, and believed the booking process to be less effortful. When the price changed, participants who formed a plan became more likely to perform a target behavior compared to those who did not form a plan. Perceptions of effort increased among those who formed a plan, but decreased among those who did not. The effect of the interaction between price change and plan on likelihood to book the trip is fully mediated by the perceived effort required to engage in the behavior.

In summary, forming a plan is often beneficial, but primarily when engaging in the necessary behaviors seems highly effort once a plan has been made. The challenge is to teach people when planning will be beneficial, versus detrimental, to their aspirations. Making people feel like the necessary activities to perform a behavior are easy will decrease engagement in the behavior when a plan has been formed. In these cases, "not forming a plan" is the best advice people might receive.

Consider it Done!:
The Cognitive Effects of Unfulfilled Goals are Eliminated by Making a Plan

EXTENDED ABSTRACT

The human mind is remarkably well designed for goal pursuit. Attention, perception, thoughts, and attitudes all become tuned to help one pursue a goal. The mind vigorously promotes this intense focus on a goal, protecting it from distractions and resuming it after

it has been interrupted. Even when one is not consciously working toward a goal, the mind keeps the goal active in the unconscious, maintaining vigilance for opportunities to fulfill it. Thus, once a goal is chosen, the mind has many processes to promote its pursuit. The standard view has held that the various cognitive processes related to unfulfilled goals cease when the goal is attained. This view has been favored in theories of goal pursuit and has found support in empirical research. However, the present investigation tested the hypothesis that many of the goal promotion processes can cease long before attainment — specifically, when a plan is made.

Planning has been studied recently in the form of implementation intentions, which are highly specific prescriptions for what to do under what circumstances (Gollwitzer, 1999). Such plans turn control of goal pursuit over to automatic, unconscious processes, which can resume goal pursuit at the appropriate time or place specified in the given plan. Once a plan is made, the unconscious knows how and when to act, and so in a sense the uncertainty of the unfinished task is resolved. The implication then is that a plan may render many of the cognitive activities related to the goal unnecessary. We predicted that contributing to goal pursuit through plan making could satisfy the various cognitive processes that usually promote goal pursuit, thereby causing them to cease.

In each of the studies reported, we activated unfulfilled goals and measured the extent to which they persisted in the mind during later tasks. In Study 1, participants selected tasks or goals from their own lives that needed to be done, and then we measured how much people's minds wandered while reading a novel that had nothing to do with the unfulfilled tasks. Unfulfilled tasks made people's minds wander, thereby reducing their ability to read and understand the novel. But participants who made a plan to get their personal tasks done were able to read with less mind wandering. Despite having had an unfulfilled goal activated, they exhibited few intrusive thoughts about their goals and were relatively well able to read and concentrate on material unrelated to their goals.

Studies 2 and 3 examined goal accessibility. In Study 2, participants reflected on an upcoming final exam, and thoughts related to doing well on the exam remained highly accessible during a later word stem completion task. This effect was eliminated, however, among participants who made a plan for when and how to study for the exam. Study 3 examined the accessibility of means of goal achievement. It used one goal that most young people embrace (to live a fit and healthy life) but that remains unfulfilled for most. Reflecting on this unfulfilled goal caused the various means of reaching it to become highly accessible, as indicated by goal-relevant answers on a word completion task. Once again, having made a plan eliminated the effect. Study 3 also showed that the various effects (persistent activation over time as well as reduced activation after planning) were obtained mainly among participants for whom the unfulfilled goal had high personal importance.

Study 4 replicated the effects of plans using an experimentally assigned task. The unfulfilled goal to do well on a later laboratory task interfered with performance on a separate, unrelated task in the interim (solving anagrams). Making a plan eliminated the interference effect as in the previous studies. More important, Study 4 showed that most participants did actually follow the plans they had made — and the degree to which they followed their plans was closely linked to the improvement in performance on the anagram task. Thus, the more people made plans that they were actually going to use, the more they were freed from intrusive thoughts about the unfilled goal while working on the unrelated task. To put it another way: What reduced cognitive activity from unfinished tasks

was making highly specific plans that were actually going to be used to finish those tasks.

By planning for their goals, people can better manage their multiple pursuits. It has been well documented that specific plans increase success (Gollwitzer, 1999), and they do so in part by making pursuit of the goal more automatic. When a detailed plan has been made, one no longer has to think about the goal to fulfill it (Brandstätter, Lengfelder, & Gollwitzer, 2001). Apparently, a plan can also reduce the amount of thoughts and attention that are typically recruited in service of an unfulfilled goal. Thoughts of an incomplete goal do not necessarily persist until the goal is fulfilled – making a plan is sufficient to eliminate the various cognitive effects of unfulfilled goals. Planning may therefore represent a crucial strategy for the management of multiple goals. By planning for a goal, one can free one's thoughts and attention for other pursuits.

In Praise of Putting Things Off: Postponing Consumption Pleasures Facilitates Self-Control

EXTENDED ABSTRACT

Many approaches to self-control assume that people have two, albeit suboptimal, options when faced with a tempting yet unwanted pleasure – *give in* to or *give up* the pleasure (Baumeister, Heatherton, and Tice 1994; Baumeister and Heatherton 1996; Giner-Sorolla 2001; Kivetz and Keinan 2006; Myrseth, Fishbach, and Trope 2009). Giving in entails a short burst of pleasure, but is quickly overrun by feelings of guilt for transgressing from long-term goals. In contrast, giving up a temptation is just plain psychologically painful and taxing. Research indicates that deprivation typically backfires, leading to increases rather than decreases in consumption (e.g., Vohs and Heatherton 2000). In the current research, we investigate a third option, postponement, which was hypothesized to facilitate self-control in the face of consumption pleasures without feelings of self-denial or loss.

Postponement entails "having it later", whereas deprivation mandates "not having it at all". Thus, although postponing means not consuming in the present, it allows people to consume, albeit at a later date. Postponement was briefly suggested as a desire-reduction strategy (Hoch and Loewenstein 1991) but to date has received scant (if any) empirical attention. In three experiments, we tested whether postponement can in fact reduce desire for a hedonic consumption pleasure, and whether this reduction in desire in turn facilitates self-control. We theorize that in the short run, postponement 1) reduces the motivational conflict associated with giving in versus giving up a tempting option, and, consequently, 2) encourages self-control by dampening the desire for the affectively powerful temptation. In the long run, we hypothesize that the lack of reinforcement helps ensure that the already weakened hedonic impulse continues to decay, thereby facilitating self-control. In all three experiments, described next, the short- and long-run consequences of postponement were compared to the two outcomes most frequently investigated in self-control research, satiation (giving in) and deprivation (giving up). In

experiment 2, a delay of gratification condition (giving up on a small reward now to obtain a larger reward later) was also included.

In experiment 1, we tested the behavioral consequences of postponement for both short and long-term consumption. At time 1, participants were asked to watch a short film-clip. Ostensibly to enhance the feeling of actually being in the movies, a bowl of M&Ms was placed in front of participants. Participants randomly assigned to the *satiation* condition were allowed to eat freely. Those participants assigned to the *deprivation* condition were asked not to eat any of the M&Ms. Participants in the *postpone* condition were asked not to eat the M&Ms; instead they could have a snack later on, if they liked. At the end of the experiment, all participants were given the opportunity to eat M&Ms in private. Results indicated that participants in the postpone condition ate fewer M&Ms than participants in the deprivation condition. Consistent with work indicating that satiating the desire for a particular item reduces subsequent intake (McSweeney and Sindell 1999; Rolls, Rolls, Rowe, and Sweeney 1981), the postpone and satiate conditions were not significantly different from one another. At time 2, one day after the experiment, participants were emailed and asked to indicate their desire for M&Ms. As expected, postpone participants reported a lower desire to eat M&Ms than the other two experimental conditions. Finally, at time 3, one week after the experiment, participants indicated how much chocolate they had eaten since the experiment. Results indicated that participants in the postpone condition ate less chocolate over the course of the week, relative to the satiation and postpone conditions. Desire for chocolate 24 hours after the completion of the experiment fully mediated the effect of the manipulation on consumption over the week.

Experiments 2 and 3 were designed to assess the psychological mechanisms underlying the effect of postponement on decreased consumption. Our hypothesis was that postponement alleviates the motivational conflict between deprivation and satiation, allowing the reflective system to dominate and the impulsive system to dissipate. In experiment 2, we used an implicit measure to determine whether the hedonic or reflective system was dominant (e.g., Hofmann, Friese, and Strack 2009). Participants in the postpone condition showed heightened activation of the reflective system, whereas participants in the satiation and deprivation conditions showed heightened activation of the hedonic system. Moreover, participants in the postpone condition reported the lowest desire to eat dessert as well as the lowest levels of deprivation and loss. As expected, the delay of gratification condition mirrored the deprivation condition in terms of hedonic activation. In experiment 3, participants asked to postpone eating ice cream reported a reduced desire to eat ice cream, relative to participants assigned to the deprivation and delay of gratification conditions. Taken together, results of experiments 2 and 3 suggest

that postponement activates the reflective system, the seat of self-control, and dampens the hedonic affective response to consume the hedonic good.

In sum, results from three experiments suggest that postponing consumption activates the reflective system and reduces the affective desire for the hedonic good, enabling participants to forego consumption of hedonic pleasures, in both the short- and long-term. Theoretically, results suggest that postponement has different effects on the reflective and impulsive systems as compared to the two most common avoidance strategies – deprivation and delay of gratification. Practically, postponement seems to be a strategy that enables consumers to manage transient hedonic desires.

SPECIAL SESSION

Consumption consists of three stages: acquisition, usage and disposition (Jacoby et al. 1977, Holbrook 1987), with the first two gaining more attention from consumer researchers. Few exceptional studies include examinations of the effects of personal and situational factors on consumers' disposition decisions (e.g. Jacoby et al. 1977) and the symbolic, emotional, and ritualistic aspects of disposition (e.g. Lastovicka and Fernandez 2005). At ACR, the sessions and papers that pertain in some way to disposing have focused on issues such as environmental concerns (Alwitt and Berger 1993), charity behavior (Lee and Strahilevitz 2004), intergenerational flow of heirlooms (Heisley 1997), or rites of passages (Ozanne 1992). These rare inquiries demonstrate how studying disposing might contribute to our understanding of consumer identity projects, charity behavior, policy making and environmentalism, and the improvement of product design processes. Nevertheless, there is still much to be discovered about disposing per se and its relationship to various consumption practices. Moreover, disposing is an important area of research, now even more so than ever, due to the increasing concerns for wasting, sustainability and over-consumption.

Mindful of this state of affairs, the *Journal of Consumer Behavior* recently published a special issue on disposing. Some of the papers in that issue indicate that disposing empowers consumers (Cherrier 2009), blurs the boundary between commodity and private possession (Denegri-Knott and Molesworth 2009), bridges the past and subsequent consumption practices (Cappellini 2009) and is embedded in individual and societal values (Albinsson et al. 2009). Moving on from that 2009 issue and broadening the conceptualizations of disposition, this session shows that disposing is actually a very rich context that sheds light on and connects various topics consumer researchers have long been fascinated with. Overall, the session aims to explore a number of questions such as: How do different disposing practices create different meanings for consumers? How does disposing help consumers negotiate and deal with various (and usually conflicting) norms and identities? How do disposing practices change with lifestyle changes? And perhaps more importantly, how and what do consumers "create" through a practice that has long been regarded as the terminal stop for objects or the end of consumption, and how do practices of disposal fold back to those of consumption?

In the first paper, Ture and Ger explore the practices and processes of disposing in their relationship to the constructions and evaluations of consumers' own consumption. The authors indicate that various manners of disposing serve consumers in dealing with the conflicting ideologies and norms: the consumerist ethos of the modern consumer society they live in and the traditional norms of sociality and caring. The second study investigates disposing in the context of food consumption and preparation. Cappellini and Parsons demonstrate how the divestment of leftovers influences the planning of the meal, cooking, and storing; and thus, reveal a hierarchical pattern of weekly meals. They indicate that disposal-consumption circularity contributes to family cohesion. The third study explains how consumers' multiple roles relate to the modification of disposal practices. Focusing on working women who attempt to adapt to a "greener" lifestyle, Black and Cherrier reveal that becoming green necessitates new disposing practices and is managed through the processes of assimilation, negotiation, and rejection. However, these practices and how they are performed are contingent upon the hierarchical nature of the conflicting identities these women juggle. For all the three studies included in the session, data collection and analyses have already been completed.

The papers presented in this session provide a cross-cultural examination of disposing in a diversity of consumption contexts. In doing so, we show that disposing, as broadly construed, constitutes a site where some of the most important topics in consumer research (e.g. family construction, identity conflict, norms of consumption) overlap and intersect. As such, this session contributes to consumer behavior by moving consumer researchers towards a more comprehensive picture of "consuming". Also, focusing on disposing as an inseparable part of the consumption cycle helps us to understand not only issues such as over-consumption but also the processes through which consumers achieve, preserve or redefine desired identities and relations with others. Furthermore, we provide implications for policy makers on topics such as prevention of wasting and promotion of recycling or increasing the sustainability of products.

The session, with its presentations drawing from a diverse range of disposing contexts, bridges important topics of consumer research and is expected to be of interest to a significant amount of ACR attendees. However, we believe that researchers particularly concerned with family and individual identity formation, waste management and sustainability, and ideological aspects of consumption will benefit from the session most. With Jonathan Schroeder, who has significant works on identity, cultural aspects of consumption and gender, as our discussant, we expect this session to nurture a lively and productive discussion environment. The last 15-20 minutes of our session will be reserved for discussions, which will be guided by Jonathan Schroeder to build connections between the papers, motivate audience-presenter dialogue and underline the overall significance of the session.

An Exploration of Consumers' Use of Disposing Practices in their Daily Lives

EXTENDED ABSTRACT

In the consumer behavior literature, disposition of possessions has mostly been studied as a process through which consumers physically and emotionally detach from their possessions (Wallendorf and Young 1989). During times of transitions, disposing helps consumers cut ties with previous roles and adjust to new roles by cleansing the person from the old self and stabilizing the new identities (Schouten 1991). In the context of old age, where consumers engage in a review of life, disposition is found to be useful in dealing with concerns for continuation of legacy and self-extension (e.g. Price et al. 2000, Marcoux 2001). These studies imply that strategic choices of when and to whom to dispose special possessions are used by consumers to create

a desirable memory, gain symbolic immortality, and re-construct and legitimize their relations with certain people.

Although these studies contribute greatly to our understanding of how consumers construct meanings through disposing and use it in their identity projects, there is still much to discover about disposing. In addition to its role with special objects and/or special situations, disposing is embedded, above all, in the more mundane sphere of consumption, and is mostly employed during routine practices such as ordering of wardrobes or arranging the children's rooms (e.g. Gregson 2007). But, could such ordinary activities really have important implications for consumption studies? Recent research provides promising evidence. For example, it was found that mundane activities of domestic life are as significant as the sacred practices in creating a life history for items, moving them in an out of a network of singularized objects, and meanwhile, establishing the family identity (Epp and Price 2010). Building on these studies, we intend to explore disposing as a network of mundane practices and uncover its connections to other consumption practices as well as to consumers' identity and lifestyle construction processes. Our aim is to understand how consumers engage in and experience various processes while disposing their items, and hence to discover the consequences of these processes. With these goals in mind, we conducted in-depth interviews with 16 middle and upper-middle class men and women in Turkey, aged between 29 and 58. We also had 62 undergrad students write essays about their experiences with disposing their items. Specifically, they wrote about what items they usually dispose as well as when and how they dispose of these items. In addition, they were encouraged to reveal what motivates them to adopt certain practices of disposing over the others.

We find that disposing consists of a network of practices that are rooted simultaneously in economical, moral, social and rational domains of consumption. As such, rather than just emancipate from (Cherrier 2009) or conform to (Norris 2004) particular norms, consumers use disposing in order to negotiate conflicting norms. Both the interviews and student essays point that, living in a transitional society, our participants encounter a tension between rising consumerism and traditional social values as projected in their everyday life. They resort to disposing in order to be able to continue to consume in a relatively guilt-free manner. For example, our participants are able to un-alienate themselves by passing their items onto people in need (especially after a shopping spree) without having to compromise their consumption. That is, mundane practices of disposing serve as a bridge between the ethos of consumerism and ideals of social co-operation, solidarity, or caring for others.

Our findings also shed light on the specific ways through which disposing relates to other consumption experiences. Previous research has shown relationships between timing of disposing and the timing and financing of new acquisitions (eg. DeBell and Dardis 1979). Going beyond time and money issues, we indicate that consumers use particular manners of disposing to classify, define, and rationalize their previous or subsequent consumption. For instance, while engaging in "luxury" or "unnecessary" shopping practices, consumers predict the disposal of the items they are about to acquire, and depending on such predictions, re-define their shopping experience as "a good bargain" or even "altruistic", which facilitates the buying process. Possible discrepancies between the predicted and actual disposing episodes usually lead consumers to reflect on their past purchases and readjust their behavior at subsequent shopping trips. Consumers refer to their manners of disposing as they construct and evaluate their past consumption experiences and make decisions about the future ones.

We suggest that analyzing disposing in the realm of everyday consumption practices furnishes new insights about consumption as well as the processes and meanings of disposing. Our findings have clear implications regarding the perceived morality of consumption. In addition, our results have implications for policy makers who would like to enhance consumers' adoption of sustainable consumption and recycling activities, and for charity organizations who want to increase their donations.

Doing Family through Practices of Disposal: Enacting Affiliation and Sacrifice through the Consumption of Food Leftovers

EXTENDED ABSTRACT

This paper contributes in two key ways to our understandings of disposal. First it identifies the circularity of consumption and disposal, in particular how the meanings surrounding the processes and practices of disposal fold back into those of consumption (Thompson 1979, Gregson et al. 2007). Second, through anthropological concepts of consumption as affiliation (Douglas and Isherwood 1980) and as sacrifice (Miller 1998) it explores the ways in which the circularity of disposal contributes to family cohesion and belonging. These two aspects of disposal are investigated through an ethnographic study on everyday food consumption practices of 20 British families. The study seeks to understand how consumption of leftovers influences other consumption practices such as planning the meal, cooking and storing. It also seeks to understand how the consumption of leftovers provides a vehicle for both roles and relations in the household and the sense of family's belonging.

In general, divestment practices remain a neglected area in consumer research (Parsons and Maclaran 2009). The indifference to the topic is probably related to the marketing assumption that disposal is the last stage of goods trajectory (production-consumption-disposal) and as such it does not require particular attention (Hetherington 2004). In contradiction with this common assumption recent studies assume that disposal matters. By criticizing Douglas' (1984 [1966]) analysis of the ways in which the social world is based on binary classifications of clean-in/dirty-out and the consequences for our relative understandings of consumption/disposal, Gregson et al. (2007) point out that divestment (how, where, and when people place things) is also a consumption practice wherein "dirty" goods can be re-evaluated and re-become clean. Indeed in their divestment practices people do not simply move things out, rather they "move things along" (Gregson et al. 2007, 198) and designate them to a specific somewhere (i.e. charity shops, the street, a friend's home). Similarly Munro (1995) assumes that divestment is a consumption practice. Food disposal, which consists of multiple conduits, "has implication for the acquisition, cooking and ingestion stages in the process" (Munro 1995, 324) and as such it is part of the circularity, rather than the linearity, of food consumption. We argue here that it is through displacement that people both narrate the social order (the normative) (Gregson et al. 2007) and their belonging to it (Munro 1995). It is in fact through the continuous movement of things and owners that people materialize what such norms might be and reconstitute the self, the others and their relations with them (Gregson et al. 2007).

A first finding confirms the circularities of consumption, finding that disposal has an important impact on the entire process of food provision. In particular practices "of moving leftovers along" reveal a common hierarchical pattern of meals on a weekly basis. Leftovers are usually produced during the most important meal of the day (domestic dinner, the only cooked meal at home during working days) and they are moved to the following day's lunch or dinner. They are

also usually produced during the weekend meals and moved along during the weekday dinners. Therefore the leftovers "are moved horizontally" from a weekday dinner to another weekday dinner and are "moved vertically", down, in the weekly structure of the meals from a higher position to a lower one "weekend meals-weekday dinners", "weekday dinner- weekday lunch".

A second finding confirms that disposal is an act of affiliation to the family. Participants perceive leftovers consumption as a sacrifice, a thrift practice (Miller 1998), consisting of saving resources to be donated to an object of devotion. Indeed participants describe their consumption of leftovers as a sacrifice wherein hybrid food is transformed and re-used for a meal. This concept of 'hybrid food' encapsulates food that is neither clean nor dirty (Douglas (1984 [1966]) having been displayed previously, but not yet been cast out. Consumption of this hybrid food requires a higher degree of affiliation to the family than clean food. Resources (such as time, effort and money) saved in reusing leftovers are then invested in extraordinary food consumption, such as family celebrations, wherein the family is celebrated as an object of devotion. As others point out, in such extraordinary occasions, intimate and non intimate guests are admitted to celebrate the family. What has not been underlined is that it is not only in extraordinary food consumption that family is celebrated; rather it is in the everyday sacrifice of consuming leftovers that the affiliation to the family is reinforced and perpetuated.

This paper contributes to the current consumer research on disposal in two ways. Firstly it highlights how divestment practices are incorporated in the circular process of domestic food consumption. Moving leftovers along reveals not simply the participants' weekly hierarchical pattern of the meals but also the circular process of saving resources in ordinary meals and spending such resources in extraordinary meals. Indeed the sacrifice of consuming leftovers by family members is addressed to produce excess value which will be spent in extraordinary food occasions wherein the family as a whole entity is celebrated. Secondly this paper highlights that consuming leftovers requires a high degree of affiliation to the family, and only family members are admitted to a meal based on leftovers. Thus it is not only in extraordinary food occasions that family members reaffirm their affiliation to the household, but it is also in their everyday sacrifice that they reconstitute their object of devotion, which is the family itself.

Recycling: Yes but caring for my loved ones first! Exploring Identity Conflicts amongst "Green" Working Mothers

EXTENDED ABSTRACT

Researchers have documented that professional working mothers experience conflicting personal and social expectations. On the one hand, they strive toward self-directed accomplishments such as professional development; and on the other hand, they try to preserve traditional motherhood values for care of the children (Thompson 1996). In managing these conflicting expectations, these supermothers often opt for unsustainable consumption practices such as convenience consumption (Reilly 1982; Reilly and Wallendorf 1987) or buying pre-processed foods (Thompson 1996). As these women experience accelerated time frame, they do not often have to time and energy to integrate sustainable waste management in their lifestyle (Godbey et al. 1998).

This research considers the notions of juggling lifestyles and identity conflicts for professional working mothers who, with the goal of consuming in a more sustainable fashion, had recently diminished the amount of waste they generate and had integrated recycling

as their main disposal practice. This group typically has multiple roles and identities, such as mother, wife, homemaker, employee, and friend. We conducted in-depth interviews with six middle and upper class, professional working mothers, who lived in Toronto and moved away from wasteful practices, deliberately lowered their household waste generation and integrated recycling into their lives as a daily chore. By studying this group and probing on reasons for changing their practice of disposal, insights were gained into how recycling and sustainable waste management are performed and how such practices are influenced by self and social positions. Our analysis revealed how sustainable disposal (lower waste generation and recycling) is achieved by assimilation, negotiation or rejection.

It is clear that the findings can be effectively represented and understood using a framework of identity conflicts and strategies used to manage these conflicts (Swann 1987, Murray 2002, Ahuvia 2005). The mothers demonstrated a high level of knowledge and commitment to performing a wide range of sustainable behaviors. As well as being aware of the general concerns about the state of the ecosystem, they talked in detail about specific environmental issues such as greenhouse gas emissions, rubbish disposal and pollution in air, water and food. They also discussed what they saw as the consequences of these issues, with global warming and health problems attributed to specific concerns. It was also common for a clear link to be made between environmental concerns, the potential consequences of this and their motivation to act (based on their identity as mothers). Interestingly, few mentions were made about wanting to reduce overall consumption levels, though informants did want to reduce the impact of this consumer lifestyle and dispose accordingly. It was clear that the informants want to remain within the current consumerist society but also want it reformed. For the informants, one of the most accessible changes toward sustainability was to modify their practice of disposal. All informants integrated practices of recycling and reduced the household waste production. It was issues surrounding motherhood such as pregnancy, birth of a baby or pressure from their children that motivated these changes.

Each informant discussed how within their daily lives they performed several different roles; which contributed to a range of different social positions. It is conflict between the behaviors and values inherent within social positions and the subsequent management of this conflict that, it is argued here, can help explain change in disposal practices: moving from heavy waste generation and throwing away to limited waste generation and recycling. When exploring the conflicts and how these working mothers manage to integrate recycling in their daily routines, we did not find Ahuvia's (2005) "Demarcating," "Compromising" and "Synthesizing" strategies. Rather, when managing conflicting social positions between mother, professional worker and green consumer, our informants' interviews expressed an "assimilation" strategy. Sustainable disposal by "assimilation" is a process of rejecting, accepting or modifying the new disposal practice where rather than leading to the negotiated merging of the conflicting identities (as present in Ahuvia's synthesizing approach), values and meanings of sustainable disposal, are assimilated into prominent "core" identities without changing them. This allows respondents to reduce their amount of waste and the adoption of recycling to occur within personally and socially acceptable boundaries.

The respondents described how despite disposing of modes of behavior that they had performed for many years and then adopted different practices, they had not changed to become other identities such as radical conservationists nor had their identity as a mother changed. For example, Katherine talked about stopping the waste linked to using strong chemical household cleaners. In order to mod-

ify her waste production, she started using vinegar and baking soda but in doing so, the meaning of this sustainable disposal practices was assimilated into her conceptualization of herself as a mother *without* changing it. Here we have an example of sustainable disposal without disposing of the meaning of the practice; instead some of the meaning is transferred on to a new behavior that does not cause conflict between her multiple roles. Assimilation appears to occur because of the hierarchical nature of the conflicting identities and the central importance of motherhood to these women's sense of self. These properties do not exist in Ahuvia's examination of loved objects (2005) or Mick and Fournier's (1998) technical paradoxes.

SESSION OVERVIEW

From the zealous adoption of innovative products such as the iPhone and Wii, to the widespread passion for do-it-yourself goods, today's consumers not only value creative aspects of the goods they consume but also enjoy engaging in creative activities themselves (Dahl and Moreau 2007). To win the hearts of these consumers and thrive in a competitive global market, firms have to constantly innovate and develop creative products and services. Interestingly, though deciphering the sources of creative ingenuity is clearly important for both consumer satisfaction and corporate success, research on creativity within this context has been relatively limited (Burroughs and Mick 2004; Moreau and Dahl 2005). The purpose of this proposed special session is to draw the attention of consumer researchers to this domain, to present recent research findings, and to foster a discussion of potentially interesting questions regarding the cognitive mechanisms underlying creativity and thus spark future research. In the first of three research presentations, Mehta, Zhu, and Dahl investigate the interplay between motivations and cognitive mechanisms underlying creativity. Their research reconciles the disparate findings on the effects of monetary versus social rewards on creativity performance, and sheds light on how different motivations engender different cognitive processes. The second presentation by Rosa, Ruth, and Qualls examines how grounded cognition (i.e., modality-specific systems for vision, action, affect, etc.) and spatial working memory affect different aspects of creativity, and how consumer knowledge moderates these effects. Finally, the third presentation by Yang, Chattopadhyay, Zhang, and Dahl explores the impact of unconscious thought on creativity. These researchers show that longer duration of unconscious deliberation can actually harm, rather than boost, creativity, and that the superiority of unconscious thought pertains only to the novelty dimension of creativity but not the appropriateness dimension. Following the presentation of these research papers, James E. Burroughs, who has done extensive work in the area of creativity, will lead a discussion on the broad questions and issues pertaining to cognitive processes underlying creativity.

Contributions: This special session contributes to the ACR conference in several ways. Through the three presentations on dif-

ferent aspects of creativity and implications for consumers and firms, we bring researchers' attention to creativity research in consumer context, fostering research interests in this domain. Further, we highlight new theoretical development on the cognitive mechanisms underlying creativity, and the recent research findings on determinants and moderators of creativity. Finally, we initiate discussions among consumer researchers on the theory development and future research directions in this domain.

Likely Audience: This session would appeal to a wide range of consumer researchers, such as those interested in creativity, cognition, memory, motivation, and unconscious thought.

"Exploring the Role of External Rewards in Creative Cognition," Mehta, Zhu, & Dahl

EXTENDED ABSTRACT

Nearly three decades of research has fallen short of reaching a consensus regarding the effects of various kinds of external rewards (e.g., monetary versus social rewards such as recognition) on creativity. Some research suggests that monetary vis-à-vis social rewards reduce intrinsic motivation and are hence detrimental to creativity (Amabile 1982). While, other research suggests that monetary rewards may enhance intrinsic motivation and hence creativity, especially when the rewards are contingent on the creativity of the outcome (Eisenberger and Cameron 1996). Although, creativity is seen as a product of both motivational and cognitive processes (Runco and Chand 1995), this research has predominantly focused on motivational aspects of external rewards.

We propose that the disparate findings in the literature may stem from a limited understanding of the cognitive processes through which rewards affect creativity. Hence, in current work we address this paucity by examining the effect of rewards on cognitive processes that lead to creativity. Consistent with extant research, we focus on monetary and social-recognition rewards, and examine their impact on creativity when the contingency of the reward to the creative outcome is varied. We propose that these two rewards prompt different mental search strategies for idea generation and consequently affect creativity depending on the reward's contingency. Specifically, a social-recognition reward is likely to induce a broad and comprehensive search strategy. This is so because social rewards induce expectation of social scrutiny, which prompts individuals to engage in more broad and comprehensive information search to cover their bases (Tetlock 1983). In contrast, monetary reward induces a focused mindset and risk-seeking tendency (Eysenck and Eysenck 1982) and is hence, expected to encourage a more focused and narrower search strategy. Galileo System methodology is utilized to evaluate exploration of ideas in an individual's mental space.

Next, we propose that these alternative search strategies prompted by different rewards interact with reward contingency to jointly determine creativity. When rewards are not explicitly stated to be contingent on creativity, broader search for ideas inspired by a social-recognition reward should lead to greater creativity compared to when a monetary or no reward is offered. However, when rewards are contingent on creative performance i.e., a clear goal to be achieved is present, the focused exploration under monetary reward will occur in a domain distant from the mundane. This is because

money besides prompting a focused mindset, also induces greater risk seeking tendencies (Coles, Daniel, and Naveen 2006). Thus we should observe greater creativity under monetary reward as compared to a social-recognition reward.

To test our hypotheses, we asked 146 participants to generate as many ideas as possible to reduce teenage smoking in a 3(Reward Type: Monetary vs. Social-recognition vs. No reward) x 2(Reward Contingency: Creative-outcome vs. Control) between-subjects study. The data was subject to sets of analyses to confirm our predictions. The first set of analyses examined the creativity of the ideas generated. Ratings from twelve judges on 4 items (creative, original, novel and innovative) were used to create a creativity index for each participant. ANOVA revealed that in the control condition, the ideas generated under social-recognition reward were rated as more creative than those generated under monetary or no reward conditions. No difference was observed between the latter two conditions. For contingency condition, ideas generated under monetary reward were rated as more creative than those generated under social-recognition reward which in turn was rated as more creative than those under no reward.

Next we tested respondents' ideation patterns in their mental space i.e. the underlying cognitive process that affects creativity. First, we ascertained the position of each generated idea in conceptual space using the Galileo System of multidimensional scaling. Two expert consumer judges provided distance estimates between the ideas generated by each participant. The distance estimate between any pair of ideas represents the dissimilarity between the two, such that the ideas that are more similar are closer to each-other than those that are more dissimilar. These distance estimates were submitted to the Galileo algorithm, which generated Cartesian coordinates for ideas generated within each treatment condition. An examination of the Cartesian plots and ANOVA showed that the social-recognition reward produced ideas that were more spread out i.e., the average distance between the ideas was higher as compared to monetary or no reward conditions irrespective of contingency of rewards.

Next we analyzed the location of exploration under different treatment conditions, vis-à-vis location of the most conventional idea. First, the most conventional idea was identified from the pool of all the generated ideas and then estimates were obtained for the distances between the most conventional idea and each of the other ideas generated by each participant. These estimates were input into the Galileo algorithm to obtain respective Cartesian coordinates. Analysis of the Cartesian plots and ANOVA for mean value of the distances between the most conventional idea and all other ideas generated by a participant showed that the location of exploration from the most conventional idea was farthest for the creativity contingent monetary reward as compared to all other conditions.

Thus, this work then demonstrates that although both monetary and social-recognition rewards can enhance creativity, they operate via different mechanisms: while social recognition reward encourages broader exploration leading to higher creativity, a monetary reward induces exploration within a narrow area. However, when rewards are contingent on creativity of the outcome this narrower exploration happens at a farther distance from mundane ideas leading to higher level of creativity.

"Grounded Cognition, Spatial Working Memory and Category Experience as Influencers of Creative Imagination," Rosa, Ruth, & Qualls

EXTENDED ABSTRACT

This study explores the influence of grounded cognition – modality-specific systems for vision, action, affect, etc – on the creative imagination of consumers. It has been argued that creativity, particular when it comes to products and their use, has multiple dimensions, such as functionality and novelty. It has also been argued that creativity draws on multiple mechanisms and sources, such as analogical reasoning, memory capabilities, pre-existing knowledge schemas, personal disposition, and affective state (e.g., Price and Ridgway 1982; Amabile 1996; Dahl and Moreau 2002; Burroughs and Mick 2004, Moreau and Dahl 2005, Burroughs, Moreau, and Mick 2008). The isolated influence on novelty and functionality of higher or lower levels of grounded cognition (Barsalou 1999, 2008), however, has not been explored in consumer research. Of necessity, exploring the influence of grounded cognition on creative imagination must take into account other factors likely to affect the process, such as a person's general capacity for conceptually manipulating known components into novel arrays (e.g., spatial working memory), and general knowledge of product categories that may guide creative efforts in the development of new entries to the category. Accounting for such additional factors is part of this study.

In two experiments, participants were asked to study three simple geometric shapes that were presented as either three-dimensional wood objects or line drawings of the objects. This constitutes the grounded cognition manipulation. Subsequent to studying the components for two minutes, they were asked to without access to the components, imagine product concepts that made use of all three components, draw and give names to their creations, explain how they work and briefly describe how they felt about their creations. The creative imagination outputs from participants were assessed by independent judges for novelty and functionality as indicators of creativity. Judges were also asked to assess how study participants felt about their creations from the narratives as a measure of engagement with the task. Spatial working memory capability was assessed based on gender (females typically having greater capacity) and general knowledge of product categories was controlled for by varying the categories (e.g., personal items, tools, toys) for which participants imagined product concepts in the second experiment.

Results show that higher levels of grounded cognition (e.g., greater sensory inputs gleaned from three-dimensional wood shapes) led to increased functionality in the imagined products, while the reduced level of grounded cognition from line diagrams induced higher novelty in some situations. In addition, consumers with higher spatial memory capacity (assumed in female participants) delivered products that were more novel and functional. The effects of grounded cognition and spatial working memory were moderated, however, by changes in product category, and the effects seem to be related to gender-based norms for product category familiarity. Overall the results affirm a role for grounded cognition in creative imagination among consumers, and suggest that the influence of grounded cognition and spatial working memory on creativity may be more complex than originally envisioned. Several areas for additional research were made clear by the results.

"Unconscious Creativity: The Impact of Deliberation-Without-Attention Duration on Creative Ingenuity," Yang, Chattopadhyay, Zhang, & Dahl

EXTENDED ABSTRACT

Though deciphering the sources of creative ingenuity is important for both consumer satisfaction and corporate success, research on creativity within this context has been relatively limited (Burroughs and Mick 2004; Moreau and Dahl 2005). Given the recent findings on the superior capabilities of unconscious thought (i.e., "deliberation in the absence of conscious attention directed at the problem," Dijksterhuis et al. 2006, p.1005) in processing complex information and decision making (Dijksterhuis 2004), it is reasonable to argue that unconscious deliberation has a role to play in facilitating creativity in consumer domains.

Indeed, pioneering research has found initial evidence supporting the positive impact of unconscious thought on creativity. For example, in one study (Dijksterhuis and Meurs 2006), participants were asked to list out Dutch place names starting with the letter "A" or letter "H." Whereas those who deliberated consciously generated more names of large cities and towns, those who deliberated unconsciously reported more names of small villages. This suggests that unconscious thought may have better access to unusual, pre-stored information. A subsequent study (Zhong et al. 2008) found that, for difficult remote association test (RAT) items, a short period of unconscious thought, as opposed to an equal duration of conscious thought, increased the speed at which participants were able to respond to the RAT items correctly. However, in this study, unconscious thought did not increase the number of correct answers provided by participants. Thus, despite encouraging findings, it is unclear how the power of unconscious thought can be adequately harnessed to improve actual creativity.

The current research seeks to fill this gap in the literature and sheds light on the conditions under which unconscious thought positively impacts creative ingenuity. We follow the conceptualization that impact of unconscious thought on creativity is a two-stage process (Zhong et al. 2008). In the first phase, unconscious deliberation generates creative ideas for the target task, resulting in "deep activation" of mental constructs representing these ideas (Wegner and Smart 1997). This deliberation is a goal-driven process (Bos et al. 2007) and is monitored unconsciously (Bongers and Dijksterhuis 2009; Moskowitz et al. 2004)—once the goal of generating creative ideas is deemed completed, the unconscious ceases to deliberate about the target task. Thus, even if an individual is allotted ample time for unconscious deliberation, that person might not deliberate unconsciously for the entire duration and could stop generating creative ideas early on. In the second phase, the fruit of the unconscious labor is outputted. Because this outputting (e.g., writing down ideas) is typically a conscious process, the deeply activated constructs need to emerge from the unconscious to the conscious to be successfully realized. However, because the activation of mental constructs decays rapidly (e.g., Kiefer and Spitzer 2000), the longer the gap between the time when the constructs were activated and the time when they are outputted, the fewer of these constructs would remain activated enough to be transferred to consciousness. Thus, the combined outcome of the goal directed generation phase of unconscious deliberation and the decay of unconsciously activated mental constructs results in an inverted-U shaped relationship between duration of unconscious thinking and creativity performance—when the duration of conscious thought is short, few constructs are generated and, thus, few constructs are available to be outputted. However, when the duration is too long, some or all of the found constructs

may no longer be sufficiently activated to be consciously realized. In contrast, conscious deliberation does not hinge on the transference of unconsciously activated mental constructs to consciousness. By definition, conscious thought makes the fruit of its labor consciously available. Further, because conscious thought operates at a significantly slower speed than unconscious thought (Dijksterhuis 2004), longer duration of conscious deliberation may be beneficial to creativity performance. Therefore, the creative output of unconscious deliberation is likely to be superior to that of conscious deliberation only when deliberation duration is moderate.

Moreover, creativity performance involves two dimensions—novelty and appropriateness (e.g., Amabile 1996). Given that unconscious thought has superior capabilities in searching and associating complex knowledge bases (Dijksterhuis et al. 2006), it is reasonable to predict that deliberation-without-attention can help identify and produce more novel ideas. However, unconscious thought theory (Dijksterhuis and Nordgren 2006) also states that conscious thought excels in precision processing and following rules and constraints, whereas unconscious thought is adept at producing rough estimates. Because appropriateness is characterized by producing solutions that meet the stringent constraints of the situation, it is thus unlikely that unconscious deliberation would lead to improvement on this dimension of creativity.

We tested these hypotheses in two experimental studies. In Experiment 1, participants were first shown the target task (i.e., write down things they can do with paperclips). Those who in the conscious-thought conditions were given one (vs. three vs. five minutes) to think about how to answer the question and then two more minutes to write down their responses. Those in the unconscious-thought conditions, however, spent the first period of time on a distraction task—a two-back lexical task; they were then given two minutes to write down their answers. Two independent judges evaluated each participant's responses in terms of novelty and appropriateness. Consistent with our predictions, a curvilinear relationship was found: The novelty rating of the ideas generated by participants, first increased with the duration of unconscious deliberation, and then decreased. Further, participants in the unconscious-thought conditions outperformed those in the conscious-thought conditions when the deliberation duration was three minutes, but not one or five minutes. Also consistent with our hypothesis, no difference on the appropriateness dimension was found between the thought conditions regardless of the deliberation duration.

Whereas Experiment 1 assessed the range and the quantity of creative ideas generated, Experiment 2 focused on investigating the impact of unconscious thought on the extent to which a *single* solution for a specific task is creative. The target task in Experiment 2, i.e., designing a toy for children, not only improved the ecological validity of our research, but also helped demonstrate the real-world implications of our findings. As expected, the results of Experiment 2 were consistent with those of Experiment1: Longer duration of unconscious deliberation actually harmed, rather than boosted, creativity performance. The creative output of unconscious thought was superior to that of conscious thought only when deliberation duration was moderate, and this superiority pertained only to the novelty dimension of creativity but not the appropriateness dimension.

Roy Baumeister, Florida State University, USA

SESSION OVERVIEW

At its core, marketing is about managing consumers' desires. Indeed, managing desires could be said to be the crux of the human condition. Hence this session brings together four papers that detail how consumers manage (or fail to manage) their desires. Some of the approaches, such as Nenkov et al's and Ramanathan et al's work, are centered on the cognitive aspect of controlling desire. Our first paper, Nenkov, Haws, and Kim, instructed participants to use different mental processes to imagine what will happen if they do or do not control their desires. Their findings about which processes are best to use, for whom, and when offers self-regulators two new cognitive tools to increase the odds that they will reach their goals. The second paper by Ramanathan et al will discuss the way that consumers react when they see health claims on food items. The mere mention of a hedonic attribute, such as fat content (even statements that a food is "low fat") makes foods more appealing, whereas functional attributes, such as a food's antioxidant content, makes them less appealing. Vohs and Hofmann's papers speak to the motivation and emotional components of desire. Vohs's work shows that one central reason that prior self-control leads to later self-control failure (the ego-depletion effect) is because people experience their desires as more potent – depleted people more than others feel their emotions more strongly, feel overtaken by powerful urges to eat, and so on. Hofmann took the idea of desire to the streets and collected data on more than 7000 naturally-occurring desires. His work demonstrates people's everyday attempts to control their desires, and how they are met with varying success. In summary, each paper takes a unique and novel tack on the study of consumer desires, bridging cognitive, emotional, and motivational approaches.

This symposium is a model of "building connections," and therefore embodies the theme of 2011 ACR because the research spans various aspects of the self (cognitive, emotional, motivational, and behavioral), multiple methodological approaches, and sample characteristics. Researchers will discuss lab-based experiments as well as large-scale field studies. Data were gathered from multiple countries around the globe, which means that diverse populations are represented. Actual behavior was measured, in addition to thoughts, evaluations, and feelings. Specific groups might find this work of particular interest: scholars of self-regulation, goal achievement, motivation, and the self, along with scientists interested in judgment and decision making, eating, and addiction. In short, the findings being presented represent a wide range of approaches, and thusly will forge connections among scholars of diverse backgrounds.

How Best To Think about the Future: Which Outcome Elaboration Strategies Help Control Desire?

EXTENDED ABSTRACT

Thinking about the potential consequences of decisions is a promising strategy for controlling currently tempting desires in order to reach long-term goals (Nenkov et al. 2008; Haws et al. 2011). Because there are various ways in which one might elaborate on potential future outcomes it is important to understand which future outcome elaborations most effectively to control the desire one is facing in the present moment. In this research, we tested which outcome elaboration approaches will be most likely to help self-control. We propose that fluency between individual propensities and elaboration strategies as well as between various components of the elaboration itself will facilitate goal-directed behavior.

In our research, we first manipulate the valence of outcome elaboration and examine how these outcome elaboration approaches match with individual tendencies to elaborate on potential outcomes (EPO; Nenkov et al. 2008). Then, we turn our focus to jointly manipulating the valence and the level of abstraction of outcome elaboration and showing that there is a natural match between negative and concrete and positive and abstract outcome elaboration approaches, which enhances their effectiveness in promoting desire control. Overall, we suggest that natural matches occur that lead to enhanced desire control based on outcome elaboration.

Prior research shows that some people tend to elaborate on potential future consequences more (i.e., high EPO) than others (i.e., low EPO) and this natural tendency has been linked with an increased incidence of exerting self-control (Nenkov et al. 2008). Therefore, some understanding of the types of elaboration commonly used by those higher in EPO would be beneficial in determining the most effective outcome elaboration strategies. For example, when considering an indulgent opportunity, a decision maker could focus on the benefits (or potential positives) to be gained from yielding to desire or the costs (or potential negatives) that might be incurred. We suggest that higher EPO consumers are much more likely to focus on the potential negatives of indulgence, and that this type of outcome elaboration comes easily to them. On the contrary, lower EPO consumers fail to elaborate at all.

To test these prediction, we focus study 1 participants (n = 187) on thinking about either the positive or negative potential outcomes of yielding to desire in a domain of their choice (i.e., money or time management). Separately, we assess their individual propensity to elaborate on potential future outcomes (EPO; Nenkov et al. 2008).

Our results show that consumers higher in EPO are overall less likely to choose a vice option following outcome elaboration than their lower EPO counterparts and that negative outcome elaboration enhanced their self-control even further. Process evidence suggests that for high EPO individuals, the negatively biased outcome elaboration task was "not complex", whereas for low EPO participants, negative elaboration was more "complex" than was positive elaboration. As such, we have some initial evidence that the fluency experienced by EPO consumers when elaborating on negative potential outcomes drives their greater self-control success.

Next, we wished to further explore the role of valence in consequence elaboration and how valence might impact the nature of the consequences considered. Based on past literature (Trope, Liberman, and Wakslak 2007), we propose that there is a match between negative outcome elaboration and concrete construal level and positive outcome and abstract construal level. To test this contention, in study 2, we directed participants to elaborate on potential outcomes by focusing on either the positive or negative consequences of failing to control desires. Participants (n=103) provided potential outcomes consistent with a domain of their choice (i.e., money or time management). We then coded the consequences participants listed as: referring to why vs. how, being abstract or concrete, or referring to the short-term or long-term temporal distance. Results revealed that negative outcomes, as compared to positive ones, were more focused on how consequences can be achieved, more long-term oriented, and overall more concrete (i.e., more specific and detailed, low-level, referring to means to an end, process, planning, and details). As such, there seems to be a natural tendency for negative consequence elaboration to be more concrete.

Study 3 pinpointed the role of construal level. Participants (n=145) were given one of four instructions for potential outcome elaboration related to the self-control domain of their choice. These instructions represented a 2 (valence: positive or negative) X 2 (construal level: concrete or abstract) design. Unlike studies 1 and 2, we asked study 3 participants to consider the positive consequences of exercising self-control, rather than of yielding to desire. Our results revealed that elaborating on the negative and concrete outcomes of yielding to desire most benefitted participants' intention to control their desires. Yet, elaborating on the positive outcomes of exercising self-control also promoted effective self-control when the consequences considered were abstract rather than concrete. Process evidence suggests that the natural match between negative/concrete and positive/abstract outcome elaboration approaches explains the results.

Overall, our research provides new insights into how considering the consequences of yielding to desire can impact self-control effectiveness. Our results suggest that when it comes to outcome elaboration, one size does not fit all, and customizing elaboration on potential outcomes approach will aid goal attainment.

Not All Health Claims Are Created Equal: Dissociating the Dynamics of Guilt and Desire Invoked by Food Indulgences

EXTENDED ABSTRACT

Healthier alternatives of unhealthy foods are increasingly prominent in today's supermarket shelves. Typically, such foods feature claims stressing either the presence of food attributes that are perceived to benefit health (e.g., antioxidants, vitamins) or the absence of attributes perceived to be unfavorable for health (e.g., fat, sugar). It is assumed that such 'better-for-you' options of unhealthy food should reduce feelings of guilt associated with eating the food, arguably because the presence of health claims make their consumption easier to justify, thereby providing consumers with an implicit license to eat.

In contrast, the literature on the effects of hedonic (e.g., fun, tasty) versus functional (e.g., safe, nourishing) attributes on stimuli perception, preference, and choice predicts that consumers should eat less of unhealthy food carrying a health claim because they (unwittingly) subscribe to the unhealthy = tasty intuition. We propose a more nuanced framework suggesting that it is the nature of the attributes highlighted in a claim that determines how much of the food is consumed.

Experiment 1 showed that seemingly similar health claims attached to unhealthy food result in very different consumption patterns, despite the fact that they are all perceived as equally tasty. Claims emphasizing a functional food attribute (e.g., antioxidants) induce a significant decrease in consumption compared to a control condition, whereas claims about a hedonic food attribute (e.g., low-fat) result in a significant increase in consumption. These opposing consumption patterns, which were triggered by ostensibly similar health claims, suggest that different mechanisms are at work for health claims for attributes that highlight the hedonic qualities of the food (e.g., fat = tasty) versus claims that highlight health-related functional attributes (e.g., antioxidants=beneficial for health; cholesterol=detrimental for health).

Experiment 2 examined whether health claims featuring hedonic versus functional food attributes evoke different levels of health goal accessibility. We suggest that claims stressing functional food attributes versus hedonic attributes lead to greater accessibility of the health goal. In addition, we expected indulgence goals to be highly accessible regardless of the presence or absence of health claims and independent of the attributes emphasized in claims. Using a lexical decision task, we tested whether different claims led to different response latencies for words relating to health and indulgence. The results showed that hedonic attributes led to slower response times towards health words when compared to functional attributes, while response latencies towards indulgence words were no different across conditions.

In Experiment 3, we provide a more fine-grained analysis of the processes underlying different types of health claims by investigating the emotional consequences of conflicting goals triggered by functional versus hedonic food attributes. In particular, we dissociate the feelings of anticipated desire and guilt upon exposure to a picture of a tempting food carrying a health claim featuring either a functional or a hedonic food attribute. We recorded participants' moment-to-moment reactions regarding desire and guilt. Results

reveal that the goals activated by food attributes differing in their hedonic versus functional nature evoke very different trajectories of desire and guilt. While both types of claims provide similarly high levels of desire as they are attached to indulgences, the time course of guilt is very different in nature. Specifically, health claims featuring hedonic attributes evoke an immediate ramp up in desire for the food while guilt is at a low level. Notably, there is a gradual increase in guilt over time, suggesting that people are experiencing an ironic rebound of suppressed guilt. This finding runs counter to an ease of justification argument, which would imply reduced guilt over time. In contrast, functional attributes cause a reduced immediate desire towards temptations, suggesting an immediate devaluation of the product, coupled with a rapid ramp-up in guilt.

Together, our findings reveal that seemingly similar health claims may activate very different levels of health goal accessibility, leading to different dynamics of perceived desire and guilt and hence eventually to opposite consumption patterns of the unhealthy food they are attached to. Our findings have broad relevance to the food industry, and suggest that the nature of attributes emphasized in the health claim can have significant effects on consumption.

Engaging in Self-Control Intensifies Desires and Feelings

EXTENDED ABSTRACT

Following effortful acts of choice or self-control, people enter into a state that has been called ego depletion, which is defined by a reduced capacity to engage in further executive activities. Behavioral conflicts can be analyzed as motivations between impulse and restraint. Viewed as such, ego depletion represents a weakening of restraint. The assumption is that the impulse itself is unchanged by depletion, although this has not been tested.

The present investigation took a new approach to understanding the relations among depletion, impulse, and restraint. The core hypothesis was that ego depletion would intensify the subjective experience of feelings and desires. That is, we questioned the standard assumption that depletion weakens restraints but leaves feelings and desires unaffected. The behavioral changes that ensue during the depleted state may therefore come from not only a weakening of inner controls and restraints but also from an intensification of feelings and desires. Essentially, evaluative reactions would be intensified by depletion.

Experiment 1 tested the hypothesis that depletion would intensify emotional reactions to specific stimuli. Ego depletion was manipulated with the Stroop procedure. Some participants used their self-control to override the automatically activated information of the known meaning of the word in order to give an answer as to the color of the ink in which the word is printed. Other participants were given a nondepleting version of this task in which columns of Xs were shown and their ink color names given. The dependent measure included both positive and negative emotional responses. We presented participants with pictures known to elicit pleasant and unpleasant reactions and asked them to rate how they felt while looking at each one. The prediction was that ego depletion caused by the incongruent Stroop task would intensify both positive and negative feelings. Results supported the hypothesis: after doing the more difficult and depleting Stroop task, participants reported stronger feelings in response to emotionally evocative pictures, as compared to participants who had done the easy version of the Stroop task and not depleted their resources.

Experiment 2's self-regulatory depletion manipulation was to have participants read aloud a relatively dry, boring passage with lively verbal inflection and accompanying hand gestures. Partici-

pants in the nondepletion condition read aloud the text without specific instructions to be emotional. The outcome measure involved evaluations of stimuli for which most participants would have few or no pre-existing associations. Specifically, participants were asked to rate Chinese characters. Because no one in our sample could speak or read Chinese, these figures had no meaning to them. They could therefore only react to the aesthetic impact of the character as if it were something akin to abstract art or a figure to have tattooed on oneself. Classic work by Zajonc showed that viewers can and do have positive and negative emotional feelings about Chinese characters. Our prediction was that these feelings would be stronger in depleted than in non-depleted participants. The results supported this hypothesis, in that depletion caused people to react relatively strongly to Chinese characters. Participants reported how these characters made them feel, how attractive they were, and how much they liked each of the characters. Overall, depleted participants gave more extreme ratings than non-depleted ones.

In experiment 3, the depletion manipulation asked participants to write an essay without using the letters A or N, whereas participants no-depletion condition were asked to write an essay without using the letters X and Z. Our dependent measures were ratings and consumption of cookies in a taste-testing task. To assess the motivation to consume more cookies, participants rated their desire to have another cookie after finishing each cookie. Participants were left alone to eat and rate the cookies. The results showed that, in line with predictions, depleted participants had stronger desire than non-depleted participants to keep eating more cookies. Thus, depletion intensified the desire to eat another cookie. Consistent with previous research, participants in the depletion condition ate more cookies overall than participants in the no-depletion condition. Even more important, analyses indicated that participants' motivation to eat more cookies mediated the effect of depletion condition on number of cookies consumed.

Experiment 4 tracked subjective feelings over time. First, participants watched a videotape that contained irrelevant words onscreen. Participants in the depletion manipulation were told to "avoid looking at or reading any words that may appear on the screen," while those in the control condition were given no instructions regarding the words on the screen. After the depletion manipulation, participants were given a wrapped gift. They were allowed to open it, but were asked to wait. They used a joystick to report their momentary level of desire to open the gift. The results showed that mean desire to open the package was higher for depleted than non-depleted persons. Thus, intensification of the urge was an enduring consequence of depletion, rather than a fleeting or one-time-only experience. The peak level of desire expressed during the entire period by each depleted participants was higher than the peak level of desire reached by nondepleted participants, on average. Depleted participants were also marginally quicker than nondepleted ones to reach their peak level of desire.

In summary, we reported a series of studies that used multiple different methods and measures to test the hypothesis that depletion intensifies feelings. The depletion tasks involved cognition and emotion, attention and behavior, and inhibiting and enhancing responses. The intensified reactions included emotions and attitudes, good and bad feelings, and approach and avoidance behaviors. In short, depletion enhances feelings and evaluations of stimuli, which contributes to its effect on worsening self-regulation subsequently.

Everyday Temptations: An Experience Sampling Study on How People Control Their Desires

EXTENDED ABSTRACT

In recent years, research on human self-control has flourished. Self-control can be defined as the ability to override or change one's inner responses, as well as to interrupt undesired behavioral tendencies (such as impulses) and refrain from acting on them. However, most research has been conducted in laboratory settings even though suitable methods such as the daily construction method and experience sampling have been proposed. Given the paucity of knowledge of how people control their desires in naturalistic settings, our study sought to provide an in-depth analysis of everyday self-control through the use of experience sampling methodology. Specifically, we were driven by the following main questions: What kind of urges and desires do people experience over the course of their daily lives? To what extent do desires conflict with important long-term goals, and how often and how successfully do people resist them? Further, to what extent do people's successes and failures trigger self-conscious emotions such as guilt, pride, and regret? And do these self-conscious emotions in response to lapses aid subsequent self-control as predicted by feedback models or hinder subsequent self-control as suggested by findings on the spiraling effects of emotional distress?

To study desire and self-control in vivo, we conducted an experience sampling study on a heterogeneous sample of 205 adults in Western Europe. Participants were prompted at random with 7 signals per day over the course of a week. They indicated if they had current or recent desires and, specified the content of the desire from a list of 15 main and more than 70 subcategories. Moreover, participants provided information on the details and their possible self-control attempts: how strongly the desire was experienced, whether the desire conflicted with an important goal, whether and how they tried to resist the desire, whether they executed the desire-relevant behavior or not. In addition, participants reported their current levels of guilt, regret, and pride and reported on various circumstantial variables such as level of alcohol intoxication.

Participants reported more than 7,000 desire episodes (75% of all occasions that they were beeped). Approximately one-third of desires conflicted moderately to highly with other goals. Multilevel analyses showed that degree of conflict predicted the likelihood with which participants attempted to resist the present desire, and that resistance had a strong negative effect on enactment. Specifically, 83% of all resistance attempts were successful, leaving a nontrivial amount (17%) of self-control failures among resisted desires. Desire strength, desire-goal conflict, and successful resistance varied across domains, with sexual desires, spending impulses, and sports inclinations most likely to be successfully resisted, and desires for media use and work least likely to be successfully resisted. Self-control success was further moderated by situational factors such as alcohol consumption, ego depletion due to previous resistance attempts on the same day, and whether other people in the immediate environment already engaged in the desire-related behavior of interest.

Regarding self-conscious emotions, as expected, guilt experiences were strongest when desires were resisted but enacted (i.e., self-control failure) and pride experiences were strongest when desires were resisted and not enacted (i.e., self-control success). Feelings of regret, in contrast, were most pronounced when unproblematic (i.e., unresisted) desires were not enacted. To address the question of how previous self-conscious emotions may aid or hinder subsequent self-control, we regressed each person's conflict, resistance, and enactment reports on his or her previous feelings of guilt, regret, and pride within the same specific type of desire (e.g., sweets, beer, watching TV) and included as a moderator whether the preceding occasion counted as a lapse or not (in the case of guilt and regret), or as self-control success (in the case of pride). We found that the intensity of guilt reactions to lapses had an indirect effect on subsequent enactment via increased feelings of conflict, and a greater likelihood of resisting the problematic desire. For regret, there was only an indirect effect on subsequent conflict experiences. Pride emerged as the most potent self-conscious emotion in that pride in response to self-control success predicted less subsequent enactment. As in the case of guilt, this effect was mediated via increased conflict experiences and a greater likelihood of resistance.

In sum, these data provide rich insights into people's regular struggles and successes in overcoming temptation. Moreover, we suggest mechanisms (increasing experience of conflict, increased resistance) by which self-conscious emotions may aid subsequent self-control.

Health, Wealth, and Consumer Welfare

Eldar Shafir, Princeton University, USA

SESSION OVERVIEW

The fact that consumers need to save more and engage in healthier behaviors is beyond dispute. The key question is – what specific prescriptions can be offered based on the literature that consumers could use to change behavior and improve savings. To motivate consumers to change behavior, different strategies have been suggested such as introducing the opt-out policies while using the better choice as the default. Other programs such as saving a proportion of payroll in the saving account automatically have also been employed to increase consumer saving. This session tries to propose new approaches that help consumer act toward better welfare related with their health and wealth, investigate the psychological rationales behind it, and understand consumers' perceived wealth and debt and their subsequent financial behavior.

The first paper by *Keller and colleagues* examines people's decision in healthcare context (e.g., flu shot or automatic prescription refill) and introduces a new choice strategy: Enhanced Active Choice which is a forced-choice structure without default (e.g., choosing between getting a flu shot to reduce the risk of getting the flu vs. not getting a flu shot and increasing the risk of getting the flu). Results from four studies demonstrate that Enhanced Active Choice motivates behavior change by advantaging and increasing loss aversion for one option. Moving from the general choice policy in the healthcare domain to more specific behavior change in the financial domain, the second paper by *Soman and Zhao* examines how number of savings goal impacts consumers' savings intention. Contrary to common belief, they demonstrate that a single savings goal leads to greater savings and savings intention than multiple goals due to the implementation intention evoked by the single goal. Further, they show that this effect is attenuated when the saving is easier to implement or when multiple goals involve little competition among themselves. Although the specific studies in *Keller and colleagues* are related with healthcare decisions and the studies in *Soman and Zhao* are related with savings behaviour, the general principles of Enhanced Active Choice or using fewer number of reasons to prompt an implemental mindset can both be widely applied in healthcare, saving, donations or other domain related with consumer welfare. Finally, *Sussman and Shafir* take a different perspective and explore the psychology of perceived wealth. Their findings show that keeping positive net worth constant, people feel and are seen as wealthier when they have lower debt (despite fewer assets) because debt stands out in a positive net worth scenario. In contrast, those with nega-

tive worth feel and are seen as wealthier with greater assets (despite greater debt), because the possession of assets attracts more attention as it stands out in a negative wealth contexts. These findings have important implications on people's subsequent spending and borrowing behavior, which ultimately impacts their welfare.

The papers in this session proposal are all in advanced stages of completion. Taken together, the session is designed to provide an integrative overview of new research aimed at enhancing our understanding of consumer decision making and psychology related with their health, wealth and welfare in general. The likely audience for this session will be consumer researchers in general and specifically those who are interested in consumer's financial decision-making, consumer welfare and public policy. Thus we expect to draw the interest of a wide range of researchers. John Lynch, an expert in consumers' decision making, will lead discussions to simulate future research directions at the end of the session.

Enhanced Choice: A Method to Motivate Behavior Change

EXTENDED ABSTRACT

Enrollment in tax-favored savings plans is 50% higher when employees are automatically enrolled compared to when they opt-in (Madrian and Shea 2001). Opt-out' policies that automatically assign people to carefully selected default choices are effective for a number of overlapping reasons. *Loss aversion* encourages people to stick with the default because moving away from the default typically involves losses and gains, and losses receive disproportionate weight (Johnson and Goldstein 2003). The effect of loss aversion is further exacerbated by *present-bias* – the inordinate weight people place on costs and benefits that are immediate (O'Donoghue and Rabin 1999). *Procrastination* also works in favor of opt-out policies, again because deviating from the default often involves positive action, which people procrastinate in taking. Finally, opt-out policies exert such a strong influence on behavior in part because people assume that defaults have been selected for a reason – i.e., that defaults constitute implicit recommendations of specific courses of action (McKenzie, Liersch, and Finkelstein 2006).

Limitations of Opt-out

Yet, for all their advantages, opt-out policies have diverse and severe limitations, especially in some settings. First and foremost, because opt-out policies yield decisions through the inaction of the decision maker, they are less likely to engender the kind of committed follow-up that is often useful when it comes to implementing the decision. Family members of an elderly person facing the option of going on life support may be more likely to honor an affirmative decision by that person to eschew heroic measures than they would be to honor a decision that arose simply because the person failed to affirmatively state that they wanted such measures (Spital 1993).

Second, opt-out 'choices' in many situations are less likely to reflect decision makers' true preferences than will more active choices (Payne, Bettman, and Johnson 1993). For example, there is growing evidence that the shared optimum inherent in an automatic 401(k) enrollment plan may be inappropriate (Carroll et al. 2009) or unsustainable (Lusardi and Mitchell 2007) for some people.

Third, in some situations, passive choices are more likely to result in waste or inefficiency. If a person's failure to affirmatively

state that they don't want to recycle is taken as an intention to re-cycle, the recycling truck may end up making a lot of wasted trips to pick up recyclables that never materialize.

Fourth, opt-out choices are often legally or ethically unaccept-able. For instance, in a retirement saving context, we might want employees to sign up for "auto escalation" to boost their contribu-tions by a percentage point or so a year or sign up for a supplemen-tary retirement account (Thaler and Benartzi 2004), but it is illegal to auto-enroll employees in auto escalation plans.

Fifth, opt-out policies can be counterproductive if those who implement them view them as a substitute for other interventions, such as educational programs that give people the information they need to make an informed choice.

Finally, employers may not adopt automatic enrollment because they don't want to assume the burden of responsibility for planning for their employees. They may fear, to some extent rightfully, that some employees may interpret defaults as implicit advice (McKen-zie, Liersch, and Finkelstein 2006) and may be upset with their em-ployer during market downturns.

Active Choice: Avoiding the Problems Associated with Opt-Out

Three studies, two on organ donation (Spital 1993, 1995) and one on retirement planning (Carroll et al. 2009) attempt to achieve the same basic goal as opt-out – of ensuring that people who would benefit from an intervention, receive it – without the disadvantages of opt-out. Instead of waiting for people to opt-in, Spital (1993, 1995) found support in public opinion surveys for the idea of forcing people to choose whether they want to or don't want to donate their organs. Sixty three percent of a random sample of 1000 adults in the United States said they would support mandatory choice (Spital 1993).

In an observational study, Carroll and colleagues (2009) mea-sured the impact on savings plan enrollment in a firm that required all new employees to explicitly choose between enrolling and not enrolling in a 401(k) plan. The language (I want to enroll vs. I don't want to enroll) was deliberately designed to not advantage any one option (Carroll et al. 2009). The result was a 28% increase in enroll-ment in the "Active Decision" condition compared to when employ-ees opted-in.

Building on the research by Carroll et al. (2009) and Spital (1993; 1995) we advance the concept of forced choice by testing four important enhancements. Taking advantage of the opportunities afforded by a controlled study, we control for additional enrollment materials such as one-on-one coaching from human resources and other enrollment prompts such as reminders.

Second, we provide conceptual and empirical evidence for the cognitive processes that make Active Choice effective. We predict greater regret aversion for the new opportunity expressed as a forced choice than as a default.

Third, we examine a modified approach that we call 'Enhanced Active Choice' that advantages the option preferred by the commu-nicator by highlighting losses incumbent in the non-preferred alter-native. For example, Enhanced Active Choice might reframe the al-ternatives as a choice between: "I want to enroll in a 401(k) plan and take advantage of the employer match" versus "I don't want to enroll in a 401(k) plan and don't want to take advantage of the employer match." We believe dislike for the non-preferred alternative will be more marked when the costs of non-compliance are highlighted in the choice format.

In sum, our main hypotheses are (H1) that Active Choice ('un-enhanced' or basic and 'enhanced') will result in more compliance than opt-in non-enrollment defaults, and (H2) that Enhanced Active

Choice will result in more compliance than basic Active Choice. We test these hypotheses in four studies involving three different deci-sion tasks: intention to get a flu shot (study 1), desire to get a flu shot reminder (study 2), and enrollment and disenrollment in a prescrip-tion drug refill program (studies 3 and 4).

The Fewer the Better: Number of Goals and Savings Behavior

EXTENDED ABSTRACT

Goals play an important role in different aspects of consumer life such as risk-taking behavior (Atkinson 1957) or spending and savings behavior (Shefrin and Thaler 1988; Soman and Cheema 2004). Prior research suggests that multiple goals lead to greater per-formance (Locke and Latham 1990), or that the greater the number of means to pursue a goal, the more likely is one to pursue on that goal (Kruglanski et al. 2002). Drawing on research on implementa-tion mindset (Gollwitzer 1999), we make the opposite prediction and argue that presenting a single savings goal (e.g., saving for children's education) leads to higher saving achievement than presenting mul-tiple savings goals (e.g., saving for children's education, retirement and future housing).

Researchers on implementation intention have studied differ-ent stages that individuals go through when they make goal-related decisions (Gollwitzer 1999; Gollwitzer and Bayer 1999): an initial stage with a deliberative mindset, in which individuals are uncertain about their goals and seek to define a desired outcome by consider-ing the tradeoffs between the goals; and a subsequent stage with an implemental mindset in which individuals have already established the goal they wish to pursue and are considering when, where, and how to attain the goal. This stream of research has demonstrated that forming implementation intentions leads to more successful goal at-tainment than merely forming a goal.

While implemental mindsets can be induced in different ways such as instructing people to think about the how (vs. the why) or simply asking people to consider which of a number of alternative products they would prefer(Xu and Wyer 2007, 2008), we propose that presenting consumers with a single goal can also help evoke an implementation intention compared with multiple goals because multiple goals evoke tradeoffs consideration among goals which hin-ders people from translating the savings goals into action. However, when people only have one goal, they no longer need to make goal trade-offs and are more likely to move onto the second stage of the goal pursuance -- a position to think about implementing the goal. As a result, their commitment with the task at hand (i.e., saving) will be stronger and their savings intention will be higher. Further, based on prior research that implementation intention has its greatest benefits in complex and difficult situations (Gollwitzer 1999; Gollwitzer and Brandstatter 1997), we also expect that the advantage of a single savings goal over multiple savings goal on consumer saving will be attenuated when the goal is easy to implement.

We conducted four studies to test our hypotheses. In study 1 (n=83) which was conducted in a small town in India with local farmers and workers in a financial literacy program, we either told participants to save more to finance their children's education or to save more to finance their children's, any healthcare needs they might have, and to provide a nest-egg for when they retire. Partici-pants in the control condition were given no specific goals at all. The results showed that single goal led to higher savings rate over the next 6 months than multiple goals, followed by no specific goal at all.

In study 2 (n=194), participants in an executive skills were introduced to a hypothetical savings program that required them to deposit a minimum of $300 each month for 10 years to be invested in bonds and government securities. Participants in the difficult-to-save conditions were told that they have a monthly discretionary amount of $400 after paying for the essential monthly expenses, whereas participants in the easy-to-save conditions were told to have a monthly discretionary amount of $1200. Further, in the single goal conditions, participants were reminded that they should start thinking about providing for their children's future education. In the multiple-goal conditions, more goals were reminded (i.e., children's future education, housing expenses, retirement savings and other slush funds for emergencies). The results showed that when it was difficult to save, single goal led to higher savings intention than multiple goals; however, when it was easy to save, the advantage of single goal was attenuated. We also measured participants' implementation mindset, and found its mediation role in the aforementioned results.

In study 3 (n=156), rather than measuring participants' implementation mindset, we manipulated their mindset based on the same scenario as in study 2. We again found that single goal led to greater savings intention than multiple goals when participants didn't receive any mindset manipulation or when they received a goal intention manipulation. However, when participants received implementation intention manipulation, multiple goals led to equally high savings intention as single goal. This further confirmed implementation intention as the underlying process for the advantage of single goal over multiple goals.

Because our key premise is that multiple goals evoke trade-off consideration among the goals and thus hinder people from moving into an implemental mindset, we believe that if the competition among the multiple goals and thus the trade-off is removed, the effect of single goal over multiple goals will be attenuated. In study 4 (n=274) where we used non-competing goals (i.e., saving for future wellbeing such as peace of mind, flexibility, and independence), we indeed found that a single goal (i.e., saving for future wellbeing such as peace of mind) no longer led to higher savings intention than multiple goals, further confirming that the disadvantage of multiple goals was due to the hurtle to the implemental mindset.

Our work adds to research on financial decision making by demonstrating a new way to increase savings behaviour/intention -- limiting the number of savings goals to evoke an implementation mindset. Our findings have important implications to the goal literature, literature on attitude change (e.g., number of argument; Petty and Cacioppo 1984), and to policy-makers in encouraging consumer saving.

On Assets and Debt in the
Psychology of Perceived Wealth

EXTENDED ABSTRACT

Perceptions of wealth are central to economic behavior and feelings of well-being. To date, research on wealth perception has mostly focused on relative wealth, namely, how well off people are when compared to those around them (e.g. Frank 1999, 2007), and on conspicuous consumption, whereby people purchase visible status items to signal wealth (e.g. Heffetz 2010; Veblen 1899).

While these perspectives are important, they focus on features that, at best, act as correlates of wealth. People are influenced by the perceived wealth of others, but that, of course, does not fully correspond their actual wealth. Nor do the social motivations to impress others through financial extravagances. While important, these perspectives do not provide insight into a person's sentiments about her actual wealth. In contrast, the present studies look at wealth perception as it is influenced by factors directly related to wealth, namely, people's assets and debt. We explore how these factors shape perceptions of wealth, both one's own and others', as well as the willingness to engage in important financial transactions, including borrowing, lending, and spending, that emanate from such perceived wealth.

We first examine how full knowledge of total assets and debt enters into the perception of wealth. We find that keeping total net worth constant, people with positive net worth are seen as wealthier when they have lower debt (despite, consequently, having lower assets). In contrast, keeping total net worth constant, those with negative net worth are considered wealthier when they have greater assets (and, consequently, greater debt). Across a series of studies, we find that, when judging the wealth of people with equal positive net worth, approximately three-quarters of participants view those with lower debt and lower assets to be in a better financial position than those with higher debt and correspondingly higher assets. In contrast, when judging the wealth of people with equal negative net worth, approximately three-quarters of participants viewed those with higher debt and higher assets as in better financial position than those with lower debt and correspondingly lower assets.

We show this pattern to be robust to possible interpretations that appeal to liquidity constraints or to computational demands, and we find that it applies to participants' judgments both about themselves and about others. We also extend the findings to contexts where they yield counter-normative judgments, in which the perceptions described above persist when net worth differs by approximately 20% (e.g., where a person of $10,000 net worth but lower debt is perceived as wealthier than a person of $12,000 net worth but greater debt).

In follow-up studies, we extend these findings to several financial decisions, including reported willingness to borrow, lend, and spend. Specifically, we demonstrate that people with the preferred wealth distributions are more likely to take on additional debt, and that others are more likely to evaluate them as in a better position to borrow money. Furthermore, those with preferred wealth profiles (although equal or lower actual wealth) are willing to spend more to purchase luxury items.

To explain these results, we test the hypothesis of an attentional shift when subjects confront positive versus negative net worth scenarios. We first show a positive correlation between asset balances and perceived wealth for those with equal negative net worth ($r = .73$, $p = .017$), and an asymmetric negative correlation between asset balances and perceived wealth for those with equal positive net worth ($r = -.91$, $p < .001$). We then provide more direct evidence that in the positive net worth scenario, debt (rather than assets) draws subjects' attention, by coding participants' initial reactions to financial profiles. The burden of holding debt stands out as a salient negative relative to one's overall positive state, disproportionately affecting perception. Conversely, in negative net worth scenarios, the possession of assets attracts more attention as it stands out against one's overall negative state.

We discuss how the findings go beyond a prospect theoretic account, and we explore how they can be used to explain why some individuals are debt averse, avoiding financially wise low interest loans, while others are debt seeking, taking on economically questionable high interest loans. Finally, we consider several policy implications, with an emphasis on the consequences for borrowing among the poor.

Interestingly, the same general impulse for financial wealth and stability can trigger opposing behaviors: a striving for greater assets despite larger debt in some circumstances, and for lower debt, even

if it means lower assets, in others. Such impulses, furthermore, may not always agree with what might be best financially. For example, it is likely that those with negative net worth who are eager to borrow (and may feel wealthier as a result) will only have access to high interest loans, thus exacerbating their already precarious finances. On the other hand, those with positive net worth who could benefit from taking on low interest debt, such as student loans, may be reluctant to make a profitable investment in their education, because of its negative impact on their perceived wealth.

Impressions of financial stability, assets, and debt have been shown to impact not only financial behavior, but also overall health and well-being (Miron-Shatz 2009; Nelson, Lust, Story, and Ehlinger 2008). Better insight into the perceptions and impulses that yield financial behaviors may enrich our understanding of the relevant psychology, and contribute to behaviorally informed financial design and policy.

Ayelet Gneezy, UC San Diego, USA
Simona Botti, London Business School, UK

SESSION OVERVIEW

Optimism is an important concept in research areas as diverse as subjective wellbeing, decision making, personality, and social comparisons. Each of these areas defines optimism in slightly different ways but all agree that, despite the forces working against them, hope and wishful thinking color much of human experience. In the consumer context, individuals' tendency to be optimistic about the nature of current and future events plays a crucial role in a wide range of substantively important phenomena. As the papers in this session show, optimism can influence decisions that have serious, and sometimes long-term, consequences in domains such as health, food, gambling and ethics. The thread linking the four papers in this special session proposal is a focus on the prevalence of optimism and on its potentially negative consequences for consumers' welfare. The aim of the session is to provide a picture of current theorizing on optimism within consumer research. The session is based on 15 completed studies, across a variety of methods, research areas, and substantive settings.

The first two papers focus on the robustness and prevalence of optimism and posit that optimistic responses may emerge as a consequence of either truly held optimism or other intrapersonal or interpersonal factors. Although both papers find evidence consistent with a significant truly held optimism, the picture they portray is rather different—something that we expect to trigger a lively debate during the session. Simmons and Massey show that even in the presence of real and large accuracy incentives people remain optimistic in their predictions about future events, suggesting that optimistic responses tend to be indeed truly believed. Sweldens and colleagues investigate the role of public posturing in comparative optimism in the health domain, and conclude that a large upward bias exists in researchers' beliefs about the prevalence and magnitude of comparative optimism for negative life events. The last two papers examine the consequences of optimism, investigating contexts where optimism leads to suboptimal outcomes for consumers. Gino and colleagues hy-

pothesize that confident decision makers are more likely to cheat by overstating their current performances because they believe that they will indeed improve them in the future. Thus, managers' optimism about their ability to eventually address weaknesses in their offering leads to dishonest marketing practices that are harmful to consumers. Malkoc and colleagues investigate situations where consumers have little information about choice options, such as unfamiliar food or accommodation types, and must draw inferences about their attributes. In these cases, optimism may be misleading and even detrimental, as consumers give unwarranted positive evaluations and seek for more risk than they should.

Perhaps ironically given the topic, we expect this session to provide a lively debate and to be of interest to a substantial proportion of the ACR community. In particular, we expect the session to appeal to researchers in the decision-making area studying how individuals make predictions about the future, as well as to researchers with a substantive interest in consumer welfare. We believe that the proposal fully expresses the spirit of "building connections" that is the theme of this year's ACR. While all four papers address issues related to optimism, each provides distinct conceptual and substantive contributions in research areas that are often deemed as separate islands within the literature. Indeed, the four papers draw a bridge between organizational research on ethics, economics research on judgment under uncertainty, social psychological research on comparative judgments, and decision making research in marketing.

The Effect of Large Incentives on Optimistic Responding: Evidence That Optimism Is Real

EXTENDED ABSTRACT

Does wanting an event to happen increase the likelihood of believing that it will? Although demonstrations of optimistic biases in forecasts of task completion (Buehler, Griffin, & Ross, 1994), task performance (Camerer & Lovallo, 1999), health outcomes (Weinstein, 1980), political outcomes (Krizan, Miller, & Johar, 2010), and sporting outcomes (Massey, Simmons, & Armor, 2011) seem to support this notion, researchers have questioned whether optimistic responses really reflect true beliefs.

Because optimistic responding is typically a low-cost endeavor (i.e., incentives for making accurate predictions are usually absent or trivial), scholars have argued that people may prefer to respond optimistically even when they do not believe it. For example, a sports fan may predict that his favorite team will win an upcoming game not because he genuinely believes this but out of a low-cost desire to remain loyal to his team. Thus, optimistic responding may reflect cheap talk rather than true beliefs (cf. Armor & Sackett, 2006). Our investigation tests this hypothesis. Specifically, we investigated whether optimistic responding persists in the face of large incentives to be accurate.

In a web survey, we asked 770 NFL football fans from across the United States to predict the winner of a single game. Roughly half (the *fans*) were asked to predict a game involving their favorite team and the other half (the *non-fans*) were asked to predict a game involving two teams that they were relatively neutral about. We also manipulated incentives. Participants were promised either a small incentive ($5) or a large incentive ($50) for making an accurate prediction. If optimism is extreme cheap talk (i.e., if it is worth less than

$5), then optimism should be absent from both conditions. If optimism involves a more expensive form of cheap talk, then optimistic responding should occur within the $5 condition only (i.e., only the $50 incentive should eliminate optimism).

Oddsmakers in Las Vegas offer a point spread for each NFL game. The spread incorporates all known information in order to offer the best prediction of the game's point differential, and thus serves as an excellent normative standard against which to judge predictions (Simmons, Nelson, Galak, & Frederick, in press). Most important for our purposes, the point spread defines the most likely winner (the *superior team*) and the most likely loser (the *inferior team*). Within our fan condition, participants were marginally significantly more likely to be fans of superior teams (54.5%) than fans of inferior teams, $\chi^2(1) = 3.36$, $p = .07$. Thus, on aggregate, fans *should* exhibit optimism, because they (and everyone else) should predict that superior teams will win games. Thus, it is important to distinguish between fans of superior teams (who should predict their favorite teams to win) and fans of inferior teams (who should not). Accordingly, our analysis partitions participants into three groups: fans of superior teams ($n = 222$), (2) non-fans ($n = 363$), and (3) fans of inferior teams ($n = 185$). Optimism is manifest if fans of superior teams are more likely than fans of inferior teams to predict superior teams to win the games.

Consistent with the claim that optimistic responding reflects true beliefs, optimism was evident in both the $5 and $50 conditions. Indeed, within the $50 condition, fans of superior teams (94.6%) predicted that the superior team would win more often than did non-fans (75.8%) and fans of inferior teams (47.3%), indicating rampant optimism even when the stakes were considerable. (There were no significant effects of incentives on optimistic responding).

Thus, optimistic responding was evident even when $50 was on the line. Although this is consistent with the claim that optimistic responding reflects true beliefs rather than cheap talk, it is possible that $50 is not a large enough incentive to motivate people to make predictions that they believe. To help resolve this issue, we analyzed the predictions of "true believers," whose responses to four follow-up questions strongly implied that they believed the predictions that they made. Specifically, our sample of "true believers" (1) indicated that their predicted winner had a greater than 50% chance of winning the game; (2) indicated, on a 7-point scale, that they would be at least slightly more surprised if their predicted winner lost; (3) rated their accuracy motivation a 7 (extremely motivated) on a 7-point scale; and (4) indicated genuinely believing that their predicted winner would win the game.

If optimism is just cheap talk, then "true believers" should not respond optimistically. But they did. Indeed, even among the heavily incentivized "true believers", fans of superior teams (93.2%) predicted that the superior team would win more often than did non-fans (81.9%) and fans of inferior teams (62.2%). Thus, optimism was evident even among those who seemed to believe their predictions.

The fact that optimistic responding persisted among those who (1) were paid $50 for an accurate prediction, and (2) gave every indication that they believed their predictions, strongly supports the claim that optimism is more than just cheap talk. Though one can never definitively *prove* that an optimistic response is truly believed, we believe the onus is now on optimism's non-believers to show otherwise.

When the Personal Becomes Interpersonal: Public Posturing in Unrealistic Optimism

EXTENDED ABSTRACT

People tend to report that negative events are less likely—and positive events more likely—to happen to them than to others. Unrealistic optimism is one of the most robust empirical findings in the literature on judgment and decision making, so much so that it is widely regarded as a truism. The extant literature has identified numerous motivational and cognitive factors that contribute to this phenomenon. However, an additional cause of unrealistic optimism may be that participants in such studies are motivated to present themselves in a flattering light. After all, developing a drinking problem, being fired, and contracting venereal disease are not merely undesirable, they are also socially stigmatizing. To admit that one is likely to become an alcoholic is to say that one cannot be trusted to resist temptation; to admit that one is likely to be fired may imply that that one is not competent enough to hold down a job; and to admit that one is likely to contract venereal disease may imply that one is sexually irresponsible, dirty, or worse. Just as people tend to underreport their engagement in socially undesirable activities—such as alcohol abuse and unprotected sex (Tourangeau and Yan 2007; cf., also, Fisher 1993)—so, too, might people deny their likelihood of experiencing events that imply participation in such activities. In other words, one reason people may demonstrate an optimistic bias is simply that they lie.

The insight that socially desirable responding, self-presentational concerns, and public posturing more generally might play a role in unrealistically optimistic predictions is hardly new (e.g., Helweg-Larsen, Sadeghian, and Webb 2002; Tyler and Rosier 2009), and it is one of the reasons why research in this area is almost always conducted under conditions of anonymity. In particular, Tyler and Rosier (2009) argue that respondents can sometimes report optimistic responses because of a desire to present oneself as having a positive outlook on life. Given that such a self-image could be conveyed by responding optimistically to questions concerning virtually any prediction about the future, this account presents a troubling alternative explanation for many findings in the optimism literature. As highlighted in the examples above, however, there is another reason why people might intentionally misrepresent their beliefs about the future: the social stigma associated with specific life events. We therefore propose that optimistic responding is often the result of respondents' effort to avoid the social disapproval associated with admitting the possibility of certain life events. Our studies tested a series of predictions stemming from this theorizing.

First, if the motive to avoid event-specific social stigmas inflates unrealistically optimistic responding, then the magnitude of unrealistic optimism should vary as a function of the social sensitivity of the event in question. Thus, unrealistic optimism should be greater for socially stigmatizing events (e.g., becoming an alcoholic) than for less socially sensitive events (e.g., developing cancer). We provide support for this idea in five separate studies, spanning a variety of methods: meta-analytic, correlational, and experimental. For example, in a replication of Weinstein's (1980) seminal study, we find a strong correlation between an event's social sensitivity and the magnitude of unrealistic optimism, even controlling for a number of additional event characteristics (Study 1). Similarly, presenting a medical condition (burnout syndrome) as affecting fragile individuals leads to a large reduction in optimistic responding compared to when the same condition is described as affecting committed individuals (Study 2).

Second, the influence of event social sensitivity on unrealistically optimistic predictions should depend on individual and situational factors that are known to influence socially desirable responding. In line with this prediction, the responses of individuals with high levels of concern over impression management exhibited a stronger relationship between event sensitivity and unrealistically optimistic predications (Study 3). In Study 4 we manipulated instead the extent to which participants felt that they could be held accountable for their responses. We varied whether participants' judgments were solicited with no mention of confidentiality, with the usual assurances of confidentially, or with an "enhanced" confidentiality condition in which the anonymity of participants' responses was emphasized. We find that the relationship between event social sensitivity and likelihood estimates varies as a function of the confidentiality condition. It is noteworthy that it was not the condition in which participants were given no promise of confidentiality where we observed a difference compared with the standard confidentiality condition, but rather the condition in which we took special steps to emphasize that confidentiality (beyond what is typically done in the literature).

Finally, building on these results, we propose that past work on unrealistic optimism may exaggerate the level of optimism truly held by research participants but that this exaggeration should be limited to predictions involving socially stigmatizing events. We test this hypothesis by using event social sensitivity as a predictor in Study 5, a meta-analysis of recent unrealistic optimism literature including 27 independent studies, 8826 participants, and 102 unique events. We find that social sensitivity is a significant predictor of unrealistic optimism over and beyond other variables investigated in prior research. Remarkably, in the case of events high in social sensitivity, we find an effect size for unrealistic optimism that is about twice as large as that for events low in social sensitivity.

Too Optimistic about What the Future Holds? How Greater Confidence Can Lead to Fewer Purchases

EXTENDED ABSTRACT

Recent years have witnessed various cases of corporate scandals, in addition to a long list of unethical behaviors by companies, managers, employees and consumers. Partly because of this pervasiveness of dishonesty in organizations and society more broadly, scholars have started investigating what may explain unethical behavior. Prior research in behavioral ethics has largely conceptualized ethical decisions as a function of individual and contextual factors. For example, prior work has examined the effect of individual traits such as age and gender (e.g., Muncy and Vitell, 1992), and contextual factors such as peer beliefs (e.g., Tyson, 1992), codes of ethics (e.g., Trevino and Youngblood, 1990), culture (e.g., Donaldson and Dunfee, 1994) and relative benefits and sanctions (e.g., Trevino and Youngblood, 1990). Yet, to date, research has overlooked a potentially important factor: the level of confidence and optimism the person facing an ethical dilemma is experiencing. In this paper, we demonstrate that feelings of confidence significantly influence both unethical behavior and judgments of ethicality. We propose that feelings of confidence can lead decision makers to cross ethical boundaries by overstating their performance, by deceiving potential consumers, or by offering them products that are of low quality or have safety issues.

The story we mirror in our studies goes as follows: A decision maker (e.g., a manager) believes she is experiencing just a bad round or she is not finding all the time needed to test a product to offer to a customer. The same decision maker also believes that she will be able to catch up during the next round – or when more time is available to properly test a product which is ready for the market. The more overconfident the decision maker is, the more she is likely to experience these feelings and to have this type of beliefs about her ability to catch up in the future. In turn, these strong beliefs license her to be deceitful when explaining the feature of the product to a consumer, or to cheat by overstating performance.

Across two studies we find evidence consistent with these main hypotheses. Confident decision makers are more likely to cheat by overstating their performance, believing they'll catch up in the future, compared to people in a control condition or who are not very confident in their own abilities. In Study 1, decision makers can lie about their performance in a given round, and know that there will be other rounds subsequently. When they experience a sense of heightened confidence, they are more likely to over-report their performance believing that they will be able to catch up. Our results show that in fact they do not. Similarly, decision makers experiencing confidence are more likely to lie about features of a product so that it looks good in the eyes of potential customers compared to people in a control condition. These main finding was demonstrated in a second study in which decision makers are paid based on how consumers react to their products. In this case, a heightened sense of confidence leads decision makers to be more likely to hide problems the product has and lie about the effectiveness and quality of the product.

In this research, we also explore the effects of feeling (too) confident on judgments of ethicality. Specifically, a third study demonstrates that feelings of confidence are also related to the acceptability of different ethical behaviors in the consumer domain. Specifically, after a procedure used to induce overconfidence in half of the participants, all participants answered Vitell and Muncy's (2005) Consumer Ethics Scale, which includes four different categories of ethical behavior. The categories are: Actively benefiting from illegal activity (e.g., Changing price tags on merchandise in a retail store, or Drinking a can of soda in a supermarket without paying for it); Passively benefiting at the expense of others (e.g., Getting too much change and not saying anything, or Not saying anything when the server miscalculates the bill in your favor); Actively benefiting from questionable behavior (e.g., Breaking a bottle of salad dressing in a supermarket and doing nothing about it, or Using an expired coupon for merchandise), and No harm/no foul (e.g., Tasting grapes in a supermarket and not buying any, and Spending over an hour trying on different dresses and not purchasing any). The results of this third study show that participants who felt confident rated the various unethical behaviors as less acceptable than individuals in the control condition, suggesting that confidence may also heightened moral leniency.

Together, the results of these studies provide a rich understanding of the influence of confidence on dishonest and deceitful behavior toward others. By contributing to both research on consumer behavior and behavioral ethics, this research allows us to extend existing models of unethical decision making by focusing on the level of confidence and optimism of the wrongdoer.

When Thinking Positive Gets the Better of Us: The Role of Optimism in Uninformed Consumer Choice

EXTENDED ABSTRACT

One of the authors was recently enjoying a plate of smoked salmon at an airport restaurant. The menu indicated that the salmon would be accompanied by toasted bread and a small bowl of an unfamiliar dish called Smetana. The Smetana turned out to look (and taste) very similar to whipped butter, but in the absence of more

diagnostic information, she continued to spread it on the toasted bread without the slightest pang of guilt. Reality hit only when, after pointing at the empty Smetana bowl and asking for another one, the waiter brought what he described as "more butter." The butter was, of course, left untouched.

This paper investigates similar situations in which consumers' have limited diagnostic information about choice options and thus casts an optimistic glow on the evaluation of that option. Research has shown that individuals tend to be optimistic when assessing the likelihood of a desirable (but not undesirable) event, a bias known as the wishful thinking or desirability bias. Individuals are also unrealistically optimistic in their relative comparisons, believing that negative (positive) events are less (more) likely to happen to them than others. In this paper we build on research on positivity offset to investigate a different type of optimism related to consumers' evaluation of a decision outcome rather than to its likelihood assessment. Positivity offset is defined as the individuals' tendency to show a positive motivational approach at very low levels of evaluative activation. As a result of positivity offset, individuals may exhibit relatively positive rather than neutral expectations for unknown future events and may form positive impressions of unknown others. We therefore predict that when there is little or no diagnostic information about an option, consumers exhibit a general optimistic tendency by evaluating that option more positively than it would be warranted and thus seeking for more risk than they would have otherwise.

We tested this prediction in six studies. The first study replicated the circumstance described initially. Participants read a scenario in which they imagined being in a foreign country and tasting a local specialty. The specialty was shown in a picture illustrating a familiar bowl of whipped butter, but it was described either with less diagnostic ("Smetana") or more diagnostic ("Smetana, a whipped-butter-like spread" or "a whipped-butter spread") information. Participants were assigned to one of the three information conditions and asked to evaluate the dish. Results show that, relative to those in the two more diagnostic conditions, participants in the less diagnostic ("Smetana") condition thought that the spread was healthier, less fatty, and tastier, and reported the intention to eat more of it. Controlling for motivated reasoning (worry about weight and liking of the spread) did not alter the conclusions.

In the second study we aimed to directly rule out motivated reasoning as an alternative explanation and collect further evidence for our optimistic glow hypothesis. Participants imagined being in Turkey and having to decide whether or not to stay in an accommodation. The accommodation was illustrated in a picture showing a classic US Motel. As in the previous study, however, the accommodation was given either a non-diagnostic ("Pansiyon") or a more diagnostic ("Motel" or "Pansiyon (Motel-like)") description. To control for the motivated reasoning explanation, participants were asked to imagine either being tired, and as such motivated to stay in the accommodation, or not. Consistent with study 1, results show that participants were more likely to stay in the accommodation in the less diagnostic "Pansiyon" condition than in the other two, more diagnostic, conditions, regardless of whether or not they had a motivation to do so.

Next three studies we added more information about the evaluation target than simply an image and a short description. In studies 3 and 4, participants were told to imagine buying a bookcase from an online retailer. Participants were provided with customers' ratings of the retailer that were on average favorable (unfavorable) in the positive (negative) information condition, and with no ratings in the no-information condition. Participants were then asked whether or not they would buy the bookcase. The two studies differed in the manipulation of the mean and variance of the reported customers'

ratings. Results of both studies shows that, regardless of the rating variance, participants in the no-information condition were as likely to buy the bookcase as those in the positive information condition and more likely than those in the negative information condition. Study five replicated these findings with a different product category. In particular, participants imagined choosing a hiking trail and were provided with reviews from previous hikers. Once again, we found that participants in the no-review condition were as likely to buy the bookcase as those in the positive review condition and more likely than those in the negative review condition.

Last study moved to a real choice and consumption situation. Participants were told that the study was about tasting and evaluating Bolivian chocolates. The participants were either given no information, positive information (a vignette about the good reputation of Bolivian chocolate) or negative information (a vignette about the bad reputation of the Bolivian chocolate). In addition to tasting and evaluating the chocolate, participants were also given an option to snack on this chocolate during the 30-min session. The results showed that those who were given no information about Bolivian chocolates found it to be as tasty, high quality, and enjoyable as those who were given positive information and significantly more than those who were given negative information. More importantly, this pattern was replicated with the actual consumption of the chocolates during the study.

Overall, this set of studies supports our hypothesis that consumer are optimistic when evaluating options about which they are relatively uninformed. Participants seemed to give a "credit slack" to options about which they had less (or no) diagnostic information, with could lead to potentially harmful consequences in the cases of relatively unhealthy or unsafe alternatives, such as fatty food, shady accommodations, and untrustworthy retailers.

Paper #4: The Obligation to Choose

Sheena Iyengar, Columbia University, USA

SESSION OVERVIEW

Conflict is one of the most definitive characteristics of choice. Without it, choice would merely involve the identification of the "best" or dominant option. But in most cases choice is not this easy. Making tradeoffs between alternatives, for example, or considering multiple options often leads to excessive decision difficulty. Indeed, much work has demonstrated that choice conflict often has negative, paralyzing effects, including increased difficulty, choice deferral, procrastination, increased anticipated regret, and decreased satisfaction with the chosen option (Dhar and Simonson 2003; Iyengar and Lepper 2000; Schwartz 2004; Tversky and Shafir 1992).

But while decision difficulty can sometimes have negative consequences, new insights suggest that experiences of conflict and difficulty serve additional purposes, and have further consequences and antecedents than previously considered. While situational factors often generate difficulty, might consumers sometimes make their own choices more difficult? Either to service a goal of making a diligent decision or through struggling to make the right choice? And while difficulty is usually seen as bad, might it be beneficial in some instances?

The current session addresses these and related questions as it offers cutting-edge insights into the causes and consequences of decision difficulty in consumer choice. The first paper (Schrift, Kivetz, and Netzer) demonstrates that consumers' desire to make diligent decisions leads them search for or recall option information in a way that artificially increases choice difficulty, creating an illusion of effortful deliberation. The second paper (Sela and Berger) shows that making tradeoffs between options leads people to lose sight of which product attributes are important, making choice more difficult and decreasing satisfaction with the chosen option. While the first two papers focus on downsides of decision difficulty, the third (Etkin, Pocheptsova, and Kahn) illustrates that difficulty can actually sometimes be beneficial. When choosing between conflicting goals, difficulty can provide a signal of value, making the goals seem more important and increasing consumers' motivation to achieve them. Finally, Sheena Iyengar, one of the foremost scholars in choice difficulty, will discuss some of her recent work on individuality, choice, and freedom, and the consequences of the obligation to choose.

Taken together, the talks illuminate the informative, motivating, and even reassuring nature of choice difficulty. Given the fundamental nature of decision difficulty in consumer behavior, and the variety of topics these talks cover, the session should be of interest to a broad set of audiences. Not only should it appeal to researchers working on judgment and decision making, choice, cognition, and inference making, but also to those who study the self-concept, goals, and motivation more broadly.

Creating the Illusion of Choice by Selective Information Search and Retrieval

EXTENDED ABSTRACT

Voluminous research in behavioral decision theory and social cognition argues that consumers simplify their decisions in order to make easy, confident, and justifiable choices. Such demonstrations of effort and conflict reduction behaviors can be seen in different streams of literature such as pre-decisional distortion of information (e.g., Russo, Medvec, and Meloy 1996, 1998), motivated reasoning and judgment (e.g. Kunda, 1990; Kruglanski 1990), and confirmation bias (Lord, Ross, and Lepper, 1979). Specifically, decision makers were found to reduce the effort in choice not only by selectively searching and attending external information (e.g. Mills, 1965; Mills & Jellison, 1968) but also by selectively accessing and retrieving information from memory. As Kunda (1990) stated: "…they (people) search memory for those beliefs and rules that could support their desired conclusion."

While simplifying processes in decision-making are important and ubiquitous, recent findings demonstrate that, in some situations, consumers also complicate their decisions (Schrift, Netzer, and Kivetz 2011) and strive for compatibility between the effort they anticipate and the effort they experience. Building on this research, we demonstrate that when consumers make important choices they are motivated to engage in a deliberate decision process that adequately vets the chosen alternative. Consequently, if the decision feels too easy and one alternative seem like the obvious choice, consumers artificially construct a more effortful decision process by (i) distorting the information they recall about the available alternatives, (ii) selectively interpreting ambiguous information in a manner that intensifies the conflict in choice and prolongs the decision process, and (iii) conducting an intensive search for information prior to choice. Such tactics enable consumers to feel that a diligent process of choice was performed and essentially help them create an illusion of choice.

In a series of studies we demonstrate consumers' complicating behavior. First, we show that when faced with an important yet obvious choice, participants retrieve information from memory in a manner that intensifies the conflict in choice. Specifically, respondents distort their memory and recall the inferior alternative as more attractive, thus bolstering its evaluation. Conversely, respondents distort their memory and denigrate the leading alternative in the set by recalling its aspects more negatively. Thereby, consumers construct a more effortful choice. Interestingly, such biases in memory search and selective retrieval are temporal and occur only in the pre-decisional phase. Once the decision is made and the need for conflict disappears, consumers' memory "improves" and the distortions attenuate. We demonstrate such complicating behavior in decisions involving job candidates and dating partners.

The second manner in which consumers are found to make their decision more complex is by interpreting exiting information in a manner that intensifies the choice conflict. In particular, when confronted with important yet relatively easy decisions between two models of cars, participants interpret the relatively ambiguous car review as more positive when it pertained to the inferior option but as more negative when it pertained to the superior option. Interestingly, this behavior was observed only when participants made the choice for themselves but not when they were helping a friend with his choice. This result helps rule out several alternative explanations and supports an effort compatibility principle as an underlying mechanism.

Next, we explore a third way by which consumers artificially create a more effortful choice, namely, by conducting an extensive search for information. Specifically, when respondents face an easy (as opposed to difficult) choice of a roommate or advisor they generate more questions about the potential candidates and acquired greater amount of information from the environment prior to reaching their decision. Finally, we show that such conflict enhancement behavior is more pronounced among consumers who are intrinsically motivated to work hard and associate effort with positive outcomes (i.e., subscribe to a "protestant ethic").

Getting Mired in Simple Decisions: The Role of Shrinking Attribute Weight Variance

EXTENDED ABSTRACT

Why do seemingly simple choices sometime suck people in and end up being much more difficult than they seemed at the outset? We suggest one reason is that making tradeoffs leads people to lose sight of which product attributes are really important. When choosing a flight, for example, most people would agree a priori that price and number of connections are more important than beverages or in-flight movie selection. But while these differences in importance may seem clear in the abstract, we argue that the act of making choices often muddies the distinction. In particular, we suggest that making tradeoffs between options reduces the variance in perceived attribute importance (i.e., difference in importance ratings of the various attributes) and makes unimportant attributes seem more important. This convergence of attribute importance, in turn, often makes choice more difficult.

We suggest this effect is driven by the focus that considering tradeoffs engenders. When considering differences in attribute levels across options, people focus on comparisons between levels *within* an attribute (e.g., how much better one movie selection is than another) and pay less attention to comparisons *between* the attributes (e.g., whether movie selection is as important as price). Consequently, attribute hierarchy becomes less salient. Further, the fact that there are tradeoffs (i.e., things to forego) within each attribute leads them all to seem equally important (rather than equally unimportant). Moreover, because tradeoff-making increases perceived attribute importance, it tends to have a particularly pronounced effect for attributes that start out seeming relatively unimportant than for attributes that seem important to begin with.

We test this possibility in three experiments. In Experiment 1, we examined how making attribute tradeoffs impacts the variance in attribute importance, and in particular, the importance of relatively unimportant attributes. In the attributes-first condition, participants indicated how important each of six attributes (e.g., flight duration, number of stops, and baggage fee) would be for them when buying a flight ticket (1 = extremely unimportant; 7 = extremely important). In the evaluation-first condition, participants were shown choice options before rating the attributes. They were asked to imagine buying a domestic flight and to consider four options described on the same six attributes as in the rating task (e.g., a longer flight departing from a convenient airport but with a long overall duration versus a shorter flight from a less convenient airport).

Results demonstrate that making trade-offs led people to lose sight of which attributes are more important. The variance of attribute importances decreased significantly when participants considered the options before rating the attributes ($M = 1.62$), compared to when they first rated the attributes before seeing the options ($M = 2.34$; $p < .01$). Further, this variance shrinkage was driven by an increase in the average importance of the least important attributes (those rated as less important in a pre-test), with no change in the average perceived importance of the most important attribute (*ns*). Decreased attribute importance variance, in turn, increased choice difficulty, decreased the extent to which participants felt that one option fitted them better than others, and decreased choice satisfaction and certainty ($\alpha = .85$); $M = 4.84$ vs. $M = 5.51$; $p < .01$).

In Experiment 2, we further tested whether this effect is driven by changed perceptions of unimportant attributes. We did this by manipulating the importance of the attributes that contained the trade-offs. Participants were all shown two flight options described by eight attributes. In the unimportant trade-offs condition only the unimportant attributes (e.g., beverages and in-flight entertainment) contained tradeoffs, while in the important trade-offs condition only the important attributes (e.g., price and number of connections) contained tradeoffs. Participants then rated all the attributes on the same 7-point scales used in the prior study.

Results demonstrate that making trade-offs decreased the variance in attribute important weights when the trade-offs were on unimportant attributes ($F(1,41) = 3.96$, $p < .05$). While the importance given to more important attributes did not change across conditions ($F < .40$, $p > .50$), unimportant attributes were seen as more important when trade-offs needed to be made on those attributes ($F(1,41) = 9.38$, $p < .005$).

Experiment 3 directly tests the proposed mechanism by examining whether the effects are moderated by focus of attention within individual attributes. Participants were shown four flight options, one in each column, described by four attributes, one in each row, but we varied how the information was displayed using a manipulation shown to influence whether people process the information by options or by attributes (Wen and Lurie 2010). In the by-attributes focus condition, a horizontal box was drawn around all levels within each attribute, highlighting the values of the same attribute across options. In the by-options conditions, a vertical box was drawn around all the attributes within each option, highlighting the values of different attributes within a given option. In the control condition no boxes were used. As predicted, focusing people on comparisons within an attribute (by-attribute condition) led them to lose sight of which options were important, shrinking attribute variance and increasing the perceived importance of the unimportant attributes.

Taken together, these studies demonstrate that tradeoff making can lead people to lose sight of their priorities. Focusing on within-attribute differences causes people to see unimportant attributes as relatively more important, undermining between-attribute differences. This, in turn, can make choice more difficult and frustrating, leading people to get stuck in decisions that initially seemed rather easy.

Winning through Conflict:
When Goal-Conflict Increases Motivation

EXTENDED ABSTRACT

One important decision that people make every day is how to balance the pursuit of multiple goals. The decision becomes difficult when striving towards one goal prevents pursuit of other goals in the individual's goal system (Fishbach and Ferguson 2007; Kruglanski et al. 2002). For instance, a person may wish to get a promotion at work, but also to spend more time with family; one may want to loose weight and enjoy tasty foods, or save money for college and travel the world.

Reconciling the pursuit of multiple conflicting goals is psychologically aversive and induces decision difficulty. A consistent finding in prior literature suggests that goal conflict has a negative effect on goal pursuit, decreasing the likelihood that individuals will strive to achieve the conflicting goals. For example, among a group of smokers that wished to quit smoking, those that perceived their goal to quit smoking as conflicting with their other goals were less successful in quitting relative to those who perceived less conflict (McKeeman and Karoly 1991).

In contrast to past research, we propose that goal conflict can have a positive impact on motivation. Our proposition is based on the finding that subjective experiences of difficulty serve as input into judgment, even when judgment is unrelated to the source of experienced feelings of difficulty (Schwarz 2004). Though subjective difficulty often decreases subsequent evaluations (Novemsky et al. 2007), recent research suggests that it may also have positive effects, such as making products seem more unique (Pocheptsova, Labroo, and Dhar 2010) and instrumental to goal attainment (Labroo and Kim 2009), and increasing the perceived importance of decisions (Sela and Berger 2011). Building on this literature, we propose that subjective experience of difficulty associated with negotiating conflict among one's goals will influence evaluation of those goals. Just as people expect important decisions to be more difficult than less important decisions (Chaiken and Maheswaran 1994; Sela and Berger 2011), we believe they will expect to experience more conflict when thinking about more versus less important goals. Thus, when people experience goal conflict and associated feelings of difficulty in pursuing multiple goals, they may interpret these feelings of difficulty as a signal of goal importance.

The proposed effect of inter-goal conflict on goal importance has a number of downstream implications for goal-pursuit. The importance of one's goals is a key driver of commitment and motivation to pursue the goals; as people are more likely to strive towards more important goals (Kruglanski et al. 2002). Thus, if the subjective difficulty associated with goal conflict increases the perceived importance of one's goals, goal conflict may also increase motivation. Contrary to the previous work that has found inter-goal conflict to have a detrimental effect on goal-pursuit, we propose that people will be more motivated to pursue their goals when they feel the goals are in conflict with each other relative to when they are not.

Across a series of three studies we find consistent support for our proposition. Our first study tested the impact of goal conflict on perceptions of goal importance. Participants read a scenario where they were going on a ski trip with friends and also had an upcoming quiz in class. In the low conflict condition the quiz was three weeks before the ski trip, but in the high conflict condition, the quiz was immediately after the ski trip. Among several unrelated measures, participants rated importance of "academic success" and "spending time with friends". As we expected, participants rated both goals (to do well in school and socialize with friends) as more important when conflict was high versus low ($p < .05$).

In study 2, we tested the second part of our proposition: the effect of goal conflict on motivation. Participants were asked to list two goals that they were currently pursuing. Half of participants were asked to list two examples of how those goals were in conflict with each other (high conflict condition); the remaining half were not asked for any examples (low conflict condition). After some filler tasks, we measured how conflicted participants felt and their motivation to pursue both goals. As we expected, participants in high conflict condition were more motivated to pursue their goals ($F(1, 25) = 5.98$, $p < .05$).

Finally, Study 3 replicated the positive impact of goal conflict on motivation and showed that enhanced perceptions of goal importance mediated this effect. We activated a performance goal and a hedonic goal for all participants by asking them to endorse a series of statements related to each goal (e.g., "I want to achieve success", "I want to relax and enjoy life"). Goal conflict was manipulated by asking participants to either list two (high conflict condition) or eight (low conflict condition) examples of how these goals conflicted. Listing eight examples is expected to be more difficult, thus creating the perception that the performance and hedonic goals were in less conflict relative to the two examples condition (Schwarz et al. 1991). Next, all participants indicated their willingness to pay for several goal-related products (e.g., highlighters, movie tickets) and completed a series of measures assessing their motivation to pursue the conflicting goals and perceptions of goal importance. Results showed that participants were willing to pay more for the goal-related products when they perceived more conflict among their goals ($F(1, 68) = 3.72$, $p < .06$). Consistent with previous results, goal conflict increased perceptions of goal importance ($F(1, 67) = 5.56$, $p < .05$) and motivation $F(1, 68) = 4.16$, $p < .05$). Finally, the positive effect of goal conflict on motivation was mediated by perceived importance of both goals.

Taken together these studies demonstrate that inter-goal conflict may have a positive impact on goal-pursuit. Contrary to previous work, we find that experiencing conflict among one's goals can actually increase motivation to pursue those goals. In particular, experiencing conflict among one's goals enhances the perceived importance of those goals, which in turn increases motivation to pursue them.

The Obligation to Choose

EXTENDED ABSTRACT

In his book *Powers of Freedom*, sociologist Nikolas Rose (1999) writes:

> Modern individuals are not merely 'free to choose,' but *obliged* to be free, to understand and enact their lives in terms of choice. They must interpret their past and dream their future as outcomes of choices made or choices still to make. Their choices are, in their turn, seen as realizations of the attributes of the choosing person—expressions of personality—and reflect back upon the person who has made them. (p. 87)

This talk considers the obligation to choose from a psychological perspective, exploring its origins and its consequences for consumers today.

Academics and practitioners alike have historically assumed that our choices are based upon our preferences, and that these preferences are derived directly from our self-interests, which are apparent to one and all. However, decades of research have now demonstrated repeatedly and compellingly, across a variety of dif-

ferent choosing domains, that just as our choices are based on our preferences, our preferences are derived from our choices and the decision context (Bettman, Luce, & Payne 1998). People regularly make choices that deviate from their stated preferences (e.g. Nisbett & Wilson, 1977), and moreover, they exhibit inconsistency in the strength and duration of their stated preferences (e.g. Hsee & Hastie, 2006; Tversky, Slovic, & Kahneman 1990).

Prior research has identified both cognitive and affective factors that contribute to the instability of preferences. In addition to these previously identified causes, there is another factor at play. The act of choosing for the modern day individual is associated not only with function and value but just as significantly with identity (e.g. Berger & Heath, 2007; Simonson & Nowlis 2000). When making a choice, the average individual is not just asking him or herself, "What do I want?" but rather, "What kind of individual am I, and given who I am, what *should* I want, and given what I *should* want, what do I choose?" If choosing is seen as the means by which individuals realize themselves, the burden of choice grows considerable and unavoidable.

When constructing and expressing identity, modern individuals, particularly those immersed in more individualistic cultures, feel the pressure to establish themselves as distinct from others, yet not so different that they become outcasts (Brewer, 2003). In studies that investigate people's preferences for items ranging from the common to the unique, people believe themselves to be more unique than everyone else, but in fact they either conform to the unique items (Kim & Markus, 1999) or they choose less preferred options only in order to avoid the label of "copycat" (Ariely & Levav, 2000). Thus, the modern individual can feel obliged to sacrifice personal preference in service of maintaining the appearance of a unique and independent identity.

This problem of the obligation to choose is especially acute in a world of ever-increasing choice. On top of the social burdens of choosing, the presence of more choice imposes a cognitive burden; people have to identify the attributes of the many options and engage in the task of comparing and contrasting all of them. There is over a decade of research documenting the negative consequences of offering people more choice: people delay making the choice, even if it is to their detriment (Iyengar, Huberman, & Jiang, 2004); they make worse choices (Iyengar & Kamenica, 2010; Thaler & Sunstein, 2008, p. 159-174); they exhibit less confidence in their preferences (Chernev, 2003); and they are less satisfied with the outcomes (Iyengar & Lepper, 2000; Schwartz et al., 2004).

Furthermore, this obligation to choose does not simply lead us to larger choice sets in familiar domains but to an expansion of the range of domains in which we expect choice to be available. Individuals believe they are obligated to never say "no" to choice, even when choosing is likely to be physically and emotionally costly. Choices that were heretofore unimaginable now often make up the typical person's choosing experience over a lifespan. For example, in recent studies that compare individuals who made life and death choices for loved ones with individuals for whom someone else made the choice, the choosers are revealed as suffering more for having made the choice than the non-choosers for having been relieved of the choice (Botti, Orfali, & Iyengar, 2009).

We have come to believe that every choice is important and that we must make all our own choices, perhaps because this preserves the illusion of control. But if we want to use choice as a tool to set ourselves free and to shape our futures, then we must rethink the assumption that choosing is always an act of freedom.

Hidden in the Darkness: The Role of Dark versus Bright Sensory Cues in Consumer Decision Making

Chair: Kuangjie Zhang (INSEAD)

Paper #1: Dim or Bright? The Influence of Illuminance on Creativity

Paper #3: The Impact of Emotion on Color Preference: Evidence of Affective Fit

Chan Jean Lee, UC Berkeley, USA
Eduardo Andrade, UC Berkeley, USA

SESSION OVERVIEW

Consumers are exposed to a variety of incidental sensory cues in their every day life. An increasing body of research on sensory marketing shows that such incidental sensory cues can have far reaching impact on consumer decision making. For example, both ambient and product related sensory cues including touch (Peck 2009), scent (Morrin 2009), music (Zhu and Meyers-Levy 2005) and ceiling-height (Zhu and Meyers-Levy 2005) have been shown to impact consumers' product evaluations and preferences. Despite this growing body of research on sensory cues in marketing, relatively little is understood about how product-specific and ambient cues related to brightness interact with consumers' decision making. In an attempt to address this gap, in this session, we bring together an integrated set of three papers that elucidate the interactive relationship between dark versus bright sensory cues and consumer decision making. More specifically, this session explores two aspects of this interactive relationship. While the first two papers examine how dark versus bright sensory cues impact consumer preferences and consumer creativity, the third paper complements the first two papers by examining how consumers' affective states influence the preference for dark versus bright sensory cues.

Session Overview. The session will begin with a focus on the impact of dark versus bright ambient cues on consumer creativity. Chen Wang will present her work with Ravi Mehta, Rui (Juliet) Zhu, and Jennifer Argo. They suggest that dim (versus bright) ambience reduce individuals' inhibition, which leads to greater relational processing and subsequently results in heighted consumer creativity. Kuangjie Zhang will then present his work with Monica Wadhwa that builds on the first paper by examining the impact of dark versus bright product related cues on hedonic consumption. Specifically, they argue that consumers are influenced by the metaphoric relationship between darkness and product nature. Their findings demonstrate that when products are displayed with a dark versus bright background, it leads to greater wanting for indulgent products. Finally, Chan Jean Lee will present her work with Eduardo Andrade that complements the first two papers by examining the other side of this interactive relationship between dark versus bright sensory cues and consumer behavior. Specially, they investigate whether being in a certain affective state influences consumers' choices for bright versus muted colors. Their findings show that when in a happy state, consumers prefer products with bright colors. However, when in an unhappy state, consumers show an enhanced preference for muted colors. They suggest that this relationship is governed by the matching of one's current emotional state with the emotional tone of the color.

To increase audience participation and provide insights about the three papers, the session will involve the participation of Darren W. Dahl as a discussant. Dahl has expertise in the area of creativity, new product development, and emotions in consumption contexts. Dahl, thus, has a unique perspective for synthesizing these papers and leading a discussion about an appropriate research agenda for continued work in this area. Each presenter will limit his/her talk to 15-20 minutes, to allow ample time for Dahl to speak and to engage the audience in a discussion of research ideas.

We believe that the features of this proposal suit the evaluation criteria for ACR 2011 symposium proposals. Notably, the session includes papers that are likely to have a broad appeal, yet maintain a coherent theme. We feel that this session brings together three papers that provide cutting edge insights into the incidental, seeming irrelevant sensory cues that drive consumer behavior and decision-making. In addition to attracting researchers interested in the domains of consumer perception and sensory marketing, we expect further interest from those who work within the application areas represented.

Dim or Bright? The Influence of Illuminance on Creativity

EXTENDED ABSTRACT

Creativity prevails in the consumption domain. Although a large body of extant research has been directed in exploring factors that influence consumer's creative performance in terms of the creative process itself (Dahl and Moreau 2007; Moreau and Dahl 2005), few attempts have been made to investigate how the external environmental factors affect consumer's creativity. Thus, the current research seeks to fill this gap by studying the effect of an important environmental variable, namely, ambient illuminance, on consumers' creative performance.

The central thesis of this research is that dim ambience reduces individual's inhibition, subsequently resulting in greater relational processing, thus leading to enhanced creativity. Prior research has provided relevant support for our theorizing. Specifically, research on environmental illuminance has shown that darkness promotes aggressive behavior (Page and Moss 1976) and dishonesty (Zhong et al. 2010) by reducing individual's inhibition. Moreover, according to Viskontas et al. (2004), inhibitory mechanisms allow one to selectively attend to relevant stimuli while suppress irrelevant features to the focal problem. Therefore, people with decreased inhibition may engage in remote association and relational processing, which are crucial elements to enhance creativity (Smith 1995).

Study 1 demonstrates the basic main effect of ambient illuminance on creativity. We predict that dim (versus bright) ambience leads to relational processing and subsequently results in heightened creativity. The ambient illuminace was manipulated by the number of lights in the room. Specifically, in the dim condition, the room was lit by 2 fluorescent light tubes mounted to the ceiling, with the total luminance of 150 lux. By contrast, in the bright condition, the room was lit by 20 fluorescent light tubes, with the total luminance of 1500 lux. To measure creativity, we used the Remote Associates

Test (RAT; Mednick 1962), a task commonly used to test creative thinking. In this task, participants were asked to generate the missing target word, based on the given stimulus words that were related to the unreported target word. To assess the underlying cognitive process, we adopted the recall task from Battig and Montague (1969). In this task, participants were given a list of 36 items belonging to six categories and were asked to examine them carefully for future task. After extensive filler questions to clear memory, participants engaged in a free recall task and subsequently a cued recall task with the category names given. As predicted, those in the dim condition generated more correct answers on RAT than those in the bright condition. More importantly, the adjusted ratio of clustering (ARC; Hunt and Einstein 1981), indicating the degree of relational processing, mediates the relationship between illuminance and creativity performance.

Study 2 built on the study 1 by assessing the effect of dim versus bright illuminance on two dimensions of creativity, namely, originality and appropriateness (Burroughs et al. 2008; Moreau and Dahl 2005). We hypothesize that dim ambience leads to higher originality, whereas bright ambience enhances appropriateness. We argue that if dimness, compared to brightness, engages individuals to make unusual conceptual connections and thus promotes relational processing, it should enhance originality of the ideas. By contrast, if bright (versus dim) illuminance makes people focus on specific details of the problem and thus hinders relational processing, it should enhance appropriateness of the ideas (Dahl and Moreau 2002). In this study, the ambience manipulation remained the same as that in study 1. The main task was the shoe polish problem-solving task (Burroughs and Mick 2004), in which participants were asked to generate as many solutions as possible to polish shoes given a constrained situation. After the experiment, twelve judges were hired to evaluate the originality and the appropriateness of the generated ideas on 7-point scales. As predicted, we found that those in the dim room generated more novel but less appropriate solutions, whereas those in the bright room produced more appropriate but less novel ideas.

Study 3 seeks to replicate the effect in a different domain of ad evaluation. We hypothesize that those in the dim room, who mostly engage in relational processing, would show more favorable evaluation towards the ad containing remotely related visuals. By contrast, those in the bright room, who primarily engage in item-specific processing, would have higher evaluation towards the ad with closely associated visuals. We employed a 2 (illuminance: dim vs. bright) x 2 (ad type: remotely related vs. closely related) between subject design. The ambience manipulation remained the same as the previous studies. In the focal task, participants were asked to evaluate the ad on three items (i.e., make sense, easy to understand, creative) on 7-point scales. A 2x2 ANOVA revealed a significant interaction between illuminance and ad type. Specifically, the pattern was consistent with our hypothesis such that those in the dim room favored the remotely-related ad, whereas those in the bright room preferred the closely-related ad.

Study 4 extends previous results by testing the multi-mediation of disinhibition and relational processing. In the same lab setting, participants' creativity performance was assessed by using Brick Task (Friedman and Förster 2000), in which they were to asked to generate as many usages as possible for a brick. To measure the underlying process, we included items that assess inhibition level, and used the recall task to generate ARC as that in study 1 to assess relational processing level. By following the *Multiple-Step Multiple Mediator Model* (Preacher and Hayes 2008), we demonstrated the multi-mediation effect, such that dim ambience reduced people's in-

hibition, leading to greater relational processing, thus subsequently enhancing creativity.

Taken together, this research advances our understanding of the impact of illuminance, an important ambience variable, on consumer's creativity. Our findings have important implications on environmental planning and product design.

Vices Lurking in the Dark: The Impact of Background Color on Indulgent Consumption

EXTENDED ABSTRACT

Consumers are influenced by the metaphoric relationship between color and product nature. Prior research suggests that brightness is often associated with goodness and purity, whereas darkness is often associated with evil and sin (Meier, Robinson, and Clore 2004; Sherman and Clore 2009). For example, in the Bible, Jesus is the "light of the world," whereas Satan is the "prince of darkness." However, just as the allure of Satan's temptations is hard to resist for humans, darkness may as well be associated with sinful pleasure and indulgence. In other words, darkness conceals two components, the sinful component and the pleasurable component. Indeed, a pretest revealed that while people consider black color more sinful than white color, they also consider black color more pleasurable and fun. Similarly, indulgent or vice consumption has been characterized as both pleasurable and guilt-evoking in consumer research (Khan and Dhar 2006; Kivetz and Simonson 2002). Drawing upon an integration of these perspectives, we hypothesize that dark background as compared to bright background is likely to enhance consumers' wanting for indulgent products. However, when indulgent consumption is incongruent with consumers' overriding goal (Fishbach, Friedman, and Kruglanski 2003), dark background would make the sinful component more salient than the pleasurable component, thus reducing consumers' wanting for indulgent products.

We tested our hypotheses in a series of three studies. Study 1 tested our main hypothesis by examining consumer choices. Participants were randomly assigned to one of the two conditions (picture background: bright vs. dark). To manipulate the picture background, we used gray scale as the relevant chromatic dimension. In all studies, bright is manifested in the color white (100% gray scale), and dark is manifested in the color black (0% gray scale). All participants first evaluated an indulgent food item (i.e., a beef and cheese burger) and a healthy food item (i.e., an organic green salad with chicken). After evaluating the food items, participants proceeded to a choice question, which asked them to choose one of the two food items they would like to have for dinner. As predicted, a logit analysis revealed that dark background color led to more indulgent food choices over healthy food choices among participants. Next, we computed the wanting index by subtracting wanting score for the salad from wanting score for the burger. We examined if the differences in wanting mediated the effect of background color on food choice. Following the bootstrapping procedure (Preacher and Hayes 2008), the indirect effect of background color on choice (through wanting) was significant, whereas the direct effect of background color on food choice became not significant. Thus, wanting for vice over virtue mediated the effect of background color on food choice.

In study 2, we tested our conceptualization that this dark versus bright background effect is eliminated or even reversed when indulgent consumption is incongruent with an overriding goal. Specifically, we argue that when people are primed with a health goal, dark background would make the indulgent products more sinful than pleasurable, thus reducing the wanting for indulgent consumption. The study consisted of a 2 (goal prime: health goal vs. control) ×

2 (background color: dark vs. bright) between-subjects design. We manipulated the goal priming by asking participants to first complete a scrambled sentence task (e.g., Chartrand and Bargh 1996). In the health goal prime condition, participants were given 20 sets of five words each and asked to make sentences using four of the five words. Ten out of the 20 sentences included a word (italicized in the samples below) intended to prime a health goal (e.g., it ate she usually *healthy*, *exercise* week they every hang). In the control condition, participants performed 20 sets of five words with neutral information (e.g., you held pencil building the, she building opened door the). After the goal priming task, participants moved on to a purportedly unrelated study in which they were asked to evaluate several food items. Specifically, they were asked to report how much they wanted and how much they were willing to pay for a sequence of three indulgent food items (a beef burger, a cookie, and a meat combo sandwich). Half of the respondents were shown the pictures with dark background, whereas the other half were shown the pictures with bright background. We computed a composite wanting score and the total willingness to pay for all the three items. A significant interaction between background color and goal prime emerged. In the control condition, dark background color led to greater wanting and higher willingness to pay for the indulgent food items, as compared to bright background color. In contrast, when participants were primed with a health goal, the result reversed such that dark background color led to reduced wanting and lower willingness to pay for the indulgent food items.

Finally, we generalize our findings by moving away from the food consumption context in study 3. Specially, we examined whether the dark versus bright background color of a potential co-worker's picture also affects people's co-worker selection choice (Dhar and Wertenbroch 2000). Participants were asked to imagine that they were assigned to a project. Half of them were told that the project requires one to be proficient on social skills, whereas the other half were told that the project requires one to be proficient on technical skills. Next, participants received the pictures of two candidates (one with dark background color and the other with bright background color), and they were asked to decide whom to work with. The matching between the background color and each specific candidate picture was balanced. Interestingly, a logit analysis revealed that participants were more likely to choose a co-worker whose photo background is dark (vs. bright) for a project that requires one to be proficient on social skills (vs. technical skills).

Together, these results suggest that dark background color, as opposed to bright background color, enhance consumers' wanting for indulgent consumption, and this effect is moderated by the salience of consumers' health goal. Our findings have wide implications for product packaging and advertisement design.

The Impact of Emotion on Color Preference: Evidence of Affective Fit

EXTENDED ABSTRACT

Judgments about colors are frequent in the market place. Consumers often buy products in the colors that they find most pleasing at the time of purchase and, knowing that, firms often rely on colors to appeal emotionally and aesthetically to consumers. Colors are associated with and inducers of specific emotional states: more saturated and lighter colors are perceived to be happier, more exciting, and purer (i.e., most often, positive emotions), whereas more muted and darker colors tend to be more strongly associated with sadness, distress or disgust (i.e., most often, negative emotions). However, in spite of the robust evidence of color's impact on emotion, the literature is surprisingly silent about the inverse relationship—that is, the impact of a viewer's emotion on his/her color preference. The current research investigates how an individual's emotional state influences his or her preferences for colors that have either congruent or incongruent emotional tones. Based on the literature on emotion and aesthetics, three conflicting hypotheses have been identified: emotion-*judgment* congruence (sad (vs. control/happy) people will show decreased preference for colors in general, independent of the emotional tone of the color), emotion-*target* congruence (sad (vs. control/happy) people will show increased preference for sad colors); and emotion-target incongruence (sad (vs. control/happy) people will show increased preference for happy colors).

Across four experiments emotions were induced through videos and color preferences were measured once before and again after the emotion inducing experience to control for massive individual differences characteristic of color preference. Thus, *preference change* due to emotion induction served as the main dependent variable. We asked participants to evaluate multiple colors (20 ~ 24 colors), which allowed us to focus on general emotional tones across colors, independent of specific color characteristics.

In the first two experiments, we induced either sadness or happiness and observed how people's preference for sad (vs. happy) colored square (Exp1) and colored t-shirts (Exp2) changed. Sadness increased preference for sad colors whereas happiness increased preference for happy colors, despite the use of different color stimuli (24 colors from HSL vs. 20 colors from retailers), different context (color squares vs. color t-shirts), and different evaluator's initial impression (people initially liked the color squares in general vs. people initially disliked the colored t-shirts in general).

The increase in preference for sad colors among sad participants represents an empirically unique and theoretically challenging phenomenon. Why would sad people prefer colors that make them even sadder? We identify three potential accounts: fluency (i.e., congruent (vs. incongruent) emotional tone of the color is more easily processed, thus liked), role fulfillment theory (i.e., the emotional tone of the color fulfilling people's "expectations" more (vs. less) effectively is preferred), and attitudinal commitment (i.e., colors of which meaning is coherent with their internally justified meaning and committed attitude toward the situation are preferred). Contrary to fluency (a pure perceptual process) or the role fulfillment hypothesis (an expectation-confirmation process), the attitudinal commitment account, which is proposed here, implies that the strength of one's attitudinal commitment and the strength of a color stimulus's attitudinal signal should impact emotion-target congruence effects. Specifically, emotional experiences that reflect personal beliefs, attitudes, and meaning to which one is highly committed (i.e., experiences that are high in attitudinal commitment—e.g., sadness) are more likely to produce emotion-target congruence effects than emotional reactions which inherit little personal view or value to which an individual could be attached (i.e., experiences that are low in attitudinal commitment—e.g., visceral disgust). Likewise, colored objects that provide stronger signals of one's own attitude, taste, and values (e.g., t-shirt) are more likely to produce the emotion-target congruence effects than colored objects that are unrelated to one's values and attitudes and are often chosen based on instrumental reasons (e.g., post-its). Experiments 3 and 4 provided evidence consistent with the attitudinal commitment account and inconsistent with fluency or role fulfillment accounts. That is, people like emotion-congruent colors when they find their emotion reflects a committed (vs. not-committed) attitude toward the situation (experiment 3) and when the colored object signals (vs. not does signal) one's committed attitude (experiment 4).

People like emotion-incongruent colors when their negative emotion does not reflect their committed attitude.

Our findings shed light into some conflicting findings in the emotion and aesthetics literature. Whereas there has been evidence showing that people in negative moods like emotion-incongruent aesthetic stimuli to lift their spirits (e.g., comedy, cheerful songs, game show), there has also been evidence that people in negative emotions increase preference for mood-congruent aesthetic stimuli. Consistent with our theorizing, the emotion-target congruence effect was often observed when people personally experienced loneliness, sadness, or regret (i.e., when the negative emotion contains a committed attitude and meaning toward a situation). On the other hand, emotion-target incongruence effect was observed when negative emotion was induced through bogus lab performance feedback or physical annoyance (i.e., when negative emotion has less committed values and meaning).

Finally, our findings imply where aesthetic pleasure comes from. In spite of the importance of aesthetic pleasure in people's daily life and psychological well-being, it mostly remains mysterious for scientists due to its complexity and subjectivity. In particular, the popularity of dramas, tear-jerker stories, and gloomy music challenge attempts to theorize about aesthetic pleasure based on hedonistic principles. Our findings show that aesthetic judgment is not only a matter of context and inherent taste, but also a function of the relationship between the emotional tone the stimulus conveys and the feeling one has at the time of the evaluation. Future studies are needed to explore the important relationships among emotion, emotional tone of aesthetic stimuli, and aesthetic pleasure.

Experiencing the Senses: The Interplay of Sensory Perception and Cognition

Andrea Webb, University of Wisconsin-Madison, USA

SESSION OVERVIEW

Inputs and interactions among multiple sensory modalities and the cognitions they afford affect what we imagine, what we experience, and how we process new information. The goal of this symposium is to introduce to marketing current research exploring the interplay of cognition and sensory perception, and to inspire further research within this promising area. The four presentations will address the complex interactions of cognition and sensory perception as it applies to consumer behavior—the impact of perceptual simulation on sensory experience, metaphorical transfer of meaning from smell, the impact of visual inputs on taste perception, and the consequences of imagined haptic experience. As such, the special session is designed to provide a relatively broad overview of research connecting cognition and sensory perception, so that it has a larger scope for generating directions for future research.

The first paper by Elder and Krishna explores the impact of visual product depictions on facilitating mental simulation, and ultimately affecting behavioral intentions. Across four studies they show that visually depicting a product that facilitates more (vs. less) mental simulation results in heightened purchase intentions. Also, occupying the perceptual resources required for mental simulation attenuates the impact of visual product depiction on purchase intentions. These mental simulations are also hypothesized to occur at a more automatic level, with differential consequences from deliberate forms of imagery.

The second paper by Lee and Schwarz explores that cognitions, by way of metaphorical transfers of meanings, can affect sensory perceptions. Specifically, the authors show that participants are more accurate at identifying a smell when a related metaphorical concept is activated. Across five experiments, the authors reveal a bidirectional effect of a fishy smell on conceptual activation of "fishy" or devious behavior and "fishy" behavior on the recognition of a fishy smell.

The third paper by Poor, Krishnan, and Duhachek examines the consequences of visual images on taste perception. The authors show that visual images for unhealthy foods lead to more positive taste perceptions, whereas visual images for healthy foods lead to more negative taste perceptions. Interestingly, by depicting a person consuming the food, these effects can be reversed. The authors propose that observing consumption leads to a differential goal set, leading to altered expectations for the consumption experience.

The fourth paper by Peck, Barger, and Webb addresses the consequences of imagined touch on perceived ownership. The authors show that imagining touch can have the same effect on perceived ownership as physical touch. They additionally propose a cognitive resources explanation and test it using haptic interference. The impact of imagined touch has differential consequences depending on an individual's preference for touch information.

The underlying constructs across each of the four papers present a cohesive representation of the interaction of cognition and sensory perception. The symposium will prove beneficial not only to researchers interested in sensory perception, but also to those interested in better understanding perceptual processes and their impact on cognitive processes, imagery, and processing.

Mental Simulation from Product Depiction: When Visual Stimuli Facilitate Sensory Experience

EXTENDED ABSTRACT

We utilize the theory of grounded cognition (Barsalou 2008) to explicate the effects of mental simulations on consumer behavior. One component of grounded cognition is that our initial perceptions of an object are simulated upon subsequent encounters with not only the object itself, but also representations of that object, such as verbal and visual depictions. For example, when we use a mug, the brain encodes and integrates all of the different sensory perceptions related to the mug (e.g., how it looks, how it feels to grasp it, etc.). When we later produce knowledge of a mug, we mentally simulate prior perceptions associated with the mug, leading to neural activation of many of the same sensory regions of the brain active during perception (Goldberg et al., 2006; Simmons et al., 2005).

These simulations also include motor activity and the connection between vision and motor response. As supported by the literature, visual perceptions lead to simulations of the actions they afford (Tucker and Ellis 1998; Symes et al. 2007). For example, an object that appears to be graspable leads to mental simulations of grasping the object. We propose that the amount of mental simulation that this perception-action link affords should lead to differential consequences on behavioral intentions. With the present research, we propose that visually depicting a product which facilitates more (vs. less) mental simulation will result in higher (vs. lower) purchase intentions.

Studies 1a and 1b were designed to provide support for our initial hypothesis. The stimuli used in the studies were images of bowls of yogurt and hamburgers. The visual depictions were manipulated by flipping the image of over a vertical axis, such that the spoon (yogurt) or hand (hamburger) was oriented toward the right or the left. Participants saw one of the two images of the stimulus, and then proceeded to the questionnaire. The specific measure of interest is how likely the participant would be to purchase the item depicted. We also capture the participants' handedness.

Prior to analysis, we coded the data to reflect whether the visual depiction of the stimuli matched or mismatched the participant's

handedness. This was done in all subsequent studies. As hypothesized, when the visual orientation matched the participant's dominant hand, purchase intentions were significantly higher than the mismatch condition.

With study 2 we seek to further explore the underlying process. As we propose that it is mental simulation underlying the results, restricting the ability to mentally simulate should attenuate the effects. Recent research shows that blocking the ability to perceive has consequences on conceptual knowledge (Oberman, Winkielman, and Ramachandran 2007). As our studies examine motor simulation, we have participants engage the senses used for such simulation. We operationalize this by having participants hold an object in their hand while viewing an advertisement. We posit that this simulation blocking will attenuate the effect of visual product orientation on purchase intentions.

The design for study 2 is a 2 (orientation: match, mismatch) x 4 (simulation block: dominant, non-dominant, both hands, none) between subjects design. In the simulation block conditions, participants either held a clamp in their dominant hand, non-dominant, or did not hold a clamp while viewing the advertisements. Participants viewed four advertisements, including the target advertisement which showed a cake with the fork either on the left or right.

Our analysis revealed a significant interaction. Follow-up contrasts reveal that within the no simulation block condition, the match condition leads to significantly higher purchase intentions than the mismatch condition, replicating the findings from the prior studies. Additionally, when the non-dominant hand is blocked, the pattern of results replicates the no-simulation block condition. Within the both hand simulation block condition, there is no significant difference between orientation conditions. However, within the dominant simulation block condition, the results are reversed. Thus, when participants' actual perceptual experiences are blocked, mental simulation is impeded with consequences on behavioral intentions.

Study 3 was designed to test whether the effects of visual product depiction on mental simulation obtained in our earlier studies are more automatic than other forms of imagery. We anticipate that instructions to fully imagine interacting with the stimulus should attenuate the effect of visual product depiction on purchase intentions, as given instructions to imagine, individuals can mentally pick up and rotate the object, and the initial orientation of the object should be of less importance.

Study 3 uses a 2 (product orientation: match, mismatch) x 2 (imagine instructions: yes or no) between subjects design. In the imagine instructions condition, participants were told to imagine using the product depicted (hammer). We get a significant interaction between orientation and imagery instructions. Follow up contrasts reveal that when participants are not given instructions to imagine using the hammer, the match condition leads to significantly higher purchase intentions than the mismatch condition. When participants are instructed to imagine, there is no significant difference in purchase intentions.

We posit that the process underlying our results is mental simulation. Should it be mental simulation underlying the results, a positive experience should become more positive, and a negative stimulus should become more negative, as the simulated experience is aversive. Thus, the prediction for study 4 is that the initial positive effect of the visual depiction on purchase intentions will be reversed for a negatively valenced stimulus.

In order to test our hypotheses, we created create two sets of stimuli: one positively valenced (Asiago Cheese and Tomato Soup), and one negatively valenced (Cottage Cheese and Tomato Soup). The manipulation of visual depiction used in study 4 is made by simply altering which side of the bowl the spoon is on. This study is thus a 2 (orientation: match, mismatch) x 2 (valence: positive, negative) between subjects design.

Analysis of study 4 shows that within the positively valenced condition, the match condition leads to significantly higher purchase intentions than the mismatch condition. However, within the negatively valenced condition, the results are reversed. The findings from study 4 are supportive of a simulation account such that the visual depiction facilitates mental simulation, which in turn drives behavioral intentions.

Something Smells Fishy:
Suspicion Enhances Identification of
Fishy Smells, and Fishy Smells Arouse Suspicion

EXTENDED ABSTRACT

Across languages, suspicion can be expressed metaphorically as dislikeable odors (Soriano & Valenzuela, 2008). In English, the specific odor is fishy; if something smells fishy, it creates "doubt or suspicion" (Merriam-Webster, 2010). Extending grounded social-cognition research beyond its current focus on visual and tactile perception and on conceptual metaphors presumed to be universal (e.g., Affectionate=Warm; Moral=Pure; Important=Heavy; Powerful=High), we explore the grounding of suspicion in smell as instantiated in the English language.

Does social suspicion affect smell identification? In Experiment 1, participants were asked to close their eyes, sequentially open five test tubes wrapped in aluminum foil, sniff the content, and identify each smell. After giving instructions about this task, for half of the participants ($n = 40$), the experimenter hurriedly took away a form underneath the response sheet as if it was something participants were not supposed to see, and she remarked, "we're not trying to hide anything here." For the other half, she did not act or make the remark ($n = 40$). Next, all participants completed the smell identification task by identifying the smell of five consumer products ("autumn apple" fragrance oil, onion flakes, "creamy caramel" fragrance oil, "orange nectar" fragrance oil, and fish oil). Responses that included the item's name or any one of its ingredients were coded as *identified*. As predicted, participants induced to feel suspicious showed higher accuracy in identifying fish oil; suspicion did not affect accuracy in identifying any other smell. This pattern suggested a metaphor-specific effect of social suspicion on smell identification.

What is the psychological process that underlies this metaphor-based influence? Using an experimental causal-chain design (Spencer, Zanna, & Fong, 2005), Experiments 2-4 tested each step of our hypothesized causal chain: "Feeling suspicious → Accessibility of suspicion concepts → Accessibility of fish concepts → Identification of fishy smell."

In Experiment 2, participants were induced to feel suspicious ($n = 25$) or not induced ($n = 24$), and did a word-completion task. Of the 20 items, 10 could be completed with suspicion-related words (e.g., *doubt*, *dubious*, *suspicious*). As expected, participants induced to feel suspicious wrote more suspicion-related words; thus, a feeling of suspicion increased the accessibility of suspicion concepts.

In Experiment 3, participants were primed with suspicion concepts in a scrambled-sentence task (based on the suspicion-related items in the word-completion task of Experiment 2; $n = 57$) or primed with unrelated concepts ($n = 59$). Next, they did a word-completion task with 20 items, 10 of which could be completed with fish-related words (e.g., *fishing*, *gills*, *fin*, *tuna*). As expected, participants primed with suspicion concepts wrote more fish-related words; thus, suspicion concepts increased the accessibility of fish concepts.

In Experiment 4, participants were primed with fish concepts in a scrambled-sentence task (based on the fish-related items in the word-completion task of Experiment 3; *n* = 19) or primed with unrelated concepts (*n* = 15). Next, they completed the smell identification task used in Experiment 1. As expected, participants primed with fish concepts showed higher accuracy in identifying fish oil. There was no effect on any other smell. Thus, priming fish-related concepts specifically enhanced identification of fish oil.

Results from Experiments 2-4 suggest that the metaphor-specific effect of social suspicion on smell identification is mediated by a process of metaphoric concept association. Recognizing the unconscious nature of this process, we tested for the reversed causal effect in Experiment 5: Does incidental exposure to a fishy smell increase social suspicion? Participants were individually approached by an experimenter in a campus hallway and asked to complete an "investment decision task" (the trust game) together with another "participant" (a confederate). The participant and the confederate were each given 20 quarters. The participant first decided how much to give the confederate; any amount given would be quadrupled in value (e.g., $0.25 would become $1.00). The confederate could then decide to give any amount (all, some, or none) back to the participant. With trust, participants should give more money based on the expectation that the confederate would return a reasonable proportion of the investment; with suspicion, participants should give less money. Depending on condition, another confederate sprayed a segment of the hallway with one of three substances (fish oil, fart spray, water) while the experimenter recruited the participant (thus keeping recruitment unaffected by the smell). As predicted, participants who smelled something fishy (fish oil) invested less money than those who smelled another aversive odor (fart spray) or no odor (water). The last two conditions did not differ, indicating that the impact of a fishy smell is due to their metaphorical meaning, not mere negative affect. Thus, incidental exposure to a fishy smell increased social suspicion and undermined trust, as reflected in less cooperation in an economic trust game.

In sum, five experiments support the grounding of suspicion in smell. We find bidirectional effects, as social suspicion increases accuracy in identifying a fishy smell and exposure to a fishy smell increases social suspicion. Because the grounding is based on a metaphor, effects are specific to the metaphor and limited to a fishy smell. Our data further support the assumption that metaphor-based influences are mediated by nonconscious concept associations. These results extend grounded social-cognition research beyond the visual and tactile domains and shed light on the underlying mechanism. They also raise new questions about the operation of grounded concepts with identical structure (suspicion grounded in smell) but different cultural-linguistic instantiations (e.g., "fishy" in English).

Seeing is Believing: Exploring the Conditions Under Which Food Images Influence Taste Perceptions

EXTENDED ABSTRACT

Appetizing food images are rampant in marketing. The influence that such images have on taste perception, however, is still not well understood. In the current research, we posit that food images do influence taste perceptions, but that this relationship is moderated by the type of food featured in the ad and the image context.

When a product is consumed, its actual sensory attributes are compared and contrasted with any preexisting expectations. A mismatch between the expected and actual attributes of the product produces either positive or negative "disconfirmation" (Cardello & Sawyer, 1992). According to assimilation theory, when disconfirmation occurs, perceived product performance will assimilate (become similar) to the level of expectation (Hovland, Harvey, & Sherif, 1957). In the domain of food, this means expected sensory qualities would combine with experienced sensory qualities, causing actual evaluations to more closely resemble the expected evaluation.

Previous research by Raghunathan and colleagues (2006) demonstrated that consumers hold an implicit belief that foods characterized as healthy are less tasty than foods characterized as unhealthy and that this intuition can color consumers' inferred and actual taste evaluations. Building on this research, we propose that an image of a healthy (unhealthy) food will activate negative (positive) expectations about the tastiness of the featured food and that these expectations will combine with the actual taste experience, causing taste evaluations to more closely resemble the expected evaluation than if the same item were evaluated without image exposure. More formally:

Hypothesis 1a: Exposure to an image of an unhealthy (healthy) food will enhance (reduce) taste perceptions during subsequent consumption of that food, relative to no image exposure.

Hypothesis 1b: The number of positive minus negative sensory thoughts produced during consumption will mediate this effect.

Second, we propose that this pattern of results can be reversed when the context of the image viewed includes a person actually consuming the featured food (consummatory image). To explain this effect, we turn to the literature on goal contagion and argue that a consummatory image may prime automatic goal activation and pursuit (Aarts, Gollwitzer, & Hassin, 2004). When an individual sees an image of someone eating a healthy food, they may infer that the person is pursuing a healthy eating goal, and consequently adopt and pursue that goal themselves. In contrast, consuming unhealthy foods is a behavior often associated with the goal of seeking indulgence, which may involve mixed feelings. Thus, seeing an image of someone indulging in an unhealthy food, particularly when the person is shown eating alone, may act as a negative goal-related cue, which we argue will de-activate an indulgence goal or in other words, activate a healthy eating goal.

As such, we expect that exposure to consummatory images may automatically activate a healthy eating goal and that this temporary motivational state may color consumers' expectations about the subsequent taste experience (Markman, Brendl, & Kim, 2007). More specifically, we expect that seeing an image of someone eating a healthy (unhealthy) food will activate a healthy eating goal and that this will positively (negatively) influence expectations about the taste of goal (in)consistent food, such that when the food is then eaten, the consumer evaluates it as tasting better (worse) than if they had only seen an image of the food alone. More formally:

Hypothesis 2a: Exposure to a consummatory image of an unhealthy (healthy) food will reduce (enhance) taste perceptions during subsequent consumption of that food, relative to a pure food image.

Hypothesis 2b: The number of positive minus negative sensory thoughts produced during consumption will mediate this effect.

In experiment one, we test H1a and H1b employing a 2 (image exposure: yes, no) x 2 (food type: healthy, unhealthy) between-subjects design. Subjects were told that they would be helping pretest stimuli for a future study on food advertising. Subjects in the image exposure conditions were shown five different food images of either apples (healthy) or chocolate (unhealthy) and asked to indicate the pleasantness of each image on a nine-point scale (unpleasant-pleasant). Next, subjects tasted a sample of the same food item featured in the images, listed any thoughts they had while tasting it, and rated its taste on four nine point scales anchored by bad/good quality, flavorless/flavorful, not at all /very delicious, bad/good taste). Subjects in the no image exposure- healthy/ unhealthy conditions only completed the respective taste tests. As expected, the results showed that subjects that saw images of chocolate rated the chocolate sample better than those that only tasted the sample. In contrast, those that saw images of apples rated the apple sample worse than those that only tasted the apple. These effects were mediated by the net positive sensory thoughts produced during consumption.

In experiment two, we test H2a and H2b using a 2 (image context: food alone, food consumed) x 2 (food type: healthy, unhealthy) between-subjects design. The procedure mirrored that of experiment one, except that all subjects were exposed to a series of eighteen food images prior to the taste test. Image context was manipulated by using images that either featured only the target food item or the target food item actually being consumed. As expected, the results showed that subjects exposed to images of just chocolate rated the chocolate sample better than those that saw images of chocolate being consumed. In contrast, subjects that saw images of apples being consumed rated the apple sample better than those that saw images of just apples. These effects were again mediated by the net positive sensory thoughts produced during consumption.

Taken together, our findings show that exposure to food images primes expectations, which influence subsequent taste perceptions. More importantly, we show that the direction of this effect depends on the type of food featured and the context of the image. We are currently running additional studies, which demonstrate the generalizability of these findings and identify important boundary conditions. These findings also have important implications for marketers of both healthy and unhealthy food products, as well as consumers trying to adhere to a healthier diet.

In Search of a Surrogate for Touch: The Effect of Haptic Imagery on Perceived Ownership

EXTENDED ABSTRACT

Previous research has shown that consumers value objects more highly if they own them, a finding commonly known as the endowment effect (Thaler, 1980). This effect is not limited to legal ownership; psychological ownership, characterized by the feeling that something "is mine," also produces the endowment effect. One antecedent of psychological ownership is the ability of an individual to control an object by touching it. Peck and Shu (2009) show that when individuals are given the opportunity to touch an object (versus not), they report a greater sense of perceived ownership and value the object more highly.

If touch is not available, could imagining touch act as a surrogate? According to MacInnis and Price (1987), imaging is a resource demanding process in which sensory information is represented in working memory. Bone and Ellen (1992) conjecture that imagery "may involve sight, taste, smell and tactile sensations" (p. 93). Although research on imagery and the tactile system is limited (Klatasky, Lederman & Matula, 1993), there is some evidence for the interdependence of touch and imagery (Katz, 1925).

Since imaging requires cognitive resources and the effects of imagery are mediated by resource availability (Bone & Ellen, 1992; Unnava, Agarwal & Haugtvedt, 1996), blocking out perceptual distractions during imaging may enhance its effects. In some instances, consumer behavior researchers have instructed participants to close their eyes when imaging (e.g., Bone & Ellen, 1992; Keller & McGill, 1994 (Experiment 1); Petrova & Cialdini, 2005 (Study 3)), although this was not the focus of these studies. We hypothesize and find that closing one's eyes while imagining touching an object leads to greater psychological ownership than imagining touching an object when one's eyes are open.

An experimental study was designed to examine the effect of touch imagery on perceived ownership. The design was a 4 (imagery/touch: imagery eyes closed, imagery eyes open, no touch no imagery, touch with no imagery) x 2 (product: Koosh ball, blanket), with the first factor manipulated between subjects and the second factor varied within subjects. Three hundred and twenty-six individuals participated in the study.

Our first hypothesis predicted that when participants imagined touching the product with their eyes closed, perceived ownership would be greater than when participants imagined touching with their eyes open. We found a main effect of touch/imagery for perceived ownership. Both the touch condition and the touch imagery with eyes closed condition resulted in a significantly greater sense of ownership than the touch imagery with eyes open condition and the no touch-no imagery condition.

We next conducted a second study in order to examine the process in more detail. We hypothesized that when a person closes her eyes to imagine, she is focusing her cognitive resources, which results in similar effects to actual touch. In the second study, we had participants imagine touching a product (as in Study 1) but we manipulated whether haptic interference was present and also whether the interference "fit" with the imagined object. The design of this study was a 2 (vision: eyes open, eyes closed) x 3 (haptic stimulus: none, congruent, incongruent) with both factors manipulated between subjects. Three hundred and eighty-seven individuals participated in the study. In addition to replicating our first study, we found that when a person imagines touch with eyes closed, the presence or absence of haptic stimuli does not significantly impact haptic imaging unless the stimulus is incongruent with the product being imagined.

The third study delves deeper into both the process and the individual difference in Need for Touch (Peck and Childers, 2003). Consumers may base their product evaluations not on the product information with which they are presented, but rather on the fluency with which that information can be processed (Lee and Labroo, 2004). Since individuals high in NFT are more proficient at processing haptic information, we hypothesize that they do not need to close their eyes to effectively imagine touch, whereas individuals low in NFT do. As a result, it should be easier to interfere with the haptic imaging of a person lower in NFT. We find the predicted results in this experiment. To further elaborate on the process, we also measure the vividness of the haptic images.

We are currently conducting a study that extends the previous studies by investigating perceived control as an antecedent of perceived ownership. In the previous studies, we hypothesized that touch and haptic imaging both led to an increase in perceived ownership due to the ability to control the object. In this study, we directly measure perceived control as further evidence of the process. We also limit the time for imagining touch to provide further support for our cognitive resources explanation. Data collection is underway and the results will be available for presentation at ACR.

Innovative Community Exchange Systems: Grassroots
Social Experiments in Sustainability

SESSION OVERVIEW

Significant existing research documents the negative impact of consumption on the environment (see, for example, Kilbourne and Beckmann 1998). Less attention is given to exploring the burgeoning local experiments by individual consumers and communities who seek to live more sustainably (Prothero et al. 2011). We bring together three empirical studies of local community-based initiatives that offer alternative models of exchange based on life affirming values of sharing (Belk 2010), capacity building, and wise stewardship over the earth's limited resources.

Specifically, across the three papers, we examine the ongoing social construction and negotiation of new norms and values within three local community engagement projects: a community time bank, an online item exchange community, and ecovillages. To varying degrees, each of these experiments was inspired and is connected to international social movements; yet the exchange systems are inescapably enacted within local environs that are shaped in minor and major ways. These exchange systems are relatively new so we are able to see the actual development and formation of new social norms and community practices to affirm these values. We examine how these experiments in sustainability both expand and limit the capacities of communities to transformation. We seek to move toward a better understanding of collective efficacy and to inform the development of an applied theory of community change. These experiments provide useful insights to the challenges facing us as we move haltingly toward a more sustainable post-consumer culture (Mick 2006).

Lucie Ozanne and Julie Ozanne examine the development of a time bank community. Time banks are based on a form of community exchange that assumes everyone's time is equal in value. As such, time becomes a unit of value in which participants give and receive help in exchange for time credits. While consumers import norms and social expectations from market-mediated and family-mediated exchange, the time bank requires different norms to release its potential to enact social change.

Zeynep Arsel and Susan Dobscha examine an internet-mediated item exchange community that is international in reach but operates at a local grass roots level. This Freecycle community is often considered to be a gift economy in which people post free goods that are then presented as gifts (Giesler 2006). The authors explore contradictions between the top-down policies of an organization guided by a specific ethos and the bottom-up contestation of the local participants

engaged in meaning making. The potential of this community is at times thwarted by these organizational policies.

Rob Kozinets and Frank-Martin Belz provide perhaps the most dramatic example in their examination of intentional and sustainable communities called ecovillages. Not surprisingly, this lived experience has a more profound influence impacting members' connection to their food, the land, and one another.

Jean-Sébastien Marcoux, who is trained as an anthropologist and has published provocative work on the contrary nature of gift giving (Marcoux 2009), is well suited to comment on the contradictions found within these experiments. In conclusion, this session should be of particular interest to scholars concerned with issues such as sustainability, community building, community resilience and efficacy, sharing, gift giving, generosity, and altruism.

Building Community Efficacy through
Time Bank Exchanges

EXTENDED ABSTRACT

A time bank is a locally-based exchange system in which labor flows through non-reciprocal exchange (Seyfang 2004). Community members "deposit" an hour of labor by giving services to another time bank member and, in return, can "withdraw" an hour of service from different members (Williams 2004). The time bank in this study began in 2005 with just a handful of members and now claims over 300 members, which represents about 13% of the local town. To date, over thirty thousand hours have been exchanged and currently an average of four hundred hours is traded each month. While original members were all individuals, memberships now includes organizations ranging from the local school, radio station, medical center, community garden, and childcare facility.

Part-time field work spanned approximately eighteen months and included participant observation of both the internal administration of the time bank and external community events as well as actively trading in the time bank. Besides field notes, the data collected included focus group interviews, over twenty formal interviews, and time bank communications, trades, and publicity. Data collection is completed and the data analysis is well underway.

Time bank trades are facilitated through an online trading system, which documents the breadth and diversity of the skills that exist in the community. Thus, the community becomes aware of the latent and often untapped potential of its members, which positively impacts the community identity as resourceful. Similarly, even individuals who may feel like they have no 'marketable' skills become aware of capacities they possess that are valued by others and can be traded (e.g., companionship, canning preserves, dog walking). The time bank breaks down barriers and allows neighbors to request and offer help through indirect exchanges. Through time bank exchanges, traders become more deeply integrated into the local community. Early in the field work, traders struggled to transport social norms derived from marketplace and more familial exchange. More recently, the time bank is emerging as a community resource guided by a different logic.

While traditionally relational and reciprocal exchange is highly valued (Dwyer, Schur, and Oh 1987), the weak ties of non-reciprocal exchange allow the community to tap into the significant distributed

expertise of the community (Sampson 2002). Increasingly the time bank is seen as a way to mobilize the power of this network increasing collective efficacy and contributing to the quality of community life. Time bankers rally to engage in community projects, such as working on the summer street festival, facilitating the weekly farmers' market, participating in the annual clothes swap, and volunteering at the local visitor information center finding that even physically demanding tasks are more pleasant when shared (Belk 2010). Time bank members initiated a scheme to "tag bust" and clean-up graffiti. The time bank creatively responded to cuts in government funding by training time bankers to run physical fitness courses and adult education classes--participants then paid in time credits. The time bank is used to socialize the youngest community members on being civic minded and altruistic. For instance, the local school encourages their student body "to learn about the benefits of community and giving" through beach clean-ups and other community enhancing projects.

Rather than suffering from the classic economic free rider problem, community time wealth accrues and needs to be redistributed. Time bank members regularly gift their time credits to members who are in need of support or toward community projects. A community treasure chest of time credits enables the time bank to direct community effort to priority initiatives, such as volunteer assistance with reading recovery programs, art and drama projects, and working bees at the school. As one older informant states: "I go into the school each week and work with a few children who need a bit of extra help with reading. All my grandchildren live in the North Island, so it is lovely to have this contact with these delightful beings."

Perhaps the most dramatic example of the time bank's potential for collective efficacy and community resiliency was evidenced in the aftermath of the first New Zealand earthquake; the time bank helped people rally when the civic services became over whelmed. For instance, the health center turned to the time bank to activate members to phone elderly patients to check on their safety. When the volunteer fire brigade was besieged with calls to dismantle unsafe chimneys and structures, the time bank assisted. Members also manned the information center providing a retreat and social valve for residents to vent their anxieties. Direct support was provided to residents, whose homes were severely damaged, providing them with shelter and support. The time bank acted as a conduit of information regarding tunnel and road closures and local infrastructure and support. Perhaps most importantly, community members were given the opportunity to act constructively helping others during a crisis that often left people feeling helpless and alone.

Hybrid Pro-Social Exchange Systems:
The Case of Freecycle

EXTENDED ABSTRACT

Freecycling is an organization that facilitates non-reciprocal exchange of goods within local communities with the goal of reducing waste (Freecycle website). This exchange is pro-social since the participants who offer their possessions to others do so at a personal cost and without immediate gain (Penner et al. 2011). It is often characterized as a gift system given no financial exchange occurs; instead, the exchange is governed by a principle of generalized reciprocity across members (Nelson and Rademacher 2009). Initiated informally by a group of friends in Tucson, AZ who realized that their trash might be another's treasure (company documents), members now number over 8 million users across 85 countries. The institutional mission is to promote gifting among its members, divert goods with existing use value from landfills, and reduce the overall impact of consumption on the environment.

Freecyling provides free goods to consumers for a diverse range of reasons. The majority of the participants are similarly minded, socially cooperating, free laboring individuals who redistribute goods in a creative and novel way. In fact Nelson, Rademacher, and Paek (2007) found that members of a local Freecycle community had a distinctly less materialistic relationship with consumer culture and higher levels of civic involvement and politicized consumption than non-Freecyclers. Whereas the assumption is that Freecyclers are acting upon some greater moral imperative when they gift these items, previous research suggests that participants who joined Freecycle could actually fit into one of four categories of motivation: self-interest, decluttering, environmental concerns, and helping others (Nelson, Rademacher, and Paek 2007).

We have conducted a multi-method analysis utilizing blog mining, archival search, and interviews with 22 regular participants of Freecycling. Both authors also are active participants of the community since 2007 and exchanged goods through their local Freecycle chapters. Our data analysis revealed several interesting tensions between the goals of the institution (the owners of the Freecycle brand) and its community members (participants in local chapters). Specifically, these tensions arise from institutional norms being imposed upon the participants rather than from the patterns of consumption that emerged from freecycling. While others find improved community cohesion as a result of these pro-social communities (Ozanne and Ozanne 2010), our research suggests a more complicated picture.

Our work extends theories on exchange following Belk's (2010) article on sharing. Belk outlines a typology of marketplace exchanges that correspond to three divergent cultural patterns with their own rituals and behaviors: sharing, gift giving, and commodity trade. The case of Freecycling exhibits characteristics of all three prototypes in contrast to the organization's frame of "gifting." Furthermore, within each exchange, tensions and paradoxes arise from the institutional misalignment of norms and expectations. For example, while the mission of Freecycle is to offer and request goods free, participants are discouraged from providing information related to personal predicaments (a counterindication of sharing) and from expecting reciprocity (counterindication of gifting). We suggest that this complex and paradoxical practice of impersonal "sharing out" (Belk 2004; Widlock 2004) provides a fruitful context to further extend theories of exchange.

We find four main tensions arising from the mismatch between the institutionally imposed norms and community participation. These tensions suggest the hybrid and ambiguous status of this exchange system vis-a-vis Belk's typology. The first tension arises around the issue of materialism. While the aim of Freecycle is to reduce overconsumption, some informants are materialistic in their motives and actually hoard goods. In some ways, Freecycle allows them moral license to acquire too much. Still, we argue that this hybrid exchange system allows people to engage in variety seeking and collecting while minimizing their ecological impact when compared to buying "new" goods. The second tension arises when nontraditional items are commodified. For example, pets and personal services are considered inappropriate from the institution's perspective, whereas local participants disagree and frequently defy this rule. The third tension arises on the need for personalization and communal bonding. Freecycle's policy is to remove personal stories from listings to discourage pity exchanges and increase market efficiency. Yet, participants express a strong need for divestment rituals and the transfer of symbolic meaning of goods through storytelling. We argue that this tension creates an impediment to community, an asset that Freecycle's policies undermine or at least undervalue. The last

tension arises on the non-profit nature of the system. While no official policy exists on reselling goods, participants express conflicting views about the appropriateness of this practice. This divergence highlights the varying motives consumers have for participation in contrast to the institutionalized mission.

Finally, we argue that the institutional framing of Freecycling as a "gift economy" is oversimplified since it ignores the hybridized form of exchange. Similar to Eckhardt and Bardhi's work (2010) that found that not all consumers who used car-sharing services were motivated by environmental concerns, we suggest that a gift-based positioning does not fully capture the experiences participants have while engaging in the redistribution of goods. We further argue that institutionalized emphasis on efficiency and impersonalization impairs the community building potential that some participants value.

"The Indefinite Future":
Ideas, Ideals, and Idealized Ideology
in the Global Eco-Village

EXTENDED ABSTRACT

Intentional communities have a long and checkered history as wellsprings of social experimentation and innovative new cultural forms (Brown 2002; Sargisson and Sargent 2004). In contemporary parlance, intentional communities include not only such specific and relatively temporary (anti) consumption-related happenings as the Burning Man project (e.g., Kozinets 2002) and the Rainbow Family Gathering (Niman 1997), but also more lasting manifestations such as ecovillages, cohousing communities, residential land trusts, communes, student co-ops, urban housing cooperatives, intentional living, alternative communities, and cooperative living. Each of these is considered to be a quasi-experimental "project" where people strive to live out a common vision in their everyday lives. Oftentimes, this vision is one that combines the environmental with the communitarian and which seeks to question in a collective setting the base of values underlying contemporary consumer culture and simultaneously to explore what could or should replace it (Dawson 2010).

In this cross-cultural, longitudinally-oriented, multi-sited research, we seek to deepen our knowledge of the ideologies of consumption that support and underlie participation in one particular and ecologically-oriented form of intentional community: eco-villages. The commonly accepted and value-laden definition of ecovillages is that they are "human-scale, full-featured settlements in which human activities are harmlessly integrated into the natural world in a way that is supportive of healthy human development and can be successfully continued into the indefinite future" (Gilman 1991, quoted in Dawson 2006, p. 13).

Eco-villages are a fascinating place for consumer researchers to ponder the transition of consumer culture and contemporary society into a more eco-friendly and sustainable form for a variety of reasons. First, they come in many shapes and sizes, and thus attract consumers from the most ecologically radical to those with merely a firm commitment and interest in sustainable living. Second, they are part of an organized and successful international intentional community movement. Third, the global network of eco-villages is not only transnational but transcultural, having been partially founded on an alliance between sustainability-based communities and networks of traditional communities in developing countries. And fourth, eco-villages are explicitly ideological enterprises concerning themselves with the alteration of the economic values underpinning contemporary consumer culture, particularly, the linkage of economic growth and personal and social well being.

We begin with an overview of the core notions of intentional community. We develop our understanding of ecovillages as a concept and a movement. We then introduce our research that was conducted at three different eco-villages, speaking three different languages, in three different countries (Germany, Scotland, and French Canada). We undertook an ethnographic exploration of eco-village life and conducted (and are in the process of conducting) over one dozen interviews, as well as using participant-observational techniques. Data collection and analysis at two sites has been completed, with a second wave possible before the October presentation. Initial data collection in the third site is planned for June, and full analysis will be completed by October. As of February, we have more than enough data collected and analyzed to present, even without the third site.

As with the other presentations in this session, the members of eco-villages are concerned with sharing, capacity building, and the wise use of the planet's limited resources. However, the levels and depths of commitment, and the range of ideological engagement is more pronounced and perhaps profound. At the Findhorn ecovillage in Scotland that we studied, the ecological footprint per person is a bit over half of the UK average, which is the lowest footprint recorded for any settlement in the industrial world.

Perhaps even more interesting than the achievement of low energy usage is the means for its accomplishment. Most of the energy-saving activities also are credited with increasing the well being of eco-village members. For example, the decision by eco-villages to grow a significant amount of their own food creates a social situation where community members must work together cooperatively. Similarly, living together necessitates new social forms of engagement. The net effect, as with other types of intentional community both temporary and permanent, is that economic activity becomes local and thus ideologically linked to the immediately social. This powerful relocation of production is a common theme of the eco-village experience, along with a series of other reconnections—reconnecting people with their food, reconnecting people with their land, reconnecting people with indigenous people and practices, and reconnecting people with other people with whom they live. Add to this an educational and experiential ethos, and you have a potent potential for social change.

What is the net effect with our encounter with the distant boundaries of living as an ecovillage embedded consumer and consumer researcher? It is nothing short of informing our understanding of connection, disconnection, and reconnection. There are answers to our questions about new transitional forms of living that can lead the way to a more ecologically sustainable post-consumer culture.

Paper #3: Can Collectivism Promote Bribery?

Nina Mazar, University of Toronto, Canada
Pankaj Aggarwal, University of Toronto, Canada

SESSION OVERVIEW

With the emergence of China and India as drivers of global growth there has been a corresponding increase among Western companies to market effectively to consumers in these countries (Ecker, 2008; Tse, 2010). Global marketers often guide their market decisions by contrasting the more collectivist orientation of Easterners with Westerners' individualist orientations (Shavitt, Lee & Torelli, 2008). Building on the notion that Easterners and Westerners differ in their conceptions of individual versus collective autonomy (Menon et al., 1999), this symposium sheds light on how these culturally-patterned conceptions of autonomy shape people's judgments and behaviors. In doing so, we uncover the psychological mechanisms underlying people's tendencies to: a) switch brands when facing unsatisfactory product experiences, b) favor brands that symbolize individual autonomy, and c) rely on bribery as a business tool for gaining competitive advantage.

The first paper by Ng, Kim & Rao examines how Westerners' (Easterners') emphasis on individual (collective) autonomy affects their attributions and degree of counterfactual thinking, and their subsequent brand-switching intentions. In three studies, the authors demonstrate that for East Asians (Westerners), brand-switching intentions were higher (lower) when encountering an unsatisfactory product experience attributed to an exercise of individual versus collective autonomy (i.e., an individual vs. a group choice). In contrast, East Asians (Westerners) exhibited lower (higher) brand-switching intentions when the unsatisfactory product experience was attributed to the *failure* to exercise individual versus collective autonomy. Furthermore, the effect of unsatisfactory product experiences due to an exercise (or lack thereof) of a culturally-nurtured conception of autonomy on brand switching was mediated by the experience of counterfactual thinking and regret.

The second paper by Keh, Torelli, Hao & Chiu investigates how younger, educated Chinese consumers evaluate different types of translations (semantic, phonetic, and phonosemantic) of Western brand names, as a function of their symbolism of individual autonomy values as well as consumers' own cultural value priorities. Results from two studies demonstrate that young Chinese consumers are more likely to infer individual autonomy values from phonetic or phonosemantic brand name translations than from semantic transla-

tions, particularly for products with high and very high levels of value-expressiveness. In addition, semantic and phonosemantic translations create the favorable impression that the marketer is sensitive to Chinese culture. As phonosemantic translations benefit from both kinds of effects, they are the most favorably evaluated. Findings also reveal that phonetic translations are evaluated more positively than semantic translations, indicating that the effect of value inference is stronger than that of marketer cultural sensitivity. This is corroborated by findings showing that consumers who endorse autonomy values attribute higher levels of value congruence to the phonetic and phonosemantic brand name translations and hence like them better.

The final paper by Mazar and Aggarwal investigates the extent to which a lowered sense of personal responsibility fostered by a collective conception of autonomy influences the likelihood to bribe when entering a foreign market. In a business to business context, three studies find a significant effect of the degree of collectivism versus individualism present in a national culture on the propensity to offer bribes abroad. Furthermore, the effect is mediated by the lowered sense of personal responsibility. Together, the results suggest that the collective conception of autonomy nurtured in collectivist cultures promotes the propensity to offer a bribe in a business exchange through lower perceptions of personal responsibility for one's actions.

This session discusses very important issues in cross-cultural consumer behavior and presents the completed work from three papers. In keeping with the theme of ACR 2011, this session 'connects' research on culturally-patterned conceptions of individual versus collective autonomy to inform marketing researchers about the psychological mechanisms underlying cultural patterns of judgments and behaviors in the global marketplace. We anticipate this session will attract not only those interested in global, specific marketing issues (e.g., branding, advertising), but those interested more generally in cross-cultural consumer behavior. We will save 20-25 minutes for Ana Valenzuela, an expert in cross-cultural psychology, to discuss the presentations and to receive questions from the audience. Dr. Valenzuela will spend a few minutes integrating the implications of the three streams of research to bridge connections between the current projects and will provide a roadmap for future research. She will then moderate questions and comments from the audience.

"Sins of Omission and Sins of Commission: Differences in Brand-Switching Intentions Due to Culturally Different Theories of Agency"

EXTENDED ABSTRACT

People naturally make mistakes. When events unfold in an unsavory fashion, humans experience regret and mentally picture how those events could have unfolded differently, if they had either by acted differently, or if they had not acted in a manner that led to the unsavory outcome. Such counterfactual thinking can lead to a modification of the individual's future behavior (Roese 1994).

Recent advances in psychology have documented cross-cultural differences in the construal of agency (Menon, Morris, Chiu, and Hong 1999; Morris, Menon, and Ames 2001). In Western cultures, individualism is emphasized, while in Eastern cultures collectivism is emphasized. This difference in emphasis of individual versus group action has an impact on the degree of counterfactual thinking

that individuals might experience. That is, Westerners might experience counterfactual thinking to a greater degree due to their individual behavior, while Easterners might experience counterfactual thinking to a greater degree due to their group's collective behavior. Such differences in counterfactual thinking have implications for perceptions of regret and the intention to change behavior in the future. We examine this issue in a consumption context by varying cultural orientation, action or inaction as the cause of a regret-inducing purchase, and whether the individual or group was the agent making the original purchase decision; our dependent variable is people's brand- switching intentions as a result of the regret-inducing purchase experiences.

In study 1, we examined our core premise that Eastern and Western cultures differ in the extent to which individuals or groups are perceived to engage in action. To this end, a 2 (Cultural prime: Chinese vs. US prime) (Decision Unit: Individual vs. Group) between-subjects experiment was conducted. In order to manipulate different cultural orientations, we employed cultural priming (Chen, Ng, and Rao 2005; Ng and Houston 2006). In addition, we varied the decision context (a decision to adopt a new medicine) by stipulating that the decision was to be made either individually or collectively among a group of medical patients. An ANOVA run on consumers' propensity to act (i.e., choose the new medicine) revealed a significant two-way interaction ($F(1, 55) = 6.54$, $p < .05$), indicating a greater expectation for the individual to act in the US culture and greater expectation for the group to act in the Chinese culture. These results corroborate the idea that people's implicit theories of individual versus group agency vary across culture.

In study 2, we tested our main hypotheses by examining the degree of counterfactual thinking and brand-switching intentions. For this purpose, we employed a 2 (Cultural prime: Chinese vs. US prime) 2 (Frame: Action vs. Inaction) 2 (Decision Unit: Individual vs. Group) design, in the context of a computer purchase for a personal or family business. First, the ANOVA run on the number of counterfactual thoughts revealed a significant three-way interaction ($F(1, 275) = 27.13$, $p < .01$). Further analyses involving contrasts showed that Chinese-primed participants generated more counterfactual thoughts when the negative event occurred as a consequence of the individual's (vs. the group's) action ($F(1, 275) = 4.26$, $p < .05$). Conversely, US-primed participants generated more counterfactual thoughts when the negative event occurred due to actions of the group (vs. the individual; $F(1, 275) = 15.76$, $p < .01$). Similarly, participants in the Chinese prime condition generated more counterfactual thoughts when the group (vs. individual) failed to act ($F(1, 275) = 5.21$, $p < .05$), whereas the opposite was true for US-primed ones ($F(1, 275) = 3.28$, $p < .09$). These results indicate that individuals' propensity to experience counterfactual thinking due to an action or inaction changes when the domain of decision-making shifts from the individual to the group.

The same analysis on brand-switching intentions also revealed a similar set of findings ($F(1, 275) = 17.31$, $p < .01$). Specifically, brand-switching intentions were higher among Chinese-primed participants when the sub-par outcome occurred due to the individual's (vs. group's) actions ($F(1, 275) = 3.58$, $p < .05$), while failure due to group inaction led to greater brand-switching intentions than failure due to individual inaction. In contrast, US-primed participants exhibited the opposite pattern. Moreover, meditational analysis using the bootstrapping method confirmed the indirect effect of counterfactual thinking on brand-switching intentions.

Study 3 replicated the finding of study 2, using a different consumption context (i.e., investment brokerage firm). Similar to study 2, participants were asked to imagine that they encountered unsatis-

factory investment outcomes due to poor advice from their brokerage firm that had encouraged action (to sell their stocks) or had encouraged inaction (to not sell their stocks). The participants assigned to the group decision-making condition were asked to imagine that they were members of a finance team that invests in the stock market. In this study, we measured feelings of regret (as a proxy for counterfactual thinking) and brand-switching intention (switching to another investment brokerage firm). As expected, the 2 (Cultural prime) 2 (Frame) − 2 (Decision Unit) ANOVA revealed significant three-way interactions on both feelings of regret ($F(1, 201) = 28.83$, $p < .01$) and switching intentions ($F(1, 201) = 31.83$, $p < .01$). Further, it was found that feelings of regret mediated participants' switching intentions.

Taken together, the results provide converging evidence concerning cultural differences in counterfactual thoughts and brand-switching behavior due to differences in the expectations of group versus individual action and inaction. Theoretically, this research contributes to the emerging discipline of cross-cultural psychology and its application to consumer behavior. In particular, one novel advance includes identifying the role of the agent (the individual or group) who engages in an action (or stays passive), in the manifestation of regret. In addition, from a practical perspective, our research is likely to be of value to organizations contemplating entry into growing Eastern markets (e.g., China and India), where brand-switching intentions are shaped and formed differently than in the West, and where decisions are frequently made by groups rather than by individuals.

The Effects of Brand Translations and Their Cultural Symbolisms on Brand Evaluation among Young Chinese Consumers

EXTENDED ABSTRACT

A good brand name reduces the burden on marketing communications to build awareness and link brand associations, and plays a crucial role in influencing product evaluation and purchase decisions (Keller, Heckler, and Houston 1998). Consequently, for global brands, failure to provide proper brand name translation in the local language may lead to disastrous results (Zhang and Schmitt 2001). Due to language and cultural differences, brand name translation from Western languages into Chinese tends to be a difficult task (Zhang and Schmitt 2004). While many Western languages are phonographic, which uses either letters or syllables to represent the sound components of the spoken language, Chinese is a logographic language that is visually represented by 50,000 characters (Schmitt, Pan, and Tavassoli 1994).

There are three common ways of translating brand names into Chinese: by sound (phonetic translation), by meaning (semantic translation), and by sound plus meaning (phonosemantic translation). The present research examines how younger, educated Chinese consumers evaluate these three different types of translations of Western brand names as a function of their symbolism of individual autonomy values as well as consumers' own cultural value priorities.

Specifically, we contend that different methods of brand name translations may elicit different cultural meanings, particularly among the younger, educated Chinese consumers who are highly familiar with both Chinese and Western cultures (Zhang 2010). Among these consumers, phonetic translations will directly remind of the brand's Western origin and the dominant individual autonomy values in the West, whereas semantic translations that are decoded with reference to the Chinese language will call out associations with the conservatism values in Chinese culture (Schwartz 1992). Finally, a

phonosemantic translation contains both semantic references in the Chinese language and phonetic references in the Western language, and would elicit both conservatism values as well as individual autonomy values, respectively. These effects will be further moderated by the value-expressiveness of the product. In a collectivist society such as China, consumers are highly attentive to the symbolic meanings embodied in a brand, particularly for value-expressive products (Tse 1996). Hence, we propose that the pattern of association between brand translation and symbolic meanings will be more pronounced for products with higher (versus lower) levels of value-expressiveness.

Brand name translation should then impact brand evaluation in two different ways. First, a phonetic or a phonosemantic translation may activate favorably evaluated autonomous values that are highly regarded by young Chinese consumers, born following the institution of the one-child policy (Zhang 2009). Second, a semantic or a phonosemantic translation may create the impression that the marketer is sensitive to and respects Chinese culture, and hence increases Chinese consumers' positive attitude towards the brand translation (Koslow, Shamdasani, and Touchstone 1994). Taken together, these two mechanisms suggest that symbolic meanings inferred from brand translation and inferred marketer cultural sensitivity may have independent, additive effects on brand evaluation.

More importantly, these two effects occur simultaneously in contrasting fashion for phonetic and semantic brand translations. Although semantic brand translation benefits from greater perceptions that the marketer is sensitive to Chinese culture, it suffers from weaker associations with the favorably-evaluated autonomy values. As younger, educated Chinese consumers may find autonomy values to be particularly self-relevant, we anticipate that this drawback of semantic translations would outweigh its benefit of favorable perceptions of marketer cultural sensitivity. Although both phonetic and phonosemantic translations are favorably associated with autonomy values, only phonosemantic translation benefits from greater levels of marketer cultural sensitivity. We then predict that, in descending order, younger, educated Chinese consumers' favorability of the three forms of brand name translation are phonosemantic, phonetic, and semantic. As phonetic and phonosemantic translations (compared to semantic ones) are more strongly associated with autonomy values at higher (vs. lower) levels of value expressiveness, by extension the positive effects of these associations on brand evaluations should also be stronger for higher levels of value expressiveness.

Finally, consumers' preference for brand translation is related to their own psychological characteristics. Because consumers prefer brands that are congruent with the personality traits that constitute their self-schemas (i.e., self-congruity, Aaker 1999), those who endorse autonomy values should show a stronger preference for phonetic or phonosemantic brand name translations (relative to semantic translations) than should others who endorse conservatism values.

In study 1, young Chinese students at a large public university in Beijing (China) participated in a 3 (Value-Expressiveness of the product: low, high, or very high) × 3 (Translation: phonetic, phonosemantic, or semantic) within-subjects design. Participants indicated the human values embodied or symbolized by each brand translation and evaluated them. Later, they also rated the importance of individual autonomy and conservatism values for themselves. Results showed that participants perceived phonetic and phonosemantic translations to embody greater autonomy values than they did semantic translations, particularly for products with high and very-high levels of value-expressiveness. In addition, phonosemantic translations were evaluated more favorably than phonetic and semantic ones. Phonetic translations were also evaluated more favorably than

semantic ones for high (marginally) and very high levels of value-expressiveness. Furthermore, the self-importance of autonomy values positively predicted evaluation of phonetic translations, but only for high and very high levels of value-expressiveness.

Study 2 examined consumers' evaluations of brand name translations (phonetic, semantic or phonosemantic) of the same product brand upon making salient either the value-expressive function (high value-expressiveness) or the utilitarian function (low value-expressiveness) of the product. Participants perceived phonetic and phonosemantic translations to embody greater autonomy values than they did semantic translations, particularly when the value expressive function of the product was made salient. These associations translated into favorable brand evaluations among participants for whom autonomy values are self-relevant. In addition, relative to phonetic translations, phonosemantic translations induced perceptions that the marketer is sensitive to Chinese culture, which mediated the difference in brand evaluation between these two types of translations. In summary, our research highlights the importance of considering consumers' inferences about brand symbolism in terms of individual autonomy values when translating Western names into Chinese language, and particularly so for value-expressive products targeting younger, educated Chinese consumers.

Can Collectivism Promote Bribery?

EXTENDED ABSTRACT

Bribery is considered a morally repugnant business practice with remarkable consensus transcending national boundaries (Husted, Dozier, McMahon, & Kattan, 1996). Yet, over $1 trillion or 3% of the world Gross Domestic Product (GDP) are paid annually in bribes, stymieing economic growth and threatening democratic and moral values (The World Bank, 2004). Furthermore, cross-national data such as Transparency International's (2010) Bribe Payers Index (BPI), which rates countries on the perceived willingness of their companies to bribe abroad, suggest substantial variability across national cultures in the propensity to initiate bribes (Riaño & Hodess, 2008). What is not sufficiently considered, however, is whether and how national culture might shape individuals' propensity to initiate bribes.

A decision to offer a bribe typically involves a conflict of interest; a dilemma between behaving in accordance with one's moral standards and benefiting from bribing such as winning a contract. Standard theories of moral agency suggest that individuals can selectively disengage internal moral control to permit detrimental conduct without violating their moral standards by, for example, reinterpreting one's actions or the negative consequences of one's actions, vilifying the target of one's actions, and, most strongly, by obscuring personal causal agency through diffusion of responsibility (Bandura, Barbaranelli, Caprara, & Pastorelli, 1996; Mazar, Amir, & Ariely, 2008). The easier it is for individuals to employ any of these mechanisms, the more likely they are to engage in immoral behavior, such as initiating a bribe.

One prominent dimension of national culture is the degree of collectivism or the extent to which individuals see themselves as interdependent and part of a larger group or society (Hofstede, 1980). According to previous research, individuals in collectivist cultures tend to hold relatively more favorable attitudes toward sharing of responsibilities (Hui, 1988), see others as providing a 'cushion' for their risky actions (Hsee & Weber, 1999), make situational rather than dispositional attributions, and have a weaker sense that they themselves determine who they are (Triandis, 2001). Consequently, we hypothesized that individuals in collectivist cultures would find

it easier to disengage regulatory self-sanctions from detrimental conduct through diffusion or displacement of responsibility, and show a higher propensity to bribe abroad than individuals in individualist cultures. Further, we suggest that this effect would be mediated by collectivists' lower perceived responsibility for their actions. We tested this premise in three studies.

In the first study, we tested the correlation between a country's degree of collectivism and the propensity of its companies to offer bribes abroad while controlling for national wealth. Regression results show that the degree of collectivism was positively related to the propensity to bribe and that even after controlling for wealth it explained over half of the residual variability in the model.

Going beyond correlational data, Study 2 examined the existence and nature of a causal relationship between collectivism and bribery. In this study, participants were primed with collectivism or individualism in an experimental laboratory set-up. Results confirmed our hypothesis with participants in the collectivist condition being more willing to offer a bribe than those in the individualist condition. Importantly, participants in the collectivist condition held themselves significantly less accountable for their actions than those in the individualist condition, and this difference in perceived responsibility fully mediated the effect of the prime on participants' decision to offer a bribe.

The third study tested for the alternative account that participants' lower perceived responsibility for their actions was due to a post hoc rationalization consequent to the decision to bribe. Our results show that even in the absence of a decision to bribe, participants primed with a collectivist mindset held themselves significantly less accountable for their actions than those primed with an individualist mindset – suggesting that the effect is not due to a post-hoc rationalization of a decision to bribe.

Our research shows that the degree of collectivism influences people's willingness to offer a bribe, and that the effect is driven by people's reduced perceived responsibility for their own actions. By drawing attention to cultural orientation and the relevance of internal control mechanisms, this paper highlights the importance of understanding the psychological processes underlying cross-national differences, which would be crucial in designing a richer set of policies to curb the supply-side of corruption and its staggering costs.

SESSION OVERVIEW

Choice is widely viewed as a good thing for consumers because they know what they prefer. However, recent research has highlighted the negative consequences of choosing on consumer satisfaction (e.g., see Iyengar and Lepper, 2000). In fact, a recent meta-analysis found that the net effect on satisfaction of having more choice is unclear (Scheibehenne et al., 2010). Sometimes people benefit from a larger assortment, yet other times they find choosing from so many options to be overly costly.

The proposed symposium has four papers that all explore factors influencing the effect of choice on consumer satisfaction,, following Chernev, Bockenholt and Goodman's (2010) call for more research on moderating factors of choice overload effects. The first paper shows that choosing lowers satisfaction when it requires making a trade-off between a selfish and prosocial option. The second paper demonstrates the importance of repeated choices, as choosing increased the rate of satiation. The third paper identifies closure as a way to mitigate the negative effects of choosing from a large selection. The fourth paper establishes the role of expertise, but in sharp contrast to prior research (eg., Mogilner, Rudnick and Iyengar, 2008), as providing a large assortment in a creative task made people more satisfied with the assortment, but less satisfied with the creative process, as well as less creative.

The four papers all contribute to a common theme – identify when choosing will negatively affect satisfaction. We expect our session will generate widespread interest as it spans a range of research interests, and invoke a fruitful discussion on how these ideas can connect to the general topic of consumer well-being.

Forced to Do What I Want: When Imposing Selfishness Increases Well-Being

EXTENDED ABSTRACT

The present research investigates how choice freedom affects individual well-being when choosing between a selfish and a prosocial option. Recent research has identified situations in which externally imposed options, as opposed to free choice, increases individual well-being (Botti and Iyengar, 2004; Botti, Orfali and Iyengar, 2009). While much of this research has focused on choices where the outcomes affect the self exclusively, we instead examine choices where there is a direct trade-off between a self-benefitting option and an option that improves the welfare of others. Although classic economic theory assumes agents are strictly self-interested, there is much evidence, both from the real world as well as from tightly-controlled laboratory experiments, suggesting that people sometimes make significant self-sacrifices to help others less fortunate than themselves (Camerer and Thaler, 1995).

When faced with such trade-offs, regardless of the ultimate decision, we expect that many individuals face intrapersonal conflict. We expect that imposing a selfish option removes the experience of intrapersonal conflict. As a result, individuals can enjoy the pleasure of self-benefitting outcomes without experiencing self reproach for forgoing helping others. The studies presented here test our hypothesis that people are less happy and satisfied with outcomes when faced with a choice between a selfish and prosocial option than those who have a selfish outcome externally imposed.

In our first study participants were placed into one of three conditions. Participants in the *choice* condition were given the option to either receive a windfall sum of $3.00 or donate this money to UNICEF. Participants in the *imposed selfishness* condition received a windfall sum of $3.00, while those in the *imposed prosocial* condition donated $3.00 to UNICEF. Our main DVs include an 11 item measure of present state happiness and positive affect ($\alpha = .91$) and a two item measure of satisfaction with outcome ($\alpha = .81$). An ANOVA revealed an overall effect of condition on happiness ($F(2, 104) = 5.4$, $p = .006$) and satisfaction with the outcome ($F(2, 104) = 7.8$, $p < .001$). Specifically, participants who were forced to receive $3.00 were significantly happier ($M = 4.5$) than those who were given a choice ($M = 3.9$; $t(74) = 2.5$, $p = .01$) and those who were forced to donate ($M = 3.5$; $t(59) = 3.1$, $p = .003$). Analysis on our choice satisfaction measure revealed the same pattern of results (all p's $<.002$). Participants in the free choice condition did not significantly differ in happiness ($t(75) = 1.1$, $p = $ ns) or choice satisfaction ($t(75) = 0.94$, $p = $ ns) from those in the imposed donation condition.

One possible explanation stems from the finding that comparisons between options reduce the value of each option (Brenner, Rottenstreich and Sood, 1999). In our first study, participants in the choice condition, by design, considered both selfish and prosocial options, while those in the imposed conditions were unaware of the alternative option. It is possible that participants in the choice condition felt worse about their decision because their attention was drawn to the relative disadvantage of each option, thereby reducing the perceived value of each option.

To control for option information, we conducted a second study in which each participant was made aware of all the possible outcomes. In particular, they were told that some participants will receive $3.00 in cash while others will donate $3.00 to UNICEF. If our previous findings were solely a result of informational differences between conditions, then we should find no effects in this study where all participants have identical information. However, if the presence of choice between a selfish and prosocial option induces intrapersonal conflict, then we should find similar results as our first study.

The results of our second study support the intrapersonal conflict hypothesis. An ANOVA revealed an overall effect of condition on happiness ($F(2, 213) = 4.0$, $p = .02$) and satisfaction with the

outcome ($F(2, 213) = 9.1$, $p < .001$)). Specifically, participants who were forced to receive $3.00 were significantly happier (M = 4.1) than those who were given a choice (M = 3.6; $t(143) = 2.3$, $p = .02$) and those who were forced to donate (M = 3.6; $t(143) = 2.6$, $p = .009$). Analysis on our choice satisfaction measure revealed the same pattern of results (all p's <.001). Participants in the free choice condition did not significantly differ in happiness ($t(75) = .41$, $p = $ ns) or choice satisfaction ($t(75) = 0.72$, $p = $ ns) from those in the imposed donation condition.

Together these studies demonstrate evidence that imposing a selfish option on an individual can lead to greater positive affect and post outcome satisfaction than letting people choose between a selfish and prosocial option. When a selfish option is imposed, individuals can enjoy the pleasure from that option without feeling intrapersonal conflict. One open question is why imposed prosocial behavior fails to raise happiness, as it likewise reduces the conflict between selfishness and prosocial behavior. It is possible that when forced, individuals do not feel causal and responsible for the good deed and this feeling of ownership of the behavior is what produces happiness. Yet choosing prosocial behavior is no better for happiness because of the inherent conflict of the choice. Future research will seek to resolve these open questions.

The Chooser's Curse: The Ability to Choose Increases Satiation

EXTENDED ABSTRACT

There are only four places to have lunch near my office. I am regularly reminded of this painful fact every day around noon when I decide where to eat lunch. Although I pick whichever option sounds the best that day, the problem is that I am quite satiated with all of them. I often wonder if this daily act of deliberating and choosing heightens my satiation. In other words, would I be better off if someone simply told me where to eat lunch each day? Similarly, would I get less bored with my music if I used a shuffle feature rather than selecting each song myself? Generally speaking, do people get more satiated when they choose, or when others choose for them?

Common sense dictates that letting people choose should increase enjoyment. In fact, a core tenet of economics is that consumers maximize utility, and what they prefer can be determined from what they choose (called revealed preference). Therefore, in a repeated consumption setting, people know when their satiation is growing with an item and switch to a more preferred alternative. Only the consumer would be privy to their moment-to-moment preferences; hence, selections from any other source should be more satiating.

The present research posits that repeated choosing instead increases satiation because it makes the repetition more salient. Recent research has identified perceived repetition as an important antecedent of satiation (Redden, 2008). Kahn and Wansink (2004) similarly found that people expected to enjoy M&M candies more (and indeed ate more) when the variety of colors were easier to visually perceive. People also recovered faster from satiation when reminded of the variety of other things they had also recently consumed (Galak, Redden, and Kruger, 2009). These findings all indicate that satiation depends on the extent to which people notice the variety and repetition of what they consume.

This research proposes that choosing affects perceptions of repetition by acting as a recurring reminder that one is repeatedly having more of the same thing. Given the aforementioned work identifying perceptions of repetition as a key driver of satiation, highlighting the fact that an experience is increasingly repetitive will make it subsequently more satiating. Alternatively, if a sequence is not chosen but

instead exogenously determined (e.g., random), the repetitive nature of the consumption would be less salient. This leads to the prediction that an individual will satiate more with a sequence they choose versus a randomly selected sequence. That is, the enjoyment for people allowed to choose will decline faster with repeated consumption, and eventually be less than for those not allowed to choose. Of course, this is not saying that choosing will increase satiation in all cases (e.g., a food allergen or a hated song).

Five empirical studies confirm these predictions. All of the studies have a similar setup: some participants choose their own sequence while others receive a random sequence, and all participants rate their enjoyment at periodic intervals. Study 1 shows that participants who chose which song to hear on each trial satiated faster than those for whom each song was randomly selected. Study 2 establishes the general nature of this effect by extending it to art, and showing that it does not depend on the number of available options, or whether those options vary on each trial. Study 3 provides mediation evidence that choosing triggers thoughts of repetition that subsequently lead to more satiation. Studies 4 and 5 give further support to the proposed process by showing that cuing judgments of repetition makes a random sequence as satiating as a chosen one, and the satiating effect of choosing disappears if all of the choices are made before consumption begins. Overall, the studies provide consistent evidence that letting a person choose their own consumption sequence satiates them faster because it highlights the repetitive nature of the experience.

This research adds a new negative effect to the choice literature, and highlights repeated consumption as an important moderator. This research also deepens our theoretical understanding of the processes underlying satiation. Choosing increases satiation because it encourages thoughts of repetition. This proposed process highlights the critical role of self-reflective thoughts in determining how satiated one feels, and establishes choosing as a novel antecedent. By exploring choosing and satiation, this work joins two literature streams not typically considered together, and demonstrates their interplay. Widespread choice in consumers' everyday lives may help explain the ubiquity of satiation, and repeated choosing may be necessary to see the full effects of choosing on satisfaction.

Turning the Page: The Impact of Choice Closure on Satisfaction

EXTENDED ABSTRACT

When moving from a difficult period to another stage of life people sometimes use metaphors such as "*turning* the page", "*closing* the door", or "*turning* the back". These metaphors combine the physical act of closing with the psychological state of ending a challenging time, reflecting people's intent to make a new start. In this paper we suggest that such metaphors can play an important role in the domain of choices. We show that the physical act of closing embodied in these metaphors can psychologically bring a difficult decision process to an end and allow people to focus on their experience with the decision outcome. We refer to this process as *choice closure*.

We investigate a specific case of difficult decisions—choices made from extensive sets (Iyengar and Lepper, 2000). Research has shown that an increase in the number of options to compare during the decision process enhances regret and decreases the attractiveness of the chosen option relative to the forgone options in the postdecisional phase (Brenner, Rottenstreich, and Sood, 1999; Cameron, Wertenbroch, and Zeelenberg, 2003; Hsee and Leclerc, 1998; Inbar, Botti, and Hanko, forthcoming). By metaphorically and thus psychologically ending the decision process, choice closure can inhibit

further comparisons between the chosen and the forgone options and therefore improve satisfaction with the final outcome. This hypothesis was tested in four studies.

Studies 1 and 2 tested the predicted effect of choice closure on satisfaction by comparing choices from larger versus smaller sets. In both studies participants chose a chocolate from an assortment of either 24 (large set) or 6 (small set) chocolates. In study 1 choice closure was manipulated by asking participants to taste the chosen chocolate in front of the original assortment (no-closure) or after turning their backs to it (closure). In study 2 choice closure was manipulated by asking participants to taste the chocolate in front of a tray containing the assortment either before (no-closure) or after covering it with a transparent lid (closure). We predicted that the action of turning one's back to the choice set or covering the tray would facilitate choice closure. As hypothesized, in both studies participants in the closure condition were more satisfied than those in the no-closure condition when choosing from the larger set, but this difference was not significant in the small-set condition. As a result of this increase in satisfaction, choice closure mitigated the choice overload effect. Whereas in the no-closure condition participants choosing from the smaller set were more satisfied than those choosing from the larger set, in the closure condition this difference was not significant.

The next two studies tested the hypothesized process underlying choice closure. In study 3, we experimentally removed the link between the physical act of closing and the psychological process of choice closure by providing an external reason for closing. This study was a 2 (choice closure: closure vs. no-closure) x 2 (reason: reason vs. no reason) between-subjects design. All participants were asked to choose one biscuit to taste from among a large assortment of 24 biscuits described in a menu. Closure was manipulated by having the menu open or closed during the tasting task, whereas reason was manipulated either by providing no reason for keeping the menu open or closed or by providing a reason that was unrelated to the decision task. In the no-reason condition, the menu was kept open (no-closure) or participants were asked to close it (closure condition) after making their choice. In the reason condition participants were told that the menu had to be kept open because the experimenter had to read some information that was written inside it (no-closure) or that they had to close menu because the experimenter had to read some information that was written on its back cover (closure). Results from studies 1 and 2 were replicated in the no-reason condition: participants who physically closed the menu after making their choice indicated greater satisfaction with the selected biscuit than participants who left the menu open. As expected, however, in the reason conditions this difference in satisfaction was not significant. Also consistent with our explanation, participants who closed the menu in the no-reason condition were more satisfied than those who closed the menu in the reason condition, but there was no difference in satisfaction between participants who kept the menu open across the two reason conditions.

Study 4 directly manipulated the proposed process by varying the focus on the foregone options. This study was a 2 (choice closure: closure vs. no-closure) x 3 (focus: control vs. alternatives-focus vs. outcome-focus) between-subjects design. The procedure in the control condition was similar to the no-reason condition in study 3: participants chose a tea from a 24-tea menu and either left the menu open or closed it before drinking their selected tea. In the alternatives-focus condition, after making a choice, participants took part in a "memory enhancement technique" task that involved recalling information about the chosen and forgone options. In the outcome-focus condition participants performed a "meditation technique" that involved focusing on a single object — the chosen tea. The results in the control condition replicated our prior studies: participants in the closure condition were more satisfied with the tea selected from a large assortment than those in the no-closure condition. Consistent with our hypothesized process, the memory enhancement technique reduced participants' satisfaction in the closure condition (but had no effect on those in the no-closure condition). In contrast, the meditation technique enhanced the satisfaction of the participants in the no-closure condition (but had no effect on the participants in the closure condition).

To summarize, this paper argues that the physical action of closing triggers the psychological process of choice closure due to which consumers stop comparing the chosen and the forgone options, make peace with their decision, and start focusing on the assessment of the decision outcome. Our studies show that when choices are difficult, choice closure has a positive effect on satisfaction.

Focus! Creative Success Is Enjoyed Through Restricted Choice

EXTENDED ABSTRACT

Does increasing choice in the number of creative inputs offered to consumers (e.g., more choice in ingredients for cooking) affect their creativity? We draw on the choice literature (e.g., Iyengar & Lepper, 2000; Schwartz, 2004) to provide understanding for the counterintuitive effects we identify. We find that increasing the choice of creative inputs for consumers experienced in a creative task can hurt objective creative outcomes. Consumers that have experience and knowledge in a creative pursuit are shown to be objectively less creative with more input choice, while inexperienced consumers are relatively unaffected by differences in input choice. Based on creativity research (e.g., Henderson, 2004; Russ, 1993), we argue that it is the difficulty experienced consumers have to focus when choosing among extensive creative input options that likely results in reduced task enjoyment, which has negative implications for the consumers' creativity. In contrast, regardless of their experience level, we find that consumers perceive *themselves* as being more creative, the more choice they have. Two studies document these effects.

We first conducted an experiment on knitting, a 2 (Choice: moderate vs. extensive) x 2 (Knitting level: experienced vs. inexperienced) between-subjects design facilitated by a yarn store, where knitters received instructions. 76 knitters (74 women, mean age = 29.82 years) participated in return for a $20 gift certificate. Based on a pretest, we categorized participants who could (not) knit cables as (in)experienced. Participants were required to knit a scarf for a three-year old girl over a week, and to choose 12 balls of yarn from a display of either a moderate (6) or relatively extensive (12) color selection. Participants were provided with needles, were told to be creative and utilize only the materials provided, however they liked.

A week later, participants returned their scarf, reported how creative they thought their scarf was (1 = not at all/7 = very creative), assessed how pleasant the creative process had been (not at all/very enjoyable, very boring/very much fun). Then, two experts in creative knitting evaluated the creativity of the scarves on a 10-point scale ("not creative at all" (1)/"extremely creative" (10)). Focusing on the latter averaged measure, a 2x2 ANOVA only revealed a main effect of Choice, such that knitters with extensive rather than moderate choice reported that their scarf was *more* creative ($M_{moderate}$ = 4.55 vs. $M_{extensive}$ = 5.09, $F(1, 72)$ = 4.19, $p < .05$, r^2 = .05). We averaged the knitting experts' creativity ratings (r = .66, $p < .01$) to form an objective creativity index. A 2x2 ANOVA showed a significant two-

way interaction (F(1, 72) = 7.75, *p* < .007, r² = .10). As expected, we found a choice overload effect: scarves knit by experienced knitters under moderate rather than extensive choice were more creative (M$_{moderate}$ = 7.67 vs. M$_{extensive}$ = 5.56, t(72) = 3.80, *p* < .001, r² = .17). There was no difference for inexperienced knitters t<1. Further, the average of the two measures of knitters' enjoyment during the process (r = .29, *p* < .02) mediated the experts' ratings.

A second study tests whether restricting choice also enhances creators' ability to focus on promising creative paths, which drives the enjoyment and subsequent creativity results we observed in the knitting study. 59 experienced crafters (13 men, age = 21.2 years) created a Christmas tree ornament after choosing from a moderate or an extensive choice of shapes they could use as creative components. Orthogonally to this choice manipulation, creators were required to either rehearse a two- or an eight-digit number as they were creating their ornament (Gilbert & Osborne, 1989). We predicted that participants rehearsing a two-digit number - an effortless task - would enjoy the creative process more when provided with a moderate rather than an extensive choice of shapes, which should transcend into more creative ornaments. In contrast, participants rehearsing an eight-digit number should generally find it relatively

difficult to focus during the creative task. If restricting choice should make them generally enjoy the process more, this enjoyment should no longer translate into more creative outcomes when their ability to focus is simultaneously compromised. After collecting the ornaments from crafters, 10 peers evaluated the creativity of the ornaments (e.g., Dahl, Chattopadhyay, and Gorn, 1999) on 7-point scales ("not at all" /"extremely creative"). After averaging peers' "creative" item (Cronbach-a = .89), we ran a Choice x Rehearsed digit ANOVA using this creativity index as the dependent variable. It only revealed a significant two-way interaction, F(1, 55) = 9.22, *p* < .02, r² = .14), such that the ornaments of participants with limited choice rehearsing two digits were rated as significantly more creative compared to the ornaments of all other participants, all *p*'s < .05. As predicted enjoyment of the creative task mediated these effects, but only when crafters were not cognitively busy. This research documents a new type of choice overload effect, one durably affecting post-choice creativity. Also, while prior research found that more choice benefits (e.g., Chernev, 2003) or does not affect experienced consumers (e.g., Mogilner, Rudnick, and Iyengar, 2008), we find that more choice can hurt experienced consumers.

Interpretations and Responses to Identity Threats

SESSION OVERVIEW

It is well-accepted that consumers choose specific brands to express and reinforce their identity (Kline, Kline and Kernan 1993). A large amount of research has shown that such identity-related consumptions satisfy consumers' association and communication goals (Escalas and Bettman 2005; Cayla and Eckhardt 2008). However, recent literature has started to document how consumers strategically change their consumption behaviors in order to protect their identity or to restore their threatened identity (Gao, Wheeler and Shive 2009; White and Argo 2009). This session adds to this latter research by introducing four papers that demonstrate how consumers interpret and react to identity threats in various consumption contexts.

The first paper (Chae et al.) examines how consumers interpret a national brand failure as a social identity threat and use out-group product evaluation to restore that threatened identity. The authors find that a national brand failure can threaten consumers' social identity when such information comes from an out-group member. Thus, as a way to restore their threatened social identity, consumers derogate out-group products. The second paper (Mathews et al.) demonstrates another means consumers engage in to restore their threatened social identity. The authors document that when a particular aspect of social identity is threatened, consumers favor identity-related products when the threat is communicated publicly versus privately. Desire for self-consistency appears to drive this identity restoration behavior. The third paper (Chan and Sengupta) adds to this literature by demonstrating a novel way to induce identity threat. Specifically, when a consumer observes others being flattered, s/he is likely to experience social comparison and thus feel threatened. Interestingly, as a result, s/he will endorse the salesperson's recommendations to a greater extent as a way to reduce the threat. The last paper (Ferraro et al.) examines the identity threat from a different, yet interesting angle. Specifically, they demonstrate that conspicuous brand usage can lead to negative perception of the brand users' identity.

In sum, these papers add to our knowledge in the identity threat literature by documenting a series of important variables that can induce such threats (e.g., national brand failure, flattery), and demonstrating coping behaviors consumers engage in to protect and restore

their identity. We expect that this special session will be well-attended and will stimulate much thoughts and interests to this important research domain.

We Hate Your Products: The Effects of Social Identity Threat on Out-group Product Evaluation

EXTENDED ABSTRACT

How does Toyota Motor Corp.'s massive recall in 2009 and 2010 change the Japanese' consumption behavior? Does this recall change their attitudes toward domestic versus foreign products? In this research, we examine how consumers respond to a national brand failure. Specifically, we focus on how a national brand failure can threaten consumers' social identity, and consequently affect their evaluation of in-group versus out-group products.

Social identity theory (SIT: Tajfel and Turner 1986) postulates that individuals strive for a positive social identity. The individual's need for positive social identity leads people to create, maintain, or enhance any valued distinctiveness of the in-group. The attempt to achieve positive group distinctiveness can lead to favorable evaluation of one's own group (Brewer 1999) or derogation of out-group values (Rabbie, Benoist, Oosterbaan, and Visser 1974; Worchel, Andreoli, and Folger 1977). Of particular relevance to this research, extant literature has shown that when an out-group is perceived to threaten the group identity, people will react to the threatening out-group with hostility (Li and Brewer 2004)

Based on the SIT, we propose that a national brand failure can threaten in-group members' social identity, which consequently leads to derogation of out-group products as a means to restore the impaired identity. Importantly, we theorize that the source of such information will moderate the effect. When the national brand failure information is coming from an out-group member, it will be perceived as a threat, and thus leads to out-group product derogation. However, when such information is coming from an in-group member, it will not be perceived as a threat and will thus attenuate the above effect. A series of three studies were conducted to provide systematic support to our theorizing.

Study 1 tested our hypotheses using a failure of Samsung electronics, the largest company in South Korea. All participants were South Koreans. The study was a 3 (Brand information: Brand failure from in-group source, Brand failure from out-group source and Neutral information) X 2 (Product country of origin: Korea vs. the USA) between subject design. Participants were first asked to evaluate a short essay, which contained the Samsung brand failure information or the neutral information. The brand failure information was described to be written either by a Korean (i.e., in-group source) or an American (i.e., out-group source). People in the control condition received information about Samsung's new fridge launch with no identification of the information source. Next, participants worked on a seemingly unrelated task where they evaluated a MP3 player that was either "Made in Korea" or "Made in the USA". Participants rated the products on three 9-point scales: "good/ bad", "unfavorable/ favorable" and "dislike/ like" (White and Dahl 2006). Data analysis revealed a significant 2-way interaction. When Koreans received the Samsung failure information from an out-group member, they formed more unfavorable evaluations towards the American product than those who received the neutral information. However,

when Koreans received the Samsung failure information from an in-group member, their attitude toward the American product did not differ from that of the control group.

Study 2 replicated the out-group derogation using the context of Toyota's recall. In this study, we further demonstrated that the out-group derogation was robust even when a third party provided the brand failure information. The study was a 2(Brand Information: Brand failure vs. Neutral information) X 2 (Product country of origin: Japan vs. the U.S.A) between subject design. A procedure similar to that of Study 1 was implemented. In the brand failure condition, the writer of the article was a Canadian (i.e., a third party). The results replicated those observed in study1, such that the Japanese participants evaluated American electronics more negatively when they were presented with the brand failure versus neutral information.

Study 3 aims to provide further evidence to the underlying process. If identity threat is the underlying mechanism, then offering in-group members an opportunity to affirm their identity should attenuate the effects observed earlier (Steele 1988; Derks, van Laar, and Ellemers 2009). Study 3 was designed to test this hypothesis via a 2 (affirmation: group affirmation vs. no affirmation) X 2 (product country of origin: Made in Canada vs. Made in the USA) between subject design. All participants were Canadians in this study. We first introduced a threat manipulation by having all participants read a report about a national brand (i.e., Tim Horton) failure, written by an American. The second task involved the affirmation manipulation. In the *group* affirmation condition, participants were asked to recall the 2010 Vancouver Olympics Winter Games, which is likely to induce national pride and thus affirm Canadians' positive identity. In the *no* affirmation condition, participants were asked to recall a movie they watched or a book that they read recently. The focal task involved asking participants to evaluate an organic cereal that was either "Made in Canada" or "Made in the U.S.A". As expected, we replicated earlier findings only in the on affirmation condition, such that participants formed more negative product evaluations when it was made in the USA versus Canada. However, importantly, this effect disappeared in the group affirmation condition.

The current research offers several contributions. First, it demonstrates that a national brand failure can lead to social identity threat. Second, it extends the SIT literature by showing that the out-group derogation can be directed toward any out-group. Finally, it illustrates that group affirmation mitigate the out-group derogation induced by social identity threat.

Choosing Identity: The Effects of Publicly Versus Privately Communicated Threats on Consumer Preferences

EXTENDED ABSTRACT

Advertisers often link products to different social identities (i.e. gender, occupation, nationality). Consider a recent tagline that highlights male gender-identity: "Maximum Taste, No Sugar, and Maybe Scorpion Venom. Pepsi Max, the First Diet Cola for Men." Marketing practitioners often assume that linking the brand with an aspect of social identity leads target consumers to evaluate the brand more favorably. Recent research, however, suggests that the effectiveness of identity-linking strategies may depend on contextual factors. For instance, White and Argo (2009) find that when consumers experience a threat to an aspect of their social identity (e.g., they receive negative information about their gender identity), they sometimes avoid products associated with that identity. The present research provides evidence for the reverse effect, whereby consumers evaluate identity-linked products *more favorably* when a social identity has been threatened.

Following social identity theory (Tajfel and Turner 1979), we view social identity as encompassing one's identity derived from the groups to which the person belongs or is affiliated with. Previous research largely finds that products linked with important social identities tend to be evaluated favorably (Kleine, Kleine, and Kernan 1993). However, when an aspect of identity becomes temporarily threatened consumers sometimes respond by avoiding identity-linked products (White and Argo 2009). While these authors found the dissociative effect is mitigated for individuals who strongly value and identify with the threatened group (i.e., those high in collective self-esteem derived from that specific group), this research did not find instances of an *associative effect*, whereby a *social identity threat* induces consumers to *increase* preference for products linked to that social identity.

One instance wherein an associative effect may emerge is when the threat is communicated publicly as compared to privately. Given that people are both motivated to compensate for short comings under threat (Pyszcynski, Greenberg, and LaPrelle 1985) and to maintain self-consistency when information about the self is made public (Schlenker 1975; Tedeschi et al. 1971), receiving a *public threat* to an aspect of one's own social identity, should lead to a desire to maintain self-consistency. In the context of a publicly communicated identity threat, avoiding a product that is linked with that aspect of one's own identity would convey an inconsistent self, whereas maintaining or enhancing one's evaluations of the product would convey a more consistent self. The present research predicts and finds that consumers will be more likely to favor identity-linked products under threat when the communication is public rather than private. We anticipate that this will be pronounced among consumers high in self-consistency motives.

In study 1, participants (*n*=242) took part in a 2(Threat: no threat vs. social identity threat) x 2(Communication: public vs. private) between-subjects design. The social identity that was threatened was university student identity. Participants took part in small groups and were first exposed to a research article that either reported that their own university performed similarly to (no threat) or worse than (social identity threat) other universities in its class (White, Argo, and Sengupta 2011). Communication was manipulated by either having the experimenter read the article aloud to the participants or by having participants read it silently to themselves. Participants completed some filler items and manipulation check items. Our dependent measure was each participant's choice of either an identity-linked (clipboard displaying the university logo) or neutral (plain clipboard) at the end of the study. Binary logistic regression with threat, communication, and their interaction term as independent variables and product choice as the dependent variable revealed only a significant interaction between threat and communication (β =.80, Wald = 6.70, $p < .02$). Under conditions of identity threat, participants were more likely to chose the university clipboard when the communication was public (79%) rather than private (59%, $p < .05$). In the no threat condition, participants did not differ in their selections of the university clipboard when the communication was public (48.1%) versus private (60.6%; $p < .18$).

In study 2, participants (*n*=186) took part in a 2(Threat: no threat vs. social identity threat) x 2(Communication: public vs. private) x Self-Consistency Motives between-subjects design. Threat and communication were manipulated as in Study 1. Participants responded to 4 self-consistency motive-items (e.g., "To be consistent with who I am," "To demonstrate that I have stable preferences"). Participants also completed 4 self-enhancement motive-items (e.g., "To

look like I made good selections," "To be associated with desirable products") to rule this out as a potential explanation. They then made a series of hypothetical choices (matched for dollar value) between university-linked vs. neutral items (university bookstore or restaurant gift certificate; university t-shirt or movie passes; university hat vs. local hockey team hat). Neutral items were coded as 0 and university items were coded as 1, and the identity preference score was calculated by summing across all items. Regression analysis with threat, communication, and the continuous mean-centered self-consistency scale and all interactions as independent variables predicting the preference index revealed the anticipated 3-way interaction ($p < .05$). When under threat, those low in self-consistency did not differ in preferences in response to public vs. private communication ($p < .18$). However, when under threat, those high in consistency preferred the university products when the communication was public as opposed to private ($p < .02$). As predicted, self-enhancement motives did not moderate the effects.

When a social identity threat is communicated publicly, compared to privately, participants show greater preference for identity-linked products. We extend work that finds evidence of consumers engaging in self-enhancing self-presentational strategies in public settings (Ratner and Kahn 2002; White and Dahl 2006), to show that motives for self-consistency can also motivate consumer behavior in public contexts. Indeed, classic consumer research suggests that while consumers are often motivated to present themselves in a positive light, sometimes self-consistency motives will drive product preferences (Sirgy 1982). Finally, we contribute to literature showing associative responses to products when identity is viewed positively (Cialdini et al. 1976), to demonstrate when associative responses to identity-linked products when that particular identity is viewed in a negative light.

Observing Flattery: A Social Comparison Perspective

EXTENDED ABSTRACT

Prior research on flattery has shown that in contrast to the targets of flattery, who frequently respond positively, objective outsiders react negatively to the flatterer – in part because they are able to subject the flattering message to objective scrutiny and thus detect any underlying ulterior motive (Campbell and Kirmani 2000). What, however, if the flattery is palpably sincere – e.g., you witness a salesperson complimenting a stylishly-dressed customer on her dress sense after the customer has already made her purchases? In such cases, the use of flattery may represent a win-win persuasion tactic: a positive response from the target, without any negative reaction from observers (Vonk 2002). The current inquiry, however, draws on dual attitudes theory (Wilson, Lindsey and Schooler 2000) to posit that even when others receive compliments that observers perceive to be sincere, they still develop an automatic negative reaction (the implicit attitude) towards the flatterer because of the envy caused by social comparison. Further, this negative implicit attitude co-exists with the more neutral evaluation (the explicit attitude) that arises because of a belief in the flattery being sincere.

Apart from documenting the dual attitudes induced in observers by flattery, we add to the flattery literature in two other ways. First, we illuminate the social comparison process that induces the implicit attitude by identifying theoretically-derived boundary conditions. Second, we examine the behavioral consequences of observing sincere flattery, finding that flattery which is directed at others can function as a surprisingly effective persuasive message for observers, inducing them to act in a manner that would be desired by the flatterer – because of the observer's wish to reduce felt envy. We predict that this is particularly likely to occur after a delay, because the motivation to reduce envy can persist even after the negative reaction to the source of flattery is forgotten (cf. Kumkale and Albarracin 2004).

Five experiments tested these hypotheses. Experiment 1 used a 3 (flattery: after-purchase vs. before-purchase vs. control) x 2 (attitudes measure: implicit vs. explicit) between-subjects design to examine the thesis that observing sincere flattery induces two distinct attitudes. Participants imagined that they were shopping in a clothing store and had overheard a conversation between a stylishly-dressed shopper and a salesperson. The conversation, which contained compliments on that shopper's fashion sense, was described as occurring either before or after that shopper had made a purchase (the latter condition should increase perceptions of sincerity; cf. Campbell and Kirmani 2000). Those in the control group imagined overhearing a neutral conversation that did not contain any compliments. Participants' evaluations of the salesperson were then collected under either time-constrained (5 seconds per item; implicit measure) or unconstrained conditions (unlimited time; explicit measure). As predicted, for after-purchase (i.e., sincere) flattery, the implicit attitude was lower than the explicit attitude, but no such difference existed in the before-purchase (insincere flattery) and control conditions. Further, planned comparisons revealed that the implicit attitudes resulting from observing flattery were lower than the control group's evaluations – in both before- and after-purchase flattery conditions (thus, perceived sincerity did not enhance implicit attitudes). In contrast, explicit attitudes were lower in the before-purchase condition compared to the other two conditions.

Experiment 2a used a 2 (peer vs. non-peer) x 2 (measures of store attitudes: explicit vs. implicit) design to identify a boundary condition (based on social comparison theory) for the discrepancy between implicit and explicit attitudes. Participants were exposed to a store message containing very positive comments, which had purportedly been given to another consumer; this consumer either belonged to the same university as the participant (peer condition) or a foreign one (non-peer). Implicit or explicit store evaluations were then obtained. In the peer condition, as before, the implicit attitude was lower than the explicit attitude. However, people are less likely to be envious of dissimilar others – accordingly, no difference was found for implicit vs. explicit attitudes in the non-peer condition. This pattern of results was replicated in Experiment 2B, using within-subjects measures of implicit and explicit attitudes.

Experiment 3 used a 3 (Enhancement: self-enhancement vs. other-enhancement vs. control) x 2 (Measures: explicit vs. implicit) design to identify another boundary condition relating to social comparison. In the self-enhancement (vs. other-enhancement) condition, participants wrote about an attribute on which they rated themselves well (vs. better than others), before being exposed to the same flattery manipulation and dependent variables as in Experiment 2A. Those in the control condition proceeded directly to the flattery manipulation. In the control and self-enhancement conditions, the implicit attitude was lower than the explicit attitudes, as before. However, such a discrepancy was not observed in the other-enhancement condition (implicit attitudes improved), supporting the premise that when participants have less reason to be envious of others, the negative effects of observing flattery are diminished.

Finally, Experiment 4 examined the behavioral consequences of observing flattery. This study used a 2 (Flattery: after-purchase vs. control) x 2 (Measures: explicit vs. implicit) x 2 (Timing of behavioral measure: immediate vs. delayed) design. The procedure was the same as in Experiment 1, except that after attitude measurement, participants were also asked to report their likelihood of buying a pair of expensive, stylish jeans from the store, either immediately

or after a 30-minutes delay. The attitudes results again showed that the implicit attitude was lower than the explicit attitude in the flattery condition, with no difference observed in the control. Of more interest, while there was no difference between flattery vs. control in immediate intentions to buy the stylish jeans, this changed after a delay – observing flattery increased purchase intentions compared to the control. Finally, in this and in other studies, measures of envy provided process support for our theorizing: greater envy was reported in the flattery conditions vs. the control.

Taken together, results from our studies provide new insights into how observers react to flattery, in terms of the outcome (dual attitudes), the underlying process (relating to social comparison) as well as counterintuitive behavioral consequences.

Are They Who They Claim? Intentionality and Authenticity in Identity Signaling with Brands

EXTENDED ABSTRACT

Research on identity signaling largely assumes that observers will interpret the brand identity signal as intended. In this paper, we examine whether this is a valid assumption. Drawing a parallel between identity signaling and impression management, we suggest that identity signaling is inferred when observers think that a consumer's brand usage is motivated by a desire to gain social approval. We propose that identity signaling motives are likely to be salient when the signaler uses the brand in a conspicuous manner, i.e., intentionally draws attention to brand usage. The driver who revs up his Mustang's engine as he roars by is likely to be seen as behaving more conspicuously than the one who drives quietly. Such conspicuous behaviors will make observers suspicious about the motives underlying the behavior, leading to an inference of identity signaling.

We suggest that under some conditions, this inference of extrinsically motivated behavior will trigger perceptions that the consumer is not authentic, which we define as the degree to which the signaler is perceived as behaving in a manner consistent with her true self. Suspicion that the signaler is motivated by impression management will raise questions about the signaler's authenticity and reduce the perception that the target possesses the trait he is attempting to signal through the brand. This process is consistent with research that shows that suspicion of ulterior motives leads to inferences that the target is insincere (Campbell and Kirmani 2000; Vonk 2002). In our context, if a consumer is seen as intentionally using a brand (e.g., Apple iPad) to create an impression, she will be perceived as behaving in a manner that is unlike her true self. The observer would infer that if the consumer is using the iPad to show off, it is doubtful that she inherently enjoys it. This means that she is unlikely to possess the traits of a typical iPad user, i.e., innovativeness.

In three studies, we demonstrate that conspicuous brand usage will lead to perceptions of inauthenticity and dampen brand-relevant trait perceptions. Study 1 was a two-level, one-factor (Conspicuousness: low, high) between-subjects design. Participants engaged in a face-to-face interview with an interviewer who introduced himself as "James." James asked them to describe a special vacation they remembered. During the interview, James did or did not engage in conspicuous behavior related to BMW. In both conditions, James placed a set of car keys in front of him, with the BMW key logo visible. In the high conspicuousness condition, he also name-dropped the BMW brand. After the interview, participants were asked some questions about the interviewer, including his perceived competence (brand-irrelevant trait), wealth (brand-relevant trait), and authenticity (authentic, genuine, sincere), all on seven-point scales. Consistent with the hypothesis, the interviewer was perceived as more authentic and wealthier in the low conspicuous condition compared to the high conspicuous condition (Wealthy: M_{low} = 5.42, M_{high} = 5.00; authentic: M_{low} = 4.85, M_{high} = 4.20). However, perceived competence, the brand-irrelevant trait, did not vary across conditions (M_{low} = 5.87, M_{high} = 5.79).

Study 2 examined whether the negative effects of identity signaling were moderated by self-brand connection, which is the "extent to which consumers have incorporated brands into their self-concept" (Escalas and Bettman 2003). We hypothesized that when observers' self-brand connection was high (i.e., the brand was highly meaningful to them), they would react more positively to a target who was using the brand appropriately (i.e., low conspicuous). However, they would react more negatively to a target using the brand for extrinsic reasons (high conspicuous). The study involved one manipulated between-subjects variable (Conspicuousness: low, high) and one measured variable (Self-brand connection). Participants saw a video of a woman using an iPad in a coffee shop. In the low conspicuous condition, she holds the iPad in her hands. In the high conspicuous condition, she puts the iPad on a black stand so that the iPad is standing up on the table. In addition, she glances around the room as though to make sure others are watching. Self-brand connection was measured using the seven-item scale in Escalas and Bettman (2003). The brand relevant trait was innovativeness (combination of innovative and creative) and the brand irrelevant traits were sophisticated, stylish, classy, affluent, rich, and athletic. Extrinsic motivation was measured by three items (Elaine was trying to show off, gain approval, and impress others). Regression analysis showed significant effects of Conspicuousness on extrinsic motivation, authenticity, and perceived innovativeness. The target was perceived as more extrinsically motivated, less authentic, and less innovative when she was conspicuously using the iPad than when she was not. In addition, higher self-brand connection resulted in higher perceived authenticity and innovativeness. However, the interaction effect was not significant.

In study 3, we examined whether the negative effects of conspicuousness were moderated by perspective taking. Perspective taking involves applying aspects of the self to the target person (Davis et al 1983) and thus lessens the negative inferences made of the target. Because we see ourselves as authentic, we are more likely to see others whose perspective we take as authentic. Using the same video stimuli to manipulate conspicuousness as in study 2, the study also varied perspective taking (low, high). The results replicated the effects of study 2 when perspective taking was low; when perspective taking was high, however, conspicuous behavior did not hurt perceptions of the target. Thus, putting oneself in the other's shoes made them seem authentic and innovative even when they were using the iPad conspicuously.

Overall, these results show that conspicuous *use* of brands, as opposed to conspicuous brands, may result in an inference of identity signaling. Unless the observer is able to take the perspective of the signaler, identity signaling will result in negative perceptions of the signaler's authenticity and possession of brand-relevant traits.

When Doing Good Makes It Okay To Be Bad? New Directions in Licensing Research

SESSION OVERVIEW

Prior research has demonstrated that virtuous acts, or simply feeling virtuous, can allow people to subsequently transgress and behave in less-than-virtuous ways—a phenomenon commonly referred to as the *licensing effect* (for review see Merritt, Effron & Monin, 2010). The licensing effect has been demonstrated in a wide array of domains including, consumer choice, moral behavior, political correctness and prosocial behavior (Monin & Miller, 2001; Khan & Dhar, 2006; Sachdeva, Iliev & Medin, 2009; Mazar & Zhong, 2010). For example, participants who first imagined doing something altruistic were more likely to indulge in frivolous purchases later on (Khan & Dhar, 2006) and those who initial had an opportunity to support Barack Obama were more likely to say that a particular job was better suited for Whites (Effron, Cameron, & Monin, 2009). Interestingly, the effect does not require actual behavior and mere intentions of good behavior are enough to subsequently license bad behavior.

While the last decade has witnessed a burgeoning interest in licensing research, so far most studies have focused on demonstrating the main effect. The current session takes the research forward and examines antecedents, consequences and social implications of self-licensing. In the spirit of the conference theme of "building connection" the session includes four complementary papers (all in advanced stages) that each approach the subject from a unique angle and illuminates a new aspect of self-licensing.

The first paper by Merritt el. al. demonstrates that when people anticipate acting in a way that could seem immoral, they attempt to establish their moral values ahead of time—in other words, they strategically earn moral credentials. Authors argue that the strategic pursuit of moral credentials is intended to encourage favorable attributions for the upcoming morally ambiguous behavior. The research represents an important extension to existing work on moral licensing, which has shown that people are more likely to act in morally ambiguous ways when they have previously established their morality (Merritt et al., 2010; Miller & Effron, 2010). The present research demonstrates that people sometimes pursue moral credentials strategically when they are tempted to act in morally questionable ways.

The second paper by Polman and Khan explores interpersonal implications of self-licensing behavior and feelings. Authors show that people who believe they are virtuous lower the standards and demands of virtue for themselves, yet raise the demands for others. For example, individuals who imagined performing community service were less likely to make a donation later on but raised their expectations from others to donate. The findings suggest that good deeds can not only license less-than-virtuous behavior for the self but ironically can induce moral hypocrisy whereby people raise their demands from others.

The third paper by Ruttan examines how the nature of an initial purchase can moderate the licensing effects in subsequent purchase behavior. The authors distinguish between experiential and material purchases and show that an experiential purchase can license greater indulgence subsequently relative to an initial material purchase. For example, Ruttan finds that in a choice between a luxury and a necessity item, individuals who previously purchased an item from a set of experiential products were more likely to choose the luxury item compared to individuals who had initially purchased from a set of material products. The author explains that more positive self-attributions associated with experiential purchases license further indulgence.

The fourth paper by Zhong and Sivanathan builds on neurological and social psychology research to predict and show that physical pain can mitigate moral pain. This finding has important implications for the phenomenon of self-licensing as physical pain may compensate for less virtuous behavior and choices, which one would otherwise avoid. Consistent with this implication, participants who held a cold ice-pack while watching a series of photos of malnourished and diseased children were less willing to make a donation compared to those who held an ice-pack at room temperature. The research illustrates the role of embodied cognition in licensing effects.

Together, the papers in the session extend our understanding of the licensing effect beyond the existing literature. Given the fundamental relevance of the topic to consumer, social and political research we expect it to appeal to academics and practitioners across diverse research areas. Thus, the session is likely to foster a fruitful and interdisciplinary dialogue in the spirit of the conference theme of building connection.

The Strategic Pursuit of Moral Credentials

EXTENDED ABSTRACT

Past research on moral credentials (Monin & Miller, 2001; Effron, Cameron, & Monin, 2010) has shown that people who have had an opportunity to establish their moral values feel licensed to engage in morally ambiguous behavior. But do people attempt to credential *themselves* when they expect to need a moral license? The present research examines whether people will *strategically pursue* moral credentials in anticipation of acting in morally dubious ways. In particular, we argue that people seek to establish their morality in a preemptive attempt to ensure that their future behavior does not appear immoral to others or to themselves – in other words, to manage the attributional ambiguity that may characterize their future behavior (Berglas & Jones, 1978; Dutton & Lennox, 1974; Norton, Vandello, & Darley, 2004; Snyder, Kleck, Strenta, & Mentzer, 1979). One may seek moral credentials not only when one's intentions are truly nefarious, but also when one worries that one's intentions could *appear* so. In either case, we propose that individuals who wish to or expect to act in morally ambiguous ways will seek the "attributional cover"

(Kelley, 1973) of moral credentials. In three studies, we investigated this claim by examining how participants responded to the threat of appearing racist.

In Study 1, participants evaluated candidates for a hypothetical job. In a key condition, hiring the more qualified candidate would mean choosing a White applicant over a slightly less qualified Black applicant, a choice that might appear to reflect racial bias. As predicted, participants in this condition, relative to those in control conditions, were more likely to label others' behavior as racist prior to stating their hiring decision, in an attempt to demonstrate racial sensitivity.

Study 2 replicated the results from Study 1 and ruled out a possible alternative explanation: merely seeing racial inequality (in the candidates' qualifications) could prime racism, which could in turn lead participants to see more racism in the behaviors they evaluated. As in Study 1, participants in one condition saw a White applicant competing with a slightly less qualified Black applicant. We added a new a condition in which the White candidate was overwhelmingly and unambiguously more qualified than the Black candidate, meaning participants could pass over a Black job candidate with relatively little worry of looking racially biased. As predicted, participants only sought nonracist credentials when the difference between the candidates was smaller, and choosing the White applicant put them at risk of feeling or appearing racist.

Study 3 replicated the strategic moral credentials effect using a more direct manipulation of the threat of appearing racist and a dependent measure with more consequential implications. Participants expected to take a psychological test (the race IAT) that was described as either diagnostic or non-diagnostic of racial bias. Before taking the test, they indicated how likely they would be to hire a Black job applicant relative to other non-minority applicants. As predicted, participants who expected to take the diagnostic test, and who were presumably more worried about revealing racial bias, ranked the Black applicant higher than participants in the non-diagnostic condition or a baseline condition.

These studies suggest that individuals pursue moral credentials in order to manage the moral ambiguity surrounding their future behavior and provide attributional cover from recriminations. This research represents an important extension to work on moral licensing, which has shown that people are more likely to act in morally ambiguous ways when they have previously established their morality (Merritt et al., 2010; Miller & Effron, 2010). The present research demonstrates that people sometimes pursue moral credentials strategically when they are tempted to act in morally questionable ways. For example, someone who wishes to tell a joke that plays on stereotypes about Blacks may first note that "some of my best friends are Black," or a manager wishing to promote a male employee over an equally-qualified female employee may conspicuously suggest that his company expand its maternity leave benefits. Sometimes, pursuing credentials may allow people to act comfortably on legitimate motives (e.g., to give critical feedback to a student who happens to be a member of a minority group, or hire the most qualified candidate, regardless of race or gender); other times, it may license people to act on more nefarious (e.g., prejudicial) motives.

Although all of our studies targeted participants' concerns over appearing racially biased, we believe that people will seek moral credentials in other domains in which they fear that their future behavior may appear selfish, unfair, or otherwise immoral. People may even seek credentials in non-moral domains when they wish to engage in potentially discrediting behavior, as when someone establishes his sophistication by conspicuously expressing his love of Shakespeare and fine wine before mentioning his subscription to a celebrity gos-

sip magazine. Future research should investigate the strategic credentials effect in a range of moral and non-moral contexts.

Interpersonal Implications of Self-Licensing

EXTENDED ABSTRACT

Recent research has shown that past good deeds can liberate people to engage in less-than- virtuous behaviors that they would otherwise avoid (Khan & Dhar, 2006; Monin & Miller, 2001). While the relation between feeling virtuous and engaging in less-than-virtuous behavior is well-known, most of the literature on such licensing effects has focused on self-licensing and has generally ignored how feeling virtuous influences people's judgments of others and their behavior.

In this paper, we propose that people who believe that they are virtuous will lower the standards and demands of virtue for themselves, yet raise the bar for others. Our prediction is based on research showing that people manage and tailor judgments of themselves and others in a way that maintains a positive self-image (Jordan & Monin, 2008). For example, people predict that they would donate, cooperate in the prisoner's dilemma game, and volunteer to charitable causes — however, most people's actual behaviors fall short of their predictions (Epley and Dunning, 2000). These mistaken beliefs about self-behavior could lead to extreme, harsh, and erroneous judgments of others' behavior. Direct evidence suggests that people spontaneously think of themselves when they judge others (Balcetis & Dunning, 2005). If people are manipulated to experience a high moral self-worth, then they may predict themselves behaving in ethical ways, and subsequently apply these high standards of their predicted self-behavior to their judgments of others. As a consequence, judgments of others may suffer under the weight of these inflated, overly charitable predictions about the self. In short, we predict that while feelings of virtue will license one's own transgressions, they will have the opposite effect on judgments of others' behavior. Three studies support our prediction and the proposed mechanism.

In Study 1, participants were asked to recall either 2 or 10 recent examples of their moral behavior. Based on the logic that it is more difficult to recall 10 examples of recent moral behavior than 2 examples (cf. Schwarz et al., 1991), we predicted that the experienced difficulty associated with recalling 10 examples would undermine participants' feelings of virtue. Next, participants responded to three moral transgressions (*viz.* speeding, tax dodging, stealing) by rating how acceptable it would be if others engaged in the described behavior, or alternatively, if they themselves engaged in the described behavior. We found that participants in the virtue condition rated their own combined transgressions (M = 4.87) as more acceptable than participants in the control condition (M = 4.03, $p < .05$). In addition, participants in the virtue condition rated others' combined transgressions (M = 2.37) as less acceptable than participants in the control condition (M = 2.93, $p < .10$). Taken together, this indicates that feeling virtuous concurrently lowers the standards and demands of moral behavior that individuals have for themselves, yet raises the bar for others.

Study 2 replicated the main findings using consequential decisions and real monetary outcomes. In particular, feelings of virtue were manipulated by prompting participants to imagine that they have decided to spend a few hours doing community service. A control condition was also included in which participants were not prompted to imagine that they were doing community service. This manipulation has been used successfully in past research (Khan & Dhar, 2006) and has been shown to affect feelings of virtue but not other constructs, such as mood. Next, participants completed a pack-

et of surveys unrelated to the present study, until at the end they were asked how much they would like to donate to research on cancer — any amount from zero cents to twenty cents. Alternatively, participants were asked how much they think others should donate. We found that participants in the virtue condition donated less money (M = 3.52) than participants in the control condition (M = 5.98, *p* < .05). Moreover, participants in the virtue condition urged others to donate more money (M = 12.92) than participants in the control condition (M = 9.05, *p* < .05).

We proposed that feelings of virtue lead to overly generous predictions of moral self-behavior, which in turn lead to relaxed standards for the self and higher standards for others. Study 3 tests this mechanism by providing mediation evidence. We manipulated feelings of virtue by asking participants to write a story about themselves that included ten words such as *caring*, *generous*, and *fair*. In contrast, in a control condition participants wrote a story including words such as *book*, *keys*, and *house*. Next, participants responded to four scenarios from Allison et al. (1989) that measure self-predictions of moral behavior (e.g., "Think about Judy, who must choose between studying for an exam and driving a friend who has been called home for an emergency to the airport. If you were in Judy's position, what are the chances, from 0 to 100%, that you would drive your friend to the airport?"). Finally, participants responded to moral dilemmas describing less-than-virtuous behavior (*viz.* eating dog meat, lying on a resume), and rated how wrong it would be if others engaged in the unethical behavior, or alternatively, if they themselves engaged in the unethical behavior. We carried out two bootstrapping procedures to determine (1) whether self-predictions of moral behavior mediates the relation between feelings of virtue and judgments of the self, and (2) whether self-predictions of moral behavior mediates the relation between feelings of virtue and judgments of others. Results of the bootstrap analyses confirmed that self-predictions of moral behavior did act as a mediator in both cases (the indirect effect was estimated between -.678 and -.039 for self-judgments, and between .022 and .324 for social judgments.

In sum, the results further our understanding of the licensing effects that operate in the domain of self and how they can affect interpersonal judgment. Across three studies we observed a moral license for pursuing less-than-virtuous behavior among participants induced to experience feelings of virtue. However, the reverse occurred among judgments of others; participants induced to experience feelings of virtue evaluated others' morally dubious behaviors more negatively compared to control participants.

Frugal Materialists: Licensing and Experiential versus Materialistic Pursuits

EXTENDED ABSTRACT

Past research on licensing effects has demonstrated that preferences for an indulgent or vice item will be higher if people's prior decisions have helped to boost their relevant self-concepts (e.g., Khan & Dhar, 2006). Although past work has conceptualized vice items in terms of their relative luxuriousness, we proposed that similarly virtuous or indulgent choices will have differential effects on subsequent choice depending on their classification as experiential or material purchases (Van Boven & Gilovich, 2003; Van Boven, 2005).

Experiential purchase are different from material ones since the experiences are open to positive reinterpretation, are less prone to disadvantageous comparisons, and are more likely to cultivate successful social relationships (see Van Boven, 2005 for review). Thus, experiential purchases may have more positive self-attributions than material purchases. Building on this notion we predicted and found

that the more positive evaluations associated with experiential than with material purchases (Van Boven, Campbell, & Gilovich, 2010) will subsequently provide a moral license among individuals to select an indulgent item. Four studies provide support for our proposition.

In Study 1, 152 participants were asked to recall either a material or an experiential purchase. Participants recalled purchases that were at least $50 to ensure that the purchase was of sufficient importance to generate continued thought (cf., Carter & Gilovich, 2010). Participants also indicated the cost of the item and independent raters indicated whether participants' items were relative luxuries or necessities by rating each purchase on a nine-point scale (1 = *utilitarian*, 9 = *hedonic*) (Khan & Dhar, 2006). Following the recall task, participants indicated their willingness to pay for various experiential and material indulgent items. The results revealed that, when controlling for cost and indulgence of purchases, participants in the experiential purchase condition were willing to pay significantly more for both experiential and material items than were participants in the material purchase condition. Moreover, participants in the material purchase condition were significantly less willing to pay for future material items than for experiential items. Thus, material consumers may feel the need to 'cleanse' following consumption (Sachdeva, Iliev, & Medin, 2009).

In Study 2, we asked participants to select among an array of material purchases (electronic gadgets) or experiential purchases (vacations), and then, after a choice was made, we examined preference for a luxury item or a necessity. Consistent with the results of Study 1, participants in the material condition were significantly less likely to choose the luxury item than were participants in the experiential condition. Taken together, these results suggest that the type of purchase consumers make can influence their preferences for vice and virtue options.

In Studies 3 and 4, we examined potential mechanisms through which experiential and material purchases differentially impact subsequent choices. First, following research demonstrating that people tend to hold negative stereotypes of materialistic people, perceiving them to be more selfish and extrinsically motivated than are experiential people (Van Boven et al., 2010), we examined whether changes in self-concepts mediate the impact of material and experiential purchases on subsequent choices. The results indicated that the more positive self-attributions associated with the purchase of experiential items mediated the effect of purchase type on subsequent preference for vice or virtue items. Finally, in Study 4, we examined whether the tangible nature of material purchases makes them a more salient source of guilt than are non-tangible experiential purchases. Interestingly, results revealed that, by taking away participants' ability to view a recently selected material good, participants experienced less guilt and were less likely to purchase virtuous items in a subsequent task. The results of Study 4 suggest that material purchases "leave a trace", which may contribute to people's tendency to cleanse following material purchases.

As concerns are raised about modern society's materialistic pursuit of happiness and well-being (Fromm, 1976), it is important to understand how consumers respond to material versus experiential purchases over time. The results of the current studies provide consistent evidence that materialistic consumers experience self-image threats that may cause them to make more virtuous choices in the future. These results have important implications both for consumer welfare and for marketing practitioners. For example, marketers of more indulgent material products may highlight the experiential aspects of a product in order to boost consumers' relevant self-concepts and continue purchasing into the future.

Hurting the Body...and the Soul: Physical Pain Can Mitigate Moral Pain

EXTENDED ABSTRACT

Pain and death are part of life. To reject them is to reject life itself - Havelock Ellis

The unpleasant sensation associated with tissue damage, experienced as physical pain and the distressing experience of social estrangement, experienced as social pain, are both ubiquitous elements of human life (Wall, 1999). Our daily lives are not only met with physical bumps and bruises, but also "broken hearts", "bruised egos" and "hurt feelings". Despite the latter form of pain not resulting from bodily harm, the terms used to express them, function metonymically to describe physical pain. This metaphorical overlap has peaked the interest of researchers, in recent time, to question if both forms of *pain* are truly comparable, or simply a muddling of linguistic license (Eisenberger, Lieberman, & Williams, 2003; DeWall & Baumeister, 2006, DeWall et. al., 2010).

This work, collectively, has found the similarity between physical and social pain in fact extends beyond the linguistic overlap to share a common underlying operational system (Betti, Zappasodi, Rossini, Aglioti, & Tecchio, 2009; Eisenberger et al., 2003; DeWall & Baumeister, 2006; Dewall et. al., 2010; Lieberman et. al., 2004; Price, 2000; Rainville et. al., 1999). Specifically, these studies find that the anterior cingulated cortex (ACC) is implicated in sensing and computing the unpleasant components of both physical (Lieberman et. al., 2004; Rainville et. al., 1999) and social pain (Eisenberger et. al., 2003). Based on this work, we examine the dynamic between physical pain and social suffering. Drawing upon previous work on misattribution of arousal, we suggest that social pain may be lessened if people could misattribute the source of pain to physical causes.

A well-established line of work has found that the influence of arousal would be reduced if people could misattribute arousal to alternative sources. Dienstbier and Hunter (1971), for example, have shown that if individuals could explain away their somatic reactions to their contemplation of cheating, they were more likely to cheat. Likewise, Nisbett and Schachter (1966) found that people were better able to tolerate laboratory-induced electric shocks when provided the opportunity to misattribute pain associated arousal symptoms (e.g., palpitation, tremor) to a placebo they took before the experiment. In line with this logic, if physical pain is an integral part of social suffering such that social agony is accompanied by somatic reactions that resemble physical pain, we expect people to be better able to deal with social suffering if they could misattribute their pain to physical sources.

We test this prediction in three experiments. In the first experiment we had participants hold an icepack versus the same pack at room temperature while watching a series of photos of malnourished and diseased children. Afterwards participants were approached by the experimenter and asked whether they would be willing to donate part of the money they earned from participating in the study, to a charity. We found that participants who held the cold ice-pack while exposed to photos of suffering children were less willing to donate. Thus, experiencing physical pain not only "toughened" people when dealing with social agony but also made them less disposed to stimuli that induce sympathy.

In the second experiment, participants were shown a similar set of photographs as in Experiment 2, except that in one of the conditions each of those photos was immediately preceded by a photograph of thorny plants, designed to remind people of physical pain (Bar & Neta, 2006). In the other condition (the control condition), the proceeding photographs were soft-edged plants. Participants were then approached by the experimenter and asked for a charitable donation. We found that even the subtle reminder of physical pain through images of thorny plants, reduced donations to and unrelated charity.

Finally, the third experiment extended the effect to social pain. Participants held an icepack versus the same pack at room temperature while they engaged in an online cyber-ball game designed to create the experience of social exclusion and rejection (Williams, Cheung, & Choi (2000). In this game, participants engaged in a virtual ball-tossing exercise where they tossed a ball around with three other participants who were supposedly connected online. In actuality, a computer program controlled the throws of the other players (Williams et al., 2000). Participants received the ball twice in the beginning, but were excluded from the remaining 30 throws. We found that participants who held an cold icepack during the cyberball game reported feeling *less* excluded and rejected from others compared to those held a similar pack at room temperature. This suggests the physical discomfort of holding the cold icepack had reduced the pain from being socially rejected.

Across three studies we consistently found that physical pain helps people withstand their social suffering, and in turn can reduce their motivation to help those in need. These set of findings hold important implications to the practice of self-harm. For instance, inflicting physical pain on the self is a common part of religious ceremonies. Catholicism, Hinduism, and the Muslim religion, all have rituals that involve whipping, piercing, and other physically painful acts. Even though the impetus for inflicting physical pain vary in this context, the common underlying belief tends to be the link between physical pain and purity; physical pain can purify the soul and bring one closer to deity. Paradoxically, our findings suggest the opposite: Experiencing physical pain made it easier to navigate the social pain of seeing others suffer, and in turn reduced our willingness to help others. Taken together, this suggests that sticks and stones, not only break your bones, as indicated by the old proverb, but may also numb your pain of compassion.

When Opposites (May Not) Attract: Insights from Next-Generation Priming Influences on Consumer Behavior

Randall Rose, University of South Carolina, USA
Jayati Sinha, University of Iowa, USA

SESSION OVERVIEW

General orientation and objectives. The idea of temporary concept activation or "priming" has gained tremendous interest in consumer decision-making and consumer behavior, with recent demonstrations that consumers' adaptive functioning may actually be explained by nonconscious processes (Chartrand, Huber, Shiv, & Tanner, 2008). With it now becoming clear that consumer behavior can be automatically determined to some degree, it is important to move past the demonstration phase of automaticity research, and to to build richer and more complete theories of automatic behavior in the consumption context. In this session, our purpose is to provide next generation insights into automatic behavioral effects with a particular focus on understanding why subtly different but related primes lead to different behavioral outcomes. In particular, the four papers in this session address the following second generation research questions:

Paper 1. What are the downstream consequences for behavior of nonconscious goal fulfillment?

Paper 2. What are the neurological processes underlying the effect of the thrift and prestige primes which many marketing researchers have used?

Paper 3. Are consumers more likely to be influenced by environmental cues in certain circumstances?

Paper 4. Why do very similar priming constructs sometimes lead to very different results?

Potential audience. We expect this session to be of interest to researchers interested in the influences of primes on consumer behavior; the automatic and nonconscious psychological underpinnings of consumer behavior; and the downstream implications of said influences and processes for marketers.

Issues to be covered. These papers collectively emphasize the presumed usefulness of priming as a tool for encouraging indulgence, with the aim of the session being to highlight the circumstances in which one might actually find reversals (e.g., less consumption/indulgence) as well as the psychological and neurological underpinnings of these effects. Across the papers and paradigms, the priming stimuli and measures are related to spending/saving or indulgence/restraint-type constructs, speaking to consumers' proclivity to indulge and influence factors affecting this (automatic) tendency. Data has been collected for the studies described in papers 1 through 4. Drafts of papers 1 and 2 are available upon request.

The Competing Goal Strikes Back: Volitional Fulfillment of Nonconscious Goals Enables Opposing Goals to Rebound

EXTENDED ABSTRACT

A considerable body of research has demonstrated that environmental cues can trigger goals that are then pursued without conscious awareness (see Moskowitz, Li, & Kirk, 2004, for a review). Nonconscious goal pursuit (NCGP) research has for the most part focused on delineating the process by which single goals are selected, pursued, and fulfilled. More recently, there have been calls for researchers to answer 'second generation questions' (Bargh, 2006) such as how multiple goals interact with each other and how they interact with conscious decisions. We contribute to answering these questions by investigating how the NCGP process plays out over time for goals which chronically conflict, as understanding how individuals resolve opposing motivations is central to our understanding of the dynamics of self-regulation (Koo & Fishbach, 2009). For example, consider an individual driving to the grocery who is exposed to an environmental cue suggesting indulgence (e.g., a billboard showing a luxury ice-cream brand). Such incidental cue exposure may lead the individual to automatically pursue a goal to indulge, perhaps leading him to buy an unplanned candy bar (Chartrand, Huber, Shiv, & Tanner, 2008). In this research, our particular interest is in how the NCGP process plays out downstream from this goal-fulfilling purchase.

We explore two questions: First, can the fulfillment of a nonconsciously activated goal (hereafter the focal goal) lead a competing goal (a goal to eat healthy in the above example) to rebound and influence subsequent behavior? Second, do the volitional circumstances underlying such goal fulfillment matter? In particular, for automatically pursued goals, is any opportunity for goal-consistent behavior sufficient to fulfill the goal (i.e., passive receipt of a goal-fulfilling means, such as a candy), or does the individual need to make a volitional decision to undertake goal-consistent behavior (i.e., decision to obtain a goal-fulfilling means)? To explore these questions we utilize a sequential task paradigm in which individuals are given the opportunity to pursue a primed focal goal before being given an opportunity to pursue either the focal goal or a chronically opposing goal.

In experiment 1, we examined how the automatic pursuit and fulfillment of an *indulgence* goal influenced the subsequent pursuit of an opposing *health* goal (goals that are in chronic opposition for most individuals, Finkelstein & Fishbach 2010). We found that when no goal was primed, eating a chocolate led to an increased desire for

indulgent foods. However, when an indulge goal was first primed, eating the chocolate led to an increased desire for healthy foods. Thus, fulfillment of the primed indulge goal appeared to cause the opposing health goal to rebound. However, since all participants who ate the chocolate did so of their own choice, it is not clear whether the indulge goal was fulfilled by the mere, physical consumption of the chocolate itself or by the volitional act of choosing to consume it.

Experiment 2 was designed both to replicate the results of the first experiment using a different opposing goal pair (thrift vs. luxury), and also to disentangle the volitional act of *actively choosing* a goal-fulfilling means from its *mere receipt*. When a thrift goal was primed and followed by one's own decision to be thrifty (i.e., choosing Hanes socks), the thrift goal appeared to be fulfilled, leading to extremely high preference for the relatively more luxurious option (i.e., allocating great amounts of money to a luxury store). However, when the thrift goal (vs. neutral) was primed and was followed by unsolicited receipt of a thrifty option (i.e., being awarded Hanes socks), then the thrift goal did not appear to be satisfied, and continued to influence preference (i.e., allocating great amounts of money to an economical store). Thus, these results suggest that the nonconscious goal system is not entirely passive and suggests that fulfillment of nonconscious goals actually requires volitional intent to behave in a goal consistent way.

We find that the fulfillment of automatically pursued goals enables opposing goals to rebound and influence behavior. Importantly, it reveals that the effects of environmental primes can be substantially more complex than the single goal and behavior cases that have been previously studied. While speculative, this complexity suggests the possibility that the unconscious goal system is capable of adaptively managing multiple goals. Further, it is interesting to see that there needs to be some volition for the opposing goal to rebound after initial goal fulfillment. Simply giving participants a means to satisfy a primed goal did not generate rebound, which suggests that the primed goal is not fulfilled without people actively deciding on goal-fulfilling means. These results are fascinating as they suggest an interaction between nonconsciously primed goals and consciously made decisions. Future research should explore the level of consciousness necessary for a decision to pursue a goal be regarded as enough for goal fulfillment, how much movement toward focal goal fulfillment is necessary (i.e., make a goal-consistent decision, perform a goal-consistent behavior, perform a large amount of goal-consistent behavior) for a competing goal to rebound, and whether there are situations in which merely being given an opportunity to pursue a goal is enough to fulfill a primed goal or at least decrease its activation level, which was not the case in experiment 2. The investigation of these issues could not only provide information on how unconscious goal pursuit operates, or how conscious goal pursuit directs behavior, but also helps us understand how both interact and allow us to aid individuals in the management of their multiple goals.

In Pursuit of Luxury: Anterior Cingulate Cortex Activation in Response to Luxury Brands Depends on Goal-Congruent Cues

EXTENDED ABSTRACT

The acquisition of beautiful, costly, or prestigious goods is an age-old human consumption behavior that finds its modern expression in luxury brands. Given the strong appeal of luxury brands even in inauspicious personal or societal economic environments, two questions emerge: (a) Is there a neuropsychological component to luxury brand appeal and, (b) if so, how might environmental cues modulate neuropsychological goal value associated with indul-

gence? Goal value is the extent to which a choice option may serve as a means towards goal attainment (Hare et al. 2008). We hypothesize that there is a neuropsychological response to luxury brands that is congruent with desire or motivation (and different from more prosaic brands), but that this response depends on the presence of consumption-related cues that modulate luxury goal value. For consumers who wish to reduce their consumption of expensive luxuries, such results would provide good news. Though luxury brands "feel" good, exposure to messages of frugality reduces the value to which a brand may facilitate a goal, and, thus perhaps the temptation.

While indulgence goals may seem more prevalent in the marketplace, current consumption contexts also promote well-established goals to save. To examine neural encoding of the value by which brands may facilitate individuals' goals, we compare luxury brands to other well-regarded and familiar brands that are positioned in terms of practicality.

Research on consumer attitudes toward luxury is often limited by methods prone to socially desirable responding, self-generated validity, or the inability to articulate complex cognitive/emotional responses operating automatically. The use of fMRI methodology allows us to circumvent these issues and more directly assess neural processes underlying response to brands across conditions. Based on two recent fMRI studies that offer important insight into a neuroeconomic perspective of luxury valuation, we designed an fMRI protocol to examine activation in areas of the brain known to play a role in goal valuation (Hare et al. 2008, Plassmann et al. 2008). Research finds that rostral anterior cingulate cortex (rACC) activation is correlated with computations of amount of reward associated with an option under consideration (i.e. goal value; Litt, Plassmann, Shiv, & Rangel, 2011). Broadly speaking, automatic goal value computation would allow recognition of the means to a desirable end state and a signal to other systems regarding the degree to which an option should be approached (Ferguson & Bargh, 2004). As a basis for our research, these findings suggest a) the probable existence of a neurophysiological component to the appeal of luxury brands, b) that this valuation is likely to be goal-oriented, and c) that the rACC encodes context dependent goal valuation activation.

We propose that goal valuation effects depend on congruency between the cued goal (indulgence vs. frugality) and the brand. Secondly, we do not expect increased goal-activation for practical brand images when they are preceded by cues related to frugality, as utilitarian goals do not invoke the same degree of associated reward value. For goal and automaticity researchers, it will be interesting to see that this pattern of results is consistent with goal-means valuation rather than mere schema activation, as this distinction represents an important debate in current priming research.

To test these hypotheses, we scanned 24 participants while they viewed four cue-brand conditions in a 2 x 2 within-subjects design that crossed the consumption goal cued (indulgence or frugality) and the brand logos presented (luxury or practicality). Thus, in condition 1, three indulgence-oriented words preceded three luxury brand logos (IL); in condition 2, three frugality-oriented words preceded three practical brand logos (FP); in condition 3, three indulgence-oriented words preceded three practical brand logos (IP); and, in condition 4, three frugality-oriented words preceded three luxury brand logos (FL). Cue words were carefully chosen to avoid pejoratively nuanced consumption goals (e.g., spoiled, cheap). Brand logos were pretested to ensure familiarity and that both luxury and practical brands were equally well-regarded.

Imaging analyses indicated that, as predicted, congruency between an indulgence cue and luxury brand resulted in increased rACC activity compared to conditions where a luxury brand was

preceded by a frugality cue. We did not observe this increase in activation when a practical brand was preceded by a frugality cue. This suggests that enhanced goal-activation for luxury logos that are preceded by indulgence-oriented cues are stronger for the goal of indulgence and is not simply a mere-congruency effect. Importantly, temptations towards indulgence may be modulated by the presence of frugality cues: frugality cues preceding luxury brands reduced the goal value for luxury brands.

The contributions of this research are two-fold. First, building on recent research on relative goal value, our study shows that the appeal of luxury brands is associated with neurological responses contingent on the presence of consumption related cues—the mere presence of a luxury cue affects the valuation of luxury brand representations. This study is the first to demonstrate that goal valuation occurs automatically within a passive viewing context. Automatic valuation would be a necessary precursor to the selection of luxury goods when an indulgence goal has been activated. Second, and viewed in the light of recent research on passive goal guidance (Laran & Janiszewski, 2009), our study raises important questions regarding the nature of nonconscious goal intensity. Traditional priming studies activate goals in an on/off manner (Bosmans & Baumgartner, 2005) and goal means (brands, etc.) are generally limited to dichotomous choices. However, our study and other recent neuroeconomic studies (Hare et al. and Plassmann et al.) utilize and measure a range of and observe differences in valuation, thus suggesting that nonconsciously activated goals and subsequent behaviors are dependent on goal intensities that must reach a threshold before the goal pursuit is initiated. Thus the question remains whether goal value intensity signals may facilitate intensification of active goals and suppression of other goals to passive operation.

Are There Situations in Which Consumers Want to be Primed?

EXTENDED ABSTRACT

We propose that sometimes people "want to be primed" – that is, without explicit awareness or intent, people become more receptive to environmental influence. People become more receptive to environmental influence when the source of influence is well-liked (and less receptive when the source is disliked). Moreover, people become more receptive to environmental influence when facing difficult decisions because external cues can help make decisions. Importantly, we propose that people's receptiveness to external influence can have unintended consequences for unrelated behavioral decisions. The effect of wanting to be primed is not the same as losing self-control. Rather, we find that wanting to be primed increases indulgence when environmental cues prime "spending" but decreases indulgence when cues prime "saving." Wanting to be primed is also different from experiencing cognitive load. Indeed, we find that wanting to be primed can reverse effects in situations where cognitive load would exacerbate them. We test our hypotheses through a combination of field and laboratory studies.

To begin, we tested whether people are more receptive to priming effects when they encounter marketing stimuli that they like. In the main atrium of a university campus, where student groups and vendors set up table displays, we displayed 7 cardboard boxes (keyboard, laptop, and monitor boxes) that depicted either Dell or Apple brand logos. The experimenter stood approximately 3 meters away, to avoid being linked to the display. Passing students were offered candy in exchange for answering two short questions. First, participants imagined an upcoming shopping trip where they must decide whether to spend a lot or try and save money. Participants reported

their willingness-to-spend. The second question asked participants' liking of the brand Apple (Dell).

Pretesting suggested that Apple is associated with expensiveness and Dell with value. Therefore, exposure to Apple should prime spending and Dell should prime saving, producing different effects on willingness-to-spend. We predicted and found that brand liking moderates these effects: greater liking of Apple (Dell) increased (decreased) willingness-to-spend. Moreover, whereas liking a brand caused brand-consistent behavior, disliking a brand provoked brand-inconsistent behavior. These findings support the hypothesis that people are more (less) receptive to influence by stimuli they like (dislike).

Study 2 tested the hypothesis that people want to be primed when facing difficult decisions, and addressed an alternative explanation based on cognitive load. Cognitive load was addressed in two ways: First, by examining expected rather than actual task difficulty (which should minimize difficulty's effect on load); Second, by examining a situation where cognitive load and wanting to be primed predict different behaviors. Research suggests that people automatically react against unwanted sources of persuasion, including insincere flattery (Chan and Sengupta 2010). If cognitive load underlies the effect of difficulty, then difficulty should have no effect or even strengthen these automatic effects. However, if wanting to be primed underlies the effect of difficulty, then difficulty should reverse these effects. That is, if difficulty makes people more receptive to environmental influence, sources of persuasion would no longer be unwanted.

Study 2 used a 2 (difficult vs. easy decision) *X* 2 (expensive vs. inexpensive store) between-subjects design. Participants completed a shopping task followed by a decision-making task. Before the shopping task, participants were informed that the upcoming decision-making task was difficult (easy). This was our sole manipulation of difficulty. In the shopping task, participants evaluated a mailbox flyer containing insincere flattery – statements obviously intended to persuade readers to visit a new "designer" ("discount") department store. In the decision-making task, participants imagined needing a new apartment and choosing between one that is superior but expensive and another that is inferior but better value. The dependent measure was apartment preference.

We predicted that participants expecting a difficult (vs. easy) upcoming task would be more receptive to environmental influence. Thus, whereas participants in the easy decision condition would automatically react against the flyer's insincere flattery, participants in the difficult decision condition would not. Supporting this hypothesis, the inexpensive (vs. expensive) store flyer reduced preference for the inexpensive apartment among participants anticipating an easy decision. Conversely, the inexpensive (vs. expensive) store flyer enhanced preference for the inexpensive apartment among participants anticipating a difficult decision. These results support the hypothesis that when decisions are difficult (easy), people are more (less) receptive to environmental influence.

Study 3 examined the interaction between liking, difficulty, and brand. We reasoned that when people face difficult decisions, they want to be primed regardless of how much they like particular brands. Thus, we predicted a 3-way interaction in which liking moderates priming effects in easy decision contexts (replicating study 1's results), but not difficult contexts. We conducted the study in a mall in the days leading up to Christmas and Valentine's Day. Mall patrons shopping for gifts were offered candy in exchange for answering two questions. First, participants generated a number from 1 to 10 to express how difficult Christmas (Valentine's Day) shopping has been for them. Next, participants thought about a future shop-

ping trip, after the holiday, and indicated their willingness-to-spend on that trip (the DV from study 1). To dissociate our proposed effect from a depletion effect, whereby difficult decisions may uniformly increase willingness-to-spend, we alternated between stopping people walking by expensive and inexpensive stores. If greater shopping difficulty makes people want to be primed, the particular store participants were standing in front of would moderate willingness-to-spend.

Three key findings were obtained. First, as in study 1, liking the brand caused a priming effect and disliking it reversed the effect. Second, in line with study 2, brand's effect strengthened as perceived decision difficulty increased. Third, we obtained the predicted 3-way interaction between liking, difficulty, and brand. Only when shopping was considered easy did participants show (reverse) priming effects in response to brands they (dis)like. When shopping was considered difficult, people behaved in line with the brands' associations. Thus, decision difficulty is an important boundary condition for the effect of liking.

Collectively, these studies support the hypothesis that sometimes people are more receptive to priming effects; in particular, people want to be primed when they encounter marketing stimuli that they like and decision contexts that are difficult.

Save or Spend?: When Priming of Related Constructs Can Activate Opposing Behaviors

EXTENDED ABSTRACT

In this research we examine two related constructs (cash and credit) that when activated encourage opposing behaviors. At a functional level both serve as a medium of exchange, but we argue that credit cards and cash are forms of money that are likely to have affectively and semantically different mental representations, consequently these forms of money are likely to have different downstream behavioral implications. For example, priming potential donors with cash concepts may lead to the kind of self-sufficiency orientation (neither willing to take help nor willing to give help) that has been noted in prior research (Vohs, Mead, & Goode, 2006), but priming a different form of money such as credit cards may elicit a very different orientation. Why would this be the case?

Mere exposure to credit card brands has been shown to substantially increase spending (Feinberg, 1986). Later studies have validated the notion that credit cards do facilitate spending relative to cash (Prelec & Simester, 2001; Soman, 2001). Consumers' prior experiences of instant gratification of desire when paying with a credit card may invoke a buy-now-pay-later mentality that is strongly associated with rewards (Mendoza & Pracejus, 1997; Shimp & Moody 2000). Prior neurological studies suggest that many rewards are processed similarly in the brain (Montague, King-Casas, & Cohen, 2006). An activated generalized reward system can give rise to non-specific effects. For example, exposure to sexy cues leads to more impatience in intertemporal choice between monetary rewards (Van den Bergh, Dewitte, & Warlop, 2008). Similarly, we suggest that with repeated credit card purchase experiences ending in immediate gratification of desires, this may result in a general accessibility of benefit considerations relative to cost considerations when exposed to credit primes.

On the other hand, when paying with cash, people are acutely aware of the pain of payment (Prelec & Loewenstein, 1998) because of the vivid memory trace (Soman, 2001). Theorists generally regard social pain, monetary-loss pain, and physical pain as overlapping pain systems (Knutson et al., 2007; Rick, Cryder, & Loewenstein, 2008). Overlapping pain systems suggest a heightened sensitivity to

costs. Thus, with repeated transactions, strong associations are developed between cash as a payment mechanism and various costs or losses that are affectively negative concepts.

Because there are likely to be clear differences in the associative networks surrounding credit card and cash payments, we hypothesize that attention to dramatically different informational inputs can be induced by priming cash versus credit concepts (Bargh, 2006; Fitzsimons, Chartrand, & Fitzsimons, 2008). This activation of different associations in memory biases the processing of subsequently encountered stimuli depending on its consistency with the implications of the activated concept (Bodenhausen, 1988; Darley & Gross, 1983). Evidence that is consistent with the activated concept may receive more attention and rehearsal, and may therefore be much more likely to be incorporated into the decision maker's mental representation of the scenario compared to inconsistent information. Using these ideas in the present context, we propose that different downstream outcomes between credit card payments and cash payments arise at least in part due to the attention to *benefits* highlighted by *credit card* primes versus the attention to *costs* highlighted by *cash* primes. Costs of helping behavior could be financial as in the case of monetary contributions, or in terms of commitments of time and effort. Benefits of helping behavior could include social benefits or self-enhancement benefits.

A pretest identified the words that participants associate with credit cards and cash. Across all studies, participants initially engaged in a scrambled-sentence task, in which they constructed grammatically correct sentences using four words from a list of five scrambled words (adapted from Bargh & Chartrand, 2000).

In study 1, participants were randomly assigned to either a cash or credit card (or control) condition using a sentence unscrambling task as described. Following a short unrelated questionnaire, the participants were told that the University Student Welfare was looking for some volunteers and that any amount of time that participants can volunteer per month would be helpful. We found that participants volunteered significantly more time when primed with *credit card* ($M_{credit\ card}$ = 6.46 hours) than when primed with *cash* (M_{cash}=2.34 hours) (with participants in the control condition volunteering M = 4.03 hours). We replicated the same study with money donated as the dependent variable and found similar results.

In study 2, we explored whether participants primed with different money concepts focus differentially on either the *benefit* or *cost* aspects of the donation option and therefore, identify cost or benefit related words at different rates when participating in a word-completion task. Similar to previous studies, participants completed a scrambled sentence task meant to activate cash vs. credit card concepts. The participants were then given information about a particular charity, and the pros and cons of volunteering were listed in a paragraph. Subsequently, the participants completed a word completion task and time was measured (counterbalanced). The word completion task entailed completing 25 words which were left incomplete (9 were neutral words and rest equally split between the two conditions). As expected, participants in the *credit card* condition identified more words related to *benefits* compared to those in the cash condition (M = 1.92 vs. 1.02, $p < .05$). In contrast, those in the *cash* condition identified more target words related to *costs* than those in the credit card condition (M = 2.67 vs. 1.49, $p<.05$). In addition, we replicated the main effect findings from the previous study. In sum, our findings demonstrate that while *cash* and *credit* are both concepts related to money, they lead to opposing effects in terms of donation behavior. Further, we find evidence that this effect is at least partially due to differential activation of *benefit* versus *cost* aspects of donations.

When Looks Matter: Dynamics of Exposure and Attention in Self-Control Dilemmas

SESSION OVERVIEW

The psychological underpinnings of self-control and failures thereof have been a topic of rich debate in the literature. Much has been written about how and why people make unhealthy or unwise choices. Some researchers have explained such choices as a result of lapses in executive function due to limited resources (Baumeister, Vohs and Tice 2007), while others have argued that lower-order affective reactions towards stimuli or automatic positive attitudes towards them may drive such reactions (Hofmann, Friese and Strack 2009; Shiv and Fedorikhin 1999). What is as yet under-researched is the nature of cognitive and affective processes set into motion immediately upon exposure to a vice or virtue and how these attentional processes unfold over time. The three papers in this session provide valuable insights on how our preferences and emotions change dynamically upon exposure to tempting options.

The first paper by Dewitte and colleagues focuses on the dynamics of gaze patterns when people are making choices from pure (virtue-virtue or vice-vice) or mixed (virtue-vice) choice sets with equally attractive options. Using eye-tracking, they show that contrary to established research showing that people fixate on the option finally chosen, self-control decisions involving choices between virtues and vices elicit greater gaze fixations on the option not chosen. They suggest that people's attentional processes are actively involved in trying to distorting the value of the option that is not chosen when both options are equally attractive, a phenomenon they call preference editing. The second paper by Ramanathan and Hofmann focuses on the dynamics of felt desire and resistance towards temptations and shows that the root to indulgence decisions by impulsive individuals lies in the recurrence and stickiness of desires rather than weakening resistance, and that trying to change attention away from temptations towards healthier options may backfire if such individuals' reward circuitry has already been activated. Finally, the third paper by Rutkauskaite, Dewitte and Warlop provides insights into how people's desires towards temptations and consumption can be reduced by changing their innate preferences via pre-exposure to temptations in a non-consummatory setting. They argue that implicit or tacit norms for behavior in a given setting are more effective than explicit or stated norms, not just in the short-term in terms of reducing consumption but also altering the preferences for temptations in the long-term.

Together, these papers bring deep psychological insights about self-control hitherto unexplored in the literature. In particular, they provide a window to the role of exposure and attention in self-control dilemmas, showing how people's innate preferences can be changed either towards virtues or vices by self-initiated processes (Dewitte et al, Rutskaukaite et al), and how external attempts to change these preferences via attentional retraining (Ramanathan and Hofmann) or via explicit norms (Rutskaukaite et al) may have counter-productive effects. Using cutting-edge techniques such as eye-tracking and new analytical methods such as recurrence analysis that were originally developed in the hard sciences, the papers in this session represent the essence of the conference theme, "building connections." Within a coherent theme, the three papers represent diverse conceptual and methodological interests and have a broad appeal to audience from marketers to policy makers. All papers are in an advanced stage of completion. We expect this session to be of interest to researchers in the domains of affect regulation and self-control, as well as cognitive learning. Researchers in decision neuroscience may find the session interesting because of the potential it holds for continued exploration of basic neural mechanisms involved in self-control decisions. Scholars interested in studying the design of public policy interventions aimed at reducing indulgence and increasing healthy behavior may also find the prescriptive recommendations emerging from this session to be of interest. We thus expect an inter-disciplinary appeal from this session integrating unique methodological and theoretical contributions with pragmatic and prescriptive recommendations.

A session on exposure and attention would be incomplete without a discussion leader of the stature of Rik Pieters from Tilburg University. Rik is an expert in attentional processes and is one of the most respected researchers in the field. He will share his views on the papers and attempt to build connections among them for the benefit of the large audience that we expect this session to attract!

Gaze patterns reveal preference editing duringself-control choices

EXTENDED ABSTRACT

In this paper we address the question as to whether choosing between a fruit dessert (virtue) and a high-calorie dessert (vice) relies on the same decision process as choosing between two fruit desserts or two high-calorie desserts. In general, we question whether self-control choices rely on the value computation processes that have been documented in the decision literature (e.g. Busemeyer and Townsend 1993). We propose an alternative process that we coin 'preference editing', where the valuation of the choice options is distorted rather than computed during the decision process. We use eye-tracking methodology to document preference editing during self-control choice.

Decision models (e.g. Busemeyer and Townsend 1993) assume that decision makers stochastically sample evidence about the options in the choice set, feeding into a relative decision value, which reflects the relative advantage that one of the options has at a certain moment. Decision makers continue sampling until the relative decision value passes a decision threshold, at which point a choice is made. Krajbich, Armel, and Rangel (2010) linked this type of decision model to eye-movements. Notice that this value computation process does not affect the initial value of the options. We assume that this model has difficulties dealing with self-control choices be-

cause of the mixed nature of vice options. The alternative process, preference editing, assumes that during self-control choices, the decision maker distorts the valuation of the options as a way to cope with the decision problem (Dewitte, Bruyneel, and Geyskens 2009). This distortion process implies the value of one of the options will have become more negative than that of the other option.

To gauge the process of preference editing, we tracked people's gaze during a sequence of binary choices (cf. Krajbich, Armel, and Rangel 2010), either in mixed choice situations (vice – virtue) or in pure choice situations (vice – vice or virtue – virtue). To control for stimulus effects, each choice option served as an option in both the mixed and one of the pure choice situations. The choice options within a pair were matched on attractiveness, following the results of a pretest. Based on our preference editing model, we put forward two specific predictions about the gaze pattern during self-control choice.

The first pattern is the match between choice and the last fixation (do consumers choose what they look at last or not?). Krajbich et al.'s (2010) validated decision model predicts that the last fixation will not be on the selected option in cases where the item the decision maker looks at last is valued less than the other item. If there is no such value difference between the two options, the last fixation will be on the selected option. Our preference editing account implies that the value of the two (initially equally attractive) options will diverge during the choice process. So our first prediction states that preference editing would be revealed in people's gaze pattern when a lower proportion of last fixations would be on the chosen option in the mixed condition compared to the pure condition.

Preference editing also implies that different gaze patterns lead to the selection of the vice and the virtue, which is not the case for value computation models, when the two options were matched on attractiveness. While choosing between (equally attractive) fruit and high-calorie desserts, choosers' preference editing can go in two directions. Choosers may either downplay the health feature of the option set, which makes the virtue less and the vice more valued. Alternatively they may downplay the taste dimension of the choice set, which would make the virtue relatively more valued than the vice, leading to a relative value gap in favor of the virtue. Comparing these two preference editing paths suggests that the path towards the virtue requires longer editing than the path towards the vice. If the impact of taste is reduced (path towards choosing the virtue), the value of BOTH options is reduced in absolute terms because the virtue also scores positively on the taste dimension. In contrast, reducing the impact of health (path towards choosing the vice) works faster because it reduces the net value of the virtue while increasing the net value of the vice. This leads to our second prediction. Choosing a virtue from a virtue-vice pair will take more fixations than choosing a vice. In contrast, choosing the same virtues from virtue – virtue pairs will not take more fixations than choosing the same vices from vice – vice pairs.

We recorded 62 participants' eye-movements while they were choosing one product from 10 product pairs. Half of participants got 10 product pairs of the mixed type (vice-virtue) and the other half received a product pair series of the pure type (either virtue-virtue or vice-vice, also between subjects). Consistent with our account that self-control requires more preference editing than non-self-control choices, we found that the last fixation (the one while choosing) was less often on the selected option in self-control choice situations (67%) than in the two pure choice situations (81%, $p < .05$), although all pairs were matched on attractiveness. Also consistent with preference editing, we found that in the mixed condition, choosing the virtue required more fixations than choosing the vice ($r = .39$,

$p < .05$), but that the number of fixations did not differ between the two pure conditions (F < 1).

Our data strongly suggest that self-control choices do not trigger the standard value computation processes but rather distort valuation of the options. This implies that engaging in self-control choices may have effects on subsequent decisions as it implies preference editing (e.g. Dewitte et al. 2009). Our findings also raise the question as to what would happens in self-control situations where the two options are not matched on attractiveness. Would the value computation process suffice in this case or do these situations still require preference editing? Future research should also address the question which decision situations require preference editing and which can be solved with value computation.

Effects of Focus of Attention on Desire and Resistance Towards Temptations

EXTENDED ABSTRACT

Picture yourself at the local grocery store. As you enter, you may see a display of fruits on sale. Your eyes are drawn to the display for a while. Continuing on, you see a rich chocolate cake in the bakery section, inviting you with its sheer decadence. You look away, trying to focus on the healthier fruits instead. Yet, your eyes keep returning to the cake, drawn by its luscious, creamy, dark brown appearance. You "succumb" to the temptation and buy a large wedge of the cake.

This is a common enough story that occurs in almost everyone's life. The idea that we "succumb" to temptations has a nice Puritanical ring to it – temptations are "bad" and must be avoided. If people acted impulsively, it must be because they were weak in self-control (i.e., lacked resources or were otherwise unable to resist the temptation) or had a weak activation of "higher-order" goals such as eating healthy or saving expenses. Drawing on dual-process theories of the mind (Hofmann, Friese, & Strack, 2009; Metcalfe & Mischel, 1999; Strack & Deutsch, 2004) and the elaborated intrusion theory of desire (Kavanagh, et al. 2005), we propose instead in this paper that indulgence may be the result of a pattern of recurrent desires that lead to and are in turn driven by attentional adhesion to the tempting stimulus. We suggest that people who experience desire may get "trapped" in that state for longer periods of time. We also propose that the recurrence and stickiness in desires is affected by pre-exposure to rewards, but that the timing of pre-exposure can change the patterns of desire experienced by people.

The literature on problem behaviors commonly advocates the retraining of attention away from temptation or towards healthy or more prudent choices (Schoenmakers, Wiers, Jones, Bruce, & Jansen, 2007). We suggest that there are boundary conditions to the efficacy of these methods, and indeed, such methods may fail spectacularly under some circumstances for some people, manifesting in even stronger and more persistent desires towards temptations. Specifically, impulsive people whose reward system is already active may respond to attentional retraining with more recurrent desires towards subsequently presented temptations, potentially causing greater indulgence.

Experiment 1 examines the psychological processes underlying such attentional biases. In particular, we were interested in the dynamics of desire and avoidance towards the temptation in an attempt to determine whether indulgence is caused by strengthened desire or weakened avoidance. We changed the design of the dot probe task such that the dot probe would appear more frequently (90% of the trails) either at the location of the dessert picture or the fruit picture, thus manipulating attention in one direction. Subsequently, we

measured desire-avoidance reactions towards a tempting chocolate snack on a 2-D grid by moving a mouse cursor continuously for 60 seconds. Participants indicated whether they felt little or a lot of desire and avoidance towards the snack right at the moment on two orthogonal dimensions. Using a new technique from dynamical psychology called Recurrence Analysis, we examined the trajectories followed by the time series for desires and avoidance, specifically looking for the extent to which the trajectories visited the same region in state space over time. Results confirmed that impulsive individuals who were manipulated to attend to desserts showed higher recurrence of desires and remained longer in a state of desire but not non-impulsive individuals, suggesting only impulsive individuals kept revisiting the same hedonic goal and were trapped in that goal state for a longer period of time. This phenomenon of trapped states is described in dynamical system theory as a "fixed point attractor" wherein individuals keep returning to a given state or goal despite occasional fluctuation (Carver 2005, Vallacher and Nowak 1999).

In experiment 2, we further explore how training attention engagement towards either towards temptation or healthy options can impact subsequent behavior when reward-seeking systems are activated at different time points. We followed the same procedure as in experiment 1 except that participants were additionally asked to sample a small piece of chocolate before or after the dot probe task. Sampling even a small bite of chocolate can cause activation of the reward-seeking system (Wadhwa et al. 2008). Results showed that impulsive individuals experienced higher recurrence of desire towards temptation when manipulated to attend to desserts if sampling before. More interestingly, impulsives experienced even higher recurrence of desire when they attended to healthy options first and then sampled a temptation. This data pattern suggests that reactance against goals inconsistent with their chronic goals may arise as a consequence of forced attention engagement on healthy options among impulsive individuals, hence training to focus on virtue can be a bad strategy to reinforce healthy behavior.

In summary, our research demonstrates that indulgent behavior exhibited by impulsive individuals is an immediate consequence of an engagement bias towards temptation that results in greater desires rather than weaker self-control. However, strengthened desire is not only limited to an elevated level of desire, but also extends to a more frequent recurrence of desire state and a longer trap time in that state. Forcing attention away from the temptation may backfire, resulting in higher recurrence of desire and consequently greater indulgence in impulsive individuals.

Self-Inferred Norms Reduce Desire and Consumption through Changing Product Perceptions

EXTENDED ABSTRACT

Self-control has traditionally been seen as the struggle between desire and will-power (Hoch and Loewenstein 1991). While both components are important for explaining self-control, prior research aimed at improving self-control has predominantly focused on the willpower component, while taking the desire component as a given. Still, changing consumers' preferences and their resulting desires may prove more successful for improving consumers' self-control in the long run. Preferences are more stable than the ability to exert willpower. Imagine that you truly prefer apples over ice cream. You will take an apple not only now, but you will probably also choose apples over ice cream next time around. In contrast, if you follow your friends' explicit recommendation and deliberately choose an apple against your own taste preference, you will probably not choose apples again on future occasions. Hence, changing preferences is a

potentially more reliable tool to help consumers to deal with temptations. The current paper examines non-consummatory pre-exposure to temptation as a technique to sustainably change preference.

The potential benefits of exposure to a temptation have been subject to debate. On the one hand, pre-exposure to temptation effectively reduces desire when the control conflicts during pre-exposure and post-exposure are similar (Dewitte et al. 2009; Geyskens et al. 2008). On the other hand, physical presence often increases craving for and consumption of the tempting product (Mischel et al. 1972; Wansink 1996). We propose that the nature of normative control, which can be explicit or tacit, will moderate the effect of pre-exposure on temptation on subsequent self-control ability. Explicit consumption norms, such as those communicated by parents or marketing actions, may discourage the succumbing to temptation in the short run, as long the norm is still activated. But their effects may wane when the accessibility of the norm fades. Tacit norms, inferred from the prevalent circumstances (e.g. known rules of conduct during a formal reception) might prevent succumbing also in the longer run. Self-inferred norms urge people to actively cope with the behavioral conflict induced by the temptation. People do not need such coping strategies when explicit norms are present, which allow reliance on social force. We claim that ignoring the tempting nature of the temptation is one important way to reduce desire for a vice product and hence to deal effectively with temptation. We tested three implications of this claim. First we test whether, compared to an explicit norm, a tacit norm more effectively reduces the relative attractiveness of the vice product. Second, using multidimensional scaling, we test whether activation of tacit norms diminishes the importance of the most tempting dimension of a temptation in a perceptual map. Third, we tested whether activation of the tacit norm has more residual impact on consumption after a delay than the activation of the explicit norm. Our data are the first to show that self-inferred norms effectively change product perceptions, and through it, reduce desire and consumption of the temptation.

In two experiments, we exposed participants to a temptation in two successive phases. We manipulated the norm (explicit or tacit) during pre-exposure in the first phase, and the delay (present or absent) between two phases. We also added a control condition without pre-exposure to temptation. In the pre-exposure phase, participants engaged in a knowledge task. In the experimental condition, they matched candy flavors with wrapper colors. The context of the task strongly suggested that they should not consume. They were either told to not eat candies (explicit norm) or were told nothing (tacit norm). In the control condition, participants engaged in a similar knowledge task not involving candy (Geyskens et al. 2008). The second phase started either immediately or after a 15 minute delay. Participants were asked to taste and evaluate a different vice product. In Study 1 we measured the amount of candy consumed during the second phase (as a measure of self-control) and the change of preference ranking for the candy used in the second phase. In Study 2, we measured perceptions of drinks varying in sweetness and freshness and measured the importance of the sweetness dimension in the participants' revealed perceptual map.

In Study 1, we replicated the effect of pre-exposure to temptation (Geyskens et al 2008). Participants consumed less in the four experimental conditions than in the control condition ($F (1, 97) = 16.39$, $p < .01$). Planned contrasts showed that delay increased consumption in the explicit norm condition ($F (1, 71) = 4.84$, $p < .05$) but not in the tacit norm condition ($F < 1$). Also the findings for preference rankings were in line with predictions. The type of norm affected preferences ($F (2, 97) = 6.35$, $p < .05$): Compared to the control condition ($M = 1.52$) and to the explicit norm condition ($M =

1.00), the preference for the tempting product was lower in the tacit norm condition (M = 0.11). The former two did not differ (F (1, 97) <1). In Study 2, we found that the sweetness dimension, representing the tempting nature of the temptation in phase 1, was properly reflected in the multidimensional map of a set of 6 drinks varying on sweetness and freshness. Individual difference scaling (INDSCAL) analysis revealed that the sweetness dimension weights were significantly lower with the tacit norm (M = .98) compared to the explicit norm (M = 1.07, F (1, 57) = 4.48, p < .05) and to the control condition (M = 1.13, F (1, 57) = 7.37, p < .01), while the latter two did not differ (F<1). With a tacit norm, sweetness effectively becomes a less salient dimension in the product perceptions after exposure to a sweet temptation, whereas this is not the case with the explicit norm.

Two studies show that explicit norms enhance self-regulation in the short run, but tacit norms reduce preferences for the temptation and enhance self-regulation in the long run. The most interesting finding was that people who experience a tacit norm alter their perception of the most tempting dimension of a vice product, by diminishing its importance. From a social marketing perspective, nudging consumers to infer their own norms may be more effective for longer-lasting self-control enhancement than directly imposing the norm.

SESSION OVERVIEW

Contextual cues exert a powerful influence on consumer behavior. These types of cues may be physical, such as the way a grocery aisle is organized or the way that items are grouped. They may also be psychological, such as the way information is presented or framed. Of particular interest to marketers and consumer behavior researches alike is the influence of contextual cues on consumption. Contextual cues may increase consumption, such as when they increase perceptions of variety in the set or decrease satiation, but they may also decrease consumption, by serving as stopping rules or enhancing motivation to pursue goals of self-restraint. In addition to influencing the amount consumed, contextual cues may also change what is consumed. Consumption choices tend to be sensitive to the way that items are grouped, a phenomenon known as partition dependence; consequently, changing the way that items are grouped may alter the composition of consumers' consumption choices. In this session, we explore the impact of contextual cues on consumption across a variety of situations. Our findings bring to light new ways that contextual cues may be strategically used to influence consumption.

The first paper (Etkin and Ratner) focuses on the role of partitioning (i.e., breaking a single large quantity into multiple smaller quantities) in influencing consumption; in particular, they show that the exact same partitions can both increase and decrease consumption, depending on actual and perceived variety among items and on the magnitude of transaction costs associated with partitions. The second paper (Lasaleta and Redden) explores the role of framing on satiation. Contrary to what has been shown in previous work, these authors find that framing items as more similar can actually increase perceptions of variety, increasing consumption by reducing satiation. In the third paper, Wansink, Soman, Herbst, and Payne test the impact of contextual cues on real consumption behavior in a field study. These authors examine the impact of partitioning a grocery cart including one section specifically for fruits and vegetables on actual purchases of fruits and vegetables. Their findings show that simple contextual cues such as these partitioned grocery carts can have a real impact on consumption by altering the content of consumers' shopping carts. Lastly, Nowlis and Scott explore how the framing of numerical goals impacts consumption. When pursuing a goal to restrain consumption, these au-

thors show that range goals (e.g., consume 20-30% of the M&Ms) decrease consumption relative to number goals (e.g., consume 30 M&Ms). Further, participants with range goals reported feeling better about themselves and being more motivated to pursue their relevant goals relative to participants with number goals.

We expect that this session will be of interest to a wide audience: specifically, researchers interested in contextual cues, consumption, self-restraint, and motivation. These four papers all feature research that makes novel theoretical contributions to existing work on the impact of contextual cues on consumer behavior and are of substantive relevance for decreasing overconsumption and improving consumer health and welfare. Several studies have been conducted for each of the papers described below and several are available as working papers.

Mixed Signals: The Impact of Partitioning on Consumption

EXTENDED ABSTRACT

Previous research has made opposing predictions about how partitioning (i.e., breaking a single large quantity into multiple smaller quantities) will affect consumption. On one hand, some work has shown that partitions increase consumption (Kahn and Wansink 2004), suggesting that people might consume more from several smaller bowls of candy than from a single large bowl of candy. On the other hand, other work has shown that partitions decrease consumption (Cheema and Soman 2008; Rolls et al. 2004; Wansink 2004; Wansink, Geier, and Rozin 2011), suggesting that people might consume less from several small bowls of candy than they would from a single large bowl. What might explain these divergent findings?

We propose that partitions serve multiple roles in influencing consumption: they act both as decision points to continued consumption and as signals of variety. Partitions serve as decision points by defining the appropriate amount to consume and by drawing attention and inducing costs to keep consuming (Cheema and Soman 2008; Coelho Do Vale et al. 2008; Geier et al. 2006; Wansink et al. 2004). In their role as decision points, partitions exert a negative effect on consumption. However, partitions can also serve as signals of variety by highlighting the variety in a set of items (Kahn and Wansink 2004; Mogilner et al. 2008). In their role as signals of variety, partitions exert a positive effect on consumption (if the partitions indicate more variety than was perceived in the absence of partitions).

In the present research we identify two factors that determine how partitioning will influence consumption: the degree of variety within the set (i.e., whether items are identical or varied) and the magnitude of transaction costs coupled with the partitions. When dividing a large set of varied items, partitions can act both as decision points and as signals of variety. However, because there is no actual variety among a set of identical items, partitions primarily serve the role of decision points when separating identical items. Thus, we expect partitioning to have a more positive impact on (i.e., increasing) consumption when items are varied versus identical. Further, we expect the magnitude of transaction costs to go between partitions to exert a negative effect on consumption. Because this negative effect should be partially offset in the varied condition due to the positive influence on consumption of partitions as signals of variety, we predict the magnitude of transaction costs to go between partitions

will have a less negative impact on consumption of varied versus identical items.

Across three studies we find consistent support for our predictions. Study 1 provides a demonstration of how the effects of partitioning differ depending on the degree of variety in a set of items (identical vs. varied jellybeans) and the magnitude of transaction costs to go between partitions on consumption of a real snack. We gave participants in this study a snack of 60 jellybeans and varied whether those jellybeans were all the same flavor (identical condition) or 12 different flavors (varied condition), whether the jellybeans were partitioned (into 12 groupings) or unpartitioned, and whether partitions were primarily psychological (i.e., divided into different, adjacent small jars) or coupled with transaction costs to go between partitions (i.e., each jar was individually wrapped in saran wrap, requiring participants to unwrap each one separately). As we expected, dividing the candies with mere partitions had a more positive effect on consumption when items were varied ($F(1, 243) = 6.31$, $p < .05$) than identical ($F(1, 243) = 2.18$, $p > .1$), and the presence of a more substantial transaction cost to go between partitions (i.e., saran wrap) had a more negative effect on consumption when items were identical ($F(1, 243) = 3.89$, $p < .05$) than varied ($F < 1$).

In study 2 we sought to replicate the differential effects of partitioning on the consumption of varied versus identical items while holding the items themselves constant. We gave participants a "virtual" snack of 60 plain M&Ms that were either partitioned (i.e., depicted on a computer screen and separated by grid lines) or unpartitioned (i.e., no grid lines). To manipulate perceptions of variety, in the identical condition we reminded participants that M&Ms are all chocolate, whereas in the varied condition we reminded participants that though M&Ms are all chocolate, they come in many different colors. Consistent with the results of study 1, partitioning had a more negative effect on consumption when participants were instructed to think of the M&Ms as identical ($F(1, 204) = 10.64$, $p < .01$) than varied ($F < 1$).

Finally, in study 3 we explored the role of magnitude of transaction costs to go between partitions in influencing consumption. Participants were given a virtual snack of either varied or identical jellybeans, which were either partitioned or unpartitioned. Unlike in the previous two studies, here all partitions were coupled with transaction costs to go between partitions. In particular, we covered the partitions with virtual "lids", similar to the saran wrap used in study 1, and we required participants to remove these virtual lids before they could select the jellybeans within the partitions. We manipulated the magnitude of the transaction cost by varying the time it took participants to remove the virtual lids. In the small cost condition, the lids took one second to be removed; in the large cost condition, the lids took three seconds to be removed. As we expected, the magnitude of the transaction cost to go between partitions had a more negative effect on consumption of identical versus varied items. Specifically, consumption linearly decreased as the magnitude of the transaction cost increased when the jellybeans were identical ($F(1, 169) = 13.90$, $p < .01$), but no such trend was apparent when the jellybeans were varied ($F < 1$).

Previous research makes conflicting predictions regarding the impact of partitioning on consumption. In the present work, we offer a way to reconcile some of these opposing findings by identifying the degree of variety in a set of items and magnitude of transaction cost as two factors that determine the direction of influence of partitions. Our framework contributes to the literature on partitioning by offering a more comprehensive view of partitions as occupying multiple roles in influencing consumption behavior.

Unrelated Variety: When Greater Dissimilarity Can Increase Satiation

EXTENDED ABSTRACT

People satiate with repeated consumption, creating a "hedonic treadmill" whereby they no longer enjoy their favorites and must find new sources of enjoyment. One way to slow down satiation is greater variety. For example, Rolls et al. (1984) found that participants ate 40% more yogurt when the flavor was varied, presumably because they satiated less.

Accordingly, the prevailing belief is that greater variety slows satiation. Variety here depends on the extent to which items in the assortment share attributes (Hoch, Bradlow and Wansink 1999; Kahn and Wansink 2004; Tversky 1977). That is, variety increases as stimuli are less similar to each other, and greater dissimilarity reduces satiation. We challenge this view by showing that consumers satiate faster if two stimuli are so dissimilar that they are placed into different categories.

Categorization research shows that satiation depends on how people categorize the episodes. For instance, consumers satiated slower on jellybeans when they were subcategorized by flavor versus a single general category (Redden 2008). Subcategorization focuses people on the variety among the items they are consuming. However, we propose that when the items seem too dissimilar, people no longer consider them to be a source of variety for each other. Thus, increasing dissimilarity can reduce perceptions of variety and accelerate satiation.

Imagine dinner at a restaurant where one is bombarded by a myriad of sounds, aromas, conversations, and décor. Even so, satiation with the large chicken entrée still seems to creep in. It seems that, although immersed in variety, people consider only particular stimuli (i.e., the meal itself) as a potential source of variety. People seem to place stimuli into different subcategories, with satiation being affected only by "relevant" stimuli in the same subcategory.

Given this role of categorization, we propose a non-monotonic relationship between similarity and satiation. When similarity is high, we predict increases in similarity will increase satiation. This follows from past work on variety and satiation (e.g., Rolls et al. 1984). However, when similarity is low, we predict increasing similarity will decrease satiation because it encourages people to appreciate the full variety in the overall experience. Three studies confirm these predictions.

Study 1 asked participants (n=84) to rate their enjoyment while eating seven chocolate candies. Participants were told they would be periodically asked to also eat small crackers. In the related condition, participants were told that the crackers were another snack food; in the unrelated condition, they were told the crackers were fillers between candy ratings. Participants satiated faster in the unrelated condition than the related condition. Framing the filler crackers as another snack food (i.e., more similar) actually decreased satiation.

Study 2 replicated these results for participants (n=150) listening to a classical music piece twelve times. Here, participants were told that between clips they would hear nature sounds. Participants in the related condition were told, "from time to time, you will also hear some nature sounds that are much like music. Research has found that nature sounds follow patterns and rhythms often found in classical music." Those in the unrelated condition were told, "from time to time, you will also hear some nature sounds to fill time in between the music." Results show ratings of enjoyment declined slower in the related condition than the unrelated condition. Process evidence indicates that perceptions of variety mediate this effect – the variety

offered by nature sounds helped reduce satiation more when participants thought of them as similar and related to the classical music.

Study 3 further tests our theoretical framework by demonstrating the U-shape relationship between similarity and satiation. Participants (n=304) rated a classical music piece twelve times, with an intervening sound clip after every third play. The study followed a 2 (intervening sound clip: pop song, nature sounds) x 2 (similarity: alike, dislike) design. The pop song (U2's "With or Without You") was chosen to be mildly similar to the classical music; the nature sounds to be highly dissimilar. After hearing both clips one time, similarity was manipulated by asking participants to write how the two clips were alike (alike condition), or dislike each other (dislike condition). Results indicate an interaction between the intervening sound clip and similarity. With unrelated nature sounds, participants satiated less when focused on how these were like the classical music. Participants apparently did not view the nature sounds as a form of variety unless explicitly encouraged to consider how they are related. In contrast, for the somewhat similar pop song, participants satiated more when asked to focus on how it was like the classical music. Participants presumably already saw the pop song as offering variety in the music so pointing out the similarities increased their satiation.

In conclusion, the prevailing notion in the literature is that variety reduces satiation, and variety largely depends on the similarity of the stimuli. We propose instead that perceived variety depends on how stimuli are categorized. When seen as largely unrelated (e.g., classic music and nature sounds), increasing perceived similarity helps consumers appreciate both of these stimuli as offering variety. This may explain why people often fail to appreciate the variety around them (Galak, Redden, and Kruger 2009). It also suggests a reason why time often is not enough to recover from satiation – people see the variety of intervening experiences as unrelated to what is currently being consumed.

Partitioned Grocery Carts: How Assortment Allocation Cues Can Increase Fruit and Vegetable Purchases

EXTENDED ABSTRACT

Given increasing concerns over the growing obesity problem in the United States, large efforts have been initiated to encourage the purchase of healthier foods (Kessler 2009; Nestle 2002). Unfortunately, many attempts to encourage healthier shopping behavior – such as in-store education programs and soft drink taxes – have often been unsuccessful because they were ignored by consumers or ran counter to the incentives of supermarkets (Brownell and Frieden 2009). After these unsuccessful attempts, the question needs to be reframed: How can distracted shoppers be prompted to develop healthier shopping habits that can be profitable to grocery stores?

Two research questions are addressed: 1) How does partitioning influence purchase and assortment allocations when grocery shopping? 2) What shoppers are most influenced by partitioning? Because the use of partitioned carts could provide an inexpensive intervention which would not restrict or penalize choice, the answer to these questions would be of interest to a wide range of stakeholders:

• **Supermarkets**. Using modified shopping carts could shift the distribution of sales to higher-margin foods (such as perishable produce), and it may do so without decreasing total food sales.

• **Consumers**. A simple "half-cart" rule-of-thumb could subtly emphasize the tradeoffs between healthy and less healthy foods while grocery shopping.

• **Public Policy Officials**. Partitioned carts could be championed and more quickly accepted by supermarkets than common policy proposals that focus on nutrition information, taxation, or subsidies.

After providing an overview of decision making under nutritional uncertainty, the notion of social norms and mental accounting categorization is reviewed and related to this overlooked context of grocery shopping and grocery carts. In this context, the potentially moderating influences of the size of a shopper's family, their experience as a grocery shopper, and the extent to which they are distracted are then discussed. Study 1 examines whether shoppers purchased fruit and vegetables in proportion to the size of a cart's partition, and Study 2 examines who is most influenced by partitions.

Together, these results show that partitioning a shopping cart with colored inserts or a simple strip of yellow duct tape caused healthy choices to become salient, and it led customers to spend more money on fruit and vegetables while shopping. In Study 1, shoppers with partitioned carts purchased a combined total of 51% more fruit and vegetables than did those in the control condition ($17.54 vs. $11.61), and in Study 2, shoppers with partitioned carts purchased a combined total of 76% more ($18.81 vs. $11.61). The mere presence of these visual benchmarks increased choice set consideration and promoted purchase without any corresponding decrease of total sales per shopper.

Healthy foods are profitable foods for grocery stores to sell. There are often higher profit margins for these foods, and there are higher spoilage costs for not quickly selling them if they are perishable. Yet, the impact of partitioning is not only relevant to produce or to fruit and vegetables purchases. These were simply the operationalizations in the two studies. A retailer could just as easily use partitioning to suggest another categorization scheme, such as store brands versus national brands, or natural foods versus processed foods. Similarly, consumers could use a similar process with fat versus non-fat foods or low sodium and high sodium foods.

The Effect of Goal Specificity on Continued Consumer Goal Pursuit

EXTENDED ABSTRACT

This research focuses on the effect of goal specificity on the interest in continued goal pursuit. For example, consumers might set a specific goal to lose 2 pounds; or, consumers might set a less specific goal to lose 1 to 3 pounds. Thus, when setting a goal, consumers may consider: should my goal be a single number (i.e., a number goal) or a range (i.e., a range goal)? We examine if one type of goal is superior to the other in terms of increasing motivation to continue pursuing the goal. For example, would a consumer be more likely to stick to a weight loss goal if the goal was a specific number or if the goal could fall within a range of outcomes?

Individuals pursuing relatively more difficult and specific goals (e.g., a number goal) tend to experience greater performance levels, but lower success rates, compared to people pursuing easier and non-quantitative goals (e.g., work at a moderate pace). This phenomenon has been termed the "performance-success dilemma" (Locke and Latham 1990) since it may be easier to succeed with an unspecific goal ("just do your best") yet this can lead to lower overall performance. Prior research shows that as goals increase in specificity, performance variance decreases, when controlling for difficulty (Locke et al. 1989).

Goals can serve as reference points that influence a consumer's willingness to initiate goal pursuit and to continue to pursue the goal over time (Heath, Larrick and Wu 1999). We propose that range goals are different from number goals in important ways that influence the motivation to continue. Range goals contain two reference points (e.g., lose 5 - 15 pounds), whereas a number goal contains only one reference point (e.g., lose 10 pounds). This two reference point structure of the range goal can result in 1) greater success rela-

tive to the number goal, even when the performance level is the same and 2) perceptions that the range goal is more challenging than the number goal. We propose that a range goal offers both attainability at the low end of the range and challenge at the high end of the range; whereas a number goal will be perceived to be challenging but less attainable. We propose that consumers with range goals will be more interested in continued goal pursuit over time (vs. consumers with a number goal).

Study 1 was a 2 (goal type: number, range) x 3 (timing: T1, T2, T3) mixed design experiment. Participants were 53 females in a 10-week weight loss program, $M_{AGE} = 47$ and $M_{BMI} = 31.01$ (BMI 30+ is obese). Participants attended weekly group sessions to weigh-in and learn about healthy lifestyle practices. Although actual weight loss was not significantly different between the number goal and range goal conditions, success rates were higher for participants with range goals (vs. number goals), ($F = 8.90$; $p < .005$). People with range goals also enjoyed the process ($F = 11.22$; $p < .005$) and felt good about themselves ($F = 4.81$; $p < .05$) to a greater degree than those with number goals. We measured interest in continued goal pursuit using re-enrollment behavior at the end of the 10-week program. Participants with range goals re-enrolled at a higher rate than those with number goals ($M_R = 79.6\%$ vs. $M_N = 49.9\%$; $F = 4.44$, $p < .05$).

Study 2 was a 2 (goal type: number, range) between subjects experiment, with 110 undergraduates. Participants tried to consume as few M&Ms as possible while there were 100 M&Ms were in front of them for 40 minutes. As in study 1, consumers with range goals experienced a higher success rate than those with number goals ($M = 58.62\%$ vs. $M = 32.69\%$; $F = 7.80$, $p < .01$). Furthermore, people with range goals felt better about themselves ($M = 3.77$ vs. $M = 2.79$; $F = 6.99$, $p < .01$).

To examine the underlying process, Study 3 assigned participants to an anagram task with a low number (solve 2), high number (solve 8), or range (solve 2 – 8) goal. We found that consumers with low number goals found the goal more attainable but less challenging, people with high number goals found the goal more challenging but less attainable, and people with range goals perceived high levels of both attainability and challenge. People with range goals experienced significantly higher motivation (vs. low number and high number). The low and high number conditions led to lower motivation for different reasons. Although the low number goals led to high success rates, they lacked challenge; although the high number goals were challenging, they led to lower success rates.

In Study 4 consumers participated in a shopping task. Their goal was to save money by purchasing grocery items at the lowest price. Using their grocery list and coupon book, participants attempted to complete their shopping in four minutes. After answering a few practice questions, participants were asked to set a low number, high number, or range goal for the number of points they would earn (by saving money) in the game. As in study 3, the low number goals were more attainable but less challenging, the high number goals were less attainable but more challenging, and the range goals were both attainable and challenging. Consumers with range goals were more motivated relative to those with low or high number goals.

Study 5 examines how to improve motivation among people with a number goal. Consumers tend to think of themselves, and their performance on a task, as better than the average person in their reference group (Alicke et al. 1995). Thus, when consumers are asked to explicitly compare their performance against the performance of abstract reference group members, they tend to be happier with their own performance. Since number goals are challenging, but are less attainable (lower success rates), in Study 5, we manipulate feelings of success (independent of performance). We predict that motivation will increase for a number goal when consumers compare their performance to a peer group. Study 5 was a 2 (range, number) x 2 (control, average student) between subjects experiment. Our findings demonstrated an interaction for motivation; consumers in the number conditions experienced more motivation when they considered their performance relative to the average student; individuals in the range conditions showed no differences, presumably because they already feel good due to attaining a challenging goal.

SESSION OVERVIEW

A substantial body of consumer research has demonstrated the power of one's immediate environment on his or her judgments and decisions. Environmental cues have been shown to affect awareness of available choices, shape decision goals, and even alter how consumers process information. However, research on environmental effects has only recently begun to consider elements of the natural environment, such as sunlight and temperature, as sources of influence in decision processes. These variables, although often overlooked, are omnipresent in the lives of consumers and thus it is important to understand what effects they may have.

In this proposed session, we will be looking at cutting-edge research about environmental effects on consumer behavior. The first two papers focus on environmental factors related to weather, examining how light and temperature influence financial decisions and consumer preferences. The final two papers focus on social factors in the environment, examining how the ratio of men to women in the environment influences consumer behavior. Three of the papers combine both experimental studies and archival data, while the fourth paper uses experimental fMRI techniques to provide deeper insights into environmental effects.

In the first paper, **Reinholtz, Lee, and Pham** examine whether exposure to sunlight will increase an individual's tendency to take risks. The authors conduct a laboratory study in which they manipulate a participant's direct exposure to sunlight. Participants in the sunlight condition show an increased preference for risk. Further, the authors find evidence for their hypothesis in real world behavior, looking at both individuals parking cars illegally and baseball players stealing bases.

In the next paper, **Hong and Sun** examine another weather related environmental effect: the influence of physical temperature on a consumer's movie selection. The authors find that cold temperatures lead consumers to show a greater preference for romance movies. The authors further show that this result is driven by an association of romance movies with psychological warmth. Finally, the authors

show evidence of this effect in the real world, using data from an online movie rental business and local weather data.

The third paper moves away from cold, but continues with the theme of romance. **Craig, Wood, and Vendimia** look at how sex ratios in the immediate environment affect an individual's desire to signal status. The authors show that the presence of same-sex individuals (and thus a competitive environmental sex ratio) increase preference for status signaling compared to situations in which there are only members of the opposite sex. The authors supplement this work with a neuroimaging study that shows increased activation in a region of the brain associated with reward.

In the final paper, **Durante, Griskevicius, Simpson, and Cantu** examine the effect of environmental sex ratio (the ratio of men to women in a given location) on career choices and financial goals. The authors show that metropolitan areas with a scarcity of marriageable men tend to produce women who are more oriented towards financial success. Further, the authors show that experimentally manipulating information on local sex ratio can influence both men's and women's desires to invest in career rather than starting a family.

The papers in this session show how various aspects of the environment influence consumer's behavior in surprising ways. The papers build connections by not only examining diverse aspects of the environment, but also by using a diverse set of methodologies inside and outside the laboratory, including fMRI. This session should appeal to a wide range of audiences, including those interested in embodied cognition, conspicuous consumption, risk, neuroimaging, and evolutionary approaches.

Sunny Days, Risky Ways: Exposure to Sunlight Increases Risk Taking

EXTENDED ABSTRACT

The sun influences human life in many obvious ways. In this paper, we investigate a less obvious way in which the sun may impact human experience. Specifically, we look at the link between sunlight exposure and risk taking. Some evidence hints that exposure to sunlight may increase an individual's tendency to take risks. For example, stocks are more likely to experience positive returns on days in which there is no cloud cover over the market's host city (Saunders 1993; Hirshleifer and Shumway 2003). We extend this research by looking at other operationalizations of risk taking behavior. We use both lab and field studies to support the hypothesis that exposure to sunlight increases an individual's tendency to take risks.

In our first study, we employ a sunlight manipulation in the laboratory. We conducted the study on a sunny day and when participants entered the lab, we either had the curtains drawn (so there was no sun exposure) or the curtains up (so the sun could shine into the lab). After completing a filler task to allow for acclimation to the room conditions, participants completed the Balloon Analogue Risk Task (Lejuez et al. 2002). The BART is a standard measure of risk taking in which participants inflate a virtual balloon to the greatest level possible before it explodes. The more the participants inflate the balloon, the more they are paid for the task. However, participants earn no money if the balloon explodes (probability of explosion is an increasing function of the total number of pumps). Using the BART, we found that participants inflated the balloons to a greater level in the sunlight condition (with the shades up). In other

words, we found that sunlight exposure increased the participant's preference for risk. We also found that prior exposure to sunlight (how long participants had been in the sun that day) was also positively correlated with risk-seeking.

In our second study, we collected data at a parking lot in Singapore. Twice-a-day for two weeks, we recorded information on every car parked in the lot. Crucially, because of Singapore's parking payment system, we were able to record the time at which the driver parked the car, whether the car's legal parking period had expired, and the extent to which the car was or was not in violation. We supplemented this primary data with climate measurements from a local weather station. Using logistic regression, we found that the level of solar radiation (sunlight) at the time of parking was a positive predictor of whether the car was in violation. In other words, the sunnier it was outside when an individual parked, the more likely they were to leave their car in violation. Further, we found that higher levels of sunlight at the time of parking were correlated with more severe parking violations.

In our third study, we analyzed 40 years of historical data from Major League Baseball games. In this data, we look at attempted stolen bases as the primary measure of risk taking. We find that stolen base attempts were more likely during day games than during night games. Importantly, we find this effect attenuates for games played in indoor stadiums. Further, we find that baserunners tend to be more successful at stealing bases during night games, suggesting that the increase attempt rate for day games is not motivated by a greater likelihood of success. As a final test of our hypothesis, we merged 15 years of weather data with the baseball data set. For games played in outdoor stadiums, we find that higher levels of solar radiation are positively correlated with more stolen base attempts. Interestingly we also find a positive effect of day-time solar-radiation levels on risk taking in night games. One possible explanation for this finding is that cumulative exposure to sunlight, and not just current exposure, can lead to increased risk taking. This would be consistent with our findings in Studies 1 and 2.

In sum, across three different operationalizations, we find that exposure to sunlight is linked to increased levels of risk seeking. We find positive effects on risk taking for both current level of sun exposure and cumulative level of sun exposure. Possible mechanisms for this effect include an "affective" path and a more direct path. Although the affective path is plausible, research is mixed on the link between positive affect and risk taking. The direct path is intriguing because it implicates a more innate biological basis. It is possible that the tendency to take greater risks while the sun is shining evolved as an adaptive behavior. Current work is focusing on identifying evidence in support of one of these paths versus the other.

Warm It Up With Love: The Effect of Physical Coldness on Liking of Romance Movies

EXTENDED ABSTRACT

Are romance movies more desirable when people are cold? Building on research on embodied cognition (Barsalou 2008; Niedenthal et al. 2005), we hypothesize that physical coldness (vs. warmth) activates a desire for psychological warmth, which in turn leads to increased liking for romance movies. We tested our hypothesis in three laboratory experiments and one analysis of online movie rentals.

Study 1 tests our basic hypothesis that physical coldness leads to increased liking for romance movies. We manipulated physical coldness by giving participants a warm or a cold drink. Participants were first told that they would be taking part in a drink evaluation study. Those in the warm condition were given a cup of hot tea and those in the cold condition were given a cup of iced tea. Participants were told to finish the drink slowly while completing another study on movie preference, which was our main dependent measure. For the movie preference task, we selected four genres (romance, action, comedy, and thriller) and three movies from each genre based on the categorization used by the Internet Movie Database (IMDb.com). Participants were given the information of the movies while drinking the tea. For each movie, participants were first presented with the title, a synopsis, a fictitious viewer rating (ranging from 8.5 to 8.8 out of 10), and the genre of the movie. They were then asked to indicate how much they would like to watch the movie and how good they think the movie would be. The order of the movies presented was randomized. Thus, a 2 (physical temperature: cold vs. warm) × 4 (genre: romance vs. action vs. comedy vs. thriller) × 3 (replicate within genre) mixed design was employed, with physical temperature as a between-subject factor, and genre and replicate as within-subject factors. Consistent with our predictions, we found that physical coldness led to increased liking for romance movies, but not for other genres.

Study 2 was designed to examine the mechanism underlying the effect observed in study 1 that physical coldness increases people's liking of romance movies. We argued that the reason that physical coldness increases liking for romance movies is that physical coldness activates a desire for psychological warmth and romance movies are associated with psychological warmth. To provide evidence for this conjecture, we measured the extent to which people associated romance movies with psychological warmth. Although people in general associate romance movies with psychological warmth, there should be individual differences in terms of the extent of this association. We expected that people's perceived association between romance movies and psychological warmth would moderate the effect. Specifically, for participants who associate romance movies with psychological warmth, physical coldness would lead to increased liking for romance movies; conversely, for those who do not associate romance movies with psychological warmth, the effect of physical coldness on liking of romance movies should be attenuated. The results supported our predictions.

Study 3 was designed to examine people's lay belief about the relationship between physical warmth and psychological warmth. That is, whether they believe psychological warmth can compensate for physical coldness. To examine this issue, we manipulated the salience of people's physical temperature by varying the order of the movie preference task and the measure of physical coldness. Thus, a 2 (physical temperature: cold vs. warm) × 2 (salience of physical temperature: salient vs. nonsalient) × 3 (replicate) mixed design was used. We found that when participants' physical temperature was

measured after the movie preference task, as we did in studies 1 and 2, we replicated our earlier findings that physical coldness increases liking of romance movies; however, when participants' physical temperature was made salient by measuring it before the movie preference task, there was no effect of physical coldness on their preference for romance movies. These results seem to suggest that, at an explicit level, participants did not believe that psychological warmth can (or should) compensate for physical coldness and thus corrected for this influence.

Finally, in study 4, to demonstrate the external validity of the observed effect, we tested our hypothesis using detailed rental records from an online movie rental company in the U.S. The data span a period of nearly three years, from August 2002 to May 2005. In this study, since we could not manipulate physical temperature, we used weather temperature as a proxy for physical coldness (warmth). After controlling for customers' idiosyncratic preference for romantic movies, the availability and quality of the movies in stock, and any seasonal effect that is unrelated to temperature, we still found a significant negative relationship between weather temperature and consumption preference for romance movies; and such relationship was not observed for other major genres (action, comedy, drama, and thriller).

In sum, in three laboratory studies and one study using online movie rental data, we provide support for the hypothesis that physical coldness increases liking of romance movies, but not for other major genres. The current research adds to the growing literature on embodied cognition by showing that physical coldness activates a goal of seeking psychological warmth. Our data also seem to suggest that the association between physical warmth and psychological warmth might operate at a subconscious level and that people do not believe that psychological warmth can (or should) compensate for physical coldness at an explicit level. The current research also adds to past research on seasonality in the movie industry (Eliashberg, Elberse, and Leenders 2006; Radas and Shugan 1998) and offers practical implications for optimizing the release time for romance movies.

More than Just "Sex Sells": The Economics of Attraction Motives in Complex Social Consumption Contexts

EXTENDED ABSTRACT

Marketers often use provocative tactics to capture consumers' interest in brands, products, and messages. Ads often depict an attractive model in a sexually suggestive pose or setting even when the image has little to do with the product message. Recent research demonstrates that incidental exposure to sexual stimuli lead male consumers to choose smaller, more immediate rewards (Van den Bergh, Dewitte, and Warlop 2008) and to spend more of their resources to signal social status or uniqueness (Griskevicius et al. 2007). Many marketers might look at these effects and see them as evidence of the old business adage, "sex sells."

Recent research in consumer behavior has additionally shown that the presence of other people, even those unrelated to the consumer, activate relational goals that influence status signaling behavior (Argo et al. 2005). Here, we examine the role of a particular type of "mere presence" effect: sex ratio, or the ratio of males to females in an environment. While basic reward sensitive perspectives demonstrate that viewing attractive individuals of the opposite sex increases status signaling (Griskevicius et al. 2007) and risk taking (Ariely and Loewenstein 2006; Van den Bergh et al. 2008) through motivation for reward, both advertisements and retail environments contain more complex social groups. Specifically, it is unclear how same-sex presences may impact status and reward seeking behavior.

Derived from biological research, research on sex ratios may accurately predict the effect of a varied social environment (or advertising context) on an individual's status signaling behavior (Baumeister and Vohs 2004). Sex ratio research predicts that as the competition level increases (i.e., number of same-sex individuals relative to opposite-sex individuals increases), behaviors designed to signal status should increase. Thus, we propose a reward perspective that incorporates sex ratio and provides two behavioral studies and one neuroimaging study that support a sex ratio sensitive reward model. Across two behavioral studies that utilize priming paradigms, we demonstrate that competitive sex ratios a) increase status signaling above sex ratios that lack competition and b) depend on the attractiveness of same-sex competition.

In Study 1, we primed sex ratio using a sequence of images that depict attractive opposite and same sex faces. The study had four conditions: a Control condition with no faces and three Sex Ratio conditions that varied the ratio of same-sex individuals from zero (No Competition), to a few (Low Competition), to many (High Competition). Status signaling (operationalized as willingness to pay for status products; Griskevicius et al. 2007) was then measured for a series of status-related items in an ostensibly unrelated task. Findings showed that Low and High Competitive sex ratios result in increased status signaling relative to both No Competition sex ratios and neutral control. Thus, mere exposure to mixed-sex groups led people to be more willing to pay for status products when the sex ratio contained same-sex individuals.

Study 2 extended the findings from the first study. Using a similar paradigm as the first study, Study 2 manipulated the attractiveness of same-sex competition photos, thus varying competition not only through quantitative ratio but qualitative competitiveness. Results conceptually replicate Study 1, showing that mere exposure to competitive sex ratios led people to want to signal status. In addition, we show that the presence of attractive competitors produced to the strongest desire to signal status.

Study 3 utilized a novel functional magnetic resonance imaging (fMRI) paradigm to explore neural changes in response to sex ratios. A sex ratio model suggests that the desirability of the opposite sex increases when competition is present. Thus, we examined the brain's response to sets of images that contain either competition or no competition. Within the Nucleus Accumbens (NAcc), an area of the brain that encodes desirability (Aharon et al. 2001), we observe an increase in neural activation for pictures of attractive opposite sex faces when they have been viewed in the presence of attractive same sex faces. Thus, we find that exposure to competitive sex ratios increase reward value in the nucleus accumbens.

Our contribution is twofold: first, we find that the age old advertising maxim that "sex sells" is not as simple as conventional wisdom holds. Instead, our data suggest that the response to sexual cues is likely a complex strategic response that nonconsciously incorporates environmental conditions. Second, this study is an important step in understanding the effects of heterogeneous social groups on consumer decision making. Just as significant individuals motivate behavior (Fitzsimons and Bargh 2003), so do the psychophysical properties of a group. Overall, our results have useful implications for marketers designing advertisements depicting attractive models or retail spaces which facilitate customer—employee interaction.

The Influence of Environmental Sex Ratio on Financial Earnings

EXTENDED ABSTRACT

The ratio of males to females in the environment is known to be an important factor in determining animal behavior (Guttentag and Secord 1983). Changes in sex ratio influence behavior via the economic logic of evolutionary biology. Because it is more difficult for the plentiful sex to attract mates, the plentiful sex has to work harder for evolutionary success. The most commonly observed pattern in animal behavior is that when the opposite sex becomes scarce, individuals increase intrasexual competition.

Sex ratios also vary in human populations. For example, whereas Las Vegas, Nevada, has 1.16 men per every woman, Birmingham, Alabama, has 0.88 men per every woman (Kruger, 2009). Sex ratios can also vary between nations. Multiple Asian countries have recently become strongly male-biased. In the most striking case, China will soon have a surplus of over 40 million men, producing an adult sex ratio of over 1.2 men for every woman (Hesketh 2009).

Correlational research at the population level has begun to examine how sex ratio relates to various human behaviors. Paralleling findings in animal behavior, a scarcity of the opposite sex in human population is associated with increased competition among the plentiful sex. For example, male aggression and violence increase as populations become more male-biased (Barber 2003). Similarly, female aggression increases as populations become more female-biased (Campbell 1995). The plentiful sex appeals to amplify competition when there is a scarcity of the opposite sex.

Drawing on emerging theory in evolutionary psychology, we hypothesized that sex ratio might have a considerable effect on financial aspirations. For example, a scarcity of marriageable men might motivate women to allocate more time and effort into earning immediate monetary rewards. Although the reasons why women choose to devote a great deal of time and effort toward earning money is likely to be complex, we contend that an often overlooked factor in women's desire for monetary rewards is the ratio of adult men to women in the local population.

Study 1 looked at U.S. population data to examine the link between sex ratio and women choosing high-paying careers. We looked at sex ratio in the top 10 largest metropolitan areas in the U.S. and the percentage of women in the top 10 highest-paying careers. Findings showed that a scarcity of marriageable men was strongly related to more women entering high-paying careers. This finding, based on real-world data, suggests that the availability of mates could have important implications for whether women pursue monetary rewards.

Because earning a high salary may come at the expense of investing time into family, Study 2 tested the prediction that experimental manipulations of perceived sex ratio should influence how women prioritize earning money vs. starting a family. Women viewed photo arrays of men and women that were ostensibly indicative of the local population. The arrays were either male-skewed, female-skewed, or equal sex ratio (control). Participants then indicated their desire to pursue high-paying careers versus starting a family. Consistent with predictions, experimentally manipulated female-biased sex ratios led women to increase their desire for earning a lot of money rather than having a family.

Study 3 sought to conceptually replicate the experimental findings for women using a different sex ratio manipulation and test whether sex ratio influences men's career aspirations. Participants read news articles describing the local population as either male-biased or female-biased. Participants then indicated their desire to pursue high-paying careers versus starting a family. Findings showed that when there was a scarcity of men, women once again prioritized earning money relative to investing in family. Findings also revealed a parallel pattern for men: When women were scarce, men were more interested in pursuing high-paying careers.

Study 3 also examined a key individual difference, which provided insight into which individuals were driving the effects. We examined how sex ratio influenced desire for high-paying careers for people who differed in attractiveness, meaning that they were differentially able to compete for mates. Findings showed that a scarcity of women led men to aspire to high-paying careers when those men were more attractive. Conversely, a scarcity of men led women to aspire to high-paying careers when those women were less attractive. This pattern suggests that women who can secure a mate more easily might be less inclined to pursue a high-paying career. However, increased competition appears to motivate less attractive women to allocate greater effort to careers that offer more financial rewards.

Our findings highlight people's sensitivity to a particular feature of the social environment—the ratio of adult men to women. Just as sex ratio has important effects on animal behavior, we find that it also has theoretically consistent and important effects on humans. We find that a scarcity of the opposite-sex leads both men and

women to invest in high-paying careers. For women in particular, this suggests that whether a woman chooses a briefcase or a baby—whether she invests heavily into a career or into family—appears to be related to the local mating ecology and the availability of mates.

SESSION OVERVIEW

Obesity is on the rise. At last count, 68% of US adults were classified as overweight and 34% as obese, more than twice as many as 30 years ago (Flegal et al. 2010). Since it is unlikely that the genetic make-up of the US population has changed drastically during the last decades, the rapid increase in obesity is rather due to environmental and behavioral changes (Stroebe et al 2008). Accordingly, extant research has frequently investigated influences in the eating and food environment (Wansink 2004) and demonstrated that consumers are sometimes aware of these influences on their consumption and develop strategies to guard against them. For instance, consumers know that package size affects the amount they consume and try to protect themselves from these influences by buying smaller packages (Wansink and Park 2001; Wertenbroch 1998).

This session adds to and advances existing research in this field by presenting four paradoxical effects in the domain of food consumption that consumers might not expect or, even worse, that result from consumers' strategies to protect themselves from self-control inhibitors. The first paper by **Plassmann, Chandon, Wadhwa, Linder, and Weber** uses behavioral and fMRI studies to show that individuals perceive products labeled as "light" to be less intense in taste than products labeled "regular" and, hence, consume more of them to reach the desired flavor satisfaction. This effect is driven by an increase in wanting and helps to explain the paradoxical effect that consumers overeat "healthy" products although they expect to like them less. In the second paper, **Klesse, Goukens, Geyskens, Wertenbroch, and de Ruyter** demonstrate that dieters actively engage in variety-seeking behavior because they believe it helps them

to lose weight not knowing that this strategy often backfires. This research demonstrates that eating a variety of food items compared to eating the same food decreases individuals' monitoring capacity and makes them underestimate how much they have consumed. Moreover, they demonstrate that variety affects subsequent seemingly unrelated decisions by increasing desire for high-calorie food items. In the third paper, **Huh, Vosgerau, and Morewedge** demonstrate that complementary food consumption (foods consumed together like crackers and cheese) occurs even when the consumption of one food is only imagined. This research demonstrates that simply imagining the consumption of one food increases wanting of a complementary food. In the fourth paper, **Campbell, Manning, Leonard, and Manning** consider the effect of overweight cartoon characters on children's consumption. Specifically, they show that overweight cartoon characters make the concept of eating more salient, thus increasing children's consumption of low-nutrient food. This paper is the first to show that perceived weight of others, even fictitious characters, influences children's eating behavior.

Taken together, the papers (all in advanced stages) reveal four unobtrusive factors that foster increased calorie intake. In doing so, this session demonstrates that risks can be inconspicuous, might arise from consumers' strategies to lose weight, and affect consumers of all ages. As this session integrates diverse paradoxical eating phenomena, we believe it contributes to "building connections" by encouraging communication between researchers from different research areas: it is expected to appeal to a broad audience, especially those interested in self-control and factors that influence our consumption behavior outside of awareness.

Health Claims, Overeating, and Flavor Intensity: Behavioral and FMRI Insights into the Paradox of Low-Fat Food and High-Fat People

EXTENDED ABSTRACT

As the popularity of healthier menus increases, so does the weight of many Americans. How can we explain the American food paradox of simultaneous increase in obesity and in the popularity of healthier food choices? One explanation is that people eat more when foods are positioned as healthy, for example when they have a "low-fat" label (Chandon and Wansink 2007). However, other studies (Raghunathan, Naylor, and Hoyer 2006) have shown that people expect healthy food to taste less good. How can we reconcile these two findings and explain why people eat more when they expect the food to taste less good?

Existing research on the psychology of food consumption suggest that this paradox may be explained by calorie compensation. Stated simply, people may eat more when the food is perceived as healthy because they expect that it contains fewer calories and hence that they can eat more of it without gaining weight (Wansink and Chandon 2006). Self-control failures and goal balancing may also explain the paradox to the extent that foods positioned as healthy causes lapses in self control (Scott et al. 2008) and that the availability of healthy foods may actually increase people's motivation to consume indulgent, tasty food (Finkelstein and Fishbach 2010).

This research provides and tests another explanation of the American food paradox. Our hypothesis is that people expect food positioned as healthy to have a less intense flavor, and consume

more of it to achieve the desired levels of flavor satisfaction and satiation. This mechanism was not identified before because of the well-known difficulty for people to distinguish between the intensity and valence of flavor, especially for commercially successful foods which have mild levels of intensity and pleasant flavors (Bartoshuk et al. 2006). In other words, when people say that they expect healthy food to taste less good, what they actually mean is that they expect its flavor to be less intense. We test these predictions in three studies.

In a first study, 69 participants were asked to add milk to a chocolate or vanilla powder that was either labeled "light" or "regular". We found that people added less milk when the powder was labeled "light" (M = 101 ml, SEM = 2.9) than when it was labeled "regular" (M = 109 ml, SEM = 3.0; F(1,68) = 8.52, p = .006) yet these participants expected that they would have to drink more of the prepared drink to feel full and satiated for three hours when it was labeled "light" (M = 158 ml, SEM = 14.0) as compared to when it labeled regular (M = 129 ml, SEM = 9.3; F(1,68) = 3.19, p = .08). In addition, this effect was stronger among people with a high score on the reward responsiveness personality scale (Carver and White 1994), F(1,68) = 3.77, p = .05, suggesting that the effect is driven by an increased "wanting" for light products.

These findings suggest that participant expected the "light" powder to provide a less intense flavor, which would have to be compensated by higher quantity. These results are inconsistent with a hedonic motivation explanation since people would not drink more of a drink that they expect to taste less good. They cannot also be explained by calorie compensation, which would have led people to compensate for the lower calories of the powder by pouring more, not less, milk. Further, while self control and goal balancing theories predict the presence of healthy food to trigger consumption of indulgent food, an enhanced wanting for light and therefore healthy drink that is expected to taste less good cannot be explained by these theories.

To get a better understanding of the role played by expectations of flavor intensity in driving the results of study 1, we conducted an fMRI study to investigate the effect of nutrition and composition claims on flavor perception and its neuropsychological bases. Unlike in study 1, we compared three different types of claims that were pre-tested to have different effects on taste expectations: "organic" (seen as a promise of healthy food & better taste), "light" (healthy but low taste), and "regular" (control condition). We found that people expected to enjoy chocolate and vanilla drinks more when they were labeled "organic" (M = 6.1) versus "regular" (M = 5.6) versus "light" (M = 5.2). People also expected the taste to be significantly less intense when the foods were labeled "light" (M = 5.1) versus "regular" (M = 5.9) or "organic' (M = 6.1), although the difference between "regular" and "organic" was not statistically significant.

Analyses of the brain activity while people were consuming identical foods with the three different labels showed more activity in the brain areas that respond to flavor pleasantness (i.e. the orbito-frontal cortex) in the "organic" versus "regular" label condition, but more activity in the brain areas that respond to flavor intensity (i.e. the ventral striatum, amygdala) in the "light" versus "regular" label condition. This results support earlier findings about the unreliability of self-reported measures of flavor intensity, which did not adequately represent brain activity, and demonstrate the value of measuring brain activity to understand the effects of food claims.

Overall, our results suggest that people expect lower flavor intensity of light products, and thus eat more to achieve the same level of reward as with regular food. This may explain the paradoxical phenomenon that people overeat light products even though they expect to like them less. In an ongoing study, we are trying to understand further the process behind the effects of health and nutrition claims manipulating people reward seeking drive ("wanting") and measured subsequent consumption behavior through pharmacological interventions.

The Variety Paradox: Variety Sounds
Good but It Ruins Your Diet

EXTENDED ABSTRACT

Americans are obsessed with dieting. They try different diets and spend more than 30 billion dollar fighting fat (Freedman 2010). Many dieting programs offer a variety of diet food, suggesting that eating a variety of food is healthy and helps lose weight. In line with these claims, we find that individuals who are on a diet are more likely to integrate variety in their choice (Study 1) and believe that eating a variety of different food helps them to lose weight (Study 2). Yet research on the variety effect shows that variety increases consumption (Raynor and Epstein 2009; Rolls et al. 1981).

The primary purpose of our research is to explain the discrepancy between individuals' beliefs that variety is good on the one hand and the consequences of these beliefs on the other. Why do individuals think integrating variety into their choice is good for them if in fact it increases consumption? We present two studies that examine consumer beliefs and then conduct an experiment to explain the discrepancy.

Study 1 investigates whether consumers who want to lose weight and those that don't differ in their likelihood to switch away from a food previously eaten and try out something new. Sixty-five students either tasted a small piece of chocolate cake or chocolate waffle. Afterwards, participants went into an adjacent room one by one where an experimenter offered them the choice between a piece of cake or waffle (identical to those in the taste test). We measured variety seeking as switching away from the product eaten during the taste test. Comparing dieters and non-dieters on their likelihood to switch away from the product eaten first, shows that dieters are significantly (p =.02) more likely to integrate variety in their choices than non-dieters.

Study 2 assesses whether dieters believe that integrating variety into their choices helps them lose weight. Fifty-eight female students who wanted to lose weight were asked to carefully watch their food patterns during one week. They subsequently provided feedback about their experience. They responded to the item 'during this week, I integrated more variety in my choice than normal' and rated their dieting behavior during the week on a scale from 1 to 10 (10 = very good). A regression analysis of dieting behavior ratings on variety choice ratings as the predictor variable showed that individuals believe that integrating variety into their consumption choices is beneficial for losing weight (B = .40, p = .027).

Study 3 investigates whether eating a variety of different food items compared to eating only one type of food has an influence on how well individuals know how much they consumed. The study also examines whether the two conditions differ in the amount of calories consumers choose in a subsequent seemingly unrelated decision. Forty-six participants either ate different cookies or the same type of cookie while watching a documentary. Afterwards, participants had to indicate how many cookies they ate. Participants then left the room one by one. In an adjacent room, a researcher told them that they could pick a Santa Claus gift choosing between tangerines, almond biscuits, and chocolate.

First, we checked the accuracy of participants' assessments of how much they had consumed. The results revealed a significant difference (p = .046) between the two conditions: participants in the

no-variety condition slightly overestimated how many cookies they ate (M = .25), whereas those in the variety condition underestimated their cookie consumption (M = - 1.0). Although controlling for the absolute number of cookies consumed (quantity) slightly reduces the effect (p = .05), quantity (p = .93) cannot explain the difference in accuracy. Second, we investigated whether the two conditions differed in the amount of calories participants chose in the subsequent decision. Participants in the variety condition chose items higher in calories (159 kcal) than those in the no-variety condition (80 kcal) (p = .06). A regression analysis of number of different cookies eaten on calories chosen reveals a significant positive relationship (p = .01). Participants were more likely to select a Santa Claus gift rich in calories if they integrated more variety in their consumption of cookies.[1]

Our studies show that people who diet seek more variety and believe variety to be beneficial for them in reaching their goal to lose weight. Further, we demonstrate that integrating variety into one's food choices makes individuals underestimate how much they ate. This might provide an explanation for why consumers mistakenly believe variety to be good for them. We believe that the underestimation of how much they ate is due to the way individuals keep track of the items consumed. Specifically, we think individuals who eat two cookies track the amount of cookies consumed as an aggregate quantity while individuals who eat one vanilla cookie and one chocolate cookie might track the amounts separately, failing to add up the partitioned amounts to an aggregate number. In a follow-up experiment, we will test whether this way of 'bookkeeping' is responsible for underestimating the amount of cookies consumed.

Complementary food consumption with imagined consumption

EXTENDED ABSTRACT

A key aspect of micro-economic theories of consumer behavior is the interdependence in consumption, in particular the complementarity relations between products. Complements are goods which are customarily consumed together, for example, bread and jam or cheese and crackers. An increase in the consumption of one item causes an increase in the consumption of its complements (Bucklin, Russell, and Srinivasan 1998). Whereas prior research on product complementarity has focused on the impact of consumption/price of one item on the consumption/price of its complements, the current research examines the effect of imagined consumption of an item on subsequent actual consumption of its complements.

Research on mental imagery suggests that the processes of mental imagery are similar to the processes involved in the perception of actual stimuli. Mental imagery of an experience has been found to engage similar physiological (e.g., Huber and Krist, 2004) and neurological processes (Kosslyn, Ganis, and Thompson 2001), and to similarly affect behavioral responses (e.g., Wohldmann, Healy, and Bourne 2007) as the actual consumption experience. More recently, Morewedge, Huh, and Vosgerau (2010) demonstrated that imagined consumption of a food engenders habituation to the food as does the actual consumption. If imagined consumption can act as a substitute for the sensory experience of consuming a food, imagining consuming a food should, like actual consumption of the food, increase the subsequent consumption of its complements. Across three studies we test this proposition.

Study 1 examined whether imagined consumption of a food (grapes) increases subsequent consumption of foods complemen-

tary to the food imagined (cheese) with a 2 (imagined consumption: grapes vs. cheese) x 2 (amount of imagined consumption: small vs. large) between-subjects design. Half of participants imagined eating either 3 or 30 grapes and the other half imagined eating either 3 or 30 cheddar cheese cubes. After the imagined consumption, all participants were given a bowl containing 40g of cheddar cheese cubes and ate cheese cubes ad libitum. We found that participants who imagined eating 30 grapes ate significantly more cheese cubes than did participants who imagined eating 3 grapes. The opposite was found for, participants who imagined eating cheese cubes. Participants who imagined eating 30 cheese cubes ate significantly less cheese cubes than those who imagined eating 3 cheese cubes (Morewedge et al. 2010). These results provide initial evidence that complementary food consumption occurs even when one of the foods is imagined being consumed.

Study 2 tests whether complementarity is necessary to increase the subsequent food consumption with a 2 (imagined consumption experience: eating crackers vs. eating M&M's) x 2 (amount of imagined consumption: small vs. large) between-subjects design. Before participants actually consumed cheese as in study 1, half of participants imagined eating either 3 or 30 crackers (complementary food) and the half of participants imagined eating either 3 or 30 M&M's (non-complementary food). Participants who imagined eating 30 crackers subsequent consumed more cheese than those who imagined eating 3 crackers. However, there was no difference in cheese intake between those who imagined eating 30 M&M's and those who imagined eating 3 M&M's. The results suggest that imagining eating foods does not increase the subsequent consumption if the imagined food and the consumed food are not complements.

Two psychological processes appear to regulate food intake (Berridge 2007). One process is food liking or palatability (i.e., the pleasure derived from eating a given food), and the other is food wanting or appetite (i.e., motivation to obtain a food). We conducted study 3 to examine which process is responsible for the effect of imagined consumption of complements. Half of participants imagined eating 3 grapes and the other half imagined eating 30 grapes. After the imagined consumption of grapes, all participants indicated how pleasurable it would be to eat the cheese right then (liking) and how much they would be willing to pay for one pound of cheese (wanting). We found that participants who imagined eating 30 grapes indicated significantly higher WTP than did participants who imagined eating 3 grapes. However, liking did not differ significantly between the two conditions. The findings suggest that imagined consumption increases subsequent consumption of its complementary food by increasing wanting, but not liking, of foods complementary to the food imagined. This is consistent with the findings by Morewedge et al. (2010) that imagined food consumption engenders habituation to a food (decrease in wanting) but does not affect liking of the food.

In summary, we found that complementary food consumption occurs even when one of the foods is imagined rather than actually consumed. People who imagined eating a large amount of food (e.g., cracker) subsequently consumed more of its complementary food (e.g., cheese) than those who either imagined eating a small amount of the food or imagined eating non-complementary foods. The present investigation attests to the importance of top-down processes that regulate food consumption.

---

[1] Experiment 3 provides further evidence that dieters integrate more variety in their choice: Comparing dieters and non-dieters (variety condition) shows that dieters eat more different cookies (p =.06).

Effect of Character Weight and Health Knowledge on Children's Eating

EXTENDED ABSTRACT

Just as overweight and obesity is increasing for adults, so it is for children. Since 1980, while the adult obesity rate has doubled, the childhood obesity rate has tripled with rates now near 17% (CDC). Increasingly, overweight and obese children are being diagnosed with obesity-related diseases that were previously the domain of adults, such as Type 2 diabetes.

While recent research has focused on environmental factors that influence adults' consumption, little research examines such influences on children. Research has shown that perceived weight of others influences how much indulgent food adults eat (McFerran et al 2009, Campbell & Mohr 2011), but there has been no research that examines such effects on children. In fact, while there is a significant body of research on priming effects on adults' behavior, little research examines whether such effects occur for children as well.

The primary purpose of this research is to examine whether the weight of cartoon characters influences children's consumption of low nutrient, high calorie food (e.g., cookies). This is an important topic because while children are regularly exposed to overweight characters in entertainment and marketing, there is little evidence as to how this impacts their behavior.

Research on adults suggests that exposure to someone overweight activates an overweight stereotype that includes the ideas that overweight people over-eat indulgent foods and that they are not committed to taking care of their health. It is the activation of these parts of the stereotype that is believed to lead adults exposed to someone overweight to eat more (Campbell & Mohr 2011). This raises two questions: 1) do children hold an overweight stereotype that includes overeating and low health commitment, and 2) does exposure to an "overweight" character activate an overweight stereotype in children. The limited research on the content of children's overweight stereotypes suggests that there are developmental differences in stereotype specificity; young children merely hold general negative attitudes, with increasing specificity with age (Penny & Haddock 2007). Thus, it is unclear whether children's overweight stereotypes are specific enough to include the link between eating and becoming overweight. If this link does not exist, the body weight of characters is unlikely to influence their consumption. Second, it is unclear whether a cartoon character will serve to activate a human stereotype.

We propose that the link between eating indulgent foods, weight and health are taught to many children at a very young age. Parents and other authority figures frequently tell children to eat or not to eat certain foods and to limit consumption of indulgent foods. Thus, we propose that even young children will have a stereotype that links overweight and eating. Because children consistently see non-human characters in "human" situations, we also propose that overweight characters will activate children's overweight stereotypes and increase food consumption.

Importantly, there is evidence that in adults, increasing the accessibility of health goals or the stereotype-behavior link can reduce the effects of the prime (Campbell & Mohr 2011). Yet, with children, evidence from the development literature indicates that young children may not be able to use knowledge as a cognitive defense because of difficulty in retrieving stored information (Brucks, Armstrong, & Goldberg 1988). We propose that there will be developmental differences in children's ability to make use of their health knowledge to reduce the effects of the stereotype prime on eating.

We present three studies that, together, examine the influence of perceived weight of cartoon characters on the quantity of indulgent food eaten for children in three stages of consumer socialization: the reflective stage (ages 11 – 16), the analytical stage (ages 7 – 11), and the perceptual stage (ages 3 – 7; Roedder John 1999). Additionally, the third study will examine whether young children have the cognitive ability to make use of health knowledge to reduce the effects of the stereotype prime.

Study 1 examines the prime to behavior link for children aged 12 to 13 (n=60), and finds that children take more candies when exposed to an overweight character than when exposed to a normal weight character (M=3.7 vs M=1.5, p = .04). Considering that children's environments are much more complex than simply one prime character, study 2 examines the prime effect on behavior when the prime is a combination of an overweight and a normal weight character for children aged 13 to 14 (n=75). Results show that children take fewer candies when exposed to a normal weight character alone (Mnormal=1.7) than either an overweight character alone (Moverweight=3.2; p < .01) or the overweight and normal weight characters together (Mcombination=3.2; p < .01). Taken together, Studies 1 and 2 demonstrate the robustness of the prime to behavior link for children in the reflective stage of development.

Study 3 will examine the prime to behavior link for children in the analytical stage (age 9 – 10, n=100 – 150), and in the perceptual stage (age 6 – 7, n=100 – 150), and test whether the children have the cognitive ability to make use of health knowledge to reduce the effects of the stereotype prime. Data for this study will be collected in March and April (we have agreement from a school). We hypothesize that both groups of children will show the prime to behavior link, but that only the older group of children will have the cognitive ability to use their health knowledge to reduce the effects of the stereotype prime.

Overall, this set of studies contributes to the literatures on stereotype priming and children's development by examining the prime to behavior links of an overweight prime on children across three stages of development. We find a robust prime effect of an overweight character (alone and with a normal-weight character), and examine the potential of health knowledge activation to reduce these prime effects.

Jeffrey Shulman, University of Washington, USA

SESSION OVERVIEW

Recent findings in consumer behavior, psychology, and economics have questioned one of the key tenets of neoclassical utility theory: That preferences are stable and independent of the external environment that consumers face. Today, the general, well-accepted assumption instead is that preferences are influenced by contextual factors. One of the most important domains for the study of such influences in marketing and consumer behavior has been pricing. In fact, a vast amount of research has provided evidence for contextual price influences on people's internal notion of value as manifested in price judgments, willingness-to-pay, and product-choices (e.g., Adaval & Monroe, 2002; Alba, Mela, Shimp, Urbany, 1999; Aradhna, Wagner, Yoon, & Adaval, 2006; Janiszewski & Lichtenstein, 1999; Monroe, 2003; Niedrich, Weathers, Hill, & Bell, 2009; Simonson & Drolet, 2004). This symposium builds upon the existing body of research on reference pricing and takes an in-depth look at the underlying mechanisms via which exposure to prices influences consumers' judgments and behaviors. As such, this session offers important new insights into the power of prices and their affects on the consumer mind.

The first paper by Karmarkar, Shiv, and Knutson presents functional magnetic resonance imaging (fMRI) as well as behavioral data showing that early attention to price leads consumers to think about value, focusing the evaluation process on whether a product is *worth* the given price. That is, rather than categorizing items as liked or disliked, consumers tend to shift to a process that is more consistent with a threshold mechanism, in which a product qualifies for purchase if its value is judged to be high enough. The second paper by Bertini and Wathieu focuses on the presence or absence of a starting price for products that require a certain degree of customization (e.g., a laptop computer). Across three experiments they find that a starting price acts to split a total expense into a component related to the benefits desired by most consumers and a component related to idiosyncratic preferences. This perceptual split helps consumers to more actively realize that the product has an element of personalization, which increases their engagement in the customization-process, leading to decreased price sensitivity, higher quality perception, and

improved likelihood of purchases. The third paper by Mazar, Koszegi, and Ariely presents evidence that a target products' distribution of selling prices in the market affects individuals' expressed reservation prices for that product, and focuses on investigating the source of such context-dependency. The results from this paper rule out a rational reaction to information and favor the possibility of an error in the expression of preferences rather than the existence of true differing preferences across markets or contexts. These findings have important implications not only for consumer welfare and policy but also marketing strategy. The final paper by Cunha Jr., Saint Clair, and Shulman examines the extent to which consumer price perception and judgments of a target product are affected by the distribution of prices of non-target products when considering a product set. It identifies construal level as an important factor that influences context-dependent price judgments. Whereas consumers using low-level, concrete construal attend to specific features of the price distribution of the non-target products (e.g. the range or frequency) and their judgments contrast away from these features, consumers using high-level, abstract construal attend to global features of that price distribution (e.g. the mean) and their judgments assimilate toward these features.

In keeping with the conference theme "Building Connections," the four papers in this session bring together a variety of theoretical (reference dependence, expectation disconfirmation, range-frequency theory, construal level-theory) and methodological approaches (neuroscientific methods and experimental design) to investigate the power of prices. We believe this session will inspire interest and foster discussion on important questions such as: What are the underlying psychological mechanisms by which prices affect consumers' judgment and decision making? How can prices affect the type of information processing? What are possible mediators of those effects? and To what extent are consumer welfare and marketer demand impacted in a positive or negative way?

This symposium is likely to appeal to researchers interested in price perception, preference and choice, judgment and decision-making, situation/context effects, and inference making. The findings have important implications for marketers as well as individual consumers and policy. Note: The findings of all four papers have been written up, i.e. in manuscripts that are either prepared or under review, or near publication.

The Effects of Price Primacy on Decision Making and Perceptions of Product Value

EXTENDED ABSTRACT

When consumers first attend to a product, they are engaged affectively, causing them to categorize the item as positive or negative. Research by Knutson et al. (2007) provides evidence that individuals' evaluations and subsequent purchase decisions are predicted most strongly by this initial liking (or disliking) reaction. In contrast, price is a difficult piece of information for consumers to evaluate independently (Hsee et al. 2003, 2005). It would be reasonable then, to assume that price plays a fixed role in the computation of value and should be factored into a decision the same way at any time. However, it is also possible that encountering price early on sets a context for processing subsequent information, thus shaping product perceptions and choice behavior. Price can signal an item's value or worth, to the point that price knowledge can bias perceptions of

product quality at both the behavioral and neural level (e.g. Rao and Monroe 1989; Shiv et al. 2005, Plassmann et al. 2008). Thus we posit that price primacy leads consumers to think about value, focusing the evaluation process on whether a product is *worth* the given price. Rather than categorizing items as liked or disliked, this process would be more consistent with a threshold mechanism, in which a product qualifies for purchase if its value is judged to be high enough.

To investigate this hypothesis, seventeen individuals (9 females) made shopping decisions in an incentive compatible fMRI task adapted from Knutson et al. (2007). Across trials, a price was presented either before or after a photo of a product and participants then indicated whether they wanted to buy it (yes/no). Two of these choices were randomly selected to have real world consequences at the end of the experiment. Following the scanner task, participants listed their reservation price for each product. A value score, conceptually similar to consumer surplus, was calculated by subtracting the offered price from the individual's reservation price to determine how (in)expensive participants found each item to be. Participants also rated how much they liked each product - regardless of purchase - on a scale from 1 (Do Not Like) to 7 (Like Very Much).

Neural data were analyzed from the time during the decision process before participants indicated their choice, but when both price and product information was available to them. We focused these analyses on how price primacy influenced the neural coding of value (i.e. the integration of price and product information) and reward (i.e. liking for the product). Across trials, perceptions of value significantly correlated with brain activity in the medial prefrontal cortex (MPFC). This is consistent with previous research showing that activity in MPFC and nearby brain areas appears to be involved in integrating information such as product attributes or choice set composition, thus responding to the current worth or value of a decision target (e.g. Knutson et al. 2003, 2007; Hare et al. 2008).

Comparing product versus price primacy trials revealed qualitative differences in MPFC activity during the evaluation process. In product-first trials, MPFC activation increased for items that were subsequently purchased and decreased for items that were subsequently rejected. In price-first trials, MPFC activation also showed some increase for items that were chosen for purchase. However, for items that were not purchased, activity in these areas did not decrease, but remained at baseline. These results suggest that in product-first contexts, wanted items have a positive value but unwanted items seem to be actively rejected with an explicit assignment of a negative value. The process is quite different in price-first contexts; here, unwanted items seem to be passively excluded from consideration, or ignored, consistent with our hypothesis of a threshold-type mechanism.

Liking of the product was correlated with activity in the Nucleus Accumbens (NAcc), a brain region associated with anticipated reward (e.g. Knutson et al. 2001, 2007; Erk et al 2002, but see Hare et al. 2008). NAcc activity patterns were similar across price and product primacy trials. Similarly, no differences were found in the behavioral liking ratings for purchased products between trial types (p = .35). Such findings allow us to rule out the possibility that price primacy simply reduces engagement or liking by diminishing the reward value of the subsequently viewed product.

Together these results are consistent with our proposed framework in which price primacy specifically influences the determination of a product's value, shifting the process from a question of "do I like it" to one of "is it worth it?" In the latter case, products deemed "not worth it" are merely insufficiently positive, as opposed to actively negative in value.

Such an account also makes the interesting behavioral prediction that price primacy could specifically enhance consideration of utilitarian or practical items, because their worth is easily accessible in terms of need or functionality. Furthermore, our data suggest that price primacy should not have an impact on hedonic or frivolous purchasing. These are products whose worth can be described in terms of how strongly rewarding they are found to be, and the results from the shopping task showed that early exposure to price did not diminish liking or the reward response for desired products.

These predictions were tested in second study; a between-subjects behavioral experiment comparing purchasing rates across category (hedonic/utilitarian) and primacy (product/price; N = 122). Participants were asked to indicate their intent to purchase either four hedonic or four utilitarian products, under price or product primacy conditions. As in the fMRI task, participant decisions were incentive compatible. There was a significant interaction of category by primacy ($F(1,118) = 4.04$; $p < .05$) such that price primacy significantly increased purchase rates for utilitarian products ($F(1,118) = 8.211$; $p < .01$) but did not change rates for hedonic products ($F << 1$). The results of this experiment confirm the behavioral predictions made by the neural data.

Starting Prices and Consumer Response to Customization

EXTENDED ABSTRACT

Consumers often make decisions about products that require a certain degree of customization. From the perspective of a firm, providing customization is costly but it can lead to greater value creation and surplus extraction if a sufficient number of consumers are responsive to, and prepared to pay for, this benefit.

The way customizable products are priced in a market tends to follow a certain pattern. Instead of posting only the price a consumer is asked to pay for the good she ultimately chooses, sellers often advertise a low starting price for the base or entry model and make adjustments to this figure as additional features are chosen based on individual preferences. An airline, for example, may offer flights on a particular route at prices "starting from" a certain figure. As the traveler then makes decisions on departure day and time, departure and arrival airports, number of stops, and class of service, the actual—typically higher—fare is revealed. Similarly, manufacturers of laptop computers promote base models at starting prices and then take potential buyers through an intricate customization process that leads to the final purchase price.

Debates and regulations on "bait-and-switch" (the practice that lures consumers into a shop on the basis of a low price without actually offering any viable alternative at that price) assume that starting prices are deceptive tensile claims. The argument is that consumers are initially attracted by a low price point and, for reasons such as insufficient adjustment, switching costs, and escalation of commitment, become insensitive to or willing to accept the added expense. There is support for this view in practice, as evidenced by the acts of several customer protection agencies questioning the fairness of starting prices and trying to limit or abolish their use.

Beyond the interpretation of starting prices as pure marketing gimmick, the existing literature suggests that they might be detrimental to firms. Based on theories of reference dependence and expectation disconfirmation, one could indeed argue that consumers lured by a starting price experience will experience the incremental expense leading to the final price as a source of strong disutility that could jeopardize the transaction or damage the consumption experience.

The goal of our research is to propose and test a new understanding of the role of starting prices in the context of customization. Our explanation portrays the practice in a positive light, linking the presence of a starting price to consumer engagement in customization. Consistent with recent research describing how price can stimulate engagement and lead to new perceptions of value, we propose that a starting price acts to split a total expense into a component related to the benefits desired by most consumers and a component related to the benefits desired as a result of idiosyncratic preferences. This perceptual split helps potential buyers to more actively realize that the good has an element of personalization, which impacts demand in a positive manner to the extent that customization is beneficial and deserving of attention.

We tested our theory across three experiments in which starting prices were present or absent and in which the benefits of customization were perceived to be high or low. The general prediction was that variations in the perceived value of customization would carry over to product judgments only when a starting price was posted (to support consumer engagement in the process).

The first experiment crossed price presentation with the amount of control (low vs. high) participants exerted over the choice of customized features. Research has shown that the value of customization diminishes in the absence of self-determination. For the same desired offering, we found that adding a starting price improved likelihood of purchase and decreased price sensitivity when participants selected the customizable features, but not when the same set of features were selected by the seller.

The second experiment crossed price presentation with one of two primed judgment criteria (utilitarian vs. hedonic). Customization is expected to be beneficial when consumers seek self-expression. We reasoned self-expression is consistent with the desire to fulfill a hedonic goal, not a utilitarian goal. Similar to experiment 1, we observed a significant difference in perceived product quality across these two judgment criteria only when a starting price was introduced.

Finally, the third experiment crossed price presentation (four levels) with category expertise (low vs. high). Category expertise was measured because consumers are less likely to view customization as beneficial when they are uncertain of their own preferences (i.e., in the case of novices). The change to four price presentation levels allowed us to provide evidence for the psychological mechanism we propose. Specifically, three of these conditions included a starting price that represented a small, medium, or large portion of the final price. If consumers associate the difference between a final price and a starting price with the amount of customization present in a product, then variations in the latter should lead to changes in product perceptions. The results corroborate our theory. For expert participants, we found that perceptions of customization and product valuation were inversely related to the size of the starting price. There was no effect of price presentation for novices.

Stable Context-Dependent Preferences?
The Origin of Market Price-Dependent Valuations

EXTENDED ABSTRACT

Today, the general, well-accepted assumption is that preferences are not stable and independent of the external environment that decisions makers face but instead influenced by contextual variables. One of the most important domains for the study of such influences has been pricing. For example, anchoring individuals on an arbitrary selling price derived from their social security number subsequently affected valuations (Ariely, Loewenstein, & Prelec, 2003). However, in a typical purchase situation, whenever consumers intend to buy a familiar product, they have accumulated various experiences with the product's available market prices or at least have some expectation about the distribution of this product's selling prices at various retailers. And it is less known to what extend the knowledge of the distribution of given market prices influences consumers' internal valuations. For example, in Richard Thaler's (1985) "beer on the beach" example, which traditionally has been interpreted in terms of transaction utility, respondents provided their hypothetical willingness-to-pay for a bottle of cold beer delivered to them on the beach by a friend. Participants were told that the friend would get the beer, in one condition, from a local store and, in the other condition, from a fancy hotel. The results showed that participants' willingness-to-pay was significantly higher in the latter condition. We view these results as consistent with the idea that expectations of the distribution of market prices for a product influences consumers' valuations: Because respondents expected beer prices to be higher in the "hotel-market" than in the "local stores-market", they responded by raising their reservation price.

In the market place a product is often offered for various different prices across retailers, in particular, with various steep discounts. And even if the price-range stays the same, the distribution of these prices (i.e. their frequency) varies across time and markets, and consumers often have some experience, knowledge, or expectation of this distribution. The existing reference price literature (e.g., Aradhna, Wagner, Yoon, & Adaval, 2006; Simonson & Drolet, 2004) has not demonstrated if and how varying distributions (i.e. frequencies) of the same market prices for a product would affect individuals' internal valuations of that product, but predictions based on previously accumulated findings support the notion that the distribution should have an effect (Monroe, 2003). In particular, research on categorical price judgments based on Parducci's (1965) rang-frequency theory suggests that individuals do seem to shift their purchase decisions in response to distributional attributes such as range, modality, or skewing (e.g., Alba, Mela, Shimp, Urbany, 1999; Janiszewski & Lichtenstein, 1999). While these studies focused on price judgments rather than on valuations (maximum willingness-to-pay) and studied the influence of the price distribution of competing products in the market rather than of the target product itself in the market, along similar lines, we hypothesized that even if the range of a product's selling prices was the same, a left-skewed distribution would elicit lower reservation prices for a familiar product in comparison to a right-skewed distribution.

Our interest, however, goes beyond merely identifying another contextual factor. Instead we wanted to focus on investigating the origin of such context-dependency. That is, while the previously demonstrated anchoring effects with non-informative, irrelevant single prices (see e.g., Adaval & Wyer, 2010; Nunes & Boatwright, 2004 for incidental effects) are clearly mistakes in individuals' expressions of preferences, it is less clear whether such market-dependent valuations are necessarily mistakes and to what extent they might be stable within the same markets. At least three possible causes for such a context-dependency come to mind: 1) rational reactions to information, 2) true changes in valuations (i.e. individuals have real, that is stable, context-dependent preferences), or 3) biased (i.e. erroneous) expressions of true context-*in*dependent valuations. If reservation prices depend on the prices buyers expect to face in the market, demand will in general depend on supply, with important implications for marketers' pricing strategies and for pricing models. Therefore, understanding the source for this dependency is crucial to determine not only marketing strategy but also welfare and policy implications.

We address these questions with three studies. First, we present two experiments with a visual description of a product's market price-distribution in which we found that participants' willingness-to-pay in consequential purchasing tasks were dramatically lower when the price distribution was skewed to the left than when it was skewed to the right. More important, in these experiments we investigated possible underlying reasons for the price distribution-dependence of preferences. Our results rule out a rational reaction to information and favor the possibility of an error in the expression of one's preferences rather than the existence of true differing preferences across markets or contexts. Next, Experiment 3 replicated the findings in a setting that more closely resembled a market situation: a multi-period market simulation in which participants merely experienced the distribution of selling prices in the market. Our findings suggest that despite having stable valuations of products, consumers are rarely willing to pay that valuation when encountering lower prices unless they are prompted to think carefully about the value that the product provides to them (Experiment 2) or when they are being "reminded" that the distribution of selling prices should not matter (Experiment 1). This means that consumers might sometimes end up making sub-optimal purchase decisions and not purchase the product for a price at which they would still receive a positive net utility from it. We speculate that this systematic behavioral pattern (bias) arises from consumers being distracted by the wrong goal: instead of focusing on the utility that the product itself offers, they are shortsightedly focusing on optimizing the pleasure of getting a good deal.

Together, our results suggest that a market with its price distribution is an inherently powerful contextual variable that determines expressed preferences in purchasing decisions even for products for which consumers should have a relatively good idea of the consumption utility that it provides and in the absence of a clear, explicit anchor.

The Moderating Effect of Construal Level on Price Judgments

EXTENDED ABSTRACT

When judging multiple products, consumers' price perceptions are often influenced by the characteristics of the price distribution and price judgments are well accounted for by range-frequency theory (Parducci 1965). This theory posits that consumers focus on specific elements of the consideration set, such as the most and least expensive products (i.e., range) or the density of the distribution (i.e., frequency), and that judgments contrast away from the direction of change to these elements such that a price increase for the most expensive product makes the other products seems less expensive (Cunha and Shulman 2011; Niedrich, Sharma, and Wedell 2001). The present research demonstrates that the level of abstractness with which consumers construe product prices (i.e., construal level) moderates this standard contrast effect.

Construal level theory (CLT; for a review see Trope and Liberman 2010) contends that consumers construe stimuli on a continuum of abstractness ranging from low-level, concrete construal to high-level, abstract construal. CLT research shows that consumers processing at low construal focus on subordinate, specific features and process contrastively. In contrast, consumers processing at high construal focus on superordinate, global features and process inclusively. For example, when asked to group a multitude of items into categories, participants processing at low construal formed a large number of specified categories (e.g. snacks, sodas) while those processing at high construal formed fewer, broader categories (e.g. food,

beverages; Liberman, Sagristano, and Trope 2002). Additionally, when asked to rate the similarity between social groups (e.g. men and women, self and others), participants processing at low construal perceived less similarity while participants processing at high construal perceived more similarity (Forster 2009; Forster, Liberman, and Kuschel 2008). These findings are said to result from differential attentional focus (specific vs. global features) and processing style (contrastive vs. inclusive).

The tendency for consumers processing at low construal to focus on specific features and process contrastively is consistent with the predictions of range-frequency theory wherein consumers use specific features of the distribution as standards of comparison. However, the tendency for consumers using high construal to focus on global features of the stimuli distribution and process inclusively is at odds with range-frequency theory. What feature of a consideration set might serve as a "global feature"? Prior research has proposed the mean of a consideration set as a potential referent relative to which consumers might make judgments (Monroe 2003). Considering that the mean of a set serves as a summary measure, which captures the typicality of the elements of the set, it is plausible to conceptualize it as a global feature of a consideration set. As such, it can be predicted that consumers' processing at low construal will show results consistent with range-frequency theory in which price judgments of target products contrast away from shifts in specific elements of the context (e.g. the range). Alternatively, price judgments by consumers processing at high construal will instead assimilate toward shifts in global features (e.g. the mean).

We test this prediction in two experiments. In experiment 1 we activate low (high) construal by priming negative (positive) affect (see Gasper and Clore 2002; Labroo and Patrick 2009), while in experiment 2 we use a classification (inference) learning task (Markman and Ross 2003). After the construal manipulations, participants were randomly assigned to price-context conditions in which they saw the prices of a number of gourmet cheeses and rated them on expensiveness. A subset of these prices were target prices that remained constant across context conditions while the remaining prices were manipulated to shift the range, frequency, and mean of the set.

Across both experiments we obtain results consistent with our predictions. The construal manipulations worked as expected (ps < .01) and the interactions between construal and price-context were significant (E1: p < .05; E2: p < .01). Specifically, participants in low construal judged target prices as less expensive when the range and frequency were shifted upward but not when the mean was shifted upward; a contrast response. In comparison, participants in high construal judged targets as more expensive when the mean was shifted upward but not when the range or frequency were shifted upward; an assimilation response.

In sum, this research identifies construal level as an important factor that influences contextual price judgments. Whereas consumers using low-level, concrete construal attend to specific features of the context (e.g. the range or frequency) and their judgments contrast away from these features, consumers using high-level, abstract construal attend to global features of the context (e.g. the mean) and their judgments assimilate toward these features. This latter finding is at odds with extant research on contextual judgments, which supports range-frequency theory. For practice, the implication is that marketers may alter their perceived price position by activating high or low construal using a simple affective prime. For theory, the implication is that construal level may affect contextual judgments and information integration in general, extending beyond judgments of price alone.

SESSION OVERVIEW

Summary of Papers vis-a-vis Session Theme

Social cognition and marketing researchers have been examining how various factors such as (incidental) emotion and packaging, influence consumer decision making and perceptions (e.g., Isen et al. 1978; Pham and Raghunathan 1999; Keltner, Ellsworth, and Edwards 1993; Lerner and Keltner 2000, 2001; MacInnis and Price 1987; Wansink 1996). While individual and contextual factors have been found to affect various aspects of decision making, their influence on food consumption is not well understood. For instance, the effect of product familiarity and liking, the impact of incidental affect (consumer's mood or emotion), role of choice and self-monitoring on consumption behaviors such as the amount of a food product consumed, are research issues that have not been examined in detail in the existing literature. These are some of the questions that motivate this special session.

The research presented in this session focuses on food consumption and builds on previous literature in that area (Wansink 1994, 1996; Shiv and Fedorikhin 1999). It further builds connections with other research areas such as incidental affect (Isen 2001; Keltner, Ellsworth, and Edwards 1993; Lerner and Keltner 2000, 2001; Tiedens and Linton 2001), choice (Iyengar and Lepper 2000; Langer and Rodin 1976), self-monitoring (Snyder 1987), and product familiarity and liking (Berridge and Robinson 2003; Finlayson, King, and Blundell 2007). Specifically, the objective of the session is to present a set of studies that draw on different theoretical bases and methodological approaches to highlight various facets of food consumption and thus, present a more holistic view of this area of research. Notably, all three papers in the session highlight the impact of individual and contextual variables (product familiarity and liking, incidental affect, self-monitoring) on *actual food consumption* rather than related dependent variables such as preference or intention. Further, the papers in the proposed session combine both the marketing as well as the social cognition literature to present a broad spectrum of research with new insights into consumption behavior.

In the first paper, Carey Morewedge (CMU), Baba Shiv (Stanford University) and Emily Garbinsky (Stanford University) focus on whether product satiety influences the interval (measured in number of days) that individuals desire between consumption episodes for both, novel and familiar food products. Further, they examine the

role that product liking plays in this relationship. Results reveal a significant relationship between product satiety and the inter-stimulus interval, such that individuals who consumed more of a food product the previous day (high satiety) desired a longer delay in their delivery of the product than those in the low satiety condition. Notably, a mediation analysis revealed that the relationship between the amount of food consumed and the desired delay was mediated by individuals' decrease in product liking. However, the mediating role of product liking disappears for a familiar product. That is, although high satiety leads to increased desire for longer delays in delivery, this relationship is not mediated by product liking in the case of a familiar product. Thus, these findings replicate and extend existing findings regarding satiation and highlight the role of individual factors such as product familiarity and liking in food consumption.

The second paper focuses on attenuating the relationship between sadness and food consumption. The paper is co-authored by Nitika Garg (University of New South Wales) and Jeff Inman (University of Pittsburgh). Sadness' core appraisal theme of loss and helplessness has been known to evoke an implicit goal of reward replacement which leads sad (vs. neutral and happy) individuals to consume more of a tasty, fatty food product (e.g., M&Ms). In a series of three experiments with real food consumption, the authors suggest that sadness' influence on consumption can be attenuated by providing individuals an opportunity to choose (even if the choice is trivial) which counteracts appraisals of helplessness and enhances a sense of individual control. Notably, this holds only when the choice is relevant for 'self' (vs. 'others'). Finally, the paper tests the moderating effect of self-awareness on the sadness-consumption relationship. Overall, the studies provide theoretical moderators and mediators of the sadness-consumption relationship and reveal the underlying mechanism that might explain this relationship.

In the third paper, Brian Wansink (Cornell University) and co-authors examine how self-monitoring of one's consumption in the presence of others has a significant effect on the amount of food consumed. In an externally valid field study, the authors found that in dating couples at a movie theatre, the effect of self-monitoring on consumption varied across genders. Specifically, while women monitored how much popcorn they ate and ate less, men monitored what they ate and ate more. Follow up studies in a lab setting suggest that both ate in accordance with what they thought was appropriate for their gender. Their results suggest that increased self-monitoring in social setting affects males and females differentially because of the differences in social norms that they perceive to be applied to them.

This session brings together several leading scholars (e.g. Shiv, Wansink, and Inman) who have been very active in the field of consumption and consumer decision making. Further, the proposed session offers a variety of implications useful to *academics, consumers, managers, nutritional researchers* as well as to *public policy professionals* and highlights the impact of individual and contextual factors on consumption behavior, in particular. By employing a diverse range of theoretical constructs and exploring various moderators and mediators of food consumption, the papers in the session try to 'build and broaden' the connections across a number of research domains, thus advancing our theoretical understanding of consumption in general.

Audience Likely to Attend

Given the growing concern with over-consumption in the US and across the world, this session focuses on an important topic in consumer behavior (i.e., an examination of the effect of contextual factors on various dimensions of consumption). Participation of researchers using a combination of theoretical and methodological orientations to shed light on different aspects of food consumption (choice, nature of consumption, extent of consumption, delay in consumption), and its susceptibility to a host of individual and contextual factors such as self-monitoring, product familiarity, and affect, will help to provide a more complete picture of how consumer behavior and decision making is influenced by such factors and should appeal to a broad array of conference attendees.

Session Time Allocation

We firmly believe that interaction between the audience and the speakers is an essential ingredient to generate an insightful discussion. Thus, each speaker will be limited by the session chair to a 20 minutes presentation. The discussion leader, Baba Shiv, will then engage the audience in a discussion and interesting directions for future research in this area. It will be the aim of the session to generate a meaningful discussion on this important topic. Thus, we will try and leave as much time as possible for audience questions.

Does Liking or Wanting Determine Inter-stimulus Intervals in Food Intake?

EXTENDED ABSTRACT

The extent to which an individual likes and wants various items affects the choices that they make. While liking and wanting are similar constructs, they have typically been distinguished in the following manner: liking refers to the amount of pleasure that is derived from a stimulus while wanting refers to a desire to obtain that stimulus (Finlayson, King, & Blundell, 2007b). For this reason, liking is considered to be a hedonic or affective component while wanting has been classified in terms of motivation (Finlayson, King, & Blundell, 2007a).

Numerous studies have been conducted to show that these two constructs are indeed separable. Examples include the finding that wanting an addictive substance is not necessarily coupled with enjoyment of that substance (Robinson & Berridge, 1993) and that thwarting participants from winning a particular prize results in increased wanting of that prize (higher willingness to pay) but decreased liking (greater likelihood of switching prizes after they finally obtain it) (Litt, Khan, & Shiv, 2009). Additionally, liking and wanting have been linked to different neural substrates (Berridge, 1996) since the manipulation of dopamine has been shown to change motivated behavior (wanting) but not taste liking (Berridge & Robinson, 2003).

Knowing that liking and wanting have separate influences on behavior, the goal of this research is to investigate which construct (liking or wanting) influences the inter-stimulus interval with regard to food intake (which we define as the amount of time that passes before individuals choose to once again consume a particular food that they recently ate).

Study Method. The effects of liking and wanting were investigated for both novel and familiar food items. In Study 1, which examined a novel stimulus, participants were either assigned to the low satiety condition (where they were asked to eat 5 Nut Thins) or the high satiety condition (where they were asked to eat 15 Nut Thins). All participants were asked to provide ratings after eating each cracker regarding how much they liked the Nut Thins and the extent to which they wanted to continue eating them. The dependent variable was the number of days that each participant indicated that they would like to have a free box of Nut Thins delivered to their home. This was measured in a follow up survey that was completed the next day.

In Study 2, which examined a familiar stimulus, all procedures were identical to Study 1 with the exception that participants who were assigned to the low satiety condition were asked to eat 5 Pringles while participants that were assigned to the high satiety condition were asked to eat 15 Pringles. Once again, all participants were asked to provide ratings after eating each chip regarding how much they liked the Pringles and the extent to which they wanted to continue eating them. The dependent variable was the number of days that each participant indicated that they would like to have a free can of Pringles delivered to their home. This was measured in a follow up survey that was completed the next day.

Results. Study 1 results showed a significant relationship between satiety condition and desired delay of free boxes such that participants who consumed more Nut Thins the previous day indicated a longer delay in their delivery of free boxes, $\beta = 11.482$, $t(29) = 2.236$, $p = 0.034$. More importantly, the data also fulfilled the criteria for a mediation model (Baron & Kenny, 1986). First, satiety condition (low or high) had a significant effect on the decrement in liking ($\beta = 1.182$, $p = 0.011$). That is, participants in the high satiety condition who consumed more Nut Thins experienced a greater decrease in liking. Second, the decrement in liking significantly impacted the desired delay ($\beta = 5.218$, $p = 0.006$). Finally, when desired delay was regressed on both satiety condition and decrease in liking, the coefficient for desired delay was no longer significant ($\beta = 1.530$, $p = 0.884$).

Study 2 results once again showed a significant relationship between satiety condition and desired delivery of free boxes such that participants who consumed more Pringles the previous day desired a longer delay in their delivery of free boxes, $\beta = 0.739$, $t(33) = 2.092$, $p = 0.044$. However, the data no longer fulfilled the criteria for a mediation model.

Ongoing Work and Extensions. In follow-up investigations, we are exploring the effect of placing participants under low or high cognitive load while performing the liking and wanting rating tasks for novel stimuli. It is hypothesized that the decrement in liking will mediate the desired delay of free boxes for participants placed under low load but not for those under high load. Additionally, in future studies, we plan to obtain behavioral measures of liking and wanting in addition to measures of actual (instead of merely predicted) future consumption.

Conclusions. The results provide insight into the extent to which liking and wanting influence readiness to repeat consumption experiences. Specifically, the findings suggest that the decrease in liking that accompanies increased food consumption is an important predictor for length of time until repeated consumption when the food is novel, but when consumption involves a more familiar food, this decrease in liking is no longer relevant. Not only do the results highlight the importance of first impressions in the domain of food intake, but they also suggest that different processes may be operating during the decision of when to eat a recently consumed food depending on whether that food was novel or familiar.

Attenuating Sadness' Effect on Consumption: Helplessness, Choice, and Self-Awareness

EXTENDED ABSTRACT

Research on incidental emotion – emotion consumers imbue from their environment in isolation to the task at hand – has docu-

mented the pervasive tendency of emotions to carry over from one situation to another, coloring behavior in unrelated tasks (for reviews, see Forgas 1995; Isen 1993; Keltner and Lerner 2010; Loewenstein and Lerner 2003; Schwarz 2000). In the domain of consumption, emotions have been shown to influence in-store shopping (Woodruffe 1997) and in-home food choice (Wansink, Cheney, and Chan 2003). With the nation increasingly concerned with overeating and obesity, understanding how incidental affect influences food intake along with its mediators and moderators is an important topic.

One of the most curious carryover examples of emotion effects involves sadness and consumption. Its effects depart from what one would predict based on emotional valence. The standard prediction of a valence-based model would be that any negative emotion, including sadness, should trigger generalized negative valuation. That is, a negative state should lead one to perceive the world in negative ways. While disgust fits that predicted pattern, sadness does not. Sadness actually triggers positive valuation of new products, as measured by willingness to pay (Lerner et al. 2004).

Additionally, this carryover effect drives consumption behavior across diverse domains such as consumption and willingness to pay. In the domain of eating, for example, sadness (relative to happiness) leads to increased consumption of tasty, fattening food products, such as buttered popcorn and M&M candies (Garg, Wansink, and Inman 2007). Sadness' effect on consumption can be understood by examining its core relational theme of loss and helplessness (Lazarus, 1991) which might trigger implicit goals of reward replacement (Raghunathan and Pham 1999) and changing one's circumstances (Lerner et al. 2004). Notably, sadness is associated not with simple loss (e.g., loss of a replaceable possession) but rather with a sense of irrevocable loss (e.g., loss of a loved one). Recent research has argued that it is this combination of loss and helplessness associated with sadness that leads to compensatory tendencies (Garg and Lerner 2011).

In the present research, we hypothesize that given these underlying themes of loss and helplessness associated with sadness (Frijda, Kuipers, & ter Schure 1989; Lazarus 1991), sadness' effect on consumption can be attenuated by increasing decision makers' sense of individual control and decreasing their sense of helplessness. We focus on helplessness because it connects to the issue of control, which has proven important in guiding emotion effects, based on past investigations using the appraisal tendency framework (Garg et al. 2005; Lerner & Keltner 2000), and because it is part of sadness' core relational theme (Lazarus 1991). In the process, we replicate and extend the existing research in the sadness-consumption domain. Specifically, we conduct a series of three studies to examine whether offering a choice of a product can attenuate sadness' influence on consumption of hedonic food (in grams) and whether the focus of decision making (for self or for others) matters in the choice context. Further, we explore the role of self-awareness in the sadness-consumption relationship. Prior research (Cryder, Lerner, Gross, and Dahl 2008) has found self-focus to be a mediator of sadness' effect on willingness to pay where the more self-focused a sad individual was, the more he/she was willing to pay for an object. On the other hand, existing research also shows that self-awareness reduces intake of fatty food products (Sentyrz and Bushman 1998). These alternative views regarding the moderating effect of self-awareness on sadness' effect are tested.

Study 1 examines whether explicit choice of a hedonic (vs. a non-hedonic) good attenuates sadness' effect on hedonic food consumption. We expect that a choice will be more powerful than simple endowment because it will afford some semblance of control to individuals and might therefore alleviate the helplessness associated

with sadness. To test this hypothesis, we compare participants endowed with a hedonic gift to those who are specifically asked to choose between a hedonic gift and a non-hedonic one. A 3 (emotion: sad, happy, neutral) x 2 (choice of a gift, no-choice) between-subjects design was implemented to test the hypotheses of the study. Results find that only when sad individuals are afforded an opportunity to make a choice, does it succeed in overriding the effect on consumption (> 50% drop in amount consumed). Also as predicted, neutral and happy individuals display no drop in consumption and are similar across choice versus no-choice conditions.

Study 2 has a twofold purpose: to validate our findings from Study 1 by replicating the results and, more importantly, to clarify whether the locus of choice - for self or others – influence its efficacy in attenuating sadness' effect. Study 2 used a 2 (emotion: sad, happy) x 3 (choice for self, choice for others, no-choice) between-subjects design to examine this question. Results reveal that the effect of sadness is attenuated only when choice affects self.

The final study aims to examine whether self-awareness moderates sadness' effect. Prior research has found that participants in the high self-awareness condition (where they could see themselves in a mirror) curtail their consumption of fatty food products (Sentyrz and Bushman 1998). However, existing research also shows that sadness increases self-focus and this increased self-focus increases individuals' willingness to pay more to acquire a new object (Cryder et al. 2008). We argue that while self-awareness will attenuate consumption for individuals in other emotion conditions (e.g., neutral), it will actually amplify consumption for sad individuals. Study 3 will test this hypothesis with a 3 (emotion: sad, happy, neutral) x 2 (self-awareness: low, high) between-subjects design.

The empirical examination is well underway. Studies 1 and 2 are complete and Study 3 will be fielded in the spring of 2011. Overall, the current research aims to provide critical insight into the theoretical moderators and mediators underlying the sadness-consumption relationship. This will have important implications for the strategies employed to attenuate emotion effects and for improving our understanding of managing unbidden consumption and its negative consequences.

I am How Much I Eat:
How Self-Monitoring Influences
Food Consumption Across Genders

EXTENDED ABSTRACT

What causes us to attenuate or extenuate our consumption of food when we are with others? Past studies have identified multiple factors such as the number of companions (De Castro 1990, 1994), the attractiveness of these companions (Mori, Chaiken, & Pliner 1987), and even the serving sizes we are given (Wansink 1996; Wertenbroch 1998). Although these studies have studied each of these factors in isolation, their findings suggest that there may be systematic interactions between these factors.

This research investigates how gender-specific self-perceptions influence how closely one monitors what they eat when on a date, and how this subsequently influences how much of a food they choose to consume. Although past work has indicated that females perceive it more feminine to constrain their consumption, there is little corresponding consumption-related evidence as to what males perceive as masculine.

We often act in ways that we hope others perceive as socially desirable. This impression management motivation can cause us to monitor and modify the amount of food we eat in public, particularly in dating situations. In this research, we present a field study in a

movie theatre and two lab studies that examines whether both men and women eat in accordance with what they think is appropriate for their gender. In general, it will be examined whether increased self-monitoring in social settings differentially affects the way males and females react to larger serving size because of the differences in social norms that they perceive to be applied to them. It also influences perceptions of other males/females who ate more/less than average. Heavy male eaters were seen by males as being more masculine (being able to bench press more weight and so on), but were seen much less attractive to females.

Situational cues, such as package size, have been shown to have a powerful and unknowing influence on consumption. Interestingly, females on dates tend to exhibit a high level of self-monitoring, and render these cues as ineffective. However, males' eating behaviors are associated with their self-images to a lesser degree. The eating behavior of males, however, is associated with their self-image to a lesser degree. While more males described themselves as hearty eaters than females (Study 2), neither their self-representation strategy (Study 1), nor others' evaluation of them (Study 3) were significantly influenced by food intake. As the result, food consumption volume by males is not surprisingly more susceptible to the effect of serving size.

Malleable Memory and Consumption Decisions

SESSION OVERVIEW

Memory draws on content that one has experienced in the past, but memory for experiences—the taste of a cookie, an advertisement that we saw, or pleasant honeymoon memories—appear to be largely constructed at the time of recollection. Not only is memory influenced by various contextual factors such as the place or mood in which a past experience is recalled, people's memory of events is often inconsistent with their actual experiences (Fredrickson & Kahneman, 1993; Mitchell, Thompson, Peterson, & Cronk, 1997; Morewedge, Gilbert & Wilson 2005; Sutton, 1992; Wurtz, Kruger, Scollon, & Diener 2003). Thus, the malleability of memory provides a fruitful ground for consumer research.

This symposium takes a close look at the relationship between malleable memory and consumption decisions. In an attempt to gain better understanding of the interplay between memory construction and consumption, the papers examine how subtle contextual cues influence the actual content and the retrieval process of consumer memory, and how the constructed recollection of past product and service experiences subsequently influences current and future consumption decisions.

Galak, Kyung, Redden and Yang study the influence of subjective perception of time since the last remembered consumption of a good on satiation toward that good. They show that consumers consume less and derive less pleasure from consumption when they merely have the subjective sense of having consumed more recently (manipulated by using a scale anchored by "Now" and "One Day ago" vs. "Now" and "One Month Ago"). **Zhu and Morewedge** demonstrate that consumers tend to recall extremely positive rather than neutral and negative consumption experiences and this atypical recollection increases future consumption. Consumers appear to overweight the desirability of consumer goods and services on such atypically positive memories. Furthermore, they show that this effect is driven by motivated reasoning and it disappears when people know they will not have to repeat the consumption experience in the future. **Oyserman and Mourey** examine the impact of cultural cues on the ease of retrieval and the resultant feeling of fluency on consumption. They show that people make meaning through culture such that culturally-congruent (vs. culturally–incongruent) cues "feel right", and the resulting feelings of fluency encourages consumers to

"keep going" (vs. "stop and reconsider") in consumption and purchase contexts. Finally, **Lauga** examines how marketing cues can influence memory formation and subsequently influence consumption. Employing a modeling approach, she demonstrates that consumers base their purchasing decisions upon their recollections of product quality (which can be swayed by advertising). The results suggest that engaging in persuasive advertising might be optimal even with sophisticated consumers.

Taken together, the four papers (all in advanced stages) in this session elucidate the relationship between memory construction and consumption decisions, noting when, why and how the content and retrieval of past consumption experiences impact enjoyment and quantity of current consumption as well as the intention of future consumption.

In keeping with the conference theme "Building Connections," the papers in this session bring together a variety of theoretical approaches, including both experimental and modeling methods. As the session integrates diverse research, it is expected to appeal to a broad audience, including those interested in memory, satiation, fluency, motivated reasoning, experienced utility, consumption behaviors, and judgments and decision making. Talks will be kept brief to allow ample time for audience interaction.

Feels Far or Near? How Subjective Perception of When One Last Consumed Influences Satiation

EXTENDED ABSTRACT

Repeated consumption usually leads to a decrease in enjoyment and in motivation to consume, a phenomenon known as "satiation" (Coombs and Avrunin 1977). This process is ubiquitous and manifests in almost every consumption domain from food (Rolls, Rolls, and Rowe 1983) to massage(Nelson and Meyvis 2008). Recent work has increasingly shown that, satiation results from psychological process (McSweeney and Swindell 1999) as well as from physiological signals (O'Donohue and Geer 1985). In particular, satiation can be constructed based on whether people recall their past consumption (Higgs 2002, 2008; Rozin et al. 1998), the ease of retrieval of past consumption, and the subjective sense of how much they have consumed (Redden and Galak).

In the current research, we explore another critical antecedent to satiation – the subjective perception of when one last consumed. Across three experiments, holding constant the objective time of when a particular stimulus was consumed, we find that people feel more satiated and consume less when they merely have the subjective sense of having consumed more recently.

In Experiment 1, participants were randomly assigned to three conditions and answered questions regarding their eating behavior. Participants in the *Long Ago* and *Not Long Ago* conditions were asked to indicate when they last had anything to eat by drawing an arrow on a scale. In order to manipulate the subjective feeling of when participants last ate, the scale anchors differed by condition. For the *Long Ago* condition, the right end of the scale was anchored with "Now" and the left side was anchored with "One Day Ago". For the *Not Long Ago* condition, the right end of the scale was anchored with "Now" and the left side was anchored with "One Month Ago". In both of these conditions, participants were asked to draw the arrow starting from the right side of the scale and ending in the position

that reflects when they last ate. Participants in the *Control* condition were not presented with the scale. We found a significant effect of this manipulation on desire to eat and on hunger. Specifically, participants in the *Not Long Ago* condition wanted to eat significantly less and felt less hungry than those in the *Long Ago* condition and *Control* condition.

In Experiment 2, we replicate the findings from Experiment 1, demonstrate the effect for a non-food stimulus (music), and, most importantly, measure actual enjoyment following the manipulation. The experiment consisted of two parts, both administered in a single one-hour lab session. During the first part of the experiment, participants listened to a 30-second clip of a favorite song 12 times in a row. Then, 35 minutes after the completion of their listening experience, participants in the *Long Ago (Not Long Ago)* condition indicated when they last heard their favorite song on a 101- unmarked slider scale anchored with "1 Hour Ago" ("1 Week Ago") and "Now". As predicted, and consistent with Experiment 1, we found participants felt more satiated and enjoyed their favorite song substantially less when they felt like the first part of the experiment occurred more recently (*Not Long Ago* condition) as compared to either the *Control* or the *Long Ago* conditions.

Finally, to examine whether changing people's subjective perception of when they last ate influences their actual food purchase behavior, we conducted a field experiment with a local branch of the restaurant, Panera Bread (Experiment 3). Customers were intercepted prior to entering the restaurant and were asked to indicate when they last had anything to eat on a scale similar to the one used in Experiment 1. Next, participants were asked to indicate their subjective sense of when they last ate on a 9-point scale anchored with "Feels like it happened a while ago" and "Feels like it happened recently". Participants were then allowed to enter the restaurant and make their purchase decision. Most critically, we obtained itemized register receipts for each participant and were thus able to determine the amount of food purchased (in calories) and, presumably, consumed for each participant. As predicted, the participants in the *Not Long Ago* condition purchased food with lower caloric value than those in the *Long Ago* and *Control* conditions. Importantly, the subjective sense of when participants last ate mediated the relationship between the independent variable and the number of calories consumed.

In sum, the results of three experiments suggest that the subjective perception of when one last consumed has a significant impact on satiation. People consume less and derive less pleasure from consumption when they merely have the subjective sense of having consumed more recently.

Atypical Pasts Spur Future Consumption

EXTENDED ABSTRACT

We examine whether consumers are influenced by atypical consumption experiences and whether this biased recollection from memory influences their future consumption. Based on a substantial body of research suggesting that people tend to recall atypical events that are both memorable and unrepresentative of their class (Frederick & Kahneman 1993; Morewedge, Gilbert & Wilson 2005; Tversky & Kahneman 1973), we expect that consumers are more likely to recall extreme rather than neutral consumption instances. In particular, we predict that consumers tend to naturally recall extremely positive rather than negative product and service experiences (even in unpleasant consumption domains). We argue this is the case because (1) consumers have presumably chosen to purchase goods from certain vendor rather than another, (2) consumers often engage in motivated reasoning which leads them to confirm what they already believe while ignoring contrary evidence supporting its alternatives or negative (Kunda 1990). Further, based on evidence showing that remembered experience (but neither on-line nor anticipated experience) directly predicts the desire to repeat the experience (Wurtz, Kruger, Scollon, & Diener 2003), we predict that the biased recollection of extremely positive consumption experiences increases consumers' willingness to pay for goods and their purchase intention. In three experiments, we demonstrate the proposed phenomenon and the mediating role of pleasantness of recalled experience. We also find evidence that motivated reasoning underlies this selective accessibility effect.

Experiment 1A investigates whether consumers naturally recall extremely positive rather than neutral or negative consumption experiences. 90 students first described an airline flight, the best airline flight or three airline flights that they took that they clearly remember, and then reported the pleasantness of the experience. We found that students who recalled any air travel experience recalled an experience as good as participants who were explicitly asked to recall the best experience, whereas both recalled a significantly better experience than participants asked to recall three airline flights. Further, we found that while the first two instances described by participants who recalled three experiences were equally pleasant*, the last instance was relatively less pleasant.

Experiment 1B tests whether this biased recollection influences participants' future consumption. 106 CMU undergraduates were asked to recall either one, the best or the worst airline flight they had that they clearly remember (in a fourth condition, they didn't answer any recall question); and then indicate if they had to travel to Chicago in two weeks (1) whether they would prefer to fly or to drive and (2) what the most they would be willing to pay for a flight from Pittsburgh is. We found that participants having recalled no memory, a flight, or the best flight they could remember were willing to pay more for a flight from Pittsburgh to Chicago, and exhibited a stronger preference for flying from Pittsburgh to Chicago, as compared to participants who recalled the worst flight they could remember. There were no differences, however, in WTP and preference between the three former conditions. A separate pretest indicates that air travel is a consumption domain that CMU undergraduate students consider as pleasant. Taken together, these findings of Experiment 1 suggest that consumers tend to recall extremely positive experiments in consumption domains they find pleasant, and that this biased recollection of atypical memories spurs future consumption.

The objectives of Experiment 2 are to (1) test whether consumers naturally recall extremely pleasant experiences in negative domains and (2) test whether the effect of memory recalled on future consumption is mediated by pleasantness of recalled experience. A separate pre-test indicated that cellular customer service is a consumption domain that consumers consider as unpleasant. 158 respondents were randomly assigned to either the recall any, recall worst or recall best condition, in which they described one experience, the worst experience, or the best experience they had in the last five years with the cellphone customer service department respectively. Next all participants reported the pleasantness of the experience recalled and finally indicated the likelihood that they will switch to another provider or renew with their current provider when their contract expires. We found that participants in the recall any condition recalled an experience as good as participants in the recall best condition whereas both recalled a significantly better experience than participants in the recall worst condition. Participants who recalled any experience were as likely to stick with their current provider as participants who were explicitly asked to recall the best experience, whereas both were significantly more likely to stick with

their provider than participants recalling the worst customer service experience. The data also fulfilled the criteria for a mediation model, suggesting that the effect of memory recalled on the likelihood to switch vs. renew is mediated by pleasantness of the recalled experience.

Experiment 3 examines whether the observed selective accessibility effect is driven by motivated reasoning. If indeed consumers are motivated to remember extremely positive rather than neutral and negative experiences, they should only be motivated to do so when they have to repeat this experience again in the future. To test this idea, we asked 152 Pittsburgh pedestrians to complete a commercial evaluation study. Half of the participants were asked to evaluate two sets of beer commercials (*beer commercial next condition*) and the other half were asked to first evaluate one set of beer commercials and then evaluate one set of soda commercials (*soda commercial next condition*). All participants first viewed and rated the pleasantness of five beer commercials, including one pleasant, one unpleasant and three average commercials (based on pleasantness ratings obtained from a separate pretest). After evaluating the first set of beer commercials, participants were asked to recall and briefly describe one of the beer commercials they just watched. After describing the commercial, participants evaluated the second set of commercials (either beer or soda). As predicted, we found that participants in the beer commercial next condition were more likely to recall the best beer commercial from the first set rather than the worst or average commercials, as compared to participants in the soda commercial next condition.

If It Feels Right…Do It: Cultural Congruence as a Consumption Cue

EXTENDED ABSTRACT

On the 4th of July, do Americans put more food on a patriotic plate? Does a green border subtly encourage people to do more of a task? Can subtle exposure to traditional wedding photos make you more willing to buy an unrelated consumer product? In short, can cultural meanings deeply rooted in memory influence consumption when cued?

Culture is a meaning-making framework; the characteristic way humans perceive their environment (Triandis, 1972). In this sense, culture provides a blueprint or outline for how one is to behave and what one can expect of others across a variety of situations. What is culturally appropriate seems right, while what is culturally inappropriate seems off or wrong (Triandis, 2007). Because all of human life occurs within culture, and cultural knowledge is deeply rooted in memory, what feels right or wrong 'goes without saying'. While social scientists have long studied culture, the implications of this feeling of fluency, the telltale marker that culture is at work, has not yet been studied directly. Instead, researchers have either focused on describing a particular culture or on comparing and distinguishing between cultures, particularly contrasting East and West and describing the content and consequences of cultural 'syndromes' such as individualism and collectivism (for a review, Oyserman, Coon, & Kemmelmeier, 2002).

Rather than focusing on a specific culture or on specific differences between cultures, the current studies focus on the consequences of the feeling of fluency that being immersed in a culture provides. Within situations that are culturally appropriate, people from that culture can feel at ease, they know what to expect and how the situation will unfold. These feelings of ease can spill over into unrelated judgments, including, as we show here, consumer judgments. We build from two major tenants of behavioral decision

research and social cognition research: first, that preferences are constructed in the process of making a choice (Bettman, Luce, & Payne, 1998; Novemsky, Dhar, Schwarz, & Simonson, 2007) and second, that metacognitive judgment, the feelings that emerge while thinking, are a major source of constructed preferences (Schwarz & Clore, 1996; Schwarz, 2004). These prior studies have focused on feelings of ease or difficulty that come to mind in the process of choosing or judging. For example, they show that difficult to read print font (Song & Schwarz, 2008b) or being required to give many examples (as reviewed by Schwarz, 2004) both cue feelings of difficulty that spill over into the judgment task. Building on this prior work, in three studies we provide evidence that subtle cultural cues influence consumption such that cues congruent with deeply-rooted cultural memory "feel right," create a sense of fluency, and encourage more consumption while culturally-incongruent cues "feel wrong," create a sense of disfluency, and discourage consumption.

In our first set of studies, we had participants complete an anagram descrambling task that was framed in either a red, green, or black (control) border. After completing a series of the puzzles, participants were asked how much they would like to continue playing the game. We hypothesized that the colors green and red, well-established cultural cues for going and stopping, respectively, would wield a subtle influence on the decision to do more puzzles or not. As predicted, participants in the green condition were significantly more likely to want to do more puzzles, while those in the red condition were less likely to want to do more puzzles compared to the control group. To assess the generalizability of this initial finding, we developed a second study in which participants in a virtual restaurant buffet were asked to choose food to put on their plate and to indicate the serving size of each food they desired. Participants were randomly assigned to a green- or red-bordered plate. As predicted, participants with the green-bordered plate put significantly more food on their plate (with respect to serving size) compared to participants with the red-bordered plate.

In our second set of studies, we wanted to demonstrate that the effect of cultural congruence was not limited only to color. For this study, we conducted two separate experiments at picnics providing participants with plates decorated in holiday-congruent or holiday-incongruent themes. The experiments took place on the 4th of July and Labor Day, two patriotic American holidays. At both picnics, participants were randomly assigned into experimental (holiday-themed) and control (no-theme, white control) plate conditions. The themed plates were holiday-congruent on the 4th of July (American flag, stars and stripes) and holiday-incongruent on Labor Day (Halloween-themed pumpkins, black cats). Participants were randomly given a plate, went through the food line, and selected their food. After their selection, participants were stopped, ostensibly to chat but really to discreetly weigh their plate on a digital scale (in ounces). As predicted, cultural congruence mattered: participants put significantly more food on a holiday-congruent plate and less food on a holiday-incongruent plate compared to control.

In our third study, we wanted to demonstrate that the effects of cultural congruence could spill over from the immediate situation into an irrelevant subsequent task. The stimuli for this study consisted of wedding photographs with culturally congruent or incongruent themes. Specifically, participants were asked to rate the quality of wedding photographs for an online wedding planning site. Participants were randomly assigned to a "traditional wedding" condition – in which the photos featured a bride in a white dress, a groom in a tuxedo, a formal tiered wedding cake, and a traditional wedding party – or to a "nontraditional wedding" condition – in which the photos featured a bride in a green dress, a groom in a purple tuxedo,

a wedding cake that was neither tiered nor formal, and no wedding party. Following the rating task, participants completed an ostensibly unrelated consumption task in which they decided to purchase a fleece blanket or not. As predicted, participants who rated traditional wedding photos prior to the consumption task were significantly more likely to buy the fleece than participants who rated the nontraditional photos.

In sum, across three studies we show that culture congruence influences consumption in a variety of contexts via subtle feelings of fluency/disfluency. Theoretical and managerial implications are also discussed, including applications for brand cultures.

Persuasive Advertising with Sophisticated but Impressionable Consumers

EXTENDED ABSTRACT

The goals of advertising campaigns are diverse; they vary from creating awareness for a new product to affecting repeated purchases. To achieve these goals, firms decide not only how much to advertise but also how to advertise their products. Firms may select the content of their advertisements to convey information about their product quality directly to consumers. Firms may also choose uninformative advertisements. One explanation behind uninformative advertising is to signal product quality to consumer by "burning money." The message contents of advertisements are, in that case, irrelevant and their only effect is to reveal information indirectly to consumers. However, the content of uninformative advertisements might have a direct effect on consumers in itself, through persuasion for example. A vast literature documents and uses cognitive psychology to analyze persuasion in advertising. Firms may therefore select uninformative advertising because of its direct effect on consumers through the persuasive elements of its message. This strategic decision may also convey information to consumers indirectly and signal the product quality. The focus of this paper is to address the following questions about persuasive advertising. When consumers understand how persuasion works, will persuasive advertising ever be optimal for a firm? If the answer to the previous question is yes, will persuasive advertising always be associated with high-quality products? Finally, when firms can select persuasive or informative advertising, does one type of advertising dominate the other one?

I propose a model in which consumers are uncertain about the quality of a product sold by a monopolist. At the time of purchase, consumers do not know the exact product quality but try to assess it using their beliefs about quality. These beliefs could be, for instance, the recollections that consumers have of the product, which are generated by all past interactions between consumers and the product, including past personal experiences, word-of-mouth, official consumer reports, and of course advertisements. Some consumers having positive recollections and some consumers having negative recollections generate different beliefs about quality. The likelihood of having a positive recollection is an increasing function of quality thus recollections reveal some information about product quality. Furthermore, the firm may engage in persuasive advertising to increase the number of positive recollections. Specifically, in this paper, persuasive advertising is assumed to change the distribution of prior beliefs that consumers have about product quality. After being exposed to an advertisement, consumers might be more likely to remember the positive aspects of their last experience with the product than they would have remembered without the advertisement. In addition, consumers are sophisticated as they are fully aware that the firm can choose to engage in persuasive advertising, which increases the likelihood of positive recollections. They know whether they have seen persuasive advertisements and that they might be affected by them. However, they do not know if a positive recollection is the consequence of persuasive advertising or true experience as, of course, they do not know the recollection they would have had without persuasive advertising.

This paper shows that consumers cannot fully undo the effects of advertising, and engaging in persuasive advertising might be optimal even with sophisticated consumers. In addition, I show that persuasive advertising is not necessarily a signal of high quality. Under some market conditions, the fact that consumers fully understand the effects of advertising allows firms to signal a high quality by choosing a high price and by not engaging in advertising. If a firm chooses not to engage in persuasive advertising, consumers with positive signals know that their signals come only from the intrinsic product quality and were not artificially improved by a marketing campaign. As consumers with negative signals do not buy, the product quality has to be high enough to generate substantial positive signals and make choosing a high price profitable. As a result, choosing a high price and not engaging in advertising can help signal a high-quality product.

Depending on market conditions and the degree of advertising persuasion, persuasive advertising can signal an intermediate-quality range, a high-quality range, or even a low-quality range. Similarly, persuasive advertising is not naturally associated with high prices. Two factors drive the relationship between persuasive advertising and prices. First, firms use both price and advertising to signal their quality. Therefore, when advertising does not signal high quality, it is not associated with high prices. Second, keeping everything else constant, exposure to persuasive advertising lowers the expectation of product quality, which reflects the consumers' willingness to pay. Indeed, a positive signal with persuasive advertising does not carry as much good news as a positive signal without persuasive advertising. The latter signal was generated only through the intrinsic product quality while the former could be spurious and could have been negative without persuasive advertising.

Finally, I introduce informative advertising to study how firms use different types of advertising strategically. Informative advertising is based on a claim that is a hard/verifiable piece of information about the product. The monopolist chooses now between persuasive advertising, informative advertising, or no advertising. I show that the option of engaging in persuasive advertising might block the full unraveling of information in equilibrium. Some firms, instead of releasing some information in informative advertisements, choose persuasive advertising. Moreover, high-quality products are not always promoted with the same type of advertising. Specifically, persuasive advertising could signal a higher or lower quality product than a product promoted with informative advertising.

SESSION REVIEW

The four papers in this session uncover new and surprising factors that influence consumer well-being, from ironic effects of competition and resource depletion to culture- and age-specific definitions of happiness. Our first two papers break happiness down into joyful excitement and serene contentment. These authors find that although two people may report being equally happy, their experiences—and their ensuing choices—may be quite different. Paper 1 investigates the relationship between age, or future-thinking, and happiness type; Paper 2 takes a cross-cultural perspective, exploring surprising differences between what events European- and Asian-Americans should focus on if they want to be happier. Our final two papers explore the psychological consequences of resource-allocation. Paper 3 identifies ironic situations in which getting stuck with an inferior outcome leaves people more satisfied than competing for a superior one. Paper 4 finds that re-allocating one's own resources to other people can improve perceived financial well-being. The effects studied in these papers are not "known," and largely unexpected.

Audience and Level of Completeness

Since each paper in the session breaks meaningful new ground, we expect to generate significant interest. We expect the symposium to connect a broad ACR audience including researchers interested in happiness, economics, aging, cross-cultural comparisons, prosocial behavior, and decision making. All four papers are completed or close to completion.

Session Plan

Our goal for the session is to spark high-level thinking about the psychological drivers and marketing outcomes of consumer well-being. We plan to do this by (1) giving presenters sufficient time to clearly present their findings, and (2) encouraging audience interaction with the presenters.

Summary

In sum, while all this research addresses the topic of consumer well-being, each paper provides unique answer to the fundamental question, "What does it mean, and what does it take, to be happy?" We believe that by integrating a discussion of psychological perspectives (Papers 1 and 2), situational variables (Paper 3), and behavioral triggers (Paper 4), we will not only appeal to a broad cross-section of ACR members, but also make important theoretical and practical contributions. By integrating the commonalities in the research questions and interests among these papers, while highlighting their distinctive contributions, we hope to provide a springboard for future research.

How the Meaning(s) of Happiness Impacts Choice

EXTENDED ABSTRACT

Over the past decade, the concept of happiness has enjoyed much resonance among researchers across disciplines. Psychologists, economists, and political scientists have made tremendous strides in determining the best measures of happiness, ways to increase happiness, and why happiness is important (Diener and Chan 2011; Diener and Seligman 2002; Dunn, Aknin, and Norton 2008; Easterlin 2003; Healy, Malhotra, and Mo 2010; Isen and Labroo 2003; Kahneman et al. 2004, 2006; Lyubomirsky, Sheldon, and Schkade 2005; Mogilner 2010; Van Boven and Gilovich 2003).

This growing interest in happiness has also impacted business where researchers have begun to explore how to design organizations to increase employees' happiness (Hsieh 2010; Lyubomirsky, King, and Diener 2005), and how to create brands that cultivate consumers' happiness (Isen, Labroo, and Durlach 2004; Mogilner and Aaker 2009). For instance, in the face of the struggling economy, advertisers have looked to connect with consumers on a more simple and fundamental level by promising happiness. Examples are numerous: Nesquick claims, "You can't buy happiness, but you can drink it." Dunkin Donuts promoted a new breakfast sandwich as "The happiest sandwich on Earth," etc. Through particularly engaging efforts, marketers have also designed interactive campaigns to generate happiness. One example is Coca-Cola's recent "Open Happiness" campaign, which recognizes life's simple pleasures and encourages consumers to take a small break from the day to connect and share happiness with others.

Despite the growing interest in happiness, an empirical understanding of what "happiness" means is still limited. Indeed, the possibility that happiness may take on distinct forms remains largely unexplored. Even more scarce is research examining the impact of happiness on choice. Does the promise of happiness drive consumer choice? Or does it depend on what happiness means to that particular consumer?

Attempting to address these questions, we conducted three studies that show there are indeed distinct types of happiness—one more aligned with excitement; the other more aligned with peacefulness and calm. Furthermore, we show that the meaning of happiness is not stable, and we identify temporal focus (how present vs. future focused an individual is) to be one factor that influences which meaning individuals tend to adopt. Of central interest, we show how one's particular definition of happiness plays out to influence which option consumers are likely to choose.

Existing research has demonstrated the young people are chronically more focused on the future than older people (Carstensen, Isaacowitz, and Charles 1999; Mogilner, Kamvar, and Aaker 2011). In experiment 1, we influenced a sample of young adults (18-24 years old) to shift their focus to the present moment so as to test for the effect of temporal focus on individuals' definitions of happiness and choice between an exciting or calming option. The results revealed participants in the control condition to define happiness more in terms of feeling excited than feeling calm, whereas those who were led to shift their focus to the present moment defined hap-

piness more as feeling calm than excited. Furthermore, participants' choices between non-caffeinated teas indicated as either calming (i.e., chamomile) or exciting (i.e., peppermint) reflected how they defined happiness.

The previous experiment showed that young people could be influenced to define happiness like older people by increasing their focus on the present moment. The goal of experiment 2 was to examine whether older people could be influenced to define happiness like young people by increasing their focus on the future. Thus, a sample of older participants (50-71 years old) was first presented with a sentence unscramble priming task that exposed them to either future-focused words or neutral words. We then manipulated the extent to which participants felt excited and calm and measured how happy they felt. Specifically, participants were made to feel excited or calm by listening to either an exciting or calming version of the song, "Such Great Heights," and they rated how happy they felt while listening to each song. Participants listened to both songs, the order of which was counterbalanced between participants. The results revealed that those in the control condition felt happier when feeling calm than when feeling peaceful, whereas those in the future-focused condition felt happier when they felt excited than when they felt calm. Participants were then asked to choose which song they'd like to receive an MP3 of, and their choice of MP3 reflected their associated levels of happiness. These results imply that our finding young adults to define happiness in terms of excitement (rather than calm) in experiment 1 may be the result of their tendency to think about the future. Therefore, older adults who are influenced to shift their focus away from the present and towards the future are more likely to experience a "young" form of happiness and to choose products accordingly.

In the final experiment we relied on age to determine participants' temporal focus, and we used the same procedures as in the previous experiment. The results revealed that younger adults felt happier when they felt excited than when they felt peaceful, whereas older adults felt happier when they felt peaceful than when they felt excited. Furthermore, participants' experiences of happiness mediated their decisions between receiving an MP3 of the calming song and exciting song.

Together, these findings show that the meaning of happiness can shift both moment-to-moment and over the life course, and that one's definition of happiness predictably impacts choice.

Balancing Ideal Affects In the Pursuit of Happiness

EXTENDED ABSTRACT

The ability to understand how people can durably increase their happiness has received considerable attention in the literature (e.g., Seligman 2005). In particular, techniques such as writing about happy events were showed to have long-lasting effects on self-reported happiness.

What *type* of happy events people should focus on remains unclear. Affect Valuation Theory (Tsai 2006; Tsai et al. 2007) suggests that the desirability of different positive affect states varies across cultures. Americans seem to desire experiencing high-arousal positive (HAP) emotions (e.g., excitement), while Asians seem to prefer low-arousal positive (LAP) emotions (e.g., peacefulness). Theoretically, then, focusing on one's culturally defined ideal affect should lead to greater happiness (e.g., Lewin 1935). We question this intuition. While invariably focusing on a single type of ideal affect will positively influence happiness by moving one's actual state closer to their ideal state, it is possible that the increments in happiness will be less the longer people focus on the same ideal state, because only one

dimension of their affective spectrum is evolving (Tsai et al. 2007). For this reason, people focusing on their culturally defined ideal affect (HAP or LAP emotions) may benefit from switching their focus to the alternative ideal affect.

We tested this prediction in an experiment in which European- and Asian-Americans kept a journal of good experiences. Participants focused on either exciting good things, peaceful good things, or good things (control). We predicted that European-Americans would be happier after focusing on peaceful emotions, while Asian-Americans would be happier after focusing on exciting emotions. In addition, we predicted that the closer our participants would actually be to their culturally defined ideal affect in the beginning of the study, the more they would benefit from focusing on the alternative ideal affect.

Ninety-three European- and Asian-American students (age = 20.4 years, 71 women) participated in our study in exchange for $15. In a first session, participants reported whether they were European- or Asian-American, the extent to which they had felt a number of positive emotions (e.g., elated, enthusiastic) during the past week and indicated their current mood. All participants were then instructed to keep a journal every night for a week. Instructions for the exercise varied in that participants were asked to write about three (a) exciting things, (b) peaceful things or (c) things that went really well on that day, and why they went well. A week later, participants returned their completed journal, and reported the same measures as in the first session, and a seven-item scale assessing general life happiness (e.g., "My life could be more cheerful than it is now," "These are the best years in my life," a = .67), before being debriefed, thanked and paid.

After averaging the items measuring general life happiness, An Ethnicity x Exercise ANOVA on this index revealed a significant two-way interaction, $F(1, 87) = 5.81$, $p < .004$. Euro-Americans$_{peaceful}$ reported being happier than Euro-Americans$_{exciting}$ (M = 2.98 vs. M = 2.37 respectively, $t(87) = 2.06$, $p < .04$). Conversely, we found that Asian-Americans$_{exciting}$ were happier than Asian-Americans$_{peaceful}$ (M = 2.59 vs. M = 2.08 respectively, $t(87) = 1.97$, $p = .05$).

Focusing on participants' positive emotions and mood, a series of factor analyses revealed two recurrent factors at the end of both sessions: an HAP and an LAP emotions factor. After averaging the items for the HAP and the LAP emotions separately for each session, we computed the difference in each of these scores to create an HAP and an LAP index. An Ethnicity x Exercise ANOVA on the HAP index revealed a significant two-way interaction, $F(1, 86) = 3.56$, $p < .04$, such that Asian-Americans$_{exciting}$ reported a more positive difference in high arousal over the week, compared to Asian-Americans$_{peaceful}$ (M = 0.32 vs. M = -0.38 respectively, $t(86) = 2.21$, $p < .03$).

An Ethnicity x Exercise ANOVA using the LAP index as the dependent variable also revealed a significant two-way interaction, $F(1, 86) = 3.04$, $p = .05$, such that Euro-Americans$_{exciting}$ experienced a more positive difference in LAP emotions than Asian-Americans$_{exciting}$ (M = 0.54 vs. M = -0.21 respectively, $t(86) = 2.28$, $p < .03$), and than Euro-Americans$_{control}$ (M = -0.14, $t(86) = 2.17$, $p < .04$).

Next, we centered the high- and low arousal data at the end of the first session by transforming them into deviation scores (Aiken & West 1991). Life Happiness was regressed on high arousal, low arousal, type of happiness exercise for European-Americans and type of happiness exercise for Asian-Americans (both effects coded 1 for exciting exercise and -1 for peaceful exercise), the interaction of each type of exercise with high arousal, and the interaction of each type of exercise with low arousal. There were four significant effects: (1) an effect of high arousal, such that the greater the high arousal in the beginning of the study, the greater the eventual life happiness index, $b = .55$, $t(83) = 4.84$, $p < .001$. There was a negative

effect of type of exercise for European-Americans, such that those who worked on the peaceful exercise had a more positive life happiness index compared to those who worked on the exciting exercise, b = -.27, t(83) = 1.97, p =.05. Third, the reverse occurred for Asian-Americans, b = .28, t(83) = 2.29, p <.03. Finally, supportive of our prediction, there was a significant interaction effect between type of exercise for European-Americans and their HAP score in the beginning of the study. It was such that the greater European-Americans' HAP score initially, the greater difference in life happiness they experienced when they did the peaceful exercise rather than the exciting exercise, b = -.45, t(83) = 2.30, p < .03.

Our findings reveal that people may have a "happiness capital" associated with each type of ideal affect they focus on as a result of their culture. As people's actual affect gets closer to their ideal affect, this capital gets exhausted, and it becomes increasingly beneficial to switch to the alternative ideal affect.

Fate or Fight?

EXTENDED ABSTRACT

This research compares people's hedonic experiences in two resource allocation systems: binding assignment and free competition. In the binding assignment system, superior and inferior resources are unequally and irrevocably assigned to different individuals so that some can enjoy the superior resource without risks of losing it whereas others can only access the inferior resource. In the free competition system, each individual can compete equally for the superior resource but the winner may lose it if he/she does not stay competitive.

We seek to make two contributions here. One is methodological: to introduce an experimental procedure that mimics the two systems and allows researchers to compare people's hedonic experiences in the two systems while holding objective outcomes constant. The other is empirical: to explore whether binding assignment can be hedonically better than free competition.

The Method

Our method consists of two between-participant conditions: fate (simulating binding assignment) and fight (simulating free competition). In the fate condition, two participants are run at a time. They are seated in isolated cubicles separated by a divider, each facing a computer. The "resources" are a video and a book. The video is pretested to be more enjoyable than the book, so the video is the superior resource and the book the inferior resource. The experiment lasts a fixed period (e.g., 8 minutes), during which only one participant can watch the video and the other cannot. Who can watch the video is randomly determined at the outset and cannot be changed. The book is available to both participants, with one copy on everyone's table. Either participant can read it at any time. Participants are not allowed to do anything else.

The fight condition is similar to the fate condition except that the participants can compete equally for the video. At the beginning of the experiment, half of the video image is displayed on one participant's screen and the complementary half on the other's. Any time during the experiment, either participant can drag more of the video image toward his/her screen (and thereby away from the other's screen) by pressing a dedicated key on the computer. If the other participant does not press his/her key in response, the first participant can watch the video fully on his/her screen without having to press the key further. If both participants press their keys simultaneously, the video will move toward the participant who presses his/her key at a faster rate. As in the fate condition, each participant also has the

book and can read it at any time. Participants report their feelings during the experiment.

Note that the method is zero-sum in terms of objective outcome, in the sense that relative to fate, fight neither increases nor decreases the duration or the image size of the video. Nevertheless, fight is not zero-sum in terms of hedonic experience. This is what we discuss next.

The main finding

We have conducted several experiments using this paradigm and the main finding is:

> The fate participants – even the disadvantaged fate participants, who cannot watch the video, are happier than the fight participants.

This finding is counter-normative. Normatively the disadvantaged fate participants are in an absolutely worse situation than the fight participants, because the former have no opportunities to watch the video and the latter do. The worst scenario for the fight participants is to stop fighting for the video and read the book instead, which is no worse than the situation of the disadvantaged fate participants. Yet they are happier.

Explanation

In the fate condition, both the advantaged and the disadvantaged members can enjoy what they have with peace of mind: The advantaged members can enjoy the video without disruptions, real or imagined. The disadvantaged members, because they have no hope of accessing the video, accept their fate, ignore the video and just enjoy the book. On the other hand, participants in the fight condition lack such peace. They are not able to enjoy the video because their rivals are competing with them; nor are they willing to enjoy the book, because the video is tantalizing them. Our finding echoes recent research showing that the opportunity to ameliorate one's state can undermine one's ability to adapt to the state (e.g., Gilbert & Ebert, 2002; Smith et al., 2009).

Boundary Conditions

The reason why even the disadvantaged fate participants were happier than fight participants is that they were able to ignore the superior resource (the video) and enjoy the inferior resource (the book). This suggests two pre-conditions for the fate-better-than-fight effects: (a) that the disadvantaged and the advantaged members are isolated from each other so that the disadvantaged members cannot easily compare with the advantaged members and thereby can ignore the video they are enjoying, and (b) that the disadvantaged members can amuse themselves with the book. These two pre-conditions in turn suggest two moderators: (a) whether comparison between the disadvantaged and advantaged fate participants is inhibited or facilitated, and (b) whether the book is available or unavailable.

Consistent with the theory, we found evidence for two moderators:

> The fate-better-than-fight effects are stronger when comparison between the members is inhibited than when it is facilitated.

> The fate-better-than-fight effects are stronger when the inferior resource (the book) is available than when it is unavailable.

General Discussion

The current research suggests that an unequal assignment system may make people happier than does a free competition system

if the advantaged and the disadvantaged are segregated and the disadvantaged are given some alternative, albeit inferior, resource to enjoy.

However, the current research assumes that free competition is zero-sum in objective outcomes. Obviously, most free competition systems in the real world are not zero-sum; they may increase productivity and profit. The purpose of the current research is not to trivialize such positive outcomes, but instead to call attention to people's hedonic experiences during the process. We recommend that when assessing the overall worthiness of a system, one should consider not only the outcome produced, but also the experience evoked.

Prosperity through Philanthropy

EXTENDED ABSTRACT

Affluence is associated with luxury, wasteful consumption, and generosity. These behaviors might appear to result from an excess of resources, however scholars have noted that conspicuous consumption is high among the poor as well as the rich. A particular topic of debate among economists has been the U-shaped curve of charitable giving, that is, that the poor and the wealthy give a greater proportion of their income than does the middle class. Why do the poor give more? Part of the difference in behavior can be explained by religion, retirement status, identification with the needy, and dependence on social ties. We propose, and our experimental findings suggest, an additional explanation: the poor may give more because charity provides the psychological benefit of feeling wealthy. We propose that philanthropy may have an unintentional self-signaling effect—when we observe ourselves making charitable donations, we infer we must be prosperous. Therefore, in addition to the observed increase in happiness from charitable giving (e.g. Dunn, Aknin & Norton, 2008), givers also benefit from an increase in perceived financial well-being.

In Study 1, we documented the main effect of donations on subjective wealth. Seventy-three members of an online panel were compensated probabilistically for their participation (according to typical practice in this subject pool) with a 1/25 chance of winning a $25 Amazon.com certificate. All participants saw a picture of a very sick child from the Make-A-Child-Smile web site and read a brief biography written by the child's mother. In the Donation condition, they were asked to make a binding pledge of $5 of their $25 subject payment, so that if they were selected to receive payment, we sent a $20 certificate to the participant, and $5 to the child's family. In the Control condition, no donation was requested. All participants then responded to our Subjective Wealth Scale, comprised of statements such as "I'm well-off financially," and "Compared to the people I spend time with, I'm satisfied with my standard of living." Those who had chosen to donate reported higher subjective wealth levels (M=5.3) than those in the control condition (M=3.2). Furthermore, when we collapsed the Donation condition across both donors and non-donors, the difference remained significant ($M_{Donation}$=5.0).

There is ample evidence that recognition is a strong motivator for charitable giving, implying that when we give to charity, we are purchasing wealth and status. In the U.S., only 1% of all donations are anonymous; and when donations are publicized by tier ("Silver," "Gold," etc.), most gifts are at the lower bound of each one. We suggest that donors observe and are influenced by their own status-signaling behavior, even though the signal reveals no new information.

Gift-giving produces some of the same psychological effects as charitable donations (Dunn, Aknin & Norton, 2008), and signaling motives are strongest in romantic contexts (Griskevicius et al, 2007; Souzou & Seymour, 2005; Saad & Gill, 2003); therefore, we tested our wealth-signaling hypothesis in the domain of Valentine's day spending. Because women care more about wealth and status, men have a stronger motive to signal wealth—and this will happen during courtship, when women have incomplete information about their partners' financial status. We predicted that spending money on a Valentine would generally make givers feel wealthier, and also that this effect would be greatest among single men. We asked 99 members of an online subject pool, who had celebrated Valentine's Day with a partner, to describe their Valentine's Day, and how much money they had spent on their partner. In a conceptual replication of Study 1, we found that spending more on a Valentine was associated with increased subjective wealth (β=.22), and that this relationship was strongest for single men (β=.56). Those men had also spent the most on their Valentines ($M_{single\ men}$=$80 vs M_{total}=$40).

Finally, we explored the effect of increases in subjective wealth due to giving on product preferences. Although luxury and premium brands are associated with power and status, theorists (e.g. Bordieu, 1984) have proposed that lower-status groups embrace these behaviors because they want to emulate high-status groups; and in fact, many brands have increased their logo size during the current recession (e.g. Volkswagon, Polo). A recent empirical analysis (Han, Nunes, Dreze, 2010) found that branding was more conspicuous on lower-priced status goods, even within the same brand. We therefore tested the hypothesis that giving money, by increasing donors' perceptions of wealth and power, would decrease their need for status-signaling premium-branded products.

Two hundred ninety-one undergraduate students completed this laboratory study. Each received a sealed envelope containing $1 and was randomly assigned to one of three conditions: Give (select a DonorsChoose classroom project, and give the money to this cause), Lose (return the money to the experimenter), and Keep (pocket the money). Givers, therefore, were no wealthier than Losers, but, like the marginally better-off Keepers, had received a signal of wealth and status. Following this manipulation, all participants completed the Subjective Wealth Scale, and finally, they made a series of hypothetical product choices among 20 pairs of similar products. These products were items that participants in the study (i.e. young, unemployed, and living in a dorm) might purchase regularly. We gathered price information and photos of various pharmacy and grocery store products from drugstore.com and peapod.com, matching one store brand and one premium product in each category (e.g. StopNShop Kapop! vs Orville Redenbacher's microwave popcorn). Replicating Studies 1 and 2, Givers felt wealthier than Losers (3.9 vs 3.3), in fact, as wealthy as the Keepers (3.8). Consistent with previous literature, Losers reported stronger preferences for higher-priced branded products than Keepers did (50% vs 42%), despite feeling poorer. And consistent with our hypothesis, Givers' product preferences aligned with Keepers (only 39% premium brand choices) rather than Losers.

In sum, our current research shows that while decreasing objective wealth, giving money away can increase subjective wealth. We have gathered evidence in support of our self-signaling hypothesis, that we interpret charitable donations as signals of wealth and power, even when the donations are our own.

Servicescapes: Spaces of Representation and Dispute in Ethnic Consumer Identity Construction

SESSION OVERVIEW

Careful attention to time-space intersections is a fundamental feature of consumer research (Arnould and Thompson 2005; Peñaloza, Toulouse and Visconti forthcoming). The relevance of physical space is particularly striking when considering the powerful role of commercial spaces in shaping (and constraining) consumer identity projects (e.g., Borghini et al. 2009, Maclaran and Brown 2005). Over the past decade servicescapes (Booms and Bitner 1981)—the role of physical surroundings in consumption settings—has become an increasingly important area of consumer research. Among others, Borghini et al. (2009) have recently documented the identity enhancing and empowering potential of themed commercial spaces on retail consumers.

Studies investigating the role of the marketplace in ethnic consumer identity construction, however, have clearly prioritized *time* over *space* (Askegaard, Arnould, and Kjeldgaard 2005; Oswald 1999; Peñaloza 1994; Üstüner and Holt 2007). To date space has been mostly objectified in terms of the crystallized notions of *country of origin* and *country of destination* (Visconti 2010). This constitutes a paradoxical omission since migration should structurally stimulate reflexivity upon the movement between and within spaces. Consequently, the spaces in which migrant consumers operate require much more theoretical attention than has currently been devoted.

What happens when ethnic migrant consumers, commonly portrayed as inherently disempowered relative to the cultural majority, interact with various servicescapes both as providers and consumers of services? The goal of this session is to investigate the role of commercial and non-commercial, private and public servicescapes in the making and negotiating of ethnicity. Collectively, the three completed empirical studies demonstrate that the servicescape is not ideologically neutral nor is it epiphenomenal to the construction, contestation, and sharing of ethnic structures. Additionally, the authors show that the migrants' access, utility, and experience in consuming and producing services are highly affected by various servicescape structures.

In detail, Veresiu and Giesler first highlight the role of global cities' public and private servicescapes in enabling partial and inconsistent identity-enhancing tactics for ethnic migrant consumers,

which they define as ethnic entrepreneurship. Next, Üstüner and Thompson cast a new theoretical light on the institutional shaping of servicescape relationships by investigating the role of commercial space in mediating sociocultural differences between urban customers and migrant, rural laborers. Finally, Visconti and de Cordova document the strategic role of space in public services. Relying upon the theoretical pillars of cultural psychology, they display four forms of servicescapes in the sphere of healthcare.

Overall, this session should appeal to a broad audience, including scholars (and managers) in the field of acculturation studies, service marketing, experience management, and space/place attachment. We anticipate our discussant Lisa Peñaloza will encourage audience participation and provide important directions for future research, drawing from her pioneering studies on consumer acculturation and the contemporary marketplace. Consistent with the ACR 2011 theme, this session builds bridges on four levels: (1) contributions stem from various theoretical domains, including consumer research, cultural psychology, sociology, and anthropology; (2) the separate research streams of servicescapes and migrant identity construction are brought together; (3) the ambits of public and private servicescapes are contrasted; and, (4) managerial practices and academic reflections are conceptually integrated.

Ethnic Entrepreneurship: Creating an Identity-Enhancing Assemblage of Public and Private Servicescapes in the Global City

EXTENDED ABSTRACT

Consumer acculturation—the adaptation to an unfamiliar consumer cultural environment by ethnic minorities—is of great and growing interest to consumer researchers (Askegaard, Arnould, and Kjeldgaard 2005; Oswald 1999; Peñaloza 1994; Üstüner and Holt 2007). Previous studies have documented migrant consumers' negotiation of competing identity positions and cultural value systems in both North American and non-North American contexts. While this work is groundbreaking, it has devoted surprisingly little theoretical attention to the strategic role of market-mediated physical space in ethnic consumer identity construction. How do migrant consumers leverage their surroundings in order to construct their identities? What is the role of spaces in allowing migrant consumers to acquire agency?

To interrogate these important yet equally under researched questions, we focus on a well-defined commercial space: the servicescape. Booms and Bitner (1981) developed the concept in order to emphasize the impact of the physical environment in which the service process unfolds. Over the years, consumer research has expanded the theoretical boundaries of servicescapes by investigating retail atmospherics, themed environments, brandscapes, cybermarketscapes, retroscapes, as well as public-, private- and gendered-servicescapes (e.g., Brown and Sherry 2003; Sherry 1998; Visconti et al. 2010). Yet it is surprising to find that the role of ethnicity in servicescape structures has remained largely unexplored.

In this paper, we bring these two disparate research streams together by means of a detailed ethnographic investigation of migrant

individuals of Roma ethnicity in a particular space, the global city. Sociologist Saskia Sassen (2006) has argued that global cities play a profound role in enabling migrant consumers to create a tenuous visibility and establish a meaningful presence. We build upon her theoretical insights by investigating the role of public and private servicescapes on migrant consumer identity construction. More specifically, we develop the construct of ethnic entrepreneurship as an underrepresented mode of producerly-consumption through which an array of servicescapes found in global cities is transformed into an assemblage of deliberative relationships and resources allowing migrant individuals to leverage their ethnicity and expand their economic and social possibilities.

To illustrate ethnic entrepreneurship, we conducted a multi-sited ethnographic and netnographic (Kozinets 2002) investigation of Roma individuals in Toronto, Berlin and Pisa. The study intentionally spans three cities for the purpose of interpretive triangulation. Couched in participant observation and historical research, 70 in-depth, semi-structured interviews were completed with Roma individuals, local citizens and city officials. Roma informants were solicited through non-profit organizations and personal recommendations. During our conversations with the Roma, everyday living activities were discussed (e.g., housing, working, education, healthcare, food, clothing, and entertainment). In order to better understand the overall sociocultural and political environment of the respective cities, we also interviewed national citizens, which were solicited from anti-Roma websites and online discussion forums, as well as public officials across the social services, immigration, child welfare, education, and public shelter sectors. The data set was completed in the winter of 2010 and subsequently analyzed using a hermeneutical approach (Thompson 1997).

Our findings reveal how ethnic identity construction is mediated through the global city's public and private servicescapes. For example, we found that our informants strategically use and creatively combine all available servicescapes in the global city's network in order to reinforce their identity and the core values of their ethnicity. All of the Roma informants demonstrated an extraordinary capacity to develop and utilize personal networks not only in their narratives, but also by attempting to recruit us (in the role of researchers) to translate documents, to assist in employment search, to recommend new hospitals for long-term care, etc. We discuss these findings in detail and compare the limitations of servicescapes in a small town (Pisa) versus a global city (Toronto).

The contributions of this research are threefold. First, it advances consumer acculturation research by exploring the lucrative role of a particular space, global city servicescapes, in ethnic consumer identity construction. Second, it contributes to the research on servicescapes by analyzing the relationship between ethnicity and both public and private servicescapes. Third, this study contributes to the sociology of globalized spaces literature by interrogating ethnic entrepreneurship as the migrant consumer's contribution to reinforcing and advancing the global city theoretical construct.

How Marketplace Performances Produce Interdependent Status Games and Reconfigurations of Identity Resources: The Case of Rural Migrant Service Workers

EXTENDED ABSTRACT

This study investigates how socio-cultural differences between consumers and service workers are mediated by the institutionalized power relationships and asymmetrical interdependencies that operate in a servicescape context. These socio-cultural dimensions of servicescape interactions and institutional identities have fallen in a theo-retical blind spot that exists between the respective analytic orientations of the service relationship (Arnould 2005; Berry 2002; Vargo and Lusch 2008) and sociology of servicework paradigms (Hochschild 1983, 2003; Sherman 2007). This oversight is particularly glaring because, in the global service economy, these occupations are increasingly being filled by workers matriculating from deeply impoverished rural areas (Sassen 2006). Indeed, one of the most significant trends impacting global economic development is a massive population shift from rural to metropolitan areas (Meng 2005). Numerous studies of developing economies have documented that rural inhabitants have considerably less access to educational resources and, a higher proportion of households headed by individuals with little or no formal education, than their socio-economic counterparts in urban areas (Ferreira and Walton 2006).

These socio-economic shifts also create a structural mismatch between the socio-cultural backgrounds these service workers bring to the urban glamour zones and the aptitudes needed to effectively perform aesthetic labor (Witz, Warhurst, and Nickson 2003). Although many forms of service work fall on the low end of the income and occupational status scales, they are by no means a province for unskilled or deskilled workers. Many of these service jobs are highly interactive, requiring specific forms of cultural knowledge, practical skill, and interpersonal acumen that generate symbolic and aesthetic value for a metropolitan and well-educated clientele.

Our analysis highlights the commercially-mediated power relations that create a new class of aesthetic laborers and also bind customers' and workers' identities in a network of asymmetrical interdependencies known as figurations (Elias 1978). Our research context is the hairdressing industry in metropolitan regions of Turkey. Much like their North American and European counterparts, Turkish hair salons tend to foster long-term relationships between hairdressers and customers. These relationships also represent an intersection between the rural, socio-economic periphery of the globalizing economy and its consumer-oriented socio-economic center points (Sassen 2006).

To gain insights into the relational dynamics of this servicescape context, we interviewed 9 hair salon-owners, 11 staff at varying stages in their careers, and 11 middle or upper-middle class women who patronize such salons. The interviews were conducted in Turkish and ranged from 1 ½ hour to 2 ½ hours in length. All interviews were audio recorded and transcribed verbatim (and translated into English). Each interview began with general questions about the participants' background, personal interests and life goals, and then proceeded with queries about their specific experiences as salon workers or customers. In keeping with the conversation with a purpose of depth interviewing (McCracken 1988), participants largely set the flow of the interview, with the first author asking follow-up questions and probing for more descriptive details. In making sense of the interview data, we used an iterative, part-to-whole process of hermeneutic analysis (Thompson 1997). Initially, we first independently analyzed the entire set of transcripts and formed provisional understandings of emergent thematic commonalities.

Our analysis reveals that these servicescape figurations play out through an intricate system of interpersonal strategies and alliances. Salon owners become the de facto enforcers of customers' institutionalized authority through their actions in creating an appropriate salon aesthetic and socially conditioning (through sometimes heavy handed methods) their employees in the prevailing middle class norms. Owing to the fact that the salon is, indeed, a path for attaining economic and cultural resources, rural migrant and urban underclass men accept these modes of governance and internalize them as forms of self-improvement and in turn gradually become distanced

from their rural or squatter social networks and cultural heritages. As these men build their professional reputations as hairdressers, they also begin to believe, and not without some practical justification, that they can wield subtle forms of influence over their middle class clientele. For customers and hairdressers, the structural realities of class stratification, become less relevant to their interactions than their respective perceptions of who is being placed in a position of greater dependency over the course of the relationship.

Accordingly, customers and hairdressers' servicescape interactions are oriented toward managing and recalibrating the asymmetrical interdependencies which bind them together. In many cases, these relational practices are conventional aspects of the servicescape script. These standardized conventions enable customers to experience their class-based advantages as self-evident entitlements which can go without saying and that need no justification. For example, customers' expectations of empathy and indeed anticipatory emotional responsiveness become one of the de facto means through which they implement their class privileges over hairdressers and other salon workers.

In contradistinction to the repressive portrayals of emotional (and aesthetic) labor advanced by the sociology of servicework paradigm, we show that hairdressers (and their young apprentices) view servicescape figurations as an empowering means to pursue their own consumer-oriented identity projects, rather than as an alienating disciplinary regime. Seen in this light, the Turkish hairdressers are strategically deploying the cultural and economic resources gained through their subordinated position in these servicescape figurations to circumvent other pressing socio-cultural limits on their consumer identities.

Our analysis also brings into sharper relief how confluences of class and gender positions are manifested and negotiated in the institutional positions, interaction norms, and shifting power relations of a servicescape. On the hairdressers' side, their reconfigured identity positions demonstrate that patriarchal advantages are not equally distributed across class strata (or even geographic region as social actors move from rural to urban settings). As these working class/squatter men seek to gain higher class standing by entering the metropolitan hairdressing profession, they also abdicate some traditional forms of patriarchal authority. In effect, they are trading a subcultural species of gender capital, having currency in a socio-economically marginalized social sphere, for forms of capital (e.g., economic, social, and cultural) (Bourdieu 1990; Holt 1998) which provide more utility in metropolitan and middle class status systems.

Culturally and Linguistically Appropriated Servicescapes: The Making of Ethnicity in the Context of Healthcare Services

EXTENDED ABSTRACT

"Shoppers are not anonymous, historyless individuals when they walk in the door, and stores are not monolithic spaces that affect all who enter in uniform and predictable ways (…). In the confrontation between historically situated people and socially constructed spaces, people are repeatedly reconstructed as particular people *in that place*." (Chin 1998: 612).

Since the pioneering work of Tuan (1974) and the foundation of the servicescape concept (Booms and Bitner 1981), space in the marketplace has represented a key part of our mundane experience as both shoppers and consumers. Scholars in the field have variously defined servicescape. Tighter elaborations set the boundaries of servicescape to the built-environment and the physical components of the context in which the seller and the customer interact (Booms

and Bitner 191; Bitner 1992). Within such tangible space, the service allows for sociality but the focus remains on the "language of the objects" (Bitner 1992: 62), including ambient conditions, spatial layout, and material artifacts.

Recent positions extensively interpret the servicescape, for example by highlighting its social dimension (Tombs and McColl-Kennedy 2003). More radically, Sherry (1998: 6) draws from Relph's (1976) idea that spaces may include intentions, attitudes, purposes, and experiences. Venkatesh (1998) further expands this notion to comprise the imaginary of the cyberspace. Again, Chin (1998) argues that servicescape implies also the planning and design of physical space, and thus the intentional, purposeful making of the service model as fulfilled by its spatiality.

Our research adheres to this comprehensive formulation of servicescape. In fact, our inquiry combines the tangible and the immaterial, the functional and the symbolic components of healthcare servicescapes. In particular, we focus on the ways in which migrants are transported, accompanied, served, and assisted by healthcare services in Italy. Within these services, the aim is to investigate the role of space in the representation, making, contestation, negotiation, rejection, and socialization of ethnicity. This project is grounded on the evidence that health inequalities against ethnic minorities are perpetrated (Ibrahim 2003; Rosenbaum and Montoya 2007), due to intentional and unintentional mistakes committed along the process of service design and supply.

Empirically and methodologically, our interpretations emerge from a meta-analysis (Hunter and Schmidt 2004) of the projects we have conducted, or supervised, during the last ten years in Lombardy, Italy. One of the researchers holds a Ph.D. in marketing, and has analyzed particularly the logics, intentions, and implications of the servicescape design. The other researcher has a Ph.D. in cultural psychology and has taken part to the elaboration and testing of alternative forms of servicescape for migrant patients. Data are generated from quite an extended set of methods, including ethnography, action research, observation, participant observation, researcher introspection, questionnaire collection, group discussion, short and depth interviews with patients, doctors, and medical staff in various service settings (first aid, pediatrics, psychiatry, proximity health-services, maternity wards, etc.) and contexts (within the service, at school, at home, etc.).

Our analysis shows four main forms of servicescape, which we label: i) undifferentiated; ii) assisted; iii) ad hoc, and iv) transcultural. *Undifferentiated* servicescapes put forward a biomedical approach, which assumes that the constructs of body, health, and illness are not cultural specific. The homogenizing frame of these services, which is erroneously proposed as universalism, is detectable from physical and ideological components of the servicescape: monolingual banners and flyers, Westernized space design, presence of traditional medical personnel, and willingness to treat all customers the same regardless of their ethnic/national origin. *Assisted* servicescapes acknowledge the higher barriers that ethnic patients usually have to access and properly consume the service. Here, the built-environment reveals an attempt to facilitate ethnic customers by means of multilingual communications and the presence of professional facilitators (i.e., linguistic and cultural mediators). Third, *ad hoc* servicescapes are meant to meet the exclusive and distinctive needs of ethnic patients, and thus result in the complete revision of the physical, social, and conceptual dimensions of the servicescape. Communications are often in the languages of the customers, environments are more welcoming and informal, treatments can be alternative and conscious of cultural traditions, and the service design is frequently ethno-specific (Nathan 2001). At the same time,

socialization is enclavized since customers of the service are solely immigrants. Finally, *transcultural* servicescapes constitute the most sophisticated example of "medical pluralism" (Goldstein 2004). In this case, the areas of the servicescape mostly put under revision are the social and the immaterial ones. Socialization does not show ethnic divides but admits forms of social exchange receptive of cultural differences since the medical personnel here contests ethnocentric, univocal modes of relation. Also, the service design is totally re-framed in order to leverage cultural commonalities across ethnicities. The built environment often presents adaptations: Psychiatric services have abandoned the semiotic separation between the physician and the patient (usually imposed by the doctor's desk) in favor of a circular display of chairs where the patient, his/her relatives, and the various members of the medical team are equally titled to generate and negotiate interpretations.

Our findings demonstrate that healthcare servicescapes not only may differently incorporate ethnic customers (the four forms afore-mentioned) but also—and more intriguingly—contribute to eternize or contest ethnic structures. According to the physical, social, and ideological traits of the servicescape, ethnicity acquires completely different valences, ranging from transparency (undifferentiated services) to inconvenience (assisted services), and from otherness (ad hoc services) to open confrontation (transcultural services). As Proshanksy (1978: 150 quoted in Rosenbaum and Montoya 2007: 208) contends, "there is no physical setting that is not also a social, cultural, and psychological setting", and—we argue—also a political and ideological one.

Consumption Begins with the Eyes:
Building Connections between Vision and Consumption

Session Chair: Ann Kronrod, MIT, USA

Paper #1: Where Do You Draw the Line? Perceptual and Mental Boundaries
  Spike Lee, University of Michigan, USA
  Norbert Schwarz, University of Michigan, USA

Paper #2: Look at Me Now: Automatic Change Detection as a Moderator of Processing Fluency
  Stewart A. Shapiro, University of Delaware, USA
  Jesper Nielsen, University of Arizona, USA

Paper #3: The Glance Effect in Decision Making
  Ann Kronrod, MIT, USA
  Joshua Ackerman, MIT, USA

Paper #4: The Road to Fantasized Consumption is Paved with Visual Roadblocks
  Heather Barry Kappes, New York University, USA
  Adam Alter, New York University, USA

SESSION OVERVIEW

Objective and general orientation: The session encourages the motto for ACR2011 conference, "building connections", highlighting the multiple connections between vision and thought. Exploring the effects of what we see on what and how we think, four papers manipulate visual experiences and examine diverse outcomes at different stages of mental processing. Lee and Schwarz demonstrate that visual lines serve as mental boundaries, affect basic categorization, and have downstream consequences for social cognition. Shapiro and Nielsen are interested in the effect of a changing visual object (e.g. a moving logo) on processing fluency, resulting in higher effectiveness of the ad. Kronrod and Ackerman examine the effect of giving a glance at a familiar object on decisions made about that object. Finally, Kappes and Alter investigate the influence of visual disfluency (difficulty in perceiving written information) on fantasies about various consumption experiences.

Likely Audience and issues to be covered: The session highlights the impact of visual stimuli common in daily life (lines, familiar objects, moving logos, fussy fonts) on different stages of thought, from basic categorization and attitude formation to decision-making and fantasized consumption. We expect it to attract a diverse audience, whose fields of interest range from visual perception to grounded cognition, categorization, attitudes, fluency, decision making, fantasy and mental simulation.

Rationale and contribution to consumer research: Whether watching TV at home, browsing through the internet or scanning through products lined up on a store shelf, consumers are engaged in a process where what they see affects what they think. This session digs deeper into the effects of visual stimuli on thought, by asking questions about more advanced stages of thought, such as fantasy, albeit without neglecting the processes that lay at the base of those effects, such as categorization.

The chair will open the session with a brief overview of the tight connection between the papers and highlight the gradual thematic progression of the session from paper 1 to paper 4. Since the session is about visual effects, part of the stimuli used in the papers presented will be displayed in the room for higher vividness and involvement of the audience.

Where Do You Draw the Line?
Perceptual and Mental Boundaries

EXTENDED ABSTRACT

Concepts are organized together if they share taxonomic membership (e.g., carrot and eggplant) or thematic relationship (e.g., rabbit and carrot; Markman & Hutchinson, 1984). Both are based on concept features. But can *irrelevant* features bias categorization? In everyday parlance, "drawing a line" is used as a metaphoric expression for marking a boundary. We test whether increasing the accessibility of graphical lines is sufficient to activate the metaphoric meaning of mental boundary. Study 1 addresses basic categorization effects and subsequent studies explore downstream consequences for thinking about others (Study 2), oneself (Study 3), and one's past and present (Study 4). In all studies, students were approached on campus for voluntary participation. Questionnaires were printed on horizontally-oriented, letter-size paper.

Study 1: Taxonomic-Thematic Categorization

In two allegedly unrelated projects, participants first estimated lengths of four lines, one at the middle of each page. The lines were either horizontal ($n = 66$) or vertical ($n = 67$). Next, participants were given a triad of concepts and asked to "circle the two that are most closely related." The triad was carefully positioned with (a) the top concept above and the bottom concepts below where the horizontal lines appeared earlier and (b) the top concept right through and the bottom concepts on different sides of where the vertical lines appeared earlier.

The central concept (carrot) could be categorized taxonomically with one concept (eggplant-carrot) or thematically with another (rabbit-carrot); the latter two could not be categorized together (eggplant-rabbit). If visual lines activate mental boundaries, participants should "draw a line" between concepts on different sides. Concepts on the same side should be more likely to be categorized together; concepts crossing the mental boundary should be less likely to be categorized together.

As predicted, the two bottom concepts (eggplant and carrot) were more likely to be categorized together after seeing horizontal than vertical lines (54 vs. 26), but the top and bottom-right concepts (rabbit and carrot) were more likely to be categorized together after seeing vertical than horizontal lines (41 vs. 12), $\chi^2(1, N = 133) = 25.66, p < .001$. Apparently, visual lines steered basic categorization.

Study 2: Social Perception

Does the line effect extend to social perception? Participants listed features or traits of students in different schools. Six underlined spaces appeared on the left under the label "LAW", six on the right under "BUSINESS." The number of listed features that were different between law and business was divided by the total number of features, yielding the percentage score as dependent variable. There was a 5-inch vertical line between the two lists ($n = 21$), a 5-inch horizontal line above both lists ($n = 26$), or no line at all ($n = 23$).

As expected, participants listed more different features between law and business students if there was a line between the two lists ($M = 79\%, SD = 22\%$) than if the line was above them ($M = 64\%, SD = 26\%; t(67) = 2.01, p = .05$) or if there was no line at all ($M = 64\%, SD$

= 28%; *t*(67) = 1.99, *p* = .05). The last two conditions did not differ, *t*(67) = 0.04, *p* = .97. This pattern suggests that a visual line draws a mental boundary between two concepts only if it separates them in physical space.

An alternative account is that there is something unique about vertical lines. Mere presence of vertical lines may have activated a "categorization goal." Study 3 addressed this concern and further tested if the line effect would generalize to perception of self-other differences.

Study 3: Self-Other Perception

Participants listed features or traits of "yourself" (on the left) and "a student that can represent UM" (on the right). There were two vertical lines between the two lists (*n* = 49) or encompassing both lists (*n* = 50), or two horizontal lines encompassing both lists (*n* = 44).

Participants listed more different features between self and other if the two lists were separated by lines in the middle (*M* = 78%, *SD* = 24%) than if they were encompassed by two vertical lines (*M* = 57%, *SD* = 30%; *t*(140) = 3.70, *p* < .001) or two horizontal lines (*M* = 58%, *SD* = 29%; *t*(140) = 3.48, *p* = .001). The last two conditions did not differ, *t*(140) = 0.10, *p* = .93, suggesting that simply seeing vertical lines is not enough. The lines have to separate the concepts in physical space in order to separate them in mental space.

Study 4: Past and Present

On a one-page questionnaire, participants wrote down "a negative event that happened during the last two years" on the left and judged their life satisfaction on the right—"Taking all things together, how satisfied are you with your life as a whole these days?" and "How happy do you feel about how your life is going?" (*0 = not at all*, *10 = very much*). The two items were highly correlated (*r* = .91, *p* < .001) and averaged. A 6.5-inch line appeared either vertically between the two sides (*n* = 25) or horizontally underneath both parts (*n* = 26).

Participants were more satisfied with their life if there was a line between their past event and present judgment (*M* = 8.00, *SD* = 1.31) than if the line appeared underneath both parts (*M* = 7.06, *SD* = 1.80), *t*(49) = 2.13, *p* = .04.

Conclusions

Visual lines serve as perceptual inputs to cue categorization. It produces downstream consequences for subsequent categorization (Study 1), thoughts about social others (Study 2), oneself (Study 3), and one's past and present (Study 4). These findings combine insights from embodiment and metaphor perspectives to show how lines carve up perceptual and mental space. Follow-up work is testing how incidental exposure to carefully oriented lines may instantiate category boundaries (Bless & Schwarz, in press). Process issues and potential moderators (or as the professional jargon goes, "boundary" conditions) will be discussed.

Look at Me Now: Automatic Change Detection as a Moderator of Processing Fluency

EXTENDED ABSTRACT

Scholars have assembled an impressive body of work demonstrating how stimulus characteristics can direct attentive processing from one area of the visual field to another. Within advertising, researchers have demonstrated how specifics of ad design can direct attentive processing to important elements within a visual display (e.g. brand logos within an ad or ads within a newspaper or website), thus increasing the ad's effectiveness. Among factors known to attractive attentive processing, primarily through abrupt onsets that disrupt the visual field (Treisman 1986; Treisman and Gormican 1988), are size, contrast, and color. More recent research has demonstrated that shifts in attentive processing from one ad element to another can be initiated via preattentive processing. For example, Nielsen, Shapiro, and Mason (2010) demonstrated that preattentive processing can detect the emotionality of non-focal ad elements, and due to the sensitive nature of emotional stimuli, such detection subsequently directs attentive processing to the emotional stimulus.

The current research further examines how preattentive, or automatic, processing may affect the allocation of processing resources in ways that improve ad effectiveness through increased processing fluency. Specifically, we build on research pertaining to change blindness and change detection and demonstrate that changes in the perceptual relationship between a target stimulus (e.g. a brand logo) and other contextual elements (other elements within the ad) can be detected automatically. As a consequence of implicitly detecting a change, greater processing resources are directed to the changing stimulus without the participant's awareness. Specifically, between exposures, we subtly change relative placement of a stimulus (e.g. brand logo) within a visual scene (e.g. an advertisement) and demonstrate that participants automatically detect these changes and unknowingly increase the processing resources allocated to the changing stimulus. This in turn facilitates the amount of processing fluency that the logo enjoys. Across three experiments we demonstrate how this increased allocation of processing resources improves ad effectiveness through the metacognitive experience of perceptual fluency (as evidenced by improved response times, higher preference for the brand, and increased likelihood of brand choice).

Experiment 1 first explores the effect of automatic change detection on advertising effectiveness by demonstrating increased valuation of brand logos whose perceptual relationship with other contextual elements within an advertisement vary between exposures. Specifically, we compare the evaluation of logos that move location within an ad (changing its perceptual relationship to other ad elements) from one ad exposure to the next to the evaluation of brand logos that remain in the same location across exposures. We further manipulate awareness of the relative location and demonstrate that, consistent with prior research into the effect of metacognitive experiences on judgments, when participants are aware of a potential influence on their judgments, the positive effect of fluency is negated.

Experiment 2 achieves three goals. First, we directly measure fluency and demonstrate that fluency, as measured by faster response times, is enhanced by changing the logo's perceptual relationship with other contextual elements between exposures. Further, we demonstrate that the increased fluency is the result of automatic detection (i.e. without intention or awareness; Crabb and Dark 2003) of the location changes of the logos which directs processing resources to the changed element (ad logo) without the participant's awareness. Further, analyses on explicit logo recognition revealed no effect of change detection on logo recognition.

Experiment 3 directly contrasts our proposed resource allocation account with the alternative account that fluency may be the result of increased neural activity generated from the changing image that, in turn, increased stimulation from exposure (Janiszewski and Meyvis 2001) I in a fully crossed forced choice experiment participants are more likely to select moving over non-moving logos and importantly, logo movement had no effect on the evaluation of the advertisement within which the logos were embedded, suggesting that the increased preference for the logos is not the result of a general stimulation account, but instead is driven by an increased evaluation of only the moving logo. Thus, these results favor the resource allocation account over an increased stimulation account.

The Glance Effect in Decision Making

EXTENDED ABSTRACT

People often give a short glance at an object (e.g. one's pet) when they think about it or make decisions related to it (e.g. whether to buy a new food bowl). Allegedly, when the object of a decision is familiar and well known, there is no need to look at it in order to make decisions because the relevant information already exists in the mind. Moreover, in many cases the decision about a familiar object has nothing to do with the object's looks. Thus, a glance at one's pet would not contribute information to the decision about whether it needs a new bowl. We suggest, however, that although there are no pertinent cues in the object's external appearance or spatial location, giving the object a glance while making a decision about it can influence decision making. This may occur because a glance at the object raises the accessibility of (non-visual) information about the object that is stored in the mind (e.g. Uchida, Kepecs and Mainen 2006). We expect this Glance Effect to affect a variety of metacognitive and decision processes, including the quality of the decision, depth of thought and post decisional attitudes, such as confidence in the decision and satisfaction with it. We explore the Glance Effect in three experiments, described below.

In study 1, we show the predominance of the Glance Effect phenomenon. Forty university employees were interviewed regarding their building facilities and various objects within these buildings. Notably, the questions had nothing to do with the objects' looks (e.g. "Are there many people allergic to carpet dust here?"). After each question, the experimenter asked the participants to rate on a 7-pt scale their confidence in their reply. While the participants were giving their replies, the experimenter made record of their glances and also wrote down their replies. Out of 120 replies, 101 (84%) were

accompanied with a glance at the object, while 19 (16%) were not. Further, glances at objects produced higher confidence in subsequent decisions than decisions made without glancing.

In study 2, 152 participants answered a series of decision questions about familiar objects (e.g. "should cats be named after national heroes?"), with answers ranging from "definitely yes" to "definitely not" on a 7-pt. scale. Half of the sample saw a picture of the object (e.g. a cat) along with the question. Decision time and post decisional attitudes (perceived accuracy and correctness of the answers, as well as the difficulty to make a decision and confidence in the decision) were recorded for each item. . We find that a glance at a picture of the object elevates both one's confidence in the decision and perceived accuracy, and reduces perceived difficulty of making the decision, compared to the no glance condition. However, decisions with glances did not take significantly longer time than decisions without an image, implying no additional processing effort.

Study 3 addresses the effect of object familiarity on the role of the glance. We predict that glances will be more deliberative when objects are unfamiliar and thus information comes only from the image (Glimcher and Dorris 2004). In this experiment, we also make an initial measurement of decision quality. In a 2 (yes/no previous information) by 2 (yes/no image at decision stage) design, 240 participants were presented with 3 decision questions about unfamiliar objects (e.g. "Would you recommend planting *Acokanthera Schimperi* around a public playground?"). Response options ranged from "definitely yes" to "definitely no" on a 7-pt scale, with "I have no clue" as an additional option. Half of the sample received the question with a picture of the object and the other half saw no image. Also, prior to making a decision, half of the sample learned information about the object and the other half received no information prior to making the decision. For instance, participants learned that *Acokanthera Schimperi* is an extremely poisonous plant used to prepare poison arrows in Ethiopia. Data collection is ongoing. For the group who has prior knowledge when making the decision, we expect the image to enhance confidence in the decision, while not changing the decision itself. As a replication of the result in Study 1, we also expect no effect of glancing on decision time among these participants, as the Glance Effect does not require extra processing. However, for the group who has no previous information about the object, we expect decision time while viewing an image to increase due to the time it takes to learn the image. Further, we expect no significant difference in confidence between glance and no glance condition among these participants,) as the visual information they will receive by glancing at the objects is unrelated to the questions and therefore cannot help make a decision.

To conclude, glances can significantly affect metacognitive decision experiences such as confidence, post-decision attitudes, and they may improve decision quality as well. Understanding the role of visual information search in individuals' judgments and decisions, even judgments and decisions that are logically unconnected to this visual information, is thus important for future decision research and application. For example, marketers and consumers both may benefit from exposure to objects related to current decisions, as these decisions might involve greater deliberation, more positive attitudes, and less decision-making difficulty.

The Road to Fantasized Consumption is Paved with Visual Roadblocks

EXTENDED ABSTRACT

The consumer decision-making process begins when potential consumers imagine themselves using a product. Robust findings indicate that people choose options that they imagine will maximize their prospects of enjoyment, reward, and happiness. Thus, positive fantasies about products or experiences are often the first step toward consumption. However, little research to date has examined when people generate such positive fantasies.

We conducted a series of studies on this topic, focusing on the effect of one prominent variable: visual processing fluency, or the metacognitive experience of ease or difficulty associated with perceiving written information (cf. Alter & Oppenheimer, 2009). Experiencing disfluency—encountering visuoperceptual or other cognitive roadblocks—leads people to think more deeply and more abstractly than does experiencing fluency (Alter et al., 2007; Alter & Oppenheimer, 2008). Accordingly, we posited that disfluency should aid in generating fantasies that depict richly imagined hypothetical scenarios which transport people out of the mundane constraints of daily life. That is, disfluency should lead people to generate fantasies that are more positive and less constrained by reality.

To test these ideas, we manipulated the fluency of descriptions of various hypothetical scenarios, and asked participants to fantasize themselves in the scenarios. In multiple studies employing different paradigms, student participants who generated fantasies about scenarios such as eating a favorite candy bar, touring a dream home, and taking a vacation reported that their fantasies were more positive when these scenarios were presented in disfluent fonts than in fluent fonts. When participants were asked to write down the contents of their fantasies, and naïve raters coded the degree to which these fantasies were constrained by reality (e.g., conceding that the dream home was presently unaffordable), participants in the disfluent prompt condition were also found to have generated fantasies that were less constrained by reality than participants in the fluent condition.

Additional studies applied these ideas outside the lab. Dieters were given a fluent or disfluent prompt to fantasize about a hypothetical future after completing a weight loss program. Fantasies were seemingly less constrained by reality in response to the disfluent prompt: Participants reported thinking that it would be easier to lose their desired amount of weight after fantasizing in this condition than in the fluent fantasy prompt condition. In a second naturalistic application, raters examined whether blogs that described fantasies differed in content depending on whether the blogs were formatted fluently or disfluently. The blog descriptions were rated by separate groups of participants for positivity and for fluency (ease of reading). The fantasies were perceived to be more positive the less fluent they were, suggesting that visual disfluency prompts positive fantasies even in daily life.

The present findings differ from a plethora of existing research showing that—with some exceptions—people evaluate fluent stimuli more positively than disfluent stimuli. However, whereas these earlier findings examine the direct relationship between fluency and evaluation, we examine how fluency affects evaluation indirectly by shaping the cognitive approach that people adopt when perceiving and processing the target stimuli. That is, fluency changes the way people process information, which in turn alters their preferences indirectly. Accordingly, disfluency not only guides judgment directly by making a product feel more appealing, instrumental, or special; it also influences evaluation indirectly by stimulating unconstrained positive consumption fantasies.

These findings have clear implications for consumer behavior, as they highlight a relatively simple way to enhance enjoyment in fantasy, and to in turn increase the likelihood that a fantasized product or experience is selected amongst others. Since consumption begins when purchasers imagine the benefits of a new acquisition, advertisements and promotional material that are somewhat visually disfluent should promote consumption by compelling richer, more enjoyable fantasies. Paradoxically, then, the same cognitive roadblocks that follow metacognitive difficulty also encourage people along the road to positive fantasies.

SESSION OVERVIEW

The fact that approximately half of shoppers' purchases are unplanned to some extent and are subject to the influence of in-store factors (Inman and Winer 1998; POPAI 1995) makes in-store marketing increasingly important. The augmented significance of in-store marketing strategies makes it critical to understand the factors encouraging unplanned purchases in the store. Despite the importance of this topic, surprisingly few marketing researchers have investigated how decisions are made in the store and the relevant factors that influence unplanned buying. Most of this research focuses on the effect of contextual factors such as the existence of store display and the hedonicity of product category (Inman, Winer, and Ferraro 2009). Regarding the influence of internal factors (i.e., customer characteristics) on unplanned purchases, prior research mainly looks at relatively *static* customer traits that are fixed across shopping trips such as gender, income level, and household size (Kollat and Willett 1967). Very little research has captured the effects exerted on unplanned purchases by relatively *dynamic* shopper activities specific to each shopping trip such as shoppers' overall shopping trip goal, distance they travel in the store, composition of their shopping basket (vice vs. virtuous), and the amount of accumulated savings from their previous purchases. Furthermore, most prior studies on the influence of customer factors on unplanned buying ignore the active role played by shoppers to plan their shopping trips in order to make better in-store decisions.

The purpose of this session is to report the findings of recent research to address the gap as discussed above. Specifically, this session adds to our understanding of the influence of dynamic customer activities on unplanned buying as well as how customers actively plan their buying behavior by engaging in high-level cognitive activities such as goal setting and health self-concept management. The three papers touch on different aspects of such activities: how culture drives goal setting to plan purchases prior to entering retail stores; how consumers' accumulated saving and shopping basket composition interplay to affect their health self-concept and their following unplanned spending; and how consumers' in-store travel distance influences unplanned buying and how to design effective marketing strategy to increase unplanned purchases via increasing shoppers' path length.

The opening paper by Knox, Corsten, and Bell relies on longitudinal survey panel data collected from the United States, China, Western Europe, and Brazil to investigate cultural drivers of shoppers' tendency to plan purchases prior to entering retail stores. They specifically look at how cultures influence consumers' "pre-shopping" mental activities such as the formation of the overall trip goal and store-specific shopping objectives to generate unplanned buying. They find that unplanned purchases are the highest in the United States where the "individualism" characterizes the culture. Furthermore, individualistic cultures seem to encourage the tendency to think abstractly about shopping goals before entering the store, which, in turn, facilitates unplanned buying in the store.

In two experiments and a grocery field study, Kurt and Stilley show that the composition of the current shopping basket (i.e., virtue vs. vice) licenses subsequent impulsive spending in the in-store shopping setting, but that this effect is moderated by accumulated savings on already purchased items. Particularly, a virtuous basket composition leads to higher subsequent impulsive spending due to increased health self-concept as compared to a vice basket composition. However, when shoppers save money on earlier purchases, the licensing effect disappears as a result of a decrease in the health self-concept premium for the virtue condition.

Finally, Huang, Hui, Inman, and Suher collect grocery shoppers' in-store trip length in a field study through Radio Frequency Identification tracking. By using an instrumental variables approach, they estimate the causal effect of in-store path length on unplanned spending and find that the elasticity of unplanned spending on in-store travel distance is around 1.44. That is, increasing path length by 10% for each shopper (an average of around 140 feet) will increase unplanned spending by about 14.4%, or $2.27 per shopper. They also conduct two sets of policy experiments to investigate the effectiveness of two shopper marketing strategies, product category relocation and location-based mobile apps, in increasing in-store travel distance and unplanned spending. Their results suggest that adding an additional "planned" category into a consumer's shopping list by strategically promoting this category makes them travel longer in the store and leads to as much as 28% increase in the overall amount spent on unplanned purchases. However, relocating product categories only has a limited effect (around 5%) on increasing unplanned buying.

This session aims at enhancing our understanding of how shoppers' dynamic activities specific to each shopping trip influence their unplanned buying in the store. The papers also demonstrate how customers actively engage in mental activities such as goal setting and self concept management both before and during their shopping trips. In addition, each paper offers its unique perspective regarding the methods we can use to study the effects of these dynamic customer activities in an in-store shopping setting. The focus of this session is part of a larger literature on consumers' pre-purchase information processing and in-store decision making. This is consistent with many ACR members' research interests.

Shopping Goals and Unplanned Buying Across Cultures and Countries

EXTENDED ABSTRACT

It is difficult to overstate the importance of "unplanned buying" to retailers as they rely on incremental purchases to implicitly take

share from competitors and also to stimulate additional consumption. Unplanned buying is reportedly widespread—"Supermarkets are places of high impulse buying … – fully 60 to 70 percent of purchases there were unplanned, grocery industry studies have shown us" (p. 171 *The Science of Shopping by* Paco Underhill)—and generated when consumers are exposed to in-store marketing activity. Unplanned buying also increases in the absence of "time pressure" (e.g., Park, Iyer, and Smith 1989), consumer and category factors (Inman, Winer, and Ferraro 2009), and consumer planning and exposure to marketing on the "path-to-purchase" before entering a retail store (Bell, Corsten, Knox 2011).

In this study, we investigate how "pre-shopping" factors—the overall trip goal, store-specific shopping objectives, and prior marketing exposures that the shopper brings to the store interact with cultural factors to generate unplanned buying at the individual shopper level. Our study, unlike most prior academic studies, relies on rich survey panel data in which the same shopper is observed taking several trips. Moreover, we utilize detailed panel data collected from shoppers in the United States, Western Europe (Germany and Spain), Asia (China), and Latin America (Brazil). Shoppers were also interviewed in the home on standard measures of propensity to favor brands (over private labels), attitudes towards shopping, and methods of information gathering.

To test our hypotheses, we estimate a series of fixed effects Poisson and Tobit models in a quasi-experimental design. Specifically, the *same* shopper in a given country is observed invoking different goals, shopping in different stores, and buying under different circumstances. Across countries, shoppers are matched to allow testing of key dimensions of the cultural differentiation framework laid out in Hofstede (2001). Following the procedure in Erdem, Swait, and Valenzuela (2006), we directly integrate the cultural factors into our models of unplanned buying. We introduce a number of measures of observed heterogeneity across shoppers (e.g., demographics) to control for differences in their overall propensity to make unplanned category purchase decisions.

We have four new substantive findings. First, among the countries considered, we find that unplanned buying is the highest in the United States and that the average extent of unplanned buying within a country varies across countries in a manner consistent with Hofstede (2001). Specifically, the average rate of unplanned buying is positively related to "Individualism" in a culture and it is negatively related to "Uncertainty Avoidance". Second, at the individual level, unplanned buying not only increases with the abstractness of the overall shopping trip goal established before the shopper enters the store (Bell, Corsten, Knox 2011) but also further increases within individualistic cultures. Using an instrumental variables approach we find that the tendency to think abstractly about shopping goals is highest in individualistic cultures, i.e., there is a level effect of culture on goal abstraction, holding income and other factors constant. Third, we identify cultural determinants of store and trip-specific shopping goals. This is important because while *any* reason for choosing a store by definition has a positive effect on store traffic, not all store choice reasons have a positive effect on unplanned buying. The tendency to visit a specific store because of proximity to *other* stores, for example, is indicative of a predetermined goal for that store and therefore leads to less unplanned buying there. Finally, we identify a number of culturally-based moderators of unplanned buying. Prior research shows, for example, that consumers react to crowding by buying more variety to assert freedom (Levav and Zhu 2009) and that they do more unplanned buying in crowded stores (Bell, Corsten, and Knox 2011). Everything else held constant, this effect is amplified in Brazil and China where consumption is argu-

ably more socially construed, i.e., where consumers use brands to signal status and to indicate group membership.

We conclude the study by identifying a number of descriptive differences in routine shopping behavior across cultures, including attitudes to the shopping process and the cost benefit trade-offs made by consumers. The rich panel data for shopping trips and comprehensive in-home interview data collected by our research partner (a global CPG firm) provides a basis for a number of conjectures we intend to explore in future work. Overall, our findings illustrate that country-level variation in a remarkably ubiquitous and routine consumer behavior, i.e., unplanned buying while grocery shopping in supermarkets, is quite well predicted by cultural differences. Since cultural factors are enduring and systemic, our findings have important implications for researchers, managers, and policy makers.

Lost Your License to Spend? The Moderating Role of Savings on the Licensing Effect of Virtuous Shopping Basket Composition on Impulsive Spending

EXTENDED ABSTRACT

According to the licensing effect (Khan and Dhar 2006), committing a prior virtuous act increases one's preference for a hedonic item (versus utilitarian) as the virtuous act enhances consumers' self-concepts and mitigates the negative self-attributions resulting from the choice of the more hedonic option. While the extant literature on the licensing effect largely focuses on the impact of consumers' previous actions and choices on their relative preference for a hedonic compared to utilitarian item of the same value, this paper examines the licensing effect of virtuous acts on shoppers' wealth management, namely impulsive spending.

Impulsive spending contradicts with the goal of not spending money unnecessarily and thus, leads to negative self-attributions (Mukhopadhyay and Johar 2009). Related research suggests that although consumers often try to avoid purchases that will cause them to exceed their mental budgets (Heath and Soll 1996), they look for ways to justify excess spending above their budgets (Cheema and Soman 2006). Consistent with this view, licensing effect on impulsive spending is expected to manifest itself during a shopping trip where consumers make a series of purchase decisions. That is, given the self-indulgent nature of impulsive purchases, consumers tend to seek reasons that can help them reduce the negative self-attributions associated with impulsive spending. In this research, we propose that the composition of the current shopping basket (i.e., virtue vs. vice) will license impulsive spending in the in-store shopping setting, but that this effect will be moderated by accumulated savings on already purchased items.

Recently, studies have shown that, in a single-shot choice setting, a price discount on a hedonic item increases purchase likelihood because the discount mitigates guilt associated with purchasing the hedonic item (Mishra and Mishra 2010; Khan and Dhar 2010). Extending this work, we contend that greater savings on prior purchases can reduce positive self-attributions associated with a virtuous shopping basket. Therefore, we propose that, in a sequential choice setting, promotional savings will attenuate the licensing effect of a virtuous shopping basket composition and that this will occur because of a reduction in the health self-concept premium associated with purchasing virtuous items.

The first study consists of two phases: (1) initial choices (i.e., planned purchases amounting $4) and (2) subsequent choice (i.e., impulsive spending). Participants, who were unaware of the second phase and endowed with $4, were asked to choose one product in each of the two categories that they were shown. Those assigned to

the vice shopping basket condition chose a brand of potato chips and a brand of cookies to purchase while those in the virtuous shopping basket condition chose a brand of pretzels and a type of grapes. In all conditions, the price of the initial choices summed to $4.00, however some items were portrayed to be on sale using the following manipulation. In addition to showing participants the current price of each item, we reported the last week's price in a separate column next to the current price column. One item in the second category was noted to be on sale (with a label emphasis – *ON SALE!*) with the original price being $3.50 marked down to the sale price of $2.50 The other option within this category was sold at its regular price of $2.50. Accordingly, a participant who chose the sale item would perceive that they had saved $1.00, but total spending of all participants was actually equal to $4.00 prior to the impulsive spending task. After making their initial choices, participants were then asked to indicate their willingness to pay for Snickers bars. Consistent with the licensing effect, we find that, in the no savings condition, the virtuous shopping basket composition licenses increased impulsive spending on Snickers bars. In contrast, when participants saved money on their prior choices, the licensing effect of the virtuous basket disappears as there is no significant difference in impulsive spending between vice and virtue conditions.

The second study builds on the first study in several ways. First, we demonstrate that the licensing effect of virtuous basket composition extends to impulsive spending on a relatively *virtuous* item (Soyjoy Nutrition Bar) and that, as in Study 1, this effect does not manifest in the savings condition. Second, to better reflect the real shopping experience, we increased the number of product categories in the initial choice phase and altered the composition of the shopping baskets (e.g., 3 virtue items plus 1 vice item rather than 2 virtue items). Third, we find that virtuous basket composition leads to higher health self-concept than a vice basket composition but that savings attenuate this difference. Finally and most importantly, we show that health self-concept mediates the moderating role of savings on the effect of virtuous shopping basket composition on subsequent impulsive spending.

Furthermore, to test our thesis in a real shopping setting, we leveraged data from the field study conducted by Stilley, Inman and Wakefield (2010). In this study, 400 customers were intercepted as they entered two different grocery stores located in a southwestern city. Before they entered the store, respondents were asked to estimate how much they intended to spend in total. Since respondents kept track of their purchases in order using a hand-held scanner, we were able to measure the composition of their shopping basket and the amount of accumulated savings before they make impulsive purchases (i.e., items bought after respondents exceeded their mental budgets). We again find that lower hedonicity rating of the shopping basket is associated with higher subsequent impulsive spending only when accumulated savings are low, providing external validity for our results.

Using both simulated and real shopping data, this paper documents the moderated licensing effect of virtuous prior shopping on subsequent impulsive spending. In particular, participants who earlier purchased more utilitarian (vs. hedonic) products are later willing to spend more on impulsive purchases but only when they did not realize any savings on their prior purchases.

The Effect of In-Store Travel Distance on Unplanned Purchase with Applications to Store Layout and Mobile Shopping Apps

EXTENDED ABSTRACT

Retailers have traditionally located frequently purchased products (e.g., milk) in strategic locations that encourage shoppers to cover a longer distance in the store. In this case, consumers will be exposed to more products and in-store stimuli along the way, thus become more likely to make unplanned purchases. In addition, recent advances in location-based mobile marketing have made it possible to integrate shoppers' location with their loyalty card information and offer targeted promotions to increase distance traveled.

The effectiveness of in-store shopper marketing strategies aimed at increasing in-store travel distance is contingent on whether there is a *direct* effect of longer in-store trip distance on unplanned purchasing, and if so, the magnitude of this effect. Rather surprisingly, the academic research literature has largely been silent on this important practical issue. While Granbois (1968) and Inman, Winer and Ferraro (2009) include a metric related to trip length (e.g., number of aisles shopped) and show that it is positively correlated with the likelihood of unplanned purchases, to the best of our knowledge there has been no study that explicitly estimates the direct relationship between in-store trip length and unplanned spending. Part of the reason for this gap in research is that before the recent development of radio frequency identification (RFID) tracking, in-store trip length was difficult and costly to obtain. Further, even if in-store trip length can be measured reliably and cost-effectively, a direct interpretation of the regression coefficient of in-store path length on the amount of unplanned purchases is still misleading because in-store path length is endogenous.

The endogeneity of in-store path length is caused by omitted in-store and out-of-store variables, simultaneity/reversed causality, and measurement error. First, some omitted in-store and out-of-store variables can cause changes in both unplanned purchases and in-store path lengths. Suppose that a shopper is attracted by the display of an unplanned item and purchases that product. Then both in-store path length and the amount of unplanned purchases increase, but there is no direct causal relationship between the two, resulting in a spurious correlation. Second, since both in-store path length and the amount of unplanned purchases are generated during the same shopping trip, it is difficult to empirically tease apart the direction of causality between them. For instance, it is possible that a shopper decides to buy an unplanned product first, then incurs the additional distance to purchase that product. Third, the difficulty of accurately measuring in-store trip length may lead to a noisy measure.

To combat the aforementioned endogeneity issues, we construct an instrumental variable based on the length of a "reference path," which is determined by the store layout, a shopper's planned purchases, and an assumption about her search strategy. Specifically, we consider two possible strategies, an infinitely forward-looking traveling-salesman strategy (TSP) or a one-step-look-ahead strategy (a "greedy" algorithm). We show that the length of this reference path is strongly correlated with the length of the actual in-store path. Importantly, since the reference path is determined *before* the shopper starts her grocery trip, this instrumental variable temporally precedes the dependent variable (amount spent on unplanned purchases).

Our field study was conducted in a medium-sized grocery store located in a northwestern U.S. city. We collected data from 300 shoppers by offering each of them a $5 store gift card as participation compensation. Each participant first completed an entrance survey. The questions therein included: (1) whether they had a shopping list

today; (2) their total shopping budget; (3) whether they were shopping alone; and (4) their familiarity with the store in terms of the product locations. Finally, on a list of all product categories in the store, they checked all the products they planned to purchase during the current shopping trip. This forms the "planned" set of products for each respondent. After finishing the entrance survey, the experimenter helped participants to put on a PathTracker® belt. The RFID (Radio Frequency Identification) tag on the PathTracker® belt emits a radio frequency signal every five seconds, which is then picked up by the antennas at the perimeter of the store, allowing us to track the (x,y) coordinate of the shopper in the store at any time. We compute the total in-store path length for each shopper using their shopping path obtained from the RFID tracking. After completing their shopping trip and checking out, participants completed an exit survey in which they answered several demographic questions, including their gender, age, household size, household income, and whether they have children. The store provided the transaction history for this specific shopping trip for all of the participants. By comparing each shopper's total purchases to the planned categories stated in the entrance survey, we compute the amount of money that each shopper spent on unplanned purchases.

With our empirical data collected through the field study and having constructed a valid instrument, we estimate the causal effect of in-store path length on unplanned spending using two-stage least squares. We estimate that the elasticity of unplanned spending on in-store travel distance is around 1.44, which is 53% higher than the corresponding OLS estimate that does not account for endogeneity. To put this into perspective, for our dataset, increasing path length by 10% for each shopper (an average of around 140 feet) will increase unplanned spending by about 14.4%, or $2.27 per shopper, which is 53% higher than the (uncorrected) OLS estimate.

Having estimated the effect of in-store travel distance on unplanned purchases, we then use our econometric framework to conduct two sets of policy experiments to explore the potential effectiveness of (a) location-based mobile apps to deliver in-store targeted promotions and (b) product placement strategies in increasing unplanned purchases via increasing shoppers' path length. We find that by strategically promoting an additional product category (hence adding an additional "planned" category into a consumer's shopping list), the overall amount of unplanned purchase can be increased by as much as 28%. In contrast, we find that relocating product categories only has a limited effect (around 5%) on increasing unplanned purchases.

SESSION OVERVIEW

In decision-making or consumption, the valence of incoming information can determine its eventual effects. Losses looming larger than gains would be the canonical example of these types of differences. While that effect is quantitative, it is also possible for information to be processed in a qualitatively different manner depending on its positive or negative nature. Thus it becomes important to ask if the mechanisms engaged by incoming information do or do not depend on its valence. The 4 papers in this session examine the processing of positive versus negative inputs in different contexts. By using functional magnetic resonance imaging, these studies provide insight into the neural as well as behavioral effects of valenced information in contexts that serve to activate different processing areas of the brain. This makes the convergent methodology especially valuable, as it allows us to compare the impact of valence and the involvement of convergent and divergent brain areas across settings.

From a methodological aspect, all 4 papers in this session rely on the fMRI technique to gain insight into underlying cognitive processes. In recent years, neuroimaging techniques such as functional magnetic resonance imaging (fMRI) have provided a unique opportunity for assessing the relationship between patterns of cortical and subcortical activation in different brain areas and different aspects of cognitive processing in healthy individuals. FMRI measures the increase in oxygenated blood flow that is tightly correlated with neural (synaptic) activity. Thus fMRI images can contrast brain activity across tasks varying on specific variables of interest, potentially revealing differences in underlying mechanisms. As such, this session also provides a forum for one of the most exciting new research methodologies in consumer research.

I Can Almost Taste It Now: Tracking the Neural Effects of Anticipatory Delays on Positive and Negative Consumption

EXTENDED ABSTRACT

The question that we address in this research is how a period of anticipation might shape the neural coding of the consumption experience. More specifically, how does the brain react to positive or negative consumption experiences that occur after a brief versus a long delay?

Several studies have suggested that in many cases the anticipation of a positive or negative consumption experience can change the value that is experienced at consumption (e.g., Loewenstein, *The Economic Journal*, 1987; Nowlis et al., *JCR*, 2004). For example, Nowlis et al. (2004) show that uncertain anticipatory periods can intensify both hedonic and aversive taste experiences.

Data from neuroscientific research presents a more complicated picture. For example, in the realm of taste, anticipation evokes its own pattern of neural activity but this can include activations of some of the same neural circuitry involved in processing rewarding experiences (O'Doherty et al., *Neuron*, 2002). Thus it is possible this reward could "carry over" to the consumption experience. In addition, a period of negative anticipation or "dread" before a known experience such as an electrical shock activates many of the same brain areas that are involved in processing physical pain (Berns et al., *Science,* 2006). However, Berns et al. (2006) also found that delays before receiving a shock did not alter the eventual experience of pain. Thus, it remains unclear how anticipation can actively change the consumption experience itself and whether this is different for experiences with different valences.

A related and unexplored issue is whether the duration of the anticipatory period prior to consumption affects the consumption experience. For instance, will increasing the duration enhance or attenuate any effects on the consumption experience? To address these questions, we examined the effects of a short or long anticipation time on a positive or negative consumption experience at the neural level using functional magnetic resonance imaging (fMRI). On any particular trial, participants received a brief cue that indicated the valence of a liquid they would receive (unpleasant salty tea or pleasant sweet juice), as well as the number of seconds they would have to wait from the onset of the cue for the liquid to arrive. This anticipation period lasted either 2 (short) or 6 (long) seconds. They were further instructed to hold the liquid in their mouths until directed to swallow, and received a neutral rinse solution at the end of every trial. Thus data was collected from 17 participants who received four trial types, comprising a 2 (negative vs. positive) by 2 (2 vs. 6s) within-subject design.

We examined the first four seconds during which participants were actually tasting the sample liquid. Our focal analysis contrasted neural activity during this taste experience when duration of the anticipatory period had been long, compared to short. Activity in affective and valuation related brain areas was stronger when the participants had only had a short time to expect the onset of the taste. Specifically activity in the bilateral insula, caudate nucleus, anterior cingulate cortex and medial prefrontal cortex were all more active when taste was preceded by a short rather than a long cue. Interestingly, the overall pattern found was similar for both pleasant and unpleasant liquids.

These results suggest that the emotional or value processing of taste attenuates as the duration of anticipation gets longer. Further careful analysis is required to draw conclusions from these initial results. However, one tantalizing possibility may be that since there is overlap between neural areas involved in the anticipation and experience of taste, a long anticipatory delay allows sufficient time for the brain to react to the expected pleasant or unpleasantness of the upcoming experience. Thus by the time the stimulus itself arrives, the affective neural response has habituated.

On the surface, this appears to disagree with behavioral work such as Nowlis et al. (2004.) However, it should be noted that in those experiments, participants were unaware of when they would be receiving their outcome, thus it came as a surprise. In addition, the anticipatory period was much longer. In our experiment, the durations were defined and were within a timescale that could easily be estimated by the participant. However, given this conflict, future studies need to explore whether the impact of a post-choice delay in the consumption experience is affected by whether the delay is certain or uncertain.

A main contribution of this study lies in suggesting that the length of an anticipatory delay may decrease the intensity of the experience itself. For familiar positive outcomes, this suggests that it is better not to provide consumers information about a pleasant experience too far in advance. However, for aversive experiences it may have a silver lining, allowing people to prepare for negative events.

Neural Mechanisms Underlying Individual Variability in Susceptibility to Framing Effects

EXTENDED ABSTRACT

Context often biases decision preferences. For instance, presenting the same product attribute as a positive (i.e. 75% fat-free) or a negative frame (i.e. 25% fat) has been shown to impact customer attitudes and buying preferences. While this basic "framing effect" has been well-characterized, little is known about its underlying individual variability or about its extensions across contexts.

In a large-sample fMRI experiment (N=58), participants engaged in a risky choice task that manipulated decision frames. On each trial, participants were shown a starting amount before choosing between a "sure" and "gamble" option. The sure option was framed such that the participant could keep (gain frame) or lose (loss frame) a fixed proportion of the starting amount. The gamble option did not differ according to frame and was represented by a pie chart reflecting the probability of winning the entire starting amount. On each trial, subjects either played for themselves or for a pre-selected charity of their choice. We used four fixed starting amounts ($10, $20, $30, $40) and three different probabilities of winning (25%, 50% and 75%). The expected-value relationship between the two options varied across trials.

We observed increased gambling in loss frames (Mloss = 45%) compared to gain frames (Mgain = 28%), an effect that was greater when participants played for their chosen charity compared to themselves (t(57) = 2.79, p < 0.05). We found that distinct brain regions contributed to framing decisions involving charity and self. Strikingly, individual's relative susceptibility to self and charity framing effects was correlated with activation in ventromedial prefrontal (vmPFC). This suggests that individual differences in relative decision biases for self and charity framing effects could be rooted in value computations within vmPFC.

Contextual Influences on Neural Bases for Brand and Social Relationship Judgments"

EXTENDED ABSTRACT

Consumers' relationships to brands, particularly ones they identify closely with, have many of the same qualities as interpersonal relationships (e.g., Fournier, *JCR,* 1998). Accordingly, judgments of one's relationships with brands and with people may be subserved by the same neural system. There are, however, likely to be meaningful differences as well. Yoon et al. (*JCR,* 2006) compared personality judgments of the self to those of other persons and brands, and found reliable dissociations in patterns of neural activations underlying the judgments. Comparisons of neural responses for personality judgments about brands versus persons indicated significantly greater activation in the left inferior prefrontal cortex (LIPC). In addition, they found significantly greater activations of the medial prefrontal cortex (MPFC) for person personality judgments. They further found that although personality judgments about the self relative to other persons differentially engaged the MPFC regions, this activation pattern did not extend to judgments about brands that are self-relevant compared to brands that are not self-relevant. However, these findings do not necessarily preclude the possibility that the MPFC and reward-related regions are activated during processing of brands that invoke a strong sense of the self. In order to investigate this, we conducted two fMRI studies that examined the neural bases for judgments about positive facets of relationships with brands or people who are close (rather than distant).

Study 1 was a 2 (target: person vs. brand) x 2 (closeness to self: close vs. distant) block design in which participants made judgments about their relationships with people and brands varying in closeness to the self. The behavioral session took place approximately two weeks prior to the fMRI session. It was intended to identify six names for each of the "close" and "distant" target persons as well as six names of each of the "close" and "distant" brands for each participant. Because participants differed on which brands and persons were regarded as close versus distant, the four sets of target stimuli for inclusion in the fMRI sessions were unique to each individual.

Fifteen volunteers were recruited for the behavioral session in which participants were given a list of 85 brand names and were asked to write down the first product or service name that came to mind next to each brand. They were then instructed to keep these branded products in mind as they rated them for familiarity, attitudes, and the degree to which they identified with each of them. This was followed by ratings for 90 well-known people on familiarity, attitudes, and degree of identification. Next, the participants wrote down up to 12 names of people (with both first and last names) with whom they currently had a close relationship (e.g., mother, best friend). Finally, these 'close' persons were also rated on the same three scales.

Fourteen (7 females) of the 15 volunteers completing the behavioral session participated in the fMRI session. They were selected on the basis of our being able to identify an individual-specific set of 6 close brands, 6 distant brands, 6 close persons, and 6 distant persons. Across participants, the close and distant sets of brands were rated equivalently in terms of familiarity, but varied in the extent to which the respondents identified with them. Likewise, close and distant persons were rated similarly in terms of familiarity and attitudes, but varied in the extent to which the respondents identified with them. The brands and persons were then each divided randomly into three lists for each participant in the fMRI session. Each list thus contained two targets for each of the four treatment conditions.

Participants were scanned during three functional runs while making judgments about whether or not the word appearing with the name of a person or brand described a facet of their relationship with the target. Within each block, four trials included the same one brand (or one person) and were concurrently presented with a sequence of four different relationship words. A target (e.g, close or distant brand) was presented on the screen along with a fixation cross for 500 msec. A relationship word then appeared below the fixation cross for 4500 msec, during which time the participant made the relationship judgment. Participants indicated whether or not the word described their relationship with the given brand or person by pressing the key under their index finger for 'yes', or middle finger for 'no'. They were asked to make each judgment as quickly, yet accurately, as possible. The total fMRI session lasted about 45 minutes.

Consistent with prior findings by Yoon et al. (2006), we found that MPFC was implicated in judgments for relationship with people and LIPC for relationships with brands. Moreover, the enhanced engagement of the reward-related regions to self-relevant information was found for close person relationship judgments only, as evidenced by a significant interaction of Close minus Distant Persons, in contrast to Close minus Distant Brands. However, we did not find any support for the notion that the reward-related regions are differentially engaged during judgments about relationships with close (vs. distant) brands.

The results of Study 1, in fact, suggested that our ability to detect neural responses to judgments about relationships with brands were compromised. While the activations in reward-related regions for relationship judgments about close people were robust, they completely swamped any neural signal changes for brand relationship judgments. Based on these findings, we hypothesized that neural measures are highly sensitive to context and limiting the study task to brand relationship judgments may be necessary to observe differences in neural activations in reward-related regions. This idea was tested in a follow-up study.

In study 2, 18 (9 female) individuals participated in the behavioral and fMRI sessions that closely followed the procedures in Study 1. The target stimuli however comprised only close and distant brands. As expected, study 2 results indicated enhanced activations in the MPFC as well as the OFC for close versus distant brands.

The two studies, taken together, serve to highlight the importance of accounting for the experimental context in assessing and interpreting neural findings. Theoretical and methodological implications are discussed.

Goal-Directed Versus Habitual Responding at Different Times of Day

EXTENDED ABSTRACT

Contemporary theories of instrumental learning suggest a dual-process model: a simple, though less flexible, stimulus-response system and a more cognitive goal-directed system (Dickinson & Balleine, *Animal Learning & Behavior,* 1994). The critical distinction between the two is that the goal-directed system maintains an active representation of an outcome, or goal, such that a change in the expected outcome (or a change in a person's motivational state) should change behaviour. There is accumulating evidence that the caudate nucleus plays a role in this process, whereas its sub-cortical neighbour, the putamen, sub-serves cognitive functions more limited to stimulus-response, or habit, learning (Grahn, Parkinson, & Owen, *Progress in Neurobiology,* 2008). Measures of anatomical and functional connectivity demonstrate a clear link between the caudate and regions of the frontal lobe known to be responsible for 'executive'

functions that require the generation and monitoring of appropriate strategies, and evaluation of potential outcomes for successful performance (e.g., the globus pallidus acts as the hub for connections between caudate and frontal cortex; Doyon et al., *European Journal of Neuroscience,* 1996).

Of particular interest to this paper, is that caudate nucleus is highly innervated by dopamine neurons and that there is significant increase in the concentration of dopamine in the caudate nucleus during sleep (we measure and confirm this via related levels of cortisol in participants' saliva samples). We hypothesise that this should engage individuals in more goal-directed behaviour in the morning. In particular, it has been demonstrated that the caudate is highly involved in learning and memory, particularly regarding feedback processing (Packard, & Knowlton, *Annual Review of Neuroscience,* 2002). We therefore hypothesized that consumers would respond differently at different times of day to marketing messages that challenge versus reinforce established preferences for products or services.

Participants were immersed in an fMRI scanner throughout. During Stage 1, participants indicated their preferred brand (among 6) within 6 product categories (e.g., chocolate bars, yogurts, laundry detergents). Participants were exposed to all possible pairings within a category, providing a preference rank order.

During Stage 2, participants repeated the task, but first read a statement relating to one of the brands shown before choosing. The statements were based on known key drivers behind consumer choice in each category from TNS market research data. There were 4 statement types designed to either reinforce their brand preference or to reverse their revealed preference. Statement types 1 and 2, below, encourage switching, by devaluing the preferred brand relative to the alternative, whereas statement types 3 and 4 reinforce the previously preferred brand.

1. A positive statement about the previously non-preferred brand (e.g., if the preferred brand is compared to Cadbury's Dairy Milk: "Cadbury's Dairy Milk stimulates the brain's pleasure centres better than any other chocolate bar")

2. A negative statement about the previously preferred brand (e.g., if Mars was the preferred brand: "In blind taste tests, Mars is consistently rated as the lowest on flavour and richness against its key competitors").

3. A positive statement about the previously preferred brand (e.g., if Mars was the preferred brand: "Mars outsells every other chocolate bar on the market").

4. A negative statement about the previously non-preferred brand (e.g., if the preferred brand is compared to Twix: "Twix has the highest number of calories and additives of any chocolate bar").

The more participants engaged the goal-directed (habitual) system to make choices during stage 2, the more (less) sensitive they should be to information that devalues their preferred brand and the more they should reverse their choices from stage 1.

The data were then divided into AM vs. PM testing periods to find out whether consumers are more likely to switch (when prompted by an appropriate statement) in the morning or evening. The choice data showed that negative statements about a preferred brand and positive statements about a less-preferred brand significantly increased the tendency to select the previously less preferred brand to a greater degree in the morning than in the evening. The fMRI images show that these switching statements engaged goal-directed brain ar-

eas (caudate nucleus, globus pallidus and frontal cortex) more in the morning more than the evening.

In contrast, the habit system was more influential in the afternoon than in the morning. Positive statements about the preferred brand and negative statements about a less-preferred brand resulted in significantly higher preference consistency in the evening than the morning. The fMRI images show that reinforcing preferences resulted in greater activation in habit learning brain areas, such as the putamen.

The results show that the same information is processed differently based on the readiness of specific brain areas. Goal-directed brain areas were more active in the morning, resulting in a greater response to marketing communications that challenged revealed preferences. In contrast, habit forming brain areas were more active in the evening, resulting in a greater response to marketing messages that reinforced preferences. These results are similar to behavioural data that showed variety-seeking in terms of switching away from a leading brand was more common in the morning than in the afternoon (Roehm & Roehm, *Marketing Letters,* 2004). The authors speculated that variety seeking provided stimulation, and that the diurnal arousal-peak in the afternoon resulted in a lower utility for such stimulation. Our results suggest a different picture, namely that consumers are more habitual in their behaviour late in the day because of increased activity in the brains habitual learning areas versus goal-directed learning areas. As such, this finding builds on the result that older adults perform resource-demanding tasks—such as a message's argument strength—better in the morning than in the afternoon or evening (Yoon, Lee & Danziger, *Psychology & Marketing,* 2007).

New Insights Into The Endowment Effect And Loss Aversion

SESSION OVERVIEW

The endowment effect, introduced by Thaler (1980), follows from two fundamental findings of Tversky and Kahneman (1981): (i) reference-dependent preferences that (ii) reveal loss aversion, a heightened sensitivity to losses relative to gains. Though much is now understood about reference-dependent preferences and loss aversion, many important questions remain for marketers. For example, although it is clear that preferences are often reference-dependent, it is less clear how reference points develop and change over time. Moreover, although many researchers have identified behavior consistent with loss aversion, we know little about the explanatory power of loss aversion (versus competing accounts) across contexts, and the cognitive underpinnings of loss aversion. The objective of this session is to discuss emerging research into the nature of ownership and loss.

The four papers included in this session are all in late stages of completion (one working paper and three papers in advanced rounds of review). The first two papers focus on the source and malleability of reference points, and the latter two papers focus on the explanatory power and nature of loss aversion. Ericson will begin by presenting experiments that tease apart competing explanations for reference point formation (ownership versus recent expectations). He finds that recent expectations about owned goods (e.g., expecting not to receive them) attenuates the endowment effect, suggesting that reference points are not strictly determined by actual ownership. Then Paolacci will present experiments demonstrating that the endowment effect can be reduced by forcing owners to consider trading for "intermediate alternatives." His studies reveal that participants who trade their endowment for an intermediate alternative actually shift their reference point to that intermediate. Even participants who reject a trade to an intermediate option are affected by considering it—their reference point is weakened.

Moving the focus to loss aversion, Mishra will then present experiments that physiologically manipulate perceived ownership to examine whether the endowment effect is best explained by loss aversion or by ownership-induced attachment. She argues for a more nuanced view of the underlying process—endowed participants are strongly influenced by attachment whereas non-endowed participants are influenced by reference-dependence and loss aversion. Finally, Johnson will present research demonstrating that loss aversion is neither a simple constant, nor simply a function of individuals or attributes. Using a large-scale field experiment where individual measures of loss aversion for several attributes of a product are developed, he shows that much of the variance in loss aversion can be explained by the consumer's knowledge of the attribute and the attribute's importance to the consumer.

We expect these papers will provoke productive discussions about the nature of loss aversion, ownership, and reference points. This session will appeal to a wide range of consumer behavior scholars and especially those interested in the endowment effect, loss aversion, spending behavior, behavioral economics, and decision-making.

Expectations as Endowments: Evidence on Reference-Dependent Preferences from Exchange and Valuation Experiments

EXTENDED ABSTRACT

Evidence from a variety of settings indicates that people are loss averse: they dislike losses much more than they enjoy equal-sized gains. Yet little is known about the determination of the reference points relative to which gains and losses are defined. Kahneman and Tversky's (1979) highly influential prospect theory, where loss aversion was first introduced, left the reference point imprecise. It has often been taken to be the status quo (Samuelson and Zeckhauser 1988), meaning that individuals are reluctant to give up things they currently possess. An alternative view, advocated by Kőszegi and Rabin (2006, 2007, 2009), is that reference points are determined by recent expectations about outcomes, which need not correspond to the status quo. Since the status quo often determines expectations, much existing evidence is consistent with either alternative. However, the implications of loss aversion frequently differ depending on the assumed reference points. This study provides new experimental evidence that reference points are determined, at least in part, by expectations: people appear loss averse around their expected outcomes.

We present two experiments in which we manipulate expectations separately from endowments. Our first experiment tests whether expectations affect exchange behavior. We endow all subjects with the same item (a mug), and randomize the probability that they will be allowed to exchange that item for an alternative (a pen). We find that subjects who are more likely to expect to keep their endowed item (because they have a low probability of being allowed to exchange) are more likely to choose to keep their item if given the opportunity to exchange. This finding is predicted if individuals have expectation-based reference points, but not by theories that identify the reference point with the status quo or by theories in which preferences do not depend on reference points. It suggests that the expectation of continued ownership, rather than current formal ownership per se, induces a reluctance to part with possessions (a phenomenon Thaler [1980] called the "endowment effect"). As a consequence,

loss aversion need not impede transactions that individuals expect to occur.

Our second experiment measures the effect of expectations on subjects' monetary valuation of an item. Subjects are not initially endowed with any item, but learn that they will receive a mug for free with either high (80%) or low (10%) probability. All subjects also know that with probability 10%, they instead have a choice between the mug and money. We elicit their mug/money choices for varying amounts of money, which gives a measure of their willingness-to-accept (WTA) for the mug. To increase the precision of our estimated treatment effect, we also elicit WTA for an unrelated item, a pen. This allows us to proxy for idiosyncratic factors that affect valuation of university merchandise. We estimate that subjects who were randomly assigned to have a high expectation of leaving with the mug value the mug about 20-30% higher than subjects who were less likely to leave with the mug, an effect that is both statistically and economically significant.

Moreover, we also conduct a variation of our second experiment to untangle whether expectations matter because people experience gains and losses with respect to a reference point, or because likely ownership of an item increases individuals' estimates of its consumption utility. According to the former theory, expectations should only affect the valuation of the mug currently in a person's reference point. The latter theory, which we refer to as "motivated taste change", instead predicts that expecting to own one mug should also increase the valuation of a second, identical mug. We do not find any evidence that motivated taste change is the source of our results: subjects' expectations of getting one mug do not affect their valuation of a second mug conditional on getting the first mug.

The Intermediate Alternative Effect: Considering a Small Tradeoff Increases Subsequent Willingness to Make Large Tradeoffs

EXTENDED ABSTRACT

Countless studies have demonstrated that ownership of a good makes decision-makers reluctant to trade that good for an alternative. This "endowment effect" (Thaler 1980) is most often interpreted as a manifestation of reference-dependent preferences that exhibit loss aversion—the tendency for losses to have greater hedonic impact than comparable gains (e.g., Tversky and Kahneman 1981). We introduce a straightforward method to reduce the common reluctance to trade an endowment for a "target alternative." We propose that the process of deciding whether or not to trade the endowment for an "intermediate alternative" (an option that possesses some characteristics of the endowment and some characteristics of the target alternative) subsequently reduces the extent to which trading for the target alternative is viewed as a loss, which in turn stimulates trading. We hypothesize that this "intermediate alternative effect" operates by weakening the extent to which one's endowment is treated as a reference point. In addition, if the intermediate is actually adopted, the reference point shifts in the direction of the target alternative.

The notion that considering (even rejecting) an intermediate alternative can weaken one's reference point is consistent with work demonstrating that individuals with extensive trading experience, such as professional sports card dealers (List 2003) and real-estate investors (Genesove and Mayer 2001), are less affected by loss aversion. Facing an opportunity to trade one's endowment for an intermediate alternative might instill a "trading mindset," reducing the extent to which one's endowment represents one's reference point (cf. Knetsch and Wong 2009). This should, in turn, make the prospect of trading one's endowment feel like less of a loss.

Moreover, when people actually trade for the intermediate alternative, their reference point should shift toward the target, which should in turn increase the attractiveness of the target. This intuition builds on prior work demonstrating that similarity between alternatives reduces the reluctance to trade (Chapman 1998). Thus, people who refuse to "leap" from their endowment to a distant target alternative might instead "walk" to it.

Study 1 tested our basic behavioral hypothesis that people who consider trading their endowment for an intermediate alternative will subsequently be more likely to trade for a distant (target) alternative than people who do not initially consider the intermediate alternative. In a hypothetical concert scenario, participants were endowed with a set of four seats in a theater and were asked whether they would trade that set for an alternative set. The endowment was a set of side-by-side seats in the back of the theater, and the "target" was a set of completely separated seats in the front row, or vice versa. In the Baseline condition, participants were asked whether they wanted to trade their endowment for the target. In the Intermediate condition, participants decided whether they wanted to trade their endowment for an intermediate alternative (a set of partially separated seats in the middle of the theater) before deciding whether they wanted to trade for the target. As predicted, participants were significantly more likely to trade for the target in the Intermediate condition than the Baseline condition (47% vs. 30%).

Study 2 used real choices and examined whether trading for the intermediate shifts one's reference point or merely weakens it. The endowment was two bags of attractive M&M's (custom-printed with the school's logo), and the target was four bags of unattractive M&M's (custom-printed with a spider picture), or vice versa. There were three conditions: Baseline, Intermediate, and Parallel. The Baseline condition was the same as in Study 1. In the Intermediate condition, participants first decided whether they wanted to trade their endowment for an intermediate alternative (one attractive bag and two unattractive bags). In the Parallel condition, participants first decided whether they wanted to trade their endowment for a "parallel" alternative that differed only slightly from the endowment (differing only in the extent to which the picture was outlined vs. filled with color). Overall, consistent with Study 1, trading was significantly greater in the Intermediate condition than the Baseline condition (47% vs. 25%), with the Parallel condition falling in between (35%). When we focused only on participants who adopted either the intermediate or the parallel alternative, we found that intermediate-adopters were significantly more likely than parallel-adopters to subsequently trade for the target (63% vs. 33%). Because adopting the parallel alternative can only weaken one's reference point, but not shift it in the direction of the target, this significant difference suggests that adopting the intermediate alternative does not merely weaken the reference point, but shifts it as well.

Study 3 provided a more sensitive test of the reference point dynamics underlying the intermediate alternative effect. It was a concert scenario similar to Study 1, and there were three conditions: Baseline, Intermediate, and No Endowment. In the Baseline condition, participants were endowed with a set of side-by-side seats that were moderately far from the stage. They were then asked to imagine that they had to move to a set of side-by-side seats in the back row (even further back than the endowed set), and were asked how satisfied they would be with those seats. In the Intermediate condition, participants were first asked whether they wanted to move to a set of partially separated seats in the middle of the theater, and were then asked how satisfied they would be with the back-row seats. In the No Endowment condition, participants were simply asked how satisfied they would be with the back-row seats. Intermediate-adopters

were significantly less satisfied with the back-row seats than Baseline participants, suggesting their reference point had shifted toward the stage. Baseline participants were significantly less satisfied with the back-row seats than No Endowment participants, but there was no significant difference between intermediate-rejectors and No Endowment participants, suggesting that rejecting the intermediate weakened participants' reference point.

Taken together, the results suggest that intermediate alternatives mitigate the endowment effect. Intermediate alternatives help by weakening and, if adopted, shifting the owner's reference point. Marketers and policy makers are advised to help people walk toward the desired outcome rather than trying to force them to leap.

Attachment Without Possession:
Resolving the WTA/WTP Disparity

EXTENDED ABSTRACT

The notion of what we possess becoming an extension of ourselves is acutely realized by many of us when a scratch on our car gives us immense pain. William James aptly said "between what a man calls me and what he simply calls mine the line is difficult to draw. .... A man's Self is the sum total of all that he can call his" It is intuitive to predict over-valuing what we own. We acquire things to define who we are and over time through this need to define ourselves we start perceiving what we own to be a part of us or extensions of ourselves.

An intriguing question is, how would we value an object which feels like an extension of ourselves but we don't own it. More specifically, in this work we explored if an object is made to feel like part of one's body how would it influence valuation across two conditions: 1) when one owns the object and 2) when one doesn't own it. By answering these questions, we try to disentangle the mechanism responsible for the commonly observed WTA/WTP disparity (also known as the Endowment Effect, Thaler 1980). Two main theories have been used to explain the WTA/WTP disparity. The loss aversion account suggests that selling prices tend to be higher than buying prices because people use reference points to assess any change in their current state. For a seller whose current reference point is ownership of the object, removing the object from the endowment creates a loss. Since losses are aversive, this leads to the seller demanding a higher selling price compared to a buyer for whom obtaining an object (to an endowment without it) appears like a gain (Kahneman, Knetsch, and Thaler 1991). The mere ownership account suggests that people are reluctant to relinquish the objects they own simply because they associate those goods with themselves and become attached to them (Beggan 1992). This leads sellers to demand more than what a buyer is willing to pay for an object.

However, in studies of WTA/WTP disparity these two explanations tend to be confounded. For instance, when we consider a seller he always owns the object and also loses it in a trade. So his higher WTA could be driven by ownership as well as loss aversion. To understand which factor is playing a critical role, we need to have a seller who is less attached to it and losing it in trade. On the buyers' side, in past work we have a buyer who is always not attached to the object but considers acquiring it. So to assess the role of attachment we need to compare a buyer who is not attached to an object to a buyer who is attached to the object. This has been a challenge in controlled settings, since how can one make a buyer attached to an object that he does not own and a seller who is less attached to an object he is going to lose?

To achieve this (i.e., a buyer who is attached to the object yet does not own it), we utilized neuroscience literature on the malleabil-

ity of human perception which suggests that the representation of our body is reconstructed moment to moment based on sensory information (Damasio 1994). An important element in interpreting our embodiment is vision – e.g., how we learn to recognize ourselves in a mirror (Ramachandran and Rogers-Ramachandran 2008). The sense of sight is so strong, that when visual input conflicts with cues from other senses, vision tends to dominate. This dominance has been used to relieve phantom limb pain for amputees. Ramachandran and Blakeslee (1998) placed a mirror between an amputee's missing and existing limb. Moving the existing limb by lateral inversion in the mirror made it appear as if the missing limb was moving and eased the pain. Similar visual manipulations by synchronized tapping of a rubber hand and participants' hand have resulted in participants experiencing the sensation that the rubber hand is part of their body (Ramachandran and Blakeslee 1998, Botvinick and Cohen 1998).

Across two studies, we used the tapping manipulation to give a visual illusion that a coffee mug had become a part of the participant's body. The experimenter with her right hand tapped the mug and with her left hand synchronously tapped the participant's hand which was inside a black box. Participants who reported experiencing a sensation of the mug feeling like a part of their body formed the experimental group while those reporting no feelings formed the control group. Subsequently participants were shown the same mug and randomly assigned to the role of buyers (sellers) and their WTP (WTA) was elicited.

In study 1, WTA/WTP disparity emerged across buyers and sellers in experimental and control groups. However, compared to control group sellers, the sellers in the experimental group (who felt a sensation when the mug was tapped) indicated a significantly higher selling price (WTA). However, there was no difference in buying price (WTP) for the control versus experimental group. Study 2 replicated the findings of study 1 and also found that the experimental-group sellers generated more positive attributes for the mug than control-group sellers. Buyers in both the control and experimental group generated equal number of positive and negative attributes indicating a balanced view.

The loss aversion account would not predict any change in the difference between WTA and WTP across control and experimental groups since the tapping manipulation doesn't alter buyers and sellers reference points. The ownership account would predict an increase in both WTP and WTA from control to experimental conditions as a result of the tapping manipulation (we document change in only WTA). Our pattern of results is inconsistent with both of these accounts and hints towards a more nuanced view in which possession strongly influences sellers' WTA while reference point influences buyers' WTP.

Cognitive Moderators of Loss Aversion

EXTENDED ABSTRACT

Loss aversion suggests that losses have a greater impact upon choice than the equivalent sized gain. Despite extensive use in consumer theory, we know less about the cognitive mechanisms underlying the effects, and their implications. This raises a number of questions: Are there systematic individual or attribute differences? To what extent does cognition or affect moderate these effects?

Answering these questions has both practical and theoretical importance. In this paper, we will examine potential moderators of loss aversion, with our goal being to provide a set of facts that characterize the nature of loss aversion across attributes, individuals, and their characteristics to inform future theory.

To accomplish our goal, we extend existing methods three ways: (1) We develop methods for measuring loss aversion within individuals and use those measures to assess loss aversion for several attributes. This represents a substantial new way to view loss aversion, acknowledging that it may not be a stable individual difference variable. (2) We examine how loss aversion varies across people and attributes, rather than focusing solely on variation across people. (3) We look at moderators of loss aversion, using multi-level models to tease apart these effects. Multi-level models are useful because some potential moderators are a function of relatively stable personal characteristics (like income or age) that change slowly while other potential moderators may vary across attributes such as a consumer's rating of importance.

With few exceptions, loss aversion is assessed between respondents, comparing the average price given by two groups for a single good or attribute, making it impossible to examine individual or attribute differences. To extend this prior work, we developed a method for not only assessing loss aversion between respondents, but within a respondent applied across several attributes. To accomplish this, we asked a series of questions about the size and nature of the coefficient of loss aversion for various attributes and consumer characteristics. Specifically, respondents either gave their choice or selling price for a set of 4 car attributes: Fuel Consumption (in liters per 100 km) Comfort (leather seats, power adjustment, etc.), Safety (airbags, etc.) and Information Systems (the kind of navigation systems). These were selected to vary independently on the proposed moderators, and are important to car purchasing. After almost an hour, respondents were asked the other question, to minimize influence on one set of answers to the other.

We used a survey of 360 people conducted by personal interviews by a professional market research company. All substantive experimental factors were varied within subjects. They included our main concern: A 2 (selling vs. choosing) by 4 (attribute) factorial that elicited indifference prices.

Data was analyzed by comparing three models. The first model provides a test of one simple characterization of loss aversion, that loss aversion is a constant within an individual. Our second model allows for loss aversion to be trait-specific. Finally our third model examines if the variation in loss aversion that we see is a result of specific attribute differences in loss aversion within respondent. This third model provides the best fit for the data, suggesting that merely analyzing loss aversion as a constant or on an attribute level is not as meaningful as an analysis including variation within the individual. Additional models introduce controls and potential moderators.

In addition to the models discussed above, two overall moderators of loss aversion were discovered during analysis: expertise and age. Participants who knew more about a given attribute (fuel consumption) showed less loss aversion. Younger participants also showed less loss aversion than their older counterparts.

In conclusion, we demonstrate a method for measuring loss aversion at the individual level. This method could be of use in the analysis individual and attribute differences in loss aversion in consumer behavior in other settings. Further, we have explored the nature of loss aversion in one purchase domain, one that features substantial expenditures by actual consumers. Our basic result suggests that loss aversion is widespread in this setting. In addition, there is significant heterogeneity, and loss aversion is not simply a constant, a characteristic of an attribute or an individual. This is important,

since it suggests that choice models that employ loss aversion should model this heterogeneity. Finally, we find that a substantial amount of loss aversion can be explained by the decision maker's knowledge of the attribute, the attributes' importance to the decision-maker and finally, the individual's age. This result also has implications for the application of loss aversion, suggesting who will be the most loss averse. In particular, it emphasizes the role of specific product knowledge and suggests that some individuals, particularly those who are older or less educated, may be more likely to be loss averse.

SESSION OVERVIEW

Recent research in behavioral economics has illustrated the critical role hedonics plays in an individual's consumption decisions. For example, Prelec and Loewenstein (1998) suggested that that when making purchase decisions, people experience competition between the anticipated pleasure derived from acquiring and consuming the product and the anticipated losses incurred not only from the money given up in the transaction (product price) and the hassle of executing the payment (transaction cost) but also from the *pain of paying,* the disutility derived from parting with money. It is the outcome of this hedonic competition that results in a consumer's decision of whether or not to purchase. Interestingly, however, our understanding of the pain of paying concept is still rather vague.

The objective of the current session is to provide further evidence for the existence of pain of paying and to examine both its antecedents and consequences. With three paper presentations followed by a comprehensive discussion we seek to help foster a better understanding of the of pain of paying, including what it is, how it is experienced, what is driving it, and how it influences consumers decisions.

In the first paper, Plassmann, Mazar and Rangel used neuroimaging to examine how the human brain processes different types of costs during purchase decisions. Building upon previous research, Plassmann et al. investigated whether the neural representation of costs differ between abstract costs (e.g. paying money) and somatosensory costs (e.g. tolerating electric shocks). Although they found that purchase decisions involving money and shocks were similar on a behavioral level, they found significant differences at a neural level. More specifically, the authors found that making decisions involving somatosensory costs recruited brain areas involved in pain processing, while making decisions involving monetary prices did not. Simply put, the pain of paying (i.e. paying with money) is not experienced the same as the paying with physical pain.

In the second paper in this session, Mazar and colleagues examined with behavioral experiments whether the pain of paying is experienced as a physical pain, psychological pain, or whether it is not experienced as a pain at all. In two studies, they found that making psychological pain more salient decreased consumers' willingness to pay for hedonic as well as utilitarian products, and these differences were not driven by individual's liking of the products, their mood, or their arousal levels. Making physical pain more salient did not dif-

fer from the control group. The authors are currently running a third study, which will be completed by the time of the ACR conference. This new study, which more directly manipulates participants' experience of pain of paying while purchasing (through placebo pills), examines whether making people more/less sensitive to their pain decreases/increases their willingness-to-pay.

The first two papers complement each other and together show that the pain of paying is more closely related to psychological pain than physical pain. The third paper in this session extends this work and examines the impact that individual differences in pain of paying have on consumers' financial decisions. In their paper, Thomas and Park demonstrated that people who experience greater pain of paying are more predisposed to prepay their loans. In addition, they demonstrated the *domain specificity* of pain of paying, showing that these prepayment preferences only occur when the decisions are framed in terms of monetary gains; when gains are framed as non-monetary, pain of paying no longer has an effect on individuals preference to prepay. Together the studies in this paper suggest that financial decisions are influenced by the interaction of individuals' innate sensitivity to pain of paying and the framing of decisions.

As our purchase decisions involve a hedonic trade-off between gains and losses, a clear fundamental understanding of pain of paying and its effects is important. In keeping with the conference theme "Building Connections," the three papers in this session significantly contribute to this understanding by taking a number of different methods (e.g., neuroscience methods, behavioral experiments) and approaches (e.g., priming, decision framing) to help to define what the pain of paying is, its underlying processes, and how individual differences in pain of paying influence decisions. This session focuses on a very current topic as the pain of paying plays a crucial role in individuals' overspending and undersaving. As such, we believe this session will appeal to a wide audience at ACR. We also have a discussant, Scott Rick, with great experience and knowledge in the domain of pain of paying; he has published fMRI research looking at the neural predictors of purchases (Knutson et al., 2007) and has developed a scale to measure individual differences in pain of paying (Rick et al., 2008). His comments are sure to add further insight to the presented findings and initiate a thought-provoking and constructive debate with the audience of this session. Note: The findings of all three papers have been written up, i.e. in manuscripts that are either prepared or under review.

Is Paying Painful? Neuropsychological Underpinnings of Abstract and Somatosensory Costs During Consumer Decision Making

EXTENDED ABSTRACT

A seminal account proposed for the hedonics underlying consumption decisions distinguishes between two opposing factors: rewarding factors like the pleasure derived from consumption and aversive factors like the costs of the consumption often referred to as "pain of paying" (Prelec and Loewenstein, 1998). Previous research in neuroeconomics has investigated how decision utility computations are represented in the brain (Plassmann et al., 2007) and whether these representations differ for different modalities such as primary or secondary rewards (Chib et al., 2009). However, despite its importance for consumer decision-making, little is known about how the human brain computes aversive factors during purchasing,

namely the costs associated with the item for purchase. This is the central question of this paper. In particular, we investigated whether the representation of costs in the brain differ between abstract costs (e.g. paying money) or somatosensory costs (e.g. tolerating electric shocks) that are matched in economic value.

Consumer behavior theories have suggested that consumers consider abstract monetary prices as a potential loss that triggers a negative affective response that resembles the emotional or psychological components of pain processing (so-called "pain of paying", see (Prelec and Loewenstein, 1998, Rick et al., 2008). A recent neuroimaging study found that when subjects decide to buy, areas of the brain that are known to represent the sensation of physical (but not psychological) pain - the Insula – are less activated as compared to when subjects decide *not* to buy (Knutson et al., 2007). These results suggested that the act of paying does physically "hurt" when prices are perceived as too high, i.e. it triggers a physical pain sensation. However, these results were based on inverse inferences about the Insula as their study did not allow for comparing the act of paying with the experience of physical pain. Given that the Insula is a highly interconnected brain area that has also been found to be involved in various other mental processes important for consumer decision-making, the current findings are inconclusive. Our paper addresses these shortcomings and provides a direct test of the physical pain of paying hypothesis.

We investigated the neural basis of cost computations by scanning hungry subjects' brains (N=21, aged 18-35, mean 23.65 years) while making 280 purchasing decisions for liked food items. Subjects could either pay in monetary units ($0-$1.50) or in subjectively equivalent physical pain units (electric shocks). Several days before the fMRI experiment, we performed a calibration of each individual's subjective pain tolerance levels in which we matched their pain tolerance to monetary values using a BDM auction mechanism (Becker, DeGroot, and Marschak, 1964). Because of the characteristics of this auction, we can assume that in that pre-screening study individuals bid their 'true' utility for the right to avoid receiving an electric shock of different intensities (Wertenbroch and Skierra, 2002). During a second pre-scanning task, subjects underwent another BDM task, this time to sample subjects' willingness-to-pay (WTP) for the 40 different food items. The fMRI task consisted of two different, within-subject trial types: Trials in which subjects could decide to buy 40 food items at four different monetary prices ($0, $0.50, $1.00, $1.50) (= 160 '$ trials') and trials in which they could decide to buy the same 40 food items for tolerating pain (electric shock) at three different pain intensities (=120 'V trials') that were matched with the three different non-zero monetary prices.

For the behavioral data analysis of the main study, we created dummy variables for WTP and purchasing prices in money and physical pain trials and entered them into a mixed effects logistic regression analysis. The model was significant (Wald $\chi^2(2)$=1222.23, DF=22, p<.000) and had significant regression coefficients for each predictor ($\beta_{wtp\_\$}$ = 3.31, p<.000; β_{wtp_v} = 3.68, p<.000; $\beta_{price\_\$}$ = -2.69, p<.000; β_{price_v} =-2.52, p<.000). We tested differences in the regression coefficients between WTP and price predictors in each trial (money or shock) type and found significant differences for WTP and price in both, money and voltage trials (both p<.000). We also tested differences in the regression coefficients between money and voltage trials for WTP and price predictors and found no significant differences between trial type (price$_v$ vs. price$_\$$: p<.216; wtp$_v$ vs. wtp$_\$$: p<.09). For the fMRI data analysis we estimated a hierarchical mixed effect GLM to investigate differences and overlaps for brain areas that correlated with the size of monetary and physical pain costs. We found that the Insula, a region involved in physical pain processing, correlated positively with the size of physical pain prices, but not with the size of monetary prices (p<.005, uncorr.). A conjunction analysis revealed that no overlapping areas can be found (p<.005, uncorr.).

Taken together, these results show that while people's brains react differently to "monetary" and "physical pain" their behavior does not. Our fMRI results suggest that paying with money might trigger very different processes than those involved with more "physical" forms of costs. We suggest that the act of paying recruits systems involved in psychological rather than physical pain processing. These results call into question the current findings in the neuroscientific literature: That is, our findings call into question that for everyday consumption decisions paying triggers a similar sensation as suffering physical pain. Our results have important implications for disadvantageous decision-making such as overspending and transformative consumer research.

The Origin of the Pain of Paying

EXTENDED ABSTRACT

In our daily lives we are continuously faced with the decision of whether or not to buy different goods and services. As research from behavioral economics suggests, when purchasing a product, people experience hedonic competition between the anticipated pleasure derived from acquiring and consuming the product and the anticipated losses incurred not only from the money given up in the transaction (product price) and the hassle of executing the payment (transaction cost) but also from *pain of paying,* the disutility derived parting with money (Prelec & Loewenstein, 1998). It is the trade off between these anticipated gains and losses that determines the decision of whether or not to purchase. Interestingly, however, our understanding of the pain of paying construct is still inconclusive.

Early findings from judgment and decision making, in support of the pain of paying, demonstrated that people like to prepay for purchases and decouple spending from consumption (Prelec & Lowenstien, 1998). Recent findings from neuroeconomics (Knutson et al., 2007) went further and showed that a decision to purchase activated not only brain areas involved in reward processing (Nucleus Accumbens) but also deactivated brain areas (in particular (the anterior Insula) that have been linked not only to physical pain but also to arousal (i.e. disgust and anxiety). The current research extends these previous findings and seeks to provide a better understanding of what the pain of paying is: how is it experienced and what is driving it.

One of the biggest unknowns that the current paper is focusing on is whether the pain of paying is in fact experienced as a physical pain, psychological pain, or whether it is not experienced as a pain at all. To address this question, as a first step we examined whether making pain more salient would influence consumer's willingness-to-pay for products, and if so, which types of pain would have an influence. In Study 1 participants were primed, using a scrambled sentence task, with either psychological pain related words (e.g., *sorrow, grief, heartbreak*), physical pain related words (e.g., *aching, sore, cramps*), or neutral words (e.g., *pen, ball, carpet*). Participants were then given the opportunity to purchase a box of Godiva chocolates for real with their own money. They provided their willingness-to-pay (WTP) using a choice-based Becker-DeGroot-Marschak (BDM) auction (Becker, DeGroot & Marschak, 1964); a pre-test confirmed that only participants that understood the BDM auction-procedure proceeded to this task. Finally, participants completed liking, mood, and arousal measures. Our findings indicate that participants primed with psychological pain-related words were willing to

pay significantly less for the chocolates as compared to participants primed with neutral words or with physical pain-related words (there was no significant difference between the latter two conditions), and these differences were not driven by how much participants liked the chocolates, their mood, or their arousal (those measures were not statistically different across conditions).

Study 2 extended these results by looking at how making pain more salient would influence consumer's willingness-to-pay for a non-hedonic product with a clear and known face value: a $20 Amazon.com gift card. Similar to the first study participants were primed with either psychological pain-related words, physical pain-related words, or neutral words. They then provided their WTP for the Amazon.com gift card through a choice-based BDM auction (a pre-test confirmed that only participants that understood the BDM auction-procedure proceeded to this task). Finally, they completed liking, mood, and arousal measures. Again, we found that participants primed with psychological pain-related words were willing to pay significantly less as compared to participants primed with neutral words or with physical pain-related words, and these differences were neither driven by how much participants liked the gift card nor by participants' mood or arousal.

Study 1 and Study 2 provide support for the idea that the pain of paying might be experienced as a pain that is similar to psychological rather than physical pain. However, the support is indirect, as we did not directly manipulate participants' experience of pain while purchasing (if it exists). Instead our primes simply made pain-related concepts more salient. Furthermore, if there exists a pain of paying, making people less sensitive to it, should increase WTP. We are currently running a third study to address these two points. In particular, in Study 3, participants are given a placebo pill disguised as either a drug that decreases sensitivity to pain (either physical or psychological), a drug that increases sensitivity to pain (either physical or psychological), or a vitamin supplement (control). That is, we have five-between subjects-conditions. After taking the "medication", participants are given a series of tasks; including a purchasing task as well as a number of manipulation checks. We predict that participants who believe they have consumed a psychological pain-relieving drug will be willing to pay significantly more than participants in the other conditions, while participants given a psychological pain-enhancing drug will be willing to pay significantly less. We predict no differences in willingness-to-pay between the control and physical pain drug conditions. We expect this study to be completed by the time of the ACR conference.

Habitually Consistent, Contextually Inconsistent: Dispositional and Contextual Determinants of Financial Decisions

EXTENDED ABSTRACT

The changes in the financial services industry have expanded access to loans for the vast majority of consumers. The easy availability of loans has helped consumers to improve their quality of life and has catalyzed economic growth. However, this easy availability of loans also presents some challenges; it requires consumers to be more careful in managing their loan repayments. Not all consumers seem to be good at this. Some consumers fall into a debt trap and spend a large proportion of their income paying interest on their loans. One way consumers can reduce their interest burden is by using their disposable income to prepay (i.e., paying ahead of schedule) their loans. The present research was conceived to understand the factors that predict consumers' loan prepayment behaviors. Specifically, in this research we try to address the question: how do consumers decide whether to use their disposable income (e.g., a bonus) to prepay a loan or to use it for other purposes?

In this paper, we present two seemingly contradictory hypotheses that offer insights into how people decide whether or not to reduce their debts by prepaying their loans. The first hypothesis, the *dispositional orientation* hypothesis, posits that financial decisions are influenced by the pain of payment experienced by people. Money activates distinct cognitive and emotional responses in tightwads and spendthrifts. Tightwads relish saving money; so they are always willing to forego their current consumption to save money by prepaying their loans. Spendthrifts do not relish saving as much; they would rather have disposable cash in hand than prepay their loans. It is this difference in habitual response towards money (rather than economic valuations of financial gains) that causes the individual difference in financial management.

The second hypothesis, the *domain specificity* hypothesis, posits that the effects of dispositional orientation are restricted to monetary framing of options. Dispositional responses to money are less likely to manifest when financial gains are presented in (economically equivalent) non-monetary units. The notion that individuals differ in the way they spend and save money is not new; the subjective utility model, which is the bedrock of homo economicus' decision making, assumes that people map financial gains onto stable utility functions and people have different utility functions. However, the subjective utility model and the pain of payment model differ on one important aspect – domain specificity. Subjective utility model implies domain invariance of financial gains; that is, equivalent representations of gains should evoke the same responses from decision makers. In contrast, the pain of payment model proposes that tightwads and spendthrifts will differ in their decisions when a financial gain is presented in a monetary frame (dollars), but not when the same gain is presented in a non-monetary frame (e.g., number of installments).

Study 1 was designed to test the dispositional orientation and domain specificity hypotheses. One hundred and ninety-six adults (average age 35.3) participated in this study. A majority (77%) reported having taken a loan and 47% reported having prepaid their loans. Participants were asked to imagine that they had an outstanding loan of $8,000 from a bank that requires a monthly payment of $159 for 120 months. They were asked to consider six different loan prepayment options and for each option they had to indicate whether they would avail the option to prepay the loan, or continue with the current loan payment plan. The framing of the prepayment was manipulated; participants were randomly assigned either to monetary framing condition or non-monetary framing condition. In the monetary framing condition, prepaying the loan allowed the participant to reduce her monthly payment amount. In the non-monetary framing condition, each prepayment plan allowed them to reduce the number of monthly installments. Then to test the effect of their dispositional orientation to money, their pain of payment was measured using Rick et al.'s (2008) scale. The results revealed a predicted two-way interaction between pain of payment and monetary framing, $p < .05$. Participants with higher pain of payment were more likely to prepay the loan, but only in the monetary frame. Furthermore, follow-up process measures revealed that participants with higher pain of payment were more likely to construe loan prepayment as "saving money in the long run" than as "spending money in the short run" and this construal mediated the effect of pain of payment only in the monetary framing condition.

The pain of payment model posits that unlike tightwads, spendthrifts do not have an innate predisposition to save money. They consider money as a medium (or an instrument) to gain satisfaction. Consequently, they are more likely to compare the satisfaction from

savings with the satisfaction from spending money. This conceptualization suggests that spendthrifts' loan prepayment decisions will be contingent on the salience of alternative options. Juxtaposing and contrasting the loan prepayment option with a regretful spending option could increase the attractiveness of the former option. We investigated this issue in **study 2**. The basic setup was similar to the study 1; we manipulated monetary vs. non-monetary framing of gains from prepayment and measured pain of payment. Additionally, we introduced a third factor: an alternative avenue to spend the money. Half the participants were told that they could either use the bonus money to prepay the loan or deposit it in a savings account. The other half were told that they could either use the money to prepay the loan or use it to go on a vacation. There was a significant three-way interaction of pain of payment, gain frame, and alternative (p < .05). Analysis of simple slopes revealed that pain of payment was a significant predictor of amount prepaid only when the gain was presented in the monetary frame and the alternative was depositing money in the savings account (p < .05). Further analysis found that spendthrifts found it much easier to justify keeping money in the savings account only when the gain was presented in the monetary frame. Together, these findings characterize the complex interplay of innate dispositions towards money and framing of options in financial decisions.

SESSION OVERVIEW

Decision making is often a social process, as we are generally influenced by others' opinions while making choices, like what to order at a restaurant (Ariely and Levav 2000), how to navigate a career (Levin and Cross 2004), and which new products to purchase (Van den Bulte and Joshi 2007). Beyond traditional investigations of how individuals' attitudes and behaviors are impacted by reference group members' attitudes and behaviors, however, lies a dynamic and growing domain of social influence. The prevalence and popularity of online social networks (e.g., facebook) have enabled peers, friends, acquaintances, and even strangers to make more than 500 billion product- and service-related impressions on one another (Forrester 2010).

Ample research focuses on how social reference groups encourage others to consume. For example, Van den Bulte and Joshi (2007) focused on the diffusion of innovations, leveraging the sociological idea that some consumers are more likely than others to convince people to purchase products. Relatedly, many firms are trying to leverage these reference groups to aid marketing efforts. For example, many firms are integrating their websites with various facebook features to provide shoppers with information regarding how many people, as well as whom specifically in their social networks, "like" the consumption item.

Unfortunately, the current research on social networks presents a rosy picture which focuses on how social reference groups encourage and facilitate consumption, but ignores the reality that, in many ways, social groups are prohibitive, effectively restricting (Wooten 2006) or reducing certain consumption behaviors (Grayson and Ambler 1999). In this special session, we follow in the path of the "dark side" scholars and *extend the research on how social reference groups impact consumption by focusing on how such groups inhibit consumption*.

Specifically, the four papers proposed for this session leverage various methodological and philosophical approaches to examine situations where the attitudes of peers, friends, and social network members cause individuals to reconsider consuming an item. The first paper uses social-psychological experimentation to examine how consumers' perceptions of the influence of TV series on peers, affect consumers' own intentions to buy products placed within those series. The second paper employs experimental and quasi-experimental techniques to investigate situations where relying on advice from strong social network ties, which are proposed to be more trustworthy than weak ties (Granovetter 1973), is actually less helpful when making consumption decisions. The third paper employs qualitative methods, including text analysis, to examine how consumers use masking behaviors to avoid conflicts within one social network, while freely and openly discussing and consuming within another. The fourth paper draws upon sociological theory and uses in-depth interviews to examine how consumers (re)construct consumption narratives in an effort to both respectfully resolve between-network disagreements, and consume without dissonance.

Combined, the four papers in this session examine how social reference groups inhibit consumption. These papers make several important contributions. Theoretically, these papers extend and refine literatures concerned with understanding how social reference groups affect behaviors. Scholars concerned with topics that emphasize the importance of social groups in the consumption process, including *identity construction*, *advice acceptance*, and *the use of product ratings and reviews,* will find this session especially interesting, as the research presented sheds light on sources of and responses to reference-group-related tensions.

Practically, these papers suggest that firms should exercise caution and employ strategy when leveraging social networks, rather than immediately sharing the opinions of various social groups. Practitioners concerned with leveraging social reference groups as a way of transmitting information about peer approval or social capital will find the discussion of how groups inhibit individual consumption compelling, as it might help explain the poor results from various marketing campaigns. Lastly, this session demonstrates how theoretical advancements can occur when scholars from various backgrounds share interests in related consumption phenomena. Our authors leverage experimental social psychology, sociology, economic sociology, marketing, and anthropology to present clear examples of how social reference groups inhibit consumption.

Resisting Normative Influences in the Context of Product Placement

EXTENDED ABSTRACT

In this research we investigate how perceptions of the influence of TV series on peers impact the effects of product placements. Because people frequently interact around TV, co-viewing programs or even developing communities of consumption around them (Kozinets 2001; Schau et al. 2009), product placement effects are likely to be affected by viewers' perceptions of how others are influenced by TV series. We define these perceptions as *peer-connectedness,* in parallel to Russell et al's (2004) studies on audience connectedness.

We focus here on conditions that favor a reduction in consumers' desire to purchase placed products as a function of peer-connectedness. Peer-connectedness is proposed (and shown) to reduce consumers' desire to purchase products that appear in TV series, contingent upon some conditions, based on individual differences or contextual variables.

One of the individual difference moderators in this research is psychological reactance. Reactance (Brehm 1966) is a motivational

state due to a threat to behavioral or attitudinal freedom. People engage in opposite behavior to restore the freedom and/or adopt or avoid positions on the issue (Wright and Brehm 1982). Building on Brehm's (1966) work, other researchers proposed that people naturally vary in the degree to which they pursue these opposite behaviors and developed measures for this psychological reactance trait (Hong 1992; Hong and Page 1989). The reactance trait has been shown to be an important predictor of attitudes and behavior. For instance, individuals who score high on reactance move against expert product recommendations (Fitzsimons and Lehmann 2004), and reject goals associated with relationship partners, pursuing opposite goals instead (Chartrand et al. 2007).

The second set of moderating factors in our research are situational tendencies to conform. Conformity operates largely out of awareness. Although people consider interpersonal influences the least important factor in their decisions, these usually have one of the largest impacts (Nolan et al. 2008). Moreover, imitation studies have shown that people unconsciously imitate others as the perception of others' behaviors automatically generates behavioral outputs (Dijksterhuis and Bargh 2001) and that even brief encounters with others can increase one's tendency to subsequently choose the same brand these others buy (Ferraro et al. 2009). In this research, we employ a scrambled sentence task to non-consciously prime conformity and non-conformity (Epley and Gilovich 1999) and assess its impact on responses to product placement in TV series, depending on different levels of perceived peer-connectedness to the series.

Peer-connectedness was manipulated by explicitly communicating the percentage of peers who are connected to the series (study 1) or implicitly, through a news article focused on Generation Y (the participants' peer group) that presented a relevant peer as either highly connected or not connected to the series (study 2). Product placements were digitally inserted in visuals of the series. In study 2, conformity and non-conformity were primed experimentally in a first, unrelated part of the experiment, following Epley and Gilovich's scrambled task procedure (1999) designed to generate either high or low tendency to conform. Purchase intentions for a series of brands, including the focal brands, were measured. The psychological reactance scale (Hong 1992; Hong and Page 1989) was included in a separate section. Prior consumption of focal brands and demographic information were controlled for.

The analyses reveal a three-way interaction between peer-connectedness, conformity, and reactance. Whereas there were no significant differences in purchase intentions across conditions for participants high in reactance, there was a cross-over interaction between conformity priming and peer-connectedness amongst low reactance participants. Low reactance participants were less likely to follow a peer when primed for non-conformity and more likely to follow a peer when primed for conformity. When these participants were told that the peer was highly connected to a TV series, non-conformity priming reduced intentions to buy the products placed in the series to which that peer was highly connected. However, those low reactance participants who were told that their peer was not connected to the series were more likely to want to buy the placed products when primed for non-conformity.

Together, the series of experiments identifies conditions that trigger behavioral tendencies that go counter to the direction of the perceived influence of TV series on peers. Given that detrimental consumption practices such as smoking, doing drugs, or heavy drinking (Pechmann and Wang 2010; Russell et al. 2009) are often displayed in entertainment programs, the finding that peer-connectedness information can reduce the impact of undesirable consumption images (such as smoking) suggests that it could serve as a tool to lessen the influence of TV programs on their vulnerable audiences.

A Negative Judgment Gives Satisfaction Provided it Smacks of Jealousy: Why Negative Feedback from Strong and Anonymous Ties Inhibits Decision Making

EXTENDED ABSTRACT

A lot of evidence supports the idea that people often seek advice from people across their social networks: friends and loved ones,

acquaintances, and strangers. For example, Grannovetter (1978) acknowledges that generally speaking, close friends and loved ones give good advice because they are trustworthy and desire for us to have positive outcomes. Although prior research does not provide a full explication of how advice of varying valences is accepted across the spectrum of social network ties, it does provide insight into what consumers do with received advice. Specifically, it suggests that advice received from people with whom we share close relationships is helpful to the extent that the advice-giver is perceived as trustworthy and that trustworthiness increases with tie strength. This idea leads to our first hypothesis: usefulness of feedback increases with tie strength. This means that feedback from strangers is least useful while feedback from strong ties is most useful.

Research on social structure raises some doubt about the expected positive relationship between helpfulness and tie strength. Simmel (1908), for example, identified the potentially benevolent role of the stranger, who is "not bound by roots to the particular constituents and partisan dispositions of the group," and possesses a "distinctly objective attitude [of both] indifference and involvement" (1908, 145). These prescient words aptly characterize the modern impact of input from strangers on online websites and message boards, as well as offline interactions in restaurants and hair salons. It may be that when strangers offer input, it is deemed honest and trustworthy due to the stranger's objectivity. This leads to our second hypothesis: feedback from both strangers and strong ties is more useful than feedback from weak ties.

Nevertheless, weak ties, which are typically portrayed as untrustworthy, can be quite helpful, not due to benevolence but because they occupy "gaps" or structural holes between social network clusters (Burt 1992). Granoveter (1978; 1983) suggests that weak ties are helpful because they provide not only unique information relative to friends and loved ones, but also more reliable information relative to strangers. Granovetter also suggests that weak ties are sometimes seen as being most in competition with us. This competition takes place within the context of a "field" or social setting wherein individuals compete for social capital or the valued social relations between people (Bourdieu 1984). The quest to maximize social capital is a competition that is of great relevance, particularly when people estimate social reactions to their decisions: Making poor decisions is risky because doing so may lead to a decrease in social capital. We argue that competition for social capital is strongest between weak ties (Burt 1992; Marsden 1987). Strong ties tend to be permanent relationships which are less reliant on social capital, while anonymous relationships do not technically exist and thus do not depend on social capital. As a result, advice from weak ties, though not benevolent, is most helpful specifically because it provides social-capital related feedback. Thus, our third hypothesis is that feedback from weak ties will be more useful than that from strong or anonymous ties.

We test these three hypotheses in a series of studies. Study 1 is designed to test the three hypotheses and employs a 3 (social network tie: anonymous, weak, strong) x 2 (valence: negative, positive) design with "change in purchase intention" as the dependent measure. Results show that positive feedback from weak ties increases purchase intent significantly more than positive feedback from anonymous and strong ties. Negative feedback from weak ties decreases purchase intent significantly less than negative feedback from anonymous and strong ties. Based on these results, hypotheses one and two are rejected in favor of hypothesis three: weak ties are more helpful when making decisions than anonymous and strong ties.

Study 2 is designed to test perceived trustworthiness and perceived helpfulness of feedback as a function of social network tie and valence. This study has a 3 (social network tie: anonymous, weak, strong) x 2 (valence: negative, positive) design with perceived trustworthiness and perceived helpfulness of the feedback as dependent measures. Results show that, regardless of valence, feedback from weak ties is perceived as less trustworthy but more helpful than feedback from anonymous and strong ties. Based on these results, perceived trustworthiness is eliminated as a potential mediator for the usefulness of feedback.

Study 3 examines social capital as a moderator of the relationship found in studies 1 and 2. Study 3 employs a 3 (social network tie: anonymous, weak, strong) x 2 (valence: negative, positive) x 2 (social capital signal: low, high) design. Results show that the helpfulness of feedback from weak ties is significantly higher when the social capital signal is stronger than when it is weaker. This suggests that weak ties are more helpful than anonymous and strong ties when making decisions because they provide valuable social capital-related information.

Together, these three studies show that feedback received from trusted sources (anonymous and strong ties) is not particularly helpful when making decisions.

This research makes two significant contributions. It advances the social networks literature by demonstrating that weak ties can be more helpful than anonymous and strong ties when making decisions, not through trust but through social-capital-related signaling. It also advances the advice acceptance literature by testing a theoretical model of consumer responses to acceptance of advice within social networks, and showing that the concepts of "trustworthy" and "helpful" are not interchangeable.

Masking Behavior: Examining the Influence of Social Networks on Men's Consumption Practices

EXTENDED ABSTRACT

Recent research has explored men's shopping behavior and consumption practices (Otnes and McGrath 2001; Holt and Thompson 2004; Tuncay and Otnes 2008). However, while past research has demonstrated the influence of peers and other reference groups in consumer behavior (e.g. Bearden and Etzel 1982; Childres and Rao 1992; Escalas and Bettman 2003), research on how men's behaviors in the marketplace may be constrained or facilitated by their social networks has not been fully explored. For instance, Zayer and Neier (2011) discuss how men have "secret affairs" with certain brands of grooming products or fashion goods because they fear being ostracized by peers. Similarly, Tuncay (2005, 231) found that men often engage in "masking" behavior, or "actions individuals take to hide

or deemphasize the consumption behavior they display to others." Goffman (1956) sheds light on the potential motivations behind this masking behavior in his discussion of the presentation of self. He notes how misrepresentation, or a "discrepancy between fostered appearance and reality," can occur when the performer is not "authorized to give the performance." (1956, p. 59). That is, men may engage in masking behavior with regard to certain consumer goods because they feel they are not "authorized" to give a performance which may be perceived as outside of the boundaries of traditional heterosexual and masculine behavior. In fact, recent scholars have identified some men as culturally vulnerable in terms of their identities when they consume fashion and grooming products (Tuncay and Otnes, 2008). This is attributed to the fact that shopping in general is still deemed by society as a feminine pursuit (Miller, 1998). Indeed, past research (Belk et al., 1982, p. 4) has shown that individuals make inferences with regard to other's consumption patterns and that this phenomenon can lead to "prejudicial stereotyping."

But what roles do social networks play in this masking behavior? This research explores how men's social networks simultaneously constrain and sometimes facilitate consumption of fashion and grooming products. To explore this research question, a qualitative study was conducted with fifteen men in their 20s and 30s. Most of the informants were college-educated, working professionals and lived in urban settings. This research utilizes three qualitative methods: collage construction, in-depth interviews, and shopping with consumers. These methods have been used effectively in past consumer research. For example, Belk et al. (2003) uses collages in the exploration of consumer desire. Moreover, the shopping with consumers technique is paired with in-depth interviews in the exploration of ambivalence experienced by women during wedding dress shopping (Otnes, Lowrey, and Shrum 1997). Using these methods, over 180 pages of textual data were generated from the transcripts and field notes.

Findings suggest that men feel constrained in the performances they give with regard to masculinity and consumption, particularly in the presence of other men. Alternatively, men may be "freed" to experiment with new forms of consumption due to the influence of female others. For example, some men discussed shopping for clothes, using anti-wrinkle creams and getting pedicures and manicures at the urging of female significant others or female friends. However, they were hesitant to share that information with male others due to the potential stigma of femininity or "gayness" that was associated with those consumption practices. These findings suggest that social networks play a powerful role in men's consumption practices. Even as gender roles are shifting in today's society, traditional gender ideologies still persist and may cause tension among male consumers of fashion and grooming products because they are concerned with what others may think, particularly male others. On the other hand, female others may open up consumption possibilities for men as they urge their male partners or friends to try out new products and services.

How Consumers Rhetorically Align the Interests of Multiple Social Networks

EXTENDED ABSTRACT

The idea that consumption is "embedded" in networks of social relations is of great and growing importance to marketing theory and practice (e.g., Iacobucci 1996; Fischer, Otnes, and Tuncay 2009; Epp and Price 2008). This research proposes that consumers' individual preferences and decisions are profoundly influenced by the specific norms and beliefs that structure their immediate social environment. For instance, it is likely to assume that a woman will not use cosmetic Botox when such a move stands in sharp symbolic contrast to the ways in which an important social network (e.g., her family) defines the process of bodily aging. However, consumers are never part of only one social network. For example, although the woman's family may categorically reject Botox, her Botox-using girlfriends may perceive her family's Botox rejection as a disempowering traditionalism. Little theoretical attention has been devoted to the question of how consumers navigate these competing network interests.

In this presentation, we draw from actor-network theory in sociology (e.g., Latour 1992; Callon 1986) to develop a common process model of rhetorical alignment that explains how consumers bring the competing interests of multiple social networks together. Actor-network theory proposes that the acceptance of a certain practice (e.g., Botox consumption) presumes a network of interested actors - actors who perceive this practice as indispensible for attaining their own interests. We demonstrate how consumers draw from cultural value systems to create self-narratives that effectively translate strategic definitions of one social network (e.g., the community of Botox users) into the interests and identities of the other social network (e.g.,

the family), combating recurring accusations of betrayal and expanding the overall agentic horizon.

To illustrate the process of rhetorical alignment, we investigate the consumption of cosmetic Botox on two mutually constituted levels. First, we review the larger network of cultural norms and beliefs that motivates multiple (dis-) authenticating interpretations of cosmetic Botox and similar anti-aging solutions in a given social network. We find that these interpretations are steeped in a well-documented ideology of embodied aging (e.g., Hurd 2010; Bludau 2010) that produces multiple, competing interpretations about what constitutes a gracefully aging self and how to best accomplish it. After that, we analyze the gracefully aging self-narratives our sample of middle-class Baby Boomer women created to strategically align their Botox consumption with the goals and interests of their Botox-critical families. The latter analysis is based on in-depth interviews with 32 middle-class Baby Boomer women from Toronto (Canada).

The contributions of this presentation are threefold. First, it introduces actor-network theory to the study of networked consumption to demonstrate how consumers consolidate the exigencies of multiple social networks. Second, it demonstrates changes in the co-constitutive relationship between a given social network and the market-mediated interests of individual members. Finally, this presentation contributes to the discussion about the role of sovereignty in social networks. From a conventional theoretical standpoint, consumers are forced to resolve the tensions among multiple social networks by taking a side (e.g., with my family priorities) or by concealing an incompatible choice. However, we demonstrate how consumers create tenuous agentic space by creating self-narratives that combine seemingly competing network interests in culturally reso-

nant ways. At the same time, however, we also provide important theoretical boundary conditions, such as the existence of a culturally shared protocol of norms (here, the cultural identity model of aging gracefully).

SESSION OVERVIEW

Session Objective: The extant goals literature converges on the idea that making goal progress influences subsequent goal-pursuit actions. However, there is relatively little research devoted to understanding the antecedents that drive perceptions of goal progress. The purpose of this special session is to present current research that examines such antecedents from a variety of perspectives, and also illuminates the mechanisms by which perceptions of progress drive subsequent goal-directed behavior. In doing so, this session hopes to spark interest in a new direction for research on goals and goal-related action.

Overview: Much work in the goals arena has suggested that the perception of making goal progress has an effect on subsequent goal-directed behavior. Thus, taking a step towards goal fulfillment has been found to produce subsequent behavior that is either consistent with the goal or is disengaged from it, depending on contextual factors (Fishbach and Dhar 2005). There is, however, relatively scant research that takes a step back to examine what actually determines individuals' perceptions of progress. The papers in this session offer new insights into the goals literature by proposing a range of perspectives regarding this issue (including both situational and personality-related factors); at the same time, the papers also extend work on how and when progress perceptions influence subsequent behavior.

Papers: In the first paper, Huang, Zhang and Broniarczyk demonstrate that the interpretation of progress is contingent on whether individuals are at the initial or the advanced stage of goal pursuit. Across four studies, they show that at the initial stage of goal pursuit, individuals exaggerate their progress level, which in turn motivates them to strive for the goal. On the other hand, individuals downplay their progress level when nearing goal attainment. This discrepancy then induces greater effort in the goal pursuit. In the second paper, Campbell and Warren propose that individuals infer different perceptions of goal progress from an initial behavior, depending on whether the behavior is framed as goal-consistent or inconsistent. Among other findings, they show that even for behavior that has objectively the same magnitude (e.g., saving vs. spending $30), consumers overweigh the positive influence of goal-consistent behavior versus the negative influence of goal-inconsistent behavior when assessing

progress; in turn, this has a negative impact on goal attainment. In the third paper, Chan, Mukhopadhyay and Sengupta examine the interactive influence of optimism and mental simulation (focusing on outcome vs. process) on perceptions of goal pursuit, and its consequences on subsequent behavior. They examine this question in the context of anticipatory purchasing – defined as the purchase of products that the buyers are unable to use at the time of purchase, but would like to in the future (e.g., clothes that are currently a size too tight). Across five studies, they show that for optimists, deciding to make an anticipatory purchase heightens goal commitment under an outcome-focus, while inducing perceptions of goal progress under a process-focus: subsequent behavior is goal-consistent in the former case and goal-inconsistent in the latter. On the other hand, for pessimists, the anticipatory purchase decision actually leads to a reduction in commitment under outcome-focus (leading to goal-inconsistent later behavior), while it does not change perceptions of goal progress or commitment under a process focus. Finally, Laran examines the moderating influence of goal valence on the relationship between progress perceptions and subsequent behavior. Given an "approach pleasure" goal, a perceived lack of progress motivates goal-directed behavior when individuals focus on the end state (vs. the initial state). However, given an "avoid pain" goal, the pattern is reversed: lack of progress motivates behavior when individuals focus on initial state (vs. the end state).

Contribution: The topic of goal pursuit is both important and relevant to consumer research. Each of the four papers in this session presents novel and interesting results. Together these provide new examination of the antecedents of goal progress, as well as enhancing our understanding of consequences for goal-directed behavior. All four papers include multiple completed studies; none of the four has been presented at ACR previously. Elaine Chan (Tilburg University) will serve as the session chair. All speakers have agreed to serve and present their respective papers if this special session is accepted.

Likely audience: We believe that this session addresses an important yet under-researched aspect of goals research, and has the potential to be well attended by researchers interested in motivation, goals, and self-control. We hope that a discussion of this emerging area will spark lively and productive debate.

So Near and Yet So Far: The Mental Representation of Goal Progress

EXTENDED ABSTRACT

In the course of goal pursuit, people actively monitor their levels of progress on goal attainment, and these assessments have a profound influence on their subsequent motivation (Carver & Scheier, 1998; Louro, Pieters, & Zeelenberg, 2007). However, what determines people's assessment of their progress? Is it always the case that people try to form accurate mental representations of their progress level on a goal? In the present research, we explore the possibility that the mental representation of progress level, rather than being a faithful reflection of one's actual level of progress, can function as a self-regulatory mechanism that helps ensure the attainment of important goals.

We adopt the dynamics of self-regulation (Fishbach, Dhar, & Zhang, 2006; Koo & Fishbach, 2008) as the theoretical framework, and propose a self-regulatory analysis of people's mental representation of goal progress. We propose that when individuals have just

started pursuing a goal and have accumulated limited progress, they are primarily concerned about the attainability of the goal. Therefore, they are likely to exaggerate their progress level in their mental representation to signal a higher chance of eventual goal attainment, which helps to elicit greater motivation. However, when people have made substantial progress and are approaching the end point of the pursuit, the attainment of the goal is relatively secured and they are more concerned about reducing the remaining discrepancy. At this stage, individuals are likely to downplay their progress to create greater perceived discrepancy between their current and the ideal state, which in turn helps elicit greater effort in the pursuit.

We further propose that, because this alteration of mental representation is an instrumental mechanism to boost effort and to ensure successful goal attainment, it should occur only when efforts are necessary and effective in helping to secure the attainment of important goals. In other situations, such as when the goal is unimportant or when efforts are ineffective in helping goal attainment, such changes in mental representations should not occur.

Four studies were conducted to test present predictions. Participants in Study 1 completed a color recognition task and were offered either a low- or a high-value reward for successful completion. We manipulated their perceived stage in the pursuit by convincing participants that they either had just started the task, or were approaching the end point. We found that when participants just started the task, those aiming for high- (vs. low-) value reward exaggerated their progress in the task; conversely, when participants were approaching the end point, those aiming for high- (vs. low-) value reward downplayed their progress. Such alternation of mental representation of progress led to greater subsequent motivation in the pursuit, which was measured by greater amount of time participants spent in memorizing colors to complete the task for the reward.

In Study 2, participants completed a word identification task and were offered a limited-edition school-symbol magnet as a reward for reaching 21,500 points by the end of the task; we measured participants' willingness-to-pay for the reward as a proxy for their perceived goal value. We also manipulated their perceived stage in the pursuit by providing feedback on their current points; after answering 15 word-identification questions, participants in the initial-stage conditions received 3,157 points, whereas those in the advanced-stage conditions received 11,813 points. We measured participants' mental representation of progress and their subsequent motivation in earning more points for the reward, and found consistent patterns as in Study 1.

In Study 3, participants worked on a pitch differentiation task and were offered $20 bonus reward for reaching 23,900 points in the task. We informed participants either that pitch identification is an innate ability and cannot be improved through practice, or that it can be improved through effort. We also manipulated their perceived stage in the pursuit by providing feedback on their accumulated points (7,966 points in initial-stage conditions vs. 15,932 points in advanced-stage conditions). We found that participants only altered their mental representation of progress level when they believed that they could improve their pitch identification skills through practice, and such alteration of mental representation of progress again led to greater subsequent effort in the task.

In Study 4, we tested the hypothesis in a field study with a t-shirt donation campaign. Students were invited to donate their used t-shirts to a charitable cause, and we manipulated the importance of the goal by changing the cause for the campaign. In addition, we manipulated the stage in the pursuit by showing participants different visual stimuli: people were shown a picture of either two (initial stage) or 10 (advanced stage) full boxes of used t-shirts, presumably

the donations we have taken so far for the campaign. We measured participants' mental representations of progress by asking them to estimate the number of t-shirts in these boxes, and we recorded the number of t-shirts they donated as the indicator of their motivation to help attain this collective goal. We found that when the cause of donation was highly important (vs. less important), people exaggerated the number of used t-shirts in the picture to signal higher goal attainability when there were only two full boxes, but downplayed the number of used t-shirts when they saw 10 boxes of t-shirts. This alternation of mental representation again led to greater motivation, i.e., more t-shirts people donated to help ensure the attainment of the goal they deemed more important.

Goal Monitoring: Does One Step Forward Seem Larger Than One Step Back?

EXTENDED ABSTRACT

Consumers often pursue continuing goals, like saving for retirement or maintaining a healthy weight, where attainment depends on a number of behaviors and decisions made over time. Although the literature suggests that accurately monitoring progress towards such goals is essential for goal attainment (Baumeister and Heatherton 1996; Carver and Scheier 1982), surprisingly little research investigates whether consumers are typically accurate in monitoring goal progress. Accurate monitoring requires that consumers perceive the impact of their behaviors on goal progress in an unbiased manner. At a minimum, accuracy requires that the influence of a behavior be perceived similarly irrespective of whether that behavior moves the consumer closer to or further from goal attainment. For example, a consumer with a savings goal should perceive a $30 departure from a budget as carrying the same psychological weight regardless of whether it represents extra savings or extra spending.

The focal question of our research is whether consumers accurately weight the influence of goal-consistent behaviors, like saving $30 or resisting a scoop of ice cream, relative to goal-inconsistent behaviors, like spending $30 or eating a scoop of ice cream, on perceived goal progress. Research suggests that consumers' perceptions of progress could be biased in either direction (Baumeister et al. 2001; Ahluwalia 2002). However, because (1) consumers selectively distort information in order to maintain a positive impression of themselves (Dunning 1999, 2007; Taylor and Brown 1988), and (2) goal-consistent behaviors reflect positively on one's self whereas goal-inconsistent behavior threaten one's self-view (Prelec and Bodner 2003), we hypothesize that consumers overweight the influence of goal-consistent relative to goal-inconsistent behaviors when assessing their progress.

Our first study asked members of an online survey panel to think of a personal goal, one behavior that moved them closer to the goal, and one behavior that moved them further from the goal. Consistent with our hypothesis, respondents were more likely to recall a goal-consistent behavior than a goal-consistent behavior (89% vs. 64%); furthermore, respondents who listed both behaviors rated the goal-consistent behavior as having a larger impact than the goal-inconsistent behavior ($M = 6.7$ vs. 4.8; scale from 1-9).

Studies 2 and 3 used hypothetical scenarios to explicitly control for the magnitude of the goal-consistent and goal-inconsistent behaviors that participants evaluated. In study 2, undergraduate participants rated running one more mile as having a larger influence than running one less mile on progress towards an exercise goal ($M = 2.3$ vs. 1.4; scale from 0-4). Similarly, in study 3, undergraduate participants believed that saving an additional $30 helped their progress

towards a savings goal more than spending an additional $30 hurt it ($M$ = 4.2 vs. 3.3; scale from 1-7).

In study 4, we measured perceived goal progress indirectly by having participants estimate the calories in desserts. Because weight loss depends on the number of calories consumed, the calories in a food provide an objective measure of the impact of eating (or not eating) a food on progress towards a weight-loss goal. Consistent with the hypothesis that consumers underweight the impact of goal-inconsistent behaviors relative to goal-consistent behaviors, participants perceived desserts (i.e., a piece of cake or five ounces of ice cream) that they imagined eating as having fewer calories than desserts that they imagined foregoing (M_{cake} = 386 vs. 475; $M_{ice\ cream}$ = 197 vs. 262).

Our final two studies explored whether the tendency to overweight the impact of goal-consistent behaviors relative to goal-inconsistent behaviors is related to goal attainment. Consumers who perceive goal-consistent behaviors as having a larger influence than equivalent goal-inconsistent behaviors may think that they are making adequate goal progress even when they are not. Consequently, an optimistic goal monitoring bias may cause consumers to prematurely release their goals (Fishbach and Dhar 2004; Zhang, Fishbach, and Kruglanski 2007), thus discouraging goal attainment.

Study 5 investigates whether consumers who are typically less successful at attaining long-term goals reliant upon self-regulation are more likely to show an optimistic bias in goal monitoring than consumers who are more successful at attaining such goals. As in previous studies, undergraduate participants who imagined studying one or two additional nights thought their behavior would help their performance on an upcoming exam more than participants who imagined studying one or two fewer nights thought their behavior would hurt. Importantly, however, this tendency was less prevalent amongst participants with high self-control than participants with low self-control ($M_{high-control\ (+1SD)}$ = 4.7 vs. 4.5; $M_{low-control\ (-1SD)}$ = 4.9 vs. 3.6).

Online panel respondents in study 6 played a multi-round word game in which they won or lost points during each round. We manipulated the difficulty of the first two rounds such that most participants lost 100 points in one round and gained 100 points in another. As in previous studies, participants thought that gaining 100 points helped their progress towards a high score goal more than losing 100 points hurt it (M = 6.9 vs. 6.3; scale from 1-9). Furthermore, participants who showed a larger optimistic bias in the first two rounds performed worse in subsequent rounds than participants who showed a smaller optimistic bias ($M_{high-bias(+1SD)}$= 43.1, $M_{low-bias(-1SD)}$= 148.5; possible score range: -800 to 800).

In six studies, we show that consumers tend to overweight the impact of goal-consistent behaviors relative to goal-inconsistent behaviors. Furthermore, two studies suggest that this tendency is negatively associated with successful goal attainment. Because consumers believe that goal-consistent behaviors have a larger influence than objectively equivalent goal-inconsistent behaviors, they may believe that they are moving closer to their goals even when they are objectively not progressing. We hope that drawing attention to this bias provides a first step towards helping consumers accurately monitor their progress and, ultimately, improve their chances of reaching their goals.

The Dual Effects of Optimism on
Post-Purchase Goal Pursuit

EXTENDED ABSTRACT

Consumers often purchase products that they are unable to use at the time, in anticipation that they may be able to do so later. For instance, people may buy clothing that is currently too small, in the hope of fitting into them later. In this research, we investigate how such anticipatory purchase decisions (to buy or not) affect consumers' likelihood of engaging in subsequent behavior that is consistent with the purchase (e.g., dieting or exercising after purchasing jeans that are too small). Drawing upon the optimism, mental simulation and goals literatures, we show that the type of mental simulation (outcome- vs. process-focus) that consumers use when making their anticipatory purchase decision can lead optimists and pessimists to make differing inferences regarding commitment vs. progress towards the goal. These inferences then dictate the nature of subsequent purchase-consistent decisions.

We propose that when consumers focus on the intervening process required to make the product usable (e.g., exercising to fit into a pair of smaller-sized jeans), the purchase decision itself acts as a signal of progress towards the goal. For optimists, the sense of accomplishment triggered by the purchase decision provides a justification to stop pursuing the focal goal (Fishbach and Dhar 2005). In contrast, pessimists, because of the unfavorable expectations they chronically hold, do not view the purchase decision as progress. Consequently, we predict that optimists reduce goal-congruent actions (e.g., exercising) after the anticipatory purchase, while pessimists are not affected by this illusory progress. Further, we predict that a different pattern should emerge under an outcome focus. Here, thinking about the final outcome (e.g., looking good) during the initial purchase increases the salience of the underlying goal (e.g., a fitness goal). Such increased goal salience leads optimists and pessimists to engage in different coping strategies: optimists become more committed to the goal and therefore more likely to pursue it, while pessimists tend to react in a non-adaptive manner by disengagement – i.e., the very salience of the goal makes them ironically less likely to pursue it (Scheier et al. 1986). Accordingly, under an outcome focus, making an anticipatory purchase should induce optimists (pessimists) to increase (decrease) goal-congruent actions.

We tested these hypotheses in five experiments. Experiment 1 used a 2 (focus: outcome vs. process) x 2 (optimism: optimists vs. pessimists) x 2 (decision: buy vs. no buy) between-subjects design. Participants first took part in a survey, which included a question about the size of jeans that they could just fit in. After a filler task, they completed a different survey about buying jeans. We manipulated thought focus by asking participants to make their decisions by visualizing either the end benefits of wearing the jeans (outcome-focus) or the process they would have to go through in order to be able to fit into the jeans (process-focus). Next, they read the description of the jeans, which were always one size smaller than their current sizes. They then reported their likelihood of purchasing the jeans, which served as the measure of anticipatory purchasing. Afterwards, participants moved on to an ostensibly unrelated study, in which they reported their likelihood of trying out fitness equipment. Lastly, they filled out a standard optimism scale (Scheier and Carver 1985). As hypothesized, under process-focus, optimists displayed a reduced likelihood of trying the exercise equipment after buying (vs. not buying) the jeans, while pessimists were unaffected by their purchase decision. Under outcome-focus, on the other hand, optimists were more likely to try the equipment as a consequence of buying (vs. not buying) the jeans, while the predicted ironic effect was obtained for

pessimists: buying (vs. not buying) the jeans actually reduced the likelihood of trying the exercise equipment. This pattern of results was replicated in another study (Experiment 2) which manipulated purchase decision rather than treating it as a measured variable. Experiment 3 provided further support for our posited mechanism by measuring both goal commitment and goal progress, and obtaining findings consistent with predictions. Under a process-focus, optimists inferred greater goal progress when they decided to make (vs. not make) the anticipatory purchase, while pessimists remained unaffected. Given an outcome-focus, in contrast, deciding to make (vs. not make) the anticipatory purchase increased goal commitment for optimists, while decreasing it for pessimists.

Having obtained converging evidence for our overall framework, the next two experiments sought to provide more detailed insights into the mechanism under outcome-focus, especially that underlying the ironic effects of anticipatory purchase for pessimists. We have argued that it is the very salience of the focal goal which causes pessimists to disengage from it (leading to an ironic effect on subsequent behavior). If true, it should be possible to attenuate pessimists' decommitment by lowering the salience of the focal goal. In support of this prediction, Experiment 4 and 5 both showed that it was possible to attenuate and even reverse the ironic effect for pessimists (i.e., make them more likely to engage in goal-consistent behavior) by reducing the salience of the focal goal.

Taken together, results from these five studies, which included manipulated and measured purchase decision, chronic and situational inductions of optimism, as well as different purchase contexts, provide a nuanced perspective of how and why optimism affects goal-related action subsequent to making an anticipatory purchase decision. In doing so, this research offers new insights into the substantive domain of anticipatory purchasing, and builds theoretical knowledge in two important areas of consumer research: the literature on goals, and that on optimism.

Pleasure, Pain, and Focus on Initial vs. End States as Determinants of Motivation in Goal Pursuit

EXTENDED ABSTRACT

Research on goal pursuit has focused on two factors that determine individuals' motivation to reach their goals. One of these factors is the amount of goal pursuit an individual has engaged in (Fishbach and Dhar 2005; Kivetz, Urminsky, and Zheng 2006; Laran and Janiszewski 2009). A second factor is whether the pursuit process is focused on what has been accomplished or on what still needs to be accomplished (Zhang and Huang 2010). We explore an important determinant of people's motivation in goal pursuit, goal valence, which may interact with factors previously explored in the literature and expand previous findings. We propose that any goal pursuit process is focused on approaching pleasure or avoiding pain, as stated by the hedonic principle (Elliot and Harackiewicz 1996; Forster, Higgins, and Idson 1998), and that this goal valence will moderate the extent to which goal focus and goal progress influence motivation. When people approach pleasure (e.g., save $600 to be able to go on a cruise vacation), the goal pursuit process is motivating. Therefore, the more people look backward and focus on how much goal pursuit they have engaged in, the more motivated they are to reach the goal. When they look forward, the more there needs to be done the more motivated people are to reach the final, pleasurable end state that characterizes approaching pleasure. When people avoid pain (e.g., save $600 to pay off a debt), avoiding the initial state is motivating. Therefore, the more people look backward and focus on how close they are to the initial, painful state, the more motivated they are to reach the goal.

When they look forward, the less there needs to be done the more motivated people are to reach the final end state and avoid the initial, painful state.

The first study examine people's motivation to save $1000 to pay off a debt (avoid pain) vs. to go on a vacation (approach pleasure). The design was a 2 (goal valence: approach pleasure vs. avoid pain) by 2 (focus: backward vs. forward) by 2 (progress: smaller vs. greater) between-subjects design. We showed participants a line featuring the amount of money they had saved so far. We manipulated backward vs. forward focus by showing the quantities in a $0 to $1000 (focus on what had been saved) or a $1000 to $0 (focus on what needed to be saved) order. In the smaller (greater) progress condition, participants were told they had saved $600 ($700) so far. An ANOVA on how much effort participants were willing to put into saving money revealed an interaction of the goal valence, focus, and progress factors ($F(1, 228) = 42.84, p < .01$). When approaching pleasure, in the backward focus condition, participants were willing to put less effort into saving money in the smaller progress ($M = 6.00$) than in the greater progress condition ($M = 7.46; F(1, 228) = 8.32, p < .01$). In the forward focus condition, participants were willing to put more effort into saving money in the smaller progress ($M = 7.71$) than in the greater progress condition ($M = 5.91; F(1, 228) = 11.92, p < .01$). When avoiding pain, however, in the backward focus condition, participants were willing to put more effort into saving money in the smaller progress ($M = 7.22$) than in the greater progress condition ($M = 5.19; F(1, 228) = 11.89, p < .01$). In the forward focus condition, participants were willing to put less effort into saving money in the smaller progress ($M = 5.40$) than in the greater progress condition ($M = 7.61; F(1, 228) = 11.15, p < .01$).

In the first study, participants were told that they were paying off a debt and that they would go on vacation only if they were able to pay off the debt. In order to make this avoid-pain goal into an approach-pleasure goal, the second study told participants that they had already made a decision to go on vacation and now were paying off the debt they acquired. This would make the goal to pay off a debt not painful to start with, since it was accompanied by the decision to go on vacation. The goal amount was now $2000, and we measured how much participants were willing to save. An ANOVA on the saving measure revealed an interaction of the goal valence, focus, and progress factors ($F(1, 291) = 20.81, p < .01$). When approaching pleasure, in the backward focus condition, participants were willing to save less money in the smaller progress ($M = \$437.97$) than in the greater progress condition ($M = \$546.69; F(1, 291) = 7.79, p < .01$). In the forward focus condition, participants were willing to save more money in the smaller progress ($M = \$550.63$) than in the greater progress condition ($M = \$462.55; F(1, 291) = 4.89, p < .05$). When avoiding pain, however, in the backward focus condition, participants were willing to save more money in the smaller progress ($M = \$563.95$) than in the greater progress condition ($M = \$481.73; F(1, 291) = 4.80, p < .05$). In the forward focus condition, participants were willing to save less money in the smaller progress ($M = \$469.51$) than in the greater progress condition ($M = \$545.24; F(1, 291) = 3.73, p = .05$).

A third study demonstrated similar results within a coffee rewards program. Across three studies, we demonstrate that, in addition to goal progress and direction of focus, whether the goal is to approach pleasure or to avoid pain needs to be examined when people research motivation. We show that goal valence can completely reverse effects previously found in goal pursuit, and that having people focus on the painful or pleasurable aspects of a goal can be an important tool in motivating consumers.

Paper #4: Predicting Consumers' Selfishness versus Predicting a Consumer's Selfishness: Asymmetries in Forecasts for Individuals versus Collectives

Clayton R. Critcher, UC Berkeley, USA
David Dunning, Cornell University, USA

SESSION OVERVIEW

A charitable organization is soliciting volunteers to help with distributing food to homeless people on the weekends. Would the likelihood of volunteering change if potential volunteers suddenly happened to receive a phone call or a text message before making their decision? Would the likelihood of volunteering differ if potential volunteers were asked to think about how likely others were to volunteer vs. how likely another individual was to volunteer? A buyer and a seller are negotiating over a piece of prime real estate. Would a high level of rapport lead one of them to lie to the other? Is one of them more likely to lie if she just lost money in a lottery?

These scenarios highlight everyday situations in which people make decisions about behaving in a self-centered and potentially antisocial manner. Each paper in the session investigates either the antecedents of selfish behavior or the impact of selfish behavior on subsequent judgments and decisions. Previous research suggests that a focus on the self can have negative outcomes (Baumeister, Smart, and Boden 1996). Additionally, moral systems have been conceptualized as mechanisms to "regulate selfishness and make cooperative social life possible" (Haidt and Kesebir 2010), implicating ethicality as an antecedent of selfish behavior. While the four papers approach the notion of selfish behavior in diverse ways, each one hinges on the implication of the self as a building block for their framework.

In the first paper, Pocheptsova, Ferraro, and Abraham show that usage of mobile phones, which function as psychological and physical extensions of the self, leads to an increased self-focus which, in turn, increases selfish behavior. They show that participants placed greater value on their time after using a mobile phone and were less likely to volunteer for a charity. Next, Jap, Robertson, and Hamilton question the notion that increased rapport should lead to more pro-social behavior in negotiations. They examine the context where conflict between negotiators' core needs means that a successful deal can only be reached when one or both parties acts unethically or "misbehaves," for example, by lying to the negotiation partner. They show that the desire to build or maintain rapport can lead buyers

and sellers to engage in unethical behavior by lying in impasse settings to achieve the desired selfish outcome. In the third paper, Alter, Mazar, and Ariely show that in hot states, specifically, when considering one's financial standing as weak relative to others, people are motivated to rectify this deficiency even if they are required to engage in morally questionable conduct. However, when individuals do not feel financially worse off (i.e., are in a cold state) they fail to appreciate this drive. Participants judged immoral acts committed out of financial deprivation more harshly than when they too experienced a similar state of financial deprivation. Finally, Critcher and Dunning conclude the session by proposing that thinking about an individual's selfish behavior versus a collective of individuals' selfish behavior results in different judgments. When focusing on individuals, estimates are influenced by consideration of an internal moral conscience, whereas when focusing on collectives, estimates are influenced by a consideration of social prohibitions. The authors show that an individual consumer's behavior is perceived as more pro-social than collective consumers' behavior, and further show the relative importance of the moral conscience and social prohibitions.

This session is likely to appeal to consumer researchers who are interested in selfish behavior and consumer judgments, in general, and more specifically in self-product connections, negotiations, and moral behavior. The research has both theoretical and practical implications. Although the positive effects of self-extending possessions have been documented (Belk 1988), Pocheptsova et al. demonstrate the unintended negative consequences of the same phenomenon, suggesting direct implications for the marketing of mobile phone products as well as their use as an advertising medium. Jap et al. also demonstrate a negative consequence of selfishness. Whereas previous research has shown that rapport has positive effects, the authors find evidence of antisocial behavior as a result of individual's selfish desire to secure a deal. Alter et al. add to these findings by demonstrating unethical behavior as a consequence of an otherwise unacceptable excuse (financial deprivation), highlighting an avenue for future research that focuses on the self-relevance of such excuses. Lastly, the paper by Critcher and Dunning raises questions regarding the estimates elicited by consumer researchers in surveys about others' behavior, and whether there are fundamental differences in how individuals respond to logically equivalent questions. Additionally, the research suggests that charitable advertisements that use reference statistics focused on individuals could lead to more pro-social behavior.

Taken together, the papers in the session highlight a number of domains where consumers behave selfishly, which have implications for social welfare. Understanding the mechanisms underlying such behavior can help consumer researchers find better ways to encourage consumers to behave more pro-socially.

The "Cellph"-ish Effects of "Self"-phone Usage

EXTENDED ABSTRACT

Mobile phones have become ubiquitous in our lives (Clark and Pasquale 1996). Consequently, human-computer interaction research has focused on the potentially detrimental effects of using digital devices on human cognition and behavior (Bianchi and Phillips 2005). In a similar vein, we address how the usage of mobile phones can have unintended negative consequences on social behavior.

Past research has demonstrated the self-expressive and identity-signaling roles that possessions, products, and brands play in consumers' lives (Aaker 1999; Belk 1988). They serve as means for differentiating from others and provide reinforcement for one's identity (Escalas and Bettman 2005). Belk (1988) suggests that our possessions are part of an extended self, and that the energy we invest in objects increases their potential for self-extension. Given how much time people spend on mobile phones, they are likely to be a strong component of people's extended selves. Further, because people hold mobile phones in their hands and because mobile phones serve as the interface for communication with others, essentially operating as mouths and ears, mobile phones also can be considered as physical extensions of the self. We expect that because mobile phones are both a psychological and physical extension of the self, their use increases activation and focus on the self. This increased focus on the self causes people to pay more attention to their self-interest, and to pursue outcomes that are aligned with their self-interest, at the expense of outcomes that might be beneficial to others. In other words, people engage in more selfish behavior. To test this proposition, we ran two experiments utilizing different measures of selfish behavior – the value participants place on their time and pro-social intentions.

Participants in the first experiment were randomly assigned to either a mobile phone condition or a toy condition. Participants were asked either to spend two minutes using the mobile phone as they normally would (except for making phone calls) or using the toy to create multiple shapes. Using the toy to make multiple shapes should provide an experience similar to doing multiple activities, such as texting, playing games, etc., on a mobile phone. In this experiment, we measured the value placed on one's time in two ways. First, participants were asked to indicate whether they preferred to receive two songs downloads now or to wait and receive more song downloads in the future. The results indicate that participants in the mobile phone condition were more impatient, expressing greater preference to download two songs now rather than wait and receive more song downloads. Second, participants were asked to indicate how much they would need to be paid to complete an additional 30-minute study, with a higher dollar amount indicating more value of their time. The results support the prediction, with participants in the mobile phone condition expecting to be paid significantly more to do another study ($M = \$19.80$) than participants in the toy condition ($M = \$12.98, F(1, 44) = 6.72, p < .05$).

In experiment 1, the toy did not possess any communication capabilities so it is possible that the observed differences across conditions were not due to increased self-focus, but due to activating associations with instant gratification, which may have resulted in placing greater value on own time. Experiment 2 was designed to rule out this alternative explanation. Participants were randomly assigned to either a mobile phone condition or a Facebook condition. We chose Facebook because it allows for instant communication, which, like mobile phones, could increase the need for instant gratification. Facebook, like mobile phones, is a part of students' identities, but unlike mobile phones, is not a physical extension of the self and thus should lead to a lower focus on the self relative to mobile phones. Participants were instructed to spend three minutes using either their mobile phones or their Facebook accounts on a computer Web browser. Then, they were presented with a short description of a local charity and asked how likely they would be to volunteer for the charity, and more specifically, how likely they would be to volunteer for three-hours one Saturday a month. Participants in the mobile phone condition were less willing to volunteer in general ($M = 3.27$) or for one Saturday a month ($M = 3.53$) than participants in the toy condition were to volunteer in general ($M = 3.65, F(1, 191)$

= 4.07, $p < .05$) or for one Saturday a month ($M = 3.96, F(1, 191) = 3.95, p < .05$).

In summary, we propose that the usage of mobile phones leads to a greater focus on the self, which in turn, results in more selfish behavior. In experiment 1, we found that the usage of mobile phones affected how much people valued their time. Experiment 2 replicated these results with a different measure of self-focus and using a Facebook condition to rule out instant gratification as an alternative explanation. Taken together, these two experiments offer convergent evidence for our propositions. An implication of these findings is the need for deeper introspection on the use of devices such as mobile phones for both marketers and consumers if an unintended consequence of their usage is to make people behave in fundamentally more selfish ways.

The Dark Side of Rapport: Selfish Behavior in Negotiations

EXTENDED ABSTRACT

A considerable body of research has extolled the virtues of establishing rapport in negotiations. In conventional wisdom, negotiations have come to be seen less as a zero-sum exchange in which one side's gains can only come at the expense of the other side, and more as congenial affairs in which everyone can win. Experts on negotiation have even gone so far as to claim that the relationship among the negotiators is just as important as the substance of the negotiation (Fisher and Shapiro, 2005). Empirical work has largely supported this view. Negotiators who are high in rapport tend to be more likely to reach an agreement and more satisfied with the outcome. Although rapport generally has been found to have positive effects in standard negotiation settings, we investigate the effects of rapport in a context that has received less attention: impasse settings, where conflict between negotiators' core needs means that a successful deal can only be reached when one or both parties acts unethically or "misbehaves," for example, by lying to the negotiation partner. In a series of three experiments, we find that negotiators who have a high level of rapport are more likely to behave unethically than negotiators who have a low level of rapport.

The conventional view is that increased rapport, such as that facilitated through face-to-face communication leads to a higher incidence of ethical behavior (Naquin and Paulson, 2003). Valley, Moag and Bazerman (1998) found that individuals negotiating face-to-face are more likely to tell the truth than those negotiating either by telephone or in writing, in part because people believe that it is more costly to the relationship to lie face-to-face. Face-to-face encounters seem to prime social norms of honesty and a positive relational atmosphere (DePaulo, Kashy, Kirkendol, Wyer, and Epstein, 1996; Naquin and Paulson, 2003).

In contrast to the conventional view, we propose that in some circumstances rapport can lead to an increase in selfish behavior through deceiving the negotiation partner. At the core of our argument is the notion that sometimes negotiating involves giving the negotiation partner bad news—information that is contrary to the partner's preferences and could jeopardize coming to a successful deal. This negative information represents a psychological conflict for a negotiator who is trying to build or maintain a high level of rapport. Building rapport often involves seeking out areas of agreement, while sharing information that the partner does not like can result in conflict. Thus, we predict that when a negotiation involves core requirements that are in conflict, a negotiator seeking to build or maintain rapport may be more likely to deceive their partner than to

disappoint them with the truth—acting selfishly by lying rather than facing an unpleasant situation.

All three experiments used the Bullard Houses case, a widely used ethics case developed by Northwestern University's Dispute Resolution Research Center in the Kellogg School of Management. The case involves interactions between one buyer agent and one seller agent negotiating over a piece of prime real estate. This case was selected for these experiments because it leads to a negotiation impasse in which it is easy to misbehave ethically in more than one way and its usage across the three experiments contributes to comparability across varying manipulations and populations. Participants were assigned to dyads, with each member of the pair assigned to either the role of the buyer agent or the seller agent and given information pertinent to their role. In short, the seller's agent is required to know how the buyer will use the property, while the buyer's agent is directed not to reveal the use of the land or the buyer's identity in order to protect the firm's goals and interests. In this way, the case is intentionally constructed so as to create an impasse based on conflicting core priorities between buyer and seller agents.

In our first experiment, rapport was manipulated through the medium in which negotiations were conducted. Building on research showing that face-to-face interactions tend to foster higher levels of empathy, positive affect, mutual attentiveness and coordination, we had some pairs of participants negotiate face-to-face (high rapport) and others negotiate from separate rooms using an instant messaging program (low rapport). We found greater incidence of selfish and unethical behavior in the high rapport condition than in the low rapport condition, including 1) a greater likelihood of reaching a deal (which could only be reached if one or both parties behaved unethically; 84.6% vs. 42.9%; $X2(1) = 6.85$, $p < .01$) and 2) a content analysis of the transcripts of the negotiations, which revealed a greater incidence of misleading statements, overpromising, lying and dissembling among high rapport participants ($F(1,50) = 25.97$, $p < .001$).

Because there are more differences between face-to-face and computer-mediated negotiations than just rapport, our second experiment manipulated rapport while holding constant the medium in which negotiations were conducted. All participants in the second study conducted negotiations via instant messaging (low rapport), but some of the participants engaged in a five minute rapport-building exercise before beginning (high rapport). These participants discussed positive aspects of their student experience and shared personal information about themselves, including name, hometown and major. As in the first experiment, participants in the high rapport condition were more likely to behave selfishly and unethically, including being more likely to reach a deal (97.0% vs. 79.5%; $X2(1) = 4.41$, $p < .05$) and a self-report measure of whether they had made false statements in order to conceal their true purpose (3.5 vs. 2.6; $t = -2.12$, $p < .05$).

In the third experiment, we find that the negative effects—but not the positive effects—of high rapport are reduced when negotiators are given a simple reminder before negotiations begin that one's actions can have long-term repercussions for one's reputation. Taken together, this research supports the idea that, despite its several advantages, in certain situations rapport has a dark side, of which negotiators must be wary.

The Hot-Cold Empathy Gap: Financial Deprivation Licenses Immorality

EXTENDED ABSTRACT

Morality is considered to have evolved as a mechanism of survival, restricting excessive self-interested behavior and fostering human cooperation (Shermer 2004). The basic idea behind this assumption is that individuals strive to live in accordance with their moral standards and refrain from transgressions through motivated self-regulatory mechanisms that help them to exercise moral agency. Yet, recent theories in social cognition and morality suggest that individuals selectively disengage these mechanisms so they can engage in brief instances of questionable conduct without violating their moral standards. In particular, self-sanctions can be disengaged by reinterpreting one's actions or minimizing the negative consequences of one's actions, vilifying the target of one's actions, and, most strongly, by obscuring personal causal agency through diffusion or displacement of responsibility (Bandura, Barbaranelli, Caprara, & Pastorelli, 1996; Mazar, Amir, & Ariely, 2008). Thus, the easier it is for individuals to employ any of these mechanisms and deactivate moral control, the more likely they are to engage in immoral behavior, such as cheating, without changing their moral standards. Such processes can lead to moral hypocrisy, where people impose strict moral standards while behaving less morally (Lammers, Stapel, & Galinsky, 2010). However, researchers have yet to examine whether such moral hypocrisy is conscious and deliberate or instead represents a subconscious failure to recognize the role of transient states.

Prior research has shown that not only are individuals' preferences and behaviors state-dependent but also they misjudge and mispredict their own as well as others' preferences and behaviors across affective states. This bias has been coined the "hot-cold empathy gap" (Loewenstein, 1999). Traditionally, the "hot-cold empathy gap" has been used to explain mispredictions of how drive states caused by bodily needs such as hunger, thirst, anxiety, and exhaustion affect judgment and decision making. What is less known is to what extent this also applies to non-bodily driven states. For example, one of the most important drivers in our western, developed world is money, which enables people to acquire tangible as well as intangible commodities (social influence, adoration, happiness, etc; Lea & Webley, 2006). One of the crucial distinctions between money and more bodily drive states is that one's absolute financial standing seems to matter less than one's standing relative to other people (Shafir, Diamond, Tversky, 1997). Thus, if money is indeed such a strong motivator, we posit that feeling financially worse off than others should motivate people to rectify this deficiency even if they are required to engage in morally questionable conduct. Furthermore, we hypothesize that when individuals do not feel financially worse off (i.e., when they are in a cold state) they fail to appreciate this drive and therefore judge immoral acts committed out of financial deprivation more harshly than when they too experience a similar state of financial deprivation (i.e., when they are in a hot state).

We tested our predictions in a series of four studies. In Study 1 we administered a survey in which individuals were asked whether they agreed with the statements that (1) one's financial situation is not an acceptable excuse for dishonesty, (2) all people, regardless of their financial standing, should be held equally accountable for dishonest behavior, (3) people who are financially deprived do not deserve more leeway when they behave dishonestly, and (4) when assessing the extent to which people are honest or dishonest, one should take into account how financially deprived they are. Participants held the general belief that financial standing should not matter. Interestingly, however, Study 2 and 3 show that being financially worse off than one's peers objectively (by losing instead of winning money in a lottery) or subjectively (by asking people to write down two vs. 10 reasons why they are financially better or worse off than their peers), increased lying to earn more money in a subsequent cheating task with real consequences. Finally, in Study 4, people, who were made to feel financially worse of than their peers (i.e.,

people who wrote two reasons for why they felt deprived; "hot" state), were more lenient in their sentencing of deprived but not non-deprived offenders, while people, who were not made to feel financially worse off than their peers (i.e., people who wrote six reasons for why they felt deprived; "cold" state), did not differentiate between those offenders.

Predicting Consumers' Selfishness versus Predicting a Consumer's Selfishness: Asymmetries in Forecasts for Individuals versus Collectives

EXTENDED ABSTRACT

Marketers, policymakers, and consumers alike have cause to forecast others' morally-relevant behaviors. For example, the government may consider what percentage of consumers will submit fraudulent warranty claims. Alternatively, a charity may forecast the likelihood that a consumer will donate to charity.

These examples differ most obviously in the behavior they focus on, but they differ in another key, but heretofore unappreciated, sense. The first example focuses the forecaster on consumers in general, while the second question focuses the forecaster on an individual (though non-individuated) consumer. Both consumer behavior and JDM researchers have treated forecasts of non-individuated individuals and collectives interchangeably. But might such forecasts systematically differ?

In five studies, participants estimated what percentage of consumers would engage in a morally-relevant behavior (collective condition), or they indicated the percent likelihood that a randomly selected individual from the population would display that behavior (individual condition). These two questions are normatively equivalent; for example, from a room with 30% women, the probability than any specific person is female is also 30%. Studies 1 and 2 demonstrated that people forecast that individuals will behave more prosocially than will collectives. Studies 3 through 5 provided correlational and experimental support for why a difference emerged.

In Study 1, all participants forecasted whether others would comply with a request. We framed compliance as being helpful (compliance = pro-social condition) or as failing to stand up for what is right (compliance = anti-social condition). Participants estimated—for an individual or for a collective—whether people would comply. The predicted 2 (framing: compliance = prosocial or compliance = antisocial) X 2 (target: individual or collective) interaction emerged, $F(1, 120) = 4.14, p = .04$. Regardless of whether it meant complying or resisting compliance, individuals—more so than collectives—were predicted to behave pro-socially. Because the same behavior was framed as pro-social or anti-social, alternative explanations appealing to specific features of compliance—as opposed to its pro-sociality—are made less plausible.

In Study 2, participants estimated others' (or an other's) likelihood of engaging in a range of pro-social and anti-social behaviors (identified as highly representative of these categories through pretesting) in the next month. Conceptually replicating Study 1, a 2(behavior: pro-social or anti-social) X 2(target: individual or collective) interaction emerged, $F(1, 305) = 5.44, p = .02$. A (non-individuated) consumer was forecasted to behave more pro-socially than were consumers as a whole.

Might these differences emerge for an artifactual reason--reflecting a difference between forecasts made in continuous terms ("How likely is this consumer to….) versus discrete terms ("What percentage of consumers will…."). Study 3 addressed this concern

by eliciting all judgments in a discrete form, asking "Thinking of a randomly selected Cornellian, how many times in the next year will he or she…" versus "Thinking of all Cornell students, how many times will the average student…" The same 2(behavior: pro-social or anti-social) X 2(target: individual or collective) interaction emerged, $F(1, 218) = 11.89, p = .001$.

Why might these differences emerge? Miller (1999) suggested that consumers subscribe to a descriptive "norm of self-interest," believing others to be generally motivated by selfishness. We identified two sources of constraint on consumers' selfishness. First, consumers have an internal moral conscience that pushes them to do the right thing. Second, there are social prohibitions on anti-social behavior that constrain it. Might forecasts of individuals versus collectives differ because each target type (individual or collective) focuses the forecaster on a different consideration? One hint from past research comes from findings that suggested that people were more sensitive to internal experiences when considering an individual than a group (Hsee & Weber, 1997). Also, Flynn and Lake (2008) found that people underestimated the impact of social pressure when considering an individual's behavior.

Participants in Study 3 rated, for each behavior, how much there would be internal pressure from one's moral conscience, and how much there would be social pressure, to do the right thing. And indeed, hierarchical linear modeling showed that forecasts for individuals were influenced by how much it was assumed an internal moral conscience would lead one to behave pro-socially, whereas social forces were neglected. Forecasts for collectives showed the reverse pattern.

Studies 4 and 5 confirmed this mechanistic account experimentally. In Study 4, participants saw the same set of selfless behaviors that had been slightly modified to speak to one's moral conscience more or less. For example, in the high appeal to moral conscience condition, participants forecasted donation rates to Doctors Without Borders. In the low appeal to moral conscience condition, participants forecasted donation rates to the Chamber of Commerce. Consistent with our account, when selfless behaviors had a strong appeal to a person's moral conscience, individuals were judged as more likely to do them than were collectives, $t(234) = 3.72, p < .001$. The asymmetry was eliminated when the behaviors had low appeal to moral conscience, $t(234) = 1.25, p > .24$.

In Study 5, participants learned about a dictator game that was played either publicly (high social pressure) or anonymously (low social pressure). Participants forecasted whether dictators would behave very anti-socially, giving only one penny to the other player. A 2(public pressure: high or low) X 2 (target: individual or collective) interaction emerged, $F(1, 86) = 4.58, p = .04$. Under high social pressure, both individuals and collectives were seen as equally unlikely to be stingy, $t < 1$. But under low social pressure, collectives were forecasted to be more anti-social, $t(86) = 2.40, p = .02$. Removing the social constraints on bad behavior only influenced forecasts of collectives.

Psychologically, forecasting a consumer's behavior differs from forecasting consumers' behavior. Given this distinction has not been previously appreciated, we hope that these findings may help make sense of when and why there may be disagreements about forecasts of consumers' (or a consumer's) behavior. With an understanding of how these forecasts tend to differ, future research may uncover when forecasts of one type or the other lead to more accurate predictions of the future.

Receiving Feedback during Goal-Pursuit: When Good Hurts and Bad Helps

Paper #4: Conquering Conflict: Multifinal Means in Multiple-Goal Pursuit
Jordan Etkin, University of Maryland, USA
Francine Espinoza, European School of Management and Technology, Germany
Anastasiya Pocheptsova, University of Maryland, USA

SESSION OVERVIEW

Many of consumers' choices are goal-driven. For example, consumers may go to the gym because they value being healthy and have dinner with friends or family because they wish to maintain strong interpersonal relationships. Successful goal pursuit requires consumers not only to initiate, but to sustain motivation to pursue their desired goal(s) (Kruglanski et al. 2002). One factor that has been shown to affect motivation is feedback received during the course of goal-pursuit (Fishbach and Dhar 2004). Not surprisingly, previous research finds that receiving positive feedback regarding the success or potential success of one's goal directed efforts enhances motivation, while receiving negative feedback diminishes motivation. In this session we explore situations where feedback on goal pursuit affects motivation in unexpected ways. In particular, we look at situations where positive feedback hurts motivation and negative feedback helps motivation.

The first two papers focus on unexpected positive consequences of receiving negative feedback during goal pursuit. The paper by Berger and Pope shows that loosing by a little relative to one's competition can increase the effort invested in pursuing a goal. These authors argue that one's competition can serve as a reference point for goal pursuit; increasing motivation when slightly behind the competition. Indeed, basketball teams that were slightly behind at halftime were actually more likely to win than teams slightly ahead at halftime. The paper by Lamberton, Kristofferson, and Dahl shows that failing to obtain an envied product does not always decrease motivation to obtain it. In fact, when a low-value consolation prize is offered in place of a desired product, initial failure to obtain the envied good can actually increase purchase motivation.

The next two papers focus on unexpected negative consequences of receiving positive feedback during goal pursuit. The paper by Klein and Fishbach demonstrates that receiving premature positive news regarding the success of goal pursuit (i.e. being offered a job) decreases valuation of the outcome. Finally, Etkin, Espinoza and Pocheptsova show that though positive mood is generally thought to signal that goal pursuit is going well, it can also have a detrimental impact on subsequent motivation in multiple-goal pursuit by decreasing perceptions of means multifinality.

The four papers in this session propose to make a novel contribution to existing research on goal-pursuit by examining the impact of receiving feedback on subsequent motivation. We expect this session to be of interest to researchers working in the areas of motivation and consumer goals, as well as to those interested in the impact of contextual cues (such as framing) on consumer behavior. Each of the papers described below has multiple completed studies, and several are available as working papers.

Can Losing Lead to Winning?

EXTENDED ABSTRACT

Intuition suggests that being ahead in everything from bonus competitions to sales contests should increase the likelihood of winning. In sports, for example, teams which are ahead early in the game win over two thirds of the time and teams that are further ahead tend to win more. But could being slightly behind actually increase success? Could losing lead to winning?

We suggest this possibility based on research on goals and motivation. Although finishing part of a project or scoring a touchdown requires the same amount of effort whether a person or team is ahead or behind, goals can act as reference points (Heath, Larrick, and Wu 1999). Consequently, position relative to a goal can influence motivation in a manner consistent with Prospect Theory's key tenets (Kahneman and Tversky 1979). Loss aversion suggests that compared to people who are above their goal by a similar amount, people who are below or behind their goal will work harder because they see their performance as a loss. Further, due to diminishing sensitivity, people who are slightly below their goals should work harder than those for whom the goal is further away (Heath, Larrick, and Wu 1999; Kivetz, Urminsky, and Zheng 2006). These ideas have important implications for competition. Because winning involves doing better than adversaries, an opponent's performance should serve as a salient reference point. Consequently, whether people code their current performance as a gain or loss should depend on whether they are ahead or behind at that particular moment. As a result, being slightly behind may actually increase motivation and success.

We test how losing by a little affects motivation and performance in both the laboratory and the field. First, we analyze over 18,000 NBA basketball games (Study 1) and 45,000 collegiate basketball games (Study 2) to examine how being slightly behind at halftime affects whether teams win or lose. Building on these findings, we then use controlled experiments to directly test the causal impact of being slightly behind on individual effort (Study 3) and the role of self-efficacy in these effects (Study 4).

Study 1 consists of all NBA games played between the 1993 and 2009 seasons. Importantly, rather than just looking at overall winning percentages based on halftime score, we use a regression discontinuity design to estimate the *causal* impact of being slightly behind. Not surprisingly, the further teams are ahead, the more likely they are to win. Every two-points better a team is doing relative to its opponent at halftime is associated with a 6-8% increase in the probability of winning. There is a strong discontinuity, however, around zero. Rather than having a winning percentage that is 6-8% less than teams ahead by a point (as the model would predict), teams that are behind by one point are actually *more* likely than their opponents to win (triumphing in 58.2% relative to 57.1% of games). This is particularly noteworthy given that they are worse than their opponents

(looking at season winning percentage) and mechanically, have to score two more points than their opponent to emerge victorious. Regression specifications confirm that being slightly behind significantly increases a team's chance of winning. Overall, teams that are losing at halftime win 5.8 to 8.0% more often than expected (p's < .05). Ancillary analyses illustrate that these effects are robust to numerous controls (e.g., season winning percentage and home team) and are not due to differences in coaching. Study 2 finds similar results in NCAA games. Further, consistent with the notion that these effects are driven by motivation, minute-by-minute scoring data shows that being behind at halftime has the greatest impact immediately following when teams are behind.

Study 3 examines how competitive feedback influences effort. Participants engaged in a short competition task (pressing the 'a' and 'b' keys as quickly as possible) divided into two 30-sec periods. Between periods, participants were either told nothing or given competitive feedback: They were either told they were far behind, slightly behind, tied, or slightly ahead of another participant with whom they were competing. These conditions allow us to test whether being slightly behind increases effort, relative to being tied, being slightly ahead, or even not receiving any feedback at all. Further, they allow us to test whether the motivating effects of being behind hold even for being far behind and whether being slightly ahead induces complacency. As expected, being behind opponents led people to exert more effort, but only when they were slightly behind. Participants informed that they were slightly behind exerted more effort than participants in any of the other conditions, all ts > 1.96, ps < .05. All other conditions were equivalent, all ts < 1.0, ps > .35, indicating that being far behind did not increase effort and being slightly ahead did not decrease effort. Study 4 used a similar paradigm and shows that the motivating effects of being slightly behind are stronger among people who believe they can achieve their goal (i.e., have higher self-efficacy).

Taken together, the findings demonstrate that losing can sometimes lead to winning. Being slightly behind boosts winning among NBA and NCAA teams and experimental results show these motivating effects occur among individuals and underscore our proposed mechanism. In conclusion, encouraging people to see themselves as behind others, albeit slightly, should increase motivation and effort, and ultimately success.

Squeezing Wine from Sour Grapes: How Consolation Goods Impact Motivation to Buy an Envied Product

EXTENDED ABSTRACT

On one hand, the marketers of highly-demanded items benefit from consumer motivation: Open the doors, and rabid devotees will strip your shelves of every item in your inventory. On the other hand, recent work (Van de Ven, Zeelenberg and Pieters, 2010) suggests that individuals who walk away empty-handed may be demotivated to purchase the envied product, switching to a competitor's product or abandoning the purchase altogether. Which consumers are most likely to lose motivation to purchase an envied good in such situations? More importantly, what can marketers do to preserve, and even enhance, consumers' motivation to purchase an envied good?

Our research suggests that first, self-esteem plays a substantial role in determining the motivational effects of envy on willingness-to-pay for an initially desired product. Second, providing opportunities to obtain either high or low value consolation items alternately undermine or preserve consumers' motivation to purchase the envied good. Specifically, the possibility of obtaining a high-value consolation good facilitates the generation of positive counterfactuals

(Kahneman & Miller, 1986). These positive counterfactuals exacerbate sour grapes effects, lowering motivation to purchase the desired item. However, if individuals generate negative counterfactuals or are provided a low-value consolation opportunity in these situations, their motivation to obtain the desired good appears to be preserved or even enhanced.

Study 1 followed a 2 (winner present, winner absent) x continuously-measured self-esteem between subjects design. In a first phase of data collection, participants provided their own self-esteem level (Rosenberg, 1979) as well as their comfort in engaging in upward social comparison (Gibbons and Buunk 1999). Vancouver Canucks tickets were selected to be used as the envied good. Approximately two weeks later, participants attended a lab session. In the "winner" condition sessions, they were told that one session participant would win front row tickets to a Canucks game. The winning ticket was placed under a Confederate's seat. In the no-winner condition, participants completed all measures, still accompanied by the confederate, but no prize was discussed or awarded. Embedded in a battery of unrelated tasks, participants provided their perceptions of the confederate as well as their willingness to pay for Canucks' tickets. This willingness-to-pay measure constitutes our measure of motivation to purchase the envied good.

Higher self-esteem individuals were chronically less comfortable than their lower self-esteem colleagues with upward social comparison. This tendency appeared to lead them to provide lower ratings of a winning than a non-winning confederate. By contrast, lower self-esteem individuals showed no negative effects on the perception of the winning confederate. They did, however, show significantly lower motivation to purchase the Canucks' tickets in the winner as opposed to no winner sessions. Among these individuals, we thus see a "sour grapes" effect with regard to the envied good – seeing someone else win the tickets lowered their motivation to purchase them.

Assuming that some consumers will experience either chronic or situationally low self-esteem, how can marketers fight the sour grapes effect? In Study 2, we attempted to see if providing a consolation opportunity might reduce or even reverse these effects on participants' motivation to pursue the envied good. The envied good in this study was a Wii gaming system. To focus on product-related effects, self-esteem was first lowered by providing false feedback on GRE-type quiz performance. Procedures were then like those in study 1, including both winner and no winner sessions. However, here participants received no consolation opportunity, a high-value consolation opportunity (the chance to win a PS3 gaming system on a subsequent occasion), or a low-value consolation opportunity (the chance to win an inexpensive Catchphrase game.) In the no consolation condition, the prior sour grapes effect was replicated. Interestingly, when individuals were given a high-value consolation opportunity, motivation to buy the Wii was decreased even *more* than it had been when no consolation opportunity was offered. By contrast, providing a less-valuable consolation opportunity completely reversed the sour grapes effect. That is, a low-value consolation opportunity *heightened* participants' motivation to purchase the Wii system.

We argue that the exacerbation of the sour grapes effect in the high-value consolation case is akin to the "silver medal" effect. When offered a chance to win a relatively high-value consolation prize, participants could easily generate positive counterfactuals, experiencing strong negative affect related to the originally envied product. By contrast, positive counterfactuals are not readily activated by a low-value consolation.

To directly test this explanation, study 3 followed a 2 (positive counterfactual generation v negative counterfactual generation) x 3

(no consolation, high-value consolation good, low-value consolation) design. Participants recruited using Amazon's MTurk system (M(age) =, income =, x% male) were first placed in a low self-esteem mindset by writing a short essay about a failure experience in their life (White & Lehman, 2005). Subsequently, they read a scenario where a neighbor had won a 3D Plasma television, while they had either won nothing, won only a subsequent opportunity to win either a smaller, 2D flat-screen TV (high-value consolation) or won a chance to win a traditional CRT television (low-value consolation). They were then asked to generate either positive or negative counterfactuals regarding their situation (White & Lehman, 2005). As predicted, in the no consolation condition as well as in the high-value consolation, positive counterfactuals conditions, the sour grapes effect was replicated. However, having participants generate negative counterfactuals reversed the sour grapes effect for high-value consolation participants, such that their motivation to purchase the envied TV was significantly greater than in the no consolation prize condition.

Taken together, results from these studies support the theory that consideration of a high-value consolation opportunity can decrease motivation because the good substitute makes positive counterfactuals highly accessible. Interestingly, this offers a means by which marketers may squeeze wine from sour grapes. First, if relatively valuable consolation opportunities are available, they may be able to cue negative counterfactuals in the shopping environment. Second, marketers may both save money and enhance motivation, by providing only a token item to offset the potentially negative consequences of envy.

Feeling Good at the Right Time

EXTENDED ABSTRACT

It has long been established that people are happy when they find out they attained their goals. Research has not addressed, however, whether people hold expectations about the timing of when they would learn that they attained their goals. For example, a job applicant may expect to learn the results of the application via an official offer letter to be sent, say, a week after the final interview. But sometimes attainment news arrives sooner than expected. An HR representative may contact the job applicant with positive news before the official offer letter is sent. How do people experience premature good news? Different lines of research appear to support divergent predictions.

On the one hand, if emotion is viewed solely as a reaction to surprise (e.g. Carver & Scheier, 1990; Orthony, Clore, & Collins, 1988; see also Wilson & Gilbert, 2008), one might expect that premature news would lead to heightened positive emotion. This is because premature news is surprising not only due to its content but also due to its timing. Our research, however, predicts the opposite. We hypothesize that when news arrives prematurely, people hold back positive emotion. Specifically, we predict that compared to those who receive timely news, people who receive premature news would be less happy both when they receive premature news, and when they eventually receive timely news.

We motivate our predictions with self-regulatory theory. Specifically, people typically experience positive emotion following goal attainment and prior to disengaging from the goal (Higgins, 1987; Forster, Liberman, & Higgins, 2005). But when people perceive good news to be premature, they may not want to disengage too early. Accordingly, we hypothesize that holding back positive emotion would lead to sustained engagement in the goal.

We further hypothesize that holding back positive emotion has consequences in terms of goal value. Previous research has shown that affective cues influence goal value (Aarts, Custers, & Holland, 2007; Ferguson, 2008). Since premature news leads to the holding back of positive emotion, it consequently should lead to the devaluation of the goal.

We present three studies to support our hypotheses. In study 1, participants applied to a mock summer internship. In one condition, they received the results of their applications via hardcopy letter. In another condition, participants received the results via an unofficial computer message before receiving the official letter. We find that compared to those who received only the official letter, participants who received the premature computer message were less happy both when they received the computer message (an aversion to feeling happy too early) and when they eventually received the official letter (when they were no longer surprised).

In study 2, we replicate our finding that premature news leads to the holding back of positive emotion, as well as establish the link between emotion and goal value. Specifically, participants played a game of rock-paper-scissors in which they were told they had to win two out of three rounds. Premature news was manipulated by obligating participants in one condition to play three rounds even when they won the first two rounds. Participants in the second condition stopped playing after winning the first two rounds. The results showed that participants who had to play a third round despite winning the first two rounds were less happy after the second round than participants who won the first two rounds and stopped playing. Importantly, participants who were obligated to play three rounds and held back their happiness were also willing to accept less money for the prize they got for winning, a Twix bar.

Study 3 was conducted to replicate our previous findings and establish the link between emotion and goal engagement. Participants played a game in which they had to guess which of three face-down cards was the joker. Premature news was manipulated by letting participants in one condition flip the cards they did not pick, thus informing them that they either won or lost before revealing the identity of the card they picked. In a second condition, participants were not given the opportunity to prematurely flip any card. The results showed that participants who knew ahead of time that they won were less happy than participants who learned of their victory in an official manner. Replicating our goal devaluation finding, mediation analysis showed that participants who held back their happiness also rated winning the game as less important than participants who did not hold back their happiness, with the intensity of positive emotion as the mediator. Finally, as an operationalization of goal engagement, we gave all participants the opportunity to read a passage related to the game for as long as they liked and measured the time they spent doing so. As predicted, participants who held back their happiness also spent more time reading than participants who did not hold back their happiness. Mediation analysis indicated that holding back positive emotion mediated the effect of premature news on longer reading times.

As a whole, the present research shows that people are sensitive not only to the content of attainment information, but also to its timing. In addition, the present research reveals an ironic effect of premature news, namely that premature news leads people to maintain engagement in a goal but to end up valuing it less.

Conquering Conflict: Multifinal Means in Multiple-Goal Pursuit

EXTENDED ABSTRACT

People often have multiple goals that they wish to pursue at the same time. For example, a person may strive to be successful pro-

fessionally, spend time with family, and be healthy. Multiple-goal pursuit is inherently a complex phenomenon, requiring individuals to spread their limited pool of mental, emotional, and physical resources across several different goals (Kruglanski et al. 2002). Such multiple-goal pursuit can create the sense that one's goals are in conflict, which is a psychologically aversive state that has detrimental consequences for motivation (Emmons and King 1988; Riediger and Freund 2004).

How can people overcome inter-goal conflict and stay motivated to pursue their multiple goals? One way to attenuate the negative impact of inter-goal conflict on multiple-goal pursuit is by using means to goal attainment that are instrumental to the pursuit of not one but multiple goals at the same time. Choosing such "multifinal" means in the course of goal pursuit allows individuals to jointly pursue their multiple conflicting goals, making multifinal means (relative to unifinal means) more highly valued (Chun and Kruglanski 2005; Kruglanski et al. 2002).

Previous research on single-goal pursuit has found that positive mood signals effectiveness of goal-directed behavior and increases motivation to pursue the active goal (Louro, Pieters, and Zeelenberg 2007). We propose that in the context of multiple goals, positive affect will also influence consumers' ability to perceive means as multifinal, which will in turn negatively affect multiple-goal pursuit. Positive affect has been found to result in recognition of more, and more different, aspects or features of items (Isen et al. 1985; Isen et al. 1987), giving rise to a greater recognition of differences and increasing the complexity and richness of a set (Kahn and Isen 1993). Applying these findings to the context of multiple goals, we argue that positive mood would increase perceptions of inter-goal conflict. Further, such an increase in perception of goal-conflict would lead to increased difficulty in perceiving any single means as instrumental to several conflicting goals. Therefore, we predict that positive mood will make it more difficult to perceive multifinality among means to goal attainment, leading to lower motivation to pursue multiple goals.

Across several studies, we find support for our propositions. In study 1, we tested our basic proposition that positive mood increases perceptions of inter-goal conflict. Mood was manipulated by varying the outcome of an Ultimatum Game (positive mood = accept offer, negative mood = reject offer). Next, all participants were primed with three goals (a performance goal, a pleasure goal, and a self-improvement goal) and then reported their perceptions of conflict among the goals. To measure inter-goal conflict, we timed participants as they listed as many means as they could think of related to the three goals. Consistent with previous research that suggests inter-goal conflict has a detrimental impact on motivation, we reasoned that participants who experienced heightened inter-goal conflict (in the positive mood condition) would have more difficulty completing the means listing task relative to participants who experienced less goal conflict (i.e. negative mood). Consistent with this logic, it took participants in a positive mood more time (in seconds) to list an equivalent number of means as it did participants in a negative mood ($M_{positive}$=125.5 vs. $M_{negative}$=97.02).

Study 2 directly investigated the effect of positive mood on perceptions of means multifinality. Mood was manipulated by showing participants one of two video clips pretested to induce positive vs. negative mood. Next, instead of priming goals, we asked participants to list five important goals they were currently interested in pursuing. Finally, we asked participants to list (up to 10) means to achieve their goals and rate the extent to which the listed means served multiple goals. As we expected, participants in a positive mood perceived the means they listed as less multifinal than participants in a negative mood ($M_{positive}$=4.9 vs. $M_{negative}$=5.76).

Study 2 showed that positive mood makes perceiving means multifinality more difficult. As a result, we reason that positive mood should also decrease effort invested in using available means to goal attainment. However, this effect should be attenuated if individuals are made aware of means multifinality. Consistent with previous research that suggests positive mood is beneficial for goal pursuit (Custers and Aarts 2005; Fishbach and Labroo 2007), we expect positive mood to increase motivation in multiple-goal pursuit when available means to goal attainment are explicitly described as multifinal. In study 3 we test this reasoning by giving participants a means to multiple-goal attainment and measure the energy devoted to its use. After watching the sad versus happy videos, participants were primed with three goals (the same goals as used in study 1), and then were presented with an anagram task that was described as either unifinal (helping to achieve the first primed goal) or multifinal (helping to achieve all three primed goals). Motivation to pursue the primed goals was measured via the time participants persisted in the anagram task. We find that participants in a positive (vs. negative) mood persisted less in the task when it was presented as being unifinal ($M_{positive}$=133.88 vs. $M_{negative}$=196.15), but they persisted more than participants in a negative mood when the task was described as multifinal ($M_{positive}$=191.54 vs. $M_{negative}$=159.96), supporting our prediction.

Taken together, our findings support our proposition that positive mood leads to greater perceptions of inter-goal conflict and affects the perceptions of and use of multifinal means Our findings contribute to the literatures on mood and motivation by expanding our understanding of the interplay between emotions, means, and goal-pursuit in the context of multiple goals.

The Engaged Consumer: Creating, Disseminating, and Negotiating Value in the Realm of Social Media

Paper #3: "Hey, What's in it for Us?": How to Initiate and Maintain Participation and Collaboration with Creative Consumer Crowds

Andrea Hemetsberger, University of Innsbruck, Austria
Robert Kozinets, York University, Canada

SESSION OVERVIEW

The dissemination of communication technologies and, in particular, the transformations brought up with a social Web, confirm that our consumer culture has become deeply intertwined with an information economy. In this context, generating massive amounts of content, participating, sharing, and collaborating are some key practices daily enacted by a large number of networked individuals. Observing these changes and the new patterns of interaction among individuals, and between communally embedded individuals and companies, scholars in different fields have proposed new frameworks to understand the relationships and activities developed in this participatory, networked environment.

While an existing body of literature has problematized the relationships between marketers and communities (Kozinets 2001; Muniz and O'Guinn 2001; Schouten and McAlexander 1995), consumer researchers are only beginning to explore the dynamics between consumers and marketers who collaborate using the new social media. In this "many-to-many" model of communication, individuals who merely received content now become involved, frequently assuming a central role in the production and dissemination of value (Jenkins 2006). These new dynamics of collaboration in participatory cultures have blurred the boundaries between consumers and producers of entertainment and media content (Schau and Russell 2004), brand communications (Kozinets, de Valck, Wojnicki, and Wilner 2010), brand meaning (Muniz and Schau 2007), and overall value (Schau, Muniz, and Arnould 2009; Cova, Kozinets, and Shankar 2007). As Jenkins (2006, 3) observes, "rather than talking about [media] producers and consumers as occupying separate roles, we might now see them as participants who interact with each other according to a new set of rules that none of us fully understand."

While acknowledging that participants may have different degrees of status and influence, participatory cultures have been celebrated as avenues for consumer empowerment (Jenkins 2006). Lessig (2008, 111), for example, observes that, "in a culture in which it [participation] is common, its citizens develop a kind of knowledge that empowers as much as it informs or entertains." It is important to note, however, that in this collective, many-to-many approach, aspects other than creativity and agency have been moved unstable. As observed by Lauwaert (2009, 9), in participatory developments "not only money is fed back into the circuit of capital that moves from production to commodity to consumption and back to production, but also the voluntary, unpaid labor of devoted fans."

These reflections resonate with a recent stream of research on marketing, consumer culture, and related fields that explore the possibilities, outcomes, and implications for consumers of a co-creation economy. The exploitation of consumer (or fan) labour evoked by Lauwaert (2009) has been analytically developed by consumer researchers (Cova and Dalli 2009; Bonsu and Darmody 2008; Zwick, Bonsu, and Darmody 2008) and scholars in other disciplines (Foster 2009; Arvidsson 2008, 2005; Lazzarato 1996). Consumer culture scholars have also explored the infinitely co-creative potentialities of consumers and the benefits they extract from their creative acts (Schau et al. 2009; Kozinets, Hemetsberger, and Schau 2008; Kozinets 2001; McAlexander, Schoutern, and Koening 2002).

Building on the scholarly work described above, and observing current developments in consumer culture, this session focuses on the phenomenon of value (co)creation by consumers. Our studies, and the discussion we hope to generate during the session, represent an attempt at understanding how the shifting relations between consumers and marketers have been transformed by the current focus on more public, more community-based, more socially networked, more collective forms of interaction. Assembling connections between media studies and consumer research, and emphasizing a cultural/anthropological approach, this session will offer a refreshing perspective on the topic of collaborative value creation, which has been of interest to consumer researchers for a long time (Kozinets 1999; Schouten and McAlexander 1995; McCracken 1989).

The presentations included in this session will focus on the value creating practices of consumers involved in generating content for social media, and the online interactions of consumers as they acquire knowledge and skills to negotiate the allocation of collectively created value. In all cases, the authors have collected data, developed analyses of their datasets, and crafted preliminary manuscripts to report their findings. This session is aimed at provoking lively discussion among participants that will contribute to the refinement and further development of the papers included here, and of other scholarly research on the topic. With that in mind, presentations will be kept shorter than 20 minutes, leaving enough time for discussion and questions from the audience. The session will be mediated by colleague Hope J. Schau, a scholar renowned for her work on consumer culture, brand communities, new media, and value creation in the marketplace. Likely participants in this session are colleagues interested in marketer-consumer collaboration, value creation, social media, consumption communities, and internet-based research.

"You Guys Have Been Along Long Enough To Know": The Collective Development of Consumer Co-Creation

EXTENDED ABSTRACT

Although his meaning transfer model has been widely critiqued for its static qualities, McCracken's (1989) descriptions of culture-in-action leave no doubt as to the infinitely co-creative potentialities of consumers and their communities. Schouten and McAlexander (1995) recognized the creative activity of consumer "subcultures" and their importance to the marketing function of contemporary business. Kozinets (1996) described and argued for the importance of the intensely productive and communal activities emerging online, and explicitly

theorized the marketing implications of the "creative activity" of on-line communities and its influence on word-of-mouth and promotions (Kozinets 1999).

Almost a decade later, Prahalad and Ramaswamy (2004, 5) proclaimed that "[c]onsumers now seek to exercise their influence in every part of the business system. Armed with new tools and dissatisfied with available choices, consumers want to interact with firms and thereby co-create value." This proposition that the consumer has become a desirable co-creator of value is also central to another widely-lauded contribution, the service-dominant logic approach/brand proposed by Vargo and Lusch (2004).

These reflections have initiated a stream of research on consumer culture, marketing, and related fields that explore the possibilities, outcomes, and implications of a co-creation between businesses and communally-situated consumers. Within this literature, two oppositional perspectives emerged. First, a critical perspective conceptualizes co-creation and the new business practices proposed by its advocates as a reconfiguration of marketers' exploitation and control of consumers. From this standpoint, "the co-creation economy is about experimenting with new possibilities for value creation that are based on the expropriation of free cultural, technological, social, and affective labor of the consumer masses."(Zwick, Bonsu, and Darmody 2008, 166). Similarly, it has been proposed that when marketers foster experimentation, creativity, and interaction among consumers, they are merely investing in elements that will result in the alienation of consumers and the expropriation of their free labour by the company (Arvidsson 2005; Foster 2009). A more positive view of the phenomenon points to the (mostly non-economic) rewards and benefits available for consumers who engage in co-creation processes. Scholars subscribing to this perspective understand co-creation as an agentic and expressive act, not a deterministic response (Etgar 2008). They have investigated, for example, the personal and social benefits obtained by consumers who engage in value-creation within brand communities (Kozinets 2001, 2007; Kozinets, Hemetsberger, and Schau 2008; McAlexander, Schoutern, and Koening 2002; Schau et al. 2009) and the psychological implications of consumer participation in co-creation (Bendapudi and Leone 2003).

What is lacking, from both perspectives, is a consumer-centric understanding of what community members themselves think about the allocation of value when participating in co-creation projects with companies. Inspired by cognitive studies of consumer knowledge development (Ahluwalia and Burnkrant 2004; Campbell and Kirmani 2000; Friestad and Wright 1994, 1995), culturally situated investigations of consumer attitudes toward corporations (Giesler 2008, Arsel and Thompson 2004, Kozinets 2002), consumer thinking about their rights and responsibilities (Henry 2010), and on the development of "moral economies" in fan communities (Jenkins, Ford, and Green, forthcoming), we investigate the collective development of co-creation expertise by consumers who congregate using social media. By looking at how consumers develop co-creation expertise and build a repertory of strategies to negotiate co-created value with marketers we hope to advance our understanding of how marketers and consumers should share economic and non-economic benefits of co-creation.

To be clear, our focus is not on the development of co-creation knowledge at the individual level, nor at the widely shared, cultural level. Rather, we argue that an intermediary level of co-creation intelligence development can be identified in collectives that evolve around conversations in social media. Social media have increased consumers' ability to share, cooperate with one another, and engage in collective action with very little interference from companies. Therefore, the opportunities available for consumers to learn about collaborating with marketers have also multiplied. In order to explore this new en-vironment for understanding consumers' perspectives on co-creation, we conducted a qualitative study of the geocaching community.

Geocaching is a "global treasure-hunt" for enthusiasts who combine online communities and GPS technologies to play hide-and-seek with various "caches" in locations around the world. Geocaching was initiated in 2000 by a group of GPS enthusiasts and soon grew into a hobby practiced by an estimated 2 million people. From its inception, geocaching has motivated heavy reliance on collaboration and sharing to the refinement, development, and maintenance of the game. Currently, geocaching is a fascinating hybrid of interwoven commercial and gift economies. The main website concentrating information essential to the game is a commercial enterprise to which hundreds of volunteer players willingly contribute, and thousands of others subscribe (at an optional paid membership). Several open-source developments unfold within this website and in peripheral non-commercial websites. Geocaching is a consumer community context in which we can study the lived complexity of the commercial intertwining with the communal, and where collaboration between consumers and companies can be traced beyond the creative stage, in multiple online sites.

As suggested in Kozinets (2010), we combined netnography with traditional, in-person ethnographic techniques to investigate the online and offline activities of individuals who play geocaching. The dataset used in this paper focuses on the online aspects of the activity, and includes hundreds of pages of online data representing geocachers' interactions on different social media (e.g. online forums, blogs, Twitter) which were collected over a three-year period of participant observation online.

Preliminary results suggest that in observing, posing questions, sharing stories, and discussing critical episodes online, community members learn to differentiate between three types of co-creation projects, each of which is accompanied by a specific frame for economic and non-economic value negotiation: volunteer +community projects; company+community projects; and volunteer +company projects. Consumers draw from community-specific values and broader, external logics (e.g. work/play, market logics, web 2.0 culture) to determine adequate frames to each type of collaboration. Observing that consumers collectively gauge their expectations and demands in relation to value that is created in different collaboration modes, our study complements current understandings of consumers as co-creators of value.

Value-Creation in Brand-Related User-Generated Content on YouTube

EXTENDED ABSTRACT

The production of online, brand-related, user-generated content (UGC), is one way consumers can potentially co-create value. UGC is published content that demonstrates a degree of creative effort, which may draw on marketers' offerings, and is "created outside of professional routines and practices" (OECD 2007; Kaplan and Haenlein 2010, 61). It takes on many forms, including product reviews, social network site posts, blogs, advertisements, and contributions to collaborative projects. It may be created independently by online users, or facilitated or sponsored by firms (Berthon, Pitt & Campbell 2008; Christodoulides 2009). While research on the benefits or perils of brand-related UGC is nascent (Burmann 2010), some scholars have investigated the value that specific forms of online UGC might create for firms. For example, Chevalier and Mayzlin (2006) find that increases in positively valenced user reviews on Amazon.com and Barnesandnoble.com predicts increases in book sales, and that extremely negative reviews have a greater impact on sales than do extremely positive ones. Studying forums hosted on company websites, Chiou and Cheng (2003) find that favourableness

and frequency of brand-related UGC can influence consumer brand perceptions, with negatively valenced messages having a greater impact on low-image brands. While these studies focus on UGC more narrowly, there is also community-level research (e.g. Kozinets, Hemetsberger, and Schau 2008; Füller, Matzler and Hoppe 2008) that conceptualizes UGC as part of collective consumer innovation processes that create value for firms. Collectively, these studies provide important substantiation of the value of online UGC for firms.

Complementing research that examines the value created for firms, some research also suggests that UGC creates value for other consumers; brand community research (e.g. Kozinets 2001; Muñiz and Schau 2005) is the most prominent in this regard. For example, in a recent meta-analytic study of brand communities, Schau, Muñiz and Arnould (2009) conceptualize the practices and processes through which brand communities create value. They identify twelve value-creating practices, grouped across four thematic areas: social networking, impression management, community engagement, and brand use. Online UGC is a component of a number of the practices identified.

While it has been extremely fruitful to explore value creation in brand communities, not all brand-related UGC is created within brand communities. Indeed, the majority of consumers are probably not impassioned brand advocates or brand community members. It is thus important that we develop a better understanding of the potential value to consumers of UGC that is not generated within a brand community. Our research takes up this challenge. It examines the applicability of recent brand community research on value creation (in particular Schau, Muñiz and Arnould's (2009)) but also looks for additional types of potential value-creating elements in online brand-related UGC generated in a context that does not require or presuppose a brand community: YouTube.

YouTube is a content community (Kaplan and Haenlein 2010) and popular social media site (Burgess and Green 2009) that draws approximately 490 million unique visitors per month (Elliot 2011). More than other popular user-driven social media channels (e.g. Facebook and Twitter), YouTube hosts consistently rich UGC and more permanent and accessible records of responses to posted content. This makes it an appropriate context for exploring how value may be created in brand-related UGC, such as consumer-created videos, and the value that other consumers, such as those responding to the videos, derive from that UGC or fail to derive from that UGC. While some have argued that the practice of viewing, but not responding to UGC, itself offers value to other users by supporting contributors and the overall community (e.g. Jenkins 2006), this study will focus only on those who do publicly respond online. The data for this study consists of approximately 50 UGC 'haul' and 'outfit-of-the-day' videos, and all accompanying comments for those videos, sampled around two brands – Lululemon and American Apparel – that were posted to YouTube between June, 2010 and January, 2011.The posts were selected at random from Google search results for: 'brand' on 'site:YouTube.com'. The two brands were sampled because they generate enough interest from consumers to be featured in UGC in this content community, and are in the same category: clothing manufacturing and retailing. The number of comments per video start at zero and run into the thousands, although most range from the tens to the low hundreds.

While YouTube is not a 'brand-community', it is conceivable – since only a small percentage of social network participants create content (Burgess and Green 2009) – that brand-related video postings and comments will be dominated by motivated Lululemon or American Apparel brand community members or brand 'haters'; this does not bear out in the data set, and the focal brands are often fea-

tured, with equal emphasis, alongside a constellation of other brands. Analysis of the data set suggests that some of the value-creating practices found in brand communities, such as 'evangelizing', are mirrored in content elements of UGC found on Youtube; other community practices are not. Moreover, the UGC of these less brand-involved consumers involves elements that may not feature in UGC created within brand communities. For example, one type of content we frequently observed was "multi-brand integration," in which consumers suggest appropriate pairings of multiple brands, none of which appears focal or central to the ensemble. Analysis also seeks to establish the connection between these potentially value-creating elements of UGC and what types of value 'vocal' consumers indicate they are deriving. This research seeks to contribute to the discussion on the socially engaged consumer by broadening our knowledge of the elements of UGC that may create value, and on the types of value consumers appear to derive from UGC when they are not embedded in brand communities.

"Hey, what's in it for us?": How to Initiate and Maintain Participation and Collaboration with Creative Consumer Crowds

EXTENDED ABSTRACT

You guys have been along long enough to know": The collective development of consumer co-creation knowledge in social media

Social media have fundamentally altered our view of the consumer – from the 'passive recipient' to the 'active agent'. Literature on how to monetize social media's potential to activate consumers has exploded in recent years (Florida, 2004; Surowiecki, 2005; Tapscott & Williams, 2006) yet, the insights are mainly of tactical nature; its strategic implications are still under-theorized. But how should we initiate and maintain online cooperation with consumers? A classic answer would be to use all available channels to get access to online communities and social networks via promotional initiatives. Yet, typical exploitation strategies that aim to integrate consumer-users into marketing efforts of business organizations have also provoked susceptibility and conflict in social online media. A recent cross-cultural investigation into Facebook users' reactions to advertising attempts indicate that the respondents do not find Facebook ads informative or funny and have a low threshold level for irritation. A large majority would definitively or possibly leave Facebook if commercials on Facebook became more dynamic or mixed with friends' content (Kornum, Christensen, and Hemetsberger, under review). Similarly, Kozinets, de Valck, Wojnicki, and Wilner (2010) problematized the tensions that arise in consumer communities when community bloggers are asked to act as both, a continuing community member, as well as a marketing agent, in order to establish a trustful, credible and persuasive word-of-mouth campaign. Their findings suggest that messages need to be consistent with the goals, context and history of the blog and the bloggers, acknowledge and discharge commercial-communal tensions, and fit with the community's norms and objectives. Based on ample empirical evidence, researchers concordantly suggest that consumers should actually be treated as equivalent partners in a co-creative process of joint engagement in various value-creating practices (Merz et al., 2010; Schau, Muniz, and Arnould 2010; Kozinets, Hemetsberger, and Schau 2008). Consumers are creative, innovative participants and networked collaborators in a web of collective intelligence and partners for commercial endeavors in various ways. They are approached by companies as creative force (Tapscott and Williams 2006; Vargo and Lusch 2004; Lévy 1997), as innovators (Füller et

al., 2007; von Hippel 2005; Prahalad and Ramaswamy 2004), and as marketers, engaging in word-of mouth (Kozinets et al. 2010). In the context of creative consumer crowds, where companies' interests are less informative-persuasive but more work-oriented, tensions among company intent and consumer interests take on a different quality and rather revolve around issues of accessing resources, and ownership (Giesler and Humphreys 2007).

In this special session we would like to present a framework that addresses these issues. Our framework proposes two main forms of interaction – participation and collaboration – and discusses feasible patterns of interaction. We distinguish primarily telo- from communo-ludic oriented communities and suggest appropriate participation and collaboration strategies of two-way interaction among communities and business organizations, based on two exploratory cases of participative and collaborative practices. Depending on the communal orientation, we see both models of community activation characterized by a 5-stage process. Participation processes are characterized by: (1) motivating: the allocation of resources to the consumer community, (2) asking: launching the idea and elicitation of consumer responses, (3) measuring: the evaluation of the outcome of these processes, (4) answering: providing meaningful responses to the creative contributors of the consumer community, and (5) responding: giving back to the community. Collaboration processes encompass: (1) education: both internal and external knowledge sharing, (2) sharing: provision of appropriate resources and a type of "social contract" governing intellectual capital sharing, (3) coordination: systems and processes to streamline the active consumer participation process, (4) evaluation: a communally-directed, producer-controlled, or hybrid-cooperative model of judging output, and (5) implementation: some sort of meaningful "closure" to the process and the sharing of results or collective outcome.

Our discussion carves out important strategic and tactical implications for each of the five stages, and details their differential expression for participation and collaboration business strategies. Different forms of activation demand different input and processes on the company's side, depending on the communo-ludic or telo-specific orientation of the contributor(s). For example, although the notion of sharing is important in both types of communal interaction, the boundedness, directionality, and hierarchical control of resources can be markedly different in the pursuit of participation versus collaboration strategies. Second, whereas communo-ludic oriented contributors need a lot of communal space and exchanges, relatively little resources and know-how, telo-specific orientation is characterized by knowledge sharing and creation and access to resources. These notions have important implications for marketing theory and practice. Creative consumer crowds are equipped with different power based on their amount of social and intellectual capital. Companies who are willing to cooperate will need to legitimate their leading role through careful development of participative and collaborative practices.

SESSION OVERVIEW

Gambling is a massive industry, garnering billions of dollars in consumption across the world; global gambling revenue rose from $82.2 billion in 2005 to approximately $125 billion by the end of the decade (Associated Press 2006). As gambling grows, it also changes as it moves into the online world (Cotte and Latour 2009). Most recently, many auction shopping sites have integrated gambling elements into their design (Geibelhausen, Robinson and Cotte, 2011). This session brings together four sets of researchers who have investigated the topic of gambling from a variety of different perspectives, and with diverse methods. We are building connections between addiction psychologists, consumer psychologists, and sociologists. We are also bridging the experimental tradition to the CCT tradition to jointly investigate an important substantive consumption issue. Finally, our session discussion leader is a public health and sport marketing theorist, with more of an outsider, public-health perspective on gambling behavior. All four research teams have already collected their data and are either in early phases of analysis and interpretation (Giebelhausen, Robinson and Cotte; Humphreys and Latour) or have completed the analysis and will be submitting papers for publication soon (Noseworthy, Finlay and Cotte; Rodrigo, Finlay, and Marmurek).

The structure of the session is designed deliberately to move from the *inside out*. That is, we begin with two presentations that study problem gamblers from a psychological perspective, demonstrating how context and priming can reduce at-risk problematic gambling behavior. The data for the first two papers was gathered using a simulated casino laboratory. In the first, Noseworthy, Finlay and Cotte use music to affect dissociation; they demonstrate that the ambient context can reduce dissociation and gambling for at-risk gamblers, without affecting recreational gamblers' behavior. In the second, Rodrigo, Finlay, and Marmurek show that priming gamblers with different imagery in the casino environment can also influence their gambling behavior. After these two papers, we build a connection to the consumer world outside the laboratory, with a discussion of a new substantive gambling phenomenon. Dubbed "shambling"

by Giebelhausen, Robinson and Cotte, these authors present field data gathered online and in-person concerning penny auction sites, which are rapidly multiplying online, and which combine elements of shopping and gambling. Finally, we move to the *outside* view, concluding with Humphreys and Latour's examination of the legitimation process of online gambling; these authors use both archival and consumer survey data.

We believe the session is likely to make an important contribution to consumer research in several ways. Obviously, this is a substantively focused session, and we hope to encourage more research on what is rapidly becoming an important experiential consumption practice. But beyond this, the methodological collision of at least five major methodologies for data collection (experiments, netnography, ZMET interviews, surveys, and archival data) also demonstrates the strengths of building connections between multiple perspectives on a difficult issue. Finally, we contribute to the transformative consumer research tradition, with a clear focus on potential public policy remedies and interventions designed around consumer welfare. The potential audience for this session would also be diverse. Groups as varied as consumer psychologists interested in dissociation and temporal estimates and sociologists interested in societal processes of legitimation should all find something appealing here.

The 75 minute session would be organized as follows. Each paper will be presented in 12-15 minutes, leaving at least 15 minutes for Stephen McDaniel to offer his unique perspective and to engage the audience in active discussion of the topic. There are many ways to approach the study of gambling, and we hope to challenge audience members to get involved with the discussion and add their own unique perspectives to the session.

The Impact of Ambient Adjustments on the Temporal Monitoring of At-Risk Gamblers

EXTENDED ABSTRACT

Time and temporal issues have a long history when it comes to casino gambling. There is a common belief that casino designers actively discourage the use of temporal cues. And indeed, many casinos have neither window nor clock to infer duration of play. For many gamblers, it may be important to accurately keep track of time spent gambling, but that can be hampered if they enter a dissociative state. Dissociation is "the lack of normal integration of thoughts, feelings, and experiences" (Bernstein and Putnam 1986; 728) and involves an *aberrant perception of time* (American Psychiatric Association 1994).

Dissociative experiences occur when attention is deeply absorbed or focused, and when there is a loss of awareness or a lack of monitoring of internal states and external activities (Eisen and Lynn 2001). It also occurs during periods of fatigue, stress, or intense absorption (Csikszentmihalyi 1997). Hence, dissociation is relatively common; it equally afflicts males and females; it tends to decline with age, while being unaffected by socioeconomic status, education, religion, or place of birth (Ross, Joshi, and Currie 1991). Nevertheless, there are individuals who suffer a predisposition to dissociate. These individuals not only have difficulty self-regulating destructive patterns in their behaviour, but are also highly susceptible to external ambiguity, such that cues in the environment around them affect their psycho-emotional state (Nordin and Nylander 2007). But despite growing evidence linking dissociation and addiction, there has been

little effort to explain why there is such an overwhelming occurrence of dissociation in casino gamblers. That is, if the predisposition itself is not relegated to the gambling context, why then is dissociative behavior so prominent in casinos?

The typical casino environment is designed to coerce arousal during consumption (Jefferson and Nicki 2003). Aroused states have a tendency to lead one to focus on fewer temporal cues (Mantel and Kellaris 2003). However, music in the context can overcome this by offering a syntaxtual structure that individuals can anchor on to infer duration (Noseworthy and Finlay 2009). It could be that individuals who are predisposed to dissociation may be quite susceptible to the common casino environment. Thus, music could be used to combat a maladaptive response to gambling.

Two-hundred participants ($n = 100$ *low-risk/non-problem gamblers*; $n = 100$ *high-risk/problem gamblers*) were recruited from a prescreened sample of identified gamblers who varied in their propensity to engage in problematic gambling behavior. Each volunteer was paid $25 for their participation, and was assigned to one of two experimental conditions in a 2 (environmental stimuli: control vs. music) x 2 (gambler type: low-risk/non-problem gamblers vs. high-risk/problem gamblers) x 4 (disruption points: diss1 vs. diss2 vs. diss3 vs. diss4) mixed factorial design. Gambling disruption served as the within-subjects factor and environmental stimuli and gambler type served as between-subjects factors. Participants were randomly interrupted from play at four different intervals: 6-minutes, 10-minutes, 4-minutes, and 12-minutes. Environmental factors were varied such that in the control condition, participants gambled with no auditory interference. That is, they gambled as they would in a typical casino. The music condition differed in that a music track—developed by a media-production company—played in the background along with the ambient casino sound.

Participants were tested in a slot machine laboratory and level of dissociation was assessed on a five-point scale (never, rarely, occasionally, frequently, all the time) through five items: (1) *Did you lose track of time?*, (2) *Did you ever feel like a different person?*, (3) *Did you feel like you were in a dream?*, (4) *Did you feel like you were watching yourself gamble?*, and (5) *Did you experience memory blackout?* (Jacobs 1988). Participants responded to the same five items after each time they were disrupted from play. They were also instructed to respond in terms of the incidence of play that occurred since they were last interrupted, or in the case of the first stoppage, since their play began. Similarly, after each interruption, participants were asked to estimate the elapsed time since their last interruption.

Overall, dissociation significantly predicted participants' placement in the problematic gambling index ($\beta\beta = .31$, $t(94) = 3.19$, $p < .005$), as well as a significant proportion of variance in the index ($R^2_{adj} = .09$, $F(1, 95) = 10.17$, $p < .005$). There was a three-way interaction between disruption, gambler type, and environmental stimuli ($F(3, 94) = 4.38$, $p < .01$). Dissociation decreased as a function of disruption in play. That is, dissociation dropped from disruption point #1 to disruption point #2 ($M_{p1} = 2.00$ vs. $M_{p2} = 1.84$; $p < .001$), from point #2 to point #3 ($M_{p2} = 1.84$ vs. $M_{p3} = 1.71$; $p < .005$), and then leveled off from #3 to #4 ($M_{p3} = 1.71$ vs. $M_{p4} = 1.75$; $p > .05$). At disruption point #1, there was a significant interaction between environmental stimuli and gambler type ($F(1, 96) = 28.00$, $p < .001$). The level of dissociation in *low-risk/non-problem gamblers* (LR-NPGs) did not significantly vary with the introduction of music into the ambient environment ($M = 1.52$ vs. $M_c = 1.72$; $F < 2$). Conversely, the level of dissociation in *high-risk/problem gamblers* (HR-PGs) varied significantly with the introduction of music into the ambient environment ($M = 2.78$ vs. $M_c = 1.94$; $F(1, 96) = 36.30$, $p < .001$). A similar phenomenon occurred at disruption point #2; the level of dissocia-

tion in LR-NPGs did not significantly vary with the introduction of music into the ambient environment ($M = 1.42$ vs. $M_c = 1.60$; $F < 1.5$), but dissociation in HR-PGs did vary with the introduction of music ($M = 2.60$ vs. $M_c = 1.68$; $F(1, 96) = 33.78$, $p < .001$). The same pattern happened at disruption points #3 and #4.

High risk problem gamblers displayed understated estimates of elapsed duration (disruption point #1 = $t(1, 25) = -2.75$, $p < .05$; #2 = $t(1, 25) = -2.50$, $p < .05$; #3 = $t(1, 25) = -1.93$, $p = .06$; #4 = $t(1, 25) = -1.65$, $p = .10$). As expected, the effect became more muted as the disruption points progressed, indicating distraction helped mitigate dissociation. Importantly, HR-PGs did not display understated estimates when music was introduced in the ambient environment (*p's* ranging .21-.45 linearly across the four disruption points). This was consistent with the LR-NPGs.

The results of this study help explain the overwhelming occurrence of dissociation in casino gamblers. Although the predisposition itself is not relegated to the gambling context, dissociative behavior is so prominent in casinos partly because of the environment itself; this knowledge can be used to help at-risk gamblers. Many casino operators openly advocate mitigating problem gambling, but are reluctant to influence the recreational gambler. We show that subtle changes in the casino ambient environment can have dramatic consequences.

Measuring The Effects of Pictorial and Text Messages on Memory and Gambling Intentions Within a Casino Environment

EXTENDED ABSTRACT

Problem gambling is prevalent in today's society with the increase of available opportunities for people to gamble. Marketers and policy makers are searching for innovative ways to convey harm reduction messages to gamblers inside and outside the casino environment. This study investigated the effects of pictorial and text messaging about the risks of excessive gambling within casinos. It followed a 2 x 2 x 2 between-subjects design. The first factor was whether participants were exposed to information that primed gambling-related concepts (the consequences of excessive amounts of time and money spent) versus an unrelated at-risk concept (environmental sustainability) prior to completing subsequent experimental procedures. In an ostensibly unrelated task, respondents were asked to evaluate a brochure that had been developed to help first-year university students to adapt to life on their own. In the gambling-related condition, the brochure contained information about time and money management. In the condition unrelated to gambling, the brochure contained information about environment sustainability and tips for going green. Following exposure to brochure information, all respondents answered four questions about the effectiveness of the brochure's message and appearance.

The second factor was the presence of a pictorial versus a text message on a television screen to the right of the slot machine at which each individual was playing in a gambling setting. Text messages were in the form of three sentences (e.g., "Do you know how much money you have spent?") which appeared individually for 30-second intervals on a TV screen for 30 minutes while respondents played slot machines in the setting. Pictorial messages were three different pictures (e.g., an individual with empty pockets turned inside-out) which similarly each appeared for 30-second intervals on a TV screen for a total of 30 minutes.

The third factor was type of memory measure for the text or pictorial message following 30 minutes of play on the slot machines. Measures were either implicit (word association, stem completion)

or explicit (unaided recall, recognition). For the word association test, respondents were given a set of ten pictures and asked to write the first word that came to mind when they viewed the picture. Seven of the pictures were unrelated stimuli (e.g., a pile of crayons, a sunflower) and three of the pictures were pictorial message stimuli that had been displayed in the lab (man with empty pockets turned inside-out, set of 16 clocks set at different times). For the stem completion test, participants were given a set of ten word stems and asked to complete the stem with the word that came most easily to mind. Similarly, words relating to the primed target were included (CL_ _ _ clock; BR_ _ _ broke). The explicit recall test first asked respondents to write down anything that came to mind about the slots lab experience, after which they were asked to list everything they remember seeing in the lab. For the explicit recognition test, respondents were given a set of six questions asking them to indicate if they remembered seeing any of the messages that appeared in the slot lab ('yes' or 'no' answer).

Participants (n=201, screened to be age 19 or older, who had bet money on a slot machine in last 6 months) were greeted at the lab, instructed to complete the priming task, and asked to play slot machines for 30 minutes during which either pictorial or text messaging was present in the gambling lab. All individuals began the play task with 8000 credits, an amount found to sustain 30-minutes of play time in past studies. They were instructed that they could play for as long as they liked but were free to stop at any point in time. They were also informed that the researcher might have to ask them to stop playing if another participant arrived. This was done for all participants after 30 minutes. Individuals were either reimbursed with a course credit if they were sourced from a university participant pool or with a ballot to win a $50 cash prize (odds of 1 in 20 chances to win). Subsequent analyses confirmed that results did not vary by remuneration type. Following slot play, all participants were asked to leave the slot lab and complete the computer-assisted questionnaire. Memory measures were taken first, then all participants completed the at-risk gambling intentions scale (ARGIS) composed of five questions measuring perceived intention to gamble beyond levels of money and time spent while in the slot lab. Responses were indicated on a 7-point scale anchored by 1 "don't agree at all" to 7 "strongly agree" to questions such as, "I would gamble/play more money that I intended", "I would have trouble quitting without placing one more bet". Demographic and gambling severity information was also collected.

A random-groups ANOVA showed no effects of priming on implicit measures and a reverse effect than that anticipated for explicit recall measures. Recall was higher with no prime than with a prime. It was concluded that the processing of an earlier prime may be lost or distracting in the complex context of a gambling environment. Text messages were directionally more effective when indexed by implicit memory tests while picture messages were significantly more effective when indexed by explicit memory tests. This latter effect is consistent with the picture superiority effect (Weldon and Roediger, 1987). At-risk concepts presented pictorially in this study were better remembered explicitly than were concepts presented textually. The measure of ARGIS was lower when messages were presented pictorially and no prime was included. It appears that under conditions where participants were able to process pictorial messages in the lab (no distracting prime related to at-risk gambling concepts), recall of at-risk messages was higher, corresponding to an intent to gamble within planned levels of time and money. Results inform effective communication of harm reduction messages for marketers and policy makers. Pictorial messages which reinforce the risks of gambling should be used inside the casino, in bathrooms or even on slot machines themselves.

Shopping + Gambling = Shambling: The Online Context of Penny Auctions

EXTENDED ABSTRACT

An emerging form of e-commerce, penny auctions, has garnered recent attention from consumers, investors, and regulators. However, consumer researchers have yet to explore this new phenomenon which has been likened to a combination of bingo, online shopping and slot machine addiction. In penny auctions, consumers participate in a game where the winner is awarded the opportunity to purchase a product for pennies on the dollar. Losers, and there is no limit to the number of people that can lose in a single auction, may spend large sums and walk away empty handed. The primary distinction between penny auctions and traditional online auctions is that consumers must pay a fee each time they place a bid. Because of the collective losers' bidding fees, a product sold at a 90% discount is equivalent to a traditional retail transaction featuring a 910% mark-up (e.g., the price starts at zero, it costs $1 to place a bid, the price of the product goes up one penny for each bid placed . If an item worth $100 is sold at a 90% discount ($10), this means that there were 1000 bids placed during the course of the auction. Ignoring shipping fees, the penny action collects $1010 in total revenue and the winner must pay an additional $10 for the product. Assuming the penny auction website purchased the product at retail, which is often the case, effective markup is 910%).

While penny auctions have been equated to discount shopping and games of skill, they have also labeled by some critics as an addictive form of gambling. In this research, we provide an introduction to penny auctions, and a first step towards delineating the gambling element of this new consumption genre. We explore the meaning and experience of this game-based shopping using data gathered with Zaltman Metaphor Elicitation (ZMET) interviews. Finally, we outline some of the policy implications of our work, and situate our recommendations for consumer welfare squarely in the transformative consumer research tradition.

Since 2005, penny auctions have grown from a single auction website to more than 150 websites with millions of bidders (The Economist, 2009; Pennells, 2008). There is debate regarding the proper classification of penny auctions (Pennells, 2008; Gimein, 2009). Are they a new form of online gambling or simply a harmless variety of online shopping? A review of the penny auction's genealogy suggests the former. Penny auctions are modeled after the dollar auction game invented by game theory pioneer Martin Shubik, which relies upon the concept of escalation of commitment (Shubik, 1971; Thaler, 2009). Once the consumer has bid on an item, they have a difficult time walking away – they feel invested in the game. The combination of escalation of commitment and absurdly low prices for popular products (e.g., Apple iPad that retails for $699 selling for $18.07; Louis Vuitton and Gucci handbags advertised at 90% off) yields an environment that has been referred to as evil, dangerous and addictive (Gimein, 2009; Luscombe, 2010; Thaler, 2009). While such words would hardly be used to describe an average consumer shopping experience, they could very well be used to describe a gambling experience (Cotte 1997).

We interviewed penny auction shoppers using depth interviews with visual images, and ultimately collages, that participants create (Zaltman 1997; Zaltman and Coulter 1995). This method assumes that much of this content is non-conscious and based in images, not words (Zaltman 1997, Zaltman and Coulter 1995). The interview

technique we used helps interviewers delve into the metaphors that participants use to represent the meanings of penny auctions, either explicitly to others, or implicitly to themselves (Coulter and Zaltman 2000; Lakoff and Johnson 1980). We add to this data a more netnographic approach (Kozinets 2002), using online forum and discussion data.

Our analysis of the data sourced from online forums and our ZMET interviews suggests that many participants are resistant to the idea that penny auctions are equivalent to gambling. One key delimiter appears to be the presence or absence of a "buy-it-now" option. In some auctions, this option allows losers to apply their spent bids towards the purchase of the product they were pursuing. The argument is that you are no worse off and potentially far better off, if you use a penny auction website to acquire a product you were planning on purchasing anyway. Of course this argument presumes that individuals are bidding on items that they can afford to buy. However, much of the attraction of penny auctions is that they provide a chance to acquire things one otherwise could not afford. Presumably, this line of reasoning also assumes that individuals' interest in items is driven by something other than the price. A review of the online discussion board reveals numerous stories of consumers who found themselves bidding on items they did not particularly want. A closer examination reveals further evidence of addictive behavior including extensive credit card debt, negative impacts on work and family life, and an inability to stop despite repeated attempts.

There are a number of policy implications associated with this work. One obvious implication is that if penny auctions are a form of online gambling disguised as entertainment shopping, attention must be paid to regulate the industry to protect consumers. We plan to present our data and conclusions during the session.

Together We Stand, Divided We Fall: Categorization and the Process of Legitimation

EXTENDED ABSTRACT

There are a variety of ways in which any particular consumption practice can be categorized by consumers. Is smoking marijuana more like drinking alcohol or is it more like using cocaine? Is texting while driving more like drunk driving or more like not wearing a seatbelt? Certainly, the ways in which consumption practices are socio-culturally grouped has important implications for their legitimacy. Previous research has evaluated the role of categorization in the emergence of new products (Rosa et al 1999), the evaluation of products (Meyers-Levy and Tybout 1989), and product extensions (Park et al 1991). How does categorization—the ways in which certain consumption practices are grouped together on a socio-cultural level—affect the legitimation process?

Casino gambling has gone through almost a century of becoming a legitimate recreational experience in the United States. Casino gambling began as part of the saloon experience and became associated with western expansion. The Puritan-based culture attempted to control or ban gambling based on moral grounds from the onset (Schwarz 2006). Gambling was legalized in Nevada on March 19, 1931 and the first official casino, the Northern Club on Fremont Street, opened in Las Vegas, which would come to be known as "Sin City." Casino gambling became associated with illegal gambling circuits and legalized casinos were a place mobsters could launder their money (Manning and Samuelson 2008). The original large Strip casinos were managed or at least funded under mob figures Bugsy Siegel and Meyer Lansky. In the 1950s it was the government (namely the Committee to Investigate Organized Crime in Interstate Commerce) that opposed casino gambling and tried to clean up the mob influence. Casino gambling is now allowed in all but two U.S. states. The tavern-style casinos of the past have been replaced by mega-resort casinos which are luxurious, regulated, and funded by Wall Street. From 1992-2003, the U.S. casino industry saw its revenue more than double, from $10.2 billion to over $27 billion, and consumers spent more money in casinos than they spent on movies or amusement parks (Roush 1993; American Gaming Association 2004). Smith (1996) observed the increasing access to casino gambling and argued that the "…mythic archetype of a rugged individualist gambler" based on the wild west images of card players and urban images of pool hustlers was crumbling, and that the understood meaning of gambling was evolving into that of a safe, harmless, recreational activity.

Lotteries are a popular type of gambling most often run by governments and local states. Questions regarding legitimization of this type of gambling have not needed to be addressed like casinos because of the association with governmental entities. The first English lottery was approved by King James I in 1612 and that granted the Virginia Company of London the right to raise money to found its original settlement in the United States. Lotteries played a significant role in the financing of building and improving the colonies. However, like casinos, lotteries went through their own set of scandals. The Louisiana State Lottery (1868-1892) became the most notorious state lottery because it was a breeding ground of corruption. In 1890 Congress banned the U.S. postal service from carrying lottery tickets and in 1892 upheld a law to put a complete halt to all lotteries in the U.S. Lotteries were illegal in the United States until after World War II. It was not until the 1960's that the first modern day lotteries began to emerge as a way to raise revenue for the state governments. The first modern state lottery was established in New Hampshire in 1964 and currently there are lotteries in 42 states.

While the activity of legalized casino gambling is increasingly accepted in the United States, gambling itself remains tainted by its history. Therefore any new entity that offers consumers a gambling experience is likely required to go through its own legitimization process. We posit that the manner in which this new type of gambling is categorized will affect how it becomes legitimized. Specifically, we suggest that the expansion of lotteries and games into the online environment will be more quickly legitimated because of their relationship to state institutions, which are themselves legitimate, whereas the online casino gambling will be more slowly legitimated because of their categorization with land casinos. We also predict that legalization of online casinos is necessary for legitimization to occur, and that online gambling offered by operators of current land casinos will benefit from faster legitimation as compared to new online casino entities that have not established themselves.

Media analysis. To better understand the introduction and classification of online casino gambling, we conducted a media analysis of newspaper articles about online gambling published between 1980 and 2010. Data was collected on three topics: lottery, casinos, and online gambling. This resulted in 5,445 newspaper articles for analysis. The articles were analyzed by first selecting a subsample of 545 articles for qualitative analysis. Following qualitative analysis, an automated content analysis was conducted using a custom dictionary and two standard dictionaries to assess changes in themes concerning legitimation and categorization of gambling practices over time.

Survey. During December 2010 legalization of online gambling was being considered in the United States. At that time we conducted a national survey of 471 gamblers (246 that gamble online, 225 that only gamble in land casinos). Elsbach (1994) developed a 12-item survey to measure organizational legitimacy based on media analysis

and depth interviews. We adapted Elsbach's scale (1994) to investigate how legalization would affect consumers' perceptions of legitimization as well as future online gambling behavior.

Our findings help us better understand the legitimation process for once illegitimate consumption practices. For "sin" industries like gambling, even when legitimization occurs, any new development or extension of them brings up underlying cultural tensions and forces this new extension to go through the legitimization process all over again. We find, however, that this depends on the ways in which the consumption practice is aligned with past and future practices.

SESSION OVERVIESW

The goal of this Special Session is to report the findings of recent research aimed at understanding of a major contemporary problem in consumer finance: the causes and consequences of consumer debt. Since onset of the global economic recession in 2008-2009 levels of household debt in the United States has reached epidemic proportions, reaching $2.4 trillion--an equivalent of $7,800 per-person (American Bankruptcy Institute, 2011). Yet, as pervasive as the problem has become, economists and consumer researchers have only begun to gain a deep understanding of the psychological processes that underlie why consumers come to fall into debt, how their ongoing financial decision making is affected by it, and, most critically, what remedial steps might be taken to correct it.

The objective of this session is to present an array of recent research findings aimed at gaining such an understanding. The session will be structured around four papers that address a different related question about the antecedents and consequences of consumer debt:

1. *Origins*: What are the psychological mechanisms that cause consumers to make choices that expose them to large downstream financial risks?

2. *Processes and Consequences:* How does the presence of debt affect the quality of on-going financial decisions made by consumers, and what are the processes that lead to radical remedial actions, such as walking away from a mortgage?

3. *Individual differences*: As widespread as problems of consumer debt may be, there is also widespread variability in its severity among consumers with equivalent financial means. What cognitive trait factors might explain why some consumers are prone to recurrent problems of debt while others seem to be just as robustly skilled at avoiding it?;

4. *Remedies:* How can knowledge about (1) through (3) be used to "nudge" consumers toward better coping with

financial problems in the short run, and allow them to be better financial decision makers going forward ?

To illustrate, the opening paper of the session, "Heads in the Sand and Safe Harbors: Biases in Information Gathering about Future Financial Risks" explores theoretically and empirically a question that is often asked in the wake of major financial mistakes: why was information that would have altered consumers to coming risk not sought or attended to? The second two papers, "Time Preferences, Mortgage Choice and Strategic Default", and "Cognitive Abilities and Consumer Household Decision Making", then turn to the study of how cognitive traits lead individuals to financial decision making errors, including poor mortgage choices and poor management of credit-card debt. Finally, "There is Light at the end of the Tunnel: Helping Consumers Avoid Financial Decision Making Biases by Inducing Broad Bracketing", proposes an approach to correcting financial myopia biases by encouraging consumers to think of the sequential, repetitive, and pervasive nature of financial decisions.

While the immediate goal of the session is to present a set of recent research findings on the study of the causes and consequences of consumer debt, it also has the longer-term goal of bringing attention to an emerging research area that has large public policy implications. It is a problem whose solutions will require the joint effort of scholars with a diversity of theoretical and methodological orientations, hence one of the secondary goals of the session is to illustrate the benefits of the accumulated knowledge that can arise from such intellectual interbreeding.

Heads in the Sand and Safe Harbors: Biases in Information Gathering about Future Financial Risks.
Robert J. Meyer, the University of Pennsylvania

EXTENDED ABSTRACT

It is often argued that the root of many poor financial decisions lies in the failure of consumers to adequately gather and interpret information that would have otherwise allowed them to avoid damaging financial events. An archetype is the Walter Madoff investment scandal, where private investors, banks, and even federal investigators appeared to turn a blind eye to evidence pointing to the scheme's underlying Ponzi structure. Yet, a limitation of such critiques that they are all done with the benefit of hindsight; it is far from clear that, given the wide variation in conflicting signals investors often receive about the risks posed by their investments, bad financial outcomes are not simple evidence that risky choices do not always pay off than a systematic bias in the gathering and interpreting of information.

The purpose of this research is to extend an emerging body of work that suggests that financial information search is often biased toward the seeking of good news and the avoidance of bad (e.g., Karlsson, Loewenstein and Seppi 2009). We examine the particular case of investments in high-risk instruments that yield a strong positive payoff in the short run but risk catastrophic collapse in the longer run. Our central hypothesis is the longer investors stay in a fund and realize abnormally high rates of return the less likely they are to seek out and/or attend to information that would call for abandonment of the fund for safer, but lower returning, alternatives. Such a bias is predicted based on two information-censoring mechanisms that have been documented in other areas of learning: confirmation biases, in

which individuals are prone to seek out information that confirms rather than disconfirms beliefs when making inferential judgments (Wason 1968), and knowledge protection biases, in which new information tends to get underweighted if would act to disrupt an existing knowledge structure (Cuhna, Janiszewski, and Laran 2008).

This general hypothesis is tested using data from a controlled laboratory experiment in which participants are given a monetary endowment that is initially invested in a risky "money machine" that provides a high rate of return for a finite investment period (20 periods). At the start participants are told that there is a possibility that the machine is infected with a virus that could wipe out the principal and all accumulated interest before the 20-period investment horizon expires. At any point they have the option to transfer all of the money they earned to a safe fund that poses no risk but that provides a low rate of return. These switching decisions are revocable, such that a participant can re-invest in the risky fund at a later point if desired. To help make the stay or switch decision, at each point in time in the simulation participants can, for a small price, purchase a research reports that provides a noisy signals of the likelihood that invested funds have a short-term risk of liquidation. At the end of the task participants are compensated based on their cumulative earnings over the 20-period investment horizon.

We first show that the optimal policy for purchasing information and making stay/switch decisions is a threshold rule mirroring that arises in two-armed bandit problems in sequential statistics (e.g., Robbins 1952). Specifically, given priors about the virus probability there exists a critical threshold sample risk probabilities τ^h and τ^l such that the participant should continue purchasing research reports until either the sample proportion of healthy reports is either less than the lower bound τ^l (in which case the machine is deemed safe and he or she should stay with the risky fund until the end) or τ^l (in which case it is deemed unsafe and the risky fund should be abandoned. The critical values of τ^h and τ^l are a time-varying function of the reliability of each sample report, the prior, the cost of information and insurance, and the participant's utility function over outcomes (or their degree of risk aversion).

Drawing on prior behavioral work on confirmation biases in learning we hypothesize that information search behavior will display an optimistic knowledge protection bias marked by two features:

1. A "head in the sand" effect in which information gathering among those who remain in the risky fund will decrease as the terminal period becomes proximate to a greater degree that that prescribed by a rational information-purchase model; and

2. An imagined-regret bias in which positive reports about the riskiness of the fund that are gathered after it is abandoned for the safe fund will trigger an excessive rate of re-investment in the high-risk instrument.

These hypotheses are tested using data from 148 participants enrolled in a Northeastern University, which provide support for the predicted information-search biases. As predicted, participants who stayed invested in the risky fund become less likely to purchase research reports that provide information about its risk status as the task proceeded. Likewise, as predicted participants exhibited a excessively high rate of return to the risky investment after having first abandoned it for a the safer fund. The data also revealed an unexpected "safe harbor" effect, where marginal rates of information gathering *increased* after participants had shifted their investments to the safe fund. That is, participants acted as if they held asymmet-

ric beliefs about the value of the research reports depending on the direction of its action implications: when they were invested in the risk fund they were reluctant to gather information that might have instructed them to seek the safer fund, but while invested in the safe fund they were more inclined to purchase reports that might have instructed them to re-invest in the riskier alternative.

Time Preferences, Mortgage Choice and Strategic Default

EXTENDED ABSTRACT

A decade ago, the subprime mortgage industry appeared to offer a promising alternative to homeowners who could not qualify for traditional mortgage financing. That promising alternative has turned out to be a nightmare, both for the lenders and homeowners. After the housing market peaked, an increasing number of American homeowners found that the underlying value of their home was less than the amount they owed on their mortgage. These homeowners had negative home equity, a situation alternatively known as having an "underwater" home.

Both the design of financial products and public policy interventions must recognize that consumers are heterogeneous. This paper investigates how individual differences in time preferences (individual differences in tastes for outcomes across time) along with other factors affect mortgage choices that lead to and follow negative home equity such as the decision to "walk away" from a mortgage that is "underwater." We focus on two related questions: First, who is more likely to have a mortgage that is larger than their current house value? Second, who is more likely to strategically default, i.e. to abandon the mortgage and move away? We are interested in mortgage choice and potential abandonment both because they are of substantial practical interest, and also because they are prototypical of many consumer choices that involve a stream of consequences across time.

In our inquiry, first, we review a traditional economic analysis of mortgage choice (Campbell and Cocco, 2003). Although that model does allow for some individual differences in tastes, we suggest some more behaviorally informed parameters of time preferences and risk taking will allow us to capture greater consumer heterogeneity in tastes, abilities, and knowledge. A quasi-hyperbolic discount function suggests that more present bias will cause decision-makers to overweight earlier consequences relative to those that may occur later (Angeletos et al. 2001; Benhabib et al. 2009; Laibson 1997). In particular, we expect present-biased respondents to tend to overweigh immediate (vs. future) consequences such as increased later payments and the risk of housing equity loss.

When abandoning an underwater mortgage, most of the costs (particularly the non-economic costs) are immediate and without

an accompanying immediate gain. Finding a rental unit, moving, potential changes of schools and loss of neighbors, might be offset by longer-term savings, because the rent may be lower than current mortgage payments. However, this choice represents more of an intertemporal tradeoff. We therefore expect individuals with more present bias to overweight these costs and be *less* likely to walk away. Thus present-biased individuals may face a form of economic double jeopardy: They are more likely to arrange a riskier mortgage, and are less likely to walk away from the consequences. In contrast, the delayed consequences of mortgage abandonment pit a near-term unattractive option (i.e. continued payment with no buildup of equity) against the longer-term benefits of potentially having positive home equity. In this case we expect people who are impatient to be *more* likely to abandon their current mortgage.

Our survey of 244 US homeowners who have mortgages (roughly half of whom were underwater) allows us to evaluate these specific hypotheses about how individual differences in values, abilities, and knowledge may be related to mortgage choices and the intentions to strategically default. The homeowners answered questions about themselves (including debt literacy, and cognitive reasoning), their home, their financial stake in the home, and about financial conditions that would prompt walking away from their mortgage. Notably, we elicit individual-level quasi-hyperbolic discounting and prospect theory parameter estimates as the first application of the adaptive method developed by Toubia et al. (2010). We then use this data in a set of regression analyses of the relationships between consumer differences in values, ability, and knowledge, home equity status and preceding mortgage decisions. We also relate consumer heterogeneity to willingness to walk away from their mortgage, and consider models that simultaneously estimate both mortgage choices. Finally, we discuss the implications of our results for the study of household financial decision-making.

In mortgage choice we find that the two separate components of time preference work in similar directions. We find that consumers who weigh immediate outcomes more heavily (more present biased), are more likely to be "underwater" with their mortgages. Similarly, those who discount the future more are also more likely to be underwater. Importantly, consumers with stronger present bias are also more likely to have initially borrowed more, a second mortgage and an adjustable interest rate. These findings do not appear to be driven by the "reverse" effect of underwater status on time preferences, nor by changes in the stringency of mortgage standards.

The importance of modeling these two components of time preferences separately is illustrated by our analysis of walking away from a mortgage. Here present bias and discount rates work, as predicted, in opposite directions. Because the costs of abandoning a mortgage are mostly in the near term, present-biased households are more likely to continue paying a mortgage, even with negative equity. In contrast, more general (i.e. exponential) time discounting was associated with a greater willingness to walk away. The findings are robust to the inclusion of several preference controls including probability weighting, sensitivity to value changes, loss aversion, debt literacy, cognitive reasoning, and demographic factors.

The present findings might appear to endorse the view that time preferences have an almost trait-like status. However, we see the discounting parameters as convenient summaries of more complex cognitive processes. That is, they reflect constructed as well as revealed values. Such a constructive process view suggests possible interventions, particularly combined with the observation that present bias has different roles in mortgage choice and in walking away. Finally, our analysis of mortgage choice and abandonment suggests principles that can be applied to many consumer decisions that, in

economics, are the province of life cycle models. These include balancing savings and retirement across the lifetime, the choice to rent or to own, and the decision to insure against longevity risk through annuities.

Cognitive Abilities and Household Financial Decision Making.

EXTENDED ABSTRACT

We analyze the effects of cognitive abilities on two examples of consumer financial decisions where suboptimal behavior is well defined. The first example refers to consumers who transfer the entire balance from an existing credit card account to a new account, but use the new card for convenience transactions, resulting in higher interest charges. The second example refers to consumers who face higher APRs because they inaccurately estimate their property value on a home equity loan or line of credit application. We match individuals from the US military for whom we have detailed test scores from the Armed Services Vocational Aptitude Battery test (ASVAB), to administrative datasets of retail credit from a large financial institution. We show that our matched samples are reasonably representative of the universes from which they are drawn. We find that consumers with higher overall composite test scores, and specifically those with higher math scores, are substantially less likely to make a financial mistake later in life. These mistakes are generally not associated with the non-mathematical component scores.

We also conduct some complementary analyses using two other data sources. We use the National Longitudinal Survey of Youth (NLSY) to show that higher ASVAB math scores are associated with lower subjective discount rates. Finally, we use the Health and Retirement Survey (HRS) to demonstrate that particular forms of cognitive ability matter for specific types of suboptimal behavior. We find that the mathematical component of the test is what matters most for financial decision making and financial wealth.. In contrast, non-mathematical aptitudes appear to matter for non-financial forms of suboptimal behavior (e.g. failure to take medicine). The HRS results also demonstrate the large ramifications of low math ability on long-term economic success.

There is Light at the end of the Tunnel: Helping Consumers Avoid Financial Decision Making Biases by Inducing Broad Bracketing

EXTENDED ABSTRACT

Narrow choice bracketing is a pervasive problem in consumer decision making: people often consider decisions in isolation rather than simultaneously assessing the consequences of a series of decisions. One of the reasons postulated for narrow bracketing is *cognitive inertia*—people's tendency to "deal with problems as they are presented to them" (Read et al., 1999, p. 188). Cognitive inertia implies that consumers fail to realize that each individual choice is one of a much larger series of choices. In the present research, we developed a manipulation to encourage consumers to broadly bracket their decisions by making them realize that choices are sequential, repetitive, and pervasive.

To induced broad bracketing, we showed participants a 6-minute video in which an actor performed various everyday actions in an apartment (e.g., eating candy, opening mail, listening to a music CD, etc.). In the *choice bracketing condition*, participants were asked to press a button whenever the actor made a choice, whereas in the *control condition*, they were asked to a non-choice judgment, such as to press a button whenever the actor touched an object with his hands. Participants in both condition identified 39 actions on average.

Study 1 examined how the choice bracketing manipulation influenced financial decision making in the domain of risk aversion. After the manipulation, participants were asked to make 20 choices between pairs of high-risk and low-risk gambles of equal expected value (e.g., 20% chance of winning $10.00 vs. 80% chance of winning $2.50). Whereas participants in the control condition were risk averse, choosing risky gambles in only 25% of the trials, participants in the choice bracketing condition were risk neutral, choosing risky gambles on 49% of the trials, consistent with the idea that participants in the choice condition were broadly bracketing their decisions and thus were more tolerant of risk.

In Study 2, following the manipulation, participants were asked to choose between pairs of gambles with ambiguous and unambiguous probabilities of winning (e.g., 40% chance of winning $20 vs. 30-50% chance of winning $21). The ambiguous gambles offered a 5% premium over the unambiguous gambles, with probability of winning in a 20% range about that of the unambiguous option. We found that participants in the choice bracketing condition were significantly less ambiguity averse, choosing the ambiguous gambles in 60% of the trials, compared to those in the control condition, who chose ambiguous gambles in 45% of the trials.

In Study 3, participants were asked to make 36 choices between pairs of immediate vs. delayed payoffs in which we varied the hyperbolic discount rate that the delayed option offered over the immediate option. We hypothesized that participants in the choice bracketing condition would be less impulsive overall and would be more sensitive to the temporal discount rate. We found a condition X discount rate interaction, such that at lower discount rates, where impatience is less costly, participants in both conditions were equally impatient, but at higher discount rates, where impatience is more costly, participants in the choice bracketing condition were significantly more patient than those in the control condition.

Study 4 explicitly tested whether the choice manipulation induced broader bracketing. Previous research has found that people are less loss averse when they have to make many decisions simultaneously rather than one decision at a time (Gneezy & Potters, 1997; Thaler, Tversky, Kahneman, & Schwartz, 1997). While participants in the control condition would be expected show this difference, if the choice condition spontaneously puts participants in a broad bracketing mindset, then we would hypothesize that those making individual decisions would be just as loss aversion as those making simultaneous decisions.

To test this hypothesis, we used a 2 (choice bracketing vs. control) X 2 (individual vs. simultaneous decisions) design. In each of 9 trials, participants could invest a portion of 100 cents in a lottery. They had a 67% chance of losing their investment and a 33% chance of gaining multiplying their investment by 3.5 times. This lottery has a positive expected return of 16.67%. In the *individual decisions condition*, participants decided how much to invest in one lottery at a time and saw the result of each lottery immediately after their decision. In the *simultaneous decisions condition*, participants had to decide how much to invest in 3 lotteries at a time, and were thus compelled to broadly bracket their decisions.

We found that while control participants invested a larger amount in the individual decisions condition than in the simultaneous decisions condition, those in the choice bracketing condition invested the same amount irrespective of whether they were asked to make decisions individually or simultaneously. In other words, the choice manipulation made participants in the individual decisions condition just like those in the simultaneous decisions condition.

Finally, Study 5 replicated and extended the finding of Study 4 using a different lottery structure. We also found that whereas the outcome on one trial (i.e., whether participants won or lost the lottery) influenced participants' decision on the next trial in the control condition, there was no such effect in the choice bracketing condition, again consistent with the broad bracketing mechanism—if people are considering many decisions simultaneously, then they should not be affected by the ups and downs of individual outcomes.

These converging findings suggest realizing that choices are sequential, repetitive, and pervasive can improve consumers' cognitive myopia in financial decision making—after seeing an actor in a video make a large number of choices, participants appear to no longer "deal with problems as they are presented to them," but instead re-construe presented problems with a portfolio mindset rather than an individual-decisions mindset. Notably, our manipulation induced broad bracketing by changing consumers' construal of their decisions instead of changing the structure of the choice task. Future research can attempt to develop educational interventions to mitigate the dark side of consumers' financial decision making in important real life decisions.

SESSION OVERVIEW

It is well accepted that default options are one of the most powerful tools in the choice architect's repertoire. Defaults have been shown to alter consumer decisions in a wide range of important domains, from organ donation (Johnson and Goldstein, 2003) to financial planning (Choi, Laibson, Madrian and Metrick 2003). Policy makers are advocating "Optimal Defaults" as a pillar of behavioral change, and marketing practitioners are increasingly utilizing defaults through tactics like starter carts and automatic re-purchasing plans. In the midst of this widespread adoption of defaults, it is vital that the theoretical community continue to develop a more thorough understanding of why and in what circumstances these effects pertain. However, while much research has shown the effect to be robust and influential across substantive policy domains, we know relatively less about the underlying processes and moderating factors which may influence how default choices impact preferences. This complicated and likely multiply determined effect demands continued attention and cooperation between scholars if we are to develop a clear understanding of how it operates The present session seeks to deepen our understanding of this important effect, specifically by working to disentangle some of the proposed processes that may give rise to default effects.

Goldstein, Dinner, Johnson and Liu (*paper 1*) divide explanations for default effects into three categories: (i) effort, (ii) implied endorsement, and (iii) reference dependence. Three studies replicate the default effect and examine the mediating power of these proposed mechanisms in depth. Focusing on the third explanation the authors utilize an aspect listing methodology to demonstrate that Query Theory can account for reference dependent preferences in defaults.

Liersch and McKenzie (*paper 2*) broaden our understanding of implicit recommendations as a mechanism of default effects. In doing so, they provide evidence for a novel moderator of defaults; trust. Two studies demonstrate that when people do not trust the source of the default, they are less likely to adhere to the default option. In fact, an unrelated mis-trust manipulation from a prior study caused people to exhibit a *reverse* of the default effect.

Danilowitz, Hoch and Dhar (*paper 3*) extend the impact of defaults to choices made from an assortment. A major difference between a single choice and assortment choice is shoppers can select both default and non-default options. Using an online shopping paradigm, three studies demonstrate that the presence of defaults increases overall amount purchased. They show popularity and variety of the default options are important moderating variables and provide initial evidence of an alternate mechanism for default effects in an assortment.

Extant research has effectively demonstrated the breadth of the default effect in a variety of domains. Together these three papers contribute to a new and deeper understanding of how default effects work to generate such profound behavioral changes. The three papers are closely focused on a single cohesive topic, but use novel perspectives and methodologies to further our understanding of the subject matter. The discussion will be detailed and diverse, capitalizing on the expertise of the authors in this subject area yet allowing for their varied approaches to the topic. This unique combination will foster an exciting and lively discussion of great interest to a wide audience.

Session Plan: Our goal for the session is to inspire a deeper level of thinking about the psychological workings of defaults. We will achieve this through the sharing of detailed new findings followed by an expert-led general discussion period. Each presenter will have 15 to 18 minutes to share their results, including clarifying questions. Dr. Jonathan Levav, a well recognized expert in defaults, assortment and choice will serve as a discussant. Following the three presentations, Dr. Levav will spend 10 minutes commenting on the papers, and then facilitate an open discussion between the panel members and audience.

Building Connections: This session will appeal to a broad cross section of ACR attendees, ranging from traditional choice theorists to process focused psychologists. In addition, these findings are of practical significance to industry practitioners and policy makers interested in utilizing default options to alter consumption behavior. In sum, these papers provide both deep theoretical and actionable practical insights into the powerful default effect. As a result, this session is the ideal cohesive and compelling platform for building connections between academic sub-disciplines, industry and policy makers.

Partitioning Default Effects

EXTENDED ABSTRACT

Many active decisions have a default option that is chosen more often than expected if it were not labeled the default. No-action defaults often affect consequential life decisions such as choices of auto insurance (E. J. Johnson, et al., 1993) and retirement savings (Madrian & Shea, 2001) which affects how billions of dollar are spent, and policy matters such as organ donation, which affects thousands of lives (Abadie & Gay, 2006; E. J. Johnson & Goldstein, 2003).

Why do default effects occur? Past research (E. J. Johnson & Goldstein, 2003; McKenzie, Liersch, & Finkelstein, 2006) has suggested that defaults may be chosen for three reasons. The first is effort: choosing the default option requires no physical action and can free one from laborious calculation. The second is implied endorsement: decision-makers may infer a default has been pre-selected due to its merit or the desires of those presenting the choice. Finally, defaults may result from reference dependence: the default option may represent a reference point which colors the evaluation of other options as gains or losses. This paper provides novel empirical evidence that reference dependence can change the evaluation of options in a way that leads to default effects, and examines how various

factors relate to the likelihood of choosing the default. We generate these hypotheses in the theoretical framework of Query Theory (E. J. Johnson, Haubl, & Keinan, 2007; E. U. Weber, et al., 2007).

Isolating specific causes of the default effect is important for generating interventions to change the frequency of default-based choice. For example, if effort causes a default to be chosen more frequently, making execution of the choice easier should reduce default effects. Thus, when a policy maker or marketer presents a decision maker with a choice they should consider the effects of various defaults as well as understand their cause.

The experiments in this work examine participant's choices between either a cheap, but inefficient Incandescent Light Bulb, or an efficient, but expensive Compact Fluorescent Light Bulb (CFL), a choice which on aggregate can affect roughly $600 million in annual US energy costs (EnergyStar, 2010). The first experiment examines the relative effects of these three explanations on the choice of a default option. The second experiment extends these results by introducing an external measure of effort. In the third experiment we manipulate the queries shown to participants in order to test for a relationship between query consideration and choice. Effort is measured by self-reports in Experiment 1 and by reaction times in Experiment 2. Implied endorsement is measured, as in McKenzie, Liersch and Finkelstein (2006), by using the decision-makers' perceptions. The effect of reference dependence on the evaluation of the options is measured using an aspect listing protocol, a method that has been used to study the endowment effect (E. J. Johnson, Haubl, & Keinan, 2007), attribute labeling (D. J. Hardisty, Johnson, & Weber, 2010) and intertemporal choice (Weber, et al., 2007)

We explore the ability of one specific memory-based view, Query Theory, to account for reference dependent preferences in defaults. Query Theory suggests that when individuals are making a decision they: (1) identify different arguments in decision making by making unique queries, such as generating reasons for or against owning a particular object, and (2) execute these queries sequentially. Further, because of output interference (Anderson, Bjork, & Bjork, 1994; Roediger, 1973), the order of executing these queries determines what is recalled, and consequently preferred. Specifically, the first query results in the retrieval of a greater number of reasons and therefore has more impact than the second query. If Query Theory produces reference dependent preferences in default choices, then we would predict that the existence of a default option will make queries in favor of that option be listed earlier and more often.

Then, according to Query Theory there is support following two hypotheses:

(1) Order hypothesis: Participants are more likely to retrieve positive aspects of the default object and negative aspects of the non-default object before considering negative aspects of the default and positive aspects of the non-default.

(2) Content hypothesis: Participants are more likely to retrieve positive aspects of the default object and negative aspects of the non-default object than to retrieve negative aspects of the default and positive aspects of the non-default.

Following Hypotheses (1), a corollary would be that manipulating the order in which queries are requested will also affect the decision in a ways that can mediate a default effect. Further, we expect these differences in retrieval to both predict choice and to mediate the effects of defaults.

Across all experiments we keep a common scenario in which the participant must choose between Compact Fluorescent Light bulbs (CFL) or Incandescent Light bulbs. The scenario describes renovations done at the participant's home where one of the bulb types has been installed, and thus becomes the de facto default. A contractor then offers the participant the opportunity to switch from the default bulb for no additional cost. Light bulbs are chosen as the focus of this study because of the associated energy savings from reduced electrical consumption. The participants are split into two groups with the default bulb depending on the condition. All three experiments have a minimum of 2 between-participants conditions where the default bulb is either an Incandescent or a CFL.

To investigate the query theory hypothesis, participants record thoughts (i.e., considered aspects of the choice) while making the decision. In Experiment 1 aspects are listed concurrently to determine how thoughts differ during the decision making process. In Experiment 2 aspects are listed retrospectively, which allows for measurement of choice decision time without the contaminating effort of aspect listing. Experiment 3 uses a 2×2 design varying the type of default bulb and aspect listing order, which means first listing aspects for the default and then listing aspects against the default, or the reverse. Following the light bulb scenario, participants completed a questionnaire to assess implied endorsement as well as demographics.

In Defaults We Trust

EXTENDED ABSTRACT

Research has shown that people tend to adhere to choice defaults (e.g., Johnson & Goldstein, 2003). For example, employees are more likely to participate in a retirement plan when Human Resources Departments set the default as "participate", rather than "not participate" (a "default effect"; Madrian & Shea, 2001). Although default effects are probably multiply determined, recent findings have shown that defaults are at least sometimes perceived to be the recommended course of action -- an implicit recommendation -- which helps explain default effects (McKenzie, Liersch, & Finkelstein, 2006). This implies that trust may play a role in default effects: If people do not trust the source of the default, they may be less likely to exhibit default effects.

To evaluate this hypothesis, we conducted an initial experiment involving over 400 participants. In Experiment 1, participants were first asked to imagine the existence of a new company – ImaginationCo – that provided innovative and exciting new products and services. They were then told that in an attempt to reach new customers, ImaginationCo partnered with an established company who owned a large consumer database (which included their information). Finally, participants were informed that the established company sent them a survey asking for decisions about their potential relationship with ImaginationCo. (To make results more generalizable, participants were randomized to one of eight established companies: HP; Dell; Wal-Mart; Target; McDonald's; In-N-Out; The Wall Street Journal; or The National Enquirer.)

The survey involved a series of choices about whether to receive coupons and special offers from ImaginationCo, and whether to give ImaginationCo personal information such as home address and email. In one condition, the default was "do", while in another condition the default was "do not", send me information about, or give my personal information to, ImaginationCo. After completing the survey, participants answered a variety of demographic questions (e.g., gender; age). Embedded in these questions was a question about trust in the established company – i.e., "To what extent do you agree with the following statement?: [Wal-Mart] has a lot of integrity and elicits a high degree of trust." Participants answered this question on a scale of 0-7, where "0" was "strongly disagree" and "7" was "strongly agree".

Results of Experiment 1 showed the typical default effect. Importantly, a regression analysis indicated that there was a significant positive linear relationship between the size of the default effect and trust level in the established company – i.e., as the default effect decreased, so did levels of trust. For example, when trust in the established company was high (participants with trust ratings of 5-7), default effects were substantial: The average participant in the "do" default condition chose to receive or give information to ImaginationCo over 50% of the time, while those in the "do not" default condition chose to receive or give information a little more than one third of the time. However, there was no default effect when trust was low (participants with trust ratings of 0-2).

A second experiment examined whether participants who were deceived in a prior unrelated study were less likely to adhere to default effects when completing the questionnaire from Experiment 1. The reasons for this study were twofold. First, whereas Experiment 1 showed a correlation between default effects and trust, Experiment 2 aimed to establish causality between trust violations (in this case, via incidental deception) and diminished default effects. Second, understanding how different types of trust violations impact default effects is of importance. For example, deception has been shown to be particularly damaging to trust, in some cases making trust irreparable (Schweitzer et al., 2006). Thus, exploring how deception affects people's willingness to adhere to defaults provides a meaningful test of Experiment 1 findings.

Experiment 2 was identical to Experiment 1 with one critical exception. Whereas the level of trust was not independently manipulated in Experiment 1, it was independently manipulated via incidental deception in Experiment 2 to establish a causal arrow from trust violations to diminished default effects. In particular, before participants completed the "ImaginationCo" questionnaire from Experiment 1, all participated in an initial "eye tracking" study. In the eye tracking study, participants were told that their eye movements were being tracked while looking at a picture. However, eye movements were not being tracked. Critically, for one group of participants (n=22), they were told of this deception (the "deception" group) immediately after the eye tracking study. However, for another group (n=22), they were not told (the "no deception" group). Both groups of participants then completed the "ImaginationCo" questionnaire from Experiment 1.

Results of Experiment 2 showed that when making a choice to "receive" information, the "no deception" group exhibited substantial default effects, while the default effect was *reversed* for the "deception" group. For decisions related to "giving" personal information to ImaginationCo – which may have already induced skepticism (Brown & Krishna, 2004) – there was no significant default effect for those who had, or had not been deceived. Results suggest that trust causally impacts people's willingness to stay with the default option.

In sum, findings from Experiment 1 support the notion that defaults act as implicit recommendations: To the extent that people do not trust the source of the default, people are less likely to take the recommended course of action (i.e., they are less likely to stay with the default). In fact, in Experiment 2, while default effects were robust for non-deceived participants, deceived participants exhibited a default effect *reversal*, suggesting the possibility that implicit advice may not simply be ignored, but rejected, when trust is violated. Such reputational influences on default effects should be considered when establishing defaults. Defaults have not only proven effective in business contexts (Johnson et al., 2002), but also in areas such as retirement savings (Madrian & Shea, 2001) and organ donation (Johnson & Goldstein, 2003), where the positive social impact of default effects is potentially large. However, if trust in defaults' sources is compromised – as can be the case in political and corporate environments – people may discontinue adhering to default options, thereby limiting their influence.

When Shopping Carts come Pre-Loaded: Default Effects in Assortments

EXTENDED ABSTRACT

Most research that has examined the effect of a default option to date has focused on binary choices, when one of two options is designated the default. The common finding is that an option is more likely to be selected when it is the default vs. when it is not. For example Johnson and Goldstein (2003) show that in a choice between being an organ donor or not, most people will choose be a donor if that is the default. However, if not donating is the default, most people will instead choose to not donate. Unlike binary choices that force consumers to choose a single option, in many real world situations consumers can choose multiple options from a choice set. For example, when shopping for groceries one is not forced to choose a single item – either milk or eggs. Instead, shoppers can select both milk *and* eggs. When the choice situation allows a consumer to select more than one option, it is unclear how setting some of the items as defaults will impact the overall number of products purchased. A major difference between a single choice and assortment choice is that shoppers can include both default and non-default options in their final selections.

Building on Yaniv and Schul (1997) we propose that when defaults are present in an assortment people employ two distinct criteria to select items for purchase. When they consider adding new products to the purchase set, people compare it against a higher, inclusion threshold. If they are instead evaluating a default option, they will compare the product against a lower exclusion threshold, to determine if they should remove the item. We test the overall effect and our explanation by presenting assortments where default options vary across purchase conditions. In each experiment participants were presented with a specific online shopping goal, such as buying food for a party or stocking a new home office, and then they were asked to select as many items as they wished to purchase from an assortment of 16 products. In the default conditions, some or all the items were pre-checked for purchase (depending upon the experiment) and the respondent could uncheck them. In the no-default control conditions, respondents were simply shown a list of the assortment and asked to select as many as they wished to purchase.

In Study 1 we investigate the basic default effect within a large assortment. Ninety-eight adult participants (34 male, $M_{age} = 38$ $SD = 13.4$) were recruited from an online panel and randomly assigned to one of two conditions: all defaults vs. no defaults. Participants were told to imagine they were hosting a gathering, and were shopping for party snacks that could be delivered by a local retailer. They were then shown a 16 item assortment of drinks, desserts, fried foods and healthy snacks. In the all default condition all 16 items were pre-checked for purchase when the assortment appeared on the screen, while in the no default condition none of the items were pre-checked. Respondents in the all default condition purchased more total items than people in the no default option condition ($F_{(1, 97)} = 26.78$, $p < .001$). This finding was replicated in a second, office supply shopping scenario ($F_{(1, 97)} = 19.33$, $p < .001$).

As stated previously, we posit that shoppers select more items in the default condition because they use a higher threshold to add new products than they do to retain default products. Two studies test our explanation by varying whether the default items are among the most or least attractive options in the assortment. We

expect that designating unattractive options as default will result in a larger final purchase. This occurs because when the defaults are unattractive respondents compare them against the lower threshold, and retain some of those less appealing options they would not have added. Everyone then adds the attractive options, which exceed the higher "add" threshold. Study 2 tests this hypothesis using the same scenario and assortments described above, with either the four most or four least popular items from study 1 pre-checked as the defaults, and a no-default control condition. Two important results emerged. First, when the four most attractive items were the default, people purchased a similar amount as the no default condition; $M = 5.7$ vs $M = 5.4$, n.s.. This is consistent with the hypothesis that the most popular default options generally exceed the "add" threshold, and so were chosen whether they were defaults or not. Second, participants in the least popular condition purchase more of their unpopular default items, and more items overall, $M = 6.4$, $F(1, 124) = 4.07$, $p<.05$. This supports our hypothesis that when the less popular items are defaults, participants use the lower, "remove" criterion, and retain those items in their purchase set, and then evaluate other, higher valued options against the "add" threshold.

A final study shows that the arrangement default options can prime a specific mindset, such as variety seeking, which in turn lowers the "add" and "remove" thresholds for products that increase variety. Because the 16 item assortment consists of four sub-categories (e.g. desserts, fried foods) a set of four default options can be constructed that is either high in variety (one from each of the different sub-categories) or low in variety (all four from one sub-category). We predict that in a variety seeking mindset the evaluation thresholds will be lowered for options which add to variety. Therefore variety seekers will both retain more of the default options, and choose more non-default options, resulting in a larger purchase. Study 3 tests this hypothesis by presenting one product from each of the four sub-categories as pre-checked in the high-variety condition, while pre-checking four products from one sub-category in the low-variety condition. As predicted, when participants see the high-variety defaults they adopt a variety seeking mindset ($M_{High} =3.2$ $M_{Low} =2.9$ $F(1,191)= p <.01$), subsequently purchase more items overall,($F(1,320) = 1178$ $p < .001$), and their final choices are drawn from a more sub-categories, 2.9 vs. 2.5.

The current research extends our understanding of the powerful default effect into consumer choice from assortments, and offers support for a novel and straightforward dual threshold mechanism for default effects.

Control Freaks: Exploring When and Why
Consumers Seek Control through Consumption

Paper #4: The Beauty of Boundaries: When and Why We Seek Structure in Consumption
Keisha Cutright, University of Pennsylvania, USA

SESSION OVERVIEW

Objective: The belief that we have control over outcomes in our lives is considered to be a primary motivator of behavior—the reason we keep fighting towards our goals and the reason we aren't paralyzed by fears of what the future holds (e.g., Kelley, 1971; Miller, 1979). However, events often arise that threaten this sense of control, from terrorist attacks and natural disasters to the temptations and relationships of daily life. This session explores how consumption plays a critical role in one's ability to restore a sense of control in the face of such threats. More specifically, this session identifies situations that trigger an individual's need for control and explores how a variety of behaviors serve this need. Consistent with the conference theme of "building connections," our session takes a set of intriguing, yet previously isolated behaviors and demonstrates how they each serve a common goal.

General orientation: The focus of the session is on what instigates an individual's need for control and the resulting impact on consumption behavior. We begin by exploring the control that individuals assert over the self and its impulses. We then expand our view of control to explore the control that individuals seek to assert over others. Finally, we broaden our lens even further to investigate the control that individuals seek to assert over the environment. After the 15 minute presentations, we will discuss the implications of the research for developing integrative theories of control that illuminate the role of consumption.

Likely audience: The true appeal of this session is that while the papers are tightly connected around individuals' basic motivation to control their lives, each paper is different enough to generate interest from a broad audience. The session's papers will attract researchers interested in topics such as personal control, power, compensatory consumption, goal striving, self-regulation, nonconscious influences, shopper-marketing, variety-seeking and aesthetics.

Issues and topics: The Lee et al. paper begins the session by exploring how shopper marketing often induces consumers to assert greater control over their lives, particularly as it relates to controlling their impulses to spend money on vices. The second paper, Rucker et al., broadens our investigation of control beyond individuals'

impulses and investigates how we assert control over others (i.e., power) through our purchases. The authors explore how feeling powerless drives behavior differently depending on product status and the purchase recipient. The third and fourth papers focus on the tools that individuals use to assert a feeling of control over their environments more generally. Levav and Smeesters demonstrate that when feelings of isolation instigate a desire for control, individuals assert control over the environment by seeking variety in their product choices. Cutright's research demonstrates that when feelings of control are threatened, individuals seek environments with greater order and structure.

Contribution: This session's major contribution is in providing a broad view of the ways that consumers' desire for control can be instigated and resolved. By doing so, this session connects consumption behaviors that might have otherwise continued to be viewed as isolated, unrelated behaviors (e.g., avoiding vices, seeking variety, preferring boundaries, choosing status products). In doing so, this session "builds connections" that will generate a more complete understanding of when and why a desire for control drives consumption behavior.

State of completion: The papers included in this session are at advanced stages of completion, but have not yet been accepted at any journals. The authors are eager to receive feedback.

When Shopper Marketing Backfires

EXTENDED ABSTRACT

Retailers often try to entice shoppers to spend with a variety of shopper marketing tools. From conspicuous product samples and promotional coupons, to subtle sounds and scents in the retail environment, prior research has shown that these marketing devices can induce shoppers to loosen their purse strings. In this work, we investigate when such shopping prompts might backfire. We propose that shopping prompts can have two conflicting outcomes: while they can stimulate the desire for instant gratification and induce greater spending, they can also lead shoppers to exercise greater self-control in order to counter these temptations to spend. The net impact of shopping prompts thus depends on the relative magnitudes of these two effects.

To test the possibility that shoppers prompted to shop might ironically exercise greater restraint in their spending, we conducted two field experiments, one in a crowded campus supermarket in the U.S., and the other in a convenience store in Asia.

A total of 200 regular shoppers participated in **Experiment 1**. Upon entering the store, half of these shoppers were first offered a regular shopping basket from the store, whereas the other half of the shoppers was not offered a shopping basket. The results revealed that shoppers who were offered a basket spent significantly less than those who were not offered a basket ($p = .03$). Importantly, both shoppers who accepted the basket and those who did not accept the basket spent less than shoppers who were not offered a basket.

In **Experiment 2**, we used a different method to prompt shopping in the store. A total of 230 regular shoppers participated in this experiment and were randomly assigned to one of two conditions: half of them received a \$1-off coupon and a promotional flyer, whereas the other half received a coupon but not a flyer. The pro-

moted items (displayed on the flyer with color pictures) were mostly hedonic vices (e.g., branded sweet drinks, chocolates, and snacks).

This experiment produced three main findings: (1) shoppers who received a promotional flyer spent less than those who did not ($p = .03$); (2) analyzing the type of products shoppers purchased (based on shoppers' shopping receipts), we found that shoppers who received a flyer bought a larger proportion of utilitarian virtue products (vs. hedonic vice products), compared to those who did not receive a flyer ($p = .04$); and, (3) there was no difference in shoppers' rated attractiveness of the promotional items across conditions, or the number of promotional items they actually purchased in the store.

Experiments 1 and 2 indicate that shoppers who are prompted to shop may ironically spend less than those who are not similarly prompted to shop. The differential impact of shopping prompts on the purchase of vice versus virtue products further suggests the validity of our proposed self-control account.

We tested directly whether priming shopping can activate the higher-order goal of prudent shopping in **Experiment 3**. Participants (N=39) were randomly assigned to either a *shopping-prime* condition or a *control* condition. They were shown a series of 15 photographs and instructed to evaluate the technical qualities (composition and lighting) of each photograph. Participants in the *shopping-prime* condition were shown 10 photographs depicting shopping activities plus five other filler photographs, while participants in the *control* condition were shown 10 photographs depicting people engaging in activities unrelated to shopping (e.g., jogging, talking on a phone) and the same five filler photographs. Next, in a purportedly unrelated task, they were asked to rate the importance of a number of different goals to them when they shop, including the target goal ("being careful not to overspend.") Consistent with our self-control account, participants in the *shopping-prime* condition rated the target goal significantly higher than control participants ($p = .03$).

Our proposed explanation for the possible failure of shopping prompts to achieve their objective involves the activation of higher-order goals by these prompts, and thus increased shopper motivation to exercise restraint in spending. However, such restraint may not apply to all types of products. In particular, some products are relative vices (e.g., cigarettes, ice cream) that provide immediate rewards but long-term costs, while others are relative virtues (e.g., vitamins, apples) that might be associated with some immediate costs but provide significant rewards in the long run. Prior research has shown that relative vices tend to be associated with greater feelings of guilt and whose consumption are often deliberately constrained and rationed, whereas relative virtues are less likely to be targets of consumption self-control (Wertenbroch 1998). Hence, if tempting shopping prompts can induce shoppers to exercise greater self-control, we expect this tendency to be more pronounced if these shopping prompts are targeted at vices rather than at virtues. If this hypothesis holds, it will also help rule out alternative accounts such as shopper reactance to marketing persuasion—since these alternate accounts should apply to all types of products.

To test whether tempting participants to shop would result in reduced purchase of vice (vs. virtue) products, in **Experiment 4**, 64 participants were randomly assigned to one of four conditions in a 2 (Shopping Prime: Yes vs. No) X 2 (Type of Products: Vice vs. Virtue) between-subjects design. They were first asked to complete the same photograph-evaluation task as in experiment 3. Thereafter, they were invited to shop in a mock store set up in the lab. Half of these participants were shown an assortment of vice products (chocolates, candies, etc.) whereas the other half were shown an assortment of virtue products (hand sanitizer, pens). Consistent with our hypothesis, participants who were primed to shop spent less when they were exposed to vice products, compared to those who were exposed to virtue products or those who were not primed to shop (interaction effect: $p = .05$).

Overall, our research lends support to the notion that, in order to maximize marketing effectiveness, it is critical for marketers and retailers to consider not only the characteristics of shopper marketing, but also how these marketing tools interact with shopper motivation and the immediate shopping environment to affect shopper response.

Powerlessness and Consumption: The Shaping of Who and What we Value

EXTENDED ABSTRACT

Power—the perceived or actual control one has over resources or people— is a fundamental force behind human behavior (Magee and Galinsky 2008). However, only recently has power been brought into marketing to understand consumer behavior. It has been argued that because states of powerlessness are aversive consumers seek to alleviate them by altering the way they consume (Rucker and Galinsky 2008). In particular, it has been proposed that low power increases consumers' desire for high-status products and for conspicuous consumption. For instance, Rucker and Galinsky (2008) found that low-power individuals, compared to high-power and baseline participants, were willing to pay more for status-related objects.

In addition to the finding that powerlessness shapes what consumers value (i.e., status products), recent findings (Rucker, Dubois and Galinsky 2011) have shown that powerlessness can shape who consumers value. Specifically, Rucker and colleagues (2011) found that low-power participants placed a greater value on others and thus spent more on purchases for them. In contrast, high-power participants placed a greater value on the self and spent more on themselves. Of note, in this research the authors did not manipulate product status, but rather used products that did not have associations to status (e.g., everyday chocolates).

At first blush, the two papers may potentially seem at odds. That is, the original work by Rucker and Galinsky (2008) found that low-power increased consumers' spending, presumably on items they intended to acquire for themselves, whereas Rucker and colleagues (2011) suggested low-power increased spending on gifts for others and not for purchases for oneself.

We propose that the effects of powerlessness on who and what consumers value play out in a dynamic fashion depending on the product status and the purchase recipient when both are explicitly brought to the forefront of consumers' attention. First, in the case of products that lack an association with status, we suggest that compensatory motives will not be met by acquiring the product. As a consequence, the value of the recipient should be the focal factor in how power affects consumers' behavior. As such, we would expect that the findings of Rucker et al. (2011) would perfectly replicate among objects unrelated to status.

Second, in the case of high-status products, we predict that the specific value of status to high and low power participants will be salient, and that this may dominate the relative value of self versus others fostered by power. When the product is for oneself, we hypothesize that low-power participants will value a status object more for the self than high-power participants, consistent with Rucker and Galinsky (2008). In contrast, when products are associated with high status but purchases are directed at others, we do not expect differences. This is because given the product status would make the needs of low-power participants salient, a focus on their own needs may prevent them from spending more on others or thinking about the relative value of others.

These ideas are tested across two experiments, using different power manipulations and dependent measures. Experiment 1 uses high-status products and crosses power with product recipient. Experiment 2 focuses on both high and low status products crossed with power and product recipient.

Experiment 1. Participants were randomly assigned to a role of high power (i.e., a boss) or low power (i.e., an employee) for a later task in the experiment. Subsequently, as part of an ostensibly unrelated task, they were offered the opportunity to purchase Godiva chocolates (pre-tested to be perceived as high status, $p < .01$) for themselves or another person. Results were conceptually consistent with Rucker and Galinsky (2008) when the purchase was for themselves: low-power participants spent more than both baseline and high-power participants, $ps < .05$, which did not differ from one another, $p > .7$. In contrast, when the intended recipient was another person, there were no observed differences in the amount individuals spent, $p > .4$. This latter outcome is consistent with the idea that when a product is associated with status, but for another person, low-power participants don't value it more than high-power participants because the high level of status of the product leads them to focus on their own goals rather than on the value of others.

Experiment 2. Participants were randomly assigned to a 3 (Power: low, high, baseline) × 2 (Purchase Recipient: self, other) × 2 (Product Status: low, high) × 2 (Category: Chocolate, Restaurant) between-participants design. They received an ad copy for either chocolates or a restaurant and asked how much they would be willing to pay for a bag of chocolates or a dinner at the restaurant (stimuli adapted from Rucker, et al., 2011). The ad copy was used to manipulate power, product status and intended recipient. To manipulate power, the ad either began with, "Remember a Time You Felt Powerless?" or "Remember a Time You Felt Powerful?" In the baseline condition, the ad did not mention anything. To manipulate status, the ad featured a picture for a product pre-tested to be either low or high in status. The low-status product featured Hershey's Kisses (a pizza parlor), whereas the high-status product featured Godiva Gems (a fine French restaurant). To manipulate the intended recipient, the ad copy ended with "A Perfect Gift to Give Yourself" or, "A Perfect Gift to Give Others."

As product category did not interact with our other variables of interest, we collapsed across this dimension. A significant 3-way interaction between power, product status, and intended recipient emerged, $p = .01$. Among status products, we replicated experiment 1's findings. Among non-status products, results confirmed our hypotheses and replicated Rucker et al. (2011). When the intended recipient was oneself, high-power participants were willing to pay more than low-power participants, $p < .05$. This pattern reversed when the intended recipient was another person, with low-power participants willing to pay more than high-power participants, $p < .01$.

Overall, the present findings replicate and provide new insights into how powerlessness drives consumption.

Seeking Variety to Overcome Social Exclusion

EXTENDED ABSTRACT

With the growing popularity of online social networks and wireless technologies, personal social communication has decreased and Americans are feeling increasing social isolation. Social isolation thwarts various basic human needs (Kipling 2007); in this research we focus on the need to assert control and mastery over one's environment. We study the effect of social exclusion on decision-making and hypothesize that people who are made to feel socially isolated attempt to assert mastery and control over their environment through their choices. Previous research demonstrates that in Western cultures people seek variety as a form of self-expression and to assert themselves in their environment (Kim and Drolet 2003, Levav and Zhu 2009). Thus, we examine how social isolation leads to variety seeking choices, and how these are moderated and mediated by desire for control and locus of control across five studies.

In **study 1**, participants were asked to complete a personality scale and then given one of three (randomly assigned) types of bogus feedback about their results (see Twenge et al. 2001). In the exclusion condition they were told that they would end up lonely in life; in the inclusion condition they were told that they would end up having good social relationships in life; and in the misfortune condition they were told they would end up having some sort of physical misfortune later in life. The latter condition was added to control for the effect of negative affect on choice. Finally, we also included a control condition where people did not complete the personality questionnaire. Having received the feedback, participants were asked to complete an ostensibly unrelated study in which they could choose any five candy bars out of a bowl containing eight different candy bars. Participants in the loneliness condition sought significantly more variety than those in the inclusion, misfortune, or control conditions. The latter three conditions did not differ from each other.

In **study 2,** we manipulated social exclusion using a task in which participants were asked to play a three-player Internet ball-tossing game called Cyberball. Depicted on the screen were three "Cyberball" icons, intended to represent three other ostensible players, and an animated hand at the bottom of the screen, intended to represent the participant. Participants had no information about the (fictional) other players and were told that they would never meet them. We operationalized exclusion versus inclusion by manipulating the number of ball tosses to the participant. In the exclusion condition, the participant only received two tosses at the beginning of the game. In the inclusion condition, the participant received the ball as often as the other players. In the control condition, participants did not play the Cyberball game. Following the game, participants completed a desire for control scale, followed by a choice task similar to study 1. We found that participants in the exclusion condition picked a greater variety of flavors than those in the inclusion or control conditions. The inclusion and control conditions did not differ from each other. More importantly, we found that desire for control fully mediated the effect of the exclusion manipulation on participants' variety-seeking.

In **study 3**, we replicated the Cyberball manipulation, but followed the game with a filler task that included Rotter's locus of control scale. Next, participants proceeded to a choice task similar to the previous studies. We replicated the results of study 2, but found a greater effect for participants for participants who were high in locus of control (i.e., those who had an external locus of control). Thus, participants who tended to believe in their ability to exert control over their environment were more likely to seek variety in the face of social exclusion.

In **study 4**, we tested whether we could eliminate our effect by manipulating people's theories about the meaning of the choices they make. We used the same feedback manipulation as in study 1, followed by a short essay based on Millard's theory of reasoned action in which people read that choice is a vehicle for self-mastery or choice is not a vehicle for self-mastery. We find that our social exclusion manipulation only led to variety seeking for participants who read the self-mastery essay but not for those who read the opposite.

Finally, in **study 5** we tested whether an intervening opportunity to exert control eliminates socially excluded participants' need to

seek variety. Participants completed the same bogus feedback task as in study 1, and then played a round of the dictator game in which they were either the recipient or the dictator (or a control condition where no game was played). This was followed by a candy choice as in study 1. We found that participants who were led to believe that their future would be lonely and who played the role of dictator—thus exerting control—no longer sought variety in the subsequent candy choice task. In contrast, their counterparts who played the role of recipients did seek variety, just like control participants who were led to believe in a lonely future but did not play the dictator game.

The Beauty of Boundaries: When and Why
We Seek Structure in Consumption

EXTENDED ABSTRACT

To avoid feeling as if the outcomes in their lives are randomly determined, individuals often choose to believe instead that they have personal control over their lives. In other words, they believe that they can intentionally produce desired outcomes and prevent undesired ones (Skinner, Chapman, and Baltes 1988). But, how do people respond when their perceptions of control are threatened? How do they avoid the anxiety-provoking fear of a random world?

This research demonstrates that one way that people respond to threats to their personal control is by seeking order and structure in their consumption environments and choices, or "structured consumption." I suggest that one intriguing way that individuals achieve a sense of "structured consumption" is by seeking boundaries in their physical environment. I posit that boundaries, by their very nature, dictate where things belong and consequently represent the establishment of order and structure in the environment. Such boundaries can include the tangible aspects of products, such as the frame surrounding a painting. However, boundaries can also be intangible, such as when a distinct place is identified for a given object and is differentiated from that of others without the presence of a physical border. As an example, organized environments (i.e., space that is organized such that everything is in its place) reflect the presence of strong intangible boundaries. I posit that when feelings of control are low, individuals desire the sense of order and structure that such boundaries provide.

Several experiments were conducted to test this hypothesis. In **study 1**, I manipulated feelings of control by giving people high control or no control over a series of loud noises using a classic noise manipulation (Glass, Singer & Friedman 1969). Participants then chose between a postcard with a clear boundary around it versus one that contained the same content, but without the boundary. The results indicated that those in the low control condition were more likely to choose the bounded postcard than those in the high control condition.

In **study 2**, I illustrated how this preference is mediated by individuals' desire for structure. Individuals were assigned to a writing exercise that manipulated their feelings of control (without impacting mood or esteem.) They were assigned to a low control, high con-

trol or neutral condition. In the low control condition, participants wrote about a positive outcome in their lives when they were not in control. In the high control condition, they wrote about a positive outcome when they were in control (Kay et al. 2008). In the neutral condition, participants wrote about a movie that they saw and enjoyed. They were then asked mediating questions about their desire for structure. Finally, they were asked to choose between a bounded and an unbounded logo across 10 different pairs of logos (in addition to fillers). Individuals in the low control condition were more likely to choose the logos with boundaries than those in the high control condition. The neutral and high control conditions did not differ from one another. Importantly, the relationship between control and logo preferences was mediated by individuals' enhanced motivation for structure when feelings of control were low.

In **study 3**, I demonstrated how this desire extends beyond tangible boundaries to the more intangible boundaries that appear in retail settings using a 2 (control: low vs. high) x 2 (convenience store design: organized vs. disorganized) between-subjects design. Participants were first assigned to a low or high control condition (see study 2). They were then assigned to shop in either an organized store (i.e., strong boundaries) or disorganized store (i.e., weak boundaries) in the lab. The dependent variable was the number of items participants chose in the store. When individuals were in the low control (but not high control) condition they were more likely to buy items from the store if they were in the organized (vs. the disorganized) store. Moreover, individuals were more likely to buy items in the organized store if they were in the low control condition than if they were in the high control condition. This pattern of results was mediated by individuals' enhanced appreciation for boundaries when in the low control (vs. the high control) condition.

Finally, in **study 4**, I explored why boundaries are valuable as a means of structure. I focus primarily on the functional benefits offered by boundaries. I posit that when individuals are low in control they are more likely to feel overloaded by the number of things that could happen to them, and thus feel overwhelmed by the number of things to which they need to pay attention in their environment (i.e., attentional overload). Boundaries, by containing objects in a given space, should help alleviate such feelings of overload by allowing individuals to focus more easily on the aspects of the environment. In this study, I manipulated feelings of control (see study 2) and then measured individuals' feelings of attentional overload. Next, I measured individuals' preferences for a painting with a clear boundary around it versus the same painting without the boundary. Results indicated that individuals in the low control condition were more likely to choose the painting with the boundary around it. This was driven by the increased feelings of attentional overload among the low control participants.

Together, these four studies illustrate a novel means by which individuals respond to personal control threats. Seeking order and structure through boundaries may not only allow individuals to avoid fears that the world is random, but may also lend confidence to the idea that they can reassert control over the more structured environment.

SESSION OVERVIEW

In recent years, a large number of findings have emerged on the topic of grounded cognition. For example, we now know that moral dirtiness is experienced as a need to physically cleanse (Zhong and Liljenquist 2006), that touching a warm cup increases warmth perception in the personality of others (Williams and Bargh 2008), that fishy taste can increase suspicion (Lee and Schwarz 2011), that the sensation of approaching an object in space or time can make an outcome appear more positive (Labroo and Nielsen 2010), and that one can literally wash away post decisional dissonance (Lee and Schwarz 2010b). This multitude of findings offers some commonalities but also highlight several differences. For instance, in contrast to several decades of research on priming that at best provided limited or mixed evidence pertaining to cross modal effects, with most findings suggesting that accessible knowledge is applied within activated cognitive structures and only if the information is considered diagnostic, these findings on grounded cognition present robust evidence of cross modal knowledge transfer effects. On the other hand, a systematic understanding of when and why these effects arise and how they relate to each other is lacking.

The current session brings together four papers each exploring one of four different ways in which cognition may be grounded. Across four papers, we discuss (a) how thought can be interpreted as suggesting that abstract domains may be grounded in metaphorical thinking, (b) how incidental sensory experiences influence judgment, (c) when physical experience may be necessary at least in part for affective experience during social perception, and (d) psychological existentialism and how the physical world can leave behind metaphoric residues. Each of them can influence consumer decision making.

The first paper by Zhang and Schwarz investigates issues pertaining how thought about abstract domains such as time is metaphorically grounded in more concrete domains such as space. Thus, thinking about time (e.g., future vs. past) increases attention to the corresponding direction in the dimension of space (right vs. left). The second paper by Mehta et al. then investigates how thought is

grounded in sensory experience, and how incidental sensory experiences can influence judgment and behavior in unrelated domains. In particular, physical experience of warm/cool serves as an intermediate between two different dimensions of cognition that are grounded in it, namely color and interpersonal warmth. As a result, seeing the warm color may activate the consequential judgment and behavior of being helpful through inducing the actual feeling of warmth, resulting in donating of time rather than money. The third paper by Zhou and Labroo implicates the role of the physicality in affective experience arising from social perception. The data suggest that an experience of gustatory sweetness might constitute at least part of the affective response to others' smile--satiating people with sweet foods appears to make them unable to experience affective response to genuine smiles of others. The final paper by Xu et al. brings together ideas of existentialism and sympathetic magic to suggest that as the world often leaves residues of sweat, dust, and contaminants, many other acts leave virtual residues. Thus, luck is sticky, and washing hands after experiencing good/bad luck wipes off the residuals of previous luck.

Introductory remarks will introduce these conceptually distinct classes of grounding effects and each speaker will link to the conceptual framework to explore similarities and differences between each set of findings. In addition, the last 10 minutes of the session will be devoted to tying the papers together and encouraging questions from and discussions with the audience in order to develop a more enriched understanding of grounded effects. In line with the theme of ACR of "building connections," the primary goal of this session is to develop conceptual frameworks and provide structure to understanding grounded cognition effects. The session participants will illuminate different ways in which grounded effects occur and connect the findings more generally to past cognitive perspectives. The session will raise questions about the state of the area of grounded cognition and highlight avenues for future research.

We expect this session will be of interest to a broad audience at ACR. Not only is this a topic of emerging interest, but future theoretical developments in this area are likely to tie back to and draw from past research on priming, mimicry, metaphor, and feelings and sensations. A more integrated understanding of issues pertaining to grounded cognition is also likely to develop knowledge in these basic areas this research draws from.

Past to the Left, Future to the Right: How Does Thinking about Time Affect Choice

EXTENDED ABSTRACT

As research in embodied cognition indicates, abstract concepts, such as time, are understood and structured through metaphorical mappings from more concrete and experiential domains, such as space (Clark, 1973; Lakoff and Johnson, 1980). Across languages people use spatial metaphors to talk about time. For example, in English, we say that a technology is "ahead of its time", or that a project is "far behind schedule". Using spatial metaphors to describe time enforces associations between the two domains and imports relational structures from space to time. In fact, recent evidence suggests that people do not only talk about time in spatial terms, but they also use their spatial knowledge to think about time. Boroditsky and colleagues (Boroditsky 2000, 2001; Boroditsky, Fuhrman, and Mc-

Cormick, 2010; Fuhrman and Boroditsky 2010; Santiago et al. 2007) showed that people are able to use information made available by spatial primes to think about time. They further showed that metaphorical mappings between time and space are directional, with the directionality being language specific. For example, English speakers project the past to the left side in space and the future to the right, while Hebrew and Arabic speakers do the opposite. Such directional relations have cognitive and behavioral consequences. For example, people respond to a time related stimulus (e.g., a picture that represents the past) faster when the response format is consistent with their time representation (e.g., hitting a key on the left); they also order cards that represent current, past, and future events accordingly.

The current research provides a first experimental test of whether the directional relation between time and space affects consumer choice. Specifically, we test whether English speakers are more likely to choose items displayed on the left when making a choice pertaining to the past, but displayed on the right when a choice pertaining to the future. We propose and show that when making a choice pertaining to future or past time points, people initially attend to alternatives in the corresponding areas of their visual field, which advantages choice alternatives displayed in the respective area. Finally, this research also speaks directly to a theoretical question about the inferential structure of the spatial-temporal metaphor: whether there is a continuous relation between space and time along the whole mental "time line" or just a dichotomous left-right relation. These issues are addressed in three studies.

In study 1, participants were asked to think about either their last vacation trip, or their next vacation trip. Then, they were shown four pictures of natural sceneries, all printed in color and presented horizontally, covering the width of a letter-size page presented in landscape format. The order of pictures was counterbalanced and participants were asked to choose the picture that best captures how they feel about their past/future vacation trip. By coding the picture locations as 1, 2, 3, and 4 (from left to right), ordinal regression shows that, on average, the pictures chosen to describe a past vacation are .55 units to the left of pictures chosen to describe a future vacation, independent of the actual content of the pictures. This result also suggests that the reconstruction of past events and the imagination of future ones may be disproportionately influenced by cues that appear in different areas of the visual field.

Study 2 replicates study 1 in a product choice context. Participants were asked to report the approximate date of their last/next vacation. Then, they were shown four photo albums with detailed information, arranged horizontally in color print on letter-sized paper in landscape format. Participants were asked to choose an album for keeping photos from that past/future trip. Linear regression shows a significant positive relationship between the temporal distance of the reported vacation and the position of the picture chosen. The further the trip is in the past (future), the more participants chose albums displayed on the left (right), independent of the specific features of the albums shown. This result not only demonstrates an influence of the spatial-temporal metaphor on product choice, but also reveals a continuous mapping between time and space, suggesting that the spatial-temporal metaphor works not only on a directional level, but also on a quantitative level.

Study 3 sheds light on how spatial-temporal associations translate into choice. Participants were presented with a list of 10 positive adjectives, arranged horizontally on letter-sized paper in landscape format in counterbalanced order. They were asked to choose the three words from this list that are most vs. least descriptive of what they were like 5 years ago vs. will be like 5 years into the future; this results in a 2 (most vs. least descriptive) x 2 (past vs. fu-

ture) between-subjects design. Replicating studies 1 and 2, the same words were more likely to be selected as descriptive of one's past self when displayed on the left, but as descriptive of one's future self when displayed on the right. However, when the task was to select words that are not descriptive, this directional influence reversed. This reversal suggests that attention plays a critical role in this process: When thinking about the past (future), participants first attend to the left (right). All words they see are desirable for describing the self, resulting in their acceptance when the task is to select descriptive words, but in their rejection when the task is to select non-descriptive words.

In combination, these studies provide first evidence for metaphorical mapping effects in the visual display of choice alternatives. People think about time in analogy to space and treat time as moving in the direction of writing. In an English language context, this directs attention to the left for the past, but to the right for the future, giving choice alternatives displayed in the respective space an advantage.

Warm Or Cool Color? Exploring the Effects of Color on Donation Behavior

EXTENDED ABSTRACT

Color is a fundamental aspect of human perception. Every visual stimulus processed by the human perceptual system contains color information (Elliot and Maier 2008). Thus, it is no surprise that extensive research has been done to examine the effects of color on human cognition and behavior, such as test performance (Soldat et al.1997), creativity (Mehta and Zhu 2009), mate preference (Elliot et al. 2010), and consumer buying processes (Bellizzi et al. 1983). A large portion of this line of research has focused on the differential impacts of warm versus cool colors (e.g., Elliot et al. 2010; Mehta and Zhu 2009). Warm and cool colors are distinguished based on their wavelength (Bellizzi et al. 1983). Longer wavelength colors (e.g., red and yellow) are known as warm colors whereas short wavelength colors (e.g. blue and green) are known as cool colors.

We extend this line of research by examining the effects of warm versus cool colors on prosocial behavior, particularly donation behavior. Building on recent research on embodied cognition, we hypothesize that warm (vs. cool) colors are likely to induce differential feelings of ambient temperature (i.e., warmer vs. cooler), activate warmth (vs. competence) concepts, and subsequently enhance donations in terms of time (vs. money). Theories on embodied cognition suggest that cognitive thoughts are grounded in the same neural systems that govern sensation, perception and action (Barsalou 1999; Connell 2007). Thus, sensory data, such as visual information and physical sensations, is stored together in memory with associated mental concepts or experiences. Once the sensory data is experienced, other related components, such as other physical sensations and the corresponding concepts are likely to be activated as well.

Along this line of arguments, we hypothesize that warm versus cool colors can make people actually feel warmer versus cooler. In daily life, warm colors are usually associated with situations that involve warmer temperatures, such as the sun, fireplace, and tropical areas. Similarly, cool colors are usually associated with situations that involve cooler temperatures, such as ocean and forest. Embodied cognition suggests that sensations that share similar affect states are usually stored together in memory (Barsolou 2008; Connell 2007). Thus, it is possible that exposure to warm (cool) colors would induce warmer (cooler) feelings of ambient temperature.

Next, we posit that these warmer (cooler) physical sensations are likely to activate warmth (competence) related concepts. This is

again consistent with theories on embodied cognition which suggests that embodiments, such as physical sensations, are stored together with corresponding semantic concepts in memory, and thus the experience of embodiment can activate the corresponding concept and vice versa (Barsalou et al. 2003). Warmth and competence are the two fundamental dimensions in social judgments through the lens of stereotypes (Aaker et al. 2010; Fiske et al. 2002). For example, rich people are often seen as high in competence whereas the elderly are usually perceived as high in warmth (Fiske et al. 2002). Because abstract concepts are metaphorically based on concrete physical experiences, the feeling of warmer ambient temperature when one is exposed to warm colors might activate warmth-related concepts, such as being a warm and friendly person. Similarly, the feeling of cooler temperature when one is exposed to a cool color will may activate cool concepts, such as being confident and competent (Scherbaum and Shepherd 1987).

Finally, we posit that these alternative concepts (warmth vs. competence) will affect donation behavior differently. If a helping behavior demands more personal warmth or closeness (e.g., spending time with others; Nock and Kingston 1988), the exposure of warm color would enhance such behaviors. However, if a helping behavior demands more competence (e.g., giving money to others; Tang 1992), the exposure of cool color might enhance such behaviors. A series of four studies provide support to our theorizing.

Study 1 demonstrated that a warm (vs. cool or neutral) color led to greater helping behavior when it primarily involves time commitment. Participants completed a computer based study, where the screen background color was used to manipulate color. The color was either warm (yellow) or cool (light blue). The focal task involved having participant imagined three scenarios where they had to help a friend, an acquaintance and a stranger in need and their likelihood to help was measured. Data revealed that those in the warm color condition were more likely to offer help than those in the other conditions. Study 2 demonstrated that when the helping context specifically involved money donation, cool color helped.

Study 3 tested the underlying processes for the above observed effects. The study employed a 2 (color: warm vs. cool) X 2 (nature of donation: money vs. time) between subjects design. Participants were presented with an ad for an NGO seeking help either with volunteering time or donating money. We replicated findings from previous studies, and more importantly demonstrated the process mechanism. Specifically, initial evidence suggests that warm (cool) colors make people feel warmer (cooler) which then activates warmth (competence) perceptions, and consequently prompts people to donate more of their time (money).

The final study was a field experiment. We manipulated color through survey papers. We randomly stopped participants outside of a mall and asked them to indicate their intention to donate to an organization either in terms of money or time. Results replicated our lab study.

Eat Sweet, See Deceit: Does Gustatory Sweetness Underlie Smile Perception

EXTENDED ABSTRACT

The ability to recognize genuineness in the facial expressions of another individual is an important aspect of everyday social and consumer functioning, but might this ability be impacted by a person's chronic desire for or momentary consumption of sugar? In the current research we suggest that the gustatory experience of sweetness can satiate a person's desire for sweetness and as a consequence raise the threshold level of what is considered sweet. We further sug-gest that the detection of sweetness in another person's emotional expressions such as a genuine smile relies on simulating the action which may include muscles involved in the gustatory experience of sweetness. Thus, once a person has been satiated with sweet foods, the person will be less able to detect genuine sweetness in others emotional expressions, because being satiated with sweetness raises the threshold level of what is considered sweet.

Recent research suggests the detection of a genuine smile from fake may rely on the somatosensory simulation of smiles that enables perceivers to experience the meaning of the smile as genuine or non-genuine. The idea is that different facial musculature is involved in expression of different types of emotion, and genuine versus non-genuine smiles involve the activation of different groups of muscles (Frank, Ekman, & Friesen, 1993; Miles & Johnston, 2007). A genuine smile has smoother and more regular facial movements compared to non-genuine smile (Hess & Kleck, 1994). Moreover, simulation of these facial expressions helps perceivers understand how that smile feels and to distinguish a genuine smile from a non-genuine one based on the affective experience produced by simulating it. For example, mimicry helps people distinguish genuine smiles from non genuine ones (Niedenthal et al. 2009). Surakka and Hietanen (1998) additionally found that objectively genuine smiles induced higher pleasurable experience in perceivers than non-genuine smiles. Moreover, restricting a person's ability to mimic the emotional expressions of others by injecting Botox (vs. Restylene) reduces the pleasurable experiences associated with seeing smiling others (Havas et al. 2010). But might the gustatory experience of sweetness also numb these sweet sensations and reduce pleasure associated with genuine smiles, leading people to see such smiles as fake? Two studies investigated this issue.

In Study 1, individual differences of participants in preference for sweetened over non-sweetened options were assessed first in a multi-part survey. Later, participants viewed 20 clips of smiles with 10 portraying objectively genuine smile (a.k.a. Duchenne smile) and 10 portraying objectively non-genuine smile (a.k.a. non-Duchenne smile); and indicated the pleasantness of the affective feeling elicited by each smile. We hypothesized that people with a stronger sweetness preference would rate others' smiles as less pleasant because the sweet sensation produced by simulated smiles is likely to be below their preferred level of sweetness. However, such a relationship, if exists, should hold only when perceivers actually simulate the smiles they see. Given that automatic simulation of smile was greatly attenuated when viewing Non-Duchenne smiles compared to Duchenne ones (Surakka & Hietanen, 1998), we also predicted that the negative relationship between preference for sweetness and pleasant feeling generated by viewing smile would be stronger for Duchenne smiles than Non-Duchenne smile. The results are in supportive of our predictions: for Duchenne smile, a significant negative correlation between sweet preference and pleasant feeling elicited by the smiles emerged; whereas for non-Duchenne smiles, this negative correlation was almost non-existent.

Study 2 was conducted to investigate whether participants' judgment of smile would be affected if their sweet sense were fatigued by ingesting high-sugar content food. Participants were randomly assigned to one of four experimental conditions. Those in a sweet or a salty condition were asked to eat high-sugar content and high-sodium content snack respectively under the guise of a food tasting task. Those in the sweet thoughts (positive affect) or the neutral affect condition completed an essay task, where they were asked to write about a past episode where they felt lucky or how to use their cellphones to send text message, respectively. After the experimental manipulations, participants in all four groups watched the same 20

videos used in Study 1 and classified each smile as either fake or genuine. The idea is that if sweet sensation is at least part of the affective experience generated by the simulation of other's smile, then it should be possible to attenuate the intensity of affective experience by first adapting the sweet sense. Assuming that affective experience engendered by simulated smile indeed forms the basis for understanding smile (Maringer et al., in press), we predicted that the adaptation of sweet sense would make participants more likely to judge a smile as non-genuine. We also expected the increased likelihood of interpreting a smile as non-genuine after sweet adaptation to be smaller in the in the cases of Non-Duchenne smiles than Duchenne ones because the former tended be simulated to a lesser degree than latter. The results support our hypothesis. Specifically, higher proportion of Duchenne smiles were judged as fake in the sweet-snack condition compared to the other three conditions; whereas the proportion of non-Duchenne smiles judged as fake did not differ across the conditions.

Overall, our studies support the idea that sweet sensation might constitute at least part of the affective experience generated by the simulation of perceived smiles and hence play a role in the understanding of others' smiles. It seems that when people describe a smile as sweet, they do taste a tinge of sweetness.

Washing Away Your Luck: Physical Cleansing Affects Risk-Taking Behavior

EXTENDED ABSTRACT

Anecdotes suggest that people attempt to improve their luck by touching lucky persons or objects (Radford & Radford, 1961) and attempt to maintain or change their luck through strategic cleansing behaviors. For example, British fishermen used to abstain from washing during a period of good catches for fear of washing their luck away (Radford & Radford, 1961). Similarly, gamblers and athletes keep wearing the same unwashed socks or shirts during a winning streak, but welcome clean cloths after a losing streak (Gmelch, 1974; Vyse, 1997). These practices suggest a belief that good or bad luck is an essence attached to the self or to objects, which can be transferred (Wohl & Enzle, 2002) as well as washed away.

The belief that one may "wash away" one's luck suggests that the psychological impact of washing extends beyond the metaphorical link between physical and moral purity identified in recent embodiment research. For example, washing one's hands alleviates the upsetting consequences of one's own and others' unethical behavior (Zhong & Liljenquist, 2006) and attenuates the impact of disgust on moral judgment (Schnall, Benton, & Harvey, 2008). Conversely, engaging in a moral transgression elicits a desire to clean the "dirty" body part (Lee & Schwarz, 2010a; Zhong & Liljenquist, 2006). Going beyond the moral domain, Lee and Schwarz (2010b) found that washing one's hands can eliminate post-decisional dissonance effects in a free-choice paradigm, leading them to suggest that washing can more generally "wipe one's slate clean" by metaphorically removing traces of the past. However, that cognitive dissonance is an aversive arousal state (Zanna & Cooper, 1976) and shares this characteristic with people's responses to moral transgressions (Haidt, 2001). In both cases, the promises of a metaphorical cleansing may match the person's desire to alleviate a negative state. If so, the clean-slate effect (Lee & Schwarz, 2010b) may be limited to things people want to "wash their hands of" – experiences that are negative, though not necessarily immoral. As the above superstitious behaviors indicate, bad luck is one of the negative experiences that prompt washing. In contrast, good luck is something that motivates the avoidance of washing, presumably in an effort to preserve one's good luck. It is

not clear whether incidental physical cleansings only clean the slates we want to clean, removing only undesired traces of the past, or they also remove even traces we'd rather preserve. Two experiments were conducted to address these questions.

In experiment 1, participants were first asked to recall either an incident in which they had good luck financially or an incident in which they had a bad luck financially. Then, in an ostensibly unrelated product evaluation, all participants evaluated an antiseptic wipe – half examined the wipe without actually using it, whereas the others tested it by cleansing their hands. Finally, participants worked on a managerial decision task with choice between a riskless option (i.e., To reject a product improvement recommendation and stay with current level of profitability) and a risky option (i.e., To adopt the product improvement recommendation, which has 75% chance of succeeding and increasing the profit and 25% chance of failing and decreasing the profit). We found that without a hand-cleaning, participants who recalled past good luck were more likely to choose the risky option than those who recalled past bad luck. Thus, accessible memories of past luck influenced current risk taking. More important, the influence of past luck was significantly attenuated by hand cleaning: Participants who recalled past bad luck were more likely to choose the risky option when they had cleaned their hands than when they had not; conversely, participants who recalled past good luck were less likely to choose the risky option when they had cleaned their hands than when they had not. Therefore, good and bad luck can be "washed away".

Experiment 2 tests the robustness of the observed effects by providing participants with a salient current episode of good or bad luck, namely a winning or losing streak in a real gamble. Specifically, participants received an initial endowment of $100 HKD, which they could use to gamble. At the end of the first round of gambling, participants were self-selected into three categories: good luck (i.e., who had a winning streak), bad luck (i.e., who had a losing streak), and mixed luck (i.e., who had both winning and losing bets). Next, in an ostensibly unrelated product evaluation study, all participants evaluated organic hand soap; half examined the soap without actually using it, whereas the other half tested the soap by washing their hands. Finally, participants participated in a second round of gambling. They received an additional endowment of $50 and could bet any amount from $0 to $50. If they bet $X and won, they earned an additional $X, otherwise they lost the money they had bet. The amount of their bet serves as the dependent variable. The results showed that participants who had good luck in the initial round of gambling bet more money in the second round than participants who had bad luck. More importantly, participants who had bad luck in the first round bet more money in the second round if they had washed their hands. In contrast, those who had good luck in the first round later bet less money if they had washed their hands. Because losses loom larger than gains (Kahneman & Tversky, 1979), participants with mixed luck would resemble participants who experienced bad luck, and they bet more after washing than not washing their hands.

In sum, our studies show that people perceive good and bad luck as an essence that can not only be transferred by touching lucky people or objects (Wohl & Enzle, 2002), but also removed with soaps and wipes. Second, our findings bear on an issue that has received little attention in embodiment research: is the influence of metaphors limited to conditions where the metaphor is consistent with the person's goals and desires? The answer is that accessible applicable metaphors exert their influence independent of the person's motivation.

SESSION OVERVIEW

Environmental conservation is a major concern for countries, marketers, and consumers. Virtually every choice that consumers make has an environmental impact, which degrades or improves the state of the environment and its natural resources. Consumers are increasingly aware of their impact on the environment. In response, marketers have offered a growing array of products and services for facilitating more green consumption behavior. While making environmentally friendly choices may be guided by deeply held values (e.g., moral identity; Aquino and Reed 2002, Leonard-Barton 1981) or logic (e.g., cost-effectiveness; Hahn 2000), this session takes a different approach. More recently, researchers have attempted to gain a better understanding of more transitory factors and psychological mechanisms that influence conservation behavior (e.g., Goldstein, Cialdini, and Griskevicius 2008). Building upon these ideas, we focus on how both momentary situations and self-perceptions significantly influence consumers' decisions to engage in more or less green behavior. Since situations and self-perceptions are highly malleable, this session offers important insight into affecting larger scale conservation through everyday choices made by consumers. Our aim is to investigate and foster discussion around an important question: when and why will consumers choose to conserve through their consumption choices? This symposium argues that greener consumption is more multiply determined than many have assumed to date and focuses on two key factors: incidental cues and momentary self-perceptions.

The first two papers examine how incidental cues influence conservation. The second two papers focus on how momentary self-perceptions shape green behaviors. Together we present evidence and develop frameworks which explore when and why consumers engage in green behaviors. Mazar, Caruso, and Zhong demonstrate that environments which prime the color green elicit different consumption behaviors depending on the context in which relevant associations are activated. Zhu and Kalra show that incidental cues to non-excessiveness of one resource influences consumers usage of a

different resource. Jordan, Gino, Tenbrunsel, and Leliveld demonstrate how augmenting consumers' self-image and moral reference points influences their choices of conservation and ethical behaviors. Finally, Cavanaugh, Gino, and Fitzsimons identify when and why consumers choose to give green and ethically superior gifts to others.

In keeping with the conference theme "Building Connections," the papers in this session bring together a variety of theoretical approaches and investigate different mechanisms for impacting green behavior, which are likely to inspire interest and debate. For instance, under what circumstances does priming versus shifting motivation account for conservation behavior? How do self-perceptions interact with environmental factors to influence conservation? How broadly do these effects hold across different types of conservation-related consumption behaviors?

This symposium is likely to appeal to researchers interested in social cognition, social influence, moral psychology, relationships, and transformative consumer research. The research presented contributes to our understanding of when and why consumers behave the way they do in the domains of resource usage, ethical gift-giving, and socially conscious consumption behaviors more generally. These findings have important implications for marketers, individual consumers, and society. Note: Each speaker has agreed to serve (presenters noted with single asterisk) if the proposed session is accepted. All of the research described below has been written up, i.e. in manuscripts that are either prepared, under review, or near publication.

Greed or Green? The Impact of the Color Green on Conservation of Monetary and Natural Resources.

EXTENDED ABSTRACT

Green signifies life and nature and has become synonymous with the movement to raise awareness and concern for the environment (Mazar & Zhong, 2010). In fact, manufacturers even use green packaging just to create the impression that their products are environmentally friendly (Chandler & Schwarz, 2010). Incidentally, green is also the color of paper money in the U.S., and is associated with greed and envy. Thus, the same color can be associated with both conscientious and selfish behaviors.

The present research explores whether priming the color green can elicit different behaviors depending on the context in which the prime-relevant associations are activated. A large literature on priming has reported that social behaviors can be elicited by subtle contextual cues. For example, exposure to pictures of exclusive restaurants can improve manners in a subsequent eating task (Aarts & Dijksterhuis, 2003). These results are often interpreted as due to contextual cues activating associated norms and goals that lead to consistent behaviors. For instance, because the Apple brand tends to be associated with originality, briefly exposing consumers to the Apple logo increases their creativity on a subsequent idea generation task (Fitzsimons, Chartrand, & Fitzsimons, 2008).

More recently, researchers have attempted to gain a better understanding of the mechanisms by which these effects operate (e.g., Bargh, 2006). Factors that influence the effect of primes include personal characteristics of the people exposed to the prime (e.g., novices vs. experts; Mandel & Johnson, 2002; see also Wheeler & Berger, 2007) as well as the features of the judgment target (e.g., level of ambiguity; Higgins, 1996) or the situation (e.g., desirability of the behavior; Macrae & Johnston, 1998). Building upon these ideas, we

suggest that the same prime can activate different behaviors depending on the context. Specifically, exposure to green color in the context of environmental decisions might make the eco friendliness association salient and prime environmentally friendly, conscientious behavior, whereas exposure to green color in the context of financial decisions might make the money and greed association salient and produce behaviors that aim to promote self interest. We test this prediction in three studies.

In Study 1, 146 visitors to a museum engaged in a hypothetical dictator game in which they were given $20 to divide with another anonymous participant. Some of the participants completed this questionnaire in a room with a green floor and green walls, whereas others completed it in an adjacent room with a black floor and off-white walls. Participants who made their allocation decision in the green room kept more of the money for themselves (*M*=$12.26, *SD*=4.16) than participants who made their allocation decision in the non-green room (*M*=10.29, *SD*=3.46), *t*(144)=3.11, *p*=.002.

In Study 2, 72 students seated in individual cubicle desks in a lab participated in a product test study, in which they were asked to mix their own powder-drink by adding water to it and then rate the attractiveness of the color of the drink and how quickly the powder dissolved. Participants were given a measuring cup and were instructed to go to a water station and take as much water as they felt they needed for the task. Participants were randomly assigned to one of two color conditions. Those in the green prime condition had a green placemat on their desk and a green screensaver on the computer screen, whereas participants in the control condition had a white placemat and a white screensaver.

Participants primed with the green color took significantly less water (*M*=265.3 ml, *SD*=123.5 ml) than those in the control condition (*M*=355.7 ml, *SD*=179.5 ml), *t*(66)=2.49, *p*=.015. The color prime did not affect how appealing the color of the drink looked nor how fast participants thought the powder dissolved.

In Study 3, 144 participants seated in a lab engaged in a hypothetical variant of a public goods game in which they were asked to imagine they were part of a 100-person community that was going through a challenging period. Participants were randomly assigned to one of two color conditions (green vs. control-black) and one of two context conditions (money vs. water) in a between-participants design. We manipulated the color of the screensaver and mousepad to be either both green (green condition) or both black (control condition). Those in the money condition read about a challenging economic period that limited "the amount of money available, for example, to cover utility bills," whereas participants in the water condition read about a challenging draught period that limited "the amount of water available, for example, to take showers." Participants then had to face a social dilemma, in which they were asked to indicate how much money [water] they would take for themselves, leaving less resources available for the public good.

Consistent with our prediction, we found a significant color X context interaction on the amount of resources taken, *F*(1, 140)=4.48, *p*=.036. In the money condition, participants primed with green (*M*=61.49, *SD*=32.21) took more money than participants in the control condition (*M*=54.58, *SD*=27.08); in the water condition, participants primed with green (*M*=52.30, *SD*=24.74) took less water than participants in the control condition (M = 65.21, SD = 27.68).

Across three studies we show that, compared to a neutral color, green can increase selfishness in the context of money but decrease it in the context of natural resources. These results shed further light on the processes by which nonconscious primes can elicit different patterns of behavior within the same group of people depending on which of its associations are relevant in a particular context.

Incidental Resource Cues and Conservation in Consumption

EXTENDED ABSTRACT

Conservation and environmental issues is a textbook case of a "wicked problem" as the problems are complex and ambiguous (Rittel and Webber 1973). In many consumption contexts, waste arises primarily from consumers' over-acquisition of the amount of resources required. While a rich body of research has explored factors that influence the level of consumption and provided important insights for understanding how much people consume (e.g., Folkes, Martin and Gupta 1993; Wansink 1996), prior research has not distinguished between how much is acquired versus how much is consumed and the difference between the two. We conceptualize waste in consumption as the difference between the amount of resources acquired and the amount of resources required for a consumption situation. We propose that waste in consumption has two instantiations, pure loss of resources (which occurs when the amount of resources acquired is greater than the amount of resources consumed) and inefficiency in usage (which occurs when the amount of resources consumed is greater than the amount of resources required). Conservation can be achieved by reducing both pure loss and inefficiency.

The focus of this research is to examine the impact of resource availability on conservation in consumption. We conceptualize abundance to be an excessive supply of resources whereas non-abundance is sufficient but non-excessive supply of resources. Non-abundance differs from scarcity in the sense that scarcity refers to insufficient supply of resources. We focus on situations where the supply is always sufficient but simply differs in terms of excessiveness. We anticipate that perceiving resources as non-abundant can curtail acquisition, thereby temporally prompting conservation behaviors. Evidence for our theorization can be found in the biological literature, which shows that species lower consumption rates when resources appear to become scarcer (Hanson and Leggett 1986). Additionally, the sociology literature suggests that in late-modern and industrialized society, abundance became more taken-for-granted supplanting non-abundance, which has lead to highlighted consumerism and attendant over-acquisition (Côté 1993). Broadly building upon evidence suggesting that environmental cues in a prior context can influence decision-making in subsequent unrelated contexts by affecting mental representation and accessibility of different knowledge structure (Bargh et al., 1996; Dijksterhuis, Chartrand and Aarts 2007; Förster, Liberman and Friedman 2007; Kay et al. 2004), we posit that incidental cues indicating one particular resource as non-abundant can reduce the cognitive accessibility of the general construct of abundance and trigger the tendency to conserve. Further, this conservation tendency can persist into subsequent consumption even when different resources are utilized.

Experiment 1A shows that incidental cues highlighting non-excessiveness of a resource (a pencil stub) can reduce pure loss of an unrelated resource (lead participants to acquire and waste less water in a later sampling task). Experiment 1B extends the main effect to inefficiency in usage, showing that simply taking away vs. leaving a drink bottle on participant's desk in a drink sampling reduced the amount of paper participants used in a later wrapping task.

Experiment 2 tests whether cues indicating non-abundance can reduce the accessibility of cognitive representation of the general construct of abundance. To do so, we first exposed participants to either non-abundance or abundance cues in a sampling task. We then measured the accessibility of cognitive representations of the notion of abundance employing a lexical decision task that requires participants to determine whether certain letter strings are words

or not. Consistent with our theorization, we found that participants who were exposed to the non-abundance cue responded slower to abundance related words than participants initially exposed to the abundance cue, and that there was no significant difference in the response times for neutral words across conditions.

Experiment 3 tests whether the perception of abundance vs. non-abundance is sufficient to prompt conservation in subsequent consumption. We show that providing the same amount of resource (1/3 cup of cooking oil) in a larger vs. smaller container led participants to perceive the resource as less abundance and subsequently motivated them to taking an extra action to conserve energy (turn off lights when leaving an empty room). Importantly, we find that when the cooking oil was provided in the bigger vs. smaller cup, participants still indicated that they had sufficient amount of resources. These findings suggest that the deviation from abundance (i.e., non-abundance, denoting the sufficient but non-excessive supply of resources) rather than scarcity (i.e., denoting insufficient supply) is adequate to prompt conservation behaviors.

In the last experiment, we discriminate against different theoretical accounts that could be responsible for the carry-over effect of incidental resource cues on conservation. We find that giving participants a chance to conserve in a social domain that is unrelated to consumption before taking resources for subsequent consumption attenuated the influence on non-abundance cues on conservation. These results suggest that the underlying mechanism is motivational, as once the motivation is satisfied, participants no-longer engaged in conserving behaviors. However, the non-motivational accounts of priming conservation-related concepts and traits predict the opposite pattern, as engaging in a conservation action would have made conservation-related concepts and traits even more accessible and salient. Our findings are consistent with recent literature on "green licensing" showing that purchasing green products can produce unintended effects licensing people to act unethically in subsequent tasks (Mazar and Zhong 2010).

This research offers several theoretical contributions. While extant consumer behavior literature has primarily focused on consumption, our theoretical approach also incorporates resource acquisition. While the level of specificity examined in the existing literature on supply and usage is domain specific, our research demonstrates that cues suggesting non-excessiveness of a particular resource not only influence perceptions of the cue-specific resource but also impact the cognitive accessibility of the general notion of abundance and therefore trigger conservation behaviors regarding an unrelated resource. Our findings also offer implications for marketing practitioners. From a firm's standpoint, costs can be curtailed if employees waste fewer resources. Additionally, it is in the firms' best interest that consumers waste less when (1) consumers pay a fixed price and then make consumption quantity decisions, (2) consumers have the option to use firm resources that they do not have to pay for.

Moral Compensation and the Environment: Affecting Individuals' Moral Intentions Through How They See Themselves as Moral

EXTENDED ABSTRACT

To maintain a positive moral self-image, individuals engage in compensation: current moral behavior licenses future immoral behavior and current immoral behavior stimulates future moral behavior (Jordan et al., 2011; Monin & Miller, 2001; Zhong & Liljenquist, 2006). In the current investigation, we examine the relationship between behaviors that stimulate changes to one's moral self-image (Jordan et al., 2011) and his or her ethical intentions and actions. We argue that moral compensatory effects are a function of changes to one's moral self-image. In other words, it is not the mere priming of a moral or immoral frame via one's behavior that leads to compensatory effects. But rather, such behavior must be sufficient enough to impact one's moral self-image in order to lead to compensatory effects. Recalls or priming that only lead to small changes to the moral self (i.e., are not severe) are unlikely to have an impact on one's self-image (Baumeister, 1999).

We examine this question via two studies. In Study 1, we have individuals recall either few or many (im)moral behaviors that they take in regards to the environment. In Study 2, we provide individuals with either minor or extreme feedback about the states of their moral selves. We then examine their intent to engage, as well as their actual engagement in, in various moral or immoral behaviors.

Study 1. We used a field-based experimental study to investigate the relationship between the valence and magnitude of one's moral recalls and subsequent intentions to behave ethically.

Participants, Design, and Procedures

Through a partnership with a CO2 offsetting NGO, we surveyed 186 individuals who had offset their flight emissions. These participants first recalled their past (im)moral behavior, after which they were asked about their support for programs encouraging CO^2 emission offsetting, constituting our dependent variable. We manipulated moral self-image via a 2 x 2 between-participants design: the valence of participants' recalled behavior (moral/immoral behaviors) and the magnitude of their recalled behavior (either asked to recall two or eight environment-related activities). To measure ethical intentions, individuals were then asked to indicate how likely they would be to (1) support regulations for mandatory CO^2 offsetting premiums, (2) how willing they would be to pay a mandatory premium for CO^2 offsetting, and (3) how much they support corporate initiatives to offset CO^2 emissions even if it meant them having to pay higher prices (α = .81).

Results

Replicating the moral compensation effects, we found a main effect of recall, $F(1, 185) = 4.87$, $p = .03$. Individuals who recalled environmental conservation activities reported lesser intentions to engage in activities to offset their CO^2 emissions ($M = 6.36$, $SD = 0.91$) than did those who recalled environmental destruction activities ($M = 6.55$, $SD = 0.52$). In support of moral self hypothesis, results also demonstrated an interaction between the valence of recall and the magnitude of recall, $F(1, 185) = 8.06$, $p = .005$. Those who recalled eight moral items (i.e., those that elicited a more positive moral self-image) were significantly less likely to support programs to offset CO^2 emissions than were those who recalled eight immoral items (i.e., those that elicited a more negative moral self-image), $t(185) = 3.31$, $p = .001$. However, there was no difference between individuals who recalled two moral versus two immoral items, $t(185) = 0.49$, $p = .63$.

Study 2. Study 2 extends the results of Study 1 by more obtrusively manipulating the state of individuals' moral selves via providing them with explicit moral-self feedback. Also, in contrast to Study 1, we examine the effects on both immoral behavior and environmentally-related moral behavior.

Participants were 106 students. We manipulated moral self-image by providing individuals with feedback on the states of their moral selves. Participants believed that they were participating in two separate studies. They were first asked to write about the activities they do to help the environment. We then told them that this was actually a validated measure of people's moral selves. Participants

then received one of five types of feedback: they were (1) highly above, (2) slightly above, (3) slightly below, or (4) highly below average in morality. A control condition received no feedback. They then began Study 2, which they were told was about transferring paper-and-pencil measures to the computer. They had to complete 15 math problems in their heads and had an opportunity to cheat on each. We measured how many times, out of the 15, they looked at the answers (Jordan et al., 2011; von Hippel et al., 2005). At the end of the study, we gave them a coupon, which they could cash in for a drink at the university's café (valued at €1.40) or could place in a box, and €2 would be donated to the environmental charity, Greenpeace, on their behalves.

Results

As predicted by the moral compensation hypothesis, there was an effect of moral feedback, such that individuals who received feedback that they were highly moral (M = 6.31, SD = 7.62), cheated on significantly more problems than those receiving feedback that they were highly immoral (M = 1.94, SD = 2.61), $t(18.28) = -2.18$, $p = .04$; however, consistent with the moral self hypothesis, there was no difference for those receiving feedback that they were slightly moral vs. immoral, $t(35.78) = .09$, $p = .93$. In addition, extremity of moral feedback affected individuals generosity towards the environment, $X^2(1,106) = 13.63$, $p = .02$, with 3 out of 16 individuals in the extremely moral condition versus 9 out of 17 in the extremely immoral condition donating it to Greenpeace. In contrast, these values for the slightly above and below conditions were equivalent (7/19 for the slightly above; 10/19 for the slightly below).

These findings provide support for our prediction that moral compensation operates through changes to individuals' moral self-image: one's moral or immoral self-recalls must be substantial enough to impact how much he or she sees him or herself as a moral person. Current experiments are examining actual changes to individuals' moral selves and how these changes explain these compensatory findings.

When You Don't Care Enough to Give the Very Best: When Gifting Leads to Less (vs. More) Green Choices

EXTENDED ABSTRACT

Consumers often need to decide what gifts to give to valued others. They often face choices between environmentally or ethically inferior vs. superior versions of the same gift. Do you buy a box of chocolates or Fair Trade chocolates; a bottle of wine or biodynamic wine; a cotton or organic cotton shirt; a bouquet of tulips or Rainforest Alliance Certified tulips for those you love? Retailers and media outlets increasingly emphasize opportunities to give green gifts, but we know relatively little about when and why consumers choose to give environmentally and ethically superior vs. inferior gifts. Common wisdom would suggest that consumers spend more or buy superior goods for people they care most about. However, we find that the signal value of green gifts changes across different types of relationships and gender, challenging common assumptions regarding when consumers choose to give green.

While most people claim they care about environmental conservation and view themselves as ethical individuals, it is likely that, in the past, they have chosen to purchase environmentally unfriendly or unethically produced products (e.g., products produced through child labor or environmental degradation). We know that ethicality can influence the likelihood consumers purchase products *for themselves* (Luchs, Naylor, Irwin, and Raghunathan 2009; Sen and Bhattacharya 2001; Stahilevitz and Meyers 1998). However, we

know relatively little about when and why consumers are motivated purchase green products *for others*. Research on gift-giving (Belk, 1979; Otnes and Beltramini, 1996; Vesterlund, 2006) suggests that individuals' motives for offering gifts and factors that influence gift-giving vary markedly; they include duty, self-interest, love, reciprocity, compliance with social norms, and concern for others (Goodwin, Mick and DeMoss 1990; Smith, and Spiggle, 1990; Sherry, 1983; Wolfinbarger, 1990). Notably, gifts offer an important form of symbolic communication (Sherry, 1983) and impose an identity on both the giver and the receiver (Schwartz, 1967). In sum, gift exchanges hold tremendous signal value. To date, very little is known about what drives consumers' demand for green products when given as gifts. The present research addresses this gap and asks the following question: when and why do consumers choose more vs. less green gifts for others? We investigate this question across different types of gifts and different types of relationships (i.e., romantic vs. platonic).

In study one, we examine choices of products gifted to a significant other (romantic partner) for a major holiday. The study employed a 2 (media exposure: yes vs. no) x 2 (respondent's gender: male vs. female) between-subject factorial design. The media exposure manipulation consisted of a 4-minute video from NBC's Today Show about opportunities to buy green gifts (media exposure condition) or not (no media condition) prior to making their choices. Greenness of gifts was operationalized through the use of standard vs. fair trade brands of chocolate and greeting cards. Participants examined actual products and chose one of the two products to gift to their romantic partner; 5% of the participants (randomly chosen) received the actual product of their choice. We found that the percentage of females choosing green gifts was significantly *lower* than their male counterparts. Here the green option may simply be seen as an added benefit rather than having ethicality or signaling implications. Thus, in study two we manipulate the explicitness of ethicality information.

In study two, participants were asked to choose one of two bottles of wine as a gift for their significant other for a special occasion. Study 2 consisted of a 2 media exposure (yes vs. no) x 2 (respondent's gender: male vs. female) x 2 information about ethicality (explicit vs. implicit) between-subject design. Consistent with study 1, females chose fewer green gifts for romantic others, regardless of whether the ethicality information was implicit or explicit. Since females are typically thought to be more responsive to ethical and conservation appeals, these findings are noteworthy. Under what circumstances *do* females give green gifts? In particular, to what extent does the type of relationship matter?

In studies three and four, participants chose between two bouquets of flowers for a close female friend, and we varied the durability of the ethical cue. That is, whereas the marker of ethicality on packaging (e.g., a box containing chocolate or a bottle containing wine) is fleeting, gifts with enduring markers of ethicality may offer a different and more enduring signal. In study four, flowers were accompanied by branded vases, and in study five, participants made choices of durable goods (e.g., a shirt) for a friend. Respondent's gender (male vs. female) was measured; durability of ethical cue (not durable vs. durable) and knowledge of options (recipient knows vs. recipient does not know) were manipulated between subjects. We found that females were more likely to choose the green gift options, particularly for female friends, but only when the ethical information was durable. Study six replicates and extends these findings by systematically varying the gift-recipient (romantic partner vs. friend) within a single study and providing additional process evidence.

Previous work suggests that consumers buy lower quality green products for themselves as a "costly signal" associated with status (Griskevicius, Tybur, and Bram Van den Bergh 2010). In our studies,

we investigate choices for others and hold quality constant and also offer higher quality green products. Our results show when and why consumers choose green goods for others as a way to signal distinct forms of relational value and desired impressions of the self rather than to consume in ways consistent with expressed values (i.e., pro-environmental attitudes or moral identity) or status. Across studies we find that the probability of choosing a green or environmentally friendly gift depends largely on the giver's perception of its distinct signal value to the recipient in the context of the relationship. Consumers, particularly women, are especially sensitive to the signal value of gifts and more strategic about when they choose to give ethically and environmentally superior gifts. Our findings suggest that gift-giving is not simply about the joy of giving, nor about the joy of buying green or ethically superior gifts for the sake of *being green* but rather the signaling benefit of *being seen* as green or ethical *but only* by select groups of others. The distinct asymmetries between genders in choices of gifts and distinct signaling motivations for green behaviors offer a rich area for future research.

New Theoretical, Managerial, and Societal Perspectives on the Consumer

Paper #4: Consumer Culture Theories of the Consumer and Developing New Conceptualizations

Ahir Gopaldas, York University, Canada

SEESION OVERVIEW

Objectives. The consumer in all his or her theoretical and practical manifestations ought to be a primary focus of consumer research. However, many consumer researchers are educated in only one or two dominant conceptions of the consumer (e.g., consumer as information processor, meaning maker, or utility maximizer). Much too quickly, these conceptions become taken-for-granted implicit assumptions, fostering myopic theoretical refinements rather than revolutionary theoretical breakthroughs. The objective of this special session is to awaken consumer researchers to multiple old and new ways of thinking about the consumer. Specifically, the objective of the papers is to foreground and evaluate conceptions of the consumer from role-theoretic (paper 1), managerial (paper 2), societal (paper 3), and meta-theoretical (paper 4) perspectives.

One might say that the creators of this special session snatch Consumer from his everyday job as a minion at Marketing Imaginary Limited and seat him on a curious but caring therapeutic couch. They dig deep into the unconscious of consumer experience (paper 1), consumer management (paper 2), consumer society (paper 3), and consumer research (paper 4). They analyze his job function (paper 1), ask what his managers think of him (paper 2), wonder what society expects of him (paper 3), and of course, dig up his past and imagine his possible futures (paper 4).

1. Jodie Whelan, Miranda Goode, and June Cotte filter consumer research to distill the core characteristics of the consumer role; they pinpoint *materialism*, *self-focus*, *empowerment*, and *hopefulness*. They then collect visual data to discern how individual persons actually enact the consumer role and discover five variations: the *blended* consumer, the *romantic* consumer, the *unidimensional* consumer, the *self-aware* consumer, and the defensive consumer. What these authors do for the consumer concept in consumer research is as important as what Kohli and Jaworski (1990) did for the marketing concept (a.k.a., market orientation) in marketing research – they bring a foundational and fundamental but curiously under-theorized concept to life.

2. Sarah Wilner goes where few consumer researchers have gone before – into the depths of Fortune 500 marketing departments – to explore how managers relate to their imagined consumers. Over time, the author discovers that marketer-consumer relationships range from the personal (*consumer as friend*) to the professional (*consumer as client*) and from the intimate (*relating via empathy*) to the clinical (*relating via data*). What is not revealed in this abstract is the incredible behind-the-scenes work it requires to gather such data. Beyond professional networking and international travel, this research necessitates gaining the trust of not lay consumers but highly-skilled consumer research practitioners. Illuminating both the inner workings of marketer minds and the departmental politics of product development, this paper drops us right into the *real* intersection of consumer research and marketing strategy.

3. Can Uslay, Gokcen Coskuner-Balli, and Dhruv Bhatli spotlight a curious trend in contemporary society. As institutions become more concerned with safety (under the rubric of risk management), citizens are increasingly engaging in risky consumer behavior. To solve this puzzle, this paper takes us on an exciting journey from Kennedy to Reagan, from gambling to marijuana, and from global risks to individual anxieties. When the dust settles, we discern the connection between the construction of the individualist consumer citizen and the commoditization of risk. This paper attempts the sort of macro-social analysis that too few consumer researchers dare. How are societies changing? More importantly for us, how are consumers changing? And, what are the links among these changes in societies and consumers?

4. Ahir Gopaldas first surveys how consumer culture theorists have variously conceptualized the consumer (e.g., consumer as meaning maker, self concept, relationship partner, community member, structured agent, etc.). He then identifies the unique implications of each conceptualization for collecting qualitative data, building grounded theory, and constructing marketing strategy. While other papers in this session offer new perspectives on the consumer using exciting data, this paper cashes out the empirical, theoretical, and managerial payoffs of the perspectives that already exist. Finally, and most importantly, he discusses how junior scholars can develop new conceptualizations of the consumer to answer recurring calls for 'new perspectives' in marketing theory and practice.

Questions for Discussion. In 2007, John Deighton clarified what ought to be the *core content* of consumer research: *not* general theories of human behavior that can be applied to consumption, *but* consumption-specific constructs and relationships that are our expertise exclusively. In 2010, Deborah MacInnis and Valerie Folkes took stock of the content debate in consumer research from a sociology of science perspective and offered the following conclusion: "con-

sumer behavior is distinguished from other fields [of human behavior] by its focus on a consumer role" (899). Also in 2010, the JCR editorial team invited consumer researchers to produce 'integrative summaries' and 'new perspectives' because "both types of papers are important means by which a field moves forward." Accordingly, the discussants are invited to evaluate one session-wide question and four paper-specific questions. Do the papers in this session begin to realize the increasingly unanimous vision for truly consumer-specific research? In other words, do the papers in this session re-shape the boundaries of consumer research in a visionary or dangerous direction?

1.   Does exploring the phenomenological (de)activation of the consumer role within and beyond consumption contexts sharpen or blur the boundaries of consumer research?

2.   Consumer psychology and consumer culture theory have thrived for decades on laboratory experiments and consumer ethnographies. Should we care how managers think of and relate to consumers?

3.   Most consumer researchers don't read history, let alone futures studies. Should we continue assuming consumer behavior is a hard (trans-historical) science or start observing how 'consumer' is a fragile concept evolving with society?

4.   Will positioning conceptualizations of the consumer – numerous, contested, and ever-changing as they are – at the heart of consumer research provide the discipline an enduring and anchoring theoretical puzzle or foster a Tower of Babel?

Building Connections. Consumer research has a responsibility to the broader social science community: it must lead the academic conversation on the meanings and functions of the consumer concept. This special session takes this scholarly duty to advance theories of the consumer rather seriously. However, the authors of these papers also collectively aim to make important connections across disciplinary, methodological, and social boundaries. First, although the papers are mostly crafted in the tradition of consumer culture theory, they extensively converse with other disciplines: consumer psychology (paper 1, 4), marketing strategy (paper 2, 4), and the sociology of consumption (paper 3, 4). Second, the session also connects methodological solutions to conceptual problems in a novel or at least non-routine way. By strategically employing image-based projective techniques (paper 1), extended ethnographic engagements (paper 2), multi-sited netnographic research (paper 3), and meta-theoretical analysis (paper 4), the session celebrates the diversity of methods in the qualitative marketing research toolkit (Belk 2006). Finally, this special session also hopes to build social connections in a quite literal way: the authors and discussants collectively represent 3 countries, 7 universities, and scholars at multiple stages of their career – from PhD candidates to JCR editors.

The Consumer Role: Core Characteristics and Personal Boundaries

EXTENDED ABSTRACT

Despite the centrality of the consumer role in today's society, a rich description of the role is surprisingly underdeveloped. Describing the consumer role is extremely important, because as Folkes (2002) points out, "when situational cues lead people to perceive themselves as customers, they then interpret the world differently than when they do not perceive themselves as customers, and that influences their behavior" (1). In other words, a clear definition of the consumer role will provide us with the foundation needed to further investigate the consequences of being a consumer—both within and beyond the consumer context. Using role theory and boundary theory, we first provide a detailed conceptualization of the consumer role and second, use image-based qualitative interviews to explore how individuals embody the consumer role in their daily lives.

Core Characteristics of the Consumer Role. Like actors playing specific roles, people behave in ways that are different and predictable depending on the context and the role they occupy. Broadly speaking, roles are defined as a "certain persona—replete with specific goals, values, beliefs, norms, interaction styles, and time horizons" (Ashforth, Kreiner, and Fugate 2000, 475). To simplify, we define the consumer role as the core set of characteristics that guide behavior during the pursuit and acquisition of marketplace goods and services.

To identify the core characteristics of the consumer role, we rely on a thorough literature review of the history of consumerism and research on compulsive buyers. From this, we identify four core characteristics of the consumer role: materialism, self-focus, empowerment, and hopefulness. First (and not surprisingly), the consumer role is linked to materialism. Materialism is the value an individual places on the acquisition and possession of material goods, especially for their symbolic purposes (Richins and Dawson 1992). Not only does the Veblenesque account of the rise of consumerism highlight the symbolic importance of consumer goods (Veblen 1899/1953), but compulsive buyers also tend to be highly materialistic (O'Guinn and Faber 1989). In addition, if the consumer role is materialistic, it must also be self-focused as materialism is a self-focused value (Burroughs and Rindfleisch 2002). Empowerment is another core characteristic. Stearns (2001) proposes that the consumer revolution occurred because women were desperate to regain control over their lives, a feeling that is often echoed by compulsive buyers (Faber 2000; Krueger 1988; O'Guinn and Faber 1989). Lastly, Campbell's (1987) account of the consumer role as being driven by hope, daydreaming, and disillusionment is supported by the consistent finding that compulsive shoppers have a high propensity to fantasize and are quickly disenchanted with their purchases (Faber 2000; Krueger 1988; O'Guinn and Faber 1989). Thus, we propose that the consumer role is materialistic, self-focused, hopeful, and empowering.

It is important to note that traditional role theory regards roles as shared, social conceptions that "are clearly defined and agreed upon by society" (Solomon et al. 1985, 101). Recently, however, research explores how an individual's own understanding of a social role results in a role that, to some degree, is unique to the individual (Neale and Griffin 2006). To explore how the consumer role varies across individuals, we turn to boundary theory and image-based qualitative interviews.

Consumer Role Boundaries. Individuals create boundaries to maintain or modify social roles (Nippert-Eng 1996). Depending on the strength of their boundaries, roles may be classified along an integration-segmentation continuum: integrated roles have weak and flexible boundaries and segmented roles have strong and inflexible boundaries (Ashforth et al. 2000; Clark 2000; Nippert-Eng 1996). To better understand individual variations in consumer role boundaries and their subsequent impact on the enactment of the consumer role, we conducted nine depth interviews using visual images selected by our participants (Zaltman 1997; Zaltman and Coulter 1995). Our analysis revealed five variations of the consumer role, which

we characterize along the integration-segmentation continuum as the blended consumer, the romantic consumer, the unidimensional consumer, the self-aware consumer, and the defensive consumer.

For the blended consumer, consumer role boundaries are largely non-existent. The consumer role is highly integrated and almost inseparable from other life domains. The consumer role is not the dominant role but is subsumed under another more salient role. The romantic consumer is also highly integrated but still somewhat separable. This consumer embraces the consumer role precisely because of the characteristics identified above, with little or no concern for the potentially negative consequences of being a consumer (e.g., overspending). Boundaries are virtually nonexistent, and transitioning into the consumer role occurs frequently and often unintentionally. The unidimensional consumer also embraces the consumer role, but to a lesser degree. Though this individual is materialistic, self-focused, hopeful and empowered when in the consumer role, at least one of these characteristics is clearly dominant. The self-aware consumer is mindful of both the pros and cons of being a consumer and erects some boundaries to maintain control of when and why the consumer role is entered. Lastly, the defensive consumer erects strong boundaries and is extremely weary of being under the influence of the consumer role.

In exploring the consumer role along the integration-segmentation continuum, several interesting insights emerge. First, the more segmented the consumer role, the less likely the individual is to experience both advantages and disadvantages of the consumer role. Further, maintaining extreme segmentation seems exhausting given how pervasive the consumer role is in today's society. Lastly, the more segmented the consumer role, the more mindful transitioning into the consumer role is likely to be.

Implications. Our research provides a rich conceptual description of the consumer role, while also demonstrating that this role is highly influenced by the idiosyncratic nature of consumer role boundaries. Counter to boundary theory's penchant to examine role integration/segmentation in the context of two roles (e.g., work and family), we also show that roles and their boundaries can be studied independent of other roles. Finally, our research provides the conceptual foundation necessary to explore further why people seek out the consumer role, how individuals can manage their consumer role transitions, and how the consumer role can impact behavior and relationships in non-consumer contexts.

A Less-Than-Immaculate Conception: Investigating the Relationship Between Product Developers and Their Imagined Consumer

EXTENDED ABSTRACT

Consumer researchers have examined consumers' relationships with brands, products and organizations (e.g. Fournier 1998; Muniz and O'Guinn 2001; Bhattacharya and Sen 2003) but remain largely indifferent to the perspective of the managers who produce the objects and symbols with which consumers interact (for exceptions see Cayla and Eckhardt 2006; Desroches and Marcoux 2007). This is fundamentally problematic because, "for a relationship to truly exist…the partners must collectively affect, define and redefine the relationship" (Fournier 1998:344).

Accordingly, this paper examines managers' relationships with their imagined consumers (Cayla and Eckhardt 2006) in the context of product development. Product development is a rich context for examining the relationships producers construct with consumers, because it is during this process that managers actively explore and address the fundamental nature of consumers' motivations, desires and behaviors. The study was initiated by examining the myriad of tools, artifacts and processes that are employed to construct or otherwise reify consumers in the course of product development. This foundation in turns, informs the study's focal question: What is the nature of the relationship between members of product development teams and the consumers they develop for?

Method. The author conducted a multisited ethnographic study of five Fortune 500 firms' strategic business units over 18 months. Data from focal firms was collected via semi-structured interviews with key informants; participant-observation of product development activities and collection of archival information from the firms as well as media reports. Additional interviews with informants in nine other consumer goods and consulting firms were conducted to enhance the validity of findings. Sampled firms represent multiple industries and product categories including: consumer packaged goods; consumer durables; high-tech equipment and medical services.

Findings. Relationships between members of product development teams and their consumers vary along two primary continua: a role orientation ranging from personal (e.g. consumer as friend) to professional (e.g. consumer as client) and an interaction dimension ranging from the intimate (e.g. empathy or shared experience) to the clinical (e.g. data dominates). Importantly, the nature of each manager's relationship with a given target reveals a mental model reflecting both personality traits and life experiences. Thus, managerial relationships with consumers can vary considerably, even among members of the same product development team. Conversely, managers may be motivated to revise initial schemas about consumers in the course of collective sensemaking (cf. Weick et al. 2005).

To illustrate, managers with a strong professional role orientation as well as a sense of empathy for their consumer subjects might construe the targeted consumer as a potential victim, deserving of protection or advocacy. This is the case with Katherine[1], who works in research and development for 'Better Living'[2], maker of personal care products. She explains, "I kind of see myself as a soldier for the consumer. There are definitely marketers and other people inside the company for whom it's more about chasing the money than the longer term solution…I'm more worried about the long-term consumer behavior than quarter-to-quarter" (personal interview, August 2009).

Producer-consumer relationships are subject to the vicissitudes of insight gleaned from consumer intelligence and as such are an integral factor linking consumer research and product development. For example, at 'Crunchies', a packaged food company, retail transaction data indicated that mothers of teenage boys were key buyers of the company's bestselling snack. Given stereotypes of mothers as the nuclear family's primary provider of nourishment and caretaker of health, producers assumed that the mothers would be concerned with these issues when making purchase decisions and product development efforts focused on increasing the snacks' nutritional profile. However, subsequent ethnographic research revealed that many mothers were more interested in increasing their son's social capital than salubrity. These mothers aspired to create a context in which their teen was seen by peers to have the "right stuff" (including snack foods), and for their home to become the preferred place for her son's friends to gather. The discovery of this insight instantly converted the development team's interpretation of the buyer segment from hard-to-please "Shopper Moms" to impressively cool "Kick Ass Moms."[3] This reframing of the consumer not only shifted

[3] Verbatim segment names provided by informants.

the focus of product development activity from nutrition to seasoning with adolescent appeal, it fundamentally changed the nature of the producer-consumer relationship. Once characterized by limited mutual affect and buyer-dominant power (see Hinde 1995:6), the relationship became one in which the customer not only ceded power but was also vulnerable, for both her son's popularity and her legacy as a mother were at stake. Interestingly, while the company had hired a brand consultancy to create an elaborate consumer archetype complete with a lifestyle "mood board," the director of brand innovation (and author of the "Kick Ass Mom" epithet) denied using personas as a reference or representational tool. In interviews, not one member of the team could remember the archetype's name. They did, however, all know his mom's.

Implications. Recognizing that producers, like consumers, seek and value relationships with their dyadic counterpart illuminates aspects of the logic by which consumer research is specified, interpreted and ultimately applied. However, there remain at least two significant challenges to the creation of meaningful producer-consumer relationships. The first is evinced in the remainder of Katherine's statement above, which continues: "The thing about our marketing department is that they focus max three years out and so from a brand perspective…it's still more quarter-to-quarter focus. That's how their bonuses are structured." Katherine's cynicism towards marketers on the development team reveals the inescapable tension produced by conflicting consumer orientations among members or functional areas. While copious research has examined the implications of cross-functional cooperation/conflict on new product performance, it has neither considered product developers' envisaging of consumers nor the resulting relationships a source of contestation. This finding suggests that surfacing managers' tacit relationships with consumers may aid in reducing resource-draining conflict. This might, for example, take the form of an instrument akin to the Myers-Briggs Type Indicator which could be employed to diagnose managers' predispositions and expose them to potential sources of divergence.

A second fundamental challenge is organizational turbulence. If "temporality distinguishes the relationship from the isolated transaction," (Fournier 1998:346; see also Hinde 1995:2), given the volatility of current organizational design, producers will be fated to mere transactional interactions despite their stated desire for close and sustained consumer relationships. All of the focal firms in the sample have engaged in relentless reorganization since the inception of the research project, with managers laid off or repeatedly re-assigned from key consumer research and interpretive roles. Without continuity of interaction and experience with valued consumer segment, individual managers may be unable to foster empathy for their consumer subjects, a condition Fournier et al. (1998) argue fosters a marketplace marked by consumer alienation and dissent. Senior executives, removed from day-to-day operations, understandably may not experience the same quality or intensity of consumer relationship experienced by their managers. It is imperative, therefore, that decision makers motivated to reorganize in the name of revised strategic goals be sensitized to the ramifications of frequent relational dislocation among managers and their consumers.

The Construction of the Individualist Consumer-Citizen and the Commodification of Risk

EXTENDED ABSTRACT

There is a paradox in post-industrialized societies. On one hand, societies are characterized by an increasing concern with the management of risk (Beck 1992). On the other hand, there is an increasing consumer involvement in risky activities (e.g. extreme sports, home birth, gambling, consumption of diet pills, marijuana, and junk food).

The socio-cultural conditions that gave rise to this paradox are closely linked to the construction of the individualist, self-interested citizen in free market economies (Cohen 2003). The consumerism movement initiated by Kennedy in the sixties came of age at the end of the seventies in all but emerging or closed markets. In the US, especially after the election of Reagan, neoliberal discourses with decreased government intervention gained prominence (Aaker and Day 1982). Being subject to the uncertainties of capitalism itself and facing the difficulties of calculating risks, the state transferred its responsibilities to its citizens, other market institutions (Neary and Taylor 2006), and communities of reflexive doubt (Giddens 1991). Scientific and technocratic expert communities, like the state, delegated ultimate responsibility of risk management to consumers (Thompson 2005). Furthermore, the state became increasingly involved in the commoditization of risk, as exemplified in the increasing production and marketing of gambling by the state (Young 2010).

In this cultural setting, we explore how consumers conceptualize, experience and justify their involvement with risky consumption practices. Towards this objective, we conducted a netnographic analysis to observe consumer interactions on various online consumer platforms (communities, discussion forums, blogs and social networks) focusing on consumption practices such as online gambling, marijuana consumption and drug use for weight loss and body enhancement. The data collected are mainly electronic messages exchanged by online users and were later coded and interpreted.

Implications. The contributions of this research are threefold. First, our analysis aims to assess consumers' conceptualization of various types of risks. Young (2010) suggests that there is a dialectical relationship between global and undifferentiated risk (associated with anxiety) and individual differentiated risk (associated with pleasure). Global risks are "unbounded, external and affect all society" whereas individual risks "appear as personal choice, are bounded and internal" (265). We build on his thesis by exploring the relation between global and individual risk. For example, consuming junk food is a pleasure-based consumption activity that poses individual consequences on an immediate term. However, it can also be transformed into a more global anxiety with the increasing rates of obesity and national health problems. Furthermore, we examine how anxiety-based risks are experienced at the individual level and elaborate on the multiplicity of discourses and practices these industrial risks create. For instance, consumers might share the anxiety of global warming but neither experience nor act upon it in a uniform fashion.

Second, our netnographic study illuminates the nature of consumer decision-making experiences as consumers face a multiplication of expert communities. We investigate whether consumers find the increasing individualism and commodification of risk as liberatory or overwhelming. Consumers' risk taking propensities are underlied by two forces: simplification and complification (Howard and Sheth 1969). Consumers reduce the complexity of decisions by using heuristics or shortcuts and satisficing criteria. On the other hand, the countervailing force of complification necessitates the consideration of additional options and involves risk. Our study suggests that in most developed consumer markets the need for complification is on the rise. Based on their risk-taking propensity, consumers are taking additional risk and expressing their individuality. In many cases, this creates great opportunities for marketers to recognize and respond to these individual desires with new and customized offerings (e.g. insurance policies for extreme sports and bank loans for

plastic surgery). In other cases, the outcome is tension between simplifying regulation efforts that reduce the risk-taking propensity of the population to a normative uniform/risk-averse function (e.g., do not gamble online).

Third, we demonstrate how various groups construct notions of risk and safety and how they define the boundaries of individualism and free choice. Risk and safety are legitimated and promoted in accord with the economic and political interests of the involved agents –consumers, marketers and the state. The recent discussion on the legalization of marijuana is a case in place documenting the multifaceted process of 'normalization'.

Consumer Culture Theories of the Consumer and Developing New Conceptualizations

EXTENDED ABSTRACT

This article has three objectives. First, it surveys how consumer culture theorists have variously conceptualized the consumer in consumer culture theory. Examples include the consumer as *meaning maker* (e.g., Levy 1959), *feeling being* (e.g., Hirschman and Holbrook 1982), *self concept* (e.g., Belk 1988), *metaphorical processor* (e.g., Zaltman 1995), *relationship partner* (e.g., Fournier 1988), *community member* (e.g., Muniz and O'Guinn 2001), *structured agent* (e.g., Crockett and Wallendorf 2004), *network actor* (Epp and Price 199, and *multiphrenic self* (e.g., Bahl and Milne 2010)).

Second, the article identifies the unique implications of each conceptualization for collecting qualitative data, building grounded theory, and constructing marketing strategy. For example, the conceptualization of the consumer as a *multiphrenic self* suggests motivating consumption in one of two ways. Marketers can promote a product as a self-serving solution to a particular kind of self shared by many consumers (i.e., an archetypal self). Alternatively, marketers can promote a product to the meta-self as a solution to common goal conflicts among selves. The conception also hints that new markets may be created by inventing new archetypes (e.g., *GQ* men and *Harley* bikers). To demotivate consumption, advocates could help consumers identify their multiple selves and heal their dysfunctional selves. Thereafter, consumers must learn strategies for resolving conflicts among selves (e.g., coalition), such that a few versatile consumables can serve the interests of multiple selves.

Third, and most importantly, the article discusses how theorists, especially junior scholars, can develop new conceptualizations of the consumer to answer recurring calls for 'new perspectives' in consumer and marketing research. The value of articles that explicitly or implicitly offer new conceptualizations of consumption (Belk 1988; Fournier 1998; Muniz Jr. and O'Guinn 2001) is evidenced in their relatively high citation counts, disproportionate numbers of awards, and frequent appearance in doctoral course syllabi. Owing to the importance of new conceptualizations, this article addresses the question: *how do theorists develop new conceptions?*

New conceptions develop in three main acts: ideation, construction, and publication. In the first act of ideation, the initial inspiration for new conceptions may arise from intellectual 'kindling' as diverse as cognitive dissonance, eclectic reading, empirical research, new technologies, other fields of research, lay theories, personal experience, projective exercises, theory-data tensions, or thought experiments (Langley 1999; Weick 1989; Zaltman, LeMasters, and Heffring 1982). An idea is often expressed in tropes such as analogies and metaphors (Lakoff and Johnson 1980; Morgan 1980, 1986; Weick 1989). For example, Muniz Jr. and O'Guinn (2001) began a vigorous stream of marketing literature with the simple notion that

groups of people who consume the same brand and derive benefits from shared experiences are analogous to communities.

Second, no matter how their initial idea is kindled, theorists 'discipline' their imagination (cf. Weick 1989) with theoretical materials from other disciplines to support their conceptions. Thus far, conceptual innovators in consumer research have drawn heavily on the social sciences such as anthropology, economics, psychology, and sociology and a bit less extensively on the natural sciences such as neuroscience and humanities such as literary criticism. Theorists can also discipline their imagination using empirical materials, but theory is always necessary. The theoretical approach is exemplified by Belk (1988). The author draws on multiple streams of philosophy, psychology, sociology, and anthropology to evidence the idea that consumption is often like an extension of one's self concept. The mixed theory-data approach is exemplified by Fournier (1998). The author tacks back and forth between relationship psychology and informants' longitudinal engagements with brands to explicate the idea that consumption is like an interpersonal relationship. (For a longer discussion of theory construction as disciplined imagination via problem statements, thought trials, and selection criteria, see Weick (1989).)

Third, following ideation and construction, conceptions face the arduous task of warranting publication. 'A' journals such as JCR require that authors demonstrate how their conception makes a distinct contribution to the field. Authors can choose to highlight how their new conceptualization reveals (i) new aspects of the consumer, (ii) new consumption activities, or (iii) new motivating forces. For example, Bahl and Milne (2010) inject new insight into the role of the self in consumer behavior (cf. Ahuvia 2005; Belk 1988; Sirgy 1982) on all three dimensions. (i) Consumers do not have one self concept, but multiple selves and a meta-self. (ii) Consumer choice is not as simple as negotiating whether a product matches one's identity, but having a conversation among multiple selves – a conversation that may end in various outcomes ranging from domination to coalition. (iii) Consuming is motivated by not only the need to sustain one's selves but also by the need to achieve harmony among them.

Andrea Morales, Arizona State University, USA

SESSION OVERVIEW

One popular strategy companies use is to manage consumers' perceptions of the availability of a product (Verhallen 1982; Inman, Peter and Raghubir 1997). Because people think that scarce products are more valuable, such tactic will likely increase sales. Nevertheless, the topic of scarcity has been under-researched in the marketing literature. It is imperative for marketers to learn more about when and with whom this practice will be more effective, in which other ways it could influence people's behavior, and when it could potentially backfire and hurt a firm's performance.

This special session proposal brings together four papers that study scarcity in the marketplace from four intriguing and unexplored angles. All of these papers are in advanced stages and have 3-5 completed studies. The session aims to provide a broader understanding of the phenomenon of scarcity and highlights recent developments on this topic area across different domains including social comparison, hedonic consumption, nutrition and retailing. The session demonstrates that scarcity is a complex weapon of influence (Cialdini 2001) that affects not only how much people value an object but also the way in which they feel about themselves, their enjoyment of a consumption experience, and the type of nutritional decisions they make. Moreover, this session shows that the effects of scarcity on product evaluations will vary depending on the brand and store environment.

The first paper, by Sharma and Alter, demonstrates that people will seek, select, and consume scarce items as a mechanism to cope with the negative affect associated with upward social comparison. They show that financially deprived individuals pay more attention and prefer scarce products due to their motivation to seek opportunities to restore their sense of parity relative to others. This research extends our knowledge of scarcity by showing that, ironically, the less resources people have, the higher their desire to acquire scarce rather than abundant products will be.

The second paper, by Sevilla, Redden and Zhao, shows that people will not only be more likely to prefer scarce products more when they are financially deprived, but they will also satiate from them at a slower rate when they get the opportunity to consume them. The authors show that people satiate slower during repeated consumption

of a product when it is presented to them as scarce. This effect is not explained by higher initial liking of seemingly scarce stimuli due to scarcity-quality inferences, instead, it is explained by an urge to take advantage of an apparently rare consumption opportunity, which prevents people from paying attention to the amount being consumed.

The first two papers of the session show that while people will pay more attention to scarce products when they are financially deprived, they will pay less attention to the amount consumed if they think a stimulus is scarce. This may suggest that through evolution, humans may have discovered that scarce resources are instrumental to the survival of their species, and consequently, have learned to pursue them more during hostile times, and to become less sensitive to satiation from them when they have the rare opportunity to consume them. The third paper, by Laran, Salerno and Oza, examines scarcity from a survival and consumption standpoint. They show that people will be more likely to seek highly caloric and filling foods when they are primed with survival. They explain that this behavior is due to the adoption of a mindset that leads people to maximize the use of their resources. The authors rule out alternative explanations related to a desire to seek indulgence. They also show an attenuation of the effect in cases when people's financial standing is improved and a reversal when subjects are primed with long as opposed to short term survival. This research provides an intriguing alternative explanation for people's preference to consume the highly caloric and filling "comfort foods" during difficult times.

While the first three papers of the session look at scarcity from a more intrinsic and visceral perspective, the fourth paper, by Castro, Nowlis and Morales, takes a more rational approach. The authors offer a model of how scarcity operates in the retail environment and explain the situations in which this cue increases and decreases purchase intentions. The authors show that making a product appear to be scarce has a positive effect on unfamiliar brands and a negative effect on familiar brands. This is because scarcity cues on unfamiliar brands indicate that a product is highly demanded, thus, desirable. On the other hand, scarcity cues on familiar brands serve as mental contaminants and lead to lower purchase intentions. This paper represents a different approach to the study of scarcity, as it shows that consumers do not only have affective reactions to this type of market cues, but also have come to understand them as rational indicators of how products and brands operate in the marketplace.

We hope that this session will contribute to our understanding of how consumers interpret scarcity cues in the marketplace. Hopefully, the session will point out to new research avenues and approaches to the study of this relevant marketing cue. We hope to generate an interesting discussion among members of our likely audience, which should be integrated by researchers on Retailing, Environmental cues for quality perceptions, Branding, Hedonic Consumption, Social Psychology, and all marketers in general, including practitioners. We consider that the topic of scarcity may be instrumental to build connections among people from different areas in Marketing as it is relevant to most of them, and can be studied from a wide variety of perspectives.

Beggars Will Be Choosers: Financial Deprivation Induces Responsiveness to Scarcity

EXTENDED ABSTRACT

People routinely compare themselves with others on a range of dimensions that are salient, subjectively relevant, and difficult to

evaluate objectively (Festinger 1954; Suls and Miller 1977). However, these social comparisons can be distressing when they highlight shortcomings. Specifically, comparison to a superior standard can produce negative affect and arousal, which people are motivated to resolve (Brickman and Bulman 1977; Tesser 1988). These motivations, in turn, influence how people gather, process, and remember information (e.g., Balcetis and Dunning 2006; Festinger 1957; Heider 1958; Kunda 1990). Accordingly, we combine the literatures on upward social comparison and motivation to identify a novel mechanism by which consumers might cope with the unpleasantness associated with upward social comparison. We focus on consumers' sense of financial wellbeing, and how feelings of financial deprivation can influence their responsiveness (i.e., attention, preference, choice, and consumption) to stimuli in their environment.

Financial wellbeing is ripe for social comparison, as wealth is important to most people and difficult to evaluate in the absence of comparison standards (Hsee at el. 2009). We define *financial deprivation* as a state in which consumers feel financially inferior to a salient comparison standard—either another person or their own financial position earlier in time. We suggest that financially deprived consumers are motivated to ameliorate the unpleasant arousal associated with deprivation by responding more sensitively to stimuli that have the potential to restore their sense of parity relative to others. We propose that scarce stimuli serve such a function, in contrast to stimuli that are abundantly available to others.

The existing literature provides a range of evidence that scarcity increases the desirability of goods (Fromkin 1970; Inman, Peter, and Raghubir 1997; Lessne and Notarantino 1988; Lynn 1989, 1991, 1992; Rucker and Galinsky 2008; Simonson 1992; Verhallen 1982). We extend this literature by proposing that consumers' sense of financial deprivation will interact with their responsiveness to scarcity. Specifically, we suggest that consumers will attempt to repair their sense of deprivation by attending to and possessing goods that most people cannot possess. Though non-scarce items might mitigate unpleasant affect and arousal as well, we suggest that only scarce items imply gains relative to a financially superior other person (since, in theory, scarce items are less likely to be available to that other person). Accordingly, we expect scarce items to be less desirable to financially deprived people when those items are limited due to prior consumption by (rather than supply restrictions to) the general population.

Five studies examine the influence of financial deprivation on consumer responsiveness to scarcity. Results demonstrate that: (1) financial deprivation induces sensitivity to scarce but not abundant stimuli; (2) sensitivity to scarcity explains the selection of goods that are limited versus plentiful; (3) the motivation to ameliorate feelings of deprivation prompts responsiveness to scarcity; and (4) these effects attenuate when consumers attribute their feelings to an external source.

In study 1, participants performed a discrimination task in which they determined the relative frequency of black and white gumballs in an array. However, half of the participants were instructed to identify which color was *more* frequent in the array; the other half identified which was *less* frequent. Participants also completed several questions regarding their financial wellbeing. People who felt less financially comfortable tended to discriminate between the black and white gumball colors with greater accuracy, but significantly more so when the task was a framed as a scarcity (rather than abundance) detection exercise. The interaction between participant performance and task framing (scarcity vs. abundance detection) provides preliminary evidence that people are more sensitive to scarcity cues when they feel financially deprived.

Study 2 employed a similar design, but assessed responsiveness to scarcity with a behavioral consumption measure. Participants were given a cup containing 15 M&M's of one color and 5 M&M's of another color. As expected, participants who were relatively more financially deprived tended to consume a higher percentage of the scarce rather than abundant M&M's.

In study 3, we manipulated financial deprivation by asking participants to write about a time when they felt either financially worse (deprived condition) or better (flush condition) than their peers. Participants then completed a timed discrimination task in which they estimated the relative frequency of two different characters from the "*Where's Waldo?*" book series. As predicted, participants who wrote about feeling deprived (vs. flush) did better at detecting scarce "*Where's Waldo?*" characters. This study provides causal evidence of a relationship between deprivation and sensitivity to scarcity.

In study 4, we employed a design similar to study 2 but compared deprived participants to a neutral control group consisting of participants who wrote about feeling financially matched with their peers. Participants then made several choices between various scarce and abundant goods available during "Restaurant Week." In line with the previous studies, participants who wrote about feeling deprived (versus participants in a control condition) performed with greater accuracy on a discrimination task (from study 1). Mediation analysis revealed that participants' sensitivity to scarcity (i.e., their ability to detect scarce stimuli) explained their selection of scarce rather than abundant goods.

In study 5, we found that deprived participants only preferred scarce items when they were unable to attribute the unpleasant arousal associated with deprivation to an external source. Specifically, deprived participants preferred scarce (rather than abundant) candy except when they were led to attribute their feelings to a clip of whale songs (Van Boven et al. 2010) that they had heard earlier in the experiment. This study provides evidence that deprived participants' preference for scarcity is indeed driven by a motivational component, and cannot be explained by mere priming.

This work suggests that feeling financially deprived has systematic effects on consumer attention, preference, and choice. There are many real world implications of this work, particularly given the tendency for most people to feel financially deprived at least in some contexts. The effects we illustrate speak to these implications, while addressing factors such as mood and cognitive ability. We find that beggars will be choosers—choosers who prefer what's scarce.

The Less There Is, The More I Want: The Effect of Scarcity on Satiation

EXTENDED ABSTRACT

Satiation occurs when people find a stimulus less pleasant as they consume more of it (Coombs and Avrunin 1977). Although satiation partially depends on the objective amount consumed, recent research has shown that its occurrence can be delayed (Rozin 1998, Nelson and Meyvis 2008; Redden 2008; Nelson, Meyvis and Galak (2009), accelerated (Morewedge, Huh and Vosgerau 2010), or even partly reversed (Galak, Redden and Kruger 2009) by psychological factors.

Past research on the psychological determinants of satiation has looked at aspects such as memory (Rozin 1998; Galak, Redden and Kruger 2009), imagination (Morewedge, Huh and Vosgerau 2010), categorization (Redden 2008) and consumption rate (Nelson and Meyvis 2008; Nelson, Meyvis and Galak 2009). However, no paper has investigated how different beliefs about the properties of a product affect the speed at which people satiate from it. In this research we show that merely telling people that a product is scarce will make them satiate from it at a slower pace.

Past research also has shown that scarce products are highly desirable (Verhallen 1982; Verhallen 1994; Inman, Peter and Raghubir 1997). In this paper, we manipulate people's beliefs about how scarce a product is, and observe a slower satiation rate associated to its consumption. We also show that the increased enjoyment is not due to an improvement in perceived taste associated with beliefs about higher quality of the stimulus, as ratings of initial liking are the same for stimuli that are believed to be either scarce or common. Instead, we find that attention to the quantity consumed mediates the effect. This is because when people encounter a situation where they have access to a scarce product, they will feel an urge to take advantage of this rare opportunity, and this leads them to consume it in larger amounts.

This phenomenon may have an evolutionary foundation. Covasa and Ritter (1999) have shown that rats develop the ability to become less sensitive to the consumption of oleate, an important compound present in fat. Since lipids are scarce nutrients that this species does not have frequent access to, in the rare occasions they do, they will consume it in abundant amounts, given the uncertainty about when the next time they will have access to it will be.

This reduced sensitivity to oleate in rats is similar to a human loss of the ability to keep track of consumption of a presumably scarce product. In this case, the insensitivity to satiation to a stimulus believed to be scarce is not physiological but psychological in nature, as the elements tested in our studies cannot be identified by the human body as being vital for survival as is the case of oleate in rats. Three studies provide support to our hypothesis that making people believe that a product is scarce will decrease the satiation rate during consumption.

Study 1 provides evidence for the effect in a consumption setting. We asked participants to consume chocolate and provide sequential ratings of their enjoyment of the experience in a between-subjects design. Half of the participants were told that the chocolate they were eating was made from cocoa grains that grew only in a few places of the world during a limited time every year, which led them to believe it was scarce. The other half were told that it grew in many parts of the world throughout the year, which indicated that it was widely available. It is important to mention that this scarcity manipulation did not make participants believe that one stimulus was of higher quality than the other, as they only differed in terms of their natural availability. This was reflected in our results, which showed that participants provided equal initial enjoyment ratings for the chocolate in both conditions. However, participants in the scarce condition subsequently satiated from the chocolate at a slower pace. A mediation analysis showed that the differences in the slopes of satiation between conditions, was explained by attention to the quantity being consumed.

Study 2 replicated the results of the first study and demonstrated the generalizability of the effect using Hawaiian landscapes pictures as stimuli. In a between-subjects setting similar to the one used in Study 1, it was shown that participants satiated slower from looking at the pictures when they were told that these belonged to landscapes that could be captured only during a limited time every year due to environmental factors.

Study 3 provides further support for attention to quantity as the underlying mechanism behind the effect. In a design similar to Study 1, it was shown that the difference in enjoyment of the chocolate between the scarce and the common conditions disappeared when participants were asked how many pieces of candy they had eaten at the end of every consumption episode.

This research contributes towards the understanding of the psychological nature of satiation by looking at a new dimension of the consumption experience. It is demonstrated that erroneous beliefs about the nature of a stimulus can affect the rate at which people satiate from it. This paper also introduces an additional benefit of promoting scarcity in the marketplace, as it is shown that people satiate at a slower pace from products that are claimed to be scarce, regardless of the veracity of these claims.

Survival Mindset and Food Choices

EXTENDED ABSTRACT

As the war on obesity wages on, consumer researchers remain motivated to learn more about the reasons why people continue to make poor food choices. Past research on food choice has shown that people's poor food choices can result from their own misconceptions related to food (Chandon and Wansink 2007), cognitive resources (Shiv and Fedorikhin 1999), emotional state (Ramanathan and Williams 2007), and food choices made from prior meals in the day (Khare and Inman 2006).

We propose an alternative explanation to people's unhealthy food choices. Certain people engage in a survival mindset and instinctively eat filling and high-calorie food, often without consideration of the overall healthiness or even tastiness of the food. We define survival mindset as a sense of adversity and resource deprivation that one must withstand by making the best use of one's resources in order to live longer (Hill and Stamey 1990). The concept of survival is a lingering concern as unemployment rates continue to hover around 10% within the United States (U.S. Bureau of Labor Statistics 2010). However, this sense of resource deprivation need not be economic in nature; it can refer to food, water, shelter, and other basic resources that humans require to function. This mindset, when activated, leads consumers to choose food items perceived to be more filling or higher-calorie to compensate for the sense of resource deprivation and to aid sustainability.

Across four studies, we use an array of priming procedures to activate a survival mindset, and provide evidence for the processes that lead from a survival mindset to consumers' food choices. Study 1 shows that a survival mindset leads to choices of food items perceived to be more filling (i.e., keep people fed longer). Study 2 differentiates a survival mindset from a willingness to indulge by showing that a survival mindset leads to choices of food items that are high in calories, while a willingness to indulge leads to choices of food items that are tasty. Study 3 shows that a survival mindset can lead to choices of food items that are tasty and unhealthy, but that increasing the perception of the amount of resources available attenuates the effect of a survival mindset on these choices, compared to people in a pleasure-seeking mindset. Study 4 shows that a survival mindset leads to choices of filling food items when this mindset is associated with perceptions of short duration (i.e., survival in the short term), but that it can lead to choices of healthy food items when it is associated with perceptions of long duration (i.e., survival in the long term).

Study 1 primed people with the concept of survival and found that these people are more likely to select filling food compared to people who are not primed. We either asked participants to write about what is important for survival (survival condition) or not (control condition). After the writing task, participants chose between a (less filling) grilled chicken caesar salad and a (more filling) turkey and cheese sandwich. Participants primed with survival are more likely to select the sandwich than the control group participants. Additionally, neither group differed in anxiety or mortality salience, ruling them out as alternative explanations (Greenberg, Solomon, and Pyszczynski 1997).

Study 2 primed survival versus pleasure and observed people's preferences for a foot-long sub, depending on whether the sub was framed as being high-calorie versus tasty. Participants completed a scrambled word task containing either survival words (i.e., deficiency, outlast) or pleasure words (i.e., indulgence, pleasantness). We show that people primed with the concept of survival favor the sub more when framed as high-calorie, while the pleasure primed participants favor the sub when framed as tasty. Study 2 shows that the survival prime is distinct from a pleasure prime and that people primed with survival are not choosing high calorie foods out of taste and indulgence (Raghunathan, Naylor, and Hoyer 2006).

Study 3 shows money is a moderating variable that has the potential to alleviate perceived resource deprivation and attenuate the effect of the survival prime on food choice. We used a lexical decision task to prime people with either survival or pleasure and then ask them to choose between cupcakes and a garden salad. Additionally, some participants were given one dollar under the guise of a thank you gift. Participants primed with survival selected cupcakes without money and the healthier garden salad with money. Pleasure primed participants primarily selected cupcakes regardless of receiving money or not. The results show how to assist survival-primed consumers to make healthier food decisions.

Study 4 used a procedure similar to study 1 and introduced the concept of survival duration as a moderating variable between the survival prime and food choice. We manipulated duration by having participants think about how long or short various events last and show that this carries over into how long survival is thought to last. Participants primed with the belief of short-term survival (short duration) were more likely to choose the (unhealthier) sandwich. By contrast, participants primed with the belief of long-term survival (long duration) were more likely to choose the (healthier) salad. Mediation evidence is provided, where survival short-duration participants select food according to what's filling, while the survival long-duration participants select food according to what's healthier.

Our research demonstrates people's reasons for some of their food choices. This research is unique in that no study that we know of has specifically examined how a survival mindset influences people's food choices. Oftentimes, the most filling and high-calorie foods are seen as being a sort of hedonistic "comfort food." However, our theory supports the notion that in certain circumstances, people might view these foods as purposeful and utilitarian rather than hedonistic in function. Furthermore, we find promising results in our later studies, suggesting ways in which we can attenuate the effect of the survival mindset on food choice and help consumers to make healthier food choices.

There's Only One Left, Do I Want It? : The Effects of Brand and Display Characteristics on Purchase Intentions for Scarce Products

EXTENDED ABSTRACT

Retail executives know that the presentation of their products matters. The general belief is that pristine aisles with fully stocked shelves and perfectly organized product displays can increase purchase intentions, whereas cluttered aisles with empty shelves and messy displays lower them. Although retailers currently strive to keep shelves and displays fully stocked and organized in the belief that this will maximize sales, it may be the case that this, in fact, is not the best way to increase revenues. In this paper, we examine whether, and under what conditions, the organization, appearance, and number of products on retail shelf displays will impact purchase intentions for those products.

By looking at a product display, consumers are exposed to the type of product, whether the brand is familiar or unfamiliar, how many products are available, the appearance of the product display, and the prices associated with the product. While each of these cues provides independent information about the products being displayed, we study the interactive effects of these cues on consumer inferences and purchase intentions. For example, imagine a consumer at a supermarket who is considering buying a product from a disorganized display with only one product left on the shelf. Will the scarce product availability and appearance of the display interact in a way that systematically influences the consumer's preference for the product? Prior research in the scarcity literature suggests that scarcity attributed to market conditions (i.e., popularity) should increase the desirability of a product (Verhallen 1982; Verhallen and Robben 1994). However, most of this research has not focused on how the availability of the product interacts with other important cues in the retail environment to affect purchase intentions, nor how cues in the retail environment influence perceptions of scarcity. Our research thus looks at how cues in the retail environment, such as the appearance of the shelf or the familiarity of the brands on the shelf, interact with the availability of the product to influence purchase intentions. In the proposed scenario, the fact that the display is disorganized and there is only one product left may suggest that others are buying the product; therefore, consumers may infer that the scarcity is due to popularity and preference for the product may increase. However, if consumers are familiar with the brand, then they will use other information about the product to make their decision, thereby reducing the effect of such cues on purchase intentions.

Prior research on shelf displays has focused on topics such as assortment and assortment reductions, amount of category space, number of stock keeping units, amount of space allocated to a product, shelf locations, the effectiveness of product displays, and stockouts (e.g., Chandon, Hutchinson, Bradlow and Young 2009; Turley and Milliman 2000; Fitzsimons 2000). However, little research has addressed the interaction of retail cues such as the appearance of the shelf display and the availability of the product on consumer preference.

Our research offers three important contributions. First, we examine how specific cues in the retail environment, such as the messiness of the shelf display, interact with the availability of the product (i.e., the number of products available on display) to influence perceptions of product popularity and purchase intentions. Second, we examine how the availability of the product interacts with characteristics of the product itself, such as its familiarity and whether or not it is a food product, to influence purchase intentions. Third, we show how other characteristics of the product, such as its price, moderate these effects and how these effects translate into the impressions of the store that sells them. In so doing, we are able to develop a comprehensive theoretical model of how scarcity operates in the retail environment, identifying when it increases purchase intentions, when it decreases purchase intentions, as well as the underlying mechanisms driving these two divergent outcomes.

Across a series of five studies, we find when consumers infer that products are scarce due to popularity, consumers are more likely to buy these products because of quality perceptions, but only when they are unfamiliar nonfood brands. We also find that scarce products are less likely to be purchased when they are familiar food brands because of contamination effects. In addition, we find that the price of the product is an important moderator of these effects.

Adding and Subtracting: Decision Making During Accumulation and Decumulation of Retirement Savings

Paper #3: Options, Not Returns: Overcoming the Annuity Paradox

Kirstin Appelt, Columbia University, USA
Eric Johnson, Columbia University, USA

SESSION OVERVIEW

Within the next decade, 31 million Americans will retire (Reno and Lavery 2009). On average, they will spend 20 years in retirement (National Commission on Fiscal Responsibility and Reform 2010). At the same time, the retirement landscape is changing as defined-benefit retirement plans (the employer pays a specified monthly benefit for the duration of retirement) are replaced by defined-contribution retirement plans (the employer contributes a specified amount to the employee's retirement account, but the employee is responsible for managing the account himself) (Brown, 2000). As a result, consumers are increasingly in charge of funding their own retirement and deciding how to manage their resources, at a time when their retirement is lasting longer than ever before.

Retirement decision making has two crucial phases: the accumulation of wealth approaching retirement *and* the decumulation of wealth during retirement. Evidence suggests both that many Americans do not save enough for retirement (EBRI 2010; NIA 2007; Thaler and Benartzi 2004) and that almost half of Americans are concerned that they will not be able to maintain a reasonable standard of living during retirement (Society of Actuaries 2010). However, although consumers face challenges during both accumulation and decumulation, most research has focused on the accumulation phase. This session gathers leaders in the area of consumer finance to address *both* phases of retirement decision making.

This session connects these two phases by tracing retirement decision making from accumulation through decumulation. First, Ersner-Hershfield and Goldstein discuss insufficient saving for retirement during the working years. They offer a new avenue for increasing retirement savings: Data from three studies indicate that increasing the vividness of the future self can motivate the current self to save more money for retirement.

Next, Sagara et al. focus on the importance of life expectancy for accumulation and decumulation decisions. To determine how much to save for retirement and how to spend during retirement, consumers need to estimate how long they will live. Most economic models, such as the life-cycle model (Skinner 2007), assume that consumers have rational expectations of their own life expectancy. Sagara and colleagues suggest that this may not be the case and that, instead, life expectancy is a constructed estimate that depends cru-

cially on question framing. Data from three studies show that consumers give longer life expectancies when asked about living to a certain age (vs. dying by a certain age), and that framing affects decumulation preferences.

The third paper investigates decumulation decisions in an uncertain world. Retirees have a finite amount of retirement savings, but they do not know how they will live and how long those savings must last. They are therefore faced with a large degree of longevity risk—the risk that they will outlive their assets. Annuities, which provide guaranteed lifetime income, offer a solution to longevity risk, yet few Americans purchase them. Appelt and Johnson investigate the "annuity puzzle" (Yaari 1965) from two perspectives: potential annuity features that may overcome consumers' reluctance to annuitize and individual differences that may affect annuitization. Data from two studies suggest that consumers prefer annuities that guarantee a specified number of payments (period certain annuities) or liquidity in case of emergencies (annuities with cash-back options) and that time and risk preferences moderate these effects.

Taken together, these three papers connect the accumulation and decumulation phases of retirement wealth. Because this is a developing area, we have asked John Lynch to lead the discussion. As an expert in the field of consumer finance, John will be instrumental in encouraging the building of connections. John will discuss the connections between accumulation and decumulation, with an emphasis on the contributions of the three papers to that discussion. John will also discuss how behavioral consumer finance generally and retirement decision making specifically can serve as nodes connecting different research areas as well as research and public policy. We have allotted 15 minutes for the discussion.

The recent economic crises indicate both the importance of consumer finance and the importance of behavioral factors within consumer finance. Furthermore, in the last two years, the government has shown significant interest in behavioral consumer finance with the establishment of the Consumer Financial Protection Bureau, a series of Senate committee hearings on retirement decision making, and a series of meetings about behavioral consumer finance issues in Washington, D.C. This session, which highlights new research from behavioral consumer finance, specifically retirement decision making, is well-timed and potentially influential. Given the relevance of the findings to research and public policy, we expect a broad audience, including researchers interested in consumer finance, preference construction, intertemporal choice, and framing; individuals interested in retirement issues; and policy makers.

Making the Future Self More Vivid to Increase Retirement Saving

EXTENDED ABSTRACT

The number of years that the average American will spend in retirement is at an all-time high (Lee 2001), as life expectancy at age 65 has increased to 18 years (Arias 2007). Most Americans risk outliving their retirement savings. Furthermore, despite a recent small increase in saving rates, retirement experts estimate that 43% Americans will still be unable to maintain pre-retirement standards of living in retirement (due in part to the recent reduction in home values) (Bernheim et al. 2000; Munnell, Webb, and Golub-Sass 2009). In short, people are living longer but saving less.

Under-saving is sometimes attributed to "myopia" or excessive discounting of the future. The inability to vividly imagine one's wants and desires at a distant age could account for some of the empirically observed discounting phenomena. As expressed by Parfit (1971), the failure to give adequate weight to the future might be "caused by some failure of imagination, or some false belief. It is claimed, for example, that when we imagine pains in the further future, we imagine them less vividly, or believe confusedly that they will somehow be less real, or less painful" (p. 161). Loewenstein (1996) has noted that a more vivid impression of ourselves engaging in some action in the future might intensify the emotions that are linked to thinking about that scenario. These intensified emotions might, in turn, allow an individual to be better informed regarding the future consequences of a current decision. For example, pulmonologists tend to smoke less than other doctors, in part because seeing blackened and withered lungs on a daily basis increases the negative emotions that are associated with smoking (Loewenstein 1996).

Thus, to the extent that people can feel more connected to a vividly imagined future self, they should be motivated to save money in a long-term domain. Accordingly, we conducted three experiments to examine the association between a vivid perception of one's self in the future and the propensity to save more for retirement. In Studies 1 and 2, a novel technology, immersive virtual reality (VR), was developed to make one's perception of one's future self more realistic. In study 1, a control group of college undergraduates (*n* = 25) entered an immersive VR environment and saw a digital representation of their current selves in a virtual mirror, while the experimental group of college undergraduates (*n* = 25) saw an age-morphed version of their future selves in the virtual mirror. Upon exiting the VR environment, all participants were given a hypothetical money allocation task, among other tasks. The experimental condition participants were significantly more likely to allocate money toward a hypothetical retirement savings account (*M* = $178.10) than control participants (*M* = $73.90).

In study 2, we sought to rule out two alternative explanations for our findings from study 1. First, because the monetary allocation task occurred directly after the virtual reality paradigm, it is possible that participants in the experimental condition felt pressure to allocate more to the long-term account. Thus, in study 2, we separated the virtual reality portion of the study from the decision-making portion, and provided a cover story that masked our research purposes. Secondly, it is possible that experimental condition participants in study 1 were merely primed with the concept of aging, and this prime prompted them to save more for retirement (i.e., Bargh and Chartrand 1999). As such, in study 2, we exposed participants to either their own aged avatar or another research participant's aged avatar, and did so after a lengthy experimental delay. Results indicated that participants in the future self condition demonstrated significantly more patience on financial decision-making tasks (*M* = .30) than did participants in the future other condition (*M* = -.27).

Although these findings are encouraging, there are several unresolved issues. First, this approach to virtual reality is expensive and time-consuming for participants, and most companies or banks will not be able to utilize immersive virtual reality to convince their employees or customers to adopt a longer-term perspective when making decisions about retirement savings. Secondly, experimental condition participants in Studies 1 and 2 were simply shown a neutral image of their future selves. Loewenstein's (1996) work suggests that in order to make a true connection to the future self, the future emotional consequences of current decisions must be made clear. Indeed, previous research has demonstrated that exposure to virtual cause-and-effect actions can change actual behavior. For example,

compared to a control group, when participants were shown a virtual version of themselves gaining weight, they were more likely to go to the gym (Fox and Bailenson 2008). Accordingly, study 3 used a more accessible format to address the cause-and-effect nature of retirement decision-making.

Namely, we used a web-based study design in which all participants were shown a slider bar that they could move to make allocations from a hypothetical paycheck to a hypothetical retirement account. As they moved the slider bar toward future consumption, their annual take-home pay decreased (indicated in today's dollars), but their annual retirement income increased (again, indicated in today's dollars). In the current self condition, however, participants were shown the monetary amounts as well as an image of their current self, which changed emotional expression as a function of the allocations that they chose to make (sadder as more money was allocated toward future consumption, happier as more money was allocated toward present consumption). In the future self condition, participants were shown the monetary amounts as well as an image of their future self, which changed emotional expression as a function of the allocations that they chose to make (happier as more money was allocated future consumption, sadder as more money was allocated toward present consumption). Again, results indicated that participants in the future self condition allocated a significantly higher percentage of pay toward retirement (*M* = 6.76%) than did participants in the current self condition (*M* = 5.20%). Results will be discussed in the context of Parfit's (1971) and Loewenstein's (1996) work.

Live to or Die by: Framing Effects on Life Expectations and Life Annuity Choice

EXTENDED ABSTRACT

How long do you expect to live? Answering this question is essential to making informed judgments and choices about savings, decumulation of retirement wealth, health, and many other decisions. Yaari (1965), for instance, begins his classic article on life-annuity choice by saying that "one need hardly be reminded that a consumer who makes plans for the future, must, in one way or another, take account of the fact that he does not know how long he will live (p.137)." Most lifetime consumption models assume that individuals take into account their probability of living to different ages when planning how to decumulate their assets during retirement. The importance of getting these estimates correct has become greater in recent years as employers have shifted from offering defined benefit plans, which provided income regardless of how long an individual lived, to offering defined contribution plans, under which the individual is solely responsible for ensuring that he does not run out of savings during his lifetime.

We address the issue of life expectancy and its effects on decumulation decisions through three large-scale studies. Our research questions include understanding how individuals' judgments about their life expectation probabilities may change according to how the question is framed, how these judgments are affected by the knowledge individuals have about themselves, and how these judgments affect preferences for life annuity products. We predict that beliefs about how long one might live are, like preferences, often constructed responses that will reflect seemingly irrelevant task factors (and biases) as well as valid knowledge (truth) and random error. As a result, simple changes in how questions are worded can produce substantial biases in both judgments and preferences.

In three online studies (total n = 2,172), two different frames were used to elicit individuals' probabilities for life expectancy for ages 65, 75, 85 and 95. Specifically, in one condition, respondents

were asked to provide probabilities of *living to* a certain age or older, while in the other condition, they were asked to provide probabilities of *dying by* a certain age or younger. Note that the answers to these two approaches should perfectly mirror each other if framing has no effect. Following this subjective probability task, respondents in study 2 were asked to either indicate their purchase probability for a single life annuity or their allocation of retirement assets between the annuity and a self-management option. In study 3, respondents used a type-aloud protocol to report their thoughts as they considered the probability of living to [dying by] 85 years old or older [younger]. Respondents in study 3 later coded each of their own previously-listed thoughts as emphasizing life, death, or neither, and being positive, negative, or neither.

The results from all three studies consistently indicate that question framing strongly affects both judgments and preferences. For comparison purposes, all probabilities were converted to "live to" numbers (i.e., responses to "die by" questions were subtracted from 100%). An analysis of each respondent's data to determine the elevation and slope of each probability line per respondent allowed measurement of how framing and individual differences affect the line. The coefficient for framing was significant and large for both elevation and slope, while age, health, and gender also had significant effects. Respondents asked the question framed as a "live to" prediction provided higher probabilities across all age ranges than those asked the question framed as "die by". For example, in study 1, individuals in the live-to frame thought they had about a 55% chance of being alive at age 85, whereas individuals in the die-by frame thought they had about a 32% chance. There was also a ten-year gap in median expected age of death (85 years for the live-to frame and 75 years for the die-by frame).

Does the effect of framing on probability judgments for life expectancy also affect preference for annuities? The answer is yes. Likelihood of annuity purchase was significantly affected by average predicted life expectancy as well as by framing, and self-reported health. Allocation to annuities showed weaker effects, but was still significantly affected by life expectations, health, and age. Individual difference measures for numeracy, confidence in investment ability, and importance of making money last also had significant effects on preference.

Study 3 tested whether Query Theory (Johnson, Häubl, and Keinan 2007), which suggests that framing affects responses by changing the order in which individuals consider thoughts about the various choice options, explains the effect of frame on life expectancy. We found that the framing effect for age 85 was significantly partially mediated by the relative number of thoughts in favor of being alive at age 85. As predicted, individuals had more thoughts in favor of being alive at age 85 when presented with the live-to frame (vs. the die-by frame) and this partially mediated the effect of frame on the subjective probability of being alive at age 85.

The results of these studies demonstrate that both judgments and preferences about important future events, such as how to decumulate retirement assets, are sensitive to framing effects. Although there have been many framing studies (see Keren 2011 for an overview), the vast majority have involved evaluations of objects or preferences between options. In contrast, these studies ask how framing affects a prediction question. Consistent with explanations for other framing effects, different ways of posing the same question appear to direct attentional resources to different attributes, which results in different responses (Keren 2011). In fact, our mediation analysis suggests that respondents had more positive thoughts about being alive at 85 years old in the "live-to" condition than in the "die-by" condition, and this in turn, predicted subjective probabilities of being

alive at age 85. Individual differences in age and health, which could be considered private information, also affected these predictions. Thus, it seems that judgments of an important future event, for which individuals should have both private and public information, may be "constructed" in the sense that judgments are subject to predictable biases, such as how the event is framed.

Options, Not Returns:
Overcoming the Annuity Paradox

EXTENDED ABSTRACT

When they retire, consumers are faced with decisions about managing their saving and spending, ideally providing themselves a comfortable standard of living for as long as they live. Using a limited amount of retirement savings, they must fund a retirement of unknown but potentially long duration. This presents consumers with the very real possibility that they will outlive their savings, an outcome called "longevity risk" by economists.

A life annuity is an "insurance product that allows an individual to convert a lump-sum of wealth into a stream of income that is guaranteed to last for as long as an individual (and if desired, his or her spouse) lives" (Brown 2011). Thus, an annuity is a potentially attractive solution for dealing with longevity risk. Not only does an annuity offer guaranteed lifetime income, it also typically provides a higher income than otherwise possible because the assets of those who die early subsidize the payments to those who die late (Brown 2000). Despite the economic attractiveness of annuities, few Americans choose to annuitize any of their retirement savings, a phenomenon termed the "annuity puzzle" (Yaari 1965).

In contrast to the standard life-cycle model used to analyze retirement savings and spending in economics (Skinner 2007), we suggest a behavioral model that posits relatively narrow framing, loss aversion, and quasi-hyperbolic discounting. The model suggests that annuities are unattractive for at least two reasons: First, decision-makers are loss averse and risk averse to the possibility of "losing" their retirement savings to the annuity company should they die early. Second, they discount, perhaps too much, the income stream provided by the annuity. Thus, loss aversion, risk aversion, and discounting are barriers to buying annuities. We examine the implications of this model using two strategies. First, we ask whether features designed to overcome these barriers to annuitization will be attractive to consumers. Specifically, we contrast the appeal of a standard economic feature (a higher rate of return) and two behavioral features (a guaranteed minimum term and available liquidity). Second, we ask whether individual differences in time and risk preferences, numerical ability (i.e., numeracy), and financial literacy explain annuity preferences and moderate the effects of annuity features on preference.

We conducted two web-based studies (total $n = 1,416$) using community samples of Americans aged 45 to 70 who had faced or would soon be facing retirement decisions. Participants read information about advantages and disadvantages of two options for decumulating retirement wealth: annuities and self-managed accounts. They were then presented with a general annuity followed by a series of four annuities with different features in a fractional factorial design: (1) return: low (5%) or high (7%); (2) period certain: a guaranteed minimum term of 15 years (i.e., if the annuitant dies within 15 years of purchasing the annuity, the annuitant's heirs would receive the remaining years of payments) or no guaranteed minimum term; and (3) available liquidity: a cash-back option (i.e., the annuitant or the annuitant's heirs can withdraw the balance of the annuity as a lump sum at any time) or no cash-back option. For each annuity,

participants were asked how likely they would be to purchase the annuity. In study 2, participants also completed measures of time and risk preferences as well as numeracy and financial literacy, allowing for tests of individual differences.

In study 1, consistent with the annuity puzzle, participants reported being unlikely to purchase the base annuity—an annuity offering a 5% return and no period certain or cash-back option. However this differed significantly as the features of the annuity changed: Participants were significantly more likely to purchase annuities offering either a guaranteed minimum term or a cash-back option. Interestingly, participants were insensitive to the rate of return on the annuity, equivalent to $2,000 a year on a $100,000 annuity. In other words, participants were attracted to annuities with behavioral features designed to minimize risk aversion and loss aversion, but not to an annuity offering a standard economic incentive.

In study 2, we replicated the findings from study 1 and additionally tested the impact of individual differences in preferences and abilities. For a general annuity, as predicted, participants who were present-biased were less likely to annuitize. Participants who were risk averse were marginally more likely to annuitize, which is to be expected since annuities reduce the risk of longevity. Neither numeracy nor financial literacy predicted annuity preference. Numeracy did, however, moderate the effect of rate of return such that highly numerate participants preferred the high-return annuity to the low-return annuity more than those who were low in numeracy.

Impatience moderated the effect of the period certain feature and the cash-back feature such that impatient participants preferred these options marginally more than patient participants. Risk aversion moderated the effect of the period certain feature such that risk-averse participants preferred the period certain feature more risk-seeking participants. In other words, the attractiveness of the economic incentive was moderated by numerical ability whereas the attractiveness of the behavioral features was moderated by time and/or risk preferences. Notably, financial literacy did not predict preference for annuitization or any annuity features.

These results support a more behavioral model of retirement decision making. As hypothesized by Brown (2000) and Hu and Scott (2007), retirees may be insensitive to standard economic incentives for increasing annuitization. Participants did not show a preference for an increased rate of return. Instead, they were drawn to annuities offering a guaranteed minimum term or available liquidity. This pattern of results suggests that retirees are most concerned with ensuring that, should they die early, their money does not remain with the insurance company and with having access to their money. Additionally, we find that likelihood of annuitization is driven by time and risk preferences rather than financial literacy or numeracy. These results suggest that financial education may not be sufficient to solve the annuity puzzle. Instead, to encourage annuitization, it may be better to appeal to consumers' time and risk preferences by designing annuity products that address these preferences.

When Gifts Go Unappreciated

Paper #3: When Do Gifts Help Charitable Giving and When Do They Hurt?

George E. Newman, Yale University, USA
Y. Jeremy Shen, Yale University, USA

SESSION OVERVIEW

Consumers invest considerable time and money annually on selecting gifts for others: The average American spends 15 hours gift shopping and more than $800 on gifts during the holidays alone, according to Consumer Reports. Despite the considerable investment made by givers, these gifts often fail to have the intended effect on recipients. According to Waldfogel (1993), gifts produce about 10% less satisfaction than would have been produced if the recipients had spent the same amount on themselves. The objective of this symposium is to explore the how discrepancies between giver and recipient perspectives can lead givers to invest time and resources into gifts that fail to have the intended effect on recipients.

First, Yan Zhang and Nicholas Epley will demonstrate that although gift givers believe that investing more thought into gifts will increase recipient appreciation, thoughts count for very little unless gift receivers are motivated or otherwise triggered to consider a gift giver's thoughts, such as when a friend's gift has relatively little objective value, or is considered to be objectively undesirable. Next, Mary Steffel and Robyn LeBoeuf will show that, when givers select gifts for multiple recipients, they strive to personalize gifts so as to convey an understanding of recipients' unique identities. Yet this leads them to pass up gifts that would be better liked in favor of unique gifts, even when recipients will never compare gifts. George Newman and Y. Jeremy Shen will then show that, contrary to the common-sense notion that offering a thank-you gift might encourage reciprocity, in the context of charitable giving, people are actually less likely to donate when they are given a thank-you gift for donation. Finally, for the last 15 minutes of the session, Susan Broniarczyk will provide comments on the talks and discuss broader themes and future research directions.

Together, these studies contribute to consumer theory by illuminating how psychological factors such as attention, motivation, comparisons, and incentives lead gift givers to invest time and resources into gifts that fail to have the intended effect on recipient liking and reciprocation. They further suggest practical advice to givers for better anticipating when to give a gift, what gift to give, and how to present it in such a way as to elicit the intended response. This research is of broad interest to researchers in consumer psychology in general and to researchers in gift giving, prosocial behavior, and judgment and decision making in particular.

How Surprisingly Little Thoughts Count in Gift-Giving: On Receiver's Motivated Appreciation for Giver's Thoughts

EXTENDED ABSTRACT

Gift-giving is a social exchange that includes both the objective value of a gift as well as the symbolic meaning of the exchange itself. The objective value of a gift is sometimes considered to be of secondary importance in people's evaluations of a gift, as when people claim, "it's the thought that counts," suggesting that a thoughtful gift will be appreciated more than a thoughtless gift. Based on this belief, gift givers spend a lot of time and effort to choose or design gifts, expecting that their time and effort will be appreciated when the gift is delivered.

However, because it often takes motivation and attentional resources to consider another person's thoughts, we predicted that thoughts would count for very little in evaluating gift exchanges unless gift receivers were motivated or otherwise triggered to consider a gift giver's thoughts. The tendency to focus on one self's feeling suggests that how appreciative receivers feel toward a giver would be largely determined by how they feel about the gift, but not so much by factors that are not pertain to the gift itself, such as giver's thoughts and intensions, suggesting that thoughts would count very little for receivers.

People only consider others' thought in certain situations. For instance, when others' behavior is inconsistent with one's expectations or social norms, people tend to make sense of such behaviors by appealing to underlying intentions, goals, or thoughts. In the context of gift giving and receiving, we suggest that gift receivers are motivated to think about givers' intentions and reasons of choosing a specific gift when they receive gifts that are undesirable, or of very little objective value. People usually expect to receive desirable gifts or gifts of some value to them. A gift that is undesirable or of very little objective value violates this expectation. If there is no objective value in another person's act of kindness, then a receiver would try to explain this seemingly meaningless act of kindness by justifying the symbolic meanings of this act. Receivers then shift their attention to givers' thoughts and underlying reasons of their gift choices. As a result, a receiver's gratitude would be largely influenced by the amount of apparent thought another person put into the act. Gift givers, on the other hand, are directly aware of the amount of thought they put into their gift, and therefore predict that their thoughts will "count" more than they actually do.

Four studies confirmed this prediction. In the first study, participants recalled either a past gift-giving or a gift-receiving experience. They were also instructed to recall either a liked or a disliked gift. As predicted, receivers' appreciation for desirable gifts was not correlated with how much thought they believed givers invested. For undesirable gifts, however, receivers' appreciation was highly correlated with how much thought they believed givers invested. Givers, on the contrary, predicted that their thought would be appreciated if receivers liked the gift, and that their thought would be dismissed if receivers disliked the gift. Response time results show that receivers took longer to answer the appreciation questions for undesirable gifts than for desirable gifts, suggesting that thinking about giver's thoughts takes extra effort from receivers. We replicated these results in a second study with Mother's Day gifts.

We further suggest that this inconsistency between givers and receivers would only happen between acquaintances but not strangers. For gifts given by strangers, receivers do not need to make sense of receiving an undesirable gift, so they would not consider giver's thoughts even when a gift is bad. Consistent with our predictions, a third study that involved real gift exchange returned results similar to the first two recall studies among acquaintances, but not among strangers.

The fourth experiment found that although thought counts very little in most cases, investing thoughts into a gift made givers feel more socially connected with receivers, which may help maintain and develop the relationship between givers and receivers.

This research has important implications in how to manage gift-exchanges. When choosing gifts, most people want their thoughts to be appreciated. However, our research shows that people receive extra credit for their thoughts only when they had chosen gifts disliked by receivers. Since a desirable gift is highly appreciated regardless of whether givers invest thoughts or not, maybe the most important thing for gift givers is to choose the right gift rather than investing enough thought. It is the thought that counts, this research suggests, but only when giving loved ones bad gifts.

Social Comparison in Decisions for Others:
Considering Multiple Gift Recipients Leads to Personalized but Less-Liked Gifts

EXTENDED ABSTRACT

Gift giving is a challenge, and sometimes, this challenge is compounded by having to choose gifts for multiple recipients. Having multiple recipients in mind not only means that more gifts are needed, but it may change what givers focus on when making gift selections. We hypothesize that, when people select gifts for multiple recipients, they focus on what differentiates the recipients instead of on what each would like best, leading givers to select unique gifts over gifts that would be better liked.

There are at least two reasons why such an effect might arise. First, givers may actually perceive recipients differently when they are presented together versus separately (e.g., Hsee 1996). Alternatively, givers may want to personalize gifts in order to convey an understanding of recipients' unique identities (e.g., Belk 1996; Schwartz 1967), and this personalization motive may be highlighted in the multiple-recipient context. Although it may be important to differentiate gifts when recipients are likely to compare gifts, if recipients are unlikely to do so, then it makes less sense for givers to pass up gifts that would be better liked in favor of unique gifts.

Studies 1-3 explore whether givers who are purchasing items for multiple recipients favor unique gifts over better liked gifts. In each study, givers selected a gift for one recipient or two unacquainted recipients from a list of options in which one gift would clearly be better liked by both recipients. For example, in one study, participants selected a birthday card for one or two recipients: the target recipient and another recipient who was shown laughing (suggesting that he had a better sense of humor). Although most givers in the one-recipient condition (70%) gave the target recipient the card that was rated funniest in a pre-test, in the two-recipient condition, only a minority gave him this card (26%), $\chi^2(1) = 9.03$, $p = .003$. This happened despite the fact that givers who gave one of the other cards predicted that the target recipient would enjoy that card less than did givers who gave the funny card, $t(45) = 2.38$, $p = .02$, $d = .68$.

Study 4 examined a perceptual account for the current effects. Givers either chose a gift for one friend, chose a gift for two friends, or considered both friends but only choose a gift for one. One of the available gifts was clearly the most appropriate gift. Some givers *gave* an item and others *predicted* which item the recipient(s) would choose. A contrast analysis indicated that givers were less likely to *give* the target recipient the better gift when they selected gifts for both her and another recipient (42%) than when they considered the target recipient alone (86%) or considered both recipients but selected a gift for the target recipient only (82%), $z = 3.88$, $p < .001$. Givers *predicted* that the target recipient would choose the better gift for herself regardless of condition, $\chi^2(2, N = 168) = .42$. Thus, merely considering two people together does not alter perceptions of recipients' tastes and does not drive the tendency to differentiate gifts.

Studies 5 and 6 examined whether givers differentiate gifts to convey their understanding of recipients' identities. In Study 5, participants chose between the movies *Up!* and *Star Trek* for a recipient who had a main interest in animation and a secondary interest in science fiction. Participants chose which movie would convey a better understanding of the recipient. Half of each sample considered this choice in isolation, and the other half considered this choice in the context of having already chosen to give *Up!* to another friend. Fewer thought that *Up!* conveyed a better understanding of the target when they were also giving *Up!* to another recipient (52%) than when they were getting it only for the target recipient (97%), $\chi^2(1, N = 61) = 17.39$, $p < .001$.

In study 6, givers imagined selecting gifts for two close friends, for whom they would put considerable thought into their gift choices, or for two casual acquaintances. Both recipients preferred animated movies, but the target recipient had a secondary interest in science fiction. That target recipient was less likely to receive the better gift (the animated movie) in the close-friends condition (31%) than in the casual-acquaintances condition (47%), $\chi^2(1, N = 157) = 3.97$, $p < .05$, indicating that givers were less likely to diversify their gift choices for casual acquaintances. Thus, the more motivated givers are to put thought into their selections, the more likely they are pass up better liked gifts for unique gifts.

Finally, study 7 explored whether focusing givers' attention on recipient liking, by asking them to first predict which items recipients would choose for themselves, might encourage givers to select gifts that maximize recipient liking. Indeed, givers who first predicted which items recipients would choose for themselves were more willing to give two recipients the same gift than those in the control condition, who were more likely to diversify their gift selections. (Seventy-six percent gave the target recipient the better gift in the predict-liking condition and 54% did so in the control condition, $\chi^2(1, N = 73) = 3.93$, $p < .05$.)

In sum, the social context in which a gift is selected influences gift choices. When people select gifts for multiple recipients, they focus on what differentiates recipients rather than what each recipient would like best. This leads givers to pass up gifts that they believe would be better liked for unique gifts. This tendency is rooted in the motivation to convey an understanding of recipients' unique identities and is ameliorated by encouraging givers to consider which items recipients would choose for themselves.

When Do Gifts Help Charitable Giving and When Do They Hurt?

EXTENDED ABSTRACT

Donations are one of the largest sources of revenue for most nonprofits and charities and, as a result, a great deal of research in psychology, economics, and marketing has explored what factors encourage charitable giving. This paper focuses on the effectiveness of offering small 'thank-you' gifts, such as a pen, coffee mug, or tote bag, as means of soliciting charitable donations and specifically, the factors that are likely to increase or decrease the effectiveness of such offers.

Motivated by previous work on differences between social and monetary markets (e.g., Heyman and Ariely 2004), I hypothesize that consumers may evaluate the same offer very differently depending on whether they are primed with altruistic versus market motivations. Specifically, when an offer is framed as a "donation," altruistic goals are primed and therefore, benefits to the self (such as a tote bag given as a thank-you gift) are likely to decrease charitable giving due to crowding out of altruistic motivations. In contrast, when the identical offer is framed as a purchase (e.g., a tote bag that is offered for sale), a market motivation is primed, and therefore, highlighting the potential charitable benefits should increase donations because the charitable benefit is now seen as an additional benefit of the market purchase. In other words, altruistic motivations may be "tainted" by incentives, while market motivation may only be enhanced through additional incentives (including charitable ones). These predictions were tested in a series of studies.

As an initial test of people's lay beliefs, adults were asked to predict whether a thank-you gift (a pen bearing a PBS logo) would encourage people to donate more, less, or the same amount to public broadcasting compared to a donation request that did not offer a thank-you gift. The majority of participants (68%) predicted that thank-you gifts would *increase* donation amounts. Analogously, participants predicted that the group who was offered a thank-you gift would donate significantly more money than the group who was not.

In Study 2, a new group of adult participants were presented with the same materials as in Study 1. However, the presence or absence of a thank-you gift was manipulated between-subjects. In stark contrast to Study 1, participants who were simply asked for a donation (without any offer of a thank-you gift) were willing to donate significantly more than participants who were offered a thank-you gift. Moreover, the total amount of money donated was also higher in the no-gift condition than in the gift condition. Thus, despite people's predictions, the offer of a thank-you gift actually decreased donations both in terms of the average amount per individual as well as the total amount donated.

Study 3 replicated this effect using actual donations, rather than hypothetical ones. In this experiment, participants were asked to donate a percentage of their winning from a lottery to the Save-the-Children foundation. Replicating the previous experiment, participants who were offered a thank-you gift donated significantly less compared to participants who were simply asked for a donation.

Study 4 examined the mechanism that thank-you gifts reduce donation amounts because the external incentive undermines or "crowds out" participants' altruistic motivations (e.g., Deci 1975; Lepper and Greene 1980). To test this explanation, the same gift (a cloth shopping bag bearing the organization's logo) was framed as either something that could be used in a personally beneficial way (for shopping) or in a manner that benefited others (to increase awareness of the cause). As in previous studies, participants in the no-gift condition were willing to donate significantly more than participants in the benefit-to-self condition. However, consistent with the crowding out hypothesis, participants in the benefit-to-others condition also donated significantly more than participants in the benefit-to-self condition. Donation amounts in the no-gift condition and the benefit-to-others conditions were not statistically different. Thus, merely reframing the gift as consistent with altruistic goals attenuated the negative effect of thank-you gifts on donation amounts.

Study 5 sought to test the predicted interaction effect by framing the offer as either a "donation" or a "purchase." In two donation conditions, participants were asked how much they would be willing to donate to Smithsonian Folkways recordings, a non-profit aimed at helping musicians in underprivileged countries. Half of the participants were asked how much they would be willing to donate, while the other half were asked for a donation that included an electronic mp3 album as a thank-you gift. Consistent with the previous findings, participants donated more when simply asked for a donation compared to when they were also offered a gift. In two additional conditions, participants were asked how much they would be willing to pay for an electronic mp3 album (the same as offered in the thank-you gift condition). Half of the participants were merely asked how much they would be willing to pay for the album, while the other half were told that all of the proceeds would go to benefit the Smithsonian non-profit. In these conditions, the pattern of results reversed such that participants were willing to pay more for the album when it offered a charitable benefit compared to when no benefit was highlighted. Thus, the mere framing of an offer as either a donation or a purchase seemed to moderate whether the gift increased or decreased donations.

In sum, although people have the strong prediction that the offer of thank-you gifts should increase donations, such offers actually reduce charitable donations both in terms of the average amount donated per individual as well as the total amount donated. This effect is consistent with the hypothesis that the offer of external incentives undermines or "crowds out" altruistic motivations. However, if the same offer is presented as a "purchase," additional incentives (including charitable ones) increase willingness to pay since a market, rather than altruistic goal has been activated.

SESSION OVERVIEW

Though the majority of prior research has focused on how consumers select and evaluate products for their own personal use (Bettman, Luce, and Payne 1998), there are many situations in which consumers choose for others or have products chosen for them. In these "social consumption" situations, the chooser must balance his needs and preferences with those of others. For instance, when selecting wine for the table, a diner must decide whether to choose something he personally likes or something that everyone will likely enjoy. In addition, the products chosen or received in social situations hold special meaning for consumers. First, they indicate whether the chooser is considerate of and willing to accommodate others. Second, chosen products communicate the giver's perceptions of the recipient's desires, preferences, and needs. For example, when a close friend gives an individual a book of brain teasers, she may infer that this friend thinks she enjoys being cognitively challenged. The objective of this special session is to explore these dynamics from both the perspective of the chooser and recipient.

The first two papers focus on how consumers select products to share with others and demonstrate that consumers adopt a variety of approaches when making such choices. Moore, Wu, and Fitzsimons examine how interdependent and independent individuals differ when choosing products to share with others. While interdependents consistently incorporate the preferences of others, independents generally behave selfishly when choosing—but only when they can do so without the risk of social censure. For instance, independents select a more expensive bottle of their preferred wine when choosing for a group, but are less likely to do so when dining with just one person. Yang, Chartrand, and Fitzsimon's paper examines how low and high self-monitors use stereotypes to inform their product choices in shared consumption situations. They find that, relative to low self-monitors, high self-monitors are more likely to recognize that choosing something liked by the consumption partner may not always ensure a positive interpersonal experience. For instance, when

choosing an item to consume with an attractive woman, men who are high, rather than low, self-monitors are more likely to recognize that selecting something feminine, though likely to be enjoyed by the woman, may compromise the choosers' romantic attractiveness.

The next two papers take the perspective of the recipient and examine consumers' inferences regarding whether the chooser has their best interests in mind. Ward and Broniarczyk examine how consumers interpret identity-inconsistent gifts. When consumers receive an identity-inconsistent gift from a close friend, they give their friend the benefit of the doubt and assume that the gift reflects their own identity in a way they cannot see. However, when consumers receive an identity-inconsistent gift from a distant friend, they assume that the giver is more concerned with personal convenience and saving money than with giving, and respond by distancing themselves from the giver. Aggarwal, Botti, and McGill's paper demonstrates that these dynamics also exist in customer-provider relationships. In a communal relationship, customers expect the provider's choices on their behalf to align with their own selections. However, in an exchange relationship, customers perceive the provider's choices as self-serving and in conflict with their own choices, and expect to be dissatisfied with the provider's choice. Ironically, these low expectations lead consumers to be pleasantly surprised and more satisfied with the provider's choice compared to their own choice in an exchange, but not in a communal, relationship.

These papers each demonstrate that products chosen for others hold special meaning to consumers and are important to building social ties. In other words, choosing for and receiving products from others serve as a way for consumers and firms to literally "build connections" with each other. Furthermore, the papers illustrate the important tradeoffs that people make to choose items that will fulfill their own needs and simultaneously satisfy those of the other person. By taking the perspectives of both the chooser and the recipient, by examining different chooser-receiver relationships, and by identifying unique moderators of choosing and receiving, these papers build multiple connections between the experiences of the chooser and recipient. We believe this session provides a comprehensive picture of the dynamics of social consumption and will appeal to a broad audience, including those interested in gift-giving, perspective-taking, self-construal, and relationship dynamics.

You've Got a (Bad) Friend in Me: Self-Construal and Strategic Selfishness

EXTENDED ABSTRACT

What does it mean to "choose like a good friend"? As social beings, we spend our lives in the company of others—a fact that frequently compels us to choose collectively on behalf of ourselves and those others. Do we make reservations for 6 at a bistro or a steakhouse? Watch a kung-fu flick or a comedy? Go bowling or grab a drink? Making choices can be tough enough when we're choosing for ourselves (Schwartz 2004), but the difficulties are compounded when we must consider the preferences of others in addition to our own. In this research, we examine how individuals balance self and other preferences when choosing collectively.

The importance of satisfying relationships to our physical and psychological well-being (Eisenberger, Lieberman, and Williams 2003) suggests that it might be wise to balance others' preferences

with our own in making collective decisions. In trying to ensure that everybody is happy, we stand a better chance of ensuring group harmony and strengthening our social relationships. Extant research suggests, however, that not everyone is naturally disposed to make more other-oriented choices. Specifically, those with independent self-construals have been shown to emphasize self-preferences in decision-making, while those with interdependent self-construals naturally balance self and other preferences (Cross, Bacon, and Morris 2000). For interdependents, then, "choosing like a good friend" comes easily. Thus, we suggest that in choosing for self and others, interdependents should make "friend-friendly" choices regardless of the choice situation. For independents, however, their emphasis on self preferences can be inconsistent with maintaining strong relationships and "choosing like a good friend." We argue that rather than dependably forgoing their relationships or their personal preferences, independents skillfully balance self and other in social consumption situations: they generally behave selfishly—but only when they can do so without the risk of social censure, in contexts where their selfishness can be hidden from the group. When the social situation suggests that selfish choices cannot be made without discovery, however, we suggest that independents strategically attempt to disguise their self-centered natures and make more "friend-friendly" choices.

Unlike prior research, then, which shows that interdependents are more situationally sensitive than independents (e.g., Lewis, Goto and Kong 2008; Haberstroh, Oyserman, Schwarz, Kühnen and Ji 2002), we suggest that in social consumption situations, independents behave strategically in context-sensitive ways, while interdependents are contextually insensitive. We build on this literature to examine how individuals balance their fundamental need for fulfilling relationships with their personal self-interests, and examine how individuals use the social context around them to manage their interpersonal relationships. Specifically, we suggest that interdependents reliably make choices that take the preferences of others into account along with their own—regardless of the social and choice context around them. On the other hand, we expect independents to use situational cues to strategically determine how to choose in order to preserve their social relationships while still satisfying their own preferences.

We examine the influence of self-construal on social consumption using a common collective decision: choice of wine for the table at a restaurant. Across four studies, participants were told that they were out to dinner with friends and that they had $110 to spend on one bottle of red and one bottle of white wine for the evening. Individuals then chose a bottle of red and white wine off a real wine list. We measured wine preferences (how often participants drank red versus white wine) and self-construal (Singelis 1994) as independent variables, and measured the prices and perceived quality of the red and white wines chosen as dependent variables. We expect interdependents to make balanced choices and to choose equally expensive bottles of red and white wine, regardless of their own wine preferences. Independents, on the other hand, should selfishly choose better (more expensive) wines of the type they prefer—unless this choice puts them at risk of social censure.

In study 1, we compared choosing for others in a dyadic versus a group setting. We expected that interdependents would display context insensitivity and make balanced choices regardless of the social setting, but that independents would display context sensitivity and make balanced choices only in the dyadic setting, where selfishness is harder to conceal and the risk of social censure due to selfishness is greater. As expected, personal wine preference did not influence interdependents' choices in the dyad or group conditions, nor did it influence independents' choices in the dyad condition. However, in-

dicating their context sensitivity, independents in the group condition behaved selfishly and chose more expensive red (white) wine as their preference for red (white) wine increased.

In studies 2a and 2b, we replicated and extended our group condition findings from study 1. In study 2a, we found that independents continued to choose selfishly in a group situation and that they were aware of doing so: independents rated the chosen wine bottle of their own preference as being of higher quality and more enjoyable than the other bottle, while interdependents showed no such effects. In study 2b, we replicated this finding by priming instead of measuring self-construal, and by using an actual choice measure of wine preference.

In study 3, we explored how group characteristics affect independents' choices. Specifically, we manipulated whether the group was comprised of wine experts or novices. Given that wine novices have a lower level of wine knowledge, we expected that independents would choose especially selfishly when choosing for novices because the likelihood of having their selfishness detected is low. In contrast, we expected that independents would choose less obviously selfishly when choosing for a group of wine experts. All participants were primed to be independent before choosing wine. As expected, independents chose more expensive bottles of the wine they preferred when choosing for novices, and rated this wine as being of higher quality and more enjoyable. When choosing for experts, however, independents chose equally priced bottles of red and white wine regardless of their individual preferences, though they continued to rate the bottle they preferred as being of higher quality and more enjoyable. Thus, independents again displayed context sensitivity and made less obviously selfish choices when choosing on behalf of self and experts.

Taken together, this work suggests that independents are "strategically selfish" in social consumption situations: they generally behave selfishly, but take pains to hide their selfishness when there is a risk of exposure. Thus, in contrast to prior work, we show that independents, rather than interdependents, are context sensitive in social consumption situations where they must balance their own preferences with others'. Importantly, these results are not driven by biased assumptions about others' preferences (Davis, Hoch and Ragsdale, 1986)—independents who liked red wine did not choose more expensive red wines because they assumed everyone at the table would be drinking red wine, just like them. We measured and manipulated individuals' expectations about group preferences in our studies to rule out this alternative explanation. In short, then, when selecting someone to make a decision for your group, choose interdependent individuals—or you might end up drinking a bargain blend while they enjoy an award winning vintage.

Strategic Self-Presentation in Joint Consumption: Stereotypes as Social Tools

EXTENDED ABSTRACT

Consumers often engage in shared consumption in order to become acquainted with and learn more about each other. For example, new friends may go see a movie together to socialize, or a salesperson may take a new client to dinner to learn about the client's needs. Given the importance of making a good impression in the early stages of a relationship, the products consumers choose for joint consumption are quite important and have the potential to make or break a budding relationship (Raghunathan and Corfman 2006; Ramanathan and Mcgill 2007). When consumers are just beginning to get to know each other, they have very little information regarding their consumption partner's preferences and expectations for the interaction. How might they go about making their product choices? We propose that consumers use stereotypes as a resource to help inform their choices. Because stereotypes are socially shared and provide information about social groups based on easily identified qualities (e.g., race, gender), they may prove useful in inferring the preferences and anticipating the behavior of one's consumption partner (Kunda and Thagard 1996).

However, consumers understand that simply choosing something liked by the consumption partner may not be enough to ensure a positive interpersonal experience because chosen products may communicate a number of things about themselves to others, especially if chosen products are consistent with stereotypes. In order to ensure that selected items will be favorably received, we find that consumers also consider the type of relationship they wish to pursue during the interaction and also the expectations their consumption partner might have. We find that some consumers are more adept at considering these factors than others. High self-monitors, compared to low self-monitors, have richer, more easily accessible knowledge structures regarding other people and the appropriateness of certain behaviors in specific social situations (Snyder and Cantor 1980). In turn, they use this information as a guide for monitoring their own self-presentations. Thus, high self-monitors relative to low-self monitors should be more willing and able to select products that convey impressions that facilitate positive consumption experiences.

In studies 1 and 2, we examine how male consumers' product choices may be constrained by the need to uphold the role of a masculine man when trying to pursue a romantic relationship with a female consumption partner and how these constraints shape the impressions male consumers wish to present. In study 1, we examine the social implications of expressing gender role consistent or inconsistent product preferences for males and find that males are penalized romantically (but not platonically) if they express gender role violating (i.e., feminine) product preferences.

In study 2, we explore the implications of these findings for choosing products for shared consumption. We examine how males choose products when consuming with a female, depending on whether these males are high or low self-monitors and also whether they are motivated to pursue a romantic relationship. Both low and high self-monitors relied on gender stereotypes and assumed their consumption partner would enjoy reviewing feminine TV shows and magazines (e.g., *Sex and City* and *Elle Décor*). However, they ultimately chose different products to share with their female consumption partner. When not motivated to foster a romantic relationship, high self-monitors were more likely than low self-monitors to fully accommodate their female consumption partner and select stereotypically feminine items. However, when motivated to pursue a romantic relationship, it was low self-monitors that were more likely to select feminine items while high self-monitors were more likely to select gender neutral items (e.g., *Weeds* and *Condé Nast Traveler*). This suggests that only high self-monitors realized that selecting feminine items could compromise their romantic attractiveness.

In study 3, we examine another important determinant of impression management efforts: the audience's expectations. More specifically, we study the types of impressions male consumers wish to present when selecting products to consume with a feminist consumption partner. In this study, we find that male participants used the stereotype associated with feminists to infer that she may expect him to be sexist; thus, they adjusted their joint consumption choices in an attempt to compensate for these negative expectations.

Both low and high self-monitors recognized that selecting stereotypically feminine items would likely be construed as a sign of prejudice in this study. However, only high self-monitors recognized that selecting a gender neutral item may also hold the same risks, because the feminist may interpret the selection as a compromise between the male's masculine preferences and her presumably feminine preferences. Thus, high self-monitors were more likely than low self-monitors to select masculine items in order to avoid indicating that they were applying gender stereotypes to their consumption partner. On the other hand, low self-monitors were more likely than high self-monitors to select gender neutral items because they were less likely to realize that selecting gender neutral items could be negatively received by a feminist consumption partner.

Taken together, these studies suggest that when choosing products to share with people they are unfamiliar with, consumers rely on stereotypes to help infer the preferences and anticipate the responses of their consumption partner. However, consumers differ in their willingness and ability to select products that will be favorably received. In contrast to low self-monitors, high self-monitors recognize that simply choosing something liked by the consumption partner may not be enough ensure a positive interpersonal experience, because chosen products communicate a number of things about themselves to others, especially if these products are consistent with stereotypes.

Is it Riskier to Receive than to Give?: The Effect of Social Closeness on Gift Recipients' Responses to Identity-Inconsistent Gifts

EXTENDED ABSTRACT

Behavioral scientists have long viewed personal identity as a dynamic construct, inextricably linked to the feedback one receives from both his/her social relationships and environment. People's identities are built from the outside in, as the relationships an individual holds dear shape his/her understanding of who s/he is through how s/he is seen by others (Cooley 1902; Swann et al 2000). While an individual's identity is somewhat flexible, most people are motivated to sustain a consistent and coherent sense of self and prefer to surround themselves with people who verify their self-concepts. Consequently, individuals avoid or distance themselves from relationship partners who do not affirm important identities (Swann 2005).

One important social interaction that shapes an individual's perception of him/herself and supports important social ties is the exchange of gifts (Ruth, Brunel, and Otnes 1999). When a recipient receives a gift, s/he has a porthole into how the giver perceives him/her as a gift is supposed to embody the giver's interpretation of the recipient's desires, preferences and needs and by extension, his/her identity (Belk 1999; Sherry 1983). Given that individuals' identities are responsive to interactions with their relationship partners (Josephs, Bosson, and Jacobs 2003) and that they deeply value verifying feedback from those closest to them, receiving a gift that is inconsistent with one's existing self-concept may cause the gift recipient to feel some dissonance. We predict that in response to receiving such a gift, the recipient may reduce his/her dissonance by 1) revising, expanding or changing his/her existing self-identity in order to accommodate the chosen gift or 2) withdrawing from the relationship partner in order to avoid receiving non-verifying feedback. In a two experiments, we find that depending on the social closeness between the giver and recipient and how identity-consistent the gift is, recipients exhibit each of these responses.

In study 1, using a 2 (gift: identity-inconsistent vs. identity-consistent) x 2 (social closeness of recipient: close vs. distant) experimental design, we instructed participants to recall receiving an identity-inconsistent (vs. consistent) gift from a close (vs. distant) friend. After writing about the gift, they answered questions about whether the gift had made them see themselves in a new way or changed their identity and how it had affected their friendship with the giver. As predicted, close (vs. distant) recipients were more likely to indicate that the identity-inconsistent (vs. consistent) gift had changed the way they saw themselves. Conversely, distant (vs. close) recipients were more likely to indicate that the identity-inconsistent (vs. consistent) gift had caused them to feel more socially distant to the giver.

In order to understand why recipients had different responses to identity-inconsistent gifts given by close (vs. distant) friends, we conducted a follow-up study in which we manipulated rather than measured the identity-inconsistency of the gift. In study 2, a 2 (gift: identity-consistent vs. identity-inconsistent) x 2 (social closeness of recipient: close vs. distant) experimental design, participants read a scenario about receiving an identity-consistent (vs. inconsistent) gift from a close (vs. distant) friend. In identity-consistent gift scenarios, recipients either received a CD of their favorite group's new album or a DVD of their favorite movie; in identity-inconsistent scenarios they received either a puzzle or slippers. After reading the scenario, participants answered questions about how self-reflective the gifts were.

The data reveal an identity-consistence x social closeness interaction on the self-reflectiveness of the gift such that givers felt that the identity-inconsistent (vs. consistent) gifts were more (vs. less) self-reflective when they were given by close (vs. distant) friends. In other words, recipients' judgments of the self-reflectiveness of the identity-consistent (vs. inconsistent) gift is qualified by their relationship with the recipient.

Respondents were also asked to answer the open-ended question: "Why do you think your close (vs. distant) friend chose this gift for you?" Respondents in the close friend condition indicated that they thought that their friend had chosen this gift because s/he had seen something in the gift that matched his/her identity in a way that the recipient had not seen in him/herself:

- There must have been something about the puzzle that made her think of me.

- He wanted me to explore my creative side. The puzzle would probably have some deeper meaning once finished.

On the other hand, those receiving the identity-inconsistent gift from a distant friend were not as likely to attribute such powerful insights to the gift giver and simply thought the giver did not know him/her very well and was more concerned with saving time or money than choosing something appropriate:

- She probably tried to choose something that wasn't too expensive yet too cheap.

- He didn't spend long buying it.

- He hasn't seen me in so long and doesn't know my interests that well so he went for something really safe like slippers when he should have went on his gut feeling.

The data from these two studies corroborate the prediction that close recipients are likely to change or expand the way they see themselves in order to incorporate identity-inconsistent gifts from their close friends. Furthermore, the open-ended responses indicate that they do so because they think that their close friends see something in the gift that matches a part of their identity that they are not aware of. Conversely, individuals who thought their distant (vs. close) friends had chosen an identity-inconsistent gift subsequently felt more emotionally distant from the giver.

I Didn't Think I Would l Like What You Chose for Me: Relationship Norms and Satisfaction with Consumer-versus Provider-Chosen Outcomes

EXTENDED ABSTRACT

Prior research demonstrates that personally-made, as compared to externally-made, choices lead to greater task enjoyment and more positive affect (Brehm 1966; Langer 1975). More recent research, however, has found that cultural norms regulating interpersonal exchanges may moderate these beneficial effects of self-choice (Iyengar and Lepper 1999). The present research examines the manner in which relationship norms underlying customer-provider interactions

moderate expected and actual satisfaction with a self-chosen relative to a provider-chosen outcome.

Two types of customer-provider relationships are examined: communal and exchange (Clark and Mills 1993). Communal relationships are based on a mutual concern for the partner's well-being; exchange relationships are based on the principle of *quid pro quo*. Communal and exchange relationship norms carry expectations not only about the partner's behavior but also about the partner's intentions, as they provide guidelines about the motivation underlying the interaction: a desire to satisfy the other's needs versus a desire to get something back (Clark and Mills 1993). In a communal relationship, customers are more likely to expect the provider to make choices that are in line with the choices that they themselves would make. On the other hand, in an exchange relationship, customers are more likely to perceive the provider's self-serving choices as conflicting with their own. As a result, we hypothesize customers to expect lower satisfaction with a provider- than with a self-made choice in exchange relationships but little or no difference in communal relationships. These initial expectations may exert an ironic effect when actual satisfaction is considered. Drawing on prior research on expectation confirmation and disconfirmation (Oliver 1980), we suggest that exchange customers will be positively surprised by a valued outcome chosen by the provider resulting in actual satisfaction being higher than expected satisfaction. Conversely, communal customers' expectation would be simply met by the same outcome, resulting in actual and expected satisfaction being no different. Thus, we hypothesize that the moderating effect of relationship norms would reverse when actual rather than expected satisfaction is assessed.

Four studies test these hypotheses. The first two studies examine the moderating role of relationship norms on expected satisfaction. The next two studies examine the reverse moderating effect on actual satisfaction.

In study 1, we rely on the relative salience of communal and exchange norms underlying the existing relationship between undergraduate Management students and their university. The self-choice (university-choice) context involved four Strategy courses. Regression results supported our hypothesis. At one standard deviation below the mean of the Net communality score (corresponding to a more exchange orientation), expected satisfaction in the university-choice condition was significantly lower than in the self-choice condition. However, at one standard deviation above the mean of the Net communality score (corresponding to a more communal orientation), expected satisfaction was no different across the self- and the university-choice conditions. Study 2 was conducted to replicate the effect by manipulating relationship norms and by taking more direct measure of perceived intentions underlying the two relationships. Scenarios describing interactions between a customer and a bookstore were used to prime communal or exchange relationship norms. The self-choice (bookstore-choice) context involved four books as part of a promotional give-away. As predicted, exchange participants' expected satisfaction was lower in the bookstore-choice than in the self-choice condition, whereas communal participants' ex-

pected satisfaction did not differ across the two choice conditions. A follow-up study confirmed that participants in the bookstore-choice condition were more likely to perceive the bookstore to be motivated by the customer's best interest in the communal condition but by its own best interest in the exchange condition.

The next two studies investigated the reverse moderating effect of relationship norms by examining their influence on actual rather than expected satisfaction. Study 3 was a field study involving two actual bookstores – one positioned as a communal bookstore and the other as exchange. The self-choice (bookstore-choice) context involved four books as part of an actual promotional give-away. As we hypothesized, customers of the exchange bookstore were *more* satisfied with the bookstore-chosen book than with the self-chosen book; there were no differences in satisfaction between bookstore- and self-choice customers of the communal bookstore. A post-test showed that, different from actual satisfaction, expected satisfaction follows the same pattern of results as studies 1 and 2. Study 4 examined the effect of relationship norms on actual satisfaction in a laboratory setting. Relationship norms were primed in an interpersonal context; the self-choice (company-choice) condition involved four new healthy juice options being tested by a beverage company. Measures of expected and actual satisfaction were taken. Consistent with our hypothesis, exchange participants reported a significantly higher net satisfaction change in the company-choice condition than in the self-choice condition, indicating greater actual satisfaction than expected satisfaction. However, communal participants experienced a similar net satisfaction change irrespective of whether they were in the company-choice or in the self-choice condition, indicating no difference between actual and expected satisfaction.

This paper shows that satisfaction is not necessarily greater with a self-chosen outcome, and that providers should consider the potential limitation of personal freedom when deciding to bear the costs of granting more choice opportunities to their customers. In general, if individual well-being is to be maximized, perhaps the focus should be less on who makes the final choice, and more on the type of relationship that binds those who experience the decision outcome with those who decide for them.

SESSION OVERVIEW

Objective: Counterfeit goods represent a $600-650 billion global market, and mere mention of the word "counterfeit" connotes negativity, fraudulence, and inferior quality. Countries and companies have taken significant and costly actions to deter counterfeiting for reasons ranging from lost revenue to the tarnishing of a brand. But what if counterfeit had some positive effects on companies, consumers, or brands? What if "smarter" consumers actually preferred counterfeit products more than "less intelligent" shoppers? What if an abundance of counterfeit actually *boosted* the price of a genuine product? In the spirit of "creating connections," the objective of this session is to link together several unexpected discoveries regarding counterfeit to provide a robust understanding of when counterfeit is, in fact, detrimental and when it actually might *benefit* consumers and companies producing the genuine product.

General Orientation: The present session connects several surprising findings regarding how counterfeit helps or hinders companies and consumers. The four papers included in the session address: 1) the counterintuitive benefits of counterfeit, 2) the role of consumer intelligence in perceptions of signaling and quality of counterfeit, 3) the extent to which construal level and self-goals influence preference for counterfeit or genuine products, and 4) the collateral damage effects of counterfeit on brands *other* than the brand being counterfeited. Each paper integrates with the others to collectively illustrate the "connection" among counterfeit's many components. Each presentation will last for 15-20 minutes and, afterwards, a discussion will take place regarding how the connection of these findings could motivate future research on the topic of counterfeit. Included in our group of authors is a diverse group of researchers, which should generate a lively and productive discussion.

Likely Audience: The appeal of this session is that it considers the topic of counterfeit from a variety of perspectives: consumer intelligence, market implications beyond the counterfeited brand, counterintuitive benefits, construal theory, consumer goals, public policy, and luxury/non-luxury goods. Given the diversity of approaches taken to explore the core topic of counterfeit, the issues addressed in this session should generate broad audience appeal. Thus in the spirit of the conference theme, our goal is to *connect* researchers with diverse backgrounds to have a lively, informative discussion on the subject of counterfeit.

Issues and Topics: The Poehlman et al. paper sets the stage for the session by exploring the counterintuitive benefits that counterfeit can have in the marketplace. Whereas prior research has emphasized the negative consequences of counterfeit, this paper demonstrates that perceived prevalence of counterfeit can boost the market price consumers would pay for genuine products in the marketplace. While high levels of counterfeit boost high-end brands, low perceived levels of counterfeit boost low-end brands. In either case, companies must be perceived as being active in their anti-counterfeit efforts resulting in the ironic implication that, in some cases, companies may privately need to condone and even encourage counterfeiting while publicly seeming to fight counterfeiting. Next, the Townsend et al. paper explores the tradeoff between signaling and quality with respect to counterfeit, specifically considering the role of consumer intelligence. The authors contend that "smart" consumers are more aware of the signaling power of luxury brands and of the unsubstantiated markup of some luxury products to convey "quality." As such, smarter consumers are more likely than less intelligent consumers to prefer counterfeit products to benefit from the signaling, self-presentation aspects of counterfeit while avoiding the feeling that they are paying more for quality that does not justify the premium price. The third paper, Wilcox et al., investigates how construing products at an abstract or concrete level can actually increase or decrease preference for a genuine product. Specifically, construing products concretely leads to a comparison of differences, thereby encouraging preference for a genuine product; construing products abstractly leads to thoughts of similarity, encouraging preference for a counterfeit. A self-expression goal trumps the effect, however, as consumers with the goal to self-express prefer the genuine brand regardless of processing style. Finally, the fourth paper moves beyond prior work to show how counterfeit negatively impacts brands *other than* the brand being counterfeited. Specifically, the work demonstrates the "collateral damage" a counterfeit excises on other, genuine brands that may have otherwise been purchased in the absence of the counterfeit product. The results suggest the striking finding that 90% of lost sales come from other, genuine brands and not the brand actually being counterfeited. Collectively, the papers offer four distinct perspectives on counterfeit but connect together to illustrate that counterfeit has some unexpected, surprising consequences that warrant further exploration.

Contribution: To date, surprisingly little research has addressed the topic of counterfeit and almost no research, to our knowledge, has considered the potentially beneficial effects of counterfeit. Thus, this session's major contribution is to bring counterfeit research to the forefront of consumer research, connecting both the negative and positive implications counterfeit has for consumers and companies. We also highlight the role of consumer psychology in counterfeit, linking prior work from the company's perspective with novel work from the consumer's perspective. By bridging these various perspec-

tives on the topic of counterfeiting, we seek to encourage future research on the subject that continues to link different methodologies and theoretical accounts.

Connecting Questions: Some questions to be included in the follow-up discussion are: To the extent that counterfeiting is inevitable, is it feasible for companies and consumers to benefit from counterfeit strategies? How can a company's strategy link to the findings presented here regarding the consumer psychology of counterfeit? Regarding consumer education, when might "intelligent" consumers still prefer the genuine brand? And when might "less intelligent" consumers prefer counterfeit? Is it possible to link consumer intelligence to how consumers construe products (i.e., abstractly or concretely)? When might non-counterfeited brands benefit from the presence of counterfeit (linking the first and last papers)? And perhaps the biggest "connecting" question of all is: how do we integrate the findings that counterfeit may have beneficial consequences with its known detrimental effects?

Status of Papers: All the papers included in this special session are completed or near completion.

Laud the Fraud, Just Not In Public: Counterintuitive Benefits of Counterfeit

EXTENDED ABSTRACT

For luxury brands, combating counterfeit is a top priority: in one year alone, Louis Vuitton conducted over 6,000 raids, participated in over 13,000 legal proceedings, and led to the arrest of nearly 1,000 individuals. Coach, the luxury brand famous for its handbags, even provides a step-by-step process for reporting counterfeit in its effort to curb the practice. Many companies explicitly advertise their "zero tolerance" policy with respect to counterfeit citing the lost revenues and additional costs stemming from counterfeit. Yet, surprisingly, some counterfeited brands are publicly silent on their views towards counterfeit. Nike, for example, takes a relatively quiet approach to combating counterfeit, despite footwear being the most counterfeited product category. This stark contrast in dealing with counterfeit raises some interesting questions including whether it is in a company's best interest to be perceived as taking an active or passive role in fighting counterfeit or if, in some instances, counterfeiting can even *help* a company producing the genuine brand.

The present research explores how perceptions of counterfeiting prevalence, luxury and non-luxury brand status, and company responses to counterfeit interact and affect genuine products and consumer behavior. In four studies, we demonstrate that counterfeit can both positively and negatively influence perceptions of a genuine product's market price, that the perceived status of a brand moderates the effect, and, ironically, that a company's vigilance with respect to fighting counterfeit is an essential component necessary to obtain benefits from high levels of counterfeit.

In our first study, we wanted to test our hypothesis that the perceived prevalence of counterfeit could influence perceptions of genuine brand product prices. We randomly assigned participants into one of three conditions: high-counterfeit, low-counterfeit, and control. We presented participants with a Louis Vuitton bag and asked them, relative to a counterfeit bag, how much more expensive they thought a real Louis Vuitton bag would be. On average, participants in the high counterfeit condition perceived a greater percentage difference (383%) compared to the control group (235%), while participants in the low counterfeit condition perceived a much smaller markup (183%) than the other two groups. The data from this initial provided evidence that perception of the prevalence of counterfeit does, in fact, affect perceptions of real market prices for products. This

finding supported our hypothesis that prevalent counterfeiting of a brand implies that brand is popular and valuable, which subsequently influences perceived market price of the genuine product.

In our second study, we wanted to replicate the initial finding from study one, as well as explore whether counterfeiting could have potentially beneficial effects in the marketplace in a non-luxury product domain. To test the hypothesis that the perception of high levels of counterfeit might lead consumers to increase their estimated value of a real, non-counterfeit product in the marketplace, we randomly assigned participants to high- and low-counterfeit conditions, or to a control condition. We then asked participants questions regarding perceptions of a product's real market price, counterfeit price, and cost to produce. The product used for the study was a pair of Nike brand shoes, which, aside from being a relevant product for the population (college undergrads), also represents one of the most counterfeited product categories (footwear). As predicted, when participants thought that counterfeit was pervasive, the perceived market price of a real pair of Nike shoes was significantly higher than the control group's estimated real market price. When participants thought that counterfeiting was less common, the market price of real Nike shoes was significantly lower than the control group's estimated price. The results replicate the finding from the initial study.

In our third study, we explored whether the effect found in study two generalized to all brands, even lower-status brands, or if high perceived prevalence of counterfeiting actually hurt low-end brands. We hypothesized that the "greater counterfeit means popular product" effect would not be true for low-end brands. Instead, we expected to see the opposite: high perceptions of counterfeiting for a low-status brand should hurt the real market price of the product, as cheaper substitutes are readily available. The target brand for this study was Crocs footwear, and the design was identical to that of the second study. As predicted, when participants thought counterfeit was pervasive, the perceived market price of a real pair of Crocs was significantly lower than the control group's estimated real market price. When participants thought counterfeiting was less common, the market price real Crocs shoes was significantly higher than the control group's estimated price. Thus the indirect benefit of counterfeiting on the market price of genuine products is contingent on brand status, with premium brands benefitting from more counterfeit and lower brands benefitting from less.

Our fourth study addressed the role of company vigilance in response to counterfeit. We hypothesized that, even though counterfeit may have peripheral benefits, companies must be perceived as actively combating counterfeiting or else the effects will be eliminated. To test our hypothesis, we presented participants with Nike shoes, manipulated the level of counterfeit (low vs. high) and Nike's explicit vigilance towards fighting counterfeit (active vs. passive). As anticipated, perceptions of a company's role in fighting counterfeit made a difference: benefits only accrue if the company is actively fighting counterfeit. This produces the ironic results that companies should outwardly fight counterfeit but inwardly hope their products are counterfeited to boost brand popularity and the real market price of genuine goods.

Across four studies we provide evidence for counterfeit's sometimes-counterintuitive effect of boosting the perceived market price of genuine (i.e., non-counterfeit) products. We demonstrate that when counterfeiting is perceived as being prevalent, the perceived market price of genuine, high-end products gets a boost, whereas when counterfeiting is perceived as being less common, the perceived market price of genuine, low-end products gets a boost. We also show that the effects only hold when consumers perceive that a

company is making an effort to combat counterfeiting. Theoretical and managerial implications are discussed.

"I Know Enough to Buy the Fake": Intelligence, Knowledge and the Valuation of Luxury Brands

EXTENDED ABSTRACT

One of the reasons consumers purchase publicly consumed luxury branded products is the ability of these products to signal membership in an aspirational group or to suggest something about the user's social status or wealth (Bearden and Etzel 1982, Childers and Rao 1992). At the same time, luxury brands justify their high prices by offering remarkable product quality (Garfein 1989, Quelch 1987) and product quality is also a significant reason consumers purchase luxury brands (Gentry et al 2001). Despite the interest in the topic of what values consumers ascribe to a luxury brand, less understood is how such valuations may differ systematically across individuals. In the present research we examine how general intelligence (as measured by the cognitive reflection task (Frederick 2005) and the Mill Hill Vocabulary test (Raven 1981)) as well as brand knowledge affects the propensity to value luxury brands for their high quality and/or ability to signal to others. In the process of exploring this issue we uncover surprising findings as to how these individual differences influence willingness to pay for counterfeit products.

In our first study we examine the relationship between intelligence and valuation of luxury brands for their signaling abilities. Both luxury products and brands as well as more mundane publicly displayed products have been shown to be particularly useful when attempting to reveal association with a reference group (Bearden and Etzel 1982). But not all product categories are equally adept at offering a venue for self-presentation to others. By nature goods that are used or consumed in front of others are more capable of fulfilling this purpose (Childers and Rao 1992; Shavitt, Lowrey, and Han 1992). To properly use a luxury brand for self-presentation purposes, one must be aware both that others are making inferences based on one's possessions, and also understand for which product categories this is likely to be most relevant. It seems likely that more intelligent consumers are more likely to understand that viewers will judge them by their products and also that this is only possible when the good is publicly displayed. We, therefore, hypothesized that more intelligent individuals value luxury brands more for their signaling abilities than do less intelligent individuals and, because more intelligent people are likely better able to decipher when these abilities are relevant, their valuation of luxury brands is more product-category specific. We tested this by asking respondents to choose between one option that was inconspicuously branded with a luxury brand but less well designed and one that was better designed but carried an unknown brand name. Product aesthetics is a public attribute that, like brand, viewers use to make inferences about people. Therefore, when brand is not outwardly evident, a choice driven by signaling ought to favor the highly aesthetic option, not the luxury branded option. However, such an effect should only be present for the publicly consumed product categories; with privately consumed product categories where signaling to others is much more difficult, the motive to signal ought not come into play. Indeed we found that in public product categories (jeans, jacket, purse) more intelligent individuals are more likely to select the more aesthetic option over the luxury branded option than less intelligent individuals. However, this difference disappeared in private categories (cosmetics, deodorant, nightgown). This is consistent with our hypothesis and revealed a greater understanding among the more intelligent population of when luxury brands are able to signal to others.

In our second study we examined how both intelligence and brand knowledge relates to valuation of luxury brands for their high quality. Consumers do not buy luxury brands only for the conspicuousness of the brand name and ability to signal, but also because of the superior quality that these products presumably offer (Gentry et al. 2001, Nia and Zaichkowsky 2000, O'Cass and Frost 2002, Quelch 1987). And yet, a luxury brand implies premium pricing that suggests that, although quality may be high, someone searching based on a value-per-dollar basis ought not to purchase a luxury branded product (Patrick and Hagtvedt 2009). Indeed, some have gone so far as to define luxury brands as those for which functionality to price ratio is low but which have a high ratio of high intangible benefits to price (Nueno and Quelch 1998). Our hypothesis follows that more intelligent individuals would be less likely than less intelligent individuals to value luxury brands because of the implied higher quality. While the quality of a luxury brand may be high, the evidence suggests that it is not high enough to justify the cost if an intelligent valuation is undertaken. We also offered a hypothesis about the influence of brand knowledge on propensity to value luxury brands for their quality. Because luxury brands are marketed as the utmost in quality, any past experience most likely leads to a decrease in perceptions of quality. Therefore, we also hypothesized that consumers with more brand knowledge value luxury brands less for their quality than those with less knowledge.

To test these two hypotheses we asked respondents their willingness to pay for counterfeits given the price of the relevant luxury branded good. A counterfeit good offers the same self-presentation abilities but without the presumed quality. Indeed, consumers value counterfeits more when seeking self-presentation to project a specific image and value counterfeits less when motivated by intrinsic product aspects such as quality or reliability (Wilcox, Kim, and Sen 2009). Thus, an examination of how valuation of counterfeits varies with intelligence would uncover differences in perceptions of quality as motivation for purchase of luxury brands. Subsequently, we expected more intelligent individuals and more knowledgeable individuals to value counterfeit versions of products more than would less intelligent individuals and less knowledgeable individuals, respectively. Indeed, our results confirmed our hypotheses revealing the ironic results that across both publicly and privately consumed product categories, respondents with greater intelligence or greater brand knowledge consistently valued the counterfeit products more than did less intelligent or less knowledgeable consumers.

Implications with respect to luxury brands, counterfeits, as well as consumer metacognitions are discussed.

Far Away or So Close: The Influence of Counterfeits on Genuine Brand Preference

EXTENDED ABSTRACT

Imagine that you are considering buying a new Louis Vuitton watch. As you contemplate the purchase, you notice a similar looking counterfeit Louis Vuitton watch being sold on the street. Would the presence of the counterfeit version affect your decision to buy the genuine version? The widespread presence of anti-counterfeiting efforts suggests that it will. In fact, many estimates of the economic impact of counterfeiting are predicated on the assumption that sales of counterfeit products replace the sales of genuine items. For instance, it is estimated that the luxury brand industry incurs as much as $12 billion each year in lost sales due to the purchase of counterfeit products (International Chamber of Commerce 2004). Thus, it is generally assumed that counterfeit brands reduce the demand for genuine luxury brands.

Previous research, however, offers mixed conclusions regarding the influence of counterfeits on the demand for genuine brands. Wilcox, Kim and Sen (2009) demonstrate that in many cases the presence of the counterfeit reduces consumers' desire to purchase genuine luxury brands. Commuri (2009) finds that while counterfeits can make consumers of genuine products abandon luxury brands, they may also lead them to view themselves as champions of the brand. Nia and Zaichkowsky (2000) argue that in certain contexts counterfeits can enhance demand for the real brands. Thus, while it is apparent that counterfeits can influence consumers' desire for genuine brands, it is unclear whether counterfeits have a positive or negative effect on genuine brand preference.

This current research demonstrates that the availability of counterfeit brands can decrease or increase desire for genuine luxury brands. We propose that the influence of counterfeit brands on consumers' preference for genuine luxury brands depends on consumers' processing mindset. Processing at a local, concrete level leads consumers to identify dissimilarities (Förster, Liberman, and Kuschel 2008) between the products and contrast the genuine brand with the counterfeit version. As a result, the presence of a counterfeit version increases desire for the genuine version. Processing at a global, abstract level leads consumers to identify similarities between the products and assimilate the genuine brand with the counterfeit version. As a result, the presence of the counterfeit reduces desire for the genuine version. We show that the assimilation process that reduces desire for genuine brands can be interrupted by consumers' goals. When consumers have active self-expression goals (i.e., purchase brands to express their values), which are inconsistent with counterfeit consumption, the counterfeit increases consumers' desire for the genuine version even when they process at an abstract level.

This conceptualization is investigated in three studies. In the first study, we manipulated processing style by having participants write about all of the things they consider when they think of why (abstract mindset) versus how (concrete mindset) they intend to improve their health. Then, as part of an unrelated study, they were asked to indicate their likelihood of purchasing a genuine Louis Vuitton watch when a counterfeit version was or was not available.

As expected, participants who adopted a concrete mindset were more likely to purchase the genuine watch when a counterfeit version was available compared to when one was not available. Participants who adopted an abstract mindset were less likely to purchase the genuine watch when a counterfeit version was available.

The second study replicates the results of the first study using temporal construal (immediate versus distant future) to manipulate processing style. We show that when the purchase is being made in the immediate future (concrete mindset) the counterfeit increases consumers' desire for the genuine version; when the purchase is being made in the distant future (abstract mindset), the counterfeit decreases consumers' desire for the genuine version.

Additionally, we demonstrate that priming a self-expression goal, by having participants evaluate an advertisement for an unrelated product promoting self-expression, interrupts the assimilation process when people process at an abstract level. Specially, we show that a self-expression goal increases consumers' desire for a genuine brand when a counterfeit is available, even under an abstract mindset.

The third study demonstrates that the effects observed in previous studies are due to assimilation and contrast. Specifically, we show that perceptions regarding the similarity between the genuine and the counterfeit brand mediate the influence of the counterfeit on consumers' preference for the genuine brand. Additionally, we measured the strength of self-expression goal activation in this study to demonstrate that the results in the second study were due to an active self-expression goal and not a reaction to a primed concept.

These findings suggest that goals can override processing style and have a positive effect on genuine brand preference. Thus, managers may want to consider appealing to self-expression motives through their marketing communications because doing so may increase sales, particularly in markets where counterfeits are available.

Collateral Damage Effects of Non-Deceptive Counterfeits on Legitimate Brands

EXTENDED ABSTRACT

"Non-deceptive" counterfeits are products known to be counterfeit by the end users who purchase them (Grossman and Shapiro 1988; Eisend and Schuchert-Güler 2006; Gistri et al. 2009). There is much debate around the effects of non-deceptive counterfeits on the original brands they copy. One common area of dispute is the extent to which non-deceptive counterfeit goods serve as direct substitute purchases for authentic luxury brands (Eisend and Schuchert-Güler 2006, Nia and Zaichkowsky 2000, Wee, Tan and Cheok 1995). For example, had counterfeit Gucci handbags not been available, how many consumers would have purchased an authentic Gucci handbag in their stead? (Nia and Zaichkowsky 2000, Silverstein and Fiske 2003, Van Kempen 2003)

The debate is often framed so that a direct substitution effect indicates that counterfeits are a problem; whereas the lack of a direct substitution effect shows that counterfeits are relatively benign, a victimless crime. The current research seeks to reframe this debate by introducing the notion of "collateral damage effects." Collateral damage effects occur when the purchase of a brand X fake substitutes for the purchase of a brand Y original. Take for example, a consumer who purchases a fake Gucci purse for $100. Had fakes not been available, might the consumer have spent $250 on an authentic entry-level luxury brand (like Coach in the US or Hogan in Europe)? If so, the legitimate brand suffered from unfair competition. It was penalized for following trademark law, by losing sales to a competitor operating outside the law.

Collateral damage effects come in three types: trade up, parallel, and trade down effects. Were counterfeits somehow eliminated, in a trade up effect the erstwhile counterfeit consumer would now purchase a brand which cost more than the counterfeit, in a parallel effect the consumer would purchase a brand priced the same as the counterfeit, and in a trade down effect the consumer would now purchase a brand which cost less than the counterfeit. Which of these effects occurs depends on the preferences and budget of the consumer. In our initial exploratory study we use a student sample at an Italian public university. This population often sees counterfeits as "fun" and does not always try to hide the product's counterfeit status. Therefore, the purchase of a fake does not necessarily indicate a strong desire to own a prestige brand. Furthermore, these students are often under strict budget constraints. Hence, we hypothesize that for this population, if the fakes were not available we would primarily see parallel or trade down collateral effects.

An experimental study using a within-subjects design was used to our hypothesis. The sample consisted of more than 350 female undergraduate students living in two medium-size cities of Italy. While Italy is best known for its production of legitimate luxury brands, it is also Europe's largest producer of counterfeits (OECD 2007). Subjects were required to express their purchase intention and choice among five levels of women's handbags: (1) budget products at € 30, (2) quality non-luxury brands at € 80, (3) counterfeit high-end designer luxury brands at € 80, (4) authentic entry-level luxury brands

at € 200, and (5) authentic high-end designer luxury brands at € 550. After expressing their purchase intention and choice for that consideration set, subjects repeated their purchase intention and choice for a new consideration set identical to the previous set, except with the choice of counterfeit brands removed.

To test H1 we analyzed the transition matrix, which shows how the choice of individual subjects changed from consideration set 1 (with counterfeits) to consideration set 2 (without counterfeits). Out of the 350 subjects, 48 choose counterfeit products when that choice was available. After the counterfeit option was removed from the choice set, only 3 of the 48 counterfeit choosers then chose an authentic luxury brand at € 550. The log-linear model employed fit well, supporting the hypothesis. A further examination of the data show that the 48 subjects who initially chose counterfeits, mainly selected products at same price level (€80) as the counterfeit brands

(25 subjects made this choice). The remaining 20 subjects were evenly distributed between the 10 who chose a lower priced budget brand (€30) and the 10 who stretched their budget upward to choose an entry-level luxury brand (€200).

These results suggest the importance of collateral damage effects generally as a major form of economic loss from counterfeit luxury goods, as more than 90% of the sales lost to counterfeits in this simulation came from brands other than those being counterfeited. Measured in number of items sold, counterfeits in this experiment took their biggest bite out of non-luxury brands at the same price level as the counterfeits. In addition, because the prices on luxury and entry level luxury brands are quite high, even a smaller number of lost sales in these two categories can be as significant as a much larger number of lost sales to less expensive brands.

Don't Throw Out the (Process) Baby With the (Representational) Bathwater: Boundary Conditions on Embodiment

SESSION OVERVIEW

Recently, there has been increased interest in the how embodied cues affect consumer behavior. Embodied perspectives challenge old assumptions about how knowledge is represented by demonstrating that even abstract concepts are not amodal but rather distributed across sensory systems (Barsalou, 2008). As a result, sensory cues (e.g. temperature) can lead to the activation of metaphorically related concepts (e.g. social affiliation; Williams & Bargh, 2008). However, recent embodied perspectives include additional assumptions about how embodied concepts affect choice and behavior, often assuming that their influence is automatic, without specifically testing these effects (e.g. Williams, Huang and Bargh 2009; Zhong and DeVoe 2009).

Thus embodied accounts conflate the automatic *activation* of concepts with the automatic *application* of accessible concepts to downstream choice and behavior, leaving little room for processes that are crucial to the impact of other accessible information, including bodily feedback or semantic primes (Schwarz & Clore, 2007). The three papers in this session explore the intersection between target and consumer characteristics in determining boundary conditions for embodiment effects. Despite their reliance on diverse theoretical frameworks, the papers share the common focus of moving research on embodiment from its current emphasis on existence proofs to a more nuanced understanding of how and when context determines whether embodied cues are relevant to consumers' evaluations and behavior.

In the first paper, Hadi and Valenzuela show that if an individual performs physical actions that signal humanness, anthropomorphic beliefs and emotional attachment will follow. However, they identify that the product needs to be imbued with anthropomorphic traits in order for the process to occur. In the second paper, Wang and Zhu find across five experiments, that haptic sensations of roughness can enhance prosocial behavior, but only among people who are not familiar with the target (Study 2) or among those with low trait levels of empathy (Study 3). In the third paper, Chandler, Reinhard and Schwarz show that consumers refrain from relying on embodied cues when they are aware that they may lack sufficient knowledge needed to form a judgment.

Together, these three papers highlight that the conditions under which embodied cues might influence consumer behavior are narrower than the current literature might otherwise suggest. People need to know enough about a target for accessible information to be applicable (Hadi and Valenzuela's paper) and to feel capable of making a judgment (Chandler, Reinhard and Schwarz's paper) yet at the same time the information conveyed by the cues cannot be redundant with otherwise accessible information (Wang and Zhu's paper). In the process, they emphasize the importance of connections between psychology and consumer research, that is, explanations of human behavior must not only be computationally and anatomically plausible but also explain behaviors and decisions that matter.

Our discussant, Robert Wyer, will highlight the importance of building temporal connections between research programs conducted in different eras: newer embodied approaches have found evidence supporting novel predictions that challenge some of the core assumptions of older theories of human behavior but at the same time, the empirical findings generated by older theories remain true and must be parsimoniously explained. He will discuss how process models developed in the older semantic priming literature can serve as a useful starting point for the development of embodied approaches. This will transition into an interactive discussion that should appeal not only to researchers in embodiment but also researchers grounded in more traditional approaches to cognitive psychology and consumer behavior.

SESSION FORM

The format of the session will encourage discussion and participation for the audience. Paper presentations will last 20 minutes each and the role of the traditional "discussant" will be different. After the three papers are presented, the "discussant" will limit his remarks about the topic to about 5 minutes before opening up the floor for general discussion. The "discussant" will conclude the session by integrating presentations and discussion.

When Hugs Mean Human: Antecedents and Consequences of Embodied Anthropomorphism

EXTENDED ABSTRACT

It is not uncommon for individuals to physically interact with products in a human-like manner. Children hug their teddy bears. A gambler may kiss a pair of dice, hoping for a lucky roll. One may lovingly stroke the steering wheel of a beloved car. Such examples represent affectionate physical actions towards non-human objects. Although it is often assumed that these actions are consequences of anthropomorphic thought, a growing literature emphasizes the bidirectional relationship between movements and concepts. Across three studies we demonstrate that embodied affiliative cues increase positive feelings toward objects. Importantly, we also demonstrate that these effects only occur when people make the gesture toward a target that is imbued with attributes that imply agency.

Anthropomorphism is the attribution of humanlike properties, characteristics or mental states to nonhuman agents and objects (Guthrie 1993, for a recent review see Epley, Waytz & Caccioppo, 2007). Marketers capitalize on anthropomorphic tendencies by portraying brands as having human traits and personalities (Aaker

1997). Likewise, consumers treat objects with anthropomorphic features as if they are alive and experience interpersonal emotions in reaction to those interactions (e.g., Schultz, Kleine & Kerman, 1989). Recent research suggests that these tendencies are relevant to consumer choice: the presence of anthropomorphic traits may lead to reduced replacement intentions on behalf of the consumer (Chandler and Schwarz 2010) and consumers feel more intimate with an anthropomorphized brand (Guese & Haelg 2009).

Embodied gestures of affiliation may lead to more positive attitudes towards objects. Experimental research has shown that bodily sensations are closely linked to feelings and thoughts, leading the mere experience of a bodily sensation can have an impact on an individual's thinking or feeling (Barasalou 2008). For example, unobtrusively making a facial expression that resembles a smile can lead people to form more positive evaluations of cartoons (Strack et al. 1988). Likewise, more recent research has also demonstrated that approach movements lead to more favorable (or less unfavorable) evaluations of objects (Labroo & Nielsen 2010).

In the present research, we demonstrate that affiliative gestures may lead to affiliative tendencies, but only if the target of evaluation has features that signal "humanness."

Study 1 provides initial evidence of an embodied anthropomorphism effect. The study was a field study and the design was a 2 (interaction: hug vs. no hug) X 2 (packaging: face vs. no face) between subjects design. Respondents (N=80) were stopped and asked to either examine and hug, or simply examine a product (a cell phone or dryer sheets), before evaluating it. The results produced a significant Face x Hug interaction on purchase intention ("I would buy this product"; $F(1,69) = 3.71$, $p<.05$). Simple effects analysis revealed that the physical interaction (hug) only translated into increased purchase intention for products with an anthropomorphic trait (human face).

Study 2 replicated Study 1 with a different product category (a book with or without a face on the cover), and investigated the role of anthropomorphic tendencies as a potential mediator. To the extent that affiliative gestures increase the accessibility of social concepts, they should also increase the likelihood that ambiguously anthropomorphic objects are treated as "human". The experimental was again a 2 (interaction: hug vs. no hug) X 2 (cover: face vs. no face) between subjects design. a. Results indicated a significant book cover x hug interaction on evaluation ($p< 0.03$) and purchase intention ($p< 0.06$). Further, results support a significant book cover x hug interaction on anthropomorphism ("this book has a mind of it's own") ($p< 0.06$). Anthropomorphic tendencies correlated ($r = 0.42$) with emotional attachment ("I feel connected to this book"). Additional analysis suggests that the relationship between physical interaction and evaluation is mediated by anthropomorphism.

Study 3 ($N=87$, all females) differentiated the consequences of human-like activity from those of mere bodily approach, as documented by Labroo & Nielsen (2010). The study took the form of a 3(interaction: hug vs. pull vs. hold) X 2 (cover: face vs. no face) design. The product category used was again dryer sheets. We identified significant three-way interactions on product evaluation ($p< 0.07$), purchase intention ($p< 0.02$) and emotional attachment ($p< 0.01$). The effect of hugging on evaluation, purchase intention and emotional attachment was only significant when the fabric softener package exhibited a human face. The direction of the effect for pulling the product was also significant but in the opposite direction (better evaluations and higher purchase intentions when pulling the package with <u>no face</u>). There

was no effect of human-like traits in the package when consumers just held the product.

Our findings expand our understanding of embodiment to suggest that affiliative physical actions will increase the likelihood that an ambiguously anthropomorphic object will be treated in human-like terms. Compatible with this particular gesture, this leads to more positive evaluations and increased purchase intentions. Importantly, embodied cues do not exert such an influence when they are inapplicable to the target of judgment. Thus, our research also introduces a boundary condition for such embodied effects. Future research should study whether anthropomorphic cues always increase positivity would rather depend on the valence of the human-like physical interaction.

I Can Feel It! Haptic Sensations on Prosocial Behaviors

EXTENDED ABSTRACT

The haptic sensation is an important yet the least studied sense in consumer behavior. Current research on haptic cues primarily focuses on the presence versus absence of haptic information (Peck and Childers 2003), without investigating the impact of specific haptic attributes such as texture, while touch is always present. Additionally, the dependent measures are mostly of product evaluation (Krishna and Morrin 2008), rather than actual behaviors. Finally, research on haptic cues is organized around the phenomenon itself rather than according to the processes that govern their use. In five studies we advance our understanding of the haptic sensation by studying the impact of one specific haptic attribute (i.e., rough versus smooth texture) on people's prosocial behaviors.

According to embodied cognitive perspective (Barsalou 2008), mental action is largely grounded in a physical substrate. Thus, sensory data, such as physical sensations and motor movements, is stored together in memory with associated mental concepts or experiences. When sensations are experienced they activate corresponding conceptual experiences. Following this logic, haptic roughness might trigger memories or concepts related to rough time or hardship. Prior research has shown that similar psychological experiences induced through other means enhance empathy (Batson et al. 1996; Banissy and Ward 2007). Thus, if haptic cues of roughness active associations of personal difficulty, people might experience heightened empathy towards the needy others, and subsequently engage in more helping behaviors.

The influence of haptic cues should further be determined by whether people are familiar with the target. People experience more empathy towards familiar others than unfamiliar others (Small and Simonsohn 2008). Thus, when individuals are familiar with the target, the feelings of empathy caused by haptic sensation are likely to have little benefit beyond the already high level of empathy. However, when empathetic concerns are low, additional haptic sensations or roughness are likely to increase helping behavior.

In Study 1, we demonstrate the basic effect of haptic roughness versus smoothness on willingness to help. To manipulate the haptic sensation, we used a moisturizing hand wash in the smooth condition, and a scrub hand wash in the rough condition, under the cover story of product evaluation. The dependent variable was participants' willingness to donate to two fictitious non-profit organizations. Consistent with our hypothesis, those in the rough condition showed higher willingness to donate than those in the smooth condition.

In Study 2, we tested whether haptic cues influenced familiar targets. We again manipulated the haptic sensation by using the two different hand washes. The dependent variable was again willingness to donate, but towards familiar charities (e.g., Aids.org) and unfamiliar charities (i.e., Schizophrenia Foundation) respectively. A 2x2 ANOVA revealed a significant interaction between the haptic sensation and familiarity. Specifically, for the unfamiliar charities, those in the rough condition showed higher willingness to donate than those in the smooth condition. However, for familiar charities, there was no such difference.

In Study 3, we demonstrated that empathy mediates the influence of haptic sensation and familiarity on helping behavior. Participants completed the experiment with a confederate. To induce familiarity, the dyad was asked to self disclose personal information to each other (adapted from Sedikides et al. 1999). Those in the unfamiliar condition did not perform this task. The haptic manipulation was the same as before. The participant then had an opportunity to help the confederate perform a problem-solving task. We measured whether the participant offered help or not. Finally, the participant's situational empathy level was assessed. Replicating Study 2, there was a significant interaction between familiarity and haptic sensation. Specifically, towards an unfamiliar confederate, the participant was more likely to help in the rough (vs. smooth) condition. In contrast, towards a familiar confederate, the participant was equally likely to help regardless of the haptic sensations. Extending this finding, empathy mediates this interaction effect.

In Study 4, we provided further support for the mediating role of empathy by measuring individuals' dispositional empathy level. We found that the interaction effect of familiarity and haptic sensation was only evidence among low-empathizers.

In Study 5, we tested whether our lab findings can be replicated in the field. We created a street fundraising event involving pedestrians as participants. The study had a 2 (haptic sensation) X 2 (familiarity) between subjects design. To manipulate the haptic sensation, we attached either a projection sheet or a piece of sandpaper on a clipboard that a participant had to hold while completing the survey. In the survey, participants were asked to indicate the amount of money they would like to donate to a familiar or unfamiliar charity. Results replicated those observed in Study 2.

Through a series of five experiments, conducted in both lab and field contexts, we find support to our theorizing, such that haptic sensations of roughness can enhance prosocial behavior, but only when the target is unfamiliar. Findings from this research provide important theoretical and practical implications.

When you Can't Judge a Book by its Cover: Metacognitive Inferences about Embodied Cues

EXTENDED ABSTRACT

Perceptual experiences can influence thoughts and feelings in ways predicted by conceptual metaphor theory (for a review, see Landau, Meier and Kiefer 2010). For example, physical weight can influence perceptions of importance (Jostmann, Lakens and Schubert 2009). Researchers often assume that the underlying associative processes exert the strongest influence when people know little about the target (Landau et al. 2010). If so, the impact of perceptual cues on metaphorically related judgments should be *attenuated* when more diagnostic information is available, paralleling observations in other domains (Chen and Chaiken 1999).

However, other research indicates that people refrain from relying on heuristic cues when they are aware that they may lack the knowledge needed to form a judgment (Leyens, Yzerbit, and Schadron 1992). For example, category based stereotyping is higher when people have some individuating information about the target than when they have none (Leyens et al. 1992, see also Croizet and Fiske 2000). From this perspective, perceptual cues may exert *more* influence on metaphorically related judgments when they pertain to a target about which the perceiver has at least some information. We tested this possibility by exposing participants to an incidental perceptual cue and examining the effect of this cue on related perceptual experiences (Study 1) and metaphorically related concepts (Studies 2 and 3) under conditions of high and low information. Across all three studies we find that perceptual cues have no effect when people do not have sufficient information to make a decision.

In Study 1, participants estimated the weight of a CD depicting either light or heavy visual cues. Both CDs were fictitious albums. In the heavy condition the CD cover depicted a picture of weightlifting dumbbells and was titled "With a heavy heart, I say goodbye." In the light condition, the CD cover depicted a picture of a kite floating in the sky and was titled "Float." Crucially, half of the participants were handed the CD to make the rating while the other half had the CD placed in front of them and were instructed to make their estimate without touching the CD. Weight cues influenced participants' judgments when they held the CD, leading people to perceive the CD depicting the heavy image as heavier than the CD depicting the light image. Visual weight cues did not exert an influence when they did not hold the CD.

Study 2 examined whether the influence of perceptual cues on metaphorically related judgments also depended on having sufficient knowledge to form a judgment. Participants were asked to form "impressions of a book." The book was unfamiliar (Eva Hornung's *Dogboy*) and the hardcover copy weighed either 439g or 675g, due to a concealed weight. Participants were asked to examine the book cover before answering questions; half were handed the book face up, displaying the front cover (author and title), whereas the other half were handed the book face down, displaying the back cover with a synopsis and reviews. Participants reported their interest in reading the book, how much they would pay for it and the likelihood that it would be named among the most influential books by The New York Times. The book's weight influenced participants' judgments on all three dependent variables when they saw its informative back cover, but not when they saw its uninformative front cover.

Study 3 replicates this finding using a naturalistic manipulation of whether participants had sufficient knowledge. Participants were presented with a hardcover copy of a potentially familiar book (*The Catcher in the Rye*) that was either of normal weight (404 grams) or included a concealed weight (605 grams). Participants rated its influence on American literature and indicated whether they had read the book. Consistent with our hypothesis, participants who had read *Catcher in the Rye* considered it more influential when holding the heavy rather than light copy. In contrast, participants who had not read it were unaffected by its weight.

Across all three studies, people who knew something about the target – either because they could hold it (Study 1) or received some pertinent information (Study 2) or had read it (Study 3) --*were* influenced by the book's physical weight, whereas those who knew nothing about the book *were not*. This observation has important theoretical implications. First, it extends the notion of *judgeability* from the social (Leyens et al. 1992) to the nonsocial domain. Context effects on judgment require that one forms a judgment to begin with – and having insufficient information may discourage one

from doing so. Hence, bodily sensations may only be incorporated into metaphorically related judgments when other information justifies evaluations of the target.

Second, recent embodiment research emphasized purely associative accounts (e.g. Williams, Huang and Bargh 2009; Zhong and Leonardelli 2008) that leave little room for the inferential processes underlying the impact of other subjective experiences on judgment and choice, including bodily feedback (Schwarz and Clore 2007). The present studies challenge this assumption and suggest that metacognitive assessments influence the use and disuse of sensory information in metaphorically related evaluations.

Finally, our findings highlight that additional knowledge does not always protect against the influence of incidental sensory information of merely metaphorical relevance – instead, it may increase one's susceptibility.

Harming, Stealing, Lying, and Cheating: Exploring the Antecedents and Consequences of Unethical Consumption Behavior

Paper #4: Feeling Moral about Money: How Moral Emotions Influence Consumer Spending Decisions
Hyun Young Park, New York University, USA
Tom Meyvis, New York University, USA

SESSION OVERVIEW

Consumers arguably want to be seen as (and to see themselves) as moral actors. Yet, consumers engage in unethical behaviors, including buying products that harm the environment, stealing, lying, and cheating. The over-arching theme for this session is to explore both the antecedents and consequences of these types of unethical behaviors on the part of consumers.

In the first paper, Naylor, Irwin, and Ehrich propose that willfully ignorant memory plays an important role in why consumers buy products with poor performance on ethical attributes (e.g., products that harm the environment). They show that, in order to protect themselves from emotionally-laden tradeoffs between ethical attributes and other desirable product attributes (e.g., price and quality), consumers misremember negative ethical attribute information at a greater rate than they do positive ethical attribute information. In the second paper, Jordan and Fennis examine a variety of unethical behaviors, including plagiarizing, cheating, stealing, buying stolen goods, and lying. They show that consumers are particularly likely to engage in these behaviors when they feel a lack of personal control and are exposed to information indicating that engaging in these unethical behaviors is the norm. In the third paper, Gino and Mogilner explore how a difference in short-term versus long-term focus influences the decision to behave unethically. They show that priming money leads individuals to focus on the present, thereby increasing the likelihood of cheating on a task, while priming time leads them to focus on the future, thereby decreasing the likelihood of cheating. Thus, the first three papers focus primarily on exploring why consumers engage in unethical behaviors. The fourth paper focuses instead on the consequences of unethical behaviors. Specifically, Park and Meyvis examine the impact of the specific emotions that stem from moral violations on subsequent spending decisions (e.g., donating to charities, spending on the self vs. others, etc.).

In keeping with the conference theme of building connections, each author agrees to link the antecedents of unethical behavior to its consequences (and, in the case of Park and Meyvis, the converse). Moreover, there are several common themes across pairs of papers

in the session in addition to the broader theme of understanding the antecedents and consequences of unethical behaviors. Specifically, both papers 1 and 3 explore the short-term rewards of unethical behavior; participants in paper 1 employ willfully ignorant memory because it allows them to avoid the negative emotions that come with ethical attribute tradeoffs in the short-run, while participants in paper 3 who are primed with money focus on the benefits to ethically questionable behavior in the present, not the potential long-term costs of the behavior. Papers 2 and 3 both suggest ways in which consumers can be encouraged to engage in more ethical behavior, through the use of social norms in paper 2 and by priming time (vs. money) in paper 3. Papers 3 and 4 both contribute to our understanding of the psychological meanings of money, and papers 1 and 4 both address the emotional impact of morally questionable behavior. Presenters will point out these connections during the session. Three of the papers have at least three studies completed. The authors of Paper 2 anticipate having at least one additional study completed by the time the paper would be presented.

We anticipate a wide audience for this session because it will not only contribute to the literature on moral decision making and (un)ethical consumer behavior, but will also have broad appeal to a diverse group of conference attendees, including researchers with an interest in ethical behavior, decision making, memory, social norms, the psychological effects of money, and affect.

That's Not How I Remember It: Willfully Ignorant Memory for Ethical Product Attribute Information

EXTENDED ABSTRACT

Many consumers report that they care about ethical issues and are willing to pay more for ethically produced goods (Trudel and Cotte 2008). However, products with positive ethical attributes (i.e., sustainable products) are, in many product categories, not market leaders (Porges 2007), and products that have poor performance on ethical attributes continue to sell well. For example, despite the damage to the environment from logging old-growth rainforests, consumers continue to buy cabinets, furniture, and other products made from rainforest wood (Rainforest Relief 2011). Further illustrating the problem, although a recent survey by GfK Roper Consulting found that 62% of Americans believe that environmental pollution poses a serious risk (Neff 2010), a recent Mintel study found that only 36% of Americans regularly buy green products (Mintel 2009). Taken together, findings like these indicate that, in the domain of ethically produced goods, there appears to be a gap between consumers' explicitly stated attitudes and their purchasing behavior (Devinney, Auger, and Eckhardt 2010).

Past research has addressed the causes of this gap by asking why consumers might be reluctant to buy sustainable products. Ehrich and Irwin (2005) showed that consumers, particularly those who care about the ethical issue in question, do not seek ethical attribute information at the rate they would have used the information if it were readily available. This willful ignorance is driven by a desire to avoid the negative emotions that stem from discovering that an otherwise desirable product performs poorly on an ethical attribute. Avoiding the information is a self-protection mechanism. Our primary research question expands the notion of willful ignorance: We

explore what happens if consumers are not allowed to remain will-fully ignorant, that is, when they are not allowed to ignore ethical attributes. The primary purpose of our studies, therefore, is to test whether consumers who know that a product is unethical will engage in subsequent types of self-protection mechanisms to deal with this negative information.

We propose that consumers will engage in what we call *will-fully ignorant memory*, incorrectly recalling poor performance on an ethical attribute (i.e., that furniture is made from non-sustainable rainforest wood) at a higher rate than they do positive performance on an ethical attribute (i.e., that furniture is made from sustainable tree farm wood). Because ethical attributes are linked to protected values (Baron and Spranca 1997), particularly for consumers who care deeply about these issues, it is easier to forget that a product per-forms poorly on an ethical attribute than to have to make difficult and emotion-laden tradeoffs between ethical attributes and other product attributes that the consumer finds desirable. We test our hypotheses across three studies involving hypothetical brands of desks (adapted from the stimuli used by Ehrich and Irwin 2005). The desks differed on three attributes: wood source, quality/workmanship, and price, where wood source is the ethical attribute. All three studies share a similar basic procedure; after being given an opportunity to store the information about the six desks in memory, participants were then asked to recall all of the information they could about the desks (i.e., to retrieve this information from memory) after a distracter task or tasks. In Study 1 we show that consumers are more likely to mis-remember (either recalling the information incorrectly or failing to recall any information about the attribute) that a desk is made from rainforest wood than that it is made from tree farm wood. Further, this pattern of forgetting is unique to ethical attributes (vs. attributes without ethical implications) and is especially likely to occur for those who care about the ethical issue in question (i.e., protection of the rainforests). Study 2 expands this basic methodology by testing memory at both storage and retrieval; in this study we demonstrate that willfully ignorant memory occurs both when ethical attribute in-formation is stored in memory and when it is retrieved from memory. Finally, in Study 3, we use a mood manipulation immediately before retrieval to demonstrate that a consumer's mood interacts with how much they care about the ethical issue to influence willfully ignorant memory: participants who care a great deal about the ethical issue in question who are in a negative (vs. neutral) mood are more likely to misremember poor (vs. positive) performance on an ethical attribute.

Theoretically, our results show a new and strikingly non-nor-mative reaction to ethical attributes: the people who care the most about the underlying ethical issue are less likely to accurately re-member ethical attribute information. These results add to our grow-ing knowledge of how consumers react to ethical attributes and our understanding of why purchases may show a discrepancy between ethical attitudes and behaviors. The malleability of memory protects consumers from having to make difficult decisions and, perhaps, even to persuade themselves that they are more moral decision mak-ers than they actually are. If memories are not accurate, then consum-ers are not likely to remember that they have not purchased highly ethical items in the past and may not accurately remember the ethical attributes of their current possessions.

"I Couldn't Help It": The Role of Perceived Personal Control and Social Norms in Unethical Consumer Behavior"

EXTENDED ABSTRACT

Recent research (Fennis and Aarts 2010) demonstrates that a lack of personal control, conceptualized as the experience of reduced self-agency or authorship, leads individuals to become more suscep-tible to various forms of (proximate) social influence. The current investigation extends this research into to the domain of moral judg-ment and behavior by examining how consumers lacking personal control are influenced by social norms in their environment and how this influence affects their tendency to engage in (un)ethical judg-ment and behavior. We predict that a lack of perceived control will lead to unethical behavior, but not unconditionally. Instead, we argue that impaired perceived control promotes unethical behavior only when such unethical behavior is considered a descriptive norm in the consumer's environment (i.e., the behavior is perceived to be sup-ported by a majority of like-minded consumers). Paradoxically, we also propose that experiencing impaired personal control does not produce a reduction in unethical behavior when supported by ethical descriptive norms. This is because of the proposed mechanism of the control to unethical behavior relationship: social responsibility. As others have demonstrated (e.g., Festinger 1956; Cialdini 2001), in-dividuals are most likely to look to their social environment for cues on how to think and act when the appropriate behavior is ambigu-ous (ethical situations are normally ones where the correct behavior is ambiguous, Jordan 2009). First, we propose that consumers who lack perceived control are more likely to look to the social world for cues on how to think and act (Fennis and Aarts 2010), and that such an outward search reduces their feelings of self-responsibility for the resulting behavior when they can find social norms that support such behavior. And second, we propose that such a search will only af-fect an increased engagement in unethical behavior (but not ethical behavior) because it provides a license to act immorally (consumers are more likely to engage in immoral behavior if they do not feel personally responsible for it, Jones 1991); consumers need no license to engage in moral behavior. Hence, there appears to be a clear asym-metry in the impact of social contexts on unethical behavior. In sum, we propose that perceived personal control will be the driving force behind the impact of normative social cues on (un)ethical consumer judgment and behavior.

Using a 2 (perceived personal control: low, high) x 3 (immoral social norm, moral social norm, no norm) between-participants de-sign, we examine the personal control to unethical behavior relation-ship in a context of immoral versus moral social norms communi-cated in a series of target behaviors. Participants were sixty students at a university in The Netherlands. They believed that they were par-ticipating in two separate studies: Study 1 examined personal situa-tions and Study 2 examined the types of activities that students par-ticipated in. We manipulated the experience of personal control by adapting a procedure previously developed by Whitson and Galinsky (2008), which first asked participants to recall a situation where they either *were in complete control* or *completely lacked control*. Then, in "Study 2," we asked them to report how much they planned to engage in a variety of activities in the next six months (1 = *not at all*; 7 = *definitely*). Five of these activities were unethical in nature (pla-giarize, cheat, steal small items, buy an item you know is stolen, and lie to get out of an obligation) and five were ethically-neutral (go on a foreign holiday, dine at a new restaurant, write a hand-written let-ter, attend a concert, and make an unusual recipe). Both the unethical and neutral activities were selected because of their mundane, albeit

not quotidian nature. We also told them that the computer allowed them to see other people's responses in real-time. Thus, to manipulate social norms, we manipulated whether a majority of their fellow participants reported engaging or not engaging in these behaviors via a pie chart for each target behavior. Participants in the *no norm* condition did not see this information.

Consistent with predictions, we found that for the unethical behaviors, perceived personal control and social norms interacted, $F(2, 54) = 5.06$, $p = .010$, such that a lack of personal control affected unethical behavior - but only when the individual received information that such unethical behavior was normative. Specifically, in comparison to those primed with a sense of personal control, individuals primed with a lack of personal control were more likely to engage in unethical behavior if they were exposed to the norm that a high number of like-others engaged in the behavior, $t(54) = 3.01$, $p = .002$. Individuals were not more (or less) likely to engage in these behaviors when exposed to moral norms of non-engagement, $t(54) = 0.936$, $p = .35$, nor when normative information was presented, $t(54) = -1.20$, $p = .23$. In addition, there was a marginal main effect of control, $F(1,54) = 3.02$, $p = .088$, such that lacking perceived control (M = 2.52, SD = 0.80) led to slightly more engagement in unethical behavior than did possessing perceived control (M = 2.14, SD = 0.86). However, there was no main effect of social norms, $F(2, 54) = .07$, $p = .93$. Also in line with our reasoning, perceived control and social norms did not interact to affect neutral behaviors, $F(2, 54) = .839$, $p = .45$. Although there was a main effect of social norms, $F(2, 54) = 4.79$, $p = .01$, such that social norms of engagement did increase people's reported participation in these neutral behaviors (M = 4.73, SD = 1.17), relative to social norms of non-engagement (M = 3.76, SD = 1.22), or the condition where no information on social norms was provided (M = 3.95, SD = 1.08).

From cheating to stealing, unethical behavior is problematic for suppliers, such as retail outlets, web-shops, manufacturers, and (commercial and non-commercial) service providers. This investigation demonstrates that one such influence on unethical behavior is a lack of personal control paired with immoral social norms. Current research is examining the proposed mechanism of this relationship, perceived responsibility.

Money in the Present or Time in the Future? How Switching Focus Makes People Honest

EXTENDED ABSTRACT

The accounting scandals and the collapse of billion-dollar companies at the beginning of the 21st century have forever changed the business landscape. These cases of corporate corruption add to a long list of instances of unethical behavior within organizations across a variety of settings (e.g., Frank et al., 2003): employees violate company rules, workers sabotage their peers, consumers shoplift, students cheat on exams, citizens evade taxes, and managers overstate performance to shareholders. Such unethical behaviors are costly to organizations and economic systems more broadly. Dishonest behavior is not limited to such prominent examples of one person or organization causing harm to many individuals. Although less well publicized, the small transgressions of large numbers of people have just as large an impact on our daily lives. For instance, an estimated $16 billion is losses to the US retail industry are due to the purchase, use, and then return of worn clothing (Speights & Hilinski, 2005). These losses are not caused by the behavior of just a few people regularly revolving their entire wardrobes, but by that of many individuals who are returning just one shirt or sweater.

In fact, an increasing amount of empirical evidence in social psychology, as well as in the marketing and organizational behavior literatures demonstrates that dishonesty often results not from the actions of a few people who cheat a lot, but from the actions of a lot of people who cheat a little (Mazar, Amir, & Ariely, 2008; Gino, Ayal, & Ariely, 2009). When given the opportunity to act dishonestly, many individuals do cross ethical boundaries, if only "by a little bit," rather than to the maximum extent (Ayal & Gino, 2011; Gino et al., 2009; Mazar et al., 2008).

Unethical behavior, in its various forms, is often tempting because it offers short-term benefits (i.e., monetary rewards), but it is also likely to harm an individuals' moral self-concept and to engender long-term costs (e.g., tainted reputation or lower social acceptance). For instance, a salesperson who cares about morality may be tempted to lie to a consumer interested in purchasing a product because these behaviors are associated with higher financial rewards. These short-term benefits, however, may risk long-term harm to her reputation and trustworthiness, to established relationships, and to long-term profitability. Thus, the decision to behave unethically commonly requires people to weigh two opposing forces: the desire to maximize self-interest and the desire to maintain a positive moral self-image and future relationships. To resolve the internal conflict between the short- and long-term benefits of dishonest acts, individuals must exert self-control (Mead, Baumeister, Gino, Schweitzer, & Ariely, 2009). That is, self-control is the psychological capacity that enables people to enact behaviors that are consistent with their long-term goals (e.g., of being an ethical person) and refrain from engaging in behaviors that are driven by short-term, selfish motives.

In this paper, we explore how this difference in short-term versus long-term focus influences the decision to behave unethically. We suggest that priming money leads individual to focus on the present, while priming time leads them to focus on the future. Because of this shift in focus from present to future, priming individuals with time rather than money can encourage ethical behavior.

We find evidence consistent with these predictions in three studies. In a first study, participants engaged in two-unrelated tasks. They first completed a scrambled-words task that exposed them to time-related, money-related, or neutral words (Mogilner & Aaker, 2009). In particular, participants received a list of word sets, each of which contained four words, and they were instructed to use three of the words in each set to create a sentence. Participants had three minutes to create as many sentences as possible. Upon completion of this first task, participants completed an ostensibly unrelated task: a problem-solving task under time pressure. Participants had five minutes to find the correct solution to various math problems. We gave participants the opportunity to cheat on this task by over-reporting their performance and thus earn undeserved money. The results of the study show that compared to the control condition (i.e., neutral prime), participants in the money-prime conditions were *more* likely to cheat by over-reporting performance while participants in the time-prime conditions were *less* likely to cheat.

We replicated the same findings in a second study that employed only one between subjects manipulation with two conditions: money prime versus time prime. In this second study, we used the same manipulation as in study 1 but a different task to measure our main dependent variable. The new task was a computer-based mental-arithmetic task in which participants had to calculate the answers to 20 different problems, presented individually (adapted from von Hippel, Lakin, & Shakarchi, 2005). The experimenter informed participants that the computer had a programming glitch: As they were working on each problem, the correct answer would appear on the screen unless they stopped it from being displayed by pressing the

space bar right after the problem appeared. The experimenter also informed participants that although no one would be able to tell whether they had pressed the space bar or not, they should try to solve the problems on their own (thus being honest). In actuality, this was a feature of the program and not a glitch, and the number of space-bar presses was recorded. We used the number of times participants did not press the space bar to prevent the answer from appearing as our measure of cheating. The results of this second study showed that participants cheated more frequently in the money-prime condition as compared to the time-prime condition.

Finally, we conducted a third study in which we examined the potential psychological mechanism explaining the result observed in our first two studies. The findings of this third study demonstrated that time primes, compared to money primes, discourage unethical behavior since they trigger a future rather than a present focus.

Taken together, our findings offer a potentially powerful tool to discourage dishonesty in organizations and society more broadly: inducing people to switch focus from the present to the future can encourage ethical behavior.

Feeling Moral about Money: How Moral Emotions Influence Consumer Spending Decisions

EXTENDED ABSTRACT

Much of the money we spend is money we have earned or received in some legitimate fashion. However, in some instances, we may receive money that does not make us feel all that good. Even in the absence of any illegal activity, we may feel somewhat guilty about money (e.g., when we feel we did not deserve to be paid that much) or feel angry about money (e.g., when we feel we should have been paid more than what we received). This research examines how moral emotions such as guilt and anger may change how we spend the money associated with these emotions. As such, we extend prior research that has shown that the valence of emotions attached to money can influence consumer choice (Levav and McGraw 2009) by identifying the unique consequences of different types of negative moral emotions.

We examine two groups of moral emotions: a triad of "self-focused" emotions that includes guilt, shame and embarrassment, and a triad of "other-focused" emotions that includes contempt, anger, and disgust. We examine the effect of these emotions on various spending categories including spending on self vs. others, donations to charity, savings, hedonic vs. utilitarian products, vices vs. virtues, and necessities vs. luxuries. According to the prior research on moral emotions and appraisal tendency, self-focused emotions are experienced when the *self* is responsible, whereas other-focused emotions are experienced when the *other* is responsible in a controllable situation (Tangney, Stuewig, and Mashek 2007; Lerner and Keltner, 2000). While self-focused emotions lead to behaviors that try to repair the negative consequence caused by the self, other-focused emotions result in the blaming of others and punitive behaviors. Based on these findings, we hypothesize that when people earn tainted money by committing moral violations, they will be more likely to engage in moral repair processes such as spending more on others than on themselves, and donating more to charity than those who earn untainted money. On the other hand, when people receive an unfair sum of money due to another's moral infringement, they will engage in punitive processes such as spending less on others than on themselves and donating less to charity.

We also hypothesize that emotions have differential effects on spending decisions depending on whether they are moral or non-moral. Prior research suggests that guilt leads to utilitarian or virtu-ous choice over hedonic or vicious choice to help prevent anticipated guilt or launder experienced guilt (Kahn, Dhar, and Wertenbroch, 2005). However, these findings examine non-moral guilt arising from self-control failures. We expect that guilt, shame, and embarrassment resulting from moral transgressions would not be laundered through virtuous or utilitarian spending decisions that are related to the self alone, but would be laundered only through decisions relating to the others such as donations to charity. However, we expect that these moral emotions would lead to hedonic avoidance (similar to non-moral guilt) because hedonic products exacerbate these negative moral emotions.

Finally, we confirm that moral emotions influence spending decisions only when they are associated with the money being spent and not when they are associated only with the situation in which the money was received. In line with the Emotional Accounting literature, we expect that money is labeled by moral feelings, and the moral emotion label determines how the money is spent.

In a first scenario-based study, participants who obtained a partial refund by lying about damage to the product prior to purchase felt more guilt, shame and embarrassment about the refund, and spent it more on others, donated more to charity, spent less on themselves, and spent less on hedonic products than those who received a partial refund under legitimate terms. On the other hand, participants who received a partial refund though they were entitled to a full refund felt more anger, contempt and disgust about the refund, and spent the refund less on others, donated less to charities, and spent more on themselves than those who obtained a legitimate partial refund. In a second scenario study, we observe that shame, embarrassment and guilt has a greater impact on people's spending decisions (spending on self vs. other, charitable donations, hedonic purchases) when those feelings result from a moral violation than when they result from a failure to exert self-control. Furthermore, in a third scenario study, we demonstrate that these moral feelings affect spending decisions only when they are associated with the money being spent, not when people feel the same moral emotions for a different reason.

The results of the scenario studies were replicated in studies with actual money. In Study 4, one group of participants received money as a reward for their participation in the Implicit Attitude Test that tested their prejudice against disabled people, whereas another group of participants were promised to receive the money when they faced an unwanted truth, that is, when their test results showed that they had a strong prejudice against the disabled. Compared to those who received the money as a reward for their participation, those who received money because they held a strong prejudice against the disabled experienced a greater level of self-focused emotions, and engaged in the moral-repair spending decisions as in the scenario studies. However, this effect disappeared when the participants received a negative test result, but were given the money as a reward for their participation. In Study 5, participants who received an unfair sum of money in a Dictator Game felt a greater level of anger, contempt, and disgust, which led to less spending on others vs. themselves, and less charitable donations. Again, this effect disappeared when participants received the money as a reward for their participation although they were treated unfairly during the game.

These results support our hypotheses that emotions have different influences on consumer spending decisions depending on (1) whether their source is related to moral transgressions or not, (2) whether the moral violation was committed by the self or by another, and (3) whether moral emotions are felt about the money or about the situation.

SESSION OVERVIEW

A fundamental question in consumer research is: Why do consumers often struggle to make decisions? This session takes a fresh look at the antecedents, consequences, and variants of indecisive behavior.

The first paper, by Ulkumen and Malkoc, examines situational determinants of choice conflict, as measured by response latency, as well as by self-reported choice difficulty and confidence. In order to form preferences over options, a decision maker must first distinguish among them. In this paper the authors show that a contextual manipulation designed to make the options appear more similar leads to greater difficulty making a decision. Further, the authors find that exposure to broad (vs. narrow) categories leads to greater sensitivity to an instruction to focus on similarities or differences when making a subsequent choice. In particular, participants primed to categorize broadly have greater difficulty making decisions when prompted to focus on similarities among options than when prompted to focus on differences. There is no such effect among participants primed to categorize narrowly. Taken together this research suggests that an important cause of indecision is difficulty distinguishing among options, which is strongly affected by the structure of previously encountered categories.

The second paper, by Jeong and Drolet, examines how indecisive consumers cope with their difficulty making a choice. They find that participants who are chronically indecisive tend to seek more variety. They find a similar effect among consumers who are indecisive due to situational factors (an increased number of choice options. Indecisive consumers seek more variety in order to cope with the negative emotions they experience when choosing. They show that negative emotion further increases variety-seeking among indecisive consumers. These findings provide a striking counterpoint to previous research showing that positive emotions lead to greater variety seeking. The increasing effect of positive emotion on variety-seeking does not hold for indecisive consumers who seek variety for different reasons (i.e., to cope with negative emotion) than decisive consumers.

The third paper by Fox, Barkley-Levenson, and Wieland examines the multi-dimensional character of chronic indecisiveness. In particular, they find that traditional measures of indecisiveness reflect a preference to avoid making tradeoffs or consider opportunity costs when choosing. This can give rise to impulsive behaviors for items that are considered one-at-a-time, or decision conflict when items are considered simultaneously. Moreover, these authors find that this common form of decision difficulty is one of three variants of chronic indecisiveness. The other two are a tendency to seek exhaustive information in the pursuit of the optimal choice, and a

tendency to be unprepared when the decision moment arrives to procrastination or poor organization.

Taken together, these three papers provide important new insights into the nature of indecisiveness. They suggest that there are distinct reasons why different kinds of consumers (e.g., neurotic/impulsive indecisives) may have difficulty making decisions (e.g., they have a hard time distinguishing among options and worry about making a bad decision), and they may pursue distinct coping strategies (e.g., seeking variety to avoid experiencing these negative emotions). Thus, in order to predict various manifestations of indecisive behavior, one must take into account: (1) the consumer's chronic tendencies toward different variants of indecisiveness; (2) the cognitive and motivational context of the choice elicitation; and (3) the affective consequences of various coping strategies available to consumers.

Audience. We expect this session to draw a large and diverse audience including researchers interested the general areas of decision-making and choice and researchers who are interested in the specific areas of choice difficulty, conflict and indecisiveness.

Strengths. All three papers in the session are in advanced stages; they are either under review or close to being submitted for review. They investigate a related phenomenon (indecisiveness) using a variety of different empirical approaches.

Fit and contribution. All three papers in this session deal with indecisiveness and choice conflict. Collectively they address the interaction of dispositions and situations in determining the conflict that consumers experience while choosing, and ways in which they cope with this conflict.

Session format. We will have three papers, with 15 minutes of presentation time each plus 5 minutes of Q & A time allocated to each paper. This will ensure that we have 15 minutes of discussion at the end of the session. Our discussant, Eric Johnson is a leading authority in consumer choice.

The Effect of Category Width and Comparison Orientation on Choice Conflict

EXTENDED ABSTRACT

In this research, we demonstrate the effects of categorization on decision conflict. Specifically, we show that being exposed to broad or narrow categorizations in a previous, unrelated task influences the conflict consumers experience in a subsequent choice task.

Previous research shows that various aspects of external categories can influence important decision outcomes in the same decision context, such as choice, decision difficulty and decision time. One aspect of categorization that has been shown to influence information processing is category width (CW), (Ülkümen, Chakravarti, and Morwitz 2010). Incidental exposure to narrow versus broad categorizations instigates a more multidimensional processing orientation in subsequent, unrelated decisions. In contrast, participants exposed to broad categories base their attitudes on fewer pieces of salient information, and therefore become more susceptible to context effects.

In this paper, we extend previous research by examining the effects of CW on choice conflict. When choosing between two products, consumers feel more conflicted to the extent that they focus on the similarities between them. If consumers previously exposed to broad categorizations adopt the comparison orientation made salient

by the environment, then they should focus on *either* similarities *or* differences between products. In contrast, if consumers previously exposed to narrow categorizations employ both salient and non-salient orientations, then we would expect them to consider *both* similarities *and* differences. Thus, we hypothesize that broad categorizers will take a longer time to decide, experience more choice conflict, and feel less confident about their choice when they are primed with similarities than differences. In contrast, for narrow categorizers, choice time, conflict and confidence are should not be influenced by comparison orientation. We test our predictions in four lab studies.

EMPIRICAL STUDIES

Study 1 had a 2 (CW: broad, narrow) x 2 (Focus: similarity, difference) between subjects design. Participants first completed the CW manipulation, where they responded to questions about themselves that differ in the number of response categories. For some participants, the response options constituted many, narrow categories (narrow condition), while for others, the response options comprised a few, broad categories (broad condition). Next, participants were primed with a comparison orientation by listing either similarities or differences between a pair of pictures (Markman and Gentner 1996). Participants then viewed pictures of two wristwatches and made a choice between them. Response time was recorded unobtrusively. The results suggest that in the Broad CW condition, participants took longer to make a choice when they focused on the similarities as opposed to the differences between the two watches. In contrast, in the Narrow CW condition, the focus manipulation did not influence participants' choice time.

The aim of study 2 was to examine whether the difference in choice time observed in the previous study is due to experienced conflict. Participants first completed the same CW manipulation as in study 1. Next, they were shown pictures of two wristwatches, and they were intruded to list either their similarities or differences, and to make a choice between them. We find that the conflict experienced during choice, and the decision confidence were influenced not only by the comparison orientation, but also by the width of previously encountered categories. In the Broad CW condition, participants took longer to choose, were less confident in their decision, and felt more conflicted when they focused on the similarities between two watches, than when they focused on their differences. However, these variables were not influenced by the focus manipulation in the Narrow CW condition. Moreover, conflict index mediated the interactive effect of similarity and CW on confidence.

In study 3 participants completed a different manipulation of CW (Shopping Task, Ülkümen et al 2010). After making a choice between several backpacks, participants were told their selection was out of stock and were offered an alternative backpack, which was either objectively similar to or different from their selection. We measured participants' attitudes toward the new backpack, and their consideration of similarities and/or differences while choosing. We find that the focus manipulation influenced attitudes only in the Broad CW condition, such that participants liked the new offering more when they focused on its similarity to the original backpack, than when they focused on its difference. Moreover, in the Broad CW condition participants considered relatively more differences (similarities) when they were presented with the different (similar) backpack. The focus manipulation did not influence participants' consideration of similarities and differences in the Narrow CW condition.

Participants first completed the same CW manipulation as in the first two studies. Next, they were shown a furniture catalog and told to make a choice between two target chairs. We manipulated similarity perceptions by varying the context. Viewing the two chairs in the context of other similar (different) chairs should direct participants' attention to the differences (similarities) between the two target chairs. Participants reported their decision confidence and conflict, willingness to pay for the two chairs, and their relative consideration of similarities and differences. The results on decision conflict and confidence replicated results from previous studies. Participants considered differences (similarities) more when the context primed them to focus on differences (similarities), but only in the Broad CW condition. We also found that in the Broad CW condition, the price difference between the two chairs was larger in the difference (vs. similarity) focus condition. As expected, the focus manipulation did not influence the price difference in the Narrow CW condition.

DISCUSSION

In four studies we show that the experienced choice conflict is significantly influenced not only by comparison orientation, but also by the width of categories consumers are exposed to prior to choice. Using multiple manipulations of similarity orientation, we demonstrate that consumers exposed to broad categorizations experience more choice conflict when a similarity (vs. difference) orientation is made salient. In contrast, consumers exposed to narrow categorizers consider both similarities and differences between products regardless of the salient comparison orientation.

Negative Not Positive Emotion Increases Variety-Seeking among Indecisive Consumers

EXTENDED ABSTRACT

Past research has generally found an increasing effect of positive emotion on consumers' tendency to variety-seek. The present research finds that this relationship between positive emotion and variety-seeking does not hold for indecisive consumers. Among these consumers, the opposite is true; negative emotion increases indecisive consumers' tendency to choose mixed assortments of products. The findings of this research imply that current views on when and why consumers seek variety should be revisited and revised accordingly.

One way indecisive consumers might cope with the negative emotions associate with choice is by avoiding choosing one option, which might be the "wrong" option is by choosing a mix of options. Ironically, varied choice-making involves more choice-making, thereby prolonging the negative emotion indecisive consumers seek to avoid.

The assumption that indecisive consumers are more likely to use a variety-seeking strategy and do so to cope with the negative emotions associated with choice has not heretofore been tested. To do so, we conducted three pilot experiments. Pilot 1 found that more indecisive consumers have a higher preference for variety packs compared to less indecisive consumers. In Pilot 2, consumers were asked to make a series of choices over time. Results show that indecisive consumers were more likely to change their choices versus repeat them. In summary, these two pilot experiments support the supposition that indecisive versus decisive consumers are more likely to vary their choice making. Pilot 3 shows that indecisive consumers seek variety to cope with the negative emotions associated with choice and do so successfully. In this experiment, indecisiveness was again associated with increased variety-seeking. Indecisive consumers who chose a mixture of options felt less negative emotion post-choice. Interestingly, among decisive consumers, variety-seeking was not associated with increased positive emotion post-choice.

The above findings suggest that 1) indecisive consumers variety-seek for different reasons than decisive consumers and 2) causes of increased variety-seeking among decisive consumers, such as

positive emotion, might not cause increased variety-seeking among indecisive consumers. Indeed, three experiments demonstrate that positive emotion decreases indecisive consumers' increased tendency to seek variety whereas negative emotion further increases this tendency. These experiments test the effect of positive versus negative (vs. neutral) emotion on indecisive consumers whereby indecisiveness is due to disposition (i.e. chronic indecisiveness) or due to situation; situational indecisiveness is created by "over-loading" consumers by providing them with too many choice options.

The present research explains these results by suggesting that indecisive consumers, having learned that variety-seeking is a successful strategy for coping with the negative emotions they associate with choice, generalize this lesson. They then use the strategy of variety-seeking to cope with negative emotion caused by other conditions other than indecision.

The findings of the present research imply that current views on when and why consumers seek variety should be revisited and revised accordingly.

Three Faces of Indecisiveness

EXTENDED ABSTRACT

What are the causes and consequences of indecisive behavior? To answer these questions it is helpful to understand the dimensions of chronic indecision. We recruited several samples totaling more than two thousand adult participants and asked them to rate the frequency with which they exhibit a number of different behaviors. In addition we asked participants to complete a number of related individual difference scales. Finally, we asked participants to make a number of hypothetical choices as well as consumer choices with incentive-compatible consequences.

Factor analysis of our decision behavior inventory revealed three major dimensions of indecisiveness: (1) Neurotic/Impulsive indecisiveness (e.g., "When I'm hungry I stand in front of the refrigerator for a while trying to figure out what I want"; "I try on more than one outfit in the morning before I pick one I like"); (2) Perfectionistic/Compulsive indecisiveness (e.g., "When I make a big electronics purchase I spend days or weeks thoroughly researching the options before choosing"; "I like to sleep on things before making a big decision"); (3) Unprepared indecisiveness (e.g., "When I receive an invitation for a future event such as a party or wedding, I respond yes or no right away" [reverse scored]; "I know what movie or movies I want to rent before I go to the store or online"[reverse scored]).

Type 1 behaviors correlate most strongly with traditional measures of indecisiveness (notably, Frost & Shows, 1993 and the decisiveness subscale of Need for Cognitive Closure, Webster & Kruglanski, 1994). Type 1 indecisiveness also correlates highly with several subscales of the Melbourne Decision Making Questionnaire (MDMQ, Mann et al., 1997) including hypervigilance, procrastination, and buck-passing. It is highly correlated with the decision difficulty subscale of the maximizing scale (Nenkov et al., 2008). Type 1 behavior is positively correlated with avoidant indecisiveness ("I try to put off making decisions") and aversive indecisiveness ("I become anxious when making a decision") (Spunt et al. 2009); however, when both are included in a multiple regression, only aversive indecisiveness significantly predicts type 1. Surprisingly, type I indecisiveness is *positively* correlated with urgency measures of impulsivity (Whiteside & Lyman, 2001; e.g. "I have trouble controlling my impulses"), and these individuals also report impulsive shopping behaviors (e.g., ""When I go shopping for food I end up buying things I hadn't planned to buy because they look good"). In sum, type 1 indecisive individuals dislike making decisions and are distressed by them, and thus will avoid deciding by procrastinating or deferring to others, and they avoid making tradeoffs. The impulsive behaviors exhibited by such consumers suggests that they do not tend to consider the opportunity costs of their choices.

Type 2 indecisiveness is strongly associated with the decision difficulty subscale of the maximizing scale. However, it is not correlated with any measures that reflect distress or anxiety during decision-making, such as the MDMQ hypervigilance subscale or the aversive subscale of Frost & Shows (1993). Instead, type 2 indecision exhibits a strong positive correlation with the MDMQ vigilance subscale, which captures the tendency to collect information and evaluate alternatives carefully before making a choice. Similarly, this factor is *negatively* correlated with one form of impulsivity—lack of premeditation (Whiteside & Lyman, 2001). Furthermore, type 2 indecisiveness is positively correlated with the high standards subscale of the maximizing scale, suggesting that type 2 indecisives seek exhaustive information due to a desire to select the best possible option. In sum, type 2 individuals appear indecisive because they take a great deal of time to think and research before deciding, but the decision process itself does not necessarily distress them.

Type 3 indecisiveness is not associated with having difficulty making decisions (no significant correlations with the decision difficulty subscale of maximizing or with the hypervigilance subscale of MDMQ). This factor is, however, associated with the nonplanning subscale of the Barratt Impulsivity Scale (Patton et al., 1995), suggesting that individuals high in this dimension to not plan ahead. Likewise, type 4 indecisiveness correlates strongly with the avoidant subscale of the Frost & Shows (1993), and is negatively correlated with the MDMQ vigilance scale. Overall, individuals high in type 3 indecisiveness seem to be disorganized but not distressed decision-makers, often unprepared when the decision moment arrives. Although they delay the decision-making process, type 3 indecisives do not necessarily experience difficulty when they making choices.

Subsequent studies revealed several behavioral regularities that distinguish different forms of indecisiveness. Individuals higher in Type 1 (neurotic/impulsive) indecisiveness are more susceptible to both attraction and compromise effects in choices among various consumer products, suggesting greater reliance on reason-based choice heuristics to avoid making difficult tradeoffs. In a task in which participants were presented with pairs of products available on Amazon.com, Type 1 indecisives read fewer pairs of user reviews before indicating their preferred option; they had a greater tendency to reverse their initial decisions in a task in which they chose between pairs of items that they would hypothetically save from a sinking ship. In addition they reported a greater number of items in their Amazon.com shopping carts that they had not yet purchased. All of these tendencies are consistent with the "impulsive" characterization of this dimension. Individuals higher in Type 2 (perfectionistic/compulsive) indecisiveness consumed more information before making a decision between pairs of Amazon.com products, and reported a greater number of items on their Amazon wish list. These tendencies are consistent with the notion of a compulsive search for ideal options, even if they cannot immediately be afforded (and thus remain on the wish list). Individuals high in Type 3 (unprepared) indecisiveness reported waiting longer before getting engaged to be married. Moreover, after controlling for age, gender, and education, they earn substantially less money. This is consistent with the notion that the capacity to plan ahead for decisions is associated with positive life outcomes.

The present research suggests that the dominant view of indecisiveness as a unidimensional construct must be revised, and that distinct clusters of behavior that may be deemed "indecisive" have distinct antecedents and consequences.

SESSION OVERVIEW

Research on embodied cognition proposes an intriguing counterintuitive notion that bodily states can cause cognitive states (Barsalou 2008). This is happening because bodily sensations are interlinked with a number of perceptual, motor and introspective states that have been acquired through experience (Barsalou 2008, Niedenthal, 2007). Therefore, an activation of such bodily states can have an impact on one's thinking and vice versa. For example, feeling of physical warmth has been shown to impact one's perception of interpersonal warmth (Williams and Bargh, 2008) and sensation of effort affects one's judgment of goal relevance (Labroo and Kim 2009).

In this session, we build upon the existing literature on embodied cognition in two ways. First, the papers in the session strive to build a bridge between embodied cognition literature and consumer research by proposing novel domains where bidirectional link between body and mind would affect consumer behavior. For example, Song and co-authors show how emotional expressions affect consumers' perception of the brightness of the products and suggest ways for marketers to use such metaphorical connection in strategic ways. Further, Zheng and colleagues show that negative affect can impact's one perception of fullness during food consumption and therefore leads consumers to eat less.

Second, more importantly, the session pushes the boundaries of embodied cognition research by examining <u>multi-sensory experiences</u> underlying embodiment effects. A number of papers in the session strive to integrate several modalities (including cognitive, motivational and affective processes) and therefore going beyond just reversing the link between cognition and bodily sensations shown in previous literature. For example, Pocheptsova and Labroo examine the relationship between bodily sensations, introspection and perception in the domain of cognitive performance. They show that consuming fat-rich food, remembering past consumption as well as perceiving the food to have high fat-content are interlinked

with a feeling of mental sluggishness. In similar vein, Zheng and colleagues, show that negative emotion, physical fullness and concept of heaviness are interlinked in cognition and activation of one of these modalities leads to activation of another. Finally, Kronrod and Ackerman conclude the session by showing how preventing one from embodiment of cognitions can negatively affect behavior and communication. This approach to studying embodied cognition highlights the importance of multiple modalities in cognition.

Taken together the papers in this session provide a better understanding of how multiple modalities may combine to result in embodiment effects. The papers are also closely tied together, paper 1 links affect to perception showing that smiling faces are perceived as brighter, paper 2 links affect to consumption showing that that negative feelings can make a person feel heavy, paper 3 links consumption to cognition showing that heaviness from fat but not protein consumption can result in mental exhaustion, and paper 4 links gesture to speech showing that tying hands can result in tongue tied. In introductory comments, the session chair will highlight the different modalities the papers span, and session participants will attempt to build connections between their findings and modalities considered by other session participants. The goal is to develop a better understanding of the relationship between affective experience, perception, consumption, and cognition, and to question the role that embodiment plays in these cross modal effects.

We expect that this session will be of interest to a wide audience: specifically, researchers interested in gaining the theoretical understanding of embodied cognition, as well as researchers interested in learning how research on embodied cognition can provide better insight in understanding consumer behavior. All four papers in the session feature research that makes substantial theoretical contributions to the existing embodied cognition literature while being grounded in phenomena that are marketing relevant. We hope that the session will generate fruitful discussion on the topic of integration of consumer research and embodied cognition literature.

Brighten Up: Emotional Expressions and Perception of Color Brightness

EXTENDED ABSTRACT

From cosmetics, paints, and clothing to housings, furniture, and stationeries, color is one of the most important features in products. And marketing messages regarding these various products are often accompanied by message deliverers with certain emotional expressions. While the impact of colors on consumer judgment and the impact of emotional expressions on consumer judgment had been investigated rather separately (e.g., Deng, Hui, & Hutchinson, 2010; Yeung & Wyer, 2004), many metaphoric expressions suggest that these two domains are closely integrated. For instance, the metaphoric mapping of 'brightness' and 'smiling' seems to be a universal cross-cultural phenomenon manifested in the expression 'bright smile' in many languages, including English, German, Italian, Korean, Chinese and Russian. The present research examined whether a face with emotional expression in fact influence the perception of brightness in color even when an actual perceptual difference in brightness does not exist

The most relevant work stems from metaphoric association between valence or morality and brightness (e.g., 'a bright day'). For instance, people respond faster to positive or moral words printed in white than in black, and faster to negative or immoral words printed in black than in white (Meier, Robinson, & Clore, 2004; Sherman & Clore, 2009). Furthermore, priming with positive words causes people to perceive gray patches as brighter (Meier, Robinson, Crawford, & Ahlvers, 2007). In the present research, we conducted four experiments to examine whether positive versus negative emotional expressions also influence the perception of brightness in color.

In Study 1, 171 people (120 females) participated in an online study and were presented with a set of two schematic faces side by side, one smiling and one frowning, in one of three colors (gray, yellow or red). Each face consisted of a circle with two eyes and a mouth, and the only difference between the smiling and the frowning face was the angle of the mouth. Participants were told that there is a subtle difference in stimuli color and were asked to detect which one was brighter. In Study 2, 113 people (73 female) followed the same procedure as Study 1 except that the question was phrased in terms of 'lighter' instead of 'brighter' and participants only saw one of two colors, yellow and red. In both studies, regardless of the colors and wording of questions, the majority of people chose the smiling face as brighter (lighter) than the frowning face (In all cases, more than 65% people chose the smiling face, *p*<.05).

In Study 3, 74 people (45 females) participated in an online study and were randomly presented with either the smiling or frowning gray face used in Study 1. Participants observed the stimuli at their own pace and indicated the brightness of the stimuli on a 9-point gray shades scale on the next page. Each shade of the scale differed 5 points in luminance, where 9 was the darkest (luminance = 150), 1 was the brightest (luminance = 110), and 7 was the correct shade (luminance = 140). Finally participants reported their mood on a 9-point scale (-4 = very negative to +4 = very positive) so we could ensure that the effects were not related to mood. In Study 4, 123 people (63 females) followed the same procedure as Study 3 except that the stimuli were realistic faces. We adopted the smiling and frowning gray scale images of a male model called J. J. in Ekman and Friesen's (1976) classic facial expression pictures modified by Horstmann and Bauland (2006). The stimuli differed from each other only in terms of elements to depict facial expressions. To equate facial luminance, we painted the two faces with the same pink color (hue = 9, saturation = 210, luminance = 203). The pink scale had 9 shades with a 5-point luminance difference in each shade, 9 was the darkest (luminance = 188), 1 was the brightest (luminance = 228), and 6 was the correct answer (luminance = 203). The results showed that participants perceived the smiling face as brighter (Study 3: *M* = 4.68, *SD* = 1.69; Study 4: *M* = 4.76, *SD* = 1.76) than the frowning face (Study 3: *M* = 5.51, *SD* = 1.69; Study 4: *M* = 5.36, *SD* = 1.62), *t*(72) = -2.07, *p* = .043, *d*=.49 (Study 3); *t*(121) = -1.97, *p* = .05, *d*=.35 (Study 4).

In sum, these four studies demonstrated that people perceive smiling faces as brighter or lighter than frowning faces. Our research reveals a novel link between emotional expressions and lightness perception, and these results likely have important implications for consumer behaviors. For instance, advertising campaigns for certain products that emphasize their brightening functions (e.g., cosmetics and bleach) may be more effective when they are accompanied by smiling models. On the other hand, in advertisements of products whose darkness is valued such as black attires, mascara, hair dye, and tanning products, smiles may not always be an effective strategy.

Does a Heavy Heart Create a Heavy Body?
The Connection between Conceptual, Physical and Emotional Heaviness

EXTENDED ABSTRACT

The Oxford English dictionary defines heaviness as the state or quality of being heavy to describe "weightiness and ponderousness" as well as "dejectedness of mind; sadness, grief." Thus, heaviness as a concept has meanings in the domains of weight (physical heaviness), state of mind (emotional heaviness) and, more generally, as a property of concepts.

Past research has shown that negative emotions have destructive physical consequences. Epidemiologically, negative emotions lead to a variety of diseases such as diabetes (Carnethon, Kinder, Fair, Stafford, & Fortmann, 2003) and hypertension (Everson, Goldberg, Kaplan, Julkunen, & Salonen, 1998;). However, there is little theory and empirical research on the physiological consequences of emotion.

Although the embodied emotion literature has shown that there is a linkage between emotion concepts and bodily experience, previous studies mostly focus on bodily experience as an antecedent of emotion concepts. For example, Niedenthal (2007) found that the bodily expression of emotion influence the way in which emotional information is processed. These studies manipulate bodily reactions (e.g. researchers affixed golf tees to the inside of participants' eyebrows to manipulate negative affect) to study the effect of bodily expressions on emotional information processing.

Metaphors using physiology related concepts such as "heavy hearted" and "feeling sad and heavy" depict the feeling of sad or grief in our daily life. Zhong and Leonardelli (2008) suggest that the linguistic coupling between body related words and cognition-related concepts such as feeling cold and social rejection may reflect people's predisposition to describe concepts based upon their bodily experience. Therefore, the linguistic association between sadness and heaviness may reflect sad people's bodily experience of feeling heavy.

Embodiment theories suggest that cognition not only relies on abstract and modal mental representations but also on amodal perceptual content from various sensors-motor regions in the brain that process bodily information (Barsalou, 1999; Gallese & Lakoff, 2005), which implies the linkage between emotion concepts and bodily experience. Specifically, when abstract concepts are activated, perceptual simulation occurs (Schubert, 2005). When people recall, think, read or talk about the abstract concepts, it will re-enact people's similar states based on stored sensory, motor, and introspective states that accompanied with the experience of those concepts (Barsalou, Niedenthal, Barbey, & Ruppert, 2003). For example, the activation of elderly stereotype leads to behavioral changes consistent with the concept: people actually walk slower (Bargh, Chen, & Burrows, 1996). The activation of specific emotion concepts of pride and disappointment is accompanied by changes in posture: people increase their posture height while generating of pride words (Oosterwijk, Rottevee, Fischer, & Hess, 2009). Therefore, activation of an abstract concept triggers bodily experience.

Given that negative emotion such as sadness or grief are coupled with heaviness in our daily languages and the activation of an abstract concept induces related bodily experience, we propose that conceptual heaviness and emotional heaviness will lead to physical heaviness. In the current study, we manipulated the activation of an abstract concept; heaviness, and investigate embodiment effect as consequences.

In the first study, we investigated whether conceptual heaviness will induce people's feeling of heaviness and influence their eating behavior. Sixty-six undergraduates participated in the study. They

first played a word game in which they were required to identify words in a word-grid. These words were either related to heavy (e.g.; heavy, ton, steel, sink) or words related to light (e.g., light, cloud, balloon, float). Then they proceed to a marketing product evaluation task in which they were asked to eat a sandwich and evaluate how full they felt. They were also offered a tray of mini muffins and asked to help themselves to as many as they liked. We found that individuals who were primed with heavy related words felt fuller (*M*=6.38, *SD*=1.48) compared to those who were primed with light related words (*M*=4.06, *SD*=1.7), $F_{(1,65)}=29.49$, *p*<.01. They also took less muffins (*M*=1.03, *SD*=.91) than individuals in light condition (*M*=1.91, *SD*=1.2), $F_{(1,65)}=11.6$, *p*<.01.

In the second study, we examined whether emotional heaviness will induce people's physical feeling of heaviness. Sixty-nine students participated in the study. They first watched either a five-minute long film clip from a movie. The clip was either sad, happy, or neutral. Then they evaluate an average student's weight and their own weight using multiple measures (e.g., how many bricks equal your weight, how much will a spring compress if you stand on it, how thick does ice on a lake have to be to not crack under your weight). We found that individuals who were primed with emotional heaviness perceived others as being heavier, $F_{(2,68)}=8.72, p<.01$. They also perceive themselves as being heavier, $F_{(2,68)}=5.47, p<.01$. An in the third study, we show that physical heaviness can induce a feeling of emotional heaviness.

These findings that conceptual heaviness and emotional heaviness are associated with physical heaviness are a novel extension of the embodied emotion literature. In addition, negative emotion does not only cause mental health problems but also physiological consequence- feeling of physical heaviness.

Lethargic Mind: How Perceived Fat Consumption Affects Mind's Agility

EXTENDED ABSTRACT

Fat storage is usually an indicator of (lack of) physical fitness, but can ingesting fatty foods decline one's cognitive performance? Further, does merely remembering eating fat-rich food impair one's ability to do cognitive tasks? Building on the literature of embodied cognition, we explore how the feeling of physical sluggishness that occurs after the consumption of fat-rich (but not protein rich) foods translates into similar feeling of mental sluggishness that manifests itself in one's impaired ability to perform various cognitive tasks.

The notion that cognition includes not only abstract mental representations but also a perceptual simulation has recently received increased interest in psychology and consumer behavior literature (see Barsalou 2008 for review). Such bidirectional connection between mind and body has been shown in a number of domains, including emotion (Niedenthal 2007), social isolation (Zhong and Leonardelli 2008), interpersonal perceptions (Williams and Bargh 2008) and even brand evaluations (Labroo and Nielsen 2010). Current paper expands on our understanding of embodied cognition by integrating three different modalities: bodily sensations, introspection and action. We test our proposition of multimodality of cognition in a novel domain: cognitive performance. To our knowledge, we are the first to show how actual and simulated consumption of fat-rich foods affects one's cognitive performance.

We test our hypotheses in a series of three studies. In Study 1 (n = 63) we aim at establishing the direct link between fat-rich food consumption and mental sluggishness. We propose that consumption of fat-rich foods would create a sensation of physical sluggishness, which in turn will manifest itself in mental slowness. In this study we asked participants to complete two ostensibly unrelated tasks. The first task was a taste study, during which half of participants were asked to sample eight plain crackers and another half were asked to sample the same crackers generously covered with a butter spread. After completing the taste study, participants were asked to solve a word puzzle and find as many words as they could within five minutes. We found that participants who just consumed butter found fewer words than participants who consumed just crackers. We did not observe any differences in mood between two conditions, and the difference in taste did not explain our results, when used as a covariate in the analysis.

Study 2 (n = 80) followed a similar design: participants completed a taste study and an unrelated cognitive task. However, in this study all the participants consumed exactly the same food: crackers covered with cream cheese. We used this design to rule out direct effect of consumption of fat-rich foods on mental performance. To manipulate participants' *perception* that they have just consumed a fatty food, for half of the participants we described the cream cheese as full fat (by providing them a nutrition label with high calories and fat content), whereas for another half we described the same cream cheese as being fat-free (low calories and zero fat). After completing the tasting study, participants were asked to solve 10 SAT math problems in allotted time of five minutes. Consistent with the results of Study 1, we found that participants who believed they consumed fat-rich cream cheese solved fewer math problems than did participants who believed they consumed a fat-free cream cheese. Importantly, we did not find a difference in a number of math problems attempted between the two conditions, suggesting that perceived consumption of fat does not affect one's motivation to solve problems, but rather influences one's ability to solve them. Furthermore, consistent with our theorizing, we find that participants who believed that they have consumed a full fat cream cheese rated themselves as being more tired than did the participants who believed they consumed a fat-free cream cheese.

Finally, in Study 3 (n = 53) we asked the participants to list breakfast foods they had consumed earlier in the day. Half of participants was asked to list fat-rich breakfast foods, for example, bacon and eggs, whereas another half was asked to list protein-rich breakfast foods, for example, bacon and eggs, and to describe the sensations consumption of those fat-rich or protein-rich foods entailed. This design was used to examine whether mere mental simulation of fat-rich food consumption has similar effect on cognitive performance. After completing the first part of the study, participants were asked to complete an unrelated anagrams study. In this study participants were asked to solve nine anagrams. Unlike the design of Studies 1 and 2, we did not limit the amount of time participants spent on the cognitive test and instead measured actual time spent. Consistent with our earlier results, participants that were just reminded of the fat-rich food they have consumed solved fewer anagrams than did the participants who were reminded about protein-rich foods. We did not find any difference in the time spent on anagrams between the conditions, again ruling out the potential role of motivation in explaining our results.

Using three different manipulations of fat-rich food consumption (from actual consumption to the memory of one) and across three different cognitive domains we find that consumers are less successful in cognitive tasks after consuming fat-rich foods. Further, our studies clearly show that mental sluggishness is not a result of actual physiological changes in the body or one's motivation to perform cognitive tasks. Taken together these results provide converging evidence for the connection between physical sluggishness associated with fat-rich food consumption and mental agility.

My Hands Are Tied – My Lips Are Sealed: Prevented Embodiment Limits Communicational Cooperativeness

EXTENDED ABSTRACT

According to Grice's Cooperativeness Principle (1975), to achieve a successful conversation partners make all efforts to understand and to be understood. This requires making inferences about each other in order for the speaker to adjust her/his language and for the addressee to retrieve the intended meaning of the speaker. However, interlocutors do not always make those inferences easily. One possible situation, in which inference is difficult to make, involves *prevented embodiment*. Research on embodiment reveals that bodily simulations of external social or mental states influence comprehension and perception (e.g. Wells & Petty 1980, Spivey, Tyler, Richardson, & Young, 2000). For example, Glenberg & Kaschak (2002) found that participants were faster at judging the sensibility of a sentence when its meaning (forward-backward) was compatible with the hand movement required for the response. Richardson, Spivey, Barsalou, & McRae (2003) find that the sentence-movement compatibility effect occurs even when the sentences refer to abstract actions that involve directional communication, such as "You told Liz the story" vs. "Liz told you the story".

However, to our knowledge no previous research has specifically examined how actively *preventing* the natural expression of embodiment can affect behavior and communication. In this work, we test whether limitation of embodiment would distort one partner's ability to make inferences about the other party, causing limited communicational cooperation. As comprehension is claimed to be dependent on and aided by embodiment (e.g. Lakoff & Johnson, 1999, Barsalou, 1999; Glenberg & Robertson, 2000), it makes sense that inference, which is part of comprehension, is also grounded in bodily states. But what happens when embodiment is prevented, due to situational (e.g. holding a box) or medical (e.g. broken arm) reasons? Does prevention of embodiment affect our communicational cooperativeness?

We test this effect in two hypotheses: H1: Prevented embodiment reduces cooperative communication among both parties in a conversation, resulting in: a) Lower ability of addressees to process language, which requires making effortful inferences about the speaker's intended meaning. This will occur, for instance, in comprehension of natural language vs. fixed expressions, and in non-conventional vs. conventional request phrasing; b) Lower ability of speakers to make inference about the hearer, resulting in lower ability of speakers to adjust their language to the hearer.

We examine these hypotheses in two language comprehension and one language production experiments, which manipulate prevented embodiment and measure cooperativeness in communication. Studies 1 (N=22) and 2 (N=40) test H1a. We find that comprehension of sentences containing the verb "stand" and non-conventionally phrased requests for actions that are typically performed in a standing position occurs more slowly when done in a sitting posture (which prevents the embodiment of the sense of "stand"), compared with a standing posture. However, idioms and expressions with the word "stand" and conventional requests, both requiring less inferential effort and therefore less cooperativeness, were not processed more slowly in sitting posture.

Study 3 examines H1b. Participants (N=80), half of them with their hands held in a pocket behind their backs (to prevent hand movement), were recorded while giving oral instructions for simple household tasks that require the hands, such as washing the dishes. The instructions were to be given either to imaginary human assistants, or to an imaginary helper robot, assuming that people intuitively should use different communication style with a robot vs. humans (e.g. more detailed instructions, less polite communication) intuitively attributing lesser knowledge and feelings to the robot vs. humans. The recorded instructions were then coded and analyzed. Consistent with predictions, participants with full ability to embody gave instructions to the robot, which were more detailed than their instructions to the human. These participants were less confident in the robot's understanding and tried harder to maintain coherence of their instructions to the robot than to the human. However, participants who were prevented from embodying did not manage to adjust their language to the addressees' needs. Namely, they were similarly detailed, confident and coherent with both the robot and the human.

These findings suggest that prevention of embodiment can impair various aspects of communication, including mental processes that require combination of information from multiple sources and inference making. While communication cooperativeness, as examined in this work, is important in interpersonal communication, it is also highly important in marketing communication and advertising, as well as in retail behavior and in negotiations. We intend to further inquire into the effect of prevented embodiment on general interpersonal cooperativeness, e.g. in games, within negotiation and business contexts.

All in the Family: Intra-Family Coalitional Influences on Consumption

SESSION OVERVIEW

Prior research documents the significance of family and kinship networks in brand loyalties (Cotte and Wood 2004; Fournier 1998; Hoyer 1984; Moore, Wilkie, and Lutz 2002), consumer socialization (Carlson and Grossbart 1988; John 1999; Moschis 1985, 1987), decision-making (Commuri and Gentry 2000) and intergenerational transfers (Curasi et al 2003 and 2004; Ekerdt and Sergeant 2006; Lastovicka and Fernandez 2005). However, very little research has investigated coalitional or collective consumption processes within kinship networks (Epp and Price 2008). Epp and Price (2008, p.55) argue that we might better understand consumption processes "by examining how particular brands are embedded in family and relational identity enactments." By family and relational identity enactments, they refer to the interplay among the rituals, narratives, social dramas, intergenerational transfers and everyday interactions that make up family life. They theorize that brand loyalties, consumer decision-making, consumer socialization, and intergenerational transfers often implicate multiple identity bundles in dynamic interplay within a family's social interactions and consumption practices. Specifically, they emphasize that family identity (i.e., "who we are as a family") is contingent on shared interactions among relational bundles within the family that engage in both complementary and competing consumption practices. For example, individuals, various coalitions (father/sons; mother/daughters; siblings; couple, etc), and the collective family instantiate and negotiate identity through consumption and other practices. Empirical research supports that the level of synergy and discord among individual, relational and collective identity goals is consequential for object meaning and consumption activities (Epp and Price 2010; 2011). Moreover, research shows that siblings play an important role in shaping coalitional and family consumption practices (Cotte and Wood 2004). Despite this, few studies explicitly focuses on coalitional influence. This session contributes to the emerging literature on family identity by investigating how coalitional and collective dynamics inform brand loyalty, decision-making, consumer socialization and intergenerational transfers.

This session tightly coalesces around uncovering how coalitional identities and practices interplay with family life: Epp et al uncover the role of coalitions in how family life is practiced across distances and through technologies with implications for brand loyalty. Huff and Cotte examine coalition dynamics evidenced in navigating emotionally stressful decisions about elder care for parents. Kerrane and Hogg investigate the dynamic and often volatile role of sibling relationships in consumer socialization. Connell et al demonstrate how synergy and discord among identity projects within a family impacts the intergenerational transfer of consumption practices. All four papers share an emphasis on sibling and other coalitional relationships within families. All papers touch on member roles and member identities as they intersect with the family collective identity. In addition to theoretical cohesion, the papers share a methodological focus, using depth interviews with multiple family members to reveal family consumption. Although further iterations of data analysis are possible, each of the presentations is based on completed data collection and writing is expected to be completed by the time of the conference.

We anticipate our session will have broad appeal drawing researchers interested in social and collective identity, family brand loyalties and decision making, consumption practices, consumer socialization and intergenerational transfer. In particular, although all four papers bring different perspectives all four papers engage practice theory and social identity theory with family as the focal site for investigation. As longitudinal investigations are still relatively rare and collective depth interviews are an emergent data collection method, this session will also engage the interest of interpretive researchers more generally.

Connected Coalitions: Preserving Brand Loyalty across Distances

EXTENDED ABSTRACT

Today's consumers operate in a dynamic, global environment in which family life is practiced across distances and through technologies in ways unimaginable in the past. Our study investigates the implications for marketers of "doing family" through technologies. Researchers tend to focus on culturally loaded and normatively shaped activities families consider sacred such as dinner or holiday traditions (e.g. Epp and Price 2008; Gibbs 2006; Wallendorf and Arnould 1991). It is not uncommon for brands to become caught up in our meaningful family practices (Brady 2007; Warde 2005). Given that families are quite mindful of enacting traditions, we anticipate that families would strive to hold on to these when confronted with separation.

We collected longitudinal data from 23 families experiencing a physical separation (e.g. college, commutes, divorce, military) to address this question: what conditions shape brand loyalties during separation? Phase 1 included in-depth, family interviews to identify a range of practices and embedded brands central to defining the family and its coalitions (e.g. siblings, parent-child). Phase 2 included participant diaries to track the evolution of these practices. Phase 3 consisted of follow-up family interviews, using the diary entries to attend to changes in practices, brands, and technology use.

Paradoxically, very few families performed sacred activities while separated. Although the challenge to preserve centrally-held

practices resonates, the ability to hold on to these traditions in a tech-mediated form requires tremendous creativity, mindfulness, and commitment. In contrast, everyday, coalitional activities were carried across distances more easily by the available modalities. Simple traditions that may involve only subsets of the family such as sisters sharing their favorite snack (Potter Family), mother-daughter shopping outings (Duncan Family), or brothers playing their guitars together (Thomas Family) can be important for constituting relational identities (Epp and Price 2008, 2010, 2011). These activities typically are considered profane, defined as "ordinary and part of everyday life" (Belk et al. 1989, p. 6). Simple coalitional activities establish a "shared world" among family members, are playful and naturally emergent, idiosyncratic, and may be less intentional or conscious. Among the families we interviewed, simple practices often were not recognized as important until they were missed during separation.

Several factors account for the ease of transferability of everyday coalitional practices as opposed to sacred family traditions. First, sacred activities tend to have strict minimum requirements (e.g. particular members, brands, contexts, materials, and meanings). Further, the time dependent, rigid structure and emotionality of sacred traditions are difficult to simulate with existing technologies. For example, the Foster family provided a detailed account of family dinner, but when their son Michael left for college, dinner conversation tapered, parents often read at the table, their daughter texted friends while eating, and many associated restaurants/brands were abandoned until Michael returned home. Unlike sacred family activities, coalitional activities tend to require fewer elements necessary for their performance, so contextual factors are easier to replicate. Given this, many families adapt these activities across distances relatively effortlessly (e.g. couple co-views their favorite TV shows by calling during the commercials—Moore-Mason Family). Technologies have made us more asynchronous, so time-independent, coalitional activities are better able to survive in this harsh environment. Lily Potter explains how this emerges organically among sisters: "we would open a can of condensed milk and eat it right out. So, when I do that by myself, I might text her…'I just opened a can of condensed milk!'" These nods to a once face-to-face activity accentuate the absence of another person; they prompt a previously shared world and attempt to recapture a piece of it.

Second, even in families who are motivated to maintain elaborate activities, shortcomings or differences in preferred technologies can derail their efforts. For instance, when asked what could save family dinner, the Fosters responded: "We could put a computer screen on the table and Skype you [Michael] in while we have dinner; that would be too weird though" (Jed, Father). Partly, this is a problem of mixed modalities. Although Michael is open to Skype, his parents characterize themselves as low-tech ("I hate email…I don't like to text, cell…it's just a huge intrusion" Jed, Father). Each family exists within its own technology ecology. The communication patterns both prior to and during a separation determine how, if at all, each modality is used to preserve activities and embedded brands. In comparison with elaborate activities, simple coalitional activities are likely to survive the mixed modalities dilemma. No matter which technologies comprise the family's ecology, members readily found a combination that worked. For example, co-viewing a favorite TV show could be facilitated by phone (as above), via text, or using Skype, among other modalities. Providing families with templates for how elaborate activities could be translated from face-to-face to technology-mediated could help families who have trouble envisioning such shifts and/or who view this as foreign or strange, given its absence from cultural templates for "doing family."

Third, the very structure of technology has prompted a shift from uniting families to connecting coalitions. Technology frequently favors dyads (or small coalitions), rather than facilitating family-level interactions, and this has a profound impact on the activities/brands that survive separation. Turkle (2010) echoes this point as she quotes Winston Churchill, "We shape our buildings and then they shape us" (p. 19). The technologies that dominate today can be isolating for distant families. Even when the intent is to involve a missing member—such as when Lily texts her sister to include her in the Potter family's movie night, but mom views this as excluding because texts are dyadic—technologies can fall short.

Our study suggests that firms should focus on embedding their brands in simple, coalitional activities rather than strive to find sanctuary in elaborate family traditions. Coalitions improvise these practices while separated, but companies could prompt this transformation. Minor improvements to technology, ads that depict "sharing the day," or basic templates may serve as a catalyst for families who are willing, but do not see the bridge that allows them to preserve simple activities. Managers also could provide mechanisms for translating the sacred. To do so, companies must deconstruct elaborate traditions into their various components and generate imaginative ways to repackage and transfer the sentiment. We have diverse examples in our data: sending picture texts of a life-sized cutout of a distant sister doing fun things with her family (Potter); calling to include a son in prayer time before dinner (Marino), posting videos of the family at the dog park on YouTube to include the husband (Powell), or sending postcards marked with stories of the family's travels to an absent son (Norris). These simple, yet meaningful actions initiated valued connections among coalitions. Firms could easily generate models for how brands could carry these meanings and be involved in the pieces of sacred that move across distances.

The Ambivalent Role of Adult Siblings in Family Decisions about Elder Care

EXTENDED ABSTRACT

This paper explores the experiences of adult siblings making choices about elder care for their parents, with a particular focus on the ways in which adult siblings can generate ambivalence in consumption. Decisions about elder care are rarely made by a single family member, and usually involve the family's adult children. As a result, adult siblings find themselves having to negotiate with each other and rely on each other for emotional support, because this context is typically marked by stress and tension within the family. Further, family transitions, such as the need for long-term elder care, can threaten family identity, thereby complicating consumption behavior.

Prior research has shown that family identity shapes consumption enactments within the family (Epp and Price 2008, 2010, 2011), and that siblings can play an important role in shaping each other's consumption practices (Cotte and Wood 2004). We extend this research by studying adult siblings who are faced with an important family decision yet who are no longer contained within the same household, and we pay particular attention to the ways that stressful consumption decisions are approached. Specifically, we are concerned with understanding how siblings, as a relational group within the family, reconcile discrepancies between their individual preferences and those of the group, how the consumption process is influenced by siblings, and how the family's collective sense of itself shapes and is shaped by elder care consumption for senior family members.

Using depth interviews, we uncover the ambivalent role that adult siblings play in shaping the consumption experiences of individuals. We then link these individual experiences to the role of consumption in family transitions, and the ways in which family identity both guides and challenges choice and use of elder care. We find that individuals hold unique sets of preferences (e.g., interpretation of what is best for the parent), involvement (e.g., willingness to participate in the decision process), and resources (e.g., time, money) in regard to their parents' need for elder care. When siblings combine their unique perspectives to make a family decision, discrepancies amplify the stress for each individual and for the family as a whole. Interestingly, however, the existence of siblings also seems to facilitate coping with the stress. Siblings, then, play an ambivalent role by both generating and tempering the stress associated with choosing long-term commercial elder care for a parent. The ultimate choice is further shaped by the underlying family dynamics, family identity, and the interplay between siblings. We compare and contrast the experiences of adult siblings with only children in this context, and find further support for our model; when an adult child has no siblings, decision making appears to be less complicated but the ongoing consumption appears to be more emotionally burdensome.

This research contributes to our understanding of family decision-making, the dynamic and sometimes volatile nature of sibling relationships in the family consumption process, and the ways in which family identity can both challenge and facilitate consumption. Our unit of analysis is the relational group of adult siblings, which is a novel perspective in consumer research.

Helping or Hindering? The Ambivalent Role of Siblings as Socialization Agents within Family Consumption

EXTENDED ABSTRACT

Sibling relationships have been largely overlooked within existing consumer research into the role of the family within consumer socialization (Cotte and Wood, 2004). The family has been represented as the most important consumption unit (Commuri and Gentry 2000) because it plays a significant role in the consumer socialization of children (John, 1999). So far, research attention has largely focussed on the role of parents in socializing their children into being consumers. Current research has explored the socialization styles of parents (Carlson and Grossbart, 1988) or the communication patterns that parents adopt (Carlson, Walsh, Laczniak and Grossbart, 1994) in facilitating the acquisition of consumption knowledge for children. In contrast the role that siblings may play in teaching one another consumption skills has been relatively neglected (Cotte and Wood, 2004). In this paper we specifically explore the role that siblings play within the context of consumer socialization. We focus on understanding sibling relationships ('sibship') and how such relationships, as one component of the family environment, shape the consumer socialization of children.

A series of in-depth interviews were conducted with six families in our exploratory study, capturing the stories of twenty-nine family informants. Following calls for family research that capture the dynamics of family life (Hamilton and Catterall 2006; Tinson and Nancarrow 2005) interviews were conducted with both children and their parents. Consent was sought from parents and guardians to approach their children in order to then seek the children's consent to be involved in the data collection process (Mandell 1991). Methods by which valid consent can be obtained from children were adhered to (Mason 2004). The interviews were conducted in the family home, usually in the kitchen at the dining table. Each family was visited between three and five times and interviews were conducted over

a period ranging from four to twelve months. The interviews with family members were conducted in three stages and explored themes such as family history, intra-family relationships and how family members got their own way.

Our exploratory study highlights that sibling relationships were far from static, and were often ambivalent and volatile in nature. Our family stories show how the siblings discussed consumption issues with each other. Siblings were often children's first point of contact when considering consumption issues and choices. This is significant as the children studied suggested that they would rather lose face with their siblings, who appeared to vet selected brands and products, before they ran the risk of losing face with their peers. In this case, the family provided a safe and private environment in which to seek and update their consumer knowledge about products and brands. Consumption choices, and in particular brand selection, were often shaped by siblings who were important filters, as well as sources, for market-place information.

However, given the ambivalent nature of sibling relationships each child did not have equal access to this consumption advice or approval process. We identify both supportive/co-operative and hostile/aggressive dimensions of sibling relationships. Such relationship types had implications in terms of the consumption and consumer socialization of the children studied. Where relationships were supportive siblings would lend each other help in influencing their parents to buy them products, with siblings openly discussing consumption issues and brand choices with one another. Where relationships were hostile and aggressive such information and advice sharing was not apparent, but rather siblings would deliberately withhold their opinions or consumption help, or offer incorrect opinions in the hope that this would subsequently tarnish their brother's/sister's image and reputation with their peers. As such although siblings had the potential to be important socialization agents for children, unlike the socializing actions of parents the children studied did not always have good and constructive consumer socialization intentions in mind.

Intergenerational Transfer of Consumption Practices within Families

EXTENDED ABSTRACT

Our research examines intergenerational transfers of consumption practices (ITCP). We recognize ITCPs as socially embedded in the consumption practices of families which contain multiple and sometimes conflicting identity projects across units of analysis (the individual, intra-family coalitions and the family collective). Through in-depth interviews with sixteen members of five families, we examine this complex interplay of identity projects in a given ITCP and demonstrate how identity interplay affects synergy and discord within the transfers.

Our investigation departs from prior research in three key ways. First, we examine consumption practices rather than special objects and brand preferences. Consumption practices are central to creating, sustaining and passing forward individual and collective identity (Gregson, Metcalfe and Crewe 2007; Warde 2005). However, prior research has focused on the transfer of special objects, heirlooms (Belk 1988; Curasi, Price, and Arnould 2004; Price, Arnould, and Curasi 2000), brand preferences (Cotte and Wood 2004; Fournier 1998; Hoyer 1984; Moore, Wilkie, and Lutz 2002), and wealth (Brandford 2009) without much consideration of the practices that surround them and within which objects and brand preferences are implicitly embedded. The foregrounding of objects and brand preferences is useful in understanding how their meanings are transferred

across family generations, but it obscures the intergenerational enactment of practices that is often at the heart of these exchanges.

Second, we study intergenerational transfers within families, while previous research has focused on dyads and often on just one half of the dyad (e.g., daughters in mother-daughter dyads by Moore et al 2002). ITCPs are situated within consumer collectives, such as families with identity projects at individual, coalitional and collective levels (Brewer and Gardner 1996; Epp and Price 2008) with varying degrees of synergy and discord (Epp and Price 2008; 2010; 2011). Families' ITCP may be contested as identity projects interplay. For example, a successful transfer of a consumption practice such as soccer or baseball between a father and son may stifle another son's individual identity project as he is pulled into this coalitional practice. Similarly, the embracing of soccer or baseball as a family identity may serve to exclude particular members or coalitions within the family. Hence, by examining ITCP within families, not dyads, we uncover how varying degrees of synergy and discord surrounding consumption practices affect intergenerational transfer.

Third, because we focus on consumption practices rather than objects, and networks rather than dyads, we uncover the dynamics underlying thwarted intergenerational transfers. Prior research has noted how consumers strategize and sometimes fail to transfer their special possessions to the next generation (Belk, Sherry and Wallendorf 1988; Belk, Wallendorf and Sherry 1989; Curasi, Price and Arnould 2004; Price, Arnould and Curasi 2000). Explanations for failed transfers of special possessions generally center on a failure of one generation to communicate object meanings to the next generation through stories and use. However, we show how the interplay of identity projects may lead to thwarted intergenerational transfers. Prior research occasionally describes, how the dynamics of coalitional consumption practices (such as multiple generations of males hunting or fishing together) positively impact the transfer of special objects (such as guns and fishing rods) (c.f., Price et al 2000). However, existing research does not uncover how coalitional consumption practices may negatively affect other family members who resist or are excluded. Thus, we explore both synergistic and discordant elements of consumption practices, how these implicate identity projects, how they are negotiated between and among family members, and how they influence ITCP (Epp and Price 2011).

Finding Meaning in Numbers: How Consumers Contextualize Numeric Information

SESSION OVERVIEW

The consumer research literature holds many examples where perception of magnitude influences consumer choice. Expanding a ratio scale to include more discrete units (such as from feet to inches or years to days) has been shown to encourage more discrimination along the scale (Burson, Larrick and Lynch, 2009). This can lead to choice errors when consumers over-use uninformative numerical information (such as in the money illusion effect of Shafir, Diamond and Tversky, 1997), and problems also arise when consumers fail to extract knowledge from informative numbers. This special session aims to contribute to the literature by exploring new frameworks for understanding how consumers extract meaning from numbers, when they are sensitive to changes in magnitude, and the implications for consumer choice. Contextual and task cues shift how we process numeric information and can lead to very different outcomes from otherwise equivalent information.

The first paper, by Larrick, Burson, and Kay explores when scale expansion, such as from dollars to cents or years to days, alters consumer judgment. They find that scale expansion effects are robust to incentives and independent of accountability, and that only experts weigh cues consistently across units.

The second paper, by Simonsohn, explores how the context and task cues provided by elicitation methods can influence intuitive psychological processes responsible for numeric perception and insight. He demonstrates that the psychological processes responsible for the otherwise-robust Uncertainty Effect are attenuated when respondents report willingness to pay on a list containing multiple prices (multiple-price-list elicitation). He argues that failure to elicit preferences through methods that are "psychologically compatible" with the psychological processes of interest can cause artifactual interactions with manipulations. In this case, psychologically incompatible elicitation can interfere with consumers' intuitive thought processes involved in deriving meaning from numbers and perceiving scale.

The third paper, by Shen and Urminsky, explores how consumers evaluate information in unfamiliar units. They suggest that consumers' relative attention to units and numbers determines magnitude sensitivity, and hence posit and find that unit salience has a critical role in reliance on numeric inference. They find that in the absence of a unit salience cue, consumers are highly sensitive to magnitudes with unknown units, even in single evaluation for consequential decisions with ample decision time. However, when the decision process prompts unit salience, the effect of magnitude is eliminated.

The fourth paper, by Atlas and Bartels, explores how reframing a price as a series of recurring payments (e.g. "Pennies-a-Day", Gourville, 1998) affects how consumers value a transaction's benefits. They argue that a proposed payment schedule encourages consumers to imagine commensurate benefits; hence dividing a single price into a series of recurring payments increases willingness to purchase when a transaction's benefits are more scope-insensitive than its costs. In other words, narrow framing favors scope-insensitive accounts.

Together, these four strongly interconnected papers provide new perspectives on how consumers understand and derive meaning (e.g. sense of scale) from numbers and contextual cues. Each paper will advance the field's understanding of when people are sensitive to changes in magnitude. One other common theme across each of these studies is that our results persist with high involvement, such as when subjects make incentive-compatible choices and important decisions. These perspectives yield insight into consumer choice across a wide range of settings, and carry theoretical as well as practical implications for consumer research. In particular, this proposed session builds connections between numerosity, scope insensitivity, and mental accounting in the consumer choice domain. Data collection in all papers is complete and all participants have agreed to present, should the session be accepted. The use of numeric stimuli in decision making research is ubiquitous, and we expect that the novel approaches to numeric decision making presented in this session will interest a broad range of consumer researchers. The session should be of particular interest to those interested in mental accounting and financial decision making. These topics have attracted considerable attention and interest in recent years and we anticipate that the results presented in this special session will stimulate future research. The chairs will facilitate audience discussion drawing further connections between these perspectives as well as between scale in mental accounting and other areas of consumer research.

The Effects of Scale Expansion on Preference, Prediction, and Judgment

EXTENDED ABSTRACT

Consumers often encounter quantified product information. For example, consumers might receive quantitative information about costs, energy consumption, or ratings of reliability. Each of these pieces of information is open to alternative expressions: Costs might be summarized in dollars or cents; energy consumption might be expressed per month or per year; and ratings of reliability might be on a 5-point or 100-point scale. In each case, identical ratio information is conveyed after being multiplied by an arbitrary factor. Although the informational content is held constant, scale change alters preference and judgment. Scale size matters.

A number of studies in marketing and in cognitive psychology have shown changes in scale size affect perceptions of risk (Pacini & Epstein, 1999; Stone, Yates, & Parker, 1997; Yamigishi, 1997) and changes in currency denomination affect purchase behavior (Wertenbroch, Soman, & Chattopadhyay, 2007). For example, Yamigishi

(1997) has shown that people judge ratios expressed with small numerators and denominators (6/100) as less risky than smaller ratios expressed with large numerators and denominators (57/1000). These effects have been explained in terms of decision makers focusing on the "numerosity" (Pelham, Sumatra, & Myaskovsky, 1995) of numerators, and giving little attention to the less salient denominator (Reyna & Brainerd, 2008; Stone et al., 1997). Burson, Larrick, and Lynch (2009) proposed that many previous scale change effects could be captured under a general principle of discriminability. For any ratio scale, multiplying the scale by an arbitrary factor greater than 1 increases the perceived difference between different alternatives. By increasing the perceived difference, or discriminability, on that attribute, expanded scales shift preference to an alternative favored on that scale. Burson et al. (2009) demonstrated that enhanced discriminability produced preference reversals in multi-attribute choice. In one study, two cell phone plans were expressed in terms of price per month and number of disconnected calls per 1,000 calls. Option A cost $32 per month and had 42 dropped calls per 1,000 calls; Option B cost $27 per month and had 65 dropped calls per 1,000 calls. The small difference in price and large difference in dropped calls led the majority of subjects to favor Option B. However, when the same information was presented as price per year ($384 and $324) and dropped calls per 100 calls (4.2 and 6.5), the large difference in price and small difference in dropped calls led the majority of subjects to favor Option A.

This talk will present three new studies testing moderators of scale expansion effects: Accountability, incentives, and expertise.

Accountability. We tested the effect of accountability in an employee evaluation task. Subjects were asked to rate sales people based on two attributes: Number of sales (expressed per week or per year) and number of customer complains (expressed per customer or per 100 customers). When one attribute was expanded (e.g., sales per year) the other attribute was contracted (e.g., complaints per customer). Scale expansion was crossed with an accountability manipulation in which subjects had to explain their choice. Based on previous research, we constructed competing hypotheses: Accountability would reduce scale-induced preference reversals by making subjects think harder about the information, thereby undoing the effect of arbitrary changes in scale; and accountability would increase scale-induced preference reversals because subjects would use the magnitude of (arbitrary) differences to justify their choices. Contrary to expectations, we found no interaction between scale expansion and accountability. As in previous studies, scale expansion produced a significant preference reversal; accountability had an additional main effect, shifting preference to the employee who had the most sales. This study suggests that accountability has a largely orthogonal effect to the effect of scale expansion.

Incentives and expertise. We tested the effect of incentives and expertise in a performance prediction tasks. Subjects were presented with data for 20 Major League Baseball pitchers. The names of the pitchers were masked. Subjects were given each pitcher's rate of striking out a batter and giving up home runs to a batter. Strikeouts predict better pitcher success and home runs predict worse pitcher success (as measured by a well-known statistic called "earned run average"). All subjects were paid for the accuracy of their predictions. When the rate for one statistic was expanded (e.g., home runs per 100 innings), the rate for the other statistic was contracted (e.g., strike outs per batter), creating two conditions. For each subject, we regressed his or her predictions for the 20 pitchers on the two cues to derive a weight for cue use. We found a significant effect of expansion: A cue received more weight when it was expanded than when it was contracted. Incentives do not seem to be sufficient

to eliminate the effect. We also measured expertise in baseball using both subjective measures (self-ratings of knowledge and confidence) and objective measures (a quiz about baseball statistics such as "OPS"). We found that expertise significantly moderated the effect of scale expansion. Those with low and intermediate levels of knowledge were susceptible to scale effects. However, those most expert weighted the two cues consistently regardless of how the statistics were scaled.

Psychology-Compatible Elicitations:
The Uncertainty Effect as a Case Study

EXTENDED ABSTRACT

A significant portion of consumer research has examined the impact on elicited preferences and judgments of employing alternative elicitation modes or frames. When studying unrelated phenomena, however, consumer researchers typically choose how to elicit variables of interest based primarily on convenience, be it of obtaining more data from a given number of participants, of arriving at easier-to-analyze variables, or of employing measures that are easier to explain to participants.

While it may be inevitable to in one way or another influence preferences through their elicitation, the notion of "psychology-compatible" put forward in this paper involves *elicitations that do not interfere with the psychological processes of interest to a study*.

Psychological-compatibility is violated when elicitation mechanisms have asymmetric effects across conditions; when rather than having a main effect, such as anchoring all valuations up or down, the artifactual consequences of the mechanism interacts with what the experiment seeks to manipulate.

This paper provides a concrete demonstration of the consequences of violating psychological-compatibility using the Uncertainty Effect, the valuation of a lottery below its worst outcome, as a case study. It shows that the otherwise robust finding disappears when preferences are elicited through a commonly employed mechanism, the multiple-price-list, as it reduces respondents' reliance on the psychological processes likely to be behind the Uncertainty Effect.

Multiple-price-list elicitations present participants with a table with dollar amounts listed in ascending order, and requires respondents to indicate for each price if they would be willing to pay it or not (e.g., would you pay $1 for this mug yes/no, would you pay $1.50 for this mug yes/no, etc.) They have been used for eliciting willingness-to-pay at least since the seminal paper on the endowment effect by Kahneman, Knetsch and Thaler (1990). In addition to valuations, such lists are also often employed to elicit time and risk preferences.

One appealing feature of the multi-price-list is that it lends itself to an intuitive incentive compatible design, where one of the yes/no decisions can be chosen at random to count for real payoffs.

For the purposes of the current paper, however, the central feature of the multi-price-list elicitation is the format in which it presents prices. Prior research has shown that presenting numerical stimuli side-by-side induces people to think more analytically and less intuitively, even on subsequent and unrelated questions (Hsee & Rottenstreich, 2004; Hsee, Rottenstreich, & Xiao, 2005; Zeelenberg, 1999), and to be more sensitive to differences in magnitude or scope among options (Hsee, 1996; Hsee, et al., 1999).

These findings imply that the format in which prices are presented in the multiple-price-list is likely to increase participants' overall reliance on System 2, attenuating the impact of their System 1 reactions to the stimuli being evaluated.

In addition, by providing a list of possible answers, the multiple-price-list may induce subjects to use the range of values to construct

a reasonable answer (Parducci, 1965; Schwarz, Hippler, Deutsch, & Strack, 1985; Sudman, Badburn, & Schwarz, 1996). For instance, subjects may implicitly (or explicitly) place the low and high prize on the table and select a number in between as their valuation of the lottery, effectively eliminating stochastically dominated answers from the consideration set. The multiple-price-list, then, may also act as a decision aid that bolsters the impact of System 2 on decisions.

Considering that the Uncertainty Effect is a revolutionarily important phenomenon probably caused by a System 1 process, people's intuitive negative reaction to risk (Simonsohn, 2010; Loewenstein, Weber, Hsee & Welch, 2001) and that the multiple-price-list is a commonly used elicitation technique conjectured here to attenuate the influence of System 1, the present research employs the Uncertainty Effect and multiple-price-list elicitations as a case study for introducing the notion of psychological-compatibility.

This paper presents the results from four between-subject experiments eliciting valuations for binary lotteries or for their worst outcome. Studies 1 and 2 replicate the Uncertainty Effect employing open-ended elicitations of willingness-to-pay (e.g., "what is the most you would pay?"), Studies 2, 3 & 4 do not replicate it using multiple-price-list elicitations.

If, as hypothesized, this discrepant set of results is explained by the side-by-side presentation of prices in the multiple-price-list, then the Uncertainty Effect should again be replicated if one were to modify it and present prices one at a time rather than simultaneously. Studies 3 & 4 do so and do indeed again replicate the Uncertainty Effect. Furthermore, consistent with the notion that the multiple-price-list eliminates the Uncertainty Effect by affecting the System 1 reaction to *uncertainty*, only the valuation of lotteries shifts across elicitation methods.

Making Sense of the Nonsense:
When Are Consumers Sensitive to Magnitude Variation in Unfamiliar Numerical Information?

EXTENDED ABSTRACT

A broad range of consumer decisions involve judging numerical information in conjunction with a unit of measurement, which may not be familiar to consumers. Suppose, for example, that you are traveling in a foreign country where people use units of measurement that you are not familiar with. You may need to evaluate a container with volume 128X, a distance of 3,000Y, or a product priced at Z50. How do consumers judge numerical information in unfamiliar units?

Two main streams of research provide inconsistent predictions. The literature on numerosity and the money illusion (e.g., Shafir, Diamond and Tversky 1997; Wertenbroch, Soman and Chattopadhyay 2007) found that consumers judge unfamiliar information by its face value and therefore over-use numerical information which may not be informative, demonstrating magnitude sensitivity. In contrast, research on evaluability (e.g., Hsee, Loewenstein, Blount, & Bazerman, 1999; Hsee & Rottenstreich, 1994; Hsee & Zhang, 2010; Kahneman & Knetsch 1992) found that consumers fail to make inferences from numerical information with unfamiliar or hard-to-evaluate units when judging a single stimulus. In these studies, they do not use numeric information even when it may be informative, showing magnitude insensitivity.

We in this research provide an account of when it is that consumers do and do not utilize absolute magnitude information that is displayed in unfamiliar units, in order to reconcile these inconsistent findings. We propose that whether the numerical information is incorporated into judgments depends on the degree of mental salience of the specified units. In particular, when the unfamiliar unit is salient, the consumer recognizes that the information is useless and disregards the absolute magnitude in her evaluation. However, when the unfamiliar unit is not salient and instead the number is salient, she proceeds as if the number per se is meaningful and tries to make sense of the absolute magnitude and incorporate it into her evaluation. Therefore, the unit salience determines consumers' magnitude sensitivity.

We tested our predictions in a series of three studies involving different contexts (judgments of length, price and monetary value), and involving both hypothetical scenarios and real bidding behavior. We manipulated the salience of unite by enlarging or shrinking the relative font size of the unit (between-subjects) and demonstrated that this subtle manipulation can reverse consumers' magnitude sensitivity. At the same time, we ruled out a list of five alternative explanations.

In the first study, participants evaluated the price of a hotel room in Rio. The room rate was displayed in an ad containing the numerical component of the price and a currency symbol, R. We manipulated both the numeric magnitude and the relative font size in a 2x2 between-subjects design. Half of the participants saw a label with an unfamiliar (fictional) currency symbol in relatively small font (unit salient), while the other participants saw a label with the currency symbol in a relatively large font (unit non-salient). Likewise, half of the participants saw a large-magnitude price (344) and half saw a small-magnitude price (138). We found that in the unit-non-salient condition, evaluations of the price were magnitude-sensitive but participants in the unit- salient condition were insensitive to price variation. This magnitude-sensitivity reversal occurs only for unfamiliar units. In a parallel study with an identical design except that a familiar currency symbol, $, was adopted, the reversal in magnitude sensitivity disappeared and, as expected, participants in both unit-salient and unite-non-salient conditions were price-sensitive.

In an incentive-compatible replication, participants were told that they would be bidding on an amount of a foreign currency, with the currency symbol denoted by X, and that they would find out the country of origin after bidding. In a 2x2 between-subjects factorial design, participants bid on either X6.83 or X0.69 (representing $1 in either Chinese Yuan or UK pounds, respectively). In the stimuli, either the currency symbol, X, was written in a relatively large font (unit salient) or in a relatively small font (unit non-salient); the remaining information was in a small (normal) font. The BDM procedure was adopted to encourage accurate judgments. We found that when the currency was salient, there was no significant difference in bids for the two amounts. However, when the currency was not salient, participants were magnitude sensitive and bid nearly $5 more for the larger-magnitude stimulus (X6.83) than for the small-magnitude stimulus (X0.69).

We replicate these findings in a third study, where participants made estimates based on unfamiliar units of length in which the font size and numeric magnitudes varied. We replicate the reversal of magnitude-sensitivity based on the font size when comparing moderately low and high numbers (3 vs. 12). Magnitude sensitivity for low unit-salience did not extend to a third pair of conditions, however, in which we used dramatically higher numbers in order to prompt an evaluation of the units.

We ruled out five alternative accounts of our findings across all studies. First, we found that the effect is not due to lack of attention. In the hotel study, for example, we asked participants to recall the information they saw. Data from the participants who failed to recall were excluded, though including their data did not qualitatively change the result. In addition, we found whether controlling response time or not, in the foreign currency study, did not moderate the effect, which rules out the explanation from system 1 intuitive thinking. Third, via the comparison between unfamiliar and familiar cur-

rency, we found that fluency does not play a role in the effect. Forth, emphasizing on either the outcome by bidding with real money or the process by reasoning aloud did not affect the effect, suggesting that lack of involvement also does not explain our finding. Lastly, we tried a third magnitude, a value out of a range that consumers could make sense of in a certain context, and found that they stopped showing magnitude-sensitivity. This indicates that the salience does not lead to an anchoring (on the salient component) and insufficient adjustment process.

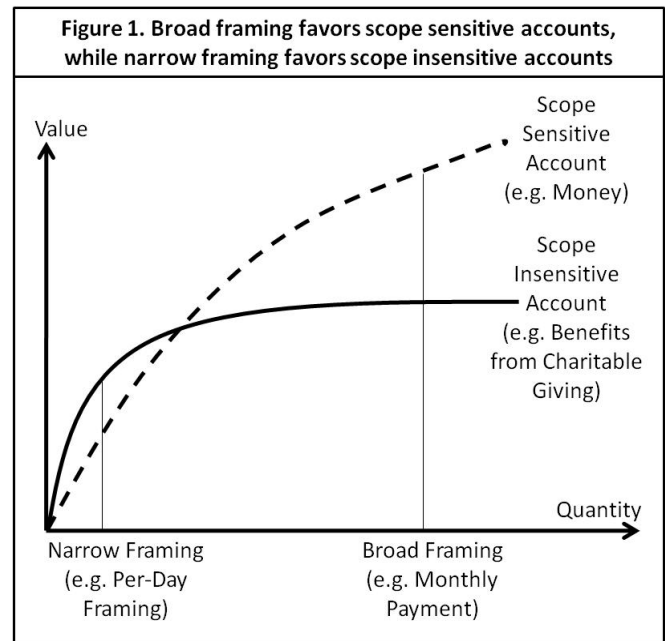
Buying Daily Pleasure with Daily Payments: Narrow Framing Favors Scope Insensitive Accounts

EXTENDED ABSTRACT

How do consumers evaluate purchases with tangible and intangible consequences distributed across time? For many decisions, consumers are faced with the difficult task of weighing a stream of intangible benefits (e.g., the increased productivity provided by a new laptop over the five years they own it) against a stream of more tangible costs (e.g., monthly installments, if the laptop is financed). Our interest in is decisions involving somewhat affectively-loaded intangible benefits, like a choice about whether leasing a flashy new car is worth hundreds of dollars each month or whether to acquiesce to an emotional plea to contribute 37 cents per day to help starving children. We propose that periodic pricing, such as per-day-framing (e.g., 37 cents a day), encourages consumers to evaluate the intangible benefits commensurate with periodic payments (e.g., the utility experienced by the thought of helping a starving child each day), while aggregate framing (e.g., $135 a year) encourages consumers to evaluate an aggregate benefit (e.g., the utility experienced by a year's worth of helping). In other words, per-day-framing encourages people to evaluate the imagined per-day benefits of purchasing.

Gourville (1998) introduced "Pennies-a-Day", which suggests that separating a cost into a series of small payments (e.g. 37 cents a day) can increase the attractiveness of a purchase opportunity because consumers assimilate the cost with the category of small, ongoing, trivial expenses retrieved from memory, such as a cup of coffee. However, we find evidence that per-day pricing can increase purchase intentions even when costs are large (i.e. outside the domain of trivial expenses), and that per-day pricing enhances consumers' perceptions of per-day benefits, which presents an alternate account of the Pennies-a-Day effect. We propose that narrowly bracketing daily prices changes consumers' representation of the transaction's intangible benefits. Consequently, the valuation of the intangible consequences influence whether narrow framing promotes purchase. Specifically, we explore the critical role of scope sensitivity over the domain of gains and losses proposed by a transaction.

Evaluations are scope insensitive when they respond to the presence of a stimulus but not changes in its magnitude (Hsee, Rottenstreich and Xiao, 2005). For example, individuals react more negatively to the news that they will lose $100 than they would if they already lost $1,900 and will now lose an additional $100. As figure 1 illustrates, narrow framing favors scope insensitive accounts, whereby the first units confer large marginal value. Importantly, McGraw, Shafir and Todorov (2010) find that monetary outcomes are often more scope sensitive than non-monetary outcomes, which may help to explain why the domain of charitable donations comprises much of the extant Pennies-a-Day literature. More generally, an effective temporal reframing strategy exists if the transaction's cost-tied-benefits are more scope insensitive than the transaction's costs. In these cases, consumers prefer more payment events to fewer payment events.

Figure 1. Broad framing favors scope sensitive accounts, while narrow framing favors scope insensitive accounts


In one study, we found that per-day pricing can increase donations outside of the 'trivial' cost domain. Consumers are more willing to pay for a luxury automobile when the price on a daily basis than on a monthly basis (6.9 vs. 5.0 on a 0-11 scale, p=0.03). This result is consistent with the "Pennies-a-Day" framework in that consumers are willing to spend more in the context of a recurring expense. However, the daily cost far exceeds $5, the previously accepted upper bound on trivial expenses (Gourville, 2003). This suggests that another process, beyond assimilation with trivial, recurring expenses, drives the Pennies-a-Day effect.

A second study explores the benefits associated with making daily payments. We find that Pennies-a-Day pricing increases a transaction's perceived benefits, and that purchase likelihood is mediated more strongly by perceived benefits than by cost triviality. In one study we asked subjects to rate their likelihood of donating a daily amount or equivalent yearly amount to a charity. In each case, the actual donation would be automatically deducted from their monthly paychecks, rendering the donation requests otherwise equivalent. We found that subjects were more willing to donate to the cause under the daily frame, and they not only expected the payment to be less costly but also expected the donation to bring them more daily pleasure. Subjects' perceptions of the daily pleasure they would obtain from the donation, as well as perceived costs, each partially mediated the effect of pricing frame on willingness to donate, and together these two factors account for 51% of the variance in willingness to donate. Additionally, we find that the projected daily pleasure accounts for willingness to purchase more strongly than evaluations of whether the cost is trivial. This result suggests that narrow, per-day framing can encourage purchase by enhancing perceived benefits tied to the purchase event.

Our framework has implications for how consumers construct value across a wide variety of situations: we propose that framing a transaction's tangible cost narrowly (e.g. per-day pricing) encourages consumers to represent intangible benefits narrowly. This can exaggerate the advantages of the transaction when its benefits are more scope-insensitive than its costs. Ongoing studies test for an expected reversal when a transaction's costs are more scope insensitive than its benefits.

The Price is Right? Effects of Internal and External Reference Prices on Consumer Judgments

Paper #3: Buying What You Can Get For Free: How Self-Presentation Motives Influence Payment Decisions in Pay-What-You-Want Contexts
  Shelle Santana, New York University, USA
  Vicki Morwitz, New York University, USA

SESSION OVERVIEW:

Product pricing is one of the most important decisions that a firm can make, yet consumers often respond to pricing information in surprising ways. For example, consumers are highly influenced by reference prices, which are sometimes provided by the firm or the context, but are often constructed by consumers as a way to help process price information. The same reference price can in some situations increase the consumer's likelihood of purchase, but in other situations may decrease it. The goal of this proposed session is to expand our current understanding of how consumers integrate and respond to internal and external reference prices. Each paper in the session investigates this research objective from a unique theoretical perspective, offering a broader view of the different ways reference prices impact consumers' consumption experiences.

The first paper by Thomas and Kyung focuses on cognitive processes that influence the recall of internal reference prices. Specifically, the authors compare the effectiveness of explicit and implicit memory-based processes consumers use when they form price magnitude judgments. Results from two experiments show that consumers' make more accurate price judgments when they use implicit memory of reference prices to form price judgments (i.e., they judge price magnitudes without trying to first recall past prices) versus when they use explicit memory (i.e., they first try to recall past prices). This research demonstrates that, ironically, in certain instances, consumers can make more accurate price judgments by *not* recalling the prices.

The second paper by Abraham, Hamilton, and Srivastava examines how partitioned pricing can form an external reference price for a product component. This external reference price in turn shapes consumers' expectations of service delivery and their subsequent attitudinal responses to service failures. The authors posit that the increased salience of a partitioned component increases consumers' performance expectations for that component. Thus, when a service failure related to that component occurs, consumers are significantly more dissatisfied when firms use partitioned pricing than when they do not. Results from four studies support their predictions and shed new light on how reference prices highlighted by partitioned pricing affect consumers' consumption experiences.

The third paper by Santana and Morwitz explores how social factors can influence how consumers form internal reference prices and how they react to external ones in pay-what-you-want (PWYW) pricing contexts. Under a PWYW pricing strategy, the seller is purely a price taker, and the consumer can pay any price they choose for a product—including zero. While the most rational response of the buyer is to pay nothing, very few consumers actually do. The authors propose and demonstrate that self presentation motives significantly influence willingness-to-pay (WTP) in PWYW contexts. Results from three studies show that individuals with high self presentation motives demonstrate a higher WTP, are more sensitive to reference prices, and express more aversion toward the PWYW experience.

Audience: The potential ACR audience for this session is quite broad. Apart from providing new theoretical insights for researchers interested in behavioral pricing, the session will attract a cross-section of ACR conference attendees who are interested in diverse areas of research such as memory and judgment, numerical cognition, customer satisfaction, and self presentation and impression management.

Level of Completeness: For all three papers, the theorizing has been completed and multiple studies have already been conducted. Since all three papers are close to completion, we expect this to be an interesting and high quality session.

Discussion Leader: The proposed session addresses important questions relating to how consumers form and use reference prices. For example, is it necessary for consumers to use explicit memory-based reference prices in determining price magnitude judgments? Does partitioned pricing pose unknown risks to the firm by inadvertently activating higher expectations for the partitioned component? Finally, what factors lead consumers to buy products that can be obtained for free? The discussion following the session is expected to focus on how these papers provide insights into answering these questions and thereby contribute to a broader and richer understanding of how consumers respond to a range of pricing scenarios they encounter in the marketplace.

Aradhna Krishna will be the discussion leader for this session. Aradhna is a recognized leader in the field of behavioral pricing research, and thus has a unique perspective for discussing these papers and leading a discussion about an appropriate research agenda for continued work in this area.

Plan for the Session: Our goal for the session is to give each presenter sufficient time to clearly present his or her findings, to encourage audience interaction with the presenters, and to facilitate a discussion about future research. We plan to allocate the session time in the following manner. Each paper will be presented for 15 minutes, followed by 5 minutes of question and answer. We will leave 15 minutes at the end of the session for a general audience discussion lead by Aradhna Krishna.

Summary: In sum, while each of the papers examines the formation and impact of reference prices, each provides different conceptual and methodological contributions. We believe that by examining a range of cognitive, attitudinal, and social factors that impact how reference prices are formed and used, we will not only appeal to a broad cross-section of ACR members, but also make an important contribution to theory. By highlighting the synergy in our research questions, we hope to provide significant insight and lay the foundation for future research on reference prices.

When Recall Disrupts Memory:
Evidence for Implicit Reference Prices

EXTENDED ABSTRACT

Consumers often evaluate offer prices by comparing them with previous prices they have encountered for the same product. Several econometric studies have shown that consumers, during their weekly trips to grocery stores, make purchase decisions by comparing the offer prices of products with prices observed on their previous trips. The memory-based comparison standard used in such price evaluations is referred to as reference price. The results from these studies suggest that consumers actually use brand- and pack-specific reference prices for such memory-based comparisons. That is, while evaluating the price of a 12 oz. pack of Starkist brand tuna, consumers use the previous week's price of the 12 oz. pack of Starkist brand tuna as the reference price. Such a conceptualization raises the inevitable question: how can consumers possibly remember the prices of hundreds of brands and products? Do they actually recall and compare the prices of so many brands and products on their weekly shopping trips? Several researchers have suggested that consumers' do not recall the prices from their memory for reference prices for such comparisons; rather, their price comparisons are based on implicit memory (Adaval and Monroe 2002; Monroe and Lee 1999; Thomas and Menon 2007; Thomas and Morwitz 2009). Implicit memory refers to the ability to use memory-based information without consciously remembering the information. Monroe and Lee (1999) characterized implicit price knowledge as the ability to "know the price without recalling it." The purpose of the present research is to study the roles of explicit and implicit memory in price comparison process.

In this research we address a hitherto unaddressed question: Does attempting to recall the reference price increase or decrease the accuracy of memory-based price comparisons? Common sense suggests that attempting to recall the reference price should not reduce the accuracy of memory-based price comparisons. That is, while judging whether an offer price is higher or lower than a reference price, consumers who try to explicitly recall the reference price should be at least as accurate as those who do not try to recall the reference price. In this paper, we suggest that this naïve view of memory may not be always correct. We posit, and empirically demonstrate, that actually trying to recall the reference price can reduce the accuracy of memory-based price comparisons.

We suggest that a reference price can be stored in memory using two distinct types of representations: 1) an analog representation on an internal number line that is not accessible to consciousness but can used in implicit memory tasks, and 2) symbolic representations that can be consciously recalled. Since a reference price can be available in implicit memory as an analog representation even when it is cannot be recalled, this literature suggests that people can make memory-based comparisons even when they are unable to explicitly recall the reference price. We posit that while comparing the prices of many products (as in a grocery store situation), recall attempts can disrupt implicit memory processes. More specifically, when people attempt to recall a reference price, they will be less accurate in judging whether the target price is lower or higher than the reference price. In contrast, when they make magnitude judgments without attempting to recall the reference price, they will be able to effectively rely on their implicit memory to judge whether the target price is lower or higher. We will refer to this effect as the Recall Induced Disruption of Implicit Memory, or simply the *memory disruption effect*.

Two experiments offer evidence for the memory disruption effect. In Experiment 1, participants were asked to respond to a simulated shopping task wherein they had to consider whether or not to include 20 different everyday grocery items in their shopping carts. After the shopping task, they were presented with a surprise memory test. They saw the 20 items again; but this time the products had new prices that could have been higher, lower, or the same as before. Their task was to identify whether the new prices are lower, higher, or the same as before. They also had the option of submitting a "don't know" response indicating that they did not know whether the magnitude of the new price is lower or higher. Half the participants (assigned to the explicit memory condition) were told that they have to try and recall the previous price before judging the magnitude of the new prices. The other half did not have to explicitly recall the previous prices before making the magnitude judgments. We examined the effect of explicit recall on judgment accuracy. As predicted, explicit recall reduced the accuracy of relative magnitude judgments. Participants in the implicit memory condition were more accurate than those in implicit memory condition, 46% vs. 38%, p < .05. Further, explicit recall did not increase incorrect judgments (p > .60), but it increased the proportion of "don't know" responses, 28% vs. 20% p < .05.

Experiment 2 replicated and extended these results in two ways. First, instead of presenting participants with a surprise recall task (incidental encoding condition), they were warned that there would be a memory test after the shopping task (intentional encoding condition). Second, we did not randomize the order of presentation to test whether the effect is caused by recall-induced interference. The effects reported previously were replicated in the intentional encoding condition as well. Additionally, although we observed the standard primacy and recency effects of order on accuracy, explicit (vs. implicit) recall did not interact with these effects. These results suggest that the memory disruption effect is not caused by recall-induced interference.

The memory disruption effect offers a more nuanced conceptualization of memory-based reference prices. Although several studies on memory have demonstrated that remembering can cause forgetting, to our knowledge none of the extant research has examined whether remembering can affect performance in a subsequent numerical judgment task. This is the first paper to demonstrate that in a numerical comparison task, trying to recall a number from memory can disrupt subsequent numerical judgments.

When Partitioning Prices, Firms Better Deliver!

EXTENDED ABSTRACT

Firms using a partitioned pricing strategy divide the price of a product or service into two or more mandatory components (Morwitz, Greenleaf and Johnson 1998). For example, an online book seller may list separate prices for a book and for shipping the book, even though the buyer must purchase both components together. Research has shown that price partitioning increases the salience of partitioned components (Bertini and Wathieu 2008; Chakravarti et al 2002) and that the nature of the components partitioned from the base price can significantly influence consumers' reactions to a firm's offers even when consumers know that the total price is the same (Hamilton and Srivastava 2008).

Because prices play a role in forming consumers' expectations about goods and services (Mitra and Fay 2010), we propose that the greater salience of the prices of partitioned components may increase consumers' expectations about the performance of these components. Expectations are consumers' pre-purchase beliefs about the performance of the product or service (Oliver and Winer 1987). If expectations serve as a referent for comparison, higher expectations may decrease satisfaction because performance less favorable than consumers' high expectations can create expectancy disconfirmation (Oliver 1980; Yi 1990).

Thus, partitioning prices may have negative consequences for firms, such as lower satisfaction with the partitioned component and even the overall transaction, when partitioned components fail to meet consumers' performance expectations. We propose that expectancy disconfirmation will mediate this effect. To test our predictions, we ran a series of four studies.

Our first two studies show that when a specific component is partitioned out of the base price, customers' expectations for that component significantly increase. In study 1, participants evaluated airline tickets for which the price of in-flight entertainment was either partitioned or included in the total price. Expectations for in-flight entertainment increased when this component was partitioned even though expectations for other components such as baggage service did not differ across conditions. We replicated this effect in study 2 for a hotel stay in which parking was either partitioned or included in the total price.

In study 3, we extended our examination to the potential downstream effects of partitioned pricing by manipulating the service experience of the customer. Participants were given price information about an airline flight in which in-flight entertainment was either partitioned or included in the total price. After responding to items measuring their expectations for the flight and their expectations for the in-flight entertainment, participants were exposed to the service delivery manipulation. In the control condition, participants read that the in-flight entertainment system worked as expected. In the mild failure condition, they read that the in-flight entertainment service shut down for about 10 minutes during the flight.

Although satisfaction with the in-flight entertainment service did not differ across the partitioned and non-partitioned conditions when there was no failure, satisfaction was significantly lower in the partitioned versus the non-partitioned conditions when there was a mild failure. We observed the same pattern of results for satisfaction with the flight, suggesting that dissatisfaction with the partitioned component bleeds over to the overall service experience. To examine the underlying process in more detail, we tested whether the difference between the expected quality of the in-flight entertainment service and its experienced quality mediated the effect. Indeed, this difference, which we label expectancy disconfirmation, mediated the effect of the interaction between service failure and partitioning on satisfaction.

In study 4, we replicated the results of study 3 in the context of attending a sports event. Participants imagined that they purchased a ticket for a football game that came with parking at the stadium on the day of the game. The price of parking was either partitioned or included in the total price. In addition to the control condition and a mild service failure condition, we included a delight condition, in which the service experience was better than expected, and a non-use condition, in which the participants imagined that they did not use the partitioned component. Overall satisfaction and satisfaction with parking did not differ significantly across the partitioned versus non-partitioned conditions in the no failure condition or in the delight condition. However, when the price was partitioned, satisfaction was significantly lower in the mild failure condition and marginally lower in the non-use condition than when the price was not partitioned. Again, expectancy disconfirmation mediated the effects.

In summary, price partitioning seems to increase consumers' expectations for partitioned components. Although there are no differences in satisfaction when firms meet or exceed expectations, we see that when partitioned components fail to meet consumers' expectations, consumers are significantly more dissatisfied when firms use partitioned pricing than when they do not. Notably, even when consumers do not encounter a service failure, they may be more dissatisfied under partitioned pricing when they do not consume the partitioned component. Given these potential negative consequences, we advocate caution in the use of price partitioning. When firms partition prices, they seem to be held more accountable for a positive service experience.

Buying What You Can Get For Free: How Self Presentation Motives Influence Payment Decisions in Pay-What-You-Want Contexts

EXTENDED ABSTRACT

When setting a price, firms can choose from a number of different strategies ranging from maximum seller control to maximum buyer control. Most firms choose the former, where the seller has maximum control and the buyer is purely a price taker—they must pay the seller's posted price to secure their desired good. However, some firms employ a Pay-What-You-Want (PWYW) pricing strategy where the buyer has maximum control and the seller is purely a price taker. In these instances, the seller must provide the good to the buyer at any price the buyer sets—including zero.

Standard economic theory holds that the most rational response by the buyer in a PWYW scenario is to pay nothing; yet, research shows that consumers rarely do (Gneezy, Gneezy, Nelson, and Brown 2010; Kim, Natter, and Spann 2009). Researchers offer a number of different explanations for this seemingly irrational behavior, including social exchange norms (Elster 1989), fairness and reciprocity (Bolton and Ockenfels 2000), and altruism (Maner and Gailliot 2007), to name a few. We add to this stream by proposing and demonstrating that consumers' self presentation motives significantly influence willingness-to-pay (WTP) in PWYW contexts.

Self presentation has been defined as the use of behavior to communicate information about oneself to others (Baumeister 1982). In a PWYW context, we posit that consumers pay more than zero because their payment acts as a means to project a favorable image of themselves to others. Therefore, we predict that the percentage of participants who pay for their product will be significantly greater than zero, and that relative to individuals with low self presentation concerns, those with high self presentation concerns will: 1) have higher WTP, 2) be more sensitive to reference prices in the environment, and 3) have a more aversive experience. The two studies we have conducted to date support these predictions.

In Study 1, participants were offered the opportunity to PWYW for a breakfast combo consisting of coffee or tea and their choice of a bagel, danish, or donut. Self presentation was manipulated by whether payment was made publicly or privately (Baumester 1982). A suggested retail price for the combo was either provided or not. We measured participants' willingness to pay, how motivated they were to impress others when they generated their payment price, and how motivated they were to spend an appropriate amount. Participants also evaluated how much they enjoyed the PWYW process, what emotions they felt, and whether they would prefer to PWYW or pay a regular posted price in the future.

As predicted, the number of subjects who paid more than zero was significantly greater than zero—in fact all subjects submitted a non-zero payment amount. Participants in the public condition had a significantly higher WTP and a motivation to impress others than their private payment counterparts. Furthermore, the motivation to impress others mediated the effect of visibility on WTP, whereas the effect of a spend accuracy motive did not. Relative to participants in the private condition, those in the public condition enjoyed PWYW less, had lower positive emotions, and had a greater preference to pay a regular posted price vs. PWYW in the future.

Study 2 tests whether our predictions hold for individuals with chronic self presentation concerns, and further examines how reference price magnitude moderates WTP and consumers' emotional reaction to PWYW. Since individuals with high self presentation concerns tend to be more attuned to social norms and cues in their environment and actively manage their behavior to please others,

we expected high self monitoring individuals to be more sensitive to reference price information. In this study, self presentation was a measured individual difference variable based on Snyder's (1974) 25-item Self Monitoring Scale. Reference price magnitude was manipulated by having the retailer provide a very low or a very high suggested price for the breakfast combo. No reference price information was provided in the control condition. We expected high self monitors to pay significantly less (more) than low self monitors when provided with a very low (high) reference price. Furthermore, we expected a more aversive subjective experience of PWYW for high self monitors.

The results supported our predictions. First, when a very low (high) reference price was provided, high self monitors paid significantly less (more) than low self monitors. In deciding on what to pay, high self monitors were more motivated by impressing others, and low self monitors were more motivated by spending the right amount of money. High self monitors reported a more aversive subjective experience, as well as higher levels of negative emotions such as anger, guilt, sadness, shame, frustration, and worry. Interestingly, the interplay between external references and self monitoring appears to influence post-purchase behavior as well. When no or low reference prices are provided, high self monitors reported being more likely to avoid the vendor in the future, but when a high reference price is provided, they are less likely to avoid the vendor in the future.

We are currently running a third study to test overt pressure as a boundary condition of self presentation motives in PWYW. Baumeister (1982) argues that if one is primarily concerned with one's public image, then conformity should decrease as overt pressure increases, since in these conditions yielding and conforming is bad for one's public image. In study 3 we manipulate overt pressure based on learning what close others pay in these settings (paying zero or very low prices). So far, preliminary results support our predictions. This study and an extension will be completed in the next few months.

In sum we show that self presentation concerns explain why consumers pay more than zero in PWYW pricing, how they react to firm provided reference prices, and how they react to social pressure. This research demonstrates the powerful effects of social forces in economic transactions, and why a buyer might prefer the economic disadvantage of traditional pricing structures over the economic advantages of PWYW.

Paper #3: Looking Ahead: Duration Markers and Their Effects on Choice

Dilip Soman, University of Toronto, Canada
Yanping Tu, University of Chicago, USA

SESSION OVERVIEW

Recently there has been growing interest in individuals' subjective sense of future time such as time perspective, time perception, or perceived temporal distance in the areas of consumer research and psychology. But still, not much is known about what influences subjective sense of time has on consumers' judgment and decision making. The proposed symposium touches on three aspects of future time judgment–time horizon perspective, perceived temporal scarcity of life, and time compartmentalization– and discusses whether and how it impacts consumer preference in various domains including preference for private vs. public consumption and intertemporal preference.

The first presentation (Sellier and Morwitz) focuses on consumers' perception of the amount of time ahead of them as being limited versus expansive, and demonstrates that such time horizon perspective influences their preference to consume alone or together. The second presentation (Kim, Zauberman, and Bettman) addresses the relationship between perceived temporal scarcity of life and subjective prospective temporal judgment, and demonstrates that consumers whose temporal scarcity of life were heightened became more impatient for delayed monetary outcomes because waiting time until the receipt of delayed rewards is subjectively expanded. The third presentation (Soman and Tu) shows that consumers compartmentalize future time using ongoing duration markers–events that occur in the same period as the present are perceived to be closer and viewed with more of an implemental mindset– and that the time compartmentalization influences preference and choices in various consumer settings.

All of these presentations demonstrate that subjective sense of future time plays a key role in driving consumers' judgment and decision making in various domains. Considering the growing interest in subjective time perception and in time-related decisions in consumer research, we expect that this symposium will attract a broad audience who are interested in time perception research or those who are interested in consumers' judgment and decision making in various domains in general.

We believe that this session will stimulate an interesting and in-depth discussion between presenters and audience, and among presenters about different aspects of subjective sense of time and their relationship to consumer decision making. To ensure enough interaction between presenters and audience, we limited the number of presentations to three but invited a discussant, Kristin Diehl, who will lead a quality discussion during the session. We believe this session will be more interactive than any other sessions at ACR.

These presentations are in a completed stage or close to completion, and are not presented in ACR conferences previously.

I Want to be Alone: The Role of Time Horizon Perspective on the Valuation of Social Presence

EXTENDED ABSTRACT

Consumers generally seek the presence of others they like when engaging in consumption activities, except in certain socially undesirable or embarrassing situations (e.g., Dahl, Manchanda and Argo 2001; Loveland, Smeesters and Mandel 2008). We ask: Do consumers ever seek to be alone, outside of socially undesirable contexts? Using Socioemotional Selectivity Theory (SST, Carstensen 1992), we develop hypotheses about the moderating impact of one factor, namely time horizon perspective (i.e., consumers' perception of the amount of time ahead of them as being limited versus expansive) on the extent to which social presence is valued. We find that consumers have a relative preference to be alone versus with someone they like when they perceive the time ahead of them as expansive rather than limited. We further show that this effect depends on whether the person or the nature of the activity, are more associated with love/caring or with knowledge/achievement.

While research has shown that time perspective influences consumers' evaluation of ads (e.g., Williams and Drolet 2005), SST and consumer research have not yet addressed the question of whether consumers' time perspective can affect overall how they value social presence. We propose that a limited time horizon should enhance the value of social presence, because consumers primarily focus on interacting with others for emotional support. In contrast, an expansive time horizon involves banking information that does not directly require the presence of others to pursue achievement-related goals. We therefore predict that consumers perceiving time as expansive versus limited should value social presence less when engaging in consumption activities.

A first pilot study tests this general hypothesis: on the street, 52 people were asked to respond to two ostensibly unrelated surveys. The first survey manipulated participants' time horizon perspective. Participants either wrote about five life projects for which they perceived they had either "limited time" or "all the time in the world" to achieve. Participants in a third - control - condition wrote about activities they liked to engage in. Next, all participants filled out an "enjoyment survey," which asked them to rate, for each of 23 activities, whether they would prefer to engage in them alone or with someone they like. The list included a broad range of activities, selected from research on well-being (Kahneman, Krueger, Schkade, Schwartz, and Stone 2004). On average across activities, participants with a limited time perception preferred to be with someone they like more than did those with an expansive time perspective. Participants in the control condition fell in-between. A cluster analysis of the activities revealed similar results for each cluster.

SST predicts that emotion-related goals or achievement-related goals receive priority depending on whether time is perceived as limited or expansive respectively. One question, then, is whether the type of person consumers envision engaging in consumption activities with moderates the main effect of time horizon we found. To examine this possibility, we ran a 2 (Time horizon: limited vs.

expansive) x 2 (Presence: congruent with emotion- vs. achievement-related goals) full-factorial design. 75 students filled out either the same Limited or Expansive time survey as before. They then were asked to read the description of either the classmate who was consistent with a love/caring or an achievement goal (consistent with a limited time or an expansive time perspective) and to picture that person in their mind, and reported the extent they would prefer to engage in the same 23 activities as before, alone versus with the person they had in mind. A 2x2 ANOVA revealed a significant two-way interaction. Participants who had thought of a love/caring related classmate wanted to be alone significantly more when time was expansive rather than limited. In contrast, participants who had thought of an achievement-related classmate equally valued social presence regardless of whether time was expansive or limited. Again, the pattern of results was the same for each cluster in a cluster analysis.

A final study examined whether the impact of time perspective on valuation of being with others changes when the consumption activity itself varies in how it relates to love and caring rather than achievement. This study was a 2 (Time horizon: limited vs. expansive) x 2 (Movie: about-love vs. about-achievement) between-subjects design. We manipulated participants' time horizon as before, before participants read one of four synopses of a soon to be released movie. Based on a pretest, two of the movies were primarily about love, while the other two were primarily about achievement. After reading these synopses, 105 participants indicated the extent to which they would prefer seeing the movie alone versus with someone they like. Because our results were identical for the two pairs of movies, we report the combined results. A 2x2 ANOVA only revealed a significant two-way interaction. Participants who had read the description of the movies about-love/caring reported wanting to be alone significantly more when time was perceived as expansive versus limited. In contrast, participants who had read the description of the movies about-achievement equally valued social presence regardless of time horizon.

While social interaction is core to our survival, we find that when consumers sense that they have a large amount of time ahead of them, they become relative loners. Our findings also suggest that additional insights may be gained from manipulating the type of other consumer presence in mere presence research.

The Impact of Perceived Temporal Scarcity of Life on Temporal Distance Judgments

EXTENDED ABSTRACT

Although theoretically future time might be infinite, the individual's own lifespan is often the most salient and natural context within which temporal duration is judged. We argue that the individual's perceived lifespan is in turn influenced by reminders of mortality (and hence scarcity of life). Thus, the extent of an individual's own perceived temporal space (i.e., the scarcity of that individual's perceived lifespan) provides the context that influences judgments of perceived temporal distance to specific future events.

When individuals are reminded of their death, it heightens their perceived temporal scarcity of life (e.g., how much time is perceived to be left in life). Their perceptions of remaining lifetime are a highly salient context for other temporal judgments for them. As a result, perceived distance to a future point in time will be inversely influenced by how much time is perceived to be left in life, just as magnitude judgment of a target stimulus is inversely related to the perceived magnitude of a context stimulus in human perception and judgment (Sherman, Ahlm, & Berman, 1978).

In study 1 we manipulated temporal scarcity of life by reminding participants of their death. To manipulate temporal scarcity of life, participants in the death condition were presented with a word-search puzzle on a computer screen, in which death-related words were embedded among other letters (King et al., 2009). For those in the control condition, a similar word-search puzzle but with neutral words was presented. Once participants found the target words, they were directed to the next screen, where their perceived temporal distance was measured. Specifically, participants were asked to think about a day in one month and then to indicate how long or short they considered the duration to be from today to a day in one month by moving a slide bar on a 150 mm continuous line scale with endpoints labeled as very short and very long. Confirming our prediction, participants who were reminded of their death perceived the same 1-month duration to be subjectively longer than those in the control condition. This effect was not driven by changes in construal level, anxiety, or emotional reactions.

In study 2 we manipulated temporal scarcity of life not by reminders of death but by simply manipulating how much time is perceived to be left in life. For this purpose, we utilized the findings of a recent neurobiological study reporting that basic human cognitive functions peak at age 39 and sharply decline thereafter (Bartzokis et al., 2009). This information should heighten the perceived temporal scarcity of life among young individuals ('There is only about 20 years before my brain breaks down!') compared to a condition providing information about one's total life expectancy, which is longer. One noteworthy feature of this manipulation is that mortality is more likely to be associated with the life expectancy condition, which is predicted to trigger less temporal scarcity in this case. Results indicated that participants in the high-scarcity condition perceived the same temporal distance on an objective scale (e.g., 3 months) to be subjectively longer than those in the low-scarcity condition.

In study 3 we manipulated temporal scarcity of life by manipulating how much time is perceived to be left in life but further tested the behavioral implications of this finding we examine the effects of perceived temporal scarcity of life for intertemporal decisions, namely the degree of impatience for delayed monetary rewards. While college students generally reveal a greater degree of impatience in intertemporal decisions than older adults (Green, Fry, & Myerson, 1994; Read & Read, 2004), we predict that impatience among college students may be further elevated by heightening their perceived temporal scarcity of life. Results in time perception replicated study 1 and 2–participants in the high-scarcity condition perceived the same temporal distance to be subjectively longer than those in the low-scarcity condition. Importantly, for impatience, as revealed in a delay-discounting task, we found that participants in the high-scarcity condition requested more money if they had to wait for three months to receive rewards than those who in the low-scarcity condition. Such changes in perceived temporal distance or impatience level were not driven by affective responses to our manipulations.

Taken together, the present research demonstrates a novel aspect of the relationship between perceived psychological space and perceived temporal distance: when psychological space associated with perceived lifespan is subjectively contracted, temporal distance judged within this space is perceived to be relatively expanded.

Looking Ahead: Duration Markers and
Their Effects on Choice

EXTENDED ABSTRACT

Consumers often need to make decisions involving outcomes that are to happen in the future. In the intertemporal choice literature, one decision that has been studied extensively is the choice between a smaller and sooner (SS), and a later and larger (LL) reward (Soman et al. 2005). A second type of decision has to do with commencing effort towards a task that is due sometime in the future (O'Donoghue and Rabin 1999). Most of the literature in this area has treated future time as a continuous variable, and very little research has attempted to study how consumers encode future time (but, see Bettman et al. 2009). The standard view of intertemporal decisions is that the key driver driving the decision should be the duration between the present and the future outcome (e.g., Ainslie and Haslam 1992).

In this research, we propose that consumers do not always encode future time as linear, but rather as categories. People routinely compartmentalize time periods into pre-determined units like days, months and years. In addition, there are many other "markers" of time that people often use in an ongoing manner - students tend to compartmentalize their time by terms, farmers by harvesting seasons, etc. (Ahn, Liu and Soman 2009; Zauberman et al. 2010). We propose that these "markers" result in a categorization process (Tversky 1985), whereby events that are to happen before the next marker loom larger than events that are to happen right after the marker. As Harry Potter noted when thinking about his Triwizard task; "February twenty fourth looked a lot closer from this side of Christmas." [from Rowling, J.K, *The Goblet of Fire*]

Consumers are consequently more likely to start expending efforts on a task that (holding actual duration constant) will occur before the marker, than for one that will happen after a marker. Likewise, the choice for an SS option decreases when the LL option is before a marker – when the LL option is beyond a marker, it seems all the more distant and not as likely to be chosen.

We conducted a series of seven field and laboratory studies to demonstrate this basic effect. In a field study, for example, farmers in India were presented with a savings plan that would earn a 20% match from the government if they deposited Rs. 5000 within six months and asked if they would open an account. Those for whom the deadline occurred in December of the same year (offer made in June) were 30% likely to open an account then, whereas those for whom the deadline was in January (offer made in July) the following year were only 8% likely. Similarly, MBA students who had consulting work due in 10 days were more likely to start working on it now if they were recruited 25 days (vs. 5 days) before a relevant marker - the formal dinner.

We propose two explanations that might underlie the effects of categorization on decision-making. First, building on the well-established notion that perceived duration drives decision making (e.g. Bettman et al. 2009), we suggest that events that occur in the same category as the present are perceived to be closer in time than those that are beyond the marker. Second, it is likely that events in the present category are viewed with more of an implemental mindset (Gollwitzer 1999) as compared to events that are to happen after the marker. We tested these two competing explanations in a further series of five studies. In one study, we manipulated markers semantically by asking participants to imagine that they would go on a weekend trip after (vs. before) a certain date. We found support for both explanations; participants in the "before" condition were more willing to start packing immediately, chose a bottle of insect repellent (rather than deferring choice) and perceived the departure date as closer. In the next study, we asked participants to think about a forthcoming event for themselves, or for someone else. Since people can only experience the implementation tendency for self, we reasoned that duration perception may vary with marker only in the "self" condition, and found supporting evidence. In a third study, we examined the effects of markers on task commitment. Participants were told that they had promised a friend to help move, but now faced a conflict. We showed participants a calendar in which the present and the move date were either in the same color-coded zone, or in different zones, and found that participants were more committed to help when the event was in the same zone. In other studies, we also found a) greater impatience for consumption that was to occur before the marker and b) a discontinuity in behavior around the marker.

Our findings suggest that consumers tend to categorize future time and use category membership to determine temporal proximity. As a result, duration markers have a surprisingly large effect on decision making. We also suggest that duration markers can be used as a self-regulation device in a "choice architecture" sense to spur individuals to action by suitably presenting duration markers that suggest that the target event will occur in this period. Our findings contribute to the literature on intertemporal choice by showing that duration markers serve as categorization criteria of "now" and "later", and thus shed light on the most fundamental process in intertemporal choice.

Paper #4: Don't Get Framed Again: How a Divergent Thought Mindset Mitigates Framing Effects

Robin Tanner, University of Wisconsin-Madison, USA
Kate E. Min, Duke University, USA
Tanya Chartrand, Duke University, USA

SESSION OVERVIEW

It is now well-established in the literature that many decisions are strongly influenced by non-conscious processing (Chartrand et al. 2008; Dijksterhuis et al. 2005). Subtle situational cues or primes can put decision makers into various mindsets and have carryover effects on subsequent decisions and judgments. What is relatively less understood is how these primes can activate not only certain goals and associations, but also different processing styles and different levels of certainty about preferences. The current set of papers, although from diverse domains, all look at the effect of priming different mindsets and processing styles on decisions, and also explore the effect of varying levels of certainty on one's choices and judgment.

Tanner, Min, and Chartrand demonstrate that inducing a divergent mindset can debias problem framing effects. People primed with a divergent mindset become more creative, and as a result, process the problem differently and become less susceptible to framing effects. Monga and Zeynep Gürhan-Canli also investigate how creativity changes one's processing style, but they apply it to a different domain: brand extensions. They show that male participants primed with a "mating," or relationship, mindset experience higher levels of creativity and evaluate more extreme brand extensions more positively. The other two projects in this session show that inducing a certain mindset can impact not only one's processing style, but also confidence in one's decisions. Jiang, Gorlin, Xu, and Dhar explore the influence of a physical attractiveness mindset on choice and find that people made of feel more attractive become more certain about their preferences, leading them to make bolder choices. Finally, Vohs and Akpinar demonstrate that religious primes increases tolerance for uncertainty and reduce desire for money, whereas money primes reduce the need to rely on religious coping.

All of the projects in this session focus on new dependent variables that have not been investigated through mindset priming: from perceptions of brand extensions to susceptibility to framing effects to bold versus timid choices. In line with this year's theme of "Building Connections," we would like to urge session participants to think about way to combine these non-conscious mindsets with different dependent variables, through the confidence and creativity mechanisms, in order to generate novel predictions.

Audience and Level of Completeness

We expect this symposium to attract a wide ACR audience including researchers interested in priming mindsets, decision automaticity and non-conscious effects, decision making, and practical implications of these effects for marketing. These four papers all feature novel connections between mindset primes and decisions, which both make a theoretical contribution and have appeal to marketing practitioners. All of the projects are completed (all of the data has been collected) or close to completion and several are available as working papers upon request.

Session Plan

Our goal for the session is to build connections among the presented mindset primes and the effects that they can have on decision-making. We plan to do this by (1) giving all presenters sufficient time to clearly present their findings, (2) encouraging audience interaction with the presenters, and (3) facilitating an interactive discussion about future research directions and marketing implications. We plan to allocate the session time in the following manner: each presenter will be allotted 15 minutes for their presentation, including a few minutes for questions and answers at the end of each presentation. We will also reserve some time for a general audience discussion lead by the session chairs. In the general discussion, we will encourage the session participants to think about the confidence and creativity mechanisms, and in light of this, to consider novel ways to combine the mindsets presented in these projects with choice and judgment dependent variables to generate new research ideas.

Of the Bold and the Beautiful: Feeling Beautiful Leads to Bolder Choices

EXTENDED ABSTRACT

Beauty has been universally prized throughout history. It has been associated with a host of positive attributes: for example, beautiful people are perceived to have more favorable personality traits, to be more socially competent, more intelligent, and are believed to have more successful life outcomes (Dion et al. 1972; Eagly et al. 1991). Despite this ingrained unconscious belief in society that "beautiful is good," the question of whether people's perceptions of their own physical attractiveness impact their decision making has been relatively unexplored. We propose that through activating the non-conscious belief that beauty is related to positive qualities, inducing a feeling of greater physical attractiveness can make people more confident, and this confidence will change their processing style, leading to different decisions. We sought to investigate the effects of beauty in the domain of choice. Previous literature in choice theory suggests that people tend to gravitate to compromise options and options that are average on all dimensions when they are experiencing choice difficulty and cannot effectively resolve tradeoffs (Dhar and Simonson 2003; Simonson and Tversky 1992). Thus, choosing compromise and all-average options represents the decision-makers inability to express a firm preference and take a stand.

Combining the literature on choice with our prediction that priming people with a beauty mindset will boost their confidence, we propose that physical beauty can alter the choices that people

make. Making people feel more physically attractive can provide them with the confidence to resolve tradeoffs and thus lead them to make bolder, more self-expressive choices. Drawing on Maimaran and Simonson (in press), who propose that choosing an extreme over a compromise option or an enriched over an impoverished option are both instances of "bold" or self-assertive choice, we argue that people who feel more beautiful will be more likely to choose enriched over impoverished options and extreme over compromise options than control participants.

Our predictions were tested in a series of three studies. In study 1 we investigated the effect of one's own perceived physical attractiveness on choice of an impoverished versus an enriched option. First, we induced a feeling of physical beauty through a mindset prime. Participants in the beauty condition listed three objects or situations that make them feel physically attractive and then wrote a short paragraph about two of those items. Control participants listed three things they did in the past week and similarly elaborated on two. Participants primed with beauty perceived themselves as more physically attractive (on a 1-9 scale) than control participants, M = 6.36 vs. 5.03, p < 0.01, indicating that the manipulation was successful. . Participants then chose between two impoverished/enriched scenarios, a vacation and a roommate scenario (adapted with changes from Shafir, 1993). Participants in the beauty condition were more likely than control participants to choose the enriched over the impoverished option both in the vacation scenario (69.7% vs. 40.6%, p < .05) and in the roommate scenario (51.5% vs. 25.0%, p < .05), supporting our prediction that those primed with beauty would make bolder choices.

In study 2 we sought to replicate our findings using another method of priming and to extend them to the compromise effect. Female participants were assigned to either the beauty or control condition. In the beauty condition, women were made to feel more attractive by looking at unattractive faces, under the cover story of judging familiarity, whereas those in the control condition evaluated city scenes. Previous research has found that women perceive themselves as more attractive after looking at people who are less attractive than they are (Cash et al. 1983). Following the prime, participants chose among three options in two scenarios: a class and a roommate scenario. Participants exposed to unattractive faces both rated themselves as more attractive on a 1 to 9 scale than control participants (M = 6.44 vs. M = 5.39 p < .01; and, as predicted, were less likely to choose the compromise option both in the class (13.9% vs. 43.8%, p < .01) and in the roommate (27.8% vs. 65.6%, p < .01) scenarios.

In study 3, we replicated the results of Study 2 and tested the mechanism behind the effect. Students, assigned to either the beauty or control condition, completed the same priming manipulation as in Study 1 and then made choices in the same compromise scenarios used in Study 2. Participants rated their self-efficacy on an 8-item generalized self-efficacy scale (Bandura, 1982). Participants primed with beauty reported higher self-efficacy on a 1 to 7 scale than control participants (M = 5.99 vs. M = 4.84, p < .01), indicating greater confidence in the ability to achieve their goals, and were less likely to choose the compromise option in both the class (19.4% vs. 41.7%, p < .05) and roommate (44.8% vs. 63.3%, p < .05) scenarios. Perceived self-efficacy mediated the effect of beauty prime on choice. When class choice was regressed on both beauty prime and self-efficacy, the effect of beauty became insignificant (Wald = 1.45, β = -.56, SE = .47, p > .1), while the effect of self-efficacy remained significant (Wald = 5.72, β = -.46, SE = .19, p < .05). The mean indirect effect from the bootstrap analysis was negative and significant (a* b = -.53), with a 95% confidence interval excluding zero (-1.08 to

-.07), indicating that participants who felt more physically attractive made more extreme choices because of their increased confidence in their abilities.

In conclusion, we demonstrate that making people feel more beautiful increases their confidence and consequently increases their ability to resolve tradeoff difficulties and leads to greater choice of self-assertive options.

Can Religion and Money Substitute for Each Other?

EXTENDED ABSTRACT

What avenues do consumers have to establish and maintain a sense of control over life's ups and downs? We proffer that religion and money are two psychological resources that people might call upon to offset feelings of uncertainty. The present research tested whether mentally activating religion or money concepts can substitute for each other when people consider coping with negative events.

Consumers sometimes try to cope with negative events through religious coping, which can emotionally offset some of the negative consequences of such events. Research has suggested that there is a psychological mechanism translating uncertainty into religious extremism (Hogg, Adelman and Blagg 2009). We tested the notion that even just activating the idea of religious concepts would give people the feeling that they can cope with uncertain events.

There is also evidence to suggest that money can aid coping with uncertain situations in life. The most basic functions of money - saving and borrowing - allow people to prepare for an uncertain future (Lonergan 2010). Having money appears to protect people from unfortunate and uncertain situations in life, mainly through providing control over outcomes (Johnson and Krueger 2006). The psychological effects of money include enhancing the belief that one can achieve his or her own goals (Zhou, Vohs and Baumeister 2009). These findings suggest that mere reminders of money could elicit the sense that one can cope with uncertain and negative situations.

The commonality between the psychological effects of money and religion suggests that money and religion might be interchangeable, in their ability to help people cope with negative and uncertain life events. When facing uncertain negative events, religious primes should increase consumers' tolerance for uncertainty, which would in turn reduce their desire for money. Money primes should reduce consumers' need to rely on religious coping. We present four studies in which we provide novel evidence for the substitution effect of religion and money.

In Study 1, we demonstrated that religious priming (versus neutral priming) led to less desire for money. Half of the participants were primed with religious concepts using the scrambled-sentence paradigm, while the others completed a neutral version. Next, participants read a list of eleven pleasant things (e.g., TV, sunshine, spring, chocolate, beach) and asked if they were willing to permanently forgo those items in exchange for 1 million Euros. As predicted, participants primed with religious concepts were less willing to exchange pleasant things for money as compared to participants primed with neutral concepts.

Study 2 tested the mediating role of tolerance for uncertainty between religious priming and desire for money. First, all participants were asked to imagine a negative event that had occurred in their life and write down their reactions towards it. Next, participants completed a word-search puzzle task, which was used to prime religious or neutral concepts. After the priming task, participants thought back to the negative life event, and rated their tolerance for

uncertainty. Participants completed a scale that assessed the degree to which participants could put up with the uncertainty due to the negative life event. Finally, participants listed 10 things that they valued in life (besides money) and then indicated whether they would agree permanently giving up each item in exchange for 1 million Euros. The results confirmed our predictions showing that mentally activating religious concepts, as opposed to neutral concepts, led to more tolerance for uncertainty regarding negative events, and which in turn weakened the desire for money. The meditational analyses were significant.

In Study 3, we manipulated the salience of money by having half of the participants count coins and Euro bills and the other half count glass beads. Then, all participants remembered a negative event that had occurred in their life and wrote down their reactions towards it. Thinking on the negative event they had described, participants completed a scale that assesses the degree to which various types of religious coping are involved in dealing with negative events. In line with the substitution hypothesis, participants who were reminded of money were less likely to rely on religious coping compared to participants under neutral conditions.

In Study 4, participants first recalled a negative event over which they did or did not have control. Next, they were randomly assigned either to money primed condition or neutral condition, which was activated by showing images of money versus seashells on the screen background used. Thinking on the negative event they had described, participants completed religious coping scale. Our results showed us money priming decreased the likelihood of relying on religious coping in the face of negative events when participants perceived that they had control over the situation, while this effect was not observed the event was perceived as uncontrollable. Individuals were more likely to rely on religious coping when they perceived not having control (compared to when they had control).

Our results imply exercising caution for religious or marketing organizations whose efforts are affected by the relationship between religion and consumption. Indeed, one of the most powerful anti-consumer movements is rooted in religious ideologies — namely, fundamental Islam's tenets encouraging modesty and protecting oneself from materialism (Kozinets and Handelman 2004). This research at the intersection of religion and money is a step in further understanding the role of religion on consumers and their consumption.

The Influence of Mating Mindsets on Brand Extension Evaluation

EXTENDED ABSTRACT

Prior research on brand extensions has focused on identifying a variety of factors that influence brand extension evaluations among consumers (Aaker and Keller 1990). One key factor is the degree to which consumers are able to see a connection between the parent brand and the extension. When consumers perceive some kind of fit between the parent brand and the extension (e.g., Gillette shampoo), the brand extension is evaluated favorably. However, when consumers perceive less fit (e.g., Gillette floor cleaner), the brand extension is evaluated negatively (Aaker and Keller 1990). Missing, however, from this research is a consideration of how transient mindsets might influence brand extension evaluations. In our research, we focus on a specific type of mindset—the mating mindset, which has generated some attention recently (Griskevicius et al. 2006).

Emerging research demonstrates that individuals in a mating mindset show boosts in creativity (Griskevicius et al. 2006). For instance, male participants, when primed with thoughts about short-term mating relationships (that is, a mating mindset), generated stories that were more creative, imaginative and original. In contrast, female participants did not show this effect. We draw upon this research to propose that male consumers in a mating mindset would be able to find novel ways to connect the brand to the extension, leading to more favorable brand extension fit perceptions and evaluations. This effect would not emerge for female consumers.

Study 1 tested our hypothesis in a 2 (mindset: mating, non-mating) x 2 (gender: male, female) between subjects design with Kodak filing cabinet and McDonald's chocolate bar as brand extension stimuli. Participants in the mating [vs. non-mating] mindset condition were asked to imagine and write about meeting someone desirable and spending a wonderful day and a dinner with this person [vs. imagine getting ready to go to a concert with a same-sex friend]. Participants responded to the brand extension using standard scales of brand extension evaluation (e.g., the brand extension is 1= poor and 7 = excellent), brand extension fit (e.g., the brand extension is 1=inconsistent with the brand and 7 = consistent with the brand) and open-ended thoughts. Our results demonstrate that male consumers in a mating mindset give more favorable responses, compared to those in a non-mating mindset. Female consumers, however, are not affected by the mindset. Male consumers in the mating mindset generate more relational thoughts (connecting the parent brand to the extension) than those in a non-mating mindset. Importantly, our results are not driven by positive mood, positive arousal, negative arousal and total thoughts.

Next, we examine how consumers respond to brand extensions from different types of parent brands, prestige versus functional brands (Park, Milberg, and Lawson 1991). Prior research has shown that prestige brand concepts (e.g., Rolex) are more abstract and hedonic than functional brand concepts (e.g., Timex), allowing prestige brands to extend more easily into distant product categories (e.g., neck ties, scarves) (Hagtvedt and Patrick 2009; Park, Milberg, and Lawson 1991). We predict that for the functional brand, male consumers in a mating mindset, due to boosts in creativity, will be able to find novel ways to link the parent brand and the extension. Thus, brand extension responses will be more favorable for male consumers than female consumers. No gender differences would be expected to emerge for extensions of prestige brands, where relational thoughts are accessible to both male and female consumers allowing both groups of consumers to connect the brand and the extension.

Study 2 tested our hypothesis in a 2 (brand: functional, prestige) x 2 (gender: male, female) x 2 (mindset: mating, non-mating) between subjects design. Honda sunglasses and BMW sunglasses were the brand extension stimuli for the functional and prestige brands respectively. Our findings confirm that for functional brands, male consumers in a mating mindset provide more favorable brand extension responses (and more relational thoughts) than female consumers. For the prestige brands, brand extension responses (and relational thoughts) of female consumers rise to the level of male consumers, in effect closing the gap between male and female consumers.

Finally, we explore the process in greater depth by examining the role of creativity. Prior research shows that when consumers want to express their creativity, they tend to perform better on creativity tasks (Fitzsimons et al. 2008). If creativity is indeed driving our effects for male consumers, we suggest that the exercise of expressing creativity in an alternative manner would satisfy the male consumers need to express creativity, thus reducing the need to express creativity while evaluating brand extensions in a subsequent task. Consequently, brand extension responses in a mating mindset will be more favorable when an alternative creativity task is absent than when it is present. In contrast, for female consumers in a mating mindset,

who do not show boosts in creativity, the presence of an alternative creativity task will not affect their brand extension responses.

Study 3 tested our hypothesis with a 2 (alternative creativity task: present, absent) x 2 (gender: male, female) between subjects design. A mating mindset was induced in all participants. In the alternative creativity task present condition, participants were asked to respond to seven problems from then Remote Associates Test (RAT; Mednick 1962) taken from Bowden and Jung-Beeman (2003). In the absent condition, participants did not complete the RAT task. As predicted, we found that male consumers gave more favorable brand extension responses when an alternative creativity task is absent than when it is present. In contrast, for female consumers, the presence (vs. absence) of an alternative creativity task did not affect their brand extension responses.

Don't Get Framed Again: How a Divergent Thought Mindset Mitigates Framing Effects

EXTENDED ABSTRACT

It is now widely accepted that individuals make different choices when faced with alternative descriptions of the same decision problem (Tversky & Kahneman, 1981). How a choice is framed appears to influence decisions of any type, including many that have fundamental consequences for the welfare of the chooser. The most prominent example of a framing effect is the now classic "Asian Disease" decision scenario (Tversky & Kahneman, 1981) in which participants are asked to choose between two programs for dealing with the outbreak of a disease which has infected 600 people. In the gain frame condition participants are told Program A would save 200 individuals with Program B having a 1/3 chance of saving all 600 lives and a 2/3 chance of saving none. In the loss frame condition, however, participants are told 400 individuals would die in Program A with Program B having a 1/3 chance of no deaths and a 2/3 chance of 600 deaths. Although both conditions present probabilistically identical choices, individuals presented with the gain frame strongly prefer the "sure" Program A option to save 200 people while those faced with the loss frame strongly prefer the "risky" Program B choice.

With such framing effects appearing to be so pervasive and research on attenuating these framing effects generally serving to demonstrate how robust they are, an important question is how can they be overcome? The present research addresses this question by taking a novel mindset approach. Specifically, we examine the effect of divergent thought mindset on how people respond to a classic decision framing problem. Depending on the particular problem, creative thinking requires differing degrees of divergent and convergent thought (Guilford, 1959). Convergent thinking can be thought of as "connecting the dots," and involves recognizing similarities between adjacent pieces of information, preserving the already known, and reapplying set techniques (Cropley, 2006). Our particular focus is on divergent thinking, which is associated with "thinking outside the box," and involves shifting perspective, seeing new possibilities, a deviation from the usual approach, and associating ideas from remote fields (Cropley, 2006). It is this broad emphasis on deviating from the usual approach which suggests the possibility that divergent thinking may help mitigate framing effects. We argue that framing effects can be conceptualized in terms of automatic associations between contextual cues and how a given decision scenario is mentally represented and processed. In the Asian disease problem, for ex-

ample, the gain and loss frames lead individuals to invoke different attitudes toward risk (Tversky & Kahneman, 1981). As such, given divergent thought's emphasis on deviating from the usual approach, an intriguing possibility is whether individuals induced to think in a divergent fashion might be less susceptible to framing effects.

In two experiments we examined the effect of a divergent thinking mindset on individuals' susceptibility to the Asian disease framing effect. In experiment 1, we utilized a general creative mindset prime manipulation (Sassenberg & Moskowitz, 2005) and asked participants to describe three situations in which they engaged in creative behavior. Responses were coded in terms of whether they best represented convergent or divergent thought. Next, participants were presented with either the gain or loss framed version of the Asian disease problem described earlier, and indicated their relative preference between the two programs on a 6-point scale anchored from "I strongly favor program A" (1) to "I strongly favor program B" (6). Participants in both the convergent thought condition (Mgain = 2.7 vs. Mloss = 4.9, F(1, 100) = 9.21, p < .01) and control condition (Mgain = 2.9 vs. Mloss = 4.1, F(1, 100) = 12.21, p < .01) were subject to the usual framing effect, that is, they indicated stronger preferences for the certain option (i.e., program A) when the alternatives were presented in terms of gains than losses. In the divergent thought condition, however, we observed no such framing effect (Mgain = 3.5 vs. Mloss = 3.7, F < 1, p = ns).

In experiment 2, our goal was to replicate the debiasing effect of divergent thought using an experimenter-provided prime. In the divergent thought condition, participants read a brief scenario about a student engaging in creative free-style rapping who had to "think outside the box" to come up with his rhymes. In the control condition participants read a scenario describing an individual engaged in mundane activities. We again found that participants in the control condition were subject to the standard framing effect and indicated a stronger preference for the certain option (i.e., program A) when the alternatives were presented in terms of gains (M = 2.7) rather than losses (M = 4.6). However, in the divergent thought condition this difference in preference across frames was substantially reduced (Mgain = 3.1, Mloss = 3.8). They were largely immune to the effect of the frames, as they were essentially indifferent between program A and program B regardless of whether they were faced with the gain or loss frame.

In sum, we found that a divergent thought mindset, whether invoked by participant-generated (experiment 1) or by experimenter-generated (experiment 2) primes, significantly armed participants from falling prey to the framing effect typically observed in the classic Asian disease problem. While existing research on attenuation of biases has tended to focus on thinking harder (e.g., LeBoeuf & Shafir, 2003), our data suggest that a subtle cue that leads individuals to automatically think in a divergent fashion is potentially more effective than a deliberate increase in conscious effort.

In future studies, we aim to better isolate the process underlying the debiasing effect, and to explore whether it extends to other heuristics and biases. On the process front, we plan to utilize time constraints (and/or cognitive load) to understand whether the debiasing process requires cognitive resources, or whether it operates purely at the heuristic level. As far as other biases are concerned, we speculate that the availability heuristic (Tversky & Kahneman, 1973), representativeness heuristic (Kahneman & Tversky, 1972), and planning fallacy (Kahneman & Tversky, 1979) might all rely to some degree on automatic associations. As such, we intend to explore if a divergent thought mindset ameliorates these biases.

SESSION OVERVIEW

Unlike objective time (i.e., standard clock time), subjective time is a highly malleable medium. For instance, time can sometimes seem to be contracted or limited, and at other times expanded or plentiful. However, in today's society, the perception of time as contracted or limited seems to be an increasingly dominant perception (e.g., Carroll 2008; Fay 1992; Robinson 1990; Robinson and Godbey 1997). Indeed, for many consumers, time has become a precious resource and the ultimate scarcity (e.g., Becker 1965; Juster and Stafford 1991; Leclerc, Schmitt, and Dube 1995). In response to this consumer trend, a great deal of time perception research has focused on identifying the factors that lead to a contracted or limited perception of time (e.g., Bailey and Areni 2006; Conti 2001; Kellaris and Kent 1992) and exploring the physical, mental, and behavioral consequences of increased time pressure and time urgency (e.g., Nationwide Mutual Insurance Company 2008; Roxburgh, 2004; Yan et al. 2003). But in a world where time is so often constricted, a better understanding of how time can be stretched is also of great importance. Specifically, what factors are capable of expanding the perception of time? And what consequences might this expanding of time have for consumer behavior and well-being? Furthermore, as much of the extant research that looks at differences in time perception has focused on relatively unchangeable factors (such as age, gender, and culture; Block, Hancock, and Zakay 2000; Block, Zakay, and Hancock 1998; Hill, Block, and Buggie 2000; McCormack et al. 1999), can we identify time-expanding factors that can be deliberately altered (so that people can expand their—or others'—perceptions of time)?

With four papers (all in the final stages of completion), this session addresses these questions, and related issues, by integrating various research perspectives in order to identify factors that lead to and the consequences that result from perceptions of expanded time. **Rudd, Vohs, and Aaker** approach these questions from an emotion perspective and identify one distinct positive emotion—awe—that makes time seem more plentiful and consumers feel less impatient. Their results also highlight potential consequences of expanding time perception, as they find that this altering of time enables awe to influence subjective well-being, preferences for experiential (versus

material) goods, and one's willingness to donate time. **Jhang and Lynch** also identify a way to expand time, as they investigate how proximity to certain goals influences perceptions of spare time (now and in the future) and explore how this affects one's desire to delay attractive interruptions. **Chance, Mogilner, and Norton** focus their attention on consumer behaviors, and illuminate a surprising way by which people can feel they have more time: by giving time to others. Compared to wasting time, spending time on oneself, and even gaining time, spending time on another (whether they are well known or not) was found to counteract perceived time famine. Finally, **Kim and Zauberman** look at how perceived durations can be expanded. Specifically, they examine how one type of sensory perception—auditory tempo—influences prospective temporal distance and the downstream consequences this has for willingness-to-pay and intertemporal choice. Taken together, these different lines of research provide diverse insights on the study of time perception yet still maintain a coherent theme.

As all four papers share a common focus on deepening our theoretical understanding of factors that influence consumers' perceptions of time, this session is likely to be of substantial interest to those active in time perception research. However, we also expect this session to have broader appeal. For instance, as each of our papers explores time perception from a different domain, this session should also appeal to those who study emotions, goals, consumer actions, sensory perceptions, and decision-making more broadly. In addition to creating connections between diverse research areas (by demonstrating time perception's applicability to many research domains), this session should also build connections between academia and industry. Specifically, this session focuses not only on advancing our theoretical understanding of time perception, but also on identifying time-expanding factors that could be potentially manipulated by marketers (in order to achieve or avoid the downstream consequences of time expansion identified in our research, such as greater willingness-to-pay and preferences for experiential alternatives). We hope that attracting a diverse audience will help facilitate a lively and fruitful discussion, and believe that the presentations on the antecedents and consequences of expanded time perception will elicit active idea generation for future research on time perception.

Awe Expands People's Perception of Time, Alters Decision Making, and Enhances Well-Being

EXTENDED ABSTRACT

Time is a scarce consumer commodity (Leclerc, Schmitt, & Dube, 1995). In fact, feeling one has too much to do and too little time is known as "time famine" (Perlow, 1999) and produces undesirable consequences including fatigue, stress, and even postponing a doctor's visit when ill (Lehto, 1998; Vuckovic, 1999). Although science cannot expand the amount of time in each day, could it shift consumers' perceptions of how much time is available? Three experiments examined whether experiencing awe can expand time perceptions and, in turn, impact consumer decision-making and well-being.

Can awe, defined as the feeling that arises when one encounters a stimulus so strikingly vast (in time, scope, complexity, ability, or power) it provokes a need to update one's mental schemas (Keltner & Haidt, 2003), increase perceived time availability? Prior research and theory suggest so. Experiences involving awe, such as optimal athletic performances (Ravizza, 1977) and spiritual events (Fredrickson & Anderson, 1999) often involve a sense of timelessness. The phenomenology of awe, therefore, suggests it might expand time perceptions. Two psychological theories are also relevant. The first is the extended-now theory (Vohs & Schmeichel, 2003), which demonstrates focusing on the present moment elongates time perceptions. Awe captivates people's attention on what is unfolding

before them, which the extended-now theory predicts would expand time perceptions. The second is Socioemotional Selectivity Theory, which shows people seek to acquire knowledge when time feels expansive (Carstensen, Isaacowitz, & Charles, 1999). Awe's triggers within people a desire to create new knowledge structures (Keltner & Haidt, 2003), which therefore may be a signal that awe leads the mind to perceive time as expansive.

Awe's predicted ability to expand time perceptions was also hypothesized to have several consequences. First, perceived time availability is thought to affect certain prosocial decisions. For instance, time scarcity hinders the tendency to help someone in distress (Darley & Batson, 1973) and is a common barrier to volunteering (Hall et al., 2009). Therefore, awe, by creating the perception of plentiful time, might increase one's willingness to spend time helping others. Second, time perception can influence people's decisions about how to live life. For instance, insufficient time is an oft-cited reason for not engaging in leisure experiences (Mannell & Zuzanek, 1991). Time perception may also influence decisions to acquire experiences versus material goods (Van Boven & Gilovich, 2003), as one inherent quality of experiential goods is they require the experiencer devote time to savor the attendant feelings and sensations (Quoidbach et al., 2010). Thus, by inducing a sense of ample time availability, awe might enhance preferences for experiences. Third, time perception is often an indicator of well-being. For instance, people who report feeling "always" rushed have lower life satisfaction than do others (Robinson & Godbey, 1997) and feeling one has little time available has been linked to depressive symptoms (Roxburgh, 2004). Thus, awe, through expanding time perceptions, might boost momentary life satisfaction.

Experiment 1 tested whether feeling awe expands time perceptions. To demonstrate that awe's temporal consequences are not characteristic of all positive emotions, awe was contrasted with happiness. Because awe is often elicited during events that one might associate with minimal time pressure (such as exposure to nature; Shiota, Keltner, & Mossman, 2007), it is possible that perceiving time as expansive is merely a prerequisite for experiencing awe, and not a consequence thereof. To address this alternative account, all participants were initially primed to perceive time as constricted, using a sentence unscramble task (Srull & Wyer, 1979). Next, participants watched either a one minute awe-eliciting or happiness-eliciting commercial for an LCD television. Participants subsequently reported their agreement on a perceived-time-availability index ("I have lots of time in which I can get things done," "time is slipping away" (reverse-scored), "time is expanded," and "time is boundless") and current emotions. Manipulation checks confirmed awe (versus happiness) condition participants experienced more awe and less happiness. An ANOVA then revealed awe (versus happiness) condition participants perceived greater time availability. Furthermore, across both conditions, stronger feelings of awe were correlated with greater perceived time availability.

Experiment 2 tested whether awe, via influencing time perceptions, affects willingness to volunteer time. In this experiment, momentary impatience was the measure of time perception, as it is associated with perceiving time as insufficient (Glass, Snyder, & Hollis, 1974; Lang & Markowitz, 1986). To elicit emotions, participants wrote about a personal experience, with those in the awe [happiness] condition writing about an experience that made them feel awe [happiness]. Participants then reported their feelings of impatience, willingness to donate time, willingness to donate money, and current emotions. Manipulation checks confirmed awe (versus happiness) condition participants experienced more awe and less happiness. An ANOVA then revealed awe (versus happiness) condition participants

reported reduced impatience and a greater willingness to volunteer time. Finally, a mediation analysis determined awe's influence on time donation was driven by its influence on time perception: Awe (versus happiness) reduced impatience, which in turn increased willingness to donate time. Importantly, the awe and happiness conditions did not differ in willingness to donate money (a non-temporal form of prosociality), ruling out the alternative explanation that awe simply increases all prosociality.

Experiment 3 tested whether awe influences well-being and consumption decisions via expanding time. To elicit emotions (awe versus neutral), participants read stories depicting prototypical elicitors of the target emotion (Griskevicius, Shiota, & Neufeld, 2010). Participants subsequently reported their feelings of impatience, momentary life satisfaction, hypothetical choices between experiential versus material goods, and current emotions. A manipulation check confirmed awe (versus neutral) condition participants experienced more awe. ANOVAs then revealed awe (versus neutral) condition participants reported reduced impatience, greater life satisfaction, and preferred more experiential (versus material) goods. Mediation analyses determined awe's influence on life satisfaction and experiential (versus material) choices was driven by its influence on time perception: Awe (versus neutral feelings) reduced impatience, which in turn increased life satisfaction and preferences for experiential goods.

In sum, awe increased willingness to volunteer time, preferences for experiential goods, and life satisfaction, all through expanding perceptions of time. Thus, awe-eliciting experiences might offer an effective solution to the feelings of time starvation that plague consumers in modern society.

Giving Time Gives You More Time

EXTENDED ABSTRACT

Many of us feel we are victims of a "time famine" (Perlow 1999), having too much to do and not enough time to do it. For example, parents are spending both more time working and more time with their children, yet still feel they are falling short (Bianchi, Robinson, and Milkie 2007)…if only there were a few more hours in a day. Given that our time is objectively constrained by a 24 hour day, and ultimately mortality, one important question is whether there are ways to feel like we have more time. We examine one way in which doing more can result in feeling less busy. In a series of experiments, we find that giving time to another person counteracts the time famine, making time feel more expansive and the future full of possibilities.

Volunteering time can benefit givers in multiple ways, from reducing depression (Musick and Wilson 2003), to improving physical health (Thoits and Hewitt 2001), to delaying death (Oman, Thoresen, and McMahon 1999). Giving support to others lessens anxiety over

one's own troubles (Krause 1986) and giving a massage can lower stress even more than receiving one (Field et al. 1998). In short, volunteering can make people healthier and happier. But no studies have yet explored the effect of giving time on time perceptions. One might expect that since adding obligations reduces the time available for other things, any additional activities, including volunteering, would amplify time-related stress. We anticipate the reverse outcome for two reasons: if giving time is meaningful, it could encourage a long-term perspective; also, precisely because donating time is indicative of a surplus of time and energy, one might infer such a surplus even when volunteering is obligatory.

In our first study, participants spent five minutes either giving time or wasting time, and then answered a series of time perception questions. Those in the giving time condition selected one of four gravely ill children, read a short biography written by the child's mother, then wrote a letter to that child—which we subsequently mailed. Those in the wasting time condition counted the "e"s in a long passage of nonsense text. Our dependent variable was endorsement of the time-focused statements from Carstensen and Lang's (1996) Future Time Perspective scale (e.g. "Most of my life lies ahead of me"). Consistent with our hypothesis, we found that individuals who had given time felt they had more time than did those who had wasted it.

Study 2 was conducted in two parts. In the morning, participants completed an online, between-subjects questionnaire which included instructions to either spend time doing something for themselves or for any other person at some point during the day. We gave no further directions regarding how this time should be spent. In the evening, participants completed a follow-up survey asking how they had spent their time, how much time they had spent, and how they felt about it, as well as measuring future outlook. We found that regardless of the amount of time spent, those who given time to another person felt that they had more time in general than those who spent time on themselves. They also reported the experience was less relaxing and enjoyable, but more meaningful and loving. These findings suggest that experiences which reduce time-related anxiety do not necessarily need to feel relaxing or fun. Additionally, those who gave time to someone else were more inclined to say it didn't feel like much time at all. This result dovetails with our finding that they also reported that the future feels longer—if you have plenty of time ahead of you, then an hour isn't much at all.

In a follow-up study, we asked participants to remember a previous instance in which they had spent time doing something for someone else or for themselves. As our dependent variable, we used a resource slack measure (Zauberman and Lynch 2005) of perceived free time. We found that, consistent with our previous results, those who remembered investing an hour or two felt they had more free time if they recalled time spent on another. However, those who remembered investing months or years (e.g. going to college or caring for a sick relative) reported having more free time after remembering something they had done for themselves. We confirm in this experiment that spending time on others can increase the amount of time you feel you have available, but that this effect is limited to small amounts of leisure time, rather than major volunteer commitments which constrain other important obligations and pursuits.

In our next study, we tested the boundaries of our effect by comparing giving time to getting time, and we explored a behavioral consequence of subjective time abundance. In this experiment, participants either gave ten minutes (editing a high school student's senior essay) or received 10 minutes (leaving the lab early). We then asked how much time they might want to devote to participating in future studies, and we followed up by measuring actual time spent.

Those in the giving time condition reported having more spare time, intended to participate in more future surveys, and were marginally more likely to actually spend more time on surveys a week later. In a follow-up study, we showed the cyclical nature of the volunteering/busy-ness relationship. We first asked participants to complete a writing exercise that primed being busy or not being busy. Next, we offered them the opportunity to leave early or to spend fifteen minutes editing an essay, as in the previous experiment. Those who had been primed with being busy were less likely to give time to help someone else.

In sum, we find that spending time on another person can make one's life feel less busy, and that feeling less busy increases the likelihood of helping out. The converse is true as well: when feeling the pressure of a time famine, we are less likely to engage in socially supportive activities that could alleviate this stress.

Proximity to a Goal and Time Slack

EXTENDED ABSTRACT

Zauberman and Lynch (2005) showed that people tend to say "Yes" to attractive opportunities in the distant future that they would say "No" to if the same activity had to be performed today or tomorrow. The present research seeks to understand what drives an individual's different perceptions of time slack ("spare time") in the near and distant future.

People believe that today they are exceptionally busy but that they will be less busy in the more distant future. Zauberman and Lynch (2005) speculated that this illusion that one will be less busy in the future than today might arise because people have formed goals for the use of their time in the very near but not the more dis-

tant future. We conjecture that people are more likely to have goals for their time for the present than for the future (Lynch, Netemeyer, Spiller, and Zammit 2010). Since goals are known to become reference points (Heath, Larrick, and Wu 1999), we suggest that people's propensity to delay investments of some resource (i.e., time) to reap a reward reflects their expected pain from not attaining the proximate goal if they accept an offer requiring the same resource. Our conjecture that goals for time use now versus in the future play a role in propensity to delay time investments additionally leads us to seek to understand how proximity to a goal influences perceptions of time slack ("spare time").

We hypothesize that we can reverse the Zauberman and Lynch (2005) finding of lesser perceived time slack for now than for some point in the future when people have a salient goal of using their time at that point in the future, but no salient goal for use of time in the very short run. In Study 1, travelers (n=75) were approached at airports when they were waiting at the gates for their flights. They reported their perceived time slack for three different points of time (i.e., now vs. that evening vs. a week later). In addition, they reported the current time, their departure time, and their arrival time. Consistent with our hypothesis, the result showed that participants perceived greater time slack for now and for the next week than for that evening. More importantly, when we used the remaining time to departure as a grouping variable or covariate, we found that temporal proximity to a goal (i.e., boarding/departure) differently influences an individual's perceptions of time slack over time. When one's flight is not scheduled to depart for an hour or more, one perceives that one has more spare time "now" than tonight: the goal of boarding is not active and the goal of evening activities is active. But when boarding time approaches, boarding becomes the focal and proximate goal, and one perceives that one has little spare time "now."

In Study 2a and 2b, we next test the premise that goal proximity affects willingness to be interrupted for some other attractive task requiring the use of the same resource (i.e., time) and whether one would prefer to be interrupted now or later. Each individual participant's goal was to win two out of four Nintendo Wii games in 10 minutes. We manipulated proximity to a goal by interrupting participants at different points of their goal progress in the first game (either at about 20-30% or 60-70% of the first game). Then, they were asked if they wanted to perform the interrupting task (i.e., another Wii game) now or in the middle of the second game. We also manipulated the attractiveness of the second game. Unsurprisingly, participants were more likely to prefer to be interrupted now versus later when the later task was attractive rather than unattractive. But, our key finding was that people were more willing to be interrupted when they had made less rather than more progress in the first game, suggesting that goal proximity-based perceptions of time slack affected their preference to delay interruption.

In sum, this paper extends the time perception literature by demonstrating that perceptions of "spare time" now and in the future are related to proximity to a goal requiring use of that time. Furthermore, goal proximity affects the strength of motivation to pursue a focal task and desire to delay "attractive interruptions" that require time as a resource.

The Impact of Auditory Tempo on Prospective Temporal Distance Judgments and Consumer Preference

EXTENDED ABSTRACT

Existing research on interval timing in the second-to-minute range has found that external tempo (i.e., repetitive stimulation by auditory or visual stimuli) influences individuals' judgments of elapsed time by changing their internal tempo, or the speed of their internal clocks. For instance, listening to fast pulses or being presented repeatedly with fast visual flickers has been shown to induce overestimation in judgment of elapsed time. In this article we demonstrate that auditory tempo, such as sine pulses or beats of music, influences judgment of future time—that is, perceived prospective temporal distance—and various time-related judgments.

Although perception of prospective temporal distance and elapsed time are not identical, there are theoretical reasons to expect that they are related. Even if we assume that prospective temporal distance is a purely abstract construct, not governed by the same process governing the perception of elapsed time (such as an internal clock), judgment of abstract information is influenced by individual experiences in related and more concrete domains (Lakoff and Johnson 1999; Landua, Meier, and Keefer 2010). When individuals judge prospective temporal distance—which is abstract information to process—their perceptions of current or elapsed time would constitute the most relevant temporal inputs that can be used to form their perception of future time. Thus, auditory tempo, which influences judgment of elapsed time, may also influence judgment of prospective temporal distance.

In Study 1, we first examined whether individuals' estimates of elapsed time are significantly associated with their prospective temporal distance. Specifically, participants judged the elapsed duration of 12 randomly presented tones lasting 2 to 30 seconds and another 12 prospective durations ranging from 10 to 60 days using a physically-unbounded psychophysical line scale. Results showed that these two types of time perceptions are significantly correlated. Such association between elapsed time perception and prospective temporal distance judgment implies that a common psychological process may be involved in both processes and that auditory tempo may influence judgment of prospective temporal distance by serving as a perceptual input for judgment of prospective temporal distance. To directly test this prediction (in Study 2 and 3) we used different speeds of sine pulse, which have been used in the elapsed time perception literature, or different beats of the same music—the tempo of the same music piece was changed either to be faster (98 beats per minute) or slower (55 beats per minute) than the original tempo (76.5 beats per minute) without changing the music's pitch—to manipulate the speed of tempo and tested whether fast tempo influences perceived length of prospective duration. Results showed that participants who listened to fast pulses judged the same prospective durations to be longer than those who listened to slow pulses.

A similar effect was observed not only for prospective temporal distance judgment but also for time estimation for various future events (Study 4). Specifically, participants who listened to the faster music estimated everyday activities such as preparing for a final exam, booting their computers, or writing an email to take longer compared to those who listened to a slower version of the same music. But, auditory tempo did not influence calorie judgment of foods, ruling out an alternative explanation that what is influenced by tempo may be judgment of number rather than judgment of duration (Study 4).

In Studies 5, 6, and 7, we tested the impact of auditory tempo on various time-related judgments such as willingness-to-pay for products with a duration attribute (Study 5), and intertemporal preferences for a product (Study 6) or for monetary outcomes (Study 7). Results confirmed that different tempos of music significantly influenced time-related judgments as predicted. Specifically, participants who listened to fast tempo music were willing to pay more for the same vacation package and revealed greater impatience for products and money when making intertemporal tradeoff decisions.

Taken together, the current research demonstrates an intriguing relationship between tempo and prospective temporal distance judgment, and its implication for consumer preference. It further suggests that elapsed time judgment and prospective temporal distance judgment are highly related (i.e., one serves as perceptual input for the other), shedding a new light on the nature of prospective temporal distance judgment.

SESSION OVERVIEW

Money is a remarkable technology fulfilling three primary functions: a medium of exchange, a unit of account, and a store of value. It is an integral part of most consumer interactions and pervades every aspect of our consumer lives. Other media of exchange, such as gift cards and reward points, fulfill similar functions and are nearly as ubiquitous. The value we place on money determines the extent to which we strive to accumulate it and our reluctance to part with it when making purchases. Normatively, money's value is determined by the utility gained by using the marginal dollar. In this session, we consider a variety of important non-normative influences on the perceived value of money and media of exchange. In doing so, we help to answer how money is psychologically imbued with value.

First, Wiltermuth and Gino show that organizing incentives such as time and money into categories increases motivation to work for those incentives. Such categories may be arbitrary, and the effect is robust to gain and loss frames; merely separating them into categories increases their value. Second, Spiller and Ariely examine how the set of possible purchases influences the value of a resource. Normatively, only the best use of a resource should affect its value. Instead, other possible but irrelevant uses affect the value placed on a resource as well. Third, DeVoe, Pfeffer, and Lee find that the accumulation of money increases the importance individuals place on money. By earning money through labor, the symbolic value of money is associated with one's self-esteem and sense of competence, thereby increasing its importance. Finally, Vohs, Lasaleta, and Sedikides show that feelings of nostalgia weaken the desire for money. Nostalgia provides a sense of social support, weakening the reliance on money to provide such support in its place, and thus decreasing its value.

Each paper advances our understanding of a truly fundamental question in consumer behavior: how do consumers value money and other media of exchange? Overall, the session provides a coherent set of distinct drivers of money's perceived value with a wide variety of implications for marketing and consumer behavior. These papers will likely appeal to researchers interested in a variety of fields including gift cards, incentives, labor, materialism, the social and cognitive roles of money, and retro brand appeals.

"I'll Have One of Each": How Separating Rewards into (Meaningless) Categories Increases Motivation

EXTENDED ABSTRACT

Researchers have long sought to understand how to foster motivation more effectively. Much of this research has highlighted rational mechanisms that increase or make salient the benefits the worker obtains by applying effort. For instance, Adam Grant's (2007, 2008) work has shown that highlighting the pro-social impact of people's work increases their motivation. Hackman and Oldham (1976) have similarly shown that task identity, task significance, and positive feedback all influence motivation. In the present research, we propose that even factors that should not rationally affect motivation may do so. Specifically, we hypothesize that categorizing rewards can increase motivation, even when those categories are arbitrary.

We put forth this hypothesis because we believe people clump rewards into categories and are more sensitive to increases in the number of categories of rewards than they are to increasing the magnitude of rewards within a category. Thus, our work draws inspiration from Thaler's (1999) work on mental accounting.

We tested our hypothesis across three experiments. In Study 1, 157 undergraduate students (53% female; M_{age} = 21.0) at a large, private university on the West Coast first completed an anagram unscrambling task (Cameron and Miller, 2010). Unbeknownst to the participants, the third and ninth anagrams were nearly impossible to solve. In one condition, successfully unscrambling anagrams ostensibly earned participants $2 per anagram solved. In another condition, successfully unscrambling anagrams allowed them to skip four minutes of a boring task. In a third condition, successfully unscrambling anagrams earned participants $1 and allowed them to skip two minutes of the boring task. Thus, these participants earned half the money and saved half the time that did participants in each of the other two conditions. The dependent variable was the amount of time participants persisted in the task. As predicted, participants in the two categories of benefit condition persisted longer (M = 9.1 minutes, SD = 3.1) than did those in the monetary benefit (M = 7.0, SD = 2.6) or time benefit conditions (M = 6.9, SD = 3.7), $ps < .05$.

Studies 2 and 3 examined the hypothesis that separating incentives into categories can increase motivation, even when those categories are meaningless. Across these studies, we instructed participants that they would be transcribing a number of sections of type-written text to help us to prepare for a future study, in which we would study how handwriting can affect the perceptions people have of others. We manipulated whether a collection of items purchased from a local dollar store were portrayed as belonging to a single category or to two categories. In the categorization condition, participants were told that Category 1 was in the Purple Storage Container and Category 2 was in the Clear Storage Container. These participants were told that they could take home one of the items from either category if they transcribed for ten minutes and that they could take home an item from the other category if they transcribed for twenty minutes. In the no-categorization condition, participants were told that they could take home one item if they transcribed for ten minutes and two items if they transcribed for twenty minutes. Participants were told that may spend as much time or as little time transcribing these sections as they liked. Participants were then told to take a look at the rewards that they could win. The rewards were not sorted into specific categories; rather, there was a mix of statio-

nery, hardware, and food items in each container. The likelihood of participants transcribing sections of text for a full twenty minutes served as the primary dependent variable.

Study 2 participants in the categorization condition were more likely to transcribe for the full twenty minutes (34.4%) than were participants in the no-categorization condition (9.7%), $p = .03$. They also reported that they were more motivated to obtain the second reward (M = 4.22, SD = 2.21) than did participants in the no-categorization condition (M = 3.07, SD = 1.95), $p = .03$. Bootstrapping analysis revealed a significant indirect effect.

Study 3 replicated the categorization effect using a loss frame. In this case, participants selected their prizes at the beginning and were asked to return one if they did not work twenty minutes and return two if they did not work for ten minutes. Motivation to obtain the second item again mediated the effect.

We conclude from our results that that separating incentives into categories can increase motivation, even when the basis for the categorization is meaningless.

Irrelevant Outside Options
Influence the Value of Money

EXTENDED ABSTRACT

How do consumers represent the value of money? We propose that holding constant the value of a resource's best use, liking for the category of possible and accessible uses is an important (but normatively irrelevant) determinant of the perceived value of money.

Economically, money is as valuable as the goods it buys. Understanding other non-normative influences on the value of money informs our understanding of consumers' propensities to spend, save, and earn money. Because money is associated with a large, heterogeneous group of products, the associations between money and its best uses are weak (Weber and Johnson 2006). As a result, other inputs associated with a resource that are not its best uses, and that are therefore irrelevant, may be likely to affect its perceived value as well. In four studies, we demonstrate that accessible but irrelevant items in the category of possible purchases affect how consumers value media of exchange. In Studies 1 and 2 we examine the perceived value of artificial media of exchange, and in Studies 3 and 4 we examine the perceived value of gift cards.

Measured set composition. In Study 1, we ask: Do resource uses other than the most valuable use affect the value of the resource? Undergraduate students (total *N*=42; usable *N*=34) learned how each of several certificates could be used to purchase one product from associated subsets of 1, 2, or 3 products. For example, one certificate could be exchanged for one product from the set: notepad, packet of pens, roll of tape. Each certificate should be worth as much as its most valuable use. Participants reported how much they would be willing to pay for each certificate and then reported how much they would be willing to pay for each product. Regressing certificate willingness to pay (WTP) on (a) set size, (b) maximum product WTP across its subset of products, (c) average product WTP across its subset of products, and (d) certificate fixed effects revealed that participants were willing to pay more for certificates associated with larger sets ($p<.0001$), marginally more for certificates associated with sets with higher maximum product WTPs ($p<.09$), and more for certificates associated with sets with higher average product WTPs ($p<.05$). Holding constant the value of the most valuable product, other less valuable products affected certificate WTP.

Manipulated set composition. In Study 2 (total *N*=83; usable *N*=71), we replicate Study 1 and manipulate the value of products. In addition to replicating Study 1's results, we find that controlling

for maximum WTP and set size, manipulating a set of products to replace a high-valued product with a low-valued product decreases WTP ($p<.0001$). Controlling for the value of the best use of a medium of exchange, experimentally decreasing the value of irrelevant options decreases the perceived value of the medium.

Category attractiveness. In Study 3, we ask: Does the effect of category attractiveness hold when considering media of exchange with which consumers have considerable experience and which are associated with broader sets of goods? Undergraduate students (*N*=100) reported WTP for five gift cards associated with real stores, the ultimate uses of those gift cards, WTP for those ultimate uses, and liking for those stores. Controlling for WTP for the ultimate use of the gift card (the normative determinant of gift card WTP), liking for the set of products offered at the store was an important determinant of card WTP (between-subject: $p<.05$; within-subject: $p<.0001$). Consumers value real-world media of exchange according to how much they like the category of products it could be used to buy, not just the actual product it will be used to buy.

Subcategory accessibility. In Study 4 (*N* = 147), we ask: Can merely increasing the accessibility in memory of an unattractive subcategory of uses (without changing the set of possible uses) decrease the perceived value of a resource? We find that it does. Our manipulation was subcategory accessibility of different ways one could spend a Barnes & Noble gift card: one third of participants generated books and textbooks they could buy (typical subcategory), one third of participants generated music and movies they could buy (atypical subcategory), and one third of participants did not generate any purchases. Making typical subcategories more accessible should have little effect on what a participant thinks about: they are already accessible. Making atypical subcategories more accessible should change what the participant thinks about: they are not already accessible. Value (our DV) was operationalized as the number of times a Barnes & Noble gift card was chosen out of ten pairwise choices against other gift cards. At the end of the study, participants reported whether they would rather use the Barnes & Noble gift card on books and textbooks or on music and movies (Category Preference).

Accessibility interacted with Category Preferences to influence Gift Card Value ($F(2, 135) = 7.88$, $p = .0006$). Individuals who preferred movies and music chose the gift card more often when music and movies were made accessible (*M*=4.94) than when nothing was made accessible (*M*=3.47) or when books were made accessible (*M*=2.80). Individuals who preferred books and textbooks chose the gift card more often when books were made accessible (*M*=6.44) or when nothing was made accessible (*M*=6.12) than when music and movies were made accessible (*M*=4.66). Most importantly, increasing the accessibility of less accessible, less valuable uses (i.e., making music and movies accessible for individuals who would prefer to buy books and textbooks) decreased the value of the gift card (*M*'s = 6.12 vs. 4.66, $p < .02$).

Liking for the category of possible accessible purchases, not just the marginal purchase, determines the perceived value of a medium. Reducing the fungibility of money may perversely increase its perceived value if eliminating unattractive uses increases liking for the category as a whole. Given that limited-use resources with attractive categories of uses are perceived as more valuable, consumers will be less likely to spend them, more likely to save them, and more likely to exert effort to earn them.

Money Makes Money More Important

EXTENDED ABSTRACT

The strange part is, the more I made, the more I got preoccupied with money. When suddenly I didn't have to think about money as much, I found myself starting to think increasingly about it. Money corrupts the mind.

–Daniel Vasella, CEO of Novartis

Although individual differences are undoubtedly important in affecting inter-individual variations in the importance people place on money, the importance of money may also be endogenously affected by *how* and *how much* money people receive. To the extent that there is variability in money's importance, the standard prediction is that more money should make money *less* important, following the principle of diminishing marginal utility. However, we argue that more money can cause people to place *greater* importance on money when it is earned from labor, because the symbolic value of money implicates one's self-esteem and is a signal of competence.

We initially tested this hypothesis by contrasting two different forms of income (labor income per hours worked versus investment income) using a nationally representative longitudinal survey that permitted us to see how changes in income affected changes in the importance people place on money. At two time periods five years apart, respondents rated the subjective importance of money (i.e., How important is having a lot of money?) on a 1 (*not at all important*) to 10 (*extremely important*) scale. We ran a first-differenced regression that removed constant individual differences and included measures of changes in the number of hours worked per week, changes in the number of household children, changes in total outstanding loans on all the property respondents owned, and changes in the total number of discretionary possessions. Consistent with the hypothesis that money that is earned from labor provides symbolic information about self-esteem and competence, changes in the amount of labor income earned per hour were positively associated with changes in the importance of money, $\beta = .04$, $t(3067) = 2.39$, $p = .017$. However, changes in investment income were negatively associated with changes in the importance of money, $\beta = -.04$, $t(3067) = 2.10$, $p = .036$.

Next, we used experiments to further explore the causal association between how and how much money is received and the subsequent importance placed on money. We wanted to see if we could experimentally manipulate "income" on a small scale and obtain similar causal effects on the importance of money by developing an experimental treatment which would clearly distinguish "earned" income with its implications for the self from income that had no relevance to people's feelings of self-esteem or competence. Towards this end, we utilized a laboratory setting where participants could be randomly assigned to experimental treatments. Specifically, some participants received unexpected additional money as part of the experiment. In a condition analogous to labor income, participants were told that they had received this unanticipated money as a consequence of their work performance—information that should directly cause them to view the money as being associated with self-esteem and competence. If the critical factor is whether or not money reflects the performance of an individual and his or her work, we thought that if people received money because of random chance, that money would not have the same implications for the self and would, therefore, not engender additional symbolic value in terms of money's importance (or at least not to the same extent). We examined participants post-manipulation ratings on the value importance of money subscale (Mitchell and Mickel 1999) that has been used in prior research. Specifically, participants rated their agreement to four statements ("I value money very highly", "Money is important", "I daydream about being rich", and "I believe the more money you have, the happier you are") on a 1(*strongly disagree*) to 7(*strongly agree*) scale.

Participants who received $10 randomly did not differ in the importance of money ($M = 5.07$, $SD = 1.32$) from their counterparts who had received $1 randomly ($M = 5.17$, $SD = 1.16$), $F(1, 28) = .83$, *ns*. However, participants who received $10 because of the performance of their labor did rate the value importance of money as significantly higher ($M = 5.50$, $SD = .84$) than participants who received $1 ($M = 4.71$, $SD = .88$), $F(1, 37) = 8.20$, $p = .007$. In a follow-up experiment, we replicated the findings of this previous study on the importance of money subscale using a different experimental task with a similar amount by source of money interaction, $F(1, 89) = 4.92$, $p = .029$. Additionally, we found that the amount by source interaction was mediated by the more proximal construct of participant's perceived competency ($z = 1.81$, $p = .07$) than by the more global construct of self-esteem ($z = .48$, $p = .63$).

By demonstrating that the amount as well as the source of income is a critical variable in how important money is to individuals, the present findings extend and elaborate on a decision making literature that attests to the fact that people do not experience all dollars as the same. Additionally, the fact that the acquisition of money from people's labor caused people to value money more supports theoretical perspectives emphasizing the symbolic value of money as distinct from instrumental or individual difference accounts explaining its importance. Money is not just a medium of exchange or a store of value, but can have drug-like properties—the more you have, the more you want. Thus, money can become even more important than its economic value alone would dictate when it is a signal of one's competency at work.

Nostalgia Weakens the Desire for Money

EXTENDED ABSTRACT

Nostalgia is commonplace in marketing, and nostalgic themes have been particularly pervasive during recent times of economic crisis. In 2009, PepsiCo launched nostalgic versions of their popular sodas, Pepsi-Cola and Mountain Dew. The so-called throwback beverages, based on original formulas and packaging, were meant to evoke sentiments of the 1960s and 1970s (Elliot 2009). Similarly, General Mills introduced retro packaging for their Big 5 cereals (Trix, Lucky Charms, Cheerios, Cinnamon Toast Crunch, and Honey Nut Cheerios) to induce a wistfulness of the past.

Despite nostalgia's pervasiveness in marketing, little is known about how nostalgia might affect spending in general – beyond spending for nostalgic products themselves. In this article, we test how nostalgia motivates consumption. We tested whether nostalgia's ability to give people a sense of social support would decrease the desire of money. In this research, we bridge two literatures: one demonstrating that nostalgia increases perceptions of social support (Wildschut et al. 2006) and another suggesting that social support and money are oppositional forces (Heyman and Ariely 2004).

We reasoned that, when people perceive they are backed by ample social support, they will find money less desirable than it would be otherwise. This reasoning comes from the idea that both money and social support enable people to get what they need from society, such as shelter, security, nourishment, and companionship (Fiske 1994; Heyman and Ariely 2004). Once a person has enough of either money or social support, she will feel that her needs are met and therefore will crave the other less. That is, if consumers be-

lieve that they can satisfy their wants and needs through social support, then their motivation for money will weaken. Four experiments tested whether the psychological state of nostalgia, due to its ability to foster a sense of social connectedness, would weaken the desire for money.

Experiment 1 induced nostalgia using copy on print advertisements. In the nostalgia condition, participants viewed advertisements that focused on nostalgic memories from one's past, whereas in the control condition participants viewed advertisements that focused on making new memories. Our operationalization of desire for money was the behavior of giving away money in a pooled investment game (Fehr and Gachter 2000). Participants had the opportunity to contribute their money to a common pool. We found that participants in the nostalgia condition gave up more of their money to the common pool than participants in the control condition.

Experiment 2 tested desire for money using the dictator game (Guth et al. 1982). This involves a one-shot exchange, in which a participant decides unilaterally how much money (if any) to give to another player with the rest of the money remaining with the participant. First, however, we used an autobiographical narrative task to differentially elicit feelings of nostalgia. Some participants wrote about a time they felt nostalgic (defined as) "a sentimental longing for a personally experienced past." Participants in the control condition were instructed to write about an ordinary event from their past. Then participants played the dictator game, in which they were always assigned to be the dictator. As predicted, participants in the nostalgic event condition gave significantly more money to the responder than those in the ordinary event condition.

Experiment 3 measured desire for money using a perceptual task – size of coins drawn. Bruner and Goodman (1947) interpreted the fact that poor children drew larger coins than wealthier children as greater motivation to have money. Participants in the nostalgia condition wrote about a nostalgic event, whereas participants in the control condition wrote about the route they took home from high school. Then ps drew on a piece of paper the size of a 50-cent piece and $1 coin. We measured the diameter of the coins, and as predicted nostalgic participants, compared to those in the control condition, drew smaller coins. We took this to signal a weaker desire for money.

Experiment 4 measured willingness to pay as the indicator of desire for money. This study returned to the advertising copy method of eliciting nostalgia (or not) in our participants. After viewing an advertisement that cued perusal childhood memories (nostalgia condition) or an advertisement that cued the idea of making new memories (control condition), they perused pictures of 24 products and were instructed to indicate their willingness to pay for each. As expected, willingness to pay among participants in the nostalgic memory condition was higher than in the control condition.

The present research tested the hypothesis that nostalgia reduces the desire for money. Prior research hinted at the idea that money and social connectedness are opposing motivational forces. Our research used this insight to test whether nostalgia would lead people to behave as if they had little motivation toward money. Four experiments supported this claim, by showing that in interpersonal and intrapersonal contexts, including spending money on products or giving it to others, people in a nostalgic mood desire money less than they would otherwise.

SESSION OVERVIEW

The purpose of this session is to deepen our understanding of consumption oriented communities, specifically bridging the conceptual gaps between various kinds of communities. Consumption oriented communities refer to groups of consumers who self-select into a group that shares a common commitment to a product class, brand, consumption activity, or consumer-based ideology. Over the past twenty years, consumer researchers have explored a variety of such collectives ranging from extreme sports groups (Celsi, Rose, and Leigh 1993), to temporary anti-brand festivals (Kozinets 2002), to in-line skating tribes (Cova and Cova 2002), to brand cults (Belk and Tumbat 2005), to brand communities (Muñiz and O'Guinn 2001), and consumption subcultures (Schouten and McAlexander 1995). In fact, over 100 different consumption communities have been discussed in marketing and consumer research journals. The prevalence of this work is not surprising giving the theoretical and practical import of consumption communities. Achrol and Kotler (1999), for example, proclaimed that the combination of consumer collectives and strategic marketing efforts "represent the most dramatic scenario of change for marketing in the next millennium" with effective management of consumer communities being a popular topic for marketing managers (Fournier and Lee 2009; Fournier, Sele, and Schoegel 2005).

Despite the prevalence of research on consumption communities, our knowledge of these communities is hindered by a lack of consistency in how these communities are conceptualized and how different kinds of communities relate to each other. To date, most research in marketing and consumer behavior has focused on one particular type of group, either a brand community (or multiple brand communities) (e.g., Schau, Muñiz, and Arnould 2009) or a consumption subculture (e.g., Beverland, Farrelly, and Quester 2010), or a consumer tribe (e.g., Otnes and Maclaran 2007). The theoretical and definitional linkages between these groups remain unknown. The purpose of this session is examine the commonalities and differences between different consumption communities to bridge the knowledge bases associated with each kind of consumption community.

Each of the papers in this session converge on this single issue: a lack of meaningful definitions and distinctions that hinders our understanding of contemporary consumption collectives. Each pa-

per also offers fruitful insights into these communities and proposes solutions to this problem. First, Thomas et al. present a conceptual paper where they discuss structural dimensions common to all consumption communities, postulating that communities, regardless of whether they are brand communities, subcultures of consumption, or tribes, vary according to these dimensions. They propose that using this cluster-based conceptualization highlights opportunities for new and important research. Next, Muñiz and Yun tackle the theoretical quandaries surrounding brand communities. Specifically articulating the need for researchers to be judicious in their application of the brand community concept, calling for theoretical rigor that encapuslates both emic and etic understandings of the dynamism and complexities of these collectives. Beverland and Farrelly follow, exploring the intricacies of subcultures of consumption. In this work, they present the processes through which consumption subcultures evolve, focusing on the often underexplored relationship between these communities and mainnstream society. Specifically, they illuminate the conceptual shortcomings of traditional subculture theory by articulating how consumption subcultures prevail in the marketplace. The session concludes with Canniford and Shankar who clarify the definitions of the three most common forms of consumption communities (brand communities, subcultures of consumption, and consumer tribes) and discuss the marketing implications derived from a better understanding of the distinctions between these communities.

We expect this session to appeal to a broad range of consumer researchers, especially those interested in consumer culture theory, subcultures of consumption, brand communities, consumer tribes, social networks, and consumer-brand relationships.

Consumption Community Dimensions

EXTENDED ABSTRACT

Consumption oriented collectives are groups of consumers who self-select into a group that shares a commitment to a product class, brand, consumption activity, or consumer-based ideology. Consumer research has explored a variety of these collectives including, but not limited to, consumer tribes (Cova and Cova 2002), subcultures of consumption (Schouten and McAlexander 1995), brand communities (Muñiz and O'Guinn 2001), brand cults (Belk and Tumbat 2005), and microcultures (Thompson and Troester 2002).

Examining the body of literature on consumption collectives as a whole, however, reveals significant ambiguity about what constitutes each type of collective and how they are similar or different. As such, researchers have struggled to both integrate work across collectivity types as well as determine how to best understand collectives that do not fall neatly into the predefined categories. To avoid this ambiguity, many researchers have simply ignored the differences between collectives, treating each collectivity as theoretical equivalents, stating that "there is no sharp theoretical distinction to be drawn between [various consumption collectives]" (Thompson and Troester 2002 p. 533). We contend, however, that the differences between collectives are theoretically meaningful and have important implications for consumer researchers and marketing practitioners. Specifically, we postulate that conceptualizing collectives as clusters of characteristics attenuates much of the theoretical ambiguity aris-

ing from trying to disentangle seemingly similar collectivity definitions. To this end, we analyzed approximately 100 papers focusing on consumption collectives published in consumer and marketing journals, identifying eight primary dimensions (described next) on which collectivities vary: duration, appeal, access, dispersion, focus, orientation towards the marketplace, structure of resource flows, and heterogeneity. Importantly, these dimensions represent continuous and interrelated spectrums.

The first dimension, time, or temporal duration, refers to the manner in which collectives differ in how long they exist. On the one hand, some collectives are temporary and form for a constrained period of time (e.g., Flash Mobs (Barnes 2006; Thorley 2009); Burning Man Festival (Kozinets 2002)). On the other hand, other collectivities are characterized by a prolonged lifespan (e.g., Apple Newton Community (Muñiz and Schau 2005)).

The second dimension, appeal, refers to the degree to which collectives are attractive to consumers. Collectives with limited appeal tend to only attract a small group of consumers. This sometimes results from the collectivity being oppositional to mainstream cultural ideologies and behaviors (Copes and Williams 2007), such as the voluntary simplicity community (Cherrier 2009). In contrast, other collectives are broadly appealing and tend to espouse values and behaviors aligned with mainstream society (e.g., the Tom Petty and the Heartbreakers brand community (Schau and Muñiz 2007)). Importantly, appeal refers to consumers' perceptions of a collectivity at a single point of time: as collectivities evolve, so does their appeal.

The third dimension, access, refers to the ease with which consumers can join a collective. This is influenced by two factors: (1) barriers to entry related to the minimum requirements for membership (i.e., obstacles consumers face in gaining entry to the collective (Von Hippel 2005)) and (2) the degree to which the collective encourages and facilities membership growth. The next dimension, dispersion, refers to the degree to which collectivities are localized (in person), dispraised (online), or hybrid (both on and offline) (Wind, Mahajan, and Gunther 2002). For example, river rafting communities (Arnould and Price 1993) typify a localized community, online communities typify dispersed groups (e.g., Mathwick, Wiertz, and Ruyter 2008), while the Hummer brand community is an example of a hybrid community (Luedicke, Thompson, and Giesler 2010).

Collectivities also differ in their focus: the degree to which they are centered on a brand, activity, or ideology. For example, the Saab community is brand focused (Muñiz and O'Guinn 2001), the surfing community is activity focused (Canniford and Shankar 2007), while the Burning Man community is predominately ideologically focused (Kozinets 2002).

The sixth dimension, orientation towards the marketplace, refers to the degree to which the marketplace plays a collaborative role in the collective. Synergistic collectives, such as the Harley-Davidson community (Schouten and McAlexander 1995), work collaboratively with the marketplace to achieve common goals. Oppositional communities, such as the Community Supported Agriculture community (Thompson and Coskuner-Balli 2007) are countercultural in nature and oppose mainstream marketplace tendencies. Collectives also differ in how the flow of resources is structured. Fournier and Lee (2009), for example, discuss different community structures (webs, hubs, pools) representing where resources are stored, dispersed, and received.

Finally, collectives differ in terms of heterogeneity. Specifically, they vary in the extent to which they exhibit diversity in how members orient towards the collective, especially with reference to the roles played within the collective, the meanings derived from membership, and the resources created within the collective (Fourni-

er et al. 2005; Thomas, Schau, and Price 2010). Communities can, therefore, be described as clusters of these eight dimensions, occupying a particular cultural space defined in relation to other communities. For example, the running community described by Thomas et al. (2010) would be characterized as an enduring, hybrid, activity focused community that is easy to join with broad appeal. It is also highly heterogeneous with diffuse resource flows and a synergistic relationship with the marketplace.

To date, consumption collective research has only explicitly articulated the focus dimension. Assessing the theoretical implications of all the dimensions, as well as clusters of dimensions, illuminates areas for future research and aids our understanding of communities. To illustrate this, we classified each community discussed in extant marketing and consumer research along the proposed dimensions, focusing on how the community was conceptualized by the researchers in terms of the dimensions, and indentified under-researched areas that have important implications for consumer research. Overall, this classification helps reduce some of the theoretical ambiguities associated with consumption collectives stemming from the parallel development of multiple streams of related research.

Refining and Extending the Concept of Brand Community

EXTENDED ABSTRACT

Since Muñiz and O'Guinn (2001) first articulated the term, brand community has been the subject of a lot of good research. It is much easier now to account for brand-centered consumer collectives and the value they produce. Still, ten years later, there remains a need for conceptual clarity. The term 'brand community' is over-applied, occasionally to the brink of irrelevance. If everything is a brand community, then nothing is a brand community.

To illuminate the theoretical quandaries surrounding consumption collectives, brand centered and otherwise, and to divine conceptual remedies, we draw upon seven years of research on the Adult Fan of LEGO (or AFOL) brand community. The AFOL brand community can be traced back to 1985 when a few adult North American LEGO enthusiasts formed the first LEGO Train club. Between 1985 and the present, what began as a small scale offline group of loosely connected North American LEGO enthusiasts developed into a global community. The LEGO Group estimates that there are currently at least 40,000 active AFOLs around the world (the LEGO Group 2009). These users interact in a variety of face-to-face and online venues (Bender 2010; Chrisman, Hanes, and Weisman 2009).

Between 2003 and 2010, we engaged in a multi-site, ethnographic research program to examine community development in the Adult Fans of LEGO community. We employed two ethnographic methods, participant observation and depth interviews. We observed AFOLs in face-to-face and online contexts. We participated in eight conventions in North America, Denmark and Germany. We observed AFOLs at smaller and local events such as visits to the LEGO factory and the LEGOLAND Park in Billund, Denmark, monthly LEGO user group meetings and locally arranged LEGO shopping trips. We closely followed several LEGO online forums, studying hundreds of conversation threads, and collecting profiles uploaded by members of the LEGO User Group Network (Lugnet.com). We conducted 25 depth interviews with members of the community.

What we see in the AFOL community helps us understand the differences between the multiple forms of consumer collectives (tribes, communities, and subcultures). First, researchers need to address the emic versus the etic issue involved in applying the label brand community. Researchers need to balance the etic perspective,

applying labels based on evidence of agreed-upon requisite markers, with the emic perspective, that is, what the community feels they are and why they feel that way. Some groups prefer to be labeled as a tribe or a subculture, possibly owing to the politics involved; being a subculture is more subversive and positions one against the mainstream. Other groups prefer the term and form community. Sometimes, a group may prefer an inaccurate term.

The LEGO data demonstrate that AFOLs are a community rather than a subculture or a tribe. The AFOLs brand community easily possesses the three markers of brand community (Muñiz and O'Guinn 2001). What we see in AFOLs is a community that is quite self-aware. They understand the significance of the form their collective assumes. Many members have pondered their collective and discussed it with other members, in both face to face and online settings. The discussions are often related to topics such as concerns about recruitment of new members, the overall wellbeing of the community, and legitimization. Although most visible in cases of boundary drawing, we assert that self-awareness is an essential part of communities' processes of coming to terms with who they are and what their community is about.

Second, researchers must understand the dynamism in these collectives over time. Communities change and evolve. For example, as a community matures and attracts new members, it evolves. Neighborhoods and cliques can develop that have their own expression of affiliation and therefore also shape the nature of the overall collective. Although extant work does not preclude this possibility, it also does not address it very explicitly, either.

In the AFOL community, we see three distinct and shifting development stages: a founding and early growth stage, a growth stage, and a midlife stage in which the community undergo changes in structure and organization. We see these developments being initiated by a series of crises that among other things have to do with growth in the number of members, new and different demands for community leadership and an increasing specialization in regards to brand usage. At the same time, we see how AFOLs eagerly embrace new information technologies and how these platforms offer new opportunities to interact and thus organize the community. We believe that insights into the way communities, tribes, and subcultures change and evolve can provide us with a much deeper understanding of what is distinct about each of the groups, but also how they may in fact be related. In further cultivating this perspective we believe that the work of organizational theorists (Greiner 1998/1972; Martin 2002; Schein 1992) is an invaluable source of inspiration.

Finally, conceptual clarity and depth must be achieved. It is essential that we develop a typology that not only includes communities, tribes, and subcultures, but also forms of affiliation that are less involved or committed, that reflect different development stages, and that account for the changes and dynamics that the different types of affiliations undergo. We further assert that it is necessary to develop a typology for the different forms of brand community, tribes, and subcultures. Fournier and Lee (2009) offer interesting ideas on different brand community forms, but their conceptualizations present some difficulties. Their categories are neither exhaustive nor exclusive. Based on their definitions, Apple could be said to exhibit characteristics of both pools (shared goals and values) and hubs (admiration for an individual via the centrality of Steve Jobs). Moreover, it is not clear from their descriptions whether or not all three of their forms possess the three key markers derived by Muñiz and O'Guinn (2001) from the sociology of community. Thus, it is unclear if these three forms are even brand communities. Still the notion of the source of the unity for the collective is valuable and should be included in any such typology.

Renewing Subcultural Ideology: Reclaiming Surf's Soul

EXTENDED ABSTRACT

Can a subculture's ideology endure in the face of mainstreaming? Subcultures often undergo an "identity crisis" when they are mainstreamed (Schouten, Martin, and McAlexander 2007; Thompson and Coskuner-Balli 2007), or when consumption practices associated with a subculture become popularized through commercial activities. Although mainstreaming results in increased interest in the subculture, tension also arises when members feel the subculture's authenticity is undermined (Thompson and Coskuner-Balli 2007; Schouten, Martin, and McAlexander 2007). In more extreme situations, the subculture's power to provide the context for self-authentication and authoritative performances is severely diminished as the subculture is no longer seen as an operant resource (Arnould, Price, and Malshe 2006).

To date, research on how subcultures respond to mainstreaming has focused on exit (whereby original members leave the subculture), or loyalty (whereby original members stay within the subculture) (Goulding and Saren 2007; Schouten, Martin, and McAlexander 2007; Thompson and Coskuner-Balli 2007), resulting in tension, fragmentation (Thompson and Coskuner-Balli 2007), and in some cases decline (Fox 1987). However, others have also implicitly identified an alternate response where the enduring power of many counter-cultural images or subcultures can be explained by cultural entrepreneurship, or the ability of the subculture to rework mainstreaming threats into an evolving narrative that continues to work for the majority of members (Heath and Potter (2005)) (see Belk and Costa (1998), Kates (2002), and Kozinets (2001) for specific examples of "reworking"). Building on the seminal framework of Hirschman (1970), we highlight that the benefits to subcultural endurance of "voice with loyalty" strategies demand greater attention in research on subcultural processes (Holt and Thompson 2004; Humphreys 2010).

Based on four years of ethnographic research in the Australian surf culture, we examine the means by which surfers ensure the endurance of the core ideology lying at the heart of their subculture. The ideological conflict at the heart of Australian surfing involved tensions between "soul surfers" (defined by their intrinsic love of surfing for its own sake) and "competitive surfers" (the latter of which were seen as the bearers of mainstreaming). Mainstreaming manifested itself within the community in three ways: breaching key performance norms, de-ritualization of subcultural performance, and the loss of object-indexicality. The tension arising from these three outcomes not only challenges the dominant ideology of soul surfers but also has a significant negative impact for all surfers as increased aggression on the beach and in the water leads to a collective "race-to-the bottom" (Heath and Potter 2005) whereby everyone's ability to achieve self-authentication is reduced.

We identified managing dialectical conflict between opposing ideologies as being central to Subcultural endurance and renewal in the face of mainstreaming. For an ideological dominance to endure, soul surfers needed to find creative solutions to the following dialectical conflict: freedom vs. anarchy; rebellion vs. conformity; and authenticity vs. fashion. To navigate these dialectical conflicts, soul surfers deployed four voice related tactics at the intra-, outer-, and inter-cultural levels to achieve three critical subcultural outcomes (threat identification, narrative updating, and attracting new recruits). These voice tactics were: creating new symbolic community boundaries (through emphasizing iconicity and indexicality), rewriting the motives of key subcultural actors (such as successful competitive

surfers), and de- and re-mythologizing cultural artifacts (such as clothing and surf boards).

Our research highlights that subcultures are decidedly more resilient in the face of commercial co-optation or mainstreaming than is often depicted in the literature. To date, much of the literature has described the relationship between subculture and commerce in terms of conquest, "selling out", and/or dilution, typically focusing on how subcultures have declined in terms of their wider cultural impact and as resources for members' life projects, or how they have been reconstituted into new cultural realities through exit. In contrast, we contend voice is central to ideological endurance in subcultures because consumers' emotional bonds remain only as long as they can keep a narrative going.

Consumption Communities

EXTENDED ABSTRACT

An unwelcome consequence of the resurgence of the concept of community in marketing and consumer research studies is the plethora of accompanying terms to describe these different forms and types of community. In this work, we clarify three of the most common community concepts to identify the difference between subcultures of consumption, brand communities, and consumer tribes. In doing so, we focus on consumer tribes and articulate the distinctive characteristics of tribes, discussing the marketing implications arising from these characteristics.

Sub-cultures of Consumption. Early theories of subculture described communities that developed strong interpersonal bonds, ritualized modes of expression, and beliefs that precluded other social affiliations in order to subvert dominant institutions such as family, schooling, and class politics (Goulding et al. 2002). Research in marketing contributed to this perspective by describing the "shared commitment to a particular product class, brand or consumption activity" that often features within subcultural communities (Celsi et al. 1993; Schouten and McAlexander 1995 p. 43). Further research, however, has explained that unlike sociological studies of subculture, consumption communities rarely display political resistance, robust social structures, or firm gender hierarchies (Martin et al. 2006). Moreover, consumers enjoy membership of a plethora of fragmented groups in which identity is constructed and discarded at will (Firat and Venkatesh 1995). Characterized as self-selecting micro-communities, these groups construct multiple trajectories of identity held together by temporary experiences and consumption activities (Belk and Costa 1998; Kates 2002; Kozinets 2001; Schouten and McAlexander 1995).

Brand Communities. A popular means to describe such micro-communities focused on brands is 'brand community,' a set of social relationships that are structured around the use of a focal brand (Muñiz and O'Guinn 2001). Shifting the emphasis away from consumers' reactions to alienating social structures, studies of brand community suggest that the shared use of products and services structures interpersonal connections amongst likeminded individuals, as well as distinction from non-users of focal brands (Muñiz and O'Guinn 2001; McAlexander and Schouten 1998; Schau et al. 2009). In particular, brand communities generate shared rituals and ways of thinking and traditions, as well as a sense of moral responsibility towards other members, and religious zeal towards the focal brand (Muñiz and O'Guinn 2001; Muñiz and Schau 2005). These characteristics enhance the co-creation of value by consumers and firms by upholding brand values, maintaining appeal, increasing members' affiliation and commitment to the brand and offering managers dialogue with loyal consumers (Brown et al. 2003; Fournier et al. 2001; McAlexander et al. 2002; Schau et al. 2009).

Consumer Tribes. Despite the theoretical usefulness and descriptive power of brand community and consumption subcultures, recent research has found that many consumption communities do not locate their socialization around singular brands or activities. Rather, consumer tribes exist when members identify with one another, have shared experiences and emotions, and engage in collective social action all of which can be facilitated through a variety of brands, products, activities, and services (Cova and Cova, 2002). What our research contributes to is to explain how these tribes form and how this interplays with marketing actions.

Consumer tribes differ from subcultures of consumption and brand communities in a number of important ways (Cova 1997; Cova and Cova 2002; Cova et al. 2007). First, tribes are multiple. Unlike subcultures of consumption and brand communities, tribes rarely dominate consumers' lives. Rather, they represent temporary escape from the stresses and pressures of the working week (Goulding et al. 2002) and membership of one kind of tribe does not preclude membership from other tribes or communities. On the contrary, tribal theory stresses the occurrence of flows between different identities under different circumstances (Bennett 1999).

Second, tribes are playful. Tied to multiplicity of membership and fluidity of identity, tribal consumption is often devoid of the long-term moral responsibility or religious zeal felt by members of a brand community (Muñiz and O'Guinn 2001; Muñiz and Schau 2005), or the respect afforded to social hierarchies and core products or activities exhibited in subcultures of consumption (Schouten and McAlexander 1995). Instead, value is placed on the possibility to invigorate passion and generate social links through deconstructing and reassembling marketplace resources (Cova et al. 2007).

Third, tribes are transient. Connected to these features of multiple identity and play, tribes emerge, and disappear as combinations of people and resources alter. This generates unpredictable and emergent processes of consumption that may be critical and liberatory at one moment, yet at the next moment mean little beyond sensory intensity and pleasure (Goulding et al., 2009). This playful acceptance of rapidly changing and contradictory meanings engenders a balance of power between consumers and producers that oscillates between manipulation and emancipation (Cova et al., 2007).

Fourth, tribes are entrepreneurial. Stemming from the possibilities for play, and an empowered and emancipated attitude to the market, are new paths for entrepreneurial ventures (Cova et al. 2007). Rather than relying on ready-made consumption resources, tribes regularly produce and customize market offerings (Kozinets 2001; 2007). These practices of bricolage alter the power balance between marketers and consumers, as tribal members take the lead in dictating procedures of co-production (Shankar et al. 2006).

Tribes offer a useful means to describe communal experiences of consumption that differ from consumption subcultures and brand communities. Tribes are not enduring subversions of dominant institutions as subcultures often are, nor do they seek iconic brands as loci for consumption experiences like brand communities. On the contrary, within tribes, the social links established between consumers– or consumer-to-consumer linking value– are more important than whatever is being consumed (Cova 1997). Moreover, unlike both subcultures and brand communities, community membership is fragmented and transient. These defining characteristics mean that the approaches to leveraging subcultures or brand community are inappropriate (e.g., Algesheimer et al. 2005; Holt 2004; McAlexander et al., 2002; Schau et al. 2009).

Compounding this problem is a tendency for tribal thinkers to favor theoretical descriptions of the commonalities and ordering structures of tribes over methods of leveraging tribes. Some authors have conceived of tribes as *marketing-proof*, capable of eluding attempts to manage or control them (Cova et al. 2007; Kozinets 2002). Others suggest that tribes are too fragmented, messy and illogical to manage effectively. Instead, managers are advised to acknowledge and respect the autonomy and integrity of a tribe (Cova and Cova 2001). Our task therefore is to investigate and explain how consumers form tribes in a manner that can be understood and replicated. In order to achieve this, we use communities of practice (Wenger 1998; 2000) as a theoretical means to understand how consumers build tribal communities and learn to be tribal.

The Face as a Picture of the Mind

Paper #3: Looking Into Future's Mirror: How Representations of the Aged Self Impact Impatience

Oleg Urminsky, University of Chicago, USA
Daniel Bartels, Columbia University, USA

SESSION OVERVIEW

As Cicero observed long ago, the face is a picture of the mind. In this symposium, we explore how facial perceptions can impact decisions related to voting, dating, sales, and personal finance. Talks will focus on both real images of faces and those that have been altered using morphing technology. The session presents novel findings using facial manipulating and judgment, an emerging research method for studying holistic decision making.

How people perceive, judge, and evaluate faces has been a central construct in basic social psychology, yet has received relatively little attention in consumer behavior. Building on methods that use novel facial morphing technology, the proposed session will contribute to a better understanding of how consumers use information about facial images to inform their decisions. The papers investigate how different aspects of facial images can affect voting decisions, mating choice, purchasing intentions, and long-term financial decision-making. This session will unify the findings of the individual papers into a broader framework for investigating the impact on consumer choice on how consumers perceive and are affected by images of the face. In contrast with much of the decision making research on these topics which focuses on deliberate processing of information, facial stimuli present an ideal context in which to systematically study the role of spontaneous holistic thinking.

In the first paper, **Olivola, Eastwick, Finkel, Ariely and Todorov** use experimental methods combined with naturalistic data from real elections, a major online dating site, and speed dating events, to show how appearance-based social inferences impact two important decision-making domains: political choice (voting) and mate choice (dating). Olivola and colleagues show how different aspects of facial appearance impact decision-making as a function of both context and the perceiver's context. In the domain of voting, the more a political candidate looked like a Republican (i.e., the greater portion of naive raters who guessed that the candidate was actually a Republican) the larger that person's vote share in conservative states, regardless of whether the candidate as actually a Republican or not. In terms of dating behavior, using data from an online data set as well as a speed-dating experiment, Olivola and colleagues demonstrate that appearing fun and outgoing afforded benefits to both male and female

male daters, while appearing smart and serious was positively related to dating success for males, but hurt females.

Next, **Tanner and Maeng** investigate the effect of morphing unfamiliar faces with those of well known public figures. Across four studies, using a variety of measures, participants show a clear preference for the morphed faces, despite a complete lack of conscious recognition of the public figures in question. This effect is shown to reverse in a set of studies conducted before and after the Tiger Woods scandal, in which unfamiliar faces were imperceptibly morphed with Woods.

In the third paper, **Urminsky and Bartels** explore the role that facial cues play in inferences and judgments concerning the self. Participants were shown photos of themselves that had either merely been aged (low change) or had been aged and also morphed with a generic demographic match (high change). When participants were prompted to first focus on their present selves, subsequently seeing high-change representations of their future selves increased willingness to pay to expedite future benefits.

Finally, discussant **Hershfield,** who has done recent work on the role of facial perception and emotion in intertemporal choice, will offer a broad discussion of the contributions of the individual papers. In contrast with a traditional discussant role, Hershfield will also describe and contrast the different facial morphing methods that have been used to impact consumer behavior. Specifically, he will present a brief primer on the ways that facial morphing technology can be used in consumer research, and will discuss the relative benefits and disadvantages of various morphing techniques (e.g., using avatars (digital representations of people) versus photographs) and software packages.

Given the relevance of the proposed topic to central issues in consumer research, this session is likely to have a significant effect on future research in a number of areas and contribute to a multi-disciplinary approach to studying facial perception and its relationship to decision-making. The goal of this session is to both present intriguing new research which employs these methods as well as to provide practical in-context information to scholars who wish to employ facial perception and facial morphing in their research. Thus, we anticipate broad interest in this session among consumer researchers. The papers employ a variety of approaches (lab and field studies, as well as the use of cutting edge technology), and the session will offer a broad perspective on the ways in which the image of the face can play a role in consumer behavior. Data collection in all papers is complete and all participants have agreed to present, should the session be accepted.

A Picture is Worth a Thousand Inferences: Appearance-Based First Impressions Predict Leader Selection and Mate Choice

EXTENDED ABSTRACT

Of all the things that people might want to carefully market, perhaps the most important is themselves. We often form opinions about the characteristics of other people from single, static samples of their appearance –the very first thing we see when, or even before, we meet them. These appearance-based first impressions of a person's characteristics can have an important impact on subsequent judgments and decisions concerning that person. Furthermore, recent research has shown that these inferences occur spontaneously and rapidly, making

them difficult to recognize or control. This talk explores the impact of appearance-based social inferences in two important decision-making domains: political choice (voting) and mate choice (dating).

In the first part of the talk, we briefly review evidence that politicians who happen to possess faces that make them look competent enjoy greater electoral success, and describe recent modeling efforts to extract the physiognomic features that govern facial competence using multi-dimensional computerized facial stimuli. We then present the results of a new study that further illustrates the surprisingly powerful influence of candidate appearances on elections. Participants in this study were shown photos of actual U.S. political candidates running for Senator or Governor. In particular, they were shown pairs of headshots representing the two rival candidates and asked to guess which one was the Republican (or Democrat). We find that the more a candidate looks like a Republican (i.e., the greater the proportion of participants who guessed that he/she was the Republican) the larger that person's vote share in conservative states, regardless of his/her actual affiliation. In contrast, we found no such relationship in liberal states, suggesting that voting in those states is less influenced by candidate appearances. The relationship between looking conservative and electoral success in right-leaning states holds when we control for incumbency status or candidate age differences, and even when we only consider elections involving Caucasian male candidates. Furthermore, we find that the looking conservative (vs. liberal) is unrelated to looking attractive, competent, or trustworthy, suggesting that the apparent effect of facial conservatism/liberalism is unrelated to inferences of more basic personality traits. These results are particularly surprising when we consider the fact that candidate photos and their political party affiliations are provided on the voting ballots.

In the second part of the talk, we turn to the domain of mate choice (dating). We describe a pair of studies examining the impact of first impressions on online matchmaking and speed dating success. Using two naturalistic data sets of real daters interacting through a major online dating site and at speed dating events, we examined the relationship between appearance-based personality trait inferences and romantic success (as measured by emails received and successful matches). Judges were shown photos obtained from the dating site or taken at the speed dating events and, using only these photos, rated daters along various personality dimensions. We find that these photo-based personality trait inferences significantly predict dater success in both the domains of Internet matchmaking and speed dating. Appearing fun and outgoing was positively related to success for both male and female daters (i.e., they we contacted by more online dating users and selected by more speed daters). In contrast, while appearing smart and serious was positively related to success for male daters, this relationship was reversed for female daters, so that women whose profile photos made them look more smart-serious attracted fewer male online dating site users. Most of these relationships remain significant when we control for attractiveness, ruling out the possibility that our results can be entirely explained as halo-effects of beauty. Furthermore, even after controlling for self-reported demographics and relationship preferences provided by daters in online profiles and speed dating questionnaires, personality trait inferences still significantly predict dater success. This suggests that photo-based first impressions can impact a decision to contact a potential mate, even when relevant information about the person is readily available. Finally, our unique data sets also allow us to measure the predictive impact of appearances in terms of other tangible dimensions. For example, we find that for male users, each standard deviation increase in how fun-outgoing one looks is equivalent to growing 7.57 inches (19.04 cm), receiving a $32,399 raise, or to a 1.5 standard deviation increase in physical attractive-

ness. Whereas for female users, each standard deviation increase in how smart-serious one looks is equivalent to gaining 46.5 pounds (21.3 kg), receiving a $27,404 salary cut, or to a standard deviation decrease in physical attractiveness.

In sum, these results suggest that, in spite of the old adage warning us not to "judge a book by its cover," people form opinions about the characteristics of others from single, static samples of their appearance and that these impressions, in turn, can even impact who they choose as leaders and lovers.

Familiarity Hijack: Imperceptible Celebrity Facial Cues Influence Trust and Preference

EXTENDED ABSTRACT

Social psychologists have long observed that individuals have a preference for people similar to themselves (Shanteau and Nagy, 1979; Park and Schaller, 2005). More recently, researchers interested in facial similarity have used new graphical technology to morph individual's own faces into the faces of others. For example, Bailenson et al. (2009) created composite images by morphing the faces of politicians with the faces of experimental participants in a ratio of 65% politician, 35% participant. This ratio is significant as the authors demonstrate that it produces composite faces within which individuals could not perceive their own image, instead believing they were viewing unaltered pictures of the politicians in question. However, attitudes toward the composites reflected a different story, with participants consistently demonstrating stronger liking for the images containing 35% of their own face, despite reporting no conscious awareness of recognizing face in the composite images.

This finding raises several interesting theoretical questions. In particular, it is not clear if liking for the composite faces was driven by similarity (as the authors argued) or familiarity since the two are essentially confounded when morphing an individual's own face into a composite image. Furthermore, familiarity could itself encompass multiple possible mechanisms, including full implicit recognition (i.e. sufficient to report trait assessments of the minority face in the morph) or implicit recognition sufficient only to retrieve a high level valence judgment of him or her. The current work explores these issues by examining the effects of morphing the faces of public figures into unfamiliar faces. Since the faces of public figures are familiar but not similar to the average individual, they provide us with a potential method of teasing apart the previously confounded effects of similarity and familiarity.

In Study 1 (N=109) participants rated the trustworthiness (a key component of source credibility) of two faces on a -5 to +5 scale. Face one (henceforth "Tiger morph") consisted of a male neutral male face morphed with 35% of the face of Tiger Woods. Face 2 ("Control morph") was the same neutral face morphed with 35% of the face of a stock model of similar age and attractiveness to Tiger Woods. Both composite images were pretested and found to be equally attractive. However, participants rated the Tiger morph as being significantly more trustworthy (M = 1.75) than the control morph (M=0.95; t(107)=-2.2, p < .03). This result pertained despite 100% of subsequently debriefed participants expressing no recognition of Tiger in the composite image. As such, these data support a familiarity explanation as underlying the effect of facial morphing on preference, but are inconsistent with a pure similarity explanation.

Study 2 was a replicate of study 1 designed to explore whether the positive trust result accrued from participants being able to report specific trait information about Tiger (which implicit recognition might enable), or whether it was simply due to participants accessing general positive perceptions of Tiger. The study was identical

to study 1 except that a 1-10 scale was used, and participants were additionally asked to report their perceptions of the athletic ability of the individual pictured. Consistent with study 1, participants rated the Tiger morph (M = 5.33) as more trustworthy than the control morph (M = 4.0, t(31) = -1.9, p < .07). However, they perceived no difference between the athletic ability of the Tiger morph (M = 2.1) and the control morph (M = 2.4, p > 0.3). As such these data support the more general valence explanation as driving the positive effect on trust, and are inconsistent with an explanation based on full implicit recognition of the individual in question.

Study 3 (N=319) enabled us to further explore whether implicit perceptions of the the general valence of the celebrity in question drove our results to date. Participants rated their likelihood to buy (1-10 scale) from one of two salesman. Face one ("control morph") was a neutral salesman image morphed with 35% of the same control face used in studies 1 and 2, while face two ("Tiger morph") consisted of the salesman face morphed with 35% of the face of Tiger Woods. Rather serendipitously, data was collected in two tranches, both before - and at the peak of - the Tiger Woods scandal. Thus study 3 was a 2 Familiarity (Tiger vs. control) X 2 Timing (pre-scandal vs. post scandal) design. Results indicated no main effect of familiarity or timing but a significant interaction between the two (F = 13.2, *p*<.001). While pre-scandal participants indicated they were more likely to buy from the Tiger morph (MTiger = 1.5, Mcontrol = 1.0) this pattern reversed post-scandal (MTiger = -.1, Mcontrol = 1.0). These results thus further support the idea that implicit recognition (of Tiger) took place to a degree sufficient for an overall valence judgment to be reported to consciousness.

One problem with studies 1 to 3 was that in each task participants were instructed to make the relevant judgments based only on the face pictured. This leaves open the possibility that the morphing manipulations may have had little effect without our explicit direction to focus on the faces, which would clearly reduce the marketing implications of the findings. To address this issue, in study 4 (N=104) participants were simply asked to view an ad for the charity Doctors without Borders, and then to rate how likely they would be to donate to the charity (1-10 scale). The ad consisted of a logo, a supposed picture of the CEO Nicolas De Torrente, and a statement from him requesting a donation. In fact, in the morph condition the pictured face consisted of the actual face of De Torrente morphed with 35% of the face of Tom Hanks, while in the control condition that face pictured was genuinely De Torrente. Despite not being instructed to pay attention to the facial component of the ad, participants reported a greater likelihood of donation (M=3.7) in the Tom Hanks condition than in the control condition (M=2.8; *t*(102) = 2.3, *p* < .03).

Looking Into Future's Mirror:
How Representations of the Aged Self Impact Impatience

EXTENDED ABSTRACT

A great deal of research has attempted to explain people's intertemporal choices, often by investigating how people think about the future in general, as well as their future needs and the future consequences of their actions. Recent research has suggested an equally important role of the way that people think of their future selves, specifically the degree to which a person feels connected to their future self (e.g. Parfit 1984, Ersner-Hershfield, Wimmer, & Knutson, 2009, Bartels and Urminsky 2010). In Bartels and Urminsky (2010), for example, participants who were manipulated (via informational or metacognitive cues) to believe that the defining elements of their personal identity would remain more stable over time were then more willing to forego near-term consumption for long-term benefits.

In this paper, we argue that visualization plays a key role in how people feel about their relationship to the future self. In particular, we propose that imagining one's future self or seeing a representation of the future self will affect how people feel about their future selves. Given the automaticity with which people process facial information, we propose that thinking of one's future self as having a more dissimilar face will correspond to a reduced motivation to provide benefits for the future self. In particular, we argue that it is the contrast between the current self and a dissimilar future facial representation of the self that reduces this motivation.

In the first phase of Study 1, we photographed participants' faces and created two representations of their aged face. The first picture merely used aging software to create a picture representing what the participant might look like when they were older. The second picture first morphed the participants' face with a generic gender and race matched face, and then applied the aging software with the same parameters. Final corrections and adjustments for hair color were conducted for both in Photoshop. These pictures were then extensively pre-tested with a separate group of participants (at a separate location, unfamiliar with the first set of participants) to assure equivalence in estimated age, attractiveness and other factors across the two photos for each participant.

In the second phase, conducted a few weeks later, participants were invited to return to the lab. They were asked to enter their current email address and then were shown one of the two pictures at random, either their merely-aged face (meant to represent minimal change) or their morphed-aged face (representing significant change while aging). Our hypothesis was that participants would spontaneously conflate visual facial change with change to personal identity and, based on prior connectedness research, would be more impatient when viewing the high-change picture. We find that participants viewing the high-change picture (vs. the low change picture) were willing to pay more in order to expedite a $100 gift certificate that they would otherwise receive in a year.

We find that participants in the merely-aged condition were more patient, and were not willing to pay as much to expedite the gift certificate, compared to participants in the morphed-aged condition. This effect cannot be accounted for by the perceived attractiveness or competence of the future self.

In Study 2, we use a similar methodology to replicate the effect with a new sample several months later. In addition, we manipulate the degree of current self vs. future contrast by asking participants in the present-salient condition to type in their current email address (as in Study 1, emphasizing the present self) before being asked to consider a picture of their future self. In the future-salient condition, participants did not enter their current email and were asked to direct their attention to picture of their future self. We find that participants in the present-salient condition replicate the effects of Study 1, and are willing to pay less when shown a more dissimilar picture of their future self. However, in the future-salient condition, the effect was reversed, such that participants were actually willing to pay more to expedite the future benefit when viewing the merely-aged face, consistent with viewing the more similar future self as sharing the same pool of resources.

Combining across the two studies, we find that participants who focus on the future picture are willing to spend *more* to speed up the gift certificate when looking at the more similar face ($42 vs. $27). In contrast, when participants' attention is first directed to their current self before looking at the future self picture, they are willing to spend less to expedite the gift certificate when the picture is more similar ($17 vs. $24, interaction p<.05).

A Longitudinal Study of Consumers' Need for Uniqueness on Development of Networks

Seung Hwan (Mark) Lee, University of Western Ontario, Canada

Gail Leizerovici, University of Western Ontario, Canada

ABSTRACT

Based on a longitudinal field study of a college dormitory network, we find that the three components of consumer's need for uniqueness (CNFU) each play a distinct role in the development of a consumer's social network. Results suggest the rate of individual's network growth (perceptual and actual) depends on individual's CNFU.

Research suggests consumers with high need for uniqueness may be both successful and unsuccessful in maintaining and attaining social relationships (Lynn & Harris, 1997; Snyder & Fromkin, 1980; Tian, Bearden, & Hunter, 2001). Unique individuals exhibit an exclusive appeal that elicits positive social evaluations (e.g. a person displaying a creative style of fashion such as a seven button suit). On the other hand, unique individuals may encounter social disapproval if they choose to be too extreme with their consumption choices (e.g., a person displaying an odd form of fashion such as an orange spandex suit). Despite these presumptions, there has been no direct attempt to explicitly investigate the social benefits and costs of being unique on the development of individuals' social network. While scholars have speculated on the social consequences of being unique (e.g., Snyder & Fromkin, 1980; Tian et al., 2001), we do not know the impact which unique consumers have on their friendship selection processes. In response, we explore an emerging social network (longitudinally) to investigate the effects of consumers' need for uniqueness (CNFU) on individuals' social network development.

There are reasons to suggest that being unique in a network can have positive and negative consequences to individuals' social network development. For instance, being too unique can result in social sanctions (Ruvio, 2008). Consumers sometimes use products that deviate from social norm (Tian et al., 2001); breaking rules or challenging existing rules at the risk of social disapproval results in negative evaluations such as the perception of poor style (Tian et al., 2001). Thus, individuals may encounter negative social reactions and social disapproval which in turn constrains one's social network development (i.e., make less friends). Conversely, scholars have suggested that the desire for uniqueness is influenced by the individual's need for social assimilation and social approval (Ruvio, 2008). Here, uniqueness is sought only to the point where it precludes individuals from social isolation or strong disapproval (Snyder & Fromkin, 1980). In such cases, consumers may use distinctiveness as an opportunity to elicit positive social evaluations through making creative choices that enhance their personal style. That is, individuals distinguish themselves in the hopes of obtaining greater social rewards (Santee & Maslach, 1982). Thus, being unique is beneficial to one's social network development (i.e., make more friends).

Given that the literature has identified that being unique has both positive and negative consequences for the consumer, our present research investigates the social benefits and costs of CNFU on individuals' social network development. Regrettably, research in this domain has a limited understanding of how CNFU influences networks. While previous research has implied numerous social outcomes for unique individuals (Ruvio, 2008; Tian et al., 2001), not much is known about how relationships are formed and maintained over time. For this reason, the current study is designed to explore the effects of CNFU on the dynamic transformation of individuals'

social network. Specifically, we ask the following questions: how does CNFU positively or negatively affect the dynamic growth of individuals' social network? How does CNFU influence consumers' choice of friendships and their ability to attract friendships in an emerging social network? These research questions provide a guiding framework for our study.

Findings from our longitudinal network research contribute to the extant literature in two distinct ways. Theoretically, we show that the extent to which individuals actively widen or condense their social network is dependent on whether they are creative with their identity or avoid peers that have similar identities. Further, the extent to which unique consumers are able to attract friendships is dependent on whether their unique display is within the confines of group norms. Furthermore, we find differences in how CNFU affects individual's perception of their social network vs. their actual network (as rated by others). These findings add to the current stock of knowledge and validate the important role of CNFU in consumer networks. Methodologically, this is one of the first longitudinal studies in consumer behavior to track the developmental patterns of an emerging social network. Using the latest social network method, the current research introduces an actor-based modelling technique (Snijde, van de Bunt, & Steglich, 2010; Snijders, Steglich, Schwinberger, & Huisman, 2007) to observe the unique effects of CNFU on individuals' social network development.

CONCEPTUAL FRAMEWORK

There is plethora of evidence to suggest that consumers have a desire to differentiate themselves from others or to "counterconform" (Berger & Heath, 2007; Snyder & Fromkin, 1980; Tian et al., 2001). Counterconformity is an individual's motivation to maintain a sense of distinctiveness; people constantly define themselves on various self-related dimensions in order to develop their exclusive social identities (Tian et al., 2001). Furthermore, when people see themselves as highly similar to others, they become motivated to seek a unique personal identity within their social environment (Berger & Heath; 2007; Snyder & Fromkin, 1980). For example, individuals who were led to believe that they were similar to others subsequently attached greater importance to being independent, placed a higher value on rare items, generated more unusual uses for an object, and conformed less with others on judgment tasks (Duval & Wicklund, 1972; Fromkin, 1970).

According to uniqueness theory, consumers are known to purchase products that serve as expressive symbols of uniqueness (Snyder & Fromkin, 1980; Tian et al., 1977). Individuals are motivated to acquire unique possession for the purpose of determining and shaping their self-image, as well as using these possessions to establish individuality within their social networks (Lynn & Harris, 1997; McAlister & Pessemier, 1982). Acquiring unique possessions ultimately provides the opportunity to signal and communicate a desired identity to others (Berger & Heath, 2007). Given that consumers are known to counterconform, this also reflects the underlying motivation behind consumers' need for uniqueness (CNFU), the trait of interest in our longitudinal study.

Consumers' Need for Uniqueness (CNFU)

Conceptually, CNFU is "the trait of pursuing differences relative to others through the acquisition, utilization, and disposition of consumers goods for the purpose of developing and enhancing one's self-image and social image" (Tian et al., 2001). Thus, CNFU is a personality trait that is related to uniqueness theory, where the underlying self presentation goal entails choosing options that have carefully considered social consequences (Worchel, Lee, & Adewole, 1975; Tian et al., 2001).

Extant literature has identified that consumers vary in the manner which they exhibit counterconforming behaviors (Ruvio, Shohan, & Brencic, 2008; Tian et al., 2001). In particular, CNFU has demonstrated that consumers can express their counterconformity via three distinct behaviours: creative counterconforming behavior, unpopular counterconforming behavior, and avoidance of similarity behavior (Ruvio et al., 2008; Tian et al., 2001). CNFU is regarded as the higher order construct that encompasses these three distinct counterconforming dimensions. Given that there are conceptual differences among the three dimensions, we predict each type of counterconforming behavior will play a distinct role in individuals' social network development.

Creative choice counterconformity (CC) refers to an individual's ability to acquire and use products that reflect a personal style which is socially accepted and valued by others (Snyder & Fromkin, 1977; Tian et al., 2001). Individuals with a high need for CC strive to establish a unique identity without risking their social reputation or image (Snyder & Fromkin, 1980). While creative choices involve some risk (Kron, 1983), these acts are made strategically in order to obtain positive social evaluations and approval from their network of friends (Santee & Maslach, 1992; Snyder & Fromkin, 1977). An example of this might be the choice to purchase and use a socially accepted electronic product, such as an iPad, in a manner that is creatively different from the norm. Thus, CC reflects individual's ability to create a personal style that is viewed as socially acceptable. It is expected CC will have a positive effect on individuals' social network development (i.e., make more friends) over time.

In contrast, consumers may make "unpopular" choices that are considered unacceptable and thus display a behavior that risks social disapproval. Unpopular choice counterconformity (UC) refers to an individual's selection of products or brands that reflect norm-breaking consumption behavior (Tian et al., 2001). Individuals with high need for UC face the risk of social disapproval because their choices may be considered taboo and socially unacceptable (Tian & Bearden, 1992). For example, an individual's choice to refrain from spending, or "downshift" (see Schor, 1998) may appear to counterconform with popular consumer culture. Such behavior may be judged as socially norm-breaking, such as when a "downshifter" decides to live off only the basic necessities. While it is possible that these choices may gain social approval over time (Heckert, 1989), violating social customs may initially draw negative social reactions from others (Santee & Maslach, 1982). In consequence, this form of behavior is likely to lower a person's social image and reputation in his or her social circles (Tian et al., 2001). Thus, UC reflects the individual's desire to challenge social norms via their engagement in unpopular decisions. It is expected UC will have a negative effect on individuals' social network development (i.e., make less friends) over time.

Finally, avoidance of similarity (AS) refers to an individual's desire to discontinue the use of or have the loss of interest in products which are mainstream in the market (Tian et al., 2001). Avoiding similarity prompts individuals to suspend the use of their current possessions and resist purchasing widely adopted products in order to avoid appearing similar to others (Ruvio, 2008). Individuals with high need for AS seek innovative trends to resist conformity (Thompson & Haytko, 1977). For example, they avoid similarity by pursuing a "minority choice" that establishes their dissimilarity from others (Tian & Bearden, 1992). This perspective embodies a rejection of popular mainstream products to subsequently enforce the individual's uniqueness via their dissimilarity. For example, an individual high in AS may choose to only purchase and wear vintage clothes. In this manner, this individual is avoiding and resisting mainstream trends and products in lieu of lesser known ones. Thus, AS is driven by an individual's motivation to avoid similar others by engaging in consumption that is deemed to be dissimilar. Further, in the pursuit of avoiding similar others, such individuals may be perceived negatively. Appearing dissimilar may result in subsequent negative judgments as such extreme consumption displays contradict socially approved signalling behaviors (i.e. see Colarelli & Dettmann, 2003). As a result, it is expected AS will negatively affect individuals' social network development over time.

METHODOLOGY

To test the influence of the three types of counterconformity, we conducted a longitudinal field study. This field study uses social network analysis to track the changing and dynamic patterns in an emerging social network. Social network analysis (SNA) has emerged as a key technique in modern research to develop a better understanding of the structures of relationships and their effects on behavior (Wasserman & Faust, 1994). Network analysis investigates the quantitative structural properties of networks which typically cannot be extracted from a study of individual or dyadic relationships (Webster & Morrison, 2004). The network data collected allows researchers to trace the connections between individuals (linkages and ties), which cannot be realized through a traditional sample survey method. Other marketing studies on CNFU that have attempted to capture relational data using traditional sample survey methods and the use of retrospective data suffer from inaccuracy in describing properties of the networks and the connections between individuals (c.f. Reingen & Kernan, 1986; Iacobucci & Hopkins, 1992). With SNA, this method allows the gathering of information from all members included within a network. This ultimately provides a significant advantage to understanding how CNFU influences social network development. Moreover, this study introduces a stochastic actor-based model to observe the change in network dynamics over time (Snijders et al., 2010). The following study captures these relational changes and simultaneously assesses the effects on CNFU on these network changes.

PARTICIPANTS AND PROCEDURE

The data were collected from 71 first year college dormitory students from a single floor at a large North American university. Participants filled out questionnaires at two different time-periods. At both time periods, a paper-and-pen questionnaire was administered for every student living on the floor. Time 1 (T1) data was collected approximately 5-6 weeks after the start of the academic school year to allow participants to have some perception of their social network. Time 2 (T2) data was collected 5-6 weeks after the start of their second semester (early February). At T1, 76 of 83 students (response rate of 92%) provided usable data for analysis. At T2, 71 of 83 students (response rate of 86%) provided usable data for analysis. However, to ensure parallel comparison between the two time-periods, we included only those that have responded in both time-period. Thus, five participants were dropped from the T1 data. Figure 1 is a graphical display of the social network over time.

Friendship Nomination. In both time periods, participants were asked to indicate their social relationships with every other student on their floor. Students were provided an alphabetical listing of all of the occupants and were asked to rate their level of friendship (1 – do not or barely know; 2 – acquaintance; 3 – friend; 4 – close friend) with every other student on the floor.

Figure 1:
Diagrams of Network Change over Time: College Dormitory Network

Time 1

Time 2
The data then was arranged into an NxN binary matrix (Wasserman & Faust, 1994). Each cell (Xij) in this matrix corresponded to i's relation to j as reported by i. Then, the network matrix was used to calculate individual's out-degree ties (the total number of people the focal person nominated as friends or close friends) and their in-degree ties (the total number of people that nominated the focal person as a friend or a close friend). Out-degree is considered to be a measure of the individual's perception of popularity and in-degree is considered to be a measure of the individual's popularity (as rated by others) in a social network (Freeman, 1979; Lee, Cotte, & Noseworthy, 2010). Given that this was a longitudinal study, we were able to track the change in development of out-degree ties and in-degree ties over time. Providing a list of participants to respondents (i.e. the roster method) helped us overcome potential recall biases and is considered to be a more reliable method of network data collection than asking respondents to come up with names on their own (Wasserman & Faust, 1994).

Consumers' Need for Uniqueness. Consumers' need for uniqueness was measured using a short-form 12-item scale adapted from Ruvio et al. (2008). A parsimonious measure of CNFU was used in favor of the original 31-item scale (see Tian et al., 2001) to minimize respondent fatigue. The 12-item CNFU index was scored on a 7-point Likert-type scale ranging from 1 to 7 with descriptive anchors "Strongly disagree" and "Strongly agree". Sample items on the scale included, "I often combine possessions in such a way that I create a personal image that cannot be duplicated" (Creative Choice), "When it comes to the products I buy and the situations in which I use them, I have broken customs and rules" (Unpopular Choice), and "I often try to avoid products or brands that I know are bought by the general population" (Avoidance of Similarity). Each component of CNFU included 4 items which was averaged to create a single factor for each dimension (for a total of three factors). An exploratory factor analysis confirmed that each of the dimensions loaded on its respective factors (.73 and above) with sufficient internal reliability (Cronbach alpha over .80). The CNFU index was assessed only at T1. CNFU was not measured again at T2 because conceptually, it is a stable trait that does not change substantially over time (Tian &

McKenzie, 2001). Methodologically, it was done to minimize survey length and respondent fatigue as each participant was asked to rate their friendship status with every other person on their floor.

DATA ANALYSIS

To analyze the effects of CNFU on individuals' social network development, a stochastic actor-oriented model of network dynamics was assessed using the SIENA 3.14 (Simulation Investigation for Empirical Network Analysis) software (Snijders et al., 2007). SIENA is part of the StOCNET program collection (Boer, Huisman, Snijders, & Zeggelink, 2007) that is used to carry out statistical estimation of dynamic actor-driven models. The actor-oriented model follows a Markov process where it is assumed that the properties of the next state depend on the properties of the previous state (Meyn & Tweedie, 1993). That is, the events of two time periods observed in this study were not assumed to be independent events. The actor-oriented model is useful for modeling network dynamics that can represent a wide variety of influences on network change, especially for representing theories about how actors alter their social ties over time (Snijders et al., 2010). This method is considered appropriate for observing the rate of change in networks and for observing the effects of personal characteristics on individuals' friendship selections over time. This technique has been successfully applied in other areas of research; scholars have investigated the effects of the big five personality traits, smoking, and delinquency behaviors on social network development (Burk, Steglich, & Snijders, 2007; Mercken et al., 2010; Selfhout et al., 2010). A technical and more detailed explanation of the processes and assumptions of this method can be found elsewhere (see Huisman & Snijders, 2003; Snijders et al., 2010).

The actor-oriented model, when elaborated upon for application use, contains parameters that are estimated from the observed data by a statistical procedure (Snijders et al., 2010). For instance, the effects of CNFU on the development of network ties are assessed by examining the parameter estimates of three selection effects: *ego effect, alter effect, and the similarity effect* (Burk et al., 2007). These selection effects are derived from a sociological understanding of relationships, where actual or perceived similarity (homoph-

ily) among friends is a result of the influence that an individual has (alter) on the focal individual (ego) (Kandel, 1978). In the context of our research, a positive (negative) ego effect implies that CNFU is positively (negatively) associated with an individual's ability to build social ties, and thus, is likely to increase (decrease) the number of friendship nominations made over time. A positive (negative) alter effect implies that CNFU is positively (negatively) associated with being attractive as a friend, and thus, is likely to result in an individual receiving more (fewer) friendship nominations over time. Lastly, a positive (negative) similarity effect implies that individuals prefer friendships with others that have similar (dissimilar) levels of CNFU (i.e., homophilous selection). Since the CNFU construct consists of multiple dimensions (creative counterconformity, unpopular counterconformity, and avoidance of similarity), these three selection effects were estimated for each of the three dimensions.

Moreover, additional effects were included in the final analysis as covariates. The analysis included three network effect covariates that naturally occur in developing networks (Mercken et al., 2010; Snijders et al., 2010). We included *density effect, reciprocity effect, and transitivity effect*. Density effect is the tendency for people to selectively nominate friends. A significant negative estimate implies that individuals do not nominate friends at random. Reciprocity ef-

fect is the tendency of individuals to reciprocate relationships. A significant positive estimate implies people tend to select those whom they share a dyadic relationship with. Finally, transitivity effect is the tendency for people to form triadic relationships over time. A significant positive estimate implies people tend to select friendships with those who are friends of friends. The inclusion of these covariates was necessary to ensure that the effects of CNFU were not confounded by these factors (Snijders et al., 2010; Wasserman & Faust, 1994).

The SIENA output provides parameter values for the selection effects and the network effects. Overall, a total of 12 parameters were simultaneously entered into a model: ego, alter, and similarity effects of each of the three CNFU dimensions plus the three covariates (density, reciprocity, and transitivity effects). The dependent variable is the change (or the lack thereof) in friendship ties from time 1 to time 2 (absent → present or present → absent). Table 1 summarizes and provides a description of each of the effects examined in this study. In addition to the studied effects, interaction terms were also created (CC x UC), (UC x AS), (CC x AS), (CC x UC x AS) and modeled separately in another analysis. However, none of the interaction terms revealed any significant results, and thus were omitted from the report.

Table 1
Description of Network and Selection Effects

Parameters	Descriptions
Network Effects:	
Density	General tendency to choose friend at random
Reciprocity	Tendency to reciprocate friendships
Transitivity	Tendency to prefer triadic closure (become friends of friends' friend)
Selection Effects:	
CC Ego	The rate CC determines social activity (friendship nomination)
CC Alter	The rate CC determines popularity (nominated by others as a friend)
CC Similarity	Preference for choosing a friend with similar CC (homophily)
UC Ego	The rate UC determines social activity (friendship nomination)
UC Alter	The rate UC determines popularity (nominated by others as a friend)
UC Similarity	Preference for choosing a friend with similar UC (homophily)
AS Ego	The rate AS determines social activity (friendship nomination)
AS Alter	The rate AS determines popularity (nominated by others as a friend)
AS Similarity	Preference for choosing a friend with similar AS (homophily)

RESULTS

Means, standard deviations, and correlations among the relevant variables at T1 and T2 are reported in Table 2. The final sample (N=71) included 37 females and 34 males. Overall, the total number of ties in the network equaled to 472 ties in T1 and 1194 ties in T2. The average out-degree and in-degree ties in T1 were 6.65. The average out-degree and in-degree ties in T2 were 16.82. Table 3 illustrates the aggregated results of the parameters modeling the selection effects (ego, alter, and similarity), as well as the network effects (density, reciprocity, and transitivity). As expected, all three of the network effects were significant predictors of network development. The density parameter was significantly negative ($B = -1.63$, $SE = .05$, $t = -30.67$, $p < .001$), indicating that people did not tend

to nominate friends at random (making friendship was a selective procedure). The reciprocity effect was significantly positive ($B = .67$, $SE = .08$, $t = 8.17$, $p < .001$), indicating people preferred to have reciprocal friendships. Lastly, the transitivity effect was significantly positive ($B = .06$, $SE = .00$; $t = 17.54$, $p < .001$), indicating people's preference to form triadic relationships over time. These results are consistent with previous longitudinal network studies in other disciplines (e.g., Burk et al., 2007; Mercken et al., 2010), further underlining the necessity to control for such network mechanisms when observing dynamic networks.

Table 2
Overall Means, Standard Deviations, and Correlations

	M (SD)	1	2	3	4	5	6	7
1. Out-Deg T1	6.65 (5.12)	1						
2. In-Deg T1	6.65 (4.68)	.45**	1					
3. Out-Deg T2	16.82 (8.67)	.57**	.13	1				
4. In-Deg T2	16.82 (5.70)	.28*	.55**	.24*	1			
5. CC	3.62 (1.26)	.12	.01	-.08	-.02	1

More importantly, the findings from the three selection effects for each dimension of CNFU provide interesting insights on the role of CNFU in emerging networks. When examining the CC param-eters, the results reveal a significant positive estimate for the CC ego effect ($B = .07$, $SE = .03$, $t = 2.39$, $p < .05$) and the CC similarity effect ($B = .30$, $SE = .16$, $t = 1.87$, $p < .1$). The results show CC is positively associated with the rate of growth in outgoing ties and the rate in which individuals select similar others over time. When

examining the UC parameters, the results show a significant positive estimate for the UC ego parameter ($B = .06$, $SE = .03$, $t = 2.10$, $p < .05$), but a significant negative estimate for the UC alter parameter ($B = -.05$, $SE = .02$, $t = -2.00$, $p < .05$). The results show UC is positively associated with the rate of growth in outgoing ties over time. Conversely, UC is negatively associated with the rate of growth in incoming ties over time. Finally, regarding the AS parameters, the results show a significant negative estimate for the AS ego parameter ($B = -.14$, $SE = .03$, $t = -4.16$, $p < .001$). In contrast to the other two dimensions, AS is negatively associated with the rate of growth in outgoing ties over time. All other effects are not significant.

GENERAL DISCUSSION

The findings clearly demonstrate that the three dimensions of CNFU each play a unique role in the development of a social network. Over time, the results suggest unique individuals have a desire to widen their personal network, but not if they have a need to avoid similar others. The results also suggest the individuals' rate of network growth diminishes if they violate social norms.

People with a higher need for CC increased their number of friendship nominations (ego effect) and tended to make friendships with those who were similar to them (similarity effect). This pattern of observed events is further supported by the *optimal distinctiveness theory* (Brewer, 1991). According to this theory, people are motivated by two competing needs: the desire to be unique (capacity to freely express his/her unique identity) and the desire to be social (capacity to socially acclimatize with their peers). Brewer argues that people's desire for uniqueness is constrained and influenced by their desire for social assimilation. That is, individuals experience social dissonance if there is an imbalance between differentiation and assimilation (Brewer, 1991).

CC individuals tend to establish their unique identity by making creative choices that are socially applauded by others (Tian et al., 2001), thereby deriving a fine balance between uniqueness and social acceptance goals. These individuals look for an optimal level of distinctiveness as the goal is to both maximize their level of differentiation and their social utility (Brewer, 1991). However in order to achieve this feat, CC individuals must actively build a personal network to increase others' exposure to their uniqueness. By enlarging their social network, CC individuals increase their opportunities to display their creative choices, fulfilling this particular social need, while also fulfilling their need for differentiation. Moreover, since CC individuals are concerned with their social identity (as much as their unique identity), they are more likely to seek individuals who will appreciate their creative efforts. Thus, CC individuals will choose to develop friendships with similar others to be able to experience their peers' support and encouragement.

Although, and counter-intuitively, the data shows CC individuals did not necessarily attract more friends over time. We know that CC individuals want to creatively differentiate themselves in the hopes of obtaining positive social rewards such as gaining more friendships and/or popularity (Santee & Maslach, 1982). However, our research shows that this does not necessarily translate into being perceived as more attractive friendship partners by others. In other words, while CC individuals believe that they develop more social ties over time, others in the social network do not have the same sentiments. Thus, the fact that CC individuals perceive that they obtain more friends than they actually do suggests an inherently erroneous overestimation of their network size. This is an important finding because it clearly delineates that what CC individuals perceive is altogether different from their reality. Thus, it is possible that these individuals are overestimating the benefit that they achieve from being creatively unique.

Next, UC was positively associated with the rate of growth in outgoing ties over time (ego effect), but was negatively associated with the rate of growth in incoming ties over time (alter effect). Similar to CC individuals, UC individuals seek to widen their social network in order to increase their exposure to others. Unfortunately, it appears that these unique displays come at a social cost. UC individuals make extreme consumption choices that are often reprimanded for deviating from the social norms and customs (Tian et al., 2001). As a consequence, they become less attractive as friendship partners because of the inherent symbolism attached to such unique consumption choices (Snyder & Fromkin, 1980; Tian et al., 1977). In addition, research has shown that people who assert their unpopular choices tend to have a lack of concern for others (Tepper & Hoyle, 1996). This lack of concern which UC individuals display in front of others may translate into loss of friendships, as they may have greater difficulty in fostering social relationships. Therefore, the inability to distinguish themselves in a socially appropriate manner, as well as their general lack of regard for others appear to be considerable factors to their lower and less popular selection rates over time.

Finally, AS was strongly negatively associated with the rate of growth in outgoing ties (ego effect). This result stands in stark contrast to the other two dimensions that imply unique individuals tend to increase their social network over time. This particular finding also indicates that people with a higher need for AS do not have the same desire to display their unique identity to others in their network. AS individuals define their unique identity by avoiding similar others (Ruvio et al., 2008). That is, instead of finding creative (such as CC) or extreme (such as UC) ways to diverge from the norm, AS individuals would avoid others to reduce the risk of having their identity copied (Tian et al., 2001). Prior research suggests that people diverge in their consumption choices to ensure that others will make desired identity inferences about them (Berger & Heath, 2007). That is, a large part of maintaining the unique self is by deciding whom to communicate this unique identity to. Given this motivation, AS individuals will actively seek to reduce their social network in order to maximize their unique appeal as well as to protect their unique identity from becoming mainstream. When personal networks get larger, the impact of one's uniqueness becomes marginalized, particularly in cases where there are others who possess similar identities. Therefore, AS individuals will actively seek to reduce their network to enforce and maintain their distinct identities.

Collectively, these results illustrate an interesting narrative. First, it appears that unique individuals who strive to be creative (CC) or unpopular (UC) with their choices widen their social network in an effort to further promote their unique characteristics. In contrast, unique individuals who strive to avoid similar others (AS) are more cautious of maintaining their unique appeal, and in turn reduce the size of their network in order to protect their identity from becoming common and diluted. This suggests individuals' desire to attain or maintain social ties is dependent on one's specific uniqueness motivation. Second, it appears that CC individuals tended to bond together over time. Since CC individuals are more conscious of the social outcomes of their unique identity, these individuals are more likely to stick together to support each other's unique identity. Finally, consistent with previous research, UC individuals experienced a negative social outcome (i.e., were regarded less attractive as friends) despite the perception that they had built a larger network.

Individuals high in CNFU tend to make choices that mirror their underlying counterconforming motivations. Such choices can extend beyond the relationships developed with others, to consumption decisions made to reflect their individual preferences. For example, these individuals may prefer distinct product designs and attributes

that are not likely to be possessed by others (Snyder & Fromkin, 1980). In response, marketers have tried to generate ad messages that portray uniqueness appeals and product scarcity appeals as a means of attracting those who desire to be dissimilar from others (Lynn & Harris, 1997; Snyder, 1992). Given this real effort and trend, the findings from this research stand to contribute to the body of work used by today's marketing practitioners.

Our findings suggest that unique individuals (for example, CC / UC) have a desire to actively build their personal network with specific motivations in mind. While some individuals may strive to find other creatively likeminded friends (CC), others may strive to stick to a rather small network of individuals who exhibit dissimilar preferences (AS). As a result, marketers are advised that highlighting the social benefits of a unique product can act as a tool for enhancing a particular individual's social appeal. In particular, our results show that CC and UC individuals appear to have a clear desire to build their social network. However, these groups of individuals also seem be unsuccessful in doing so. Furthermore, our findings suggest that unique individuals are less attractive as social partners if they are in violation of social norms (UC). Hence, too much extremity in product designs, for example, which is incongruent with social norms, may create challenges for counterconforming consumers looking to maintain their social relationships. To circumvent this issue, marketers could emphasize the "optimal distinctiveness" (Brewer, 1991) of their extreme product offerings. This provides clarity regarding the product's capacity to provide social differentiation, while simultaneously balancing the importance of and providing social assimilation.

This study has several limitations. First, the current study is limited to the confines of the artificial boundary of the network as the data contains only the friendships that were developed within the same floor. Although these floor friends represent an important part of one's social environment, it is possible that the results may be confounded by the friendships that were formed outside of this network (e.g., other floors, other dorms, etc.). Second, the SIENA model is limited to assessing dichotomous network ties (0 for absence, 1 for presence); thus, the network data fails to capture the effect of CNFU on the strength of relationship ties. Third, SIENA analysis makes the assumption that all network members are equally available as potential friends. However, this study may contain biased parameters as people who are roommates or live in the same wing of the floor may have a higher likelihood of forming friendships. Finally, the longitudinal data was collected within a short period of five months. It is possible that examining only two data points in five months may be too restrictive, and more data in successive waves may be necessary to capture the broader extent of peoples' social network development.

Despite these shortcomings, this study offers important advantages. Logistically, the impact of potential antecedents to network development is best observed in a group of individuals brought together into the same setting at the same time. In the past, CNFU has primarily been studied at the individual level. This research contributes by providing a more macro-level view of the influence that CNFU has on individuals' social networks. Further, this study is among the first longitudinal studies in consumer behavior to track the developmental patterns of a social network. Aside from its theoretical advances, the present study provides a methodological contribution to the marketing field by presenting actor-based modeling techniques to observe the growth and development of networks. The use of an actor-oriented model provides significant advantages over other traditional methods as it is a useful statistical technique for modeling dependencies beyond dyadic relationships (Steglich et al., 2010).

In conclusion, given the lack of research in this area, we recommend exploring other individual characteristics or traits as well as moderators that may differentially influence the development of consumer networks. Further, more research in the area of CNFU is encouraged to uncover its impact on individuals' network outcomes. Finally, the actor-oriented model presented here may be applied to other areas in marketing to address a variety of network-related questions. Thus, it would be fruitful for researchers to utilize this modeling technique to further extend our discipline's knowledge of consumer networks.

Discourses of Technology Consumption:
Ambivalence, Fear, and Liminality

Margo Buchanan-Oliver, University of Auckland, New Zealand
Angela Cruz, University of Auckland, New Zealand

ABSTRACT

Why are consumer narratives of technology consumption fraught with ambivalence (Mick and Fournier 1998), identity tensions (Schau and Gilly 2003), anxiety (Meuter et al. 2003; Mick and Fournier 1998), and even fear (Clarke 2002; Helman 1988; Virilio 1997)? What is it about technology consumption, an arguably everyday experience in the context of increasingly ubiquitous digital, biomedical, information and communication technologies in today's "technology-intensive" markets (John, Weiss, and Dutta 1999, 78), that evokes such primal reactions in consumers? In the seemingly banal act of consuming technology, what exactly comes under threat?

To explore these questions, we turn to the emerging discourse of posthumanism as articulated by Campbell, O'Driscoll, and Saren (2005), Giesler (2004), Giesler and Venkatesh (2005), Schroeder and Dobers (2007), and Venkatesh, Karababa, and Ger (2002). Significantly, posthumanist discourses challenge the underlying assumptions of the predominant information processing paradigm, which frames the majority of research on technology consumption (e.g. Bettman 1979; Bettman, Luce, and Payne 1998) and focus on how consumers mentally process the functional benefits of technology products. Within this paradigm, the following metaphors of consumers and their technologies remain unquestioned: firstly, technology is a positive enabler, secondly, the consumer is a disembodied consciousness, and thirdly, technology is extrinsic to human identity.

In challenging these prevailing metaphors, the emerging posthuman paradigm instead acknowledges multiple and complex framing views around technology consumption which are already widespread in popular imagination and other academic disciplines. In particular, the concept of liminality provides a potent deconstruction of these metaphors. Liminality refers to a hybrid condition characterised by ambiguity, indeterminacy, contradiction, incoherence, and blurring of boundaries. Within popular culture, the genre of science fiction sees classic literary texts (e.g., Gibson's (1986) 'Neuromancer', Asimov's (1967) 'I, Robot', Huxley's (1955) 'Brave New World') and popular films (e.g., 'The Terminator', 'Blade Runner', and 'The Matrix') representing a liminal vision of human-machine interactions alongside their psychological and socio-cultural repercussions. These rich discourses are similarly well-entrenched in academic disciplines ranging from media and communications studies (Turkle 1984, 1997) to cognitive neuropsychology (Clark 2003), to cultural studies and critical theory (Balsamo 1996; Shilling 2005; Stone 1996).

These liminal visions, however, are fraught with pervasive anxieties and tensions. Virilio (1997, 20), for instance, in his account of the social destruction wrought by information technology and global media, vividly articulates a fear of technology in depicting

> the catastrophic figure of an individual who has lost the capacity for immediate intervention … and who abandons himself for want of anything better, to the capabilities of captors, sensors and other remote control scanners that turn him into a being controlled by the machine.

In a similar vein, Woodward (1994) writes that "most of us fear the future prospect of frailty as a cyborg, ""hooked up" … to a machine." Even though such texts often draw on spectacular imagery to underline the implications of technology consumption, they have

significant impact on consumers' lives as they infuse and inform the wider circuits of meaning (McCracken 1986) which shape the way consumers imagine and interact with their technologies.

While previous studies have examined visual representations of posthumanism as represented by the figure of the cyborg (Campbell et al. 2005; Schroeder and Dobers 2007; Venkatesh et al. 2002), our approach is more theoretical. We present the concept of liminality as a recurrent theme within interdisciplinary theoretical discourses of technology consumption and explore its key thematics in terms of four liminal tensions: bodies/machines, human/nonhuman, past/future, and here/not-here. We consider the implications of this concept for extending the paradigm of posthuman consumer research and uncovering fundamental ambivalences, tensions, and fears concerning technology consumption. We argue that marketers and advertisers need to reflect on such concerns in their communication of technology products in order to pierce the heart of what technology means to consumers and achieve deep resonance with their target audience.

METHODOLOGY

We carried out a wider project seeking to explicate the range and complexity of theoretical discourses which shape narratives and practices of technology consumption. In doing so, we followed an interdisciplinary approach to theory development. We sourced key interdisciplinary conceptual works lensing technology consumption using keyword searches in ACR proceedings and ABI/Inform, and further expanded our list of source texts through reference list and Google Scholar searches. Applying a discourse analysis methodology situated within hermeneutic interpretivism (Crotty 1998), main concepts and key themes were induced from each source text and categorised into broader themes. A "hermeneutical back and forth between part and whole" (Spiggle 1994, 495) was facilitated through constant comparison between the literature sources and the emerging theoretical framework. This enabled the development of provisional categories for subsequent exploration, thereby aiding the induction of broader, underlying themes from these sources.

We found the concept of liminality to be a recurrent central theme in the academic literature examined. We further found two main discursive strands of body-machine liminality and space-time liminality, within which key liminal tensions between bodies/machines, human/nonhuman, past/future, and here/not-here are articulated. Drawing on exemplary source texts, we discuss these findings in the following section.

FINDINGS: LIMINALITY IN TECHNOLOGY CONSUMPTION

The Concept of Liminality

Liminality refers to a hybrid condition characterised by ambiguity, indeterminacy, contradiction, incoherence, and blurring of boundaries. Originally theorised by Turner (1967) as a key characteristic of the second stage of ritual involving a passage between two states, liminality refers to "a state of transition between two or more boundaries" (Campbell et al. 2005, 346). In anthropological conceptions (Turner 1967), the liminal moment is seen as a temporary state in between, which is eventually resolved through a boundary crossing or role transition.

However, liminality can also describe an underlying condition which pervades all aspects of consumers' reality, being and experience, in that all dichotomies, boundaries and 'states' of being are partial and transitional. A liminal view of consumer experience asserts that consumer meanings, identities, and experience are transitional and dynamic rather than absolute and natural. This perspective asserts the essential unsustainability of traditional dichotomies such as human/machine, mind/body and real/virtual, which are revealed to be artificial constructions.

The theme of liminality plays a key role in Haraway's (1991) seminal 'Cyborg Manifesto', in which the figure of the cyborg is used to underline and celebrate the hybridity, contingency, partiality, and incoherence of embodied subjectivity. A figure which is both human and machine, both flesh and metal, both spiritual and material, and ambiguous in gender, the cyborg for Haraway (1991) embodies liminality in its juxtaposition of contradictory opposites and in its potential to break down traditional dichotomies between human and animal, organism and machine, physical and non-physical. In this vein, Venkatesh et al. (2002, 446) also write that the emerging posthuman paradigm "views the intersection of human and machine as a postmodern possibility in contrast to the received view under modernist thinking which considers these two entities as distinctly separate."

Thus we can already see the radical potential and concurrent threat posed by a liminal worldview, in its dissolution of modernist boundaries and its insistence in partiality. Furthermore, as liminal states of being do not fit in easily with regular narratives or extant categories, they tend to be conceived as polluted, taboo, and associated with impurity, alterity, exclusion, danger and Otherness (Clarke 2002). Hence, what boundaries are thus contaminated when we consider technology consumption through a liminal perspective? To answer this, we develop two key discursive strands which further explicate and expand this concept: body-machine liminality and space-time liminality.

Body-Machine Liminality

Body-machine liminality refers to a blurring of boundaries between bodies and machines, making it increasingly difficult to delineate differences between human bodies and their nonhuman machines. While body-machine liminality is articulated in a wide range of representational and embodied practices including anthropomorphism in advertisements (Dobers and Schroeder 2001) and the cosmetic modification of the human body (Balsamo 1996, Featherstone 2000, Schouten 1991), we focus our discussion on two key liminal tensions between bodies/machines and human/nonhuman.

Bodies/machines. Ideas of the body and the machine metaphorically inform and shape one another. As metaphorical associations between bodies and machines are repeatedly re-iterated in linguistic discourse, audiovisual representation and embodied practice, resemblances between bodies and machines in appearance or behaviour are underlined (Schroeder and Dobers 2007).

On one hand, the appearance and performance of the machine is often understood to be like the appearance and performance of the human body. This metaphorical association serves to transfer our understanding of the familiar domain of the human body to help us understand potentially abstract domains of technological functioning. Schroeder and Dobers (2007) for instance, cite the example of a print advertisement which uses commonplace understandings of the human digestive system to represent data storage in computers. While there may be a tendency for this trope to be used to communicate functional benefits, the converse notion that machines break down and are as imperfect and vulnerable as the human body is under-

standably absent in aspirational marketing communications which position technological offerings as infallible.

At the same time as our understanding of technology is informed by our understanding of the human body, the increased adoption of these technologies into the everyday means that the opposite also happens: our understanding of machines come to structure the ways in which we understand ourselves (McLuhan 1967; Turkle 1984, 1997). The human body is increasingly seen as a machine – an assemblage of multiple parts and systems whose parts can be replaced when broken and whose performance can be optimised.

Human/nonhuman. Additionally, the metaphor of technology as a tool, suggesting that which is external to and distinct from the body, is rendered less compelling than the metaphor of technology as prosthesis, suggesting something which, in addition to extending human capability, is incorporated into the self and inevitably comes to constitute one's sense of who one is. Zylinska (2002, 3) points out this "inherently prosthetic nature of human identity" in which humans extend themselves with technologies that either literally or figuratively become incorporated as part of the self. Similarly, Balsamo (1996) theorises that there are 'degrees of cyborgism' rather than a reductive human-machine dichotomy. Indeed, Haraway's (1991, 150) statement that "we are all chimeras, theorized and fabricated hybrids of machine and organism" has become increasingly relevant in light of commonplace technologies such as pacemakers and hearing aids.

However, we must emphasize that prostheticism is not limited to biomedical technologies, but also applies to everyday prosthetic devices such as cell phones and laptops. Clark (2003) insists that prostheticism characterises humans' everyday interaction with technology, casting humans as 'natural-born cyborgs' in our unique and inherent capacity to think and feel through our best technologies. He argues that the inherent plasticity of the human brain is such that human subjectivity is necessarily diffused over a fluid and interactive network of biological and non-biological components. In this view, there is no reason for the 'biological skin-bag' to be privileged as the site of human subjectivity (Clark 2003). Indeed, it is when technologies become transparent in use that we feel they are part of us and inseparable from our bodies, such that "technologies can alter, augment, and extend our sense of presence and our potential for action" (Clark 2003, 125).

This everyday fusion between the body and technology is dramatically visualised in images of cyborgs, in which non-biological material literally pierces, merges with, or enters the 'biological skin-bag' (Clark 2003). However, because this image of the cyborg violates extant categories and destabilises what it means to be human, it commonly invokes notions of Otherness, the abject and the unnatural, carrying with it mythic resonances of Frankenstein's monster and evoking anxieties and fears around pollution, contamination, recombination and miscegenation (Helman 1988). The increasingly pervasive notion of technology-as-prothesis, as represented by the image of the cyborg, can therefore potentially provoke ambivalent identifications and fearful reactions in consumers – a sense in which technology consumption renders us both human and nonhuman.

Space-Time Liminality

Technology consumption also confounds the experience of presence. This is explored in the discursive strand of space-time liminality, which underlines how technology enables various modes of 'space-shifting' and 'time-shifting'. Here, technology consumers experience being both 'elsewhere' and 'elsewhen', confounding modernist conceptions of space and time as fixed and linear. Indeed,

a consideration of the spatiotemporal dynamics of technology consumption uncovers its inherent paradoxes, as explored in the liminal tensions of past/future and here/not-here.

Past/future. Technology facilitates 'time travel' by allowing consumers to experience times apart from and in addition to the present, thereby challenging conceptions of time as linear and unidirectional. Technology often facilitates a Janus-faced time perspective, characterised by a simultaneous gaze to the future and the past. On one hand, technology is strongly associated with and represented using futuristic images, with technology being seen to propel us into the future and draw futuristic conceptions of progress into our everyday realities (Davis 2004). On the other hand, technology also preserves memories and history. In particular, through the proliferation of recording technologies (Manuel 1993) such as video cameras, consumers can readily preserve particular moments in time and to access their pasts in an 'untarnished' way.

Over and above this, technology is implicated in shaping a dynamic relationship to time which resists simplistic categorisations of past, present, and future. Consider, for instance, how the act of using a camera involves a Janus-faced gaze to both past and future: in the act of taking a picture, there is a translation of the present moment into a documented past for consumption in the future. In this way, the past is always present in the future, and vice versa.

Here/not-here. Technology also confounds the conception and experience of space. As technology enables us to extend our subjectivities beyond our immediate physical surroundings, the location of the individual subject with respect to the biological body becomes increasingly complicated (Stone 1996) and the subjective experience of space is transformed.

Consider, for instance, the experience of telepresence, which simply refers to being in two places at once. Steuer (1992, 76, cited in Hoffman and Novak 1996) defines telepresence as the "mediated perception of an environment", a subjective state in which the consumer perceives both his or her immediate physical environment as well as a computer-mediated environment. Here, telepresence refers to the experience of being drawn into the space of the screen as exemplified in an immersive video gaming experience (Darley 2000). With an emphasis on the social, Minsky (1980) defines telepresence as social presence in the absence of physical presence. This conception of telepresence can be divided into real-time telepresence, involving the simultaneous co-presence of communicating parties through technologies such as the telephone or instant messaging, and virtual telepresence, for instance in personal websites (Schau and Gilly 2003) which do not require real-time feedback.

Consider also the ways in which technology facilitates the division of once-coherent spaces into separate fragments, enabling consumers to set up personal boundaries within shared spaces. As an example, the act of putting on a pair of earphones allows one to set up an individual zone within the shared space of a living room or a bus, or enables one to set up a zone of privacy within a public space (Van Dorst 2005). In addition, technology facilitates the intersections of and leakages between once-separate spheres, such as the public and private spheres (Buchecker 2005; McDougal 2005). Take for instance, the use of a cell phone in a restaurant. Here, the user enters a private space within a public space, but at the same time other patrons have a glimpse of this space through the one-sided conversation. Thus there is a sense of intrusion on both ends – the private intrudes into the public as someone's conversation interrupts a meal, while the public intrudes into the private, with other people listening in on one's conversations.

In these ways, subjectivity is seen to be spread out across and between spaces in a way that resists modernist conceptions of space and confound simple dichotomies between the "real" and the "virtual". In this vein, Druckery (1996, 12) asserts that computer-mediated environments "collapse the border between material and immaterial, the real and the possible" such that dichotomies and boundaries between the 'real world' and 'virtual world' are rendered less relevant. In short, everyday instances of technology consumption can be conceptualised as liminal states, enabling consumers to straddle the boundaries between here/not-here across multiple, intersecting, and permeable spaces.

IMPLICATIONS AND FURTHER RESEARCH

Our discussion of liminality, while confined to theory, carries implications for consumers' lives. In the context of increasingly ubiquitous digital, biomedical, information and communication technologies, these interdisciplinary discourses represent wider culturally constituted meanings which impact the consumer experience of technology consumption through various circuits of meaning (McCracken 1986). As we have observed, posthuman representations already pervade advertising texts (Campbell et al. 2005; Schroeder and Dobers 2007; Venkatesh et al. 2002) and popular fiction (Asimov 1967; Gibson 1986; Huxley 1955). This underlines their potential to constitute shared cultural meanings which are used by groups

> to make collective sense of their environments and orient their members' experiences and lives… [framing] consumers' horizons of conceivable actions, feeling, and thought, making certain patterns of behaviour and sense-making interpretations more likely than others
>
> (Arnould and Thompson 2005, 869).

Through the concept of liminality as explicated in this paper, we build on the emerging paradigm of posthuman consumer culture (Campbell et al. 2005; Giesler 2004; Giesler and Venkatesh 2005; Schroeder and Dobers 2007; Venkatesh et al. 2002). We shift our attention from the visual representation of posthumanism to explicating the key dimensions of liminality as a theoretical concept. To demonstrate how a liminal frame provides a different way of understanding technology consumption, we now consider how it might extend or re-interpret extant consumer research.

As we have seen in our discussion of space-time liminality, the posthuman paradigm in explaining consumers' constructions of online identities eschews a simple dichotomy between the online self and the physical self (Schau and Gilly 2003). Indeed, this dichotomy is symptomatic of an assumed Cartesian dualism, which separates the mind from the body and privileges the rational over the embodied and holistic aspects of technology consumption (Shilling 2005). Rather, the concept of liminality emphasizes the subjective experience of presence across multiple, intersecting, and permeable spaces, in which the physical location of the body is not privileged.

In addition, our discussion of liminality further expands Mick and Fournier's (1998) paradoxes of technology, in which consumer ambivalence with respect to technology was explained through eight polar opposites which characterise technology products. We present four additional paradoxes as articulated in the key liminal tensions between bodies/machines, human/nonhuman, past/future, and here/not-here. Furthermore, over and above the idea of technology-as-tool, the concept of liminality emphasises the metaphor of technology-as-prosthesis – that which comes to be incorporated into our very selves and is constitutive of human identity and subjectivity. In doing so, this perspective reveals a deeper ambivalence which goes beyond the advantages and disadvantages of technology, and concerns its implications for how we use technology to constitute and conceive of ourselves as human.

Similarly, while Kozinets (2008) maps out various oppositional identity positions which consumers interpellate into their narratives, the underlying metaphor of technology as a tool remains unquestioned. In order to probe the deep-seated reasons for why someone interpellates a particular ideology of technology into their identity narrative, we need to consider the fundamental assumptions which underlie these identity narratives. Might Kozinets' (2008) 'Green Luddite' position, for instance, be interpreted as a selected coping strategy in response to the liminal erosion of a clearly delineated human subject?

Thus, having shown that liminality is a key concept in theoretical discourses of technology consumption, and briefly demonstrated its potential for framing consumer research, further research questions can be considered. From a theoretical perspective, are there other key concepts in interdisciplinary discourses which would similarly be useful? From an emic standpoint, to what extent do discourses of liminality pervade consumer narratives? If consumers are aware of the key paradoxes within popular cultural texts and within the broader theoretical discourses of liminality, exploring the extent to which these are articulated in their narratives and appropriated into their identity projects may reveal deeper-running complexities and tensions in consumers' views of technology. We argue that marketers and advertisers need to reflect on such complexities and tensions in their communication of technology products in order to pierce the heart of what a constantly morphing technology means to consumers, thereby assisting them to achieve deep resonance with their target audience.

CONCLUSION

In order to probe the deep-seated reasons for why consumers experience technology in particular ways (Schau and Gilly 2003), feel the way they do about technology (Mick and Fournier 1998), or interpellate particular ideologies of technology into their identity narratives (Kozinets 2008), we need to consider the fundamental assumptions which frame these experiences, feelings, and narratives. The concept of liminality, and the posthuman paradigm more broadly, provides a way to articulate how fundamental assumptions are destabilised and negotiated in consumer narratives of technology consumption. Furthermore, our discussion of key liminal tensions enables us as theorists to identify exactly what comes under threat, and why such deep-seated consumer anxieties and fears are evoked, in seemingly banal narratives of technology consumption – the hitherto unquestioned meanings of being human, having a body, and inhabiting a particular space and time. By being aware of these fundamental anxieties and fears, marketers and advertisers will be better able to communicate technology products in ways that deeply resonate with their target audiences.

"Free" Gifts and Irrational Preferences:
An Exploration for Effects of Promotional Enticements on Financial Decision Making

Nese Nasif, University of Texas, Pan American, USA

"This is the foundation of all: we are not to imagine or suppose, but to discover, what nature does or may be made to do."

-Francis Bacon (1561-1626)

1. INTRODUCTION

Behavioral economics emerged as a way to better explain, as compared to traditional economic theory, what psychological factors affect consumer decisions. Traditional finance theory assumes that investors act rationally, in that they consistently perform utility-optimizing behaviors. Choices are made through continuous and dependable cost-benefit analysis, often without direct realization of the underlying thought processes, and repeated consumption does not result in any violations of transitivity. Moreover, consumers have complete preferences (i.e. consumers *have* preferences for any set of products that are compared) which are revealed through their consumption choices of certain products at certain prices. However, researchers in other fields and contemporary economists have published criticisms to the traditional theory, citing a great deal of irrationality in observed behavior. They argue that such behavior is not new, but rather, traditional utility theory has been unable to reconcile seemingly irrational consumption decisions in economic agents.

Traditionally, economic models dismissed variation in emotional responses within market transactions, particularly those resulting from extrinsic influences, as having a significant impact on consumption preferences. That is, emotions are taken as given in an economic model, optimization of utility is revealed through consumption choices, and the rational every-consumer would not make consumption choices that left her worse off in resources and/or unhappier than a different consumption alternative. However, a great deal of observations of consumption behavior that deviates from classical utility theory necessitated new models and theoretical frameworks upon which to explain such deviations. Caplin and Leahy (2001) applied anxiety as a cost to investors' portfolio decisions. The authors found that holders of seemingly under-priced, risky securities were not considering the cost of anxiety associated with holding them. Indeed, "stock ownership entails psychic costs [because the investor] has to live with the anxiety that accompanies the holding of a risky portfolio" (p. 69). The anxiety-costs viewpoint can also help to reconcile other seemingly irrational decisions, like why people put off investing in a retirement account early in their careers when the future returns should be the highest.

Psychology has long accepted cognitive limitations in decision-making and has increasingly merged with the economics disciplines, such as finance, in order to document and attempt to explain seemingly irrational consumption. For example, both disciplines now accept the concept of "optimism bias", where otherwise risk-averse people consume financial products with provisions that are relatively risky in terms of their incomes, because they are optimistic about their future financial positions to an irrational degree (see, e.g., Ariely 2009; Lovallo & Kahneman 2003; Weinstein, 1980). Zweig (2007) illustrates this point by highlighting the fact that, although credit cards are considered to be a competitive industry, few card companies drop their yearly interest rates below 20 percent. This occurs, in part, because nearly half of all credit card users believe they will pay their credit balance in full each month. In reality, 75 percent rollover credit card balances and pay interest charges. Thus, many consumers tend to disregard the interest rate when initially obtaining a credit card, because they do not foresee ever having to use it.

Gintis (2009) argues the illogicality of economics, sociology, anthropology, and social psychology all separately attempting to explain human decisions and organization. He contends that researchers in each field continue to produce incompatible results based on varying and conflicting assumptions. Collaboration between psychology and economics, particularly, has advanced scholarly research in neurofinance. Economists, psychologists, and related business scholars have produced studies applying game theory, modified models of utility, and various decision-making experiments to consumption behaviors. Moreover, books such as *The Winner's Curse* (Thaler 1994), *Predictably Irrational* (Ariely 2008), *Buyology* (Lindstrom 2008), *Nudge* (Thaler & Sunstein 2009), *Priceless* (Poundstone 2010), among several others, have become global best-sellers, making a once enigmatic topic more accessible to the general, educated public.

Merchants exploited our irrational consumption compulsions long before scholars attempted to publish observations of such behavior. Many people fall prey to "deals", without actually thinking about the fact that they are consuming irrationally. For instance, retailers commonly use "anchor pricing" in order to encourage consumption of an item that would otherwise be considered too expensive to the consumer. Ninety dollars may seem like an exorbitant price to pay for a purse, but placed "on sale" for that amount and placed next to comparable purses that cost hundreds of dollars more, one's sentiments may change to consider the ninety-dollar purse as being reasonably priced, or even a bargain (Poundstone 2010).

In practice, businesses have profited from our irrational preferences for "free" items for quite some time. In 2000, Amazon.com offered free shipping on orders of $100 or more, and in 2003 it lowered the free shipping threshold to $25. Sales increased dramatically. Rather than paying $3.99 shipping, for instance, on a $16 book, consumers would add on a second, otherwise not demanded, book for a total of $32 in order to qualify for the "free" shipping. Thus, the consumers are increasing their purchasing volume and monetary spending, but in exchange, gaining an otherwise superfluous item and the ephemeral utility received from "free" shipping.

This paper explores the phenomenon of seemingly low-value products working as incentives to induce individuals into becoming consumers of various financial products. Choosing banking services and opening credit cards have the potential to significantly affect financial outcomes, such as credit scores, interest accumulation, and debt volume, and so we would expect consumers to place a high value on their selections of such financial products. However, in reality, we observe consumers filling out credit card applications in exchange for seemingly low-value products, such as t-shirts or one-time retail discounts, and opening checking accounts in order to receive, for example, a $50 gift card. Moreover, the prevalence of free gifts given away in exchange for the completion of a credit card application or the opening of a banking account seems to indicate that this must be a profitable practice for financial companies. If these consumption behaviors are rational, than we could assume that only the individuals who value a particular free gift object at the same level or above the value of the costs of consuming the new financial account would choose to consume the financial product tied to the free gift. Otherwise, these consumption patterns seem to violate the assumption of transitive preferences in most consumers.

Heyman and Ariely (2004) propose that the apparent irrationality occurring in the market transaction where a free item is involved should be viewed within a different context than one for positively priced products. The authors propose that consumers apply "market norms" in making decisions about products which carry a positive price. Alternatively, people

respond to free products through "social norms". Dan Ariely, along with various co-authors throughout the past decade, has conducted several experiments documenting the change in human behavior that occurs when positively priced products are adjusted to zero price. For instance, Ariely et al. (2006) offered to sell students a certain candy for 1¢, which resulted in an average purchase of four pieces. However, when the price of the candy became free, more students consumed the candy, but few took more than one piece. The authors propose that when a price was attached to the candy, it was a "market norm" to exchange money to the extent that the benefits of the candy exceeded the monetary cost. Alternatively, when offered for free, "social norms" guided consumption choices.

In a similar series of experiments, Shampanier et al. (2007) offered a popular, mass-market type of chocolate for 1¢ and a more luxurious brand of chocolate for various positive prices in different trials (e.g. 26¢ in one of the experiments). Next, they lowered the price of each by the same constant of 1¢, which made the former chocolate free and the more luxurious chocolate 1¢ cheaper. Subjects were also permitteded to select no chocolate for consumption at any stage of the experiments. The net benefit between the two products remained unchanged, since they each

decreased in price by the same amount. Economic theory would suggest that a few participants who consumed nothing could now afford to buy the low-end chocolate at its cheaper price, and the decrease in price of the higher-end chocolate may have reached the reservation prices of some people who originally chose the low-end candy. Thus, we would expect to see a marginal increase in the quantity demanded of each product. Rather, the authors found that the zero-priced chocolate experienced a sizable "overreaction" in increased demand. In particular, a majority of those who originally purchased the high-end chocolate had decided that, even with no net change in benefits between the two products, they now preferred to consume the zero-priced chocolate. Such a change in behavior, particularly in those who originally chose to consume the high-end chocolate at its higher prices violates the transitivity condition of rational preferences.

In economic theory, rational consumers will exhibit transitive preferences through their consumption choices. As shown in Figure 1, this means that if a consumer values Product A at a higher amount than Product B and values Product B at a higher amount than Product C, then it must be the case that this same consumer will value Product A at a higher amount than Product C.

Figure 1: Transitive Preferences
In order to test this rationale in the context of free gifts and two different types of retail financial products, the following hypotheses were proposed:

Hypothesis 1a: *On average, individuals will value, on their own, the products which financial companies use as free gifts at a lower value than the value they place on the costs of opening an additional credit card account.*

Hypothesis 1b: *On average, individuals will value, on their own, the products which financial companies use as free gifts at a lower value than the value they place on the costs of opening a new checking account.*

Hypothesis 2a: *On average, an individual who is not actively seeking an additional credit card will choose to complete a credit card application in exchange for certain types of free gifts.*

Hypothesis 2b: *On average, an individual who is not actively seeking a new bank checking account will choose to open a checking account in exchange for certain types of free gifts.*

Hypothesis 3a: *On average, individuals, who would not otherwise be induced to do so, will complete an application for a new credit card in exchange for certain types of free gifts, even though the costs of completing the application are higher than the individual values*

of the free gifts. That is, we will observe a violation of transitivity in consumption preferences when a particular free gift is tied to the consumption of a new additional credit card.

Hypothesis 3b: *On average, individuals, who would not otherwise be induced to do so, will open a new bank checking account in exchange for certain types of free gifts, even though the costs of opening the account are higher than the individual values of the free gifts. That is, we will observe a violation of transitivity in consumption preferences when a particular free gift is tied to the consumption of a new checking account.*

The next section describes the methodology of the experiment. Section 3 provides a discussion of the results, section 4 will conclude, and section 5 includes a discussion of potential caveats of the current experiment and suggestions for future research and follow-up to this study.

2. METHODOLOGY

2.1 Survey

In order to test the hypotheses of preferences, without biasing the survey-taker towards a particular response, three different survey instruments were created. One survey, hereafter referred to as the "gift value" survey, asked responders to write the maximum dollar amount they would pay to obtain various products. The products were included on this list because, as of this writing, they are current or past free gifts actually offered by local and national banks and credit card companies as incentives to consume new checking accounts and credit cards. A sec-

ond survey, hereafter referred to as the "finance value" survey, asked responders to write separately the minimum values of the compensation needed in order for them to fill out the application for a credit card or open a new checking account. The third and final survey, hereafter referred to as the "free gift" survey, asked responders to choose which, if any, free gifts would incite them to fill out a credit card application and which, if any, free gifts would incite them to open a checking account. The free gifts were identical to the products whose values were assessed by separate survey takers in the "gift value" survey.

Each survey was randomly distributed to a single individual, with any one person taking only one of the three types of surveys. There were several reasons for this experimental design. Although it would be ideal to test transitivity of preferences in each individual, asking each observation to value the gifts and their financial data/time/effort/etc. separately runs the risk of inducing transitivity of preferences on the "free gift" questions, since the participants would be consciously engaging in an analytical thought process that may not otherwise occur when these choices are presented in actual markets. That is, in reality, the responder may not stop to consider the valuations of bundled products separately when choosing whether or not to be incited to consume one product in exchange for the receipt of the free gift product. Having responders consider the value of everything separately, before considering the choice of signing on to a financial product paired with a free gift, may illuminate the rational or irrational behavior that would, otherwise, occur subconsciously in reality.

The downside of having each individual complete only one of the three separate surveys is that a much larger sampling is necessary in order to ensure that the distribution of individuals, in terms of their backgrounds characteristics are similarly distributed across all three surveys.

2.2 Data

In total, 214 surveys were collected, mostly from an undergraduate student population. From these surveys, 195 provided usable data. The "finance value" surveys was the only one of the three survey types that had surveys excluded from the analysis. Nineteen surveys were excluded from the analysis, either because (1) at least 50 percent of the experimental questions went unanswered or (2) the answers were extraordinary outliers[1].

3. Findings

The "gift value" survey had 78 respondents. Figure 2 illustrates the comparison of consumer-reported values with market values and Table 1 reports the descriptive statistics for each product. On average, survey respondents valued the gifts at less than their market retail value. In most of the cases, the mode of the survey respondents' valuations more closely matched with the manufacturer's suggested retail prices (MSRP) as compared to the aggregated average of all respondents. This makes sense, since we would expect a random sampling of the population to carry varying reservation prices for the same item. For example, we would expect a Dallas Cowboys supporter to value that team's fan apparel more than someone who supports another team or is disinterested in American football. Similarly, we would expect somebody who would not, otherwise, consume McDonald's food to value a $5 McDonald's gift card at a value less than $5. Thus, in order to produce more conservative results, the mode and the MSRP will be considered, in addition to survey-reported averages, in this analysis.

---

[1] For example, stating that one would fill out any arbitrary, otherwise undemanded, credit card application for no compensation resulted in the exclusion of that survey. The survey asked for responses under the assumption that the responder was not currently demanding a new credit card. Thus, there has to be some cost to fill out the application that is greater than zero, or else we would have to assume that the responder had a current demand for a new credit card. A few surveys put absurd dollar figures, including necessitating a million dollars or more in order to fill out a credit card application. It seems unlikely that the opportunity costs of time, effort, revelation of personal information, and effects on one's financial status due to filling out a credit card application would amount to such a high value. The surveys excluded for the first reason would have biased negatively the costs of consuming an additional credit card or checking account, and the surveys excluded for the latter reason would have biased positively the costs of consuming an additional credit card or checking account.

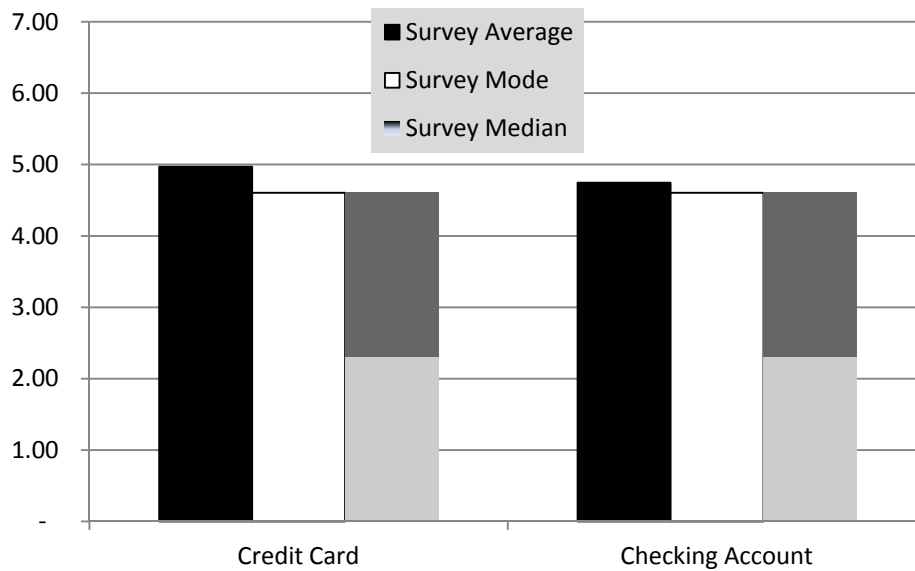
Figure 2: Log-Value of Free Gift Products
Table 1: Individual Values of "Free Gift" Products

Product (as stated on actual survey)	Survey Respondents, N = 78 (log-value in parenthesis)				MSRP
	Average	Standard Deviation	Mode		
2-GB Apple iPod Shuffle (choice of color)	$50.98 (3.93)	$2.07 (0.73)	$50		$49.00
SwissGear Backpack with laptop compartment (Black)	$35.88 (2.43)	$2.43 (0.89)	$50		$100.00
entry to win one of five Apple iPads (nationwide drawing)	$4.78 (1.57)	$3.63 (1.29)	$1		n/a
10,000 frequent flyer miles in your preferred loyalty program (assume free round-trip flight = 25,000 miles)	$38.49 (3.65)	$8.58 (2.15)	$100		n/a
Dallas Cowboys official logo shirt	$11.96 (2.48)	$4.16 (1.43)	$20		$19.99
Dallas Cowboys official logo blanket	$11.61 (2.45)	$4.04 (1.40)	$20		$29.99
coupon for 20% off of your full purchase at your favorite retailer	$4.10 (1.41)	$3.82 (1.34)	$5		n/a
$100 off of $1,000 of your credit card balance in 3 months from first use	$16.29 (2.79)	$5.35 (1.68)	$20		< $100
entry into winning one of four 2011 Toyota Tacoma compact pick-up trucks (nationwide drawing)	$8.60 (2.15)	$4.22 (1.44)	$10		n/a
2011 Spring Break t-shirt	$5.99 (1.79)	$2.53 (0.93)	$9		$19.99
2011 Spring Break beach blanket	$6.51 (1.87)	$2.64 (0.97)	$8		$17.99
$5 gift card to McDonald's	$2.75 (1.01)	$2.02 (0.70)	$5		$5
$25 Visa Gift Card	$11.76 (2.46)	$3.20 (1.16)	$25		$25 (plus loading fee)
$50 Visa Gift Card	$21.34 (3.06)	$3.71 (1.31)	$50		$50 (plus loading fee)
$75 Visa Gift Card	$29.47 (3.38)	$4.26 (1.45)	$75		$75 (plus loading fee)
$100 Visa Gift Card	$38.08 (3.64)	$4.60 (1.53)	$100		$100 (plus loading fee)

The "finance value" survey had 45 surveys. Table 3 reports the average, standard deviation, median, and mode of survey responses on how much each survey participant valued the costs of applying for a new credit card or opening a new checking account. The median and mode estimates for both products fell at $100, while the survey averages for credit cards and checking accounts fell at $115 and $144, respectively. Figure 3 illustrates the comparisons. Thus, in order to provide the most conservative estimates possible, the mode and the median will be considered, in addition to survey-reported averages, in this analysis.

Table 2: Individual Values of the Costs of Opening Financial Accounts

Product	Survey Respondents, N = 45 (log-value in parenthesis)			
	Average	Standard Deviation	Mode	Median
Personal Credit Card	$115.00 (4.74)	$3.72 (1.31)	$100	$100
Individual Checking Account	$144.11 (4.97)	$2.89 (1.06)	$100	$100

Figure 3: Log-Value of Financial Products


The "finance value" survey had a lower number of observations than the other two surveys, because, as mentioned above, some of the data gathered were unusable for the analysis due to respondent error. The end of this section provides a brief discussion of possible impediments for survey-takers in being able to respond accurately or at all to the experimental questions on this survey.

Finally, the "free gift" survey constructed a scenario where survey takers were asked to assume that each was not actively seeking a new credit card or checking account, although the respondent may be induced to consume the financial product with a large enough incentive (the consumer's reservation price). With that in mind, the respondents were asked to indicate which free gift products would induce each of them to fill out a credit card application and/or open a new checking account. There were 72 respondents to this survey, of which 58 percent stated that they would fill out a credit card application in exchange for a choice of at least one of the free gifts listed on

the survey. Another 17 percent stated that they would fill out a credit card application for a free gift but not for any of the ones listed on the survey. Only 25 percent stated that they would not be induced to fill out a credit card application for any type of free gift. With regards to a bank checking account, 72 percent of the survey respondents claimed that they would open a new checking account in exchange for one of the free gifts listed on the survey, 6 percent stated that they would open a new checking account for a free gift other than what was listed on the survey, and only 22 percent stated that they would not be incited by a free gift to open a new checking account. The details for this survey are summarized in Table 3.

Table 3: Preferences for "Free Gift" Products

Credit Card, N = 72		Checking Account, N = 72	
Free Gift	Percentage of respondents that would consume the financial product in exchange for the gift (frequency in parenthesis)	Free Gift	Percentage of respondents that would consume the financial product in exchange for the gift (frequency in parenthesis)
10,000 frequent flyer miles in your preferred loyalty program (assume free round-trip flight = 25,000 miles)	31% (22)	$25 Visa Gift Card	10% (7)
choice of Dallas Cowboys of-ficial logo shirt or blanket	22% (16)	$50 Visa Gift Card	19% (14)
coupon for 20% off of your full purchase at your favorite retailer	25% (18)	$75 Visa Gift Card	29% (21)
$100 off of $1,000 of your credit card balance in 3 months from first use	26% (19)	$100 Visa Gift Card	68% (49)
entry into winning one of four 2011 Toyota Tacoma compact pick-up trucks (nationwide drawing)	22% (16)	2-GB Apple iPod Shuffle (choice of color)	31% (22)
2011 Spring Break t-shirt or beach blanket	10% (7)	SwissGear Backpack with lap-top compartment (Black)	18% (13)
$5 gift card to McDonald's	4% (3)	entry to win one of five Apple iPads (nationwide drawing)	14% (10)
induced by at least one of the above free gifts	59% (42)	induced by at least one of the above free gifts	72% (52)
could be induced by a free gift but not any of the above free gifts	17% (12)	could be induced by a free gift but not any of the above free gifts	6% (4)
could not be induced by any free gift	25% (18)	could not be induced by any free gift	22% (16)

3.1 Discussion of Results

Much of economic theory rests on the assumption that consumers are rational agents, meaning that their preferences exhibit completeness and transitivity. Completeness essentially means that consumers have preferences for consumption choices, and transitivity ensures that preferences maintain their order. Thus, consumers should be willing to consume a financial product that they would otherwise find too costly to consume, which has a free gift attached to its consumption, only if the free gift compensates fully for the cost of consuming the financial product.

However, this experiment has shown that respondents' preferences often violated transitivity when a "free" gift was attached to the financial product. Products that would otherwise have a lower value on their own seem to increase in value to the consumer when they are presented as free gifts, rather than as products to be consumed separately from the financial product. Otherwise, a consumer that had no demand for the financial product without the free gift should not choose to consume the financial product.

None of the free gifts were valued at an amount equal to or higher than the respondents valued the costs of filling out a credit card application or opening a new checking account. This finding provides support for both Hypothesis 1a and Hypothesis 1b. If, instead, we consider the mode and the MSRP values of the $100 Visa gift card along with the mode and median values of the opening a checking account, then the costs of opening the accounts equal the

benefit value of the free gift. However, even considering this most conservative scenario, the consumer would be merely indifferent between consuming and not consuming the financial product with the $100 gift card.

Of the 72 respondents to the "free gift" survey, 59 percent stated that they would consume a new credit card, which they would not otherwise demand, for one of the listed free gifts. Similarly, 72 percent stated that they would consume a new checking account that they would not otherwise demand for one of the listed gifts. Adding in the respondents that stated that they could be induced by a free gift not listed on the survey, these figures rise to 76 percent and 78 percent, respectively. These findings support both Hypothesis 2a and Hypothesis 2b.

The finding that the average respondent values, median, and MSRP values of the free gift products are lower, often to a large degree, than the costs of consuming a financial product that was not currently demanded would lead us to believe that consumers would not be enticed to consume the financial products in exchange for the lower-valued free gifts. However, we found that a substantial proportion of respondents made the decision to consume an additional, otherwise undemanded, credit card or checking account in exchange for a free gift on the list. This fact violates the transitivity assumption of rational preferences and lends support to Hypothesis 3a and Hypothesis 3b.

4. CONCLUSION

Thaler and Sunstein (2009) note, "often people have a problem in mapping products into money" (p. 95), particularly when the direct benefits of a product in exchange for its costs are obscured in intricate pricing schemes and purchase stipulations. Such is often the case when financial products are concerned. The bundled nature of many financial products, combined with the heuristic reactions to a "free" label, may inhibit consumers from appropriately maximizing their utilities from these products. Indeed, when consuming a credit card, its main function may be to allow the delay of payments for purchases for a certain length of time, but many credit cards are accompanied by, for example, car rental insurance, rewards programs, and a spectrum of liability protections and interest rate terms. Similarly, access to ATMs and branches, paper checks, direct deposit services, and deals on associated banking products, such as mortgage loans and savings accounts, are coupled with the consumption of a checking account. Thus, the "price" at which one pays for the main function of each of these financial products actually includes the purchase of several other related services that consumers have come to expect from credit cards and checking accounts. When financial companies set a price on the main product of delayed payment, in the case of a credit card, and safe storage and distribution of money, in the case of a checking account, at zero price, consumers appear to ignore the potential opportunity costs of consuming the zero price product. As Ariely (2008) observes,

> When choosing between two products, then, we often overreact to the free one. We might opt for a FREE! checking account (with no benefits attached) rather than one that costs five dollars a month. But if the five-dollar checking account includes free traveler's checks, online billing, etc., and the FREE! one doesn't, we may end up spending more for this package of services with the FREE! account than with the five-dollar account. (p. 60)

The apparent irrationality in the consumption of retail financial products, such as credit cards and checking accounts, is exacerbated by the observations that a great deal of consumers are willing (eager?) to consume otherwise undemanded financial products in exchange for "free" items that they would otherwise assess at a value lower than what they consider to be the opportunity cost of consuming the financial product.

5. POTENTIAL CAVEATS AND SUGGESTIONS FOR FUTURE RESEARCH

As the social sciences continue to explore and attempt to model consumer behavior that seems to violate economic rationality, it is important to design experiments that more closely resemble realistic environments and contexts, than what was presented in this study, under which consumer choices occur. It would be interesting to see if different outcomes would occur under an experiment which recorded *revealed* rather than *stated* preferences.

Additionally, the purpose of this study was to verify that potential violations of transitivity exist when consumers are exposed to the bundling of free gifts with the consumption of particular financial products. It was found that a considerable amount of irrational consumption behavior exists in these markets, at least according to the standard economic definition of rational preferences which presumes transitive preferences. However, it is yet to be researched what sort of traits in a consumer, if any, are correlated with different degrees of irrationality in this context. This experiment collected some superficial demographic data on age, sex, ethnicity, education, and income.

However, it may be likely that such characteristics as, for example, risk aversion, perceptions and familiarity of particular financial products, and other consumption-related attributes are significant predictors of the variation in consumer irrationality. Successors to this study should consider closer scrutiny of each observation case.

Specific terms of financial product were not described in detail on the surveys. In a realistic setting for the consumption of these products, consumers are presented with a great deal of provisions on interest rates, fees, and information disclosure, to name a few. This leads to the difficulty for consumers to decipher the true value of such products and map them to comparable monetary values. Future research may want to control for variables associated with common stipulations that accompany credit card and checking account products.

Any future research should also consider the environment in which the financial product is marketed to consumers. For example, at major sports venues, credit card companies regularly erect booths where a t-shirt or other fan paraphernalia related to the home team is offered as the free gift in exchange for the completion of the credit card application form. This is because the card companies are aware that the value of their free gift increases or decreases within the context of the setting. (This is also why we often observe, for example, the sudden increase in the price of umbrellas by convenience stores in big cities when it's raining.) Consumers have been found to demand Dallas Cowboys fan gear at the team's football stadium during a game or a spring break t-shirt promoted by an attractive seller on the beach at South Padre Island at higher values than if they were offered these things while conducting other tasks in unrelated settings. There should also be an attempt to control for the anchoring effect created by price differences. For example, a respondent may have been willing to undertake the process of opening a checking account in exchange for a $50 gift card. However, when listed as a possible free gift next to $75 and $100 gift cards, the respondent may place less value on the $50 gift card than she would have by itself, and respond that it would take at least a $75 gift card to induce her to open the checking account.

Another caveat of the current exploration was the assumption that participants of the survey had full knowledge of the attributes of the financial and other products that they were asked to value. For instance, it may have been the case that some respondents had not ever experienced the process of opening a checking account, which would make them unable to fully associate the opportunity costs involved in that task. Similarly, certain respondents may not have been aware that the brand on the free gift product of the backpack was relatively high-end and generally associated with superior quality.

Additionally, it would be valuable to be able to study rationality of consumption within each observation case. As this study was conducted through surveys, the respondents were separated into three groups of which each took a survey on a different component of variables involved in transitivity. The alternative, where each respondent would have filled out each of the three surveys carried the risk that a significant number of respondents would have identified the research premise. This would have distorted the results if the realization of the research premise induced the respondents to provide responses that appeared rational, even if that would not be their true behavior under realistic consumption scenarios where consumers do not generally stop to consider if each purchase decision maintains transitivity. Indeed, Shampanier et al. (2007) conducted a follow-up to their candy experiments in which, this time, participants were guided through each trade-off involved in their consumption decisions, including during price changes. When participants were required to analyze the costs and benefits of each choice, the authors found that "when

people have access to available cognitive inputs" the "zero-price effect" vanishes and consumers make decisions according to their "true" or "rational" economic preferences (p. 754).

Is the Crucifix Sacred? Exploring the Catholic Consumption of sacred vessels in Building Connection with the *Sacred*

Leighanne Higgins, University of Strathclyde, UK
Kathy Hamilton, University of Strathclyde, UK

ABSTRACT

This paper aims to contribute further towards sacred consumption theories offered within consumer culture. So far, research has often pointed to instances of transcendence been found through the consumption of objects and possessions (Belk, 1988; Belk et al, 1989), white water rafting (Arnould & Price, 1993) and salsa dancing (Hamilton and Hewer, 2009). Additionally, a 'celebrity sacralization process' (Hamilton & Hewer, 2011) has been witnessed in the consumption of celebrity icons such as Barry Manilow (O'Guinn, 1991), Tom Petty and the Heartbreakers (Schau & Muniz, 2007) and Kylie Minogue (Hamilton & Hewer, 2011). In turn proving the stance taken by Belk, Wallendorf & Sherry (1989, 2) of religion being one but "not the only context in which the concept of the sacred is "operant" to be correct.

This said, relatively little research has been conducted looking at the consumption of the sacred from a religious perspective, for example within well-established religions such as Catholicism. As such the voice of the religious consumer is very much unrecognized within Consumer Culture Theory to date. This study contributes to this gap with the key aim of investigating the role of sacred vessels (religiously linked objects and services, such as crucifixes and Mass) for Catholic consumers.

THE IMPORTANCE OF RELIGION WITHIN CONSUMER CULTURE

Weber's (1930) 'Protestant Work Ethic' suggested that Puritan ethics of focus on working towards personal wealth and success, led to capitalism, secularization and "disenchantment" within society. Since Weber's concept, well-established religions and their followers have been under attack continuously, from works such as that by Gabriel Vahanian and his 'Death in God' movement of the '60's, to the numerous studies such as the 2001, 'American Religious Identification Survey' which highlighted a 9 percent decline in the number of people identifying themselves with religion. Nonetheless, in recent years there has been a resurgence in the number of people interested and consuming spirituality, in particular New-age holistic spiritualities of life (Heelas, 2008, 6), which are the consumption of spiritual experiences found "in our most valued lived experiences on what it is to be alive", but similarly are spiritualities which are "consumed, for the sake of enhancing hedonistic experiences". Heelas (2008, 6) even suggests that the popularity of the consumption of such holistic spiritualities of life might in time, "provide a worthy successor to Christianity in western settings". In short, proclaiming the situation for well-established religions such as Catholicism to be very bleak.

However, little reference, if any, is ever made to research such as the 'Beliefnet Poll' conducted in 2005, which demonstrated that 90% of Americans refer to themselves as believers. Or, the UK-wide study conducted by the charity 'Tearfund' in 2008, which found that despite perceptions of declining faith levels, 12.8 million adults in the UK go to church at least once a year. Furthermore, from the Catholic perspective, and on a global scale, the 2010 edition of the Pontifical Yearbook pointed towards an increase in the worldwide population of Catholics, with a figure of 1.166 billion, concluding that around 1 in 6 people worldwide are Catholic. Thus, there is research illustrating that the consumption of well established religions such as Catholicism is still very active and a large practice, yet as such within Consumer Culture Theory often overlooked.

CONSUMER CULTURE & SACRED CONSUMPTION

The growing abandonment of Durkheim's sacred and profane dichotomy within consumer culture, led by pioneering researchers in the field (Belk et al, 1989) and their theory of a growing sacralization of the secular and secularization of the sacred has led to the aforementioned growing acceptance of the sacred being "operant" (Belk, 1989, 8) in domains out with religion. Over the last 20 years a growing interest in consumer culture around the area of sacred consumption has occurred, resulting in shopping malls now being viewed by many as "cathedrals of consumption" (Ritzer, 2005, 7) and consumption subcultures such as that of the new bikers (Schouten & McAlexander, 1995, 50), providing "magical and otherworldly" experiences. Nevertheless, to date in consumer culture the emphasis has been upon the sacralization of the secular domains, with very little focus upon the consumption of spiritual and religious goods in order to bring about transcendental experience (Rinallo, 2009). This study will aim to contribute towards such a gap through its focus upon religiously linked objects and services, and as such a major concept used within this study has been Eliade's (1958, 9) "cryptic and clear hierophanies".

A basic description of hierophany is a manifestation of the sacred to man (Eliade, 1958). For Eliade (1958, 8) however, "some hierophanies are not clear, are indeed cryptic, in that they only reveal the sacred meaning embodied or symbolized in part, or, as it were, in code, while others (more truly *manifestations*) display the sacred in all its modalities as a whole". As such, for a Catholic consumer, a clear manifestation would be attributed to a holy site such as Lourdes, whilst an unclear or "cryptic" manifestation would be the connection build with God during the consumption of salsa dancing (Hamilton & Hewer, 2009) or other secularly deemed activities. Arnould & Price (2004, 53) echo Eliade's concept of "cryptic hierophanies", in their belief of "salvific moments" being one of three ways by which the sacred can be "identified". These moments relate to the, "unscripted eruptions of the sacred in otherwise mundane contexts" such as at "sporting events". As aforementioned, a critique in sacred consumption theory to date has been their predominant focus upon the sacralization of the secular, and through the adoption of Eliade's (1958) concept of "cryptic and clear hierophanies", we further add to this critique. As we suggest that to date, the consumption of the "cryptic hierophany" has been the focus, with very little, to no research conducted upon the consumption of "clear hierophanies", and as such this study focuses upon the "clear hierophanies", such as religiously linked objects and services, like, Mass and the crucifix, often consumed by the Catholic consumer.

In 2001, Iacobucci critiqued consumer behavior for it's lack of emphasis upon the, "'S'acred", stating that she wished to, "begin a tradition" of research that focused upon, "the subset or a narrower instantiation of the 's'acred, specifically involving an individual's experience with religion, spirituality, worship, and God" (2001, 110-111). Hence, so far within this paper, we have only referred to the un-capitalized sacred, and our reasoning for this is due to the study's grounding within platonic thinking. Iacobucci's (2001)

aforementioned differentiation between the 'small' sacred and the 'capital' Sacred, is platonic thinking at it's finest. As Plato believed that tangible things were mere forms of an Absolute, and thus Plato like Iacobucci (2001), and ourselves believe there is a difference between the form of the sacred and the Absolute Idea of the Sacred. A predominant research focus upon cryptic hierophanies, has resulted in Iacobucci's (2001) estimation that to date a metaphorical level of sacred has been researched as opposed to the Absolute level of the Sacred. We agree with this opinion and as such we will differentiate throughout this paper between the sacred and the *Sacred*, with the former relating to the sacred at a metaphorical level and the latter relating to the Absolute form of the *Sacred*.

THE RELIGION-CONSUMPTION DICHOTOMY

Focus within consumer culture has been as aforementioned on breaking down the dichotomy of the sacred and the profane, but an even greater dichotomy exists between religion and consumption, and the belief that the two of them cannot integrate. We believe this dichotomy has came about due to the generally "negative associations" (Heelas, 2008, 83) held regarding consumption. Wattanasuwan (2005, 183) discusses that we are all "enslaved" to consumption and likewise Ekstrom & Brembeck (2001, 1-2) state, "consumption (and consumerism) is gradually trickling into all areas of human life". Thus, the general negative feeling shared towards consumption by many, has led to the belief that religion and consumption cannot be mixed positively. As such, we suggest this may be the reason for a lack of focus upon the religious consumer within consumer culture to date.

However, some papers have rallied to join Iacobucci's (2001, 110-111) call for beginning "a tradition" of research focusing on an, "individual's experience with religion, spirituality, worship, and God". And in doing so have managed to demonstrate that there is no need for such a dichotomy, as religion and consumption can be and are mixed together, and positivity reigns from such mélange. Touzani & Hirschman (2008: 379) in their representation of the Muslim consumer found that, "religious patterns can be and are appropriated into consumption styles without undermining Islam itself". Similarly, Sandikci & Ger (2010, 33) found in their work that, "Islam is neither a threat nor a panacea for consumerism and capitalism", whilst Higgins & Hamilton (2011) found though their work on the consumption of sacred pilgrimage sites, like Lourdes, that the religious pilgrims accepted the near proximity of the commercialized side of Lourdes as a "modern day penance" to their pilgrimage. Furthermore, the use of the word consumption can be

dated back to biblical times, as the New Testament mentions that on Pentecost, a day of huge significance within Christianity, the Apostles were consumed by the fire of the Holy Spirit and as such became one with God. So, consumption has been around as long as religion, and likewise has been mixed together over the centuries, thus proving that there is a need for more research focused on breaking down the religion-consumption dichotomy. As such, this study will further add to this growing "tradition", by offering the voice of the Catholic consumer, and investigating the ways in which Catholic consumers consume "clearer hierophanies" such as Mass and crucifixes, as a method for building connection with God.

METHOD

It is often said that 'a chain is only as strong as it's weakest link' and due to this we thought it best to deal with what could possibly be viewed as a weakness in this study – one of the researcher's Catholic beliefs. This study was in conjunction with a wider study, investigating the affects of the current financial crisis upon the consumption of Catholic Mass in Scotland. This phenomenon was recognized within the home parish of the main researcher, and as such we adopted a single case study. Although some may argue that this is too close a position for the researcher, previous research within the area, raised awareness of the reservations many religious consumers feel at being interviewed about faith. As such through familiarity within the parish, the researcher was able to overcome the access and trust issues that can often arise in single case studies (Dutton & Dukerich, 1991). Furthermore, it was our belief, that the shared religion resulted in a high level of 'verstehen' (Wax; 1967) being encapsulated within the researcher, which was believed to only further strengthen the research, as it resonated with Schouten & McAlexander (1995:44) and their finding that deeper integration with the subculture of new bikers enabled, "access to informants near the core of the subculture" to improve greatly. Thus, as a member of the Catholic faith, the presence of 'verstehen' within the researcher enabled gaining of a better understanding of respondents.

The case study parish has the motto of "serving the community" and approximately 1200 regular Sunday mass attendees. We conducted one to one interviews with twenty-one of these regular attendees; half of the sample was generated through a response sheet distributed throughout the parish. The other half was generated through a snowballing method. All respondents were Catholic, and as shown in table one, they ranged in age, gender and occupation.

Table One: Profile of Respondents

Respondent's Name	*Gender*	*Age*	*Occupation*
Chloe	Female	50-64	Retired nurse
Craig	Male	25-34	Secondary School Teacher
Faye	Female	35-49	Unemployed
Fr. Grant	Male	50-64	Priest
Fr. Jack	Male	35-49	Parish Priest
James	Male	35-49	Ironmonger
Kevin	Male	35-49	Works in Prisons
Lisa	Female	50-64	Classroom assistant (Primary school)
Maria	Female	16-24	Works in benefits dept
Moira	Female	50-64	Seamstress

Miriam	Female	50-64	Retired Primary Teacher
Paul	Male	50-64	Retired/ Now a part-time Lolly-Pop Man
Penny	Female	50-64	Sales Assistant
Philip	Male	50-64	Retired
Rachael	Female	35-49	Nursing background/ works in health sector (NHS)
Renee	Female	65+	Retired Primary Headmistress
Ryan	Male	35-49	College Lecturer
Sally	Female	35-49	Interpreter for deaf
Sister Catherine	Female	50-64	Nun
Sister Julie	Female	35-49	Nun
Tom	Male	50-64	IT Technician

The parish priest of the single case study assisted by allowing the interviews to be conducted in a social room within the parish, providing a context where both the interviewer and the respondent felt comfortable (Thomson & Hayto, 1997). On average the interviews lasted 90 minutes. Interview discussion centered-around the aforementioned idea of Mass consumption during the current financial crisis, with peripheral discussions around coping and the sacred consumption practices adopted by Catholic consumers. This latter theme emerged from preliminary interviews whereby the theme of sacredness emerged as important and relevant to consumer culture. The interviews were audio-recorded and transcribed. A hermeneutic logic was then followed to analyze the data, following both intra-textual (Thompson, 1997) and inter-textual cycles (Thompson, 1996), whereby similar patterns and major points of difference were collated across all transcriptions.

FINDINGS

Although many themes emerged throughout the study, the key theme from the research to be discussed within this paper is that of *the consumption of sacred vessels*. However, prior to discussing this key theme, it is important to understand our findings from this research on the Catholic consumer's perceptions of the *Sacred*.

Sacred Perceptions

"It means to me the accumulated wisdom of 2000 years, where people have tried to live out their relationship with God and it becomes shared in that sort of body of teaching or way of spirituality"

(Fr Jack).

In order to understand the Catholic consumer's perception of the *Sacred*, it is important to firstly, understand respondents definition of Catholicism. The preceding definition from Fr. Jack, the parish priest of the single case study, is apt as it demonstrates a shared viewpoint amongst all participants in this study – that Catholicism is a way of life. But more than that, the reference of Catholicism being about ones 'relationship with God' indicates towards individuality being present within Catholicism, resonating with the all-embracing, universal meaning of the word. Highlighting that Catholicism can mean different things to each individual Catholic, but that at its core they will each share a set of beliefs unifying them together as one distinct religious institution. This shared unity amongst Catholic consumers was revealed in many ways throughout the study, one such way being the shared perception of the *Sacred*.

All respondents agreed that the *Sacred*, *"can be open to interpretation"* (James) and that connection with the *Sacred*, *"can come in the most strange sort of ways"* (Philip). This said, all respondents shared descriptors of the *Sacred* as being: "out of this world", "everlasting and immortally beautiful", "irreplaceable", "holy". Similarly, the respondents all shared the belief in the *Sacred* being an "intangible presence", often difficult to explain and understand.

Lisa: "*I mean people use the term 'out of this world' and it is like that in a way, it is beyond the reach yet striving to reach it*".

Fiona: "*sacred means for me, a set apartness from the daily grind of the world, it is something that is above all of that - it is something that is not of this world* ".

Craig: "*I personally would not say that the most sacred thing to me is something that I could physically hold or touch*".

Ryan: " *I think it is a personal relationship with God. Yeah, I suppose a sacred space or a sacred time is a time when you would feel very much one-to-one with God so yeah, I think it is your relationship with God*"

This shared belief in the intangible quality of the *Sacred*, resonates with Belk et al's (1989, 9) offering of "intangibles" as one of six potential sacred consumption domains. However, within Consumer Culture Theory to date, there appear issues regarding terminology, and as such our findings show that for the Catholic consumer it is the actual absolute *Sacred* which is intangible, and connection with this intangible *Sacred* is built through the consumption of religiously linked objects and services such as Mass, and the crucifix. As such, respondent's shared belief in this intangible *Sacred*, led onto deep discussion into what many would believe to be a rhetoric question – is the crucifix sacred? We found that for the Catholic consumer, the crucifix – the actual tangible, crucifix positioned within chapels, and homes, and worn upon necks worldwide – is not *Sacred*, leading onto the key theme and contribution from this study – *the consumption of sacred vessels*.

The consumption of sacred vessels

"...Give them something to look at and they will understand it, but they don't understand that presence and I don't either, but I

know it is there, and I couldn't logically try to give you an explanation, but there is something there, but we give ourselves something to fixate on" (James).

This response successfully introduces the idea of sacred vessels, as it indicates a common belief amongst Catholic consumers, that the *Sacred* sought after by mankind is untouchable and incomprehensible whilst we are living. Studies to date, on the resurgence of spiritualities of life (Hellas, 2008), and within consumer culture, have shown that, "humans are spiritual seekers, even in a consumer society that so many critics say leads to apathy and meaninglessness" (Scott & Maclaren, 2009, 60), indicating that man has an awareness of the presence of an Absolute, which for the Catholic consumer is God. But, our research suggests, in order to connect with this presence we give ourselves tangible resources to help us fixate and understand the *Sacred*. Continuously respondents illustrated that the crucifix, religious statues of Our Lady, and other saints, although special and deserving of respect, were but, "reminders", "figureheads", "connectors", "vessels" which all help the religious consumer to communicate and connect with the absolute *Sacred*, with God.

> Chloe: *" I love to light candles and pray at Our Ladies alter – but I don't look at that as being a golden calf, as Sacred, it is just a vessel in which to pray through, a vessel to get through to God".*

> Maria: "*At the end of the day the crucifix is only a wooden cross, it is more what that sort of stands for that I would class to be Sacred rather than the object or the cross itself".*

> Miriam: *"Objects cannot actually themselves be Sacred but they can focus, they can be an visual representation of something ".*

> James: *"You could remove the statue and the presence would still be there, the statue is only a figurehead".*

This vessel idea was further supported through the examples of respondent's consumption of religious jewelry such as, the wearing of medals and crucifixes upon their necks.

> James: *"I wear a crucifix – and I don't know if I would say that it was that Sacred - but it is so, so special to me. And I get up every morning and I make sure it is on the right way, it's never off my body - it's always there… but it just makes me feel as though there is somebody with me"*

> Tom: *"I wear medals round my neck and I have always worn symbols around my neck, but they are not Sacred, they are just a reminder, they are a help to me, if I forget things and all of a sudden I hear them jangle, it is a sort of wake up call".*

The wearing of such jewelry symbolizes the Catholic consumers connection with God, resonating with Fernandez & Veer's (2004, 55) work on the symbolism of jewelry during Hindu wedding rituals. And as such this research contributes further to symbolic consumption theories (McCracken, 1988).

To date, within symbolic consumption the emphasis has been upon the 'self-concept' whereby consumers "employ consumption not only to create and sustain the self but also to locate us in society" (Wattanasuwan, 2005, 179), and as such, "material possessions serve as symbolic mediators between the self and others" (Wattanasuwan, 2005, 182). Symbolic consumption, however, has been researched at more conspicuous levels (Schouten, 1991), with the aim of con-

sumption being the consumer's attempts to create the identity they wish to communicate with others. Popular New- Age spiritualities of life resonate very much with what has been looked at within symbolic consumption to date, as these spiritualities offer consumers the chance of self-spirituality, with the focus of these new-age spiritualities being "locked"(Heelas, 2008, 7) within the self. However, this study points to a different dimension of symbolic consumption. For the sacred consumption of candles, and the wearing of religious jewelry are all consumed at an individual and private level, aiding the Catholic consumer to build further their connection with the *Sacred*. But this symbolic consumption practice is not about creating an identity for others to see, but is about the personal connection build with the *Sacred*.

Furthermore, the symbolic consumption of Mass differs from that mentioned above and within symbolic consumption theories to date, as it is a shared consumption practice.

> Ryan: *"I thoroughly enjoy mass, I love the way that it crosses so many boundaries; time, history, geography, people who have died, people who are still to come, we pray for the people here now and we pray for the whole church. I think it's a deep leveller, knowing that for 12 hours before us and 12 hours after us people will still be celebrating mass throughout the world and I think that's just a beautiful concept".*

> Philip: *"I live almost six thousand miles away from my mother, and that she still goes to mass, that she will be having a different but a similar experience to me because we are part of something big".*

The idea of being part *"of something bigger than myself"* echoed amongst respondents and as such it came to the forefront that Mass is a symbolic consumption practice adopted by Catholic consumers as a way of developing and building their personal relationship with God. Further than this however, through the shared symbolic consumption of Mass, the Catholic consumer focuses not upon the self, but upon the fact that through their faith, they belong and are part of something "much bigger" than the self, and through this selflessness, the Catholic consumer is able to build connection with the entire Catholic community as well as with the *Sacred*. Belk et al (1989, 31) suggest that consumption of the sacred is rooted in consumers' needs for self-differentiation through their consumption of something out with the ordinary, in turn providing, "meaning in life and a mechanism for experiencing stability, joy, and occasionally ecstasy through connection". However our findings demonstrate the antithesis, as we demonstrate that consumption of sacred vessels enable connection with the absolute idea of the *Sacred* but also enable collectivism with the entire body of Catholicism. As such our research resonates more with Belk's (2010, 725) discussion on the idea of "sharing-in" whereby "others are included within the aggregate self". For through the shared consumption of Mass respondents felt barriers of race, age, and social-class break down between them. However, at a deeper level, the preceding usage of the word 'community' and the sharing-in amongst respondents whilst consuming Mass, enables a symbolic consumption practice that narrows the boundaries between: life and earth, the past, present and future, geographical separations, in short it symbolizes the connection build with the entire body of Catholicism as it has been for the last 2000 years, and as it will continue to be in the future.

Plato stated, "the truth of the matter, is after all, only known to God" (Plato Republic, 1954: 282). We likewise conclude that due to it's discombobulate nature, complete understanding of the

Sacred is an improbable if not impossible feat, and as such it is incorrect to state that research to date in consumer culture has focused upon the *Sacred* in it's entirety. This said, we suggest that what has been researched to date in consumer culture has in fact been the '*consumption of sacred vessels'* not the consumption of the absolute form of the *Sacred*. Thus in short, Arnould & Price's (1993) respondents consumed the sacred vessel of white water rafts as a method for building connection with their *Sacred*; likewise Hamilton & Hewer's (2009) "salseros" consumed the salsa dance floor as a sacred vessel for connecting with their *Sacred*. And in the religious context our Catholic consumers consume the crucifixes in their churches, homes, and around their necks as sacred vessels for building connection with their absolute *Sacred*. As such the material world provides a platform enabling man to connect with the *Sacred*, and likewise for the Catholic consumer the shared symbolic consumption of Mass is a sacred vessel enabling connection to be build with God, but likewise to build connection with the entire body of Catholicism.

Continuously, throughout the analysis process, we debated whether, in fact *sacred vessels of consumption* was the correct terminology. Primarily the usage of the word *vessel* was debated, especially in light of the recent work from Fernandez & Lastovicka (2011) on fetishes, which demonstrates the idea of 'conduits' with the more powerful. However, the shared usage of the word 'vessel' amongst respondents made us turn to the bible for answers, leading us to the biblical sense of the word of vessel as meaning something believed to hold or embody a particular quality and the sacred vessels discussed in this research behold a particular quality, which enables connection with the absolute *Sacred*. A priest once mentioned to us that the sign of the cross made before a prayer is the dialing of a telephone call between man and God. Likewise, for the respondents in this research the statues, the crucifix, the Mass, are not bridges or portals, for this almost gives the impression of them being immaterial and moving. Instead using the telephone metaphor, the statues, crucifix, Mass are all material telephones, which enable the dialing/ connection between man and the absolute *Sacred* to occur. Hence we remain with the term vessel, as opposed to bridge, portal or conduit to communicate the often, material nature of these metaphorical sacred vessels. Secondly, our reasons for this particular terminology stemmed from the spirituality of life movement (Heelas, 2008), which differentiates between spirituality and transcendence theism (religion), suggesting that the former is about man creating and giving meaning to life, whereas the latter is relating to the idea of being given the meaning of life from a higher being such as, God. As such we questioned if perhaps the "cryptic hierophanies" studied within consumer culture to date such as Schouten & McAlexander's (1995) new bikers, had in fact been the consumption of spirituality as opposed to sacred consumption? However, this seemed a somewhat arrogant viewpoint, and as such it did not sit well with the researchers. For who has the right to claim that the connection build with the *Sacred* through spiritualities of life, differs from those build through Catholicism or any other well-established religion? Thus we suggest that the *Sacred* is *Sacred*, and mans approximation of the *Sacred* cannot be changed, due to our inability to understand the *Sacred* in it's entirety. In turn suggesting that the *Sacred* connection built by white water rafters, salseros, celebrity aficionados, new-age life spiritualists, Catholics and a plethora of other consumers who practice sacred consumption habits is the same *Sacred*, and does not change. It is the *sacred vessels* for building connection with the *Sacred* that changes, not the over-arching Absolute itself. In saying this we recognized from our study, that the aforementioned terminological issue has

it's routes in the idea of transcendence, and as such we suggest that future research lies in furthering consumer culture's terminology, particularly in the area of transcendence.

CONCLUSIONS

This study has added to Iacobucci's (2001, 110-111) call for a "tradition" of research within consumer culture that researches "an individual's experience with religion, spirituality, worship, and God", and as such, we have shown that it is possible for consumption and religion to come together in useful ways. Hence, illustrating that the dichotomy existing between religion and consumption within consumer culture and society as a whole, should be eliminated. Our primary focus for this paper has been upon the Catholic consumption of sacred vessels to build connection with the *Sacred*. Thus, regarding theoretical contributions, we have further contributed to sacred consumption theory, but also an emergent contribution for this study has been within the area of symbolic consumption.

On deciding the title for this paper we questioned the appropriateness of the use of the question, "is the crucifix sacred?" But upon reflection we realized that without such discussion this paper and as such its realizations would never have been born. As the crucifix is key to understanding our findings and contributions to sacred consumption theory, for if the most significant symbol for one of the widest established religions is not regarded as *Sacred*, it is fair to concur that the majority of sacred consumption studies to date, if not all, have not focused upon the absolute idea of the *Sacred*. As such, we conclude that in Consumer Culture Theory to date, the *Sacred* in itself has not been studied, but in fact '*sacred vessels'* enabling connection with the absolute idea of the *Sacred* have been the predominant focus. And as such, we suggest the deconstruction of sacred consumption theory to date to incorporate such a finding.
